Now that case, gentlemen, I think is a text on which we might go on freely dilating on the benefit of puncturing the large intestine. I think it has given us a great lesson. There was a large piece of intestine entirely exposed, the ascending colon and, I believe, the greater part of the transverse colon distended tremendously and black, not from effusion of blood, but from congestion. I had been pressing and squeezing that intestine in my endeavour to get it back for I should not like to say how long, but it must have been for a great many minutes. It had been, as the Medical man expressed it, "literally mauled," and we both felt that the old man would die on the table there and then; but I could not stand by without giving him the chance any further interference might afford. So I punctured the intestine, and, after a great escape of wind, I was able to return a part of it. In the second puncture, just a little drop (about the size of a large pin's head) of black stuff oozed out, clearly blood coming from the congested walls of the intestine. I punctured four or five times until I had reduced the whole of it. No fæces escaped whatever, although during the whole of this time I was so manipulating the intestine that if it was possible anything could come out it would have done so. After the patient recovered I asked myself the question: If the large intestine, exposed to view as that was, and not supported in any way by the abdominal walls and contents, could be tapped without any escape taking place, surely, where the intestine is supported, the risk of extravasation would be greatly diminished by the natural support given to it in the abdominal cavity? I think we must draw this conclusion, then: that there are cases in which you may puncture the intestine freely, and with every prospect of affording great relief. In hernia this case clearly proves that you may resort to it, and I believe you had better adopt it if there be much trouble in returning a very large hernia. Had I learned this lesson earlier, I should have tapped long before I did. But might we not employ this treatment much earlier? If, after operating, we can reduce a strangulated hernia by pricking, which we could not reduce without,

is it not possible that we might reduce some herniæ without any operation at all? Consider a small enterocele. See the intestine bulging beyond the neck of the sac and becoming congested. See how it becomes more strangulated and congested if reduction is not effected. If you tap it you let out all the wind, the whole of the knuckle of intestine collapses, and you get only a little flaccid lump. Under these circumstances, what is there to prevent the bowel being replaced by natural agency? I confess my liking for the idea from a Surgical point of view: I think it is scientifically correct, and I see nothing to prevent it having the desired effect. I cannot recommend it practically, because I have had no experience of it; but I intend to test the value of it when a suitable case comes before me. And what would constitute a suitable case? Not those slight cases where you can return the intestine without opening the sac, because we know, as a rule, they do well. But I certainly will try it in those cases of hernia that we not infrequently get in Hospital, and sometimes even in private practice—large scrotal herniæ, and large umbilical herniæ, the interference with which is nearly always followed by death. It is quite exceptional for a large inguinal or umbilical hernia to recover after herniotomy when the sac has been opened. By opening the sac I mean not only just at the neck, but complete exposure and manipulation of the contents. In both such cases, then, I shall most certainly apply this practice. Now let us carry this thought a little further. You remember the case I related of a young lady who had strangulation of intestine, evidently from the mere grip of a coil of intestine by a band running from the loin to the bladder. The band would not yield, the intestine could not get out, and every moment rendered the strangulation more intense. Now, supposing I had tapped the intestine, and let out the wind, the bowel would have collapsed, and the bladder, as it became distended, would have allowed the intestine to escape. Then, further, in cases of twist of the intestine you might get much the same thing. When once twisted and distended, it is difficult to untwist, but if the distension is relieved by tapping, you give the bowel a chance of righting itself. Considering, then, with such examples as we have, that tapping is not attended with much danger, surely we are justified in having resort to it before any more serious operative interference, with every prospect of doing good. Do not, however, go away with the opinion that you should adopt it in all cases. But I think, taking that case I narrated as our text, in large strangulated scrotal hernia, strangulated umbilical hernia, and in all cases of acute internal strangulation due possibly to bands or twists, that we may reasonably look for very good success in its practice.

There is one other point I will just touch upon before we separate to-day, bearing upon the question of umbilical hernia. You heard me say how very fatal the treatment of umbilical hernia by operation generally is, that it is quite exceptional for recovery to take place. In all the years I have been at Guy's the only cases in which recovery has taken place have been those in which the contents of the sac have never been exposed. The stricture has been divided—I cannot say outside the sac—but an opening has been made only just sufficiently large to allow a herniotome to pass. I have had three or four such cases, and they have got well. In all the other cases, where more has been done, death has followed. I would go a little further, and say—Do not attempt to return an umbilical hernia; they are almost always chronic, slow in formation, and exist for many years before strangulation takes place. I think in large herniæ I would puncture; but when you must operate, never be tempted to expose the bowel—simply cut down on to the neck of the sac, divide the structure by a herniotome, and leave the rest to nature. You relieve the strangulation by simply dividing the neck, precisely in the same way as I believe you would relieve the strangulation by tapping the bowel.

At our next meeting, gentlemen, I propose to consider in all its bearings the operation of colotomy.

PUBLIC BATHS ON THE THAMES.—It was time some such step was taken. A bath is to be constructed off Battersea-park, and the company which has undertaken the work intends fitting up another—provided with a filtering apparatus—close to the Embankment, between the Temple and Waterloo-bridge. The late Dr. Véron, in his "Mémoires d'un Bourgeois de Paris," says that cleanliness was introduced into France after 1815, by the English; and the French might any time, during the last half-century have taken a brilliant revenge (*une revanche éclatante*) by introducing swimming-baths in London.

ORIGINAL COMMUNICATIONS.

NOTES
ON THE PATHOLOGY OF MALIGNANT
NEW GROWTHS.

By HENRY ARNOTT, F.R.C.S.,

Assistant-Surgeon to St. Thomas's Hospital, and Joint Lecturer on Morbid Anatomy in the School.

VIII.

Epithelioma—Its Distinction from Carcinoma—Its Minute Structure—Columnar-cell Epithelioma—Rodent Cancer.

THESE sketches of the various new growths, commonly called cancers, will be fitly brought to a close by a reference to the well-known disease which, from its cancer-like nature, has been usually styled "canceroid"—a term which is objectionable from its vagueness, but which aptly enough expresses the clinical characteristics of the disease.

For EPITHELIOMA—by which is meant a new growth furnished by the proliferation of the epidermis, or by the epithelium of the mucous membranes—although sometimes in its later stages thoroughly malignant, affecting chain after chain of lymphatic glands, and cropping up luxuriantly in remote viscera, as the heart and lungs, is yet a growth far more under surgical control than any of those which we have been considering. For while with our present mode of operating we hesitate to affirm too boldly that we can eradicate a scirrhus cancer by cutting it out, there are few Surgeons who would deny that they have finally extirpated a small epithelioma of the lip or scrotum by a comparatively trifling operation.

So it is that this disease has been almost always separated somewhat from the true cancers, whilst some able observers—the late Mr. Collis, of Dublin, for instance—have refused to place it in the same category at all. And yet the more modern pathologists, as Billroth and Rindfleisch, merely regard it as a variety of carcinoma, affirming a close analogy of minute structure and pointing to the difference of origin of the cells of the two growths—glandular, or surface epithelia—as constituting the sole claim to separation into distinct varieties.

Nevertheless, although both growths are made up of epithelial cells and stroma, and in certain points are closely analogous, I cannot help thinking that we, in England, are wise in keeping them distinctly apart; for both in coarse physical appearances and in minute structure the disease to be now sketched differs from that which we have described under the head of carcinoma as widely as it differs from it in the far more important features of clinical history and symptoms.

An epithelioma of the cutaneous surface, occurring usually as a shallow hard ulcer with thick fungous edges, presents a favourable specimen for exhibiting the characteristic microscopic structure of the growth, as well as its mode of origin and of invasion of the neighbouring parts. On examining a thin section from the margin of such an ulcer, one is at once struck by the fact that although here, as in carcinoma, we have before us clumps of epithelial cells in an irregularly alveolated stroma, yet the cells now differ hardly at all—save, perhaps, in their size and active nuclear proliferation—from the normal epidermis cells from which they have descended. We lack here the rich variety of cell-forms which supplant the small regular gland epithelium in carcinoma of the mamma, for instance, and at the same time we notice how comparatively slight are the fatty changes occurring in the misplaced epidermis scales. They dry up, shrivel, become squeezed by circumferential pressure into curious onion-like masses—the "globes épidermiques," "epithelial pearls," or "bird's-nest bodies" met with wherever excessive epidermis growth is in progress, but in singular and characteristic abundance in epithelioma (see Fig. 19, *a*, and Fig. 20, *a*)—or they swell up with colloid material (Fig. 19, *c*); but they seldom undergo much oily degeneration, save where inflammatory or ulcerative changes are actively at work. The cells further show a great tendency to cohere by their margins, as do normal epidermal cells, and sometimes present beautiful objects for examination with the higher powers, by dovetailing together by finely serrated edges, after the fashion of the upper cells of the healthy rete mucosum (see Fig. 19, *b*). In fact, the new growth seems to consist simply of masses of surface epithelium, which, instead of appearing above and between the papillæ, dip down amongst the connective tissue, and there actively multiplying and thriving as much from the unwonted supply of fluid

nourishment as from the absence of the desiccating process to which they are normally subjected as they are pushed on towards the surface of the body, form large tubular and

FIG. 19.

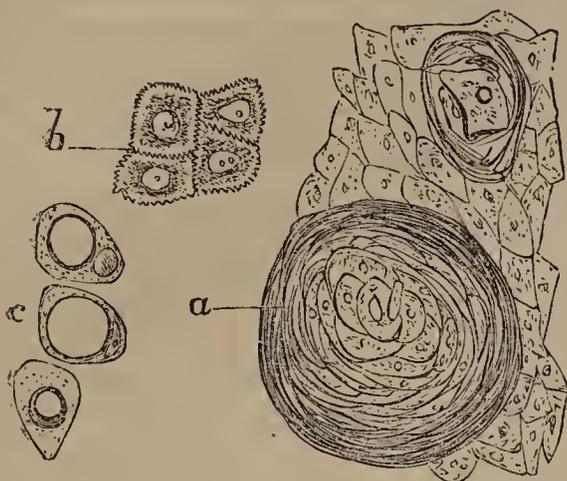

FIG. 19.—Elements from an epithelioma of the lip. Magnified 220 times. *a*, an epithelial pearl, showing the production of these bodies by the multiplication and subsequent flattening of squamous cells; *b*, serrated cells; *c*, cells containing colloid matter.

branching collections, capable of more prolific development the further they are removed from the surface, and at the same time more freely subjected to the risk of single cells being taken up and hurried away in the lymph- or blood-streams to form similar collections elsewhere.

This seems to be, indeed, what really happens in the formation of a primary epithelioma. Why this invasion of the subcutaneous tissues by epithelial elements takes place in certain cases, when all the physical conditions favourable to its production must be frequently present in any wart or condyloma, it is not easy to say; but there is nothing in the process, so far as we can observe it, to justify us in assuming a special condition of the blood as its determining cause, whilst the dispersion of the disease throughout the body—rarely considerable in its extent, seldom involving more than the nearest chain of lymphatic glands, and always presenting the same epidermis-like scales wherever the secondary growth springs up—is thoroughly and solely suggestive of transference of cells of the primary tumour and their multiplication in their new seats.

Thus, the one essential anatomical feature of epithelioma is the presence of proliferating epidermal cells in abnormal situations. So long as the change is limited to an excessive development of surface epithelium, with, it may be, considerable enlargement of the papillæ, the growth is a papilloma; or if the proliferation commence in a sebaceous gland, so long as the result is a mere accumulation of gland epithelium within the gland walls, this may go on to almost any extent, and be accompanied by secondary fatty changes, but the only issue will be a more or less inconvenient "atheromatous cyst"—both purely innocent formations. But once let the boundary be broken through, and the cells penetrate the deeper tissues, and lymphatic (or even vascular) infection may take place at any time—in all probability with a rapidity in proportion to the movement and moisture of the affected part; and with such infection the growth passes at once from amongst the innocent tumours to the cancers.

Whilst the cells of an epithelioma, therefore, differ in a marked degree from those of a carcinoma, and by reason of their tendency to mutual cohesion are not nearly so liable to be carried off to distant regions, the stroma is equally to be distinguished from that of carcinoma. In Fig. 20, which represents an epitheliomatous infiltration of the muscular portion of the tongue, the large squamous cells which have penetrated from the dorsum are seen to lie in detached clusters in the midst of a fibro-corpuseular stroma, striped muscle-fibres appearing on either side. This stroma is here clearly derived from the inter-

fibrillar connective tissue of the tongue, the invading epithelial growth being preceded by a small-celled infiltration, suggesting irritative hyperplasia of the connective-tissue nuclei—just such

FIG. 20.

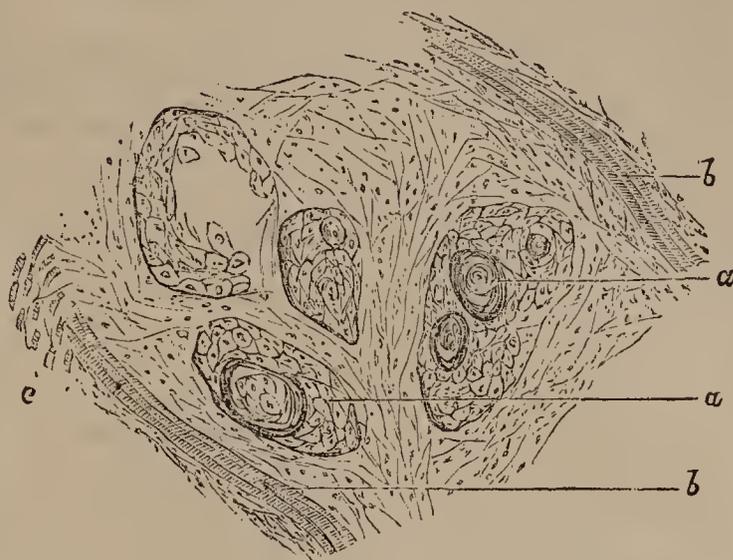

FIG. 20.—Section through an epithelioma of the tongue. Magnified about 40 times. *a*, clusters of squamous epithelium containing some "pearls," and surrounded by a fibro-corpuseular growth, furnished by the normal connective tissue of the part; *b*, striped muscular fibres; *c*, striped muscle divided transversely.

a structure as is to be met with in the neighbourhood of any active growth, and only to that limited extent deserving the name of a new formation. Hence we have here nothing like so regular an alveolar fibroid stroma as supports the cells of a carcinoma, although the increased connective-tissue growth, with probably an undue vascular supply, occupies in epithelioma an analogous position to that structure.

The coarse characters of epithelioma, the thick, mushroom-like elevations, the indurated excavations, the slow but destructive march, and the scanty, perhaps fetid, discharge, as well as the common site—an old wart, scar, or edge of an ulcer, or, in healthy parts, specially the line of junction of skin and mucous membrane, as the lip or vulva—suffice to render the diagnosis of the disease generally easy, and they are too familiar to need description here. The cut surfaces of these growths yield but a scanty juice, and what does exude is thicker and more curdy or ground-rice-like than the thin, milky juice of carcinoma, and under the microscope the cell-forms are usually tolerably characteristic (Fig 21).

FIG. 21.

FIG. 21.—Scraping from a coarse epithelioma of the arm. Magnified 220 times.

Where similar changes affect such mucous surfaces as are clothed with columnar epithelium, the resulting new growth

(a) In a paper contributed to the St. Thomas's Hospital Reports for 1871 ("On the Therapeutical Importance of Recent Views of the Nature and Structure of Cancer") I have tabulated seventy-three cases of epithelioma recorded by me in the cancer tables of the Middlesex Hospital, with the object of setting forth this connexion which exists between the physical conditions of locality and the malignancy of the disease. It is there shown "that the cases showing contamination of the glands and other parts are precisely those in which the growth is subjected to the greatest amount of movement. Thus, in the lip, tongue, genitals, groin, hand, and heel, the glands were affected in from 50 to 100 per cent. of the whole number of cases; whilst the disease attacking the less movable parts of the face spread to the glands in a proportion of only 21.7 cases, and in the leg and scrotum remained absolutely local."

(b) It is interesting to note that, just as Cornil and Ranvier have described direct communications between the lymphatics and the stromal alveoli of carcinoma, so Köster states that the tubes of squamous epithelium which dip down from the surface into the deeper parts lie within lymphatic vessels. This is, however, an opinion which has not been at all generally accepted, and although it would certainly explain very simply those cases in which gland implication occurs, such extension of the disease is not nearly so constant nor so early as one would expect it to be did the first traces of the morbid infiltration bear such close relation to the lymphatic channels as Köster indicates.

presents a corresponding variety of appearances, the cells being mostly arranged in the same way, and bearing a like relation to the stroma of overgrown connective tissue. But from the peculiar cell-forms present in these cases, and the greater moisture and vascularity of the parts affected, both the superficial and the microscopic characters undergo considerable and striking modifications.

Such growths occur not infrequently in the stomach and intestines. Where they clearly originate in a proliferation of the lining cells of the tubular glands they are often called "adenoma"; but since secondary growths having the same structure are met with occasionally in the liver and elsewhere, and since the only difference between these tumours and those surface epitheliomata which take their rise in the sebaceous glands of the skin is based upon the distinct forms of the cells furnishing the starting-point of each, it seems inconvenient to make such "adenomata" a special variety of new growth, and, with some pathologists, to speak of them as "adenoid carcinomata."

RODENT CANCER, as the well-known "rodent ulcer" was styled by the late Mr. C. H. Moore in his treatise on the subject, although, no doubt, sometimes presenting clinical features which sufficiently warrant its being classed amongst the cancers, yet does not seem to me to possess any properties, either clinical or anatomical, which justify its being placed in a distinct class by itself. The portion of Mr. Moore's book which deals with the histology of the subject is not characterised by the admirable clearness of the rest of the essay; but the want has been amply supplied by a paper in the last volume of the *Pathological Transactions* by Mr. Hulke. Mr. Hulke gives a lucid description of six cases of rodent ulcer, and subjoins beautiful drawings of the microscopical appearances present. In all of these instances the growth was the same—an infiltration of the irritated subcutaneous connective tissue with a small oval-cell growth, whose elements were exactly comparable to the cells of the rete mucosum of the skin, these cells being arranged in large masses or in smaller bud-like processes. It would hence appear that in these cases the new growth consisted of a proliferation and deep infiltration of the undermost cells of the epithelium. In examinations made by myself of instances of well-marked rodent ulcer, I have found, besides the cell-growth described by Mr. Hulke, more distinct evidences in some of the thicker parts of the edges of the ulcers of ordinary squamous-cell epithelioma, with even rough "bird's-nest" bodies (such as are described as occasionally present in Mr. Moore's work); and I am therefore inclined to group these "rodent ulcers" with the epitheliomata, explaining their very slow progress and comparative immunity from gland contamination by their situation—always to a great extent free from movement, moisture, or rich vascular supply.

TYPHOID FEVER.

By CHARLES ORTON, L.R.C.P. Edin.,
Hon. Medical Officer, North Staffordshire Infirmary.

THE Ironmarket is a very wide street—one of the two principal streets in the borough of Newcastle-under-Lyme. It has a gentle rise from No. 1 to No. 10, and then descends rather abruptly. No. 1 is a corner house of three storeys and a cellar, but with "no back premises whatever."

No. 2, the house with which we have to deal, is a draper's shop of three storeys, with no entrance from the Ironmarket save through the shop. The courtyard, eight yards by four, is common to three houses, and contains one watercloset, also common—very. Besides the shop and show-room, immediately above there is a sitting-room, small and dark, opening into the kitchen and into the cellar, with one window looking into the yard and another with a prospect of tiles and a wall of an inn three to four feet distant. There are seven bedrooms—of the front attic I will say nothing; a second bedroom, ventilating into the yard, is just large enough to hold a bed and little else. The bedroom over the dark sitting-room is under six feet in height, and a back attic where the three assistants slept is immediately under the tiles and amongst the beams. It is about twelve feet long by nine broad, highest beam about six feet from the floor, and the top of the window about three feet and a half. I have little hesitation in calling it unsuitable as a sleeping apartment for three young men.

As the sanitary state of the premises of this part of the town will no doubt form a subject of inquiry by the local authorities I will not anticipate what may then be possibly found to be

wrong, or what opinion may be formed as to the probable cause of the outbreak.

Of the nine inmates (ten with the child) of this house, all were young, and all have been stricken down with fever; in all probability it has been typhoid, but as can easily be imagined I was only too anxious to get rid of cases from such a pest-house. I therefore cleared them off as soon as possible before symptoms developed, but in several cases—I believe in all—too late. At present, however, I have only forwarded reports of the three cases which have been under my care throughout the attack. The history of the other cases I hope, through the kindness of several Medical brethren, to be able to send you hereafter.

To this house I was called on the evening of December 10, 1871, to see Mrs. D., aged 26, naturally rather a delicate person. I found her suffering from bronchitis, constantly coughing, with little or no expectoration, high temperature, headache, and feeble. She had been assiduously nursing her child, who had had bronchitis, and who had only recovered a week before. She had, therefore, been pulled down by loss of rest and anxiety. I ordered poultices to the chest, back and front, and prescribed bicarbonate of potash and vin. ipecac. On the 12th the chest symptoms were much relieved, but the feverish symptoms increased. Soon tympanitis, though slight, set in, and the characteristic typhoid spots appeared. The bronchitis ceased, profuse perspirations supervened, small quick pulse, low muttering delirium, and diarrhoea marked the progress of this case to its fatal termination on the night of December 21. On the evening of the 21st the temperature was 103° F. On the 20th the brandy-and-milk was not administered, as it should have been, for the stated reason that it made Mrs. D. conscious, so that she could hear the ravings of her husband.

On December 16, 1871, Mr. D. took to his bed. He had been struggling to hold up for some days. On the 20th the delirium which had been gradually coming on became so violent that he tried to jump through the window, and partially succeeded—would undoubtedly have done so had it not been for the courage of the nurse, who resolutely held to him, while a few others as resolutely stuck to the door on the outside. On my arrival I chloroformed him and gave him thirty drops of liq. opii, and on leaving him after a few hours I gave him a grain of powdered opium. During twenty-four hours he took four grains of powdered opium and fifty or sixty drops of liq. opii. He refused resolutely to take anything for upwards of two days, but then took milk freely. Diarrhoea in this case was not severe, but took place without the patient's knowledge for some days. The temperature never rose above 105·5°. He became fairly conscious about December 26 or 27, and was informed in a day or two afterwards by the minister of his wife's death and burial. This of course caused great depression, and brandy was administered occasionally until January 20, 1872, on which day he was removed to another house. He has only taken one half-pint of brandy and a bottle of sherry. I prescribed chlorate of potash and hydrochloric acid from the commencement, milk, ice, and opiate draughts, with the effect of which I was highly pleased.

Mary R., aged 12, servant. Left the house ill on December 14, 1871, and was treated in her own home in Newcastle. During the first fortnight she took nothing but one pint of milk and six teaspoonfuls of brandy per day; since then, milk, tea, and half a pint of brandy per week. I gave her but two bottles of medicine—pot. chlor. and acid. hydrochlor. dil. when diarrhoea was rather severe.

On January 17, 1872, when I last saw her, she was downstairs for the first time, fairly convalescent, still persevering with her milk-and-brandy—half a pint or rather less of the latter per week. I did not interfere, being content to leave well alone. With regard to stimulants, (a) though I will not plead guilty to having ordered them indiscriminately, I have taken, and do now take, in young people especially, the inclination of the patients as a guide; and if they feel the better for the administration of stimulants, I continue the administration thereof, and if they do not I have no hesitation in throwing them over, honestly believing that many, very many, cases will do as well and better without.

For the history of the cases I now forward I am indebted to my Medical brethren whose names are mentioned, and to whom I beg to express my thanks for their kindness.

G. A. Craig, M.B., of Birmingham, writes January 22, 1872, that he is attending Miss N., who is suffering from enteric fever. At one time hæmorrhage from the nose was so

(a) How interesting it would be to know how many examples of drinking habits had been "formed" purely from Medical advice. I have never known a case occur in my practice.

violent that she was in great danger of sinking, but is now recovering. Temperature reached 103°. Absence of diarrhoea throughout. No other cases have occurred either in the house or neighbourhood.

Mr. B. H. Herbert, of Uttoxeter, says (January 23, 1872): "The case of S. H., which you allude to, is undoubtedly enteric fever. He first came under my care a fortnight ago, suffering from headache and weariness, pulse 120, heat of skin—for the first week the temperature was over 103°—some pain in the bowels, with tympanitis and diarrhoea, very little delirium, and no well-defined rash. Progressing favourably."

I am now attending also Mrs. D., aged 62, with fever—temperature over 102°, pulse 100, tongue dry, slight delirium, tympanitis, but no diarrhoea—but having only seen the case once, I do not like to give a decided opinion as to its being strictly of the enteric type.

Dr. Greatrex, of Kildgrove, on January 19, 1872, sends the following remarks of the case of Mr. H.:—"Every symptom of typhoid was present. Delirious the greater part of the time. He went sixty hours without any sleep, and then slept four hours and awoke refreshed, after a dose of the syrup of hydrate of chloral. He rallied for a couple of days and then fell off again. The diarrhoea was not so bad as it generally is in severe cases. The lower jaw was spasmodically opened and closed for an hour at a time. The arms were also convulsed. He was always delicate from childhood, and some years ago had convulsions, when the same spasmodic opening and shutting of the jaw was a most distressing symptom." This case ended fatally ten days after his return home.

Mr. B. is still suffering from febricula, but is getting better.

Dr. Gooday, of this town, attended Mary H., servant, aged 20. I also saw her. Though she was long ill, Dr. Gooday regarded it as a mild case of typhoid fever. She has now recovered.

Concerning the case of Mrs. D., senior, Mr. Herbert wrote to me on January 30 to inform me of her death. Tympanitis continued, but no diarrhoea. Extensive congestion of the posterior portions of both lungs. The bronchi afterwards became implicated. From the first the throat presented a diphtheritic appearance, and in all probability the trachea contained a similar kind of exudation. The temperature ranged between 100 $\frac{2}{3}$ ° and 104°. Pulse from 100 to 140. It was no doubt enteric fever.

Mr. S. H. is progressing favourably. No other cases have occurred.

From the Medical attendant of Miss T., sister to Mrs. D., jun., I have not heard at present, but from her friends I hear that she has had enteric fever, and is recovering.

The order in which they were taken ill was as follows:—

1. Mary H., aged 20, servant, left on December 5, 1871. Recovered.
2. Mary R., aged 12, servant, left on December 8, 1871. Recovered.
3. Mrs. D., aged 26, to whom I was called in on December 10, 1871. Died.
4. Mr. D., aged 26, taken ill about December 10, 1871. Recovered.
5. Miss N., aged 18, milliner, left on December 18, 1871. Recovered.
6. Mr. B., aged 17, assistant, left on December 18, 1871. Recovered.
7. Mr. H., aged 16, assistant, left on December 22, 1871. Died.
8. Miss T., aged about 22, sister of Mrs. D., jun., left on December 22, 1871. Recovered.
9. Mr. S. H., aged 16, assistant, left on January 6, 1872. Recovered. Mr. H. had, however, been complaining of feeling ill for a week or ten days before this.
10. Mrs. D., aged 62, mother of Mr. D., left on January 16, 1872. Died.

The latter case came to this fatal spot on December 12, and was very little in either sick room, principally in the kitchen. Thus we see that the whole of the usual residents in this house and two visitors have been stricken down by fever. No other cases have occurred in the adjoining houses or neighbourhood, nor, so far as I can hear, in any of the localities where the other cases were sent.

In the present stage of our belief as to the cause of typhoid fever, I think we shall be clearly able to trace the outbreak in this instance to sewage emanations. I have before mentioned how close, ill-ventilated, and confined were the rooms of this house. On examining the drains, it was found that the main drain from the house and from the water-closets passed under the floor of the shop—not sufficiently low to drain the cellars, as the main sewer in the Ironmarket is not deep enough to do so. Therefore, if any leakage took place at any time there was plenty of

room to hoard it; if merely escape of gases, the inmates of the shop must suffer from the stench, and this was by no means seldom—sometimes even, I am told, unbearable. In the back kitchen is a water-closet, unused for some time past, but connected with the sewer, said to be well trapped; and above this kitchen is a small store-room, where some portion of the food of the establishment was kept; and above, too, was the sleeping apartment of the three assistants. Thus through the shop and through the kitchen could these poisonous emanations have reached the inmates. The water used was good, conducted through pipes from a distance of about ten miles. There had been no case of typhoid in the town that I can hear of; no death from it registered for some time past. The Sanitary Act, like many other Acts, no doubt took up an immense amount of the time of the members of both Houses to make it law. Having become law, members immediately proceeded to pass other Acts, leaving this to become almost useless. Would it not be wise of our legislators to inquire sometimes whether the provisions of an Act are put into force? In many, if not most small towns, the Sanitary Act is next-door neighbour to a dead letter.

Newcastle-under-Lyme.

REPORTS OF HOSPITAL PRACTICE

IN

MEDICINE AND SURGERY.

MIDDLESEX HOSPITAL.

ABSTRACT OF A CLINICAL LECTURE ON ERYTHEMATOUS LUPUS.

By ROBERT LIVEING, M.D., Physician to the Hospital.

GENTLEMEN,—I propose to direct your attention this afternoon to an interesting case of erythematous lupus now in our Hospital; but before doing so I shall take this opportunity of making a few introductory remarks on lupus generally, in order to point out with greater clearness the distinctive characters of the erythematous form.

Lupus may be defined to be a local disease, chiefly attacking the skin, and especially the skin of the face. It consists essentially in an infiltration of the cutis, with a peculiar cell formation, which undergoes degeneration, and leads subsequently to the destruction of the invaded tissue and the production of a permanent cicatrix. Of the exciting causes of lupus we know little or nothing—it is never contagious, and very seldom hereditary, though we may admit that a scrofulous diathesis is a predisposing cause of its development.

There are several modes of classifying or distinguishing the different varieties of this malady. The commonest, simplest, and perhaps the most scientific is to recognise only two classes—(1) Lupus vulgaris and (2) Lupus erythematosus. Historically, also, this division is interesting, inasmuch as Lupus vulgaris was accurately described long ago by Willan, while the true nature of Lupus erythematosus was first recognised in our own time by Cazenove.

Now, although this division has the merit of simplicity, it is not quite sufficient for descriptive purposes. A disease which assumes such varied forms as Lupus vulgaris requires some further subdivision to aid and give method to our descriptions. Hence we may conveniently adopt the following nomenclature, and classify the different forms of lupus under the following heads:—(1) Lupus tuberculosus; (2) Lupus vulgaris exedens; (3) Lupus vulgaris non-exedens; (4) Lupus syphiliticus; (5) Lupus erythematosus.

I am well aware of many defects in this mode of classification; but, on the whole, I believe it to be the most convenient that we can at present adopt. Under one or other of these heads it is quite possible to arrange all the varieties of lupus commonly met with. I must warn you, however, against the mistake of supposing that there is any essential difference between these varieties. They one and all possess in common the distinctive characters of true lupus.

Now let me say a few words in explanation of the names I have adopted.

Tubercular lupus is the *lupus of childhood*, though not strictly confined to the very young. It shows itself in the form of small nodules or tubercles, appearing on the face, about the size of a split pea or larger. These little elevations are elastic, painless, often of a bluish hue, rather vascular, and with little tendency to spread or ulcerate unless the disease be injudi-

ciously treated. Many of you may remember a little girl who was for some time under my care with this variety of lupus, and who gradually improved under cod-liver oil and mild local treatment. Hebra, I believe, uses the term "tubercular lupus" in a less restricted sense.

Lupus exedens is the *lupus of young adult life*, and is, unfortunately, the most common kind. It has the well-known characteristic feature of ulcerating deeply into the cutaneous and neighbouring tissues, and produces the most frightful disfigurement, while it heals with thick scars, like those of a burn. This form is most common between puberty and 25.

The name lupus non-exedens is a very inappropriate one as applied to any particular variety, and yet it is one that we can hardly entirely dispense with. It is generally used to indicate certain forms of lupus vulgaris which do not tend to produce open sores or ulcerate deeply into the tissues invaded. It may be said to occupy a position intermediate in its anatomical characters between lupus exedens and lupus erythematosus.

By syphilitic lupus I do not mean a syphilitic ulceration resembling lupus, but a true lupus which is modified in its characters and appearance by a *constitutional syphilitic taint*. It is generally, though not always severe, and spreads deeply into the subcutaneous tissues. It is important to distinguish this form of lupus from the more common syphilitic ulceration of the nose, inasmuch as the latter is more rapid in its progress, and far more amenable to treatment. Besides these four principal names that I have used for the purpose of classification, there are many other terms applied to the disease under discussion—terms all more or less useful for the purposes of description, but which, for the sake of perspicuity, I have avoided—such, for example, as "serpiginosus," "hypertrophicus." Again, we have the impetiginous lupus of Mr. Startin, and the lupus psoriasis of Mr. Hutchinson—the latter a non-exedent form of the disease, which appears in scattered patches about the body, and has a close superficial resemblance to psoriasis. All these and the other forms to which I have referred may be considered as varieties of lupus vulgaris.

In typical erythematosus lupus we recognise some very distinctive features, of which the most important are the following:—(1) In the first place it is the *lupus of middle age*; (2) it is much more common in women than in men; (3) it begins in the sebaceous glands and hair follicles; (4) it spreads slowly, and has little tendency to form open ulcers; (5) it attacks chiefly the papillary layer of the skin, and leaves smooth white scars, which are covered with cuticle, and are neither hard nor puckered.

I will now read you a brief history of the case before us (taken by Mr. Charlesworth):—C. N., aged 54, unmarried, of a consumptive family. When aged about 16 some of the early symptoms of phthisis developed, and she was sent to the Isle of Wight, where she recovered. Since that time she has enjoyed pretty good general health, with the exception of a severe attack of ague while living in a fen district. There is no history of syphilis, hæmorrhoids, or uterine disorders. The skin disease from which she now suffers began about ten years ago by the formation of a small reddish dry patch on the back of the right hand, of about the size of a florin; subsequently two similar patches formed on the left upper arm, and one on the right thigh; all these patches gave rise to considerable itching. The disease on the head began about six or seven years ago, and at the present time it affects the scalp, forehead, and face; on the latter it is arranged in a symmetrical manner somewhat resembling a butterfly in shape. The lower margins of both orbits, the fore part of the nose, the upper lip and mouth, are free. The skin over the scalp is freely movable, and the eruption in this situation is of a glistening appearance, and has a red base covered with thin white scales; scattered here and there are white, smooth, even scars. Over the forehead are some dry superficial scales. The hair over the part affected is almost destroyed, but nowhere is the sensibility of the skin impaired. The facial eruption, which is the most recent, is of a much brighter colour, with irregular, well-defined margins, studded with small tubercles, some of which are isolated; it seems in a more active condition. The right upper eyelid is healthy, while the skin of the left is affected and a little contracted at the inner side, so as to prevent the eyeball being properly covered by the lid. The whole surface of the eruption is dry, attended with little pain, but is very irritable.

Allow me now to call your attention to the leading features of this case, and the characters by which we arrive at a diagnosis.

Firstly, then, our patient is of the female sex, and I may remind you that erythematosus lupus is far more common in women than in men. Mr. Naylor, indeed, estimates the pro-

portion as about eight or ten to one. Again, you will remember that this variety is essentially the *lupus of middle age*; and in accordance with this view we find in the case before us that the age of 40 was attained before the disease made its appearance. It is true that Dr. T. Fox states (at page 206 of his work on "Skin Diseases") that erythematosus lupus "mostly attacks children, and especially those of the lower orders." It is, however, more than possible that Dr. Fox would at the present time modify this statement; you must not, therefore, attach too much importance to it. Neumann justly remarks that the disease "is rare under the age of 20."

Last, but not least, we have the history and character of the eruption. It is of about ten years' standing, and began by the formation of a red erythematosus patch on the back of the hand, and another, a little latter, on the forehead. The former of these has remained almost stationary since its first appearance, and contrasts remarkably with the latter, which has gradually spread with perfect symmetry over the central part of the scalp, producing baldness, and leaving perfectly smooth white scars, which are neither raised, puckered, nor depressed; the skin retains its elasticity, and the scalp is movable. The disease has spread downwards as well as upwards; it has invaded the bridge of the nose, and then spread laterally over both cheeks, always keeping a perfectly symmetrical course, so that the two sides of the face are equally affected, and thus a butterfly-shaped patch is formed, leaving the skin under the eyes, on the forehead of the nose, and around the mouth perfectly healthy.

This gradual and *symmetrical* spreading of the disease is very characteristic of this variety. Again, note especially the well-defined and slightly raised margin of the patch, the colours of which contrast remarkably with the healthy skin around, while here and there a tiny tubercle springs up just beyond it, showing distinctly the direction in which the disease is progressing—namely, at its circumference.

The whole patch has a red base, and is sparingly covered with thin white and dry scales. Nowhere has there been open ulceration except on the right cheek, which shows a few white lines of scars, evidently caused by the healing of small ulcers, the possible result of too vigorous local treatment.

These patches are nearly painless, but are at times attended with severe itching, which has been noticed as a frequent symptom in erythematosus lupus. The sense of touch, as far as we can determine, remains as perfect as ever. All this is in accordance with our usual experience of the malady. The exceptional feature, however, in this instance, is the large extent of surface involved in the course of ten years. We may, indeed, look upon the case as intermediate between lupus vulgaris non-exedens and lupus erythematosus, but approaching more nearly to the latter, though, like the inhabitant of a border-land, partaking of the characters of both races.

We may ask, Is the disease in this instance modified by any syphilitic taint? In reply, I would merely remark that the patient lost her teeth at an early age, and that we have no history of congenital syphilis to assist us in arriving at a positive conclusion on this point.

I will now direct your attention to the morbid anatomy of this disease. The earliest indication of a pathological process going on in the skin is the appearance of a patch of erythema, which is not at first very persistent. After a time we find that the walls of the sebaceous glands of the skin affected become thickened with fibrous tissue and cells, and their ducts plugged with altered sebum of dark-greenish colour, producing a peculiar and characteristic dotted appearance. (Very well shown in this drawing of Hebra's.)

Similar changes occur in the hair follicles, and, as a consequence, baldness is produced. The papillæ are also invaded, and are said by Neumann to be immensely enlarged. The new cell-growth does not generally extend into the deeper layers of the corium. As a subsequent change, the sebaceous glands and the pigmentary layer of the skin are entirely destroyed, and we have produced the well-known smooth white scars which are plainly seen on the scalp of our patient. In some very mild cases the scar left is so slight as to be quite-imperceptible; these cases are, however, exceptional.

The diagnosis of erythematosus lupus, except in its earliest stage, is not generally difficult, though if hastily examined it might be mistaken for a patch of dry scaly eczema or psoriasis, especially if, as sometimes happens, it is thickly covered with white scales. To assist our diagnosis we must bear in mind the appearance of the erythematosus patch, with its well-defined margin and red base, the comparatively small extent and slow progress of the disease, the history of the case, the part affected, and, above all, the fact that neither eczema nor

psoriasis leave scars or produce the peculiar alterations in the function and structure of the sebaceous glands which are characteristic of erythematous lupus.

Prognosis.—The prognosis is in the case before us, I need hardly say, unfavourable, as the disease is of long standing, and has made great progress.

Treatment.—With regard to the treatment of this most obstinate malady I have little that is satisfactory to tell you. Nevertheless, it is quite certain that under judicious management the progress of many cases is arrested which would otherwise only pass from bad to worse. Our first care must always be not to do harm; for it is a very easy matter, when strong caustics are used, to leave our mark, and produce a severe scar where nature would have left but a smooth and slight one. In addition, we should always bear in mind that erythematous, in common with most other kinds of lupus, is always influenced unfavourably by exposure.

Of the many remedies that have been recommended, not one can be said to produce with certainty a marked effect on the progress of the disease. Amongst the most useful may be mentioned cod-liver oil, arsenic, and small doses of perchloride of mercury, and perhaps the most generally useful of all—viz., combinations of the iodine and bromine salts. Our patient is at the present time taking, by Mr. Nunn's advice, the Woodhall bromo-iodine water, from the well-known Lincolnshire spring, which has proved in his hands a successful remedy in more than one case of lupus.

In choosing local applications you must beware of strong caustics. If they are used at all, they should be applied with great care, and only along the border of the lupus patch. Of milder remedies, blistering is one of the most useful, especially if it is combined with other treatment, such as the use of a weak nitric acid lotion, or the application of some form of tar. Hebra strongly recommends a plan by friction with soft soap, and the occasional use of soft soap plasters. The application of mercurial plaster is, perhaps, more generally useful than any other local remedy. You must, however, be prepared to find that the treatment which succeeds in one case may be unsuccessful in another, and that in many cases you can only hope to palliate or relieve the disease without producing a permanent cure.

SATURDAY, APRIL 20, 1872.

THE ROYAL ORTHOPÆDIC HOSPITAL.

WE understand that at the Special Court of Governors of this Hospital held on Monday, the 8th inst., Lord Ebury expressed his regret that he could not stay to second Lord Abinger's motion, because he had to take the chair at a meeting at another Hospital, where similar differences had arisen. We trust that his Lordship's meeting went off more happily than did the one at the Royal Orthopædic Hospital, and that voters were not manufactured for it, as they were for the one he left. But in

the letter which Mr. Brodhurst did us the honour to address to us last week he said, "Prior to most of the annual and special courts an active canvass for new governors has taken place—a practice which, it is well known, prevails in almost every institution in which there are pending existing questions." If by this statement Mr. Brodhurst means that at most Hospitals the laws or by-laws allow governors to vote at meetings, though they have only just become governors, we must take leave to doubt its accuracy. Our impression is that, as a rule, no governor can vote at meetings unless he has been a governor for some months. Undoubtedly there are exceptions, but we certainly have believed that, as a general rule, some care was thus taken to prevent meetings of governors from being swamped by new votes created for a special purpose. If we are wrong, and Mr. Brodhurst is right, it is high time that all governors really interested in the wellbeing of the institutions they support should see that their laws are revised on this point. No Medical officer is secure, and no institution can work well and safely, where such a power of making immediately efficient votes exists. Mr. Brodhurst says, "prior to most of the annual and special courts" the active canvass for new governors has taken place—which may mean, we suppose, that new governors are specially canvassed for only for matters of general business and questions of general management; and, indeed, we have heard that even at the Royal Orthopædic Hospital newly made governors do not vote at elections of Medical officers—so gross an abuse of the power of the purse not being allowed even there. A moment's thought and consideration should suffice to show anyone that, even with such limitation, the rule must be a bad one, and that the power it gives might be used to support any kind of abuse and ill-management, while the occurrences at the Royal Orthopædic Hospital have proved that, if it may not be used to elect Medical officers, it can be used to get rid of them, or to convert an Assistant-Surgeon into a full Surgeon without his having to face the usual ordeal of an election. If it is true that "in almost every institution in which there are pending existing questions" the practice prevails of making faggot-votes, of making instantaneously voting governors, at a guinea a piece, more or less, some good may come of the occurrences at that institution, for surely such a power cannot be allowed to exist after it has been shown to what purposes it may be put. Such a law is made, no doubt, with the idea that it may bring in funds to an institution, and some time may pass before its power for evil is shown; but that once proved, no excuse can be accepted for allowing it to remain. The governors of the Royal Orthopædic Hospital must, if they wish that institution to prosper, see to this and to other evils, of the existence of which so much has been heard of late. We do not propose to enter here into the question of the general management or ill-management of the institution; but, did we wish to do so, we could hardly desire better proofs of the need of thorough investigation and reform than may be gathered from the speech made in defence of the Committee by their deputy chairman. Meanwhile, let us suggest to gentlemen who may be feeling disposed to find fault with the present Senior Surgeon that they might consider whether they ought not rather to pity him. Is he not evidently the victim of a bad law, and of over-zealous and enthusiastic friends?

Who can suppose for a moment that a man of his standing and position in the Profession would willingly or wilfully make, or cause to be made, use of votes to work such results as of necessity followed the carrying the report of the Committee of the Royal Orthopædic Hospital? But if the laws of the Hospital allowed such votes to be made, how could he, an officer of the Hospital, prevent it? And if people were so thoughtless as to send their names and subscriptions to him, how could he refuse to transmit them to the Secretary? Was it for him to place any impediments in the way of those who desired to support the institution? Even Lord Abinger does

not deny that the proceedings were legal, but he asks, "Was such conduct loyal?" Loyal to whom? some may inquire. Is not an officer of an institution bound to be loyal to its committee? The late House-Surgeon, Dr. Bourne, chose to be loyal—at least, no doubt he thought so—to his patients rather than to the Committee; and he fell. Messrs. Tamplin and Adams failed, say the Committee, in loyalty to them; and Messrs. Tamplin and Adams have fallen. One of the staff has observed the laws of the institution, and been loyal to the Committee, and from being Assistant-Surgeon he has become Senior Surgeon. But shall he be blamed therefor? Has he not said that he "is sorry for the result of the annual meeting"? While laws exist, are they not to be obeyed, whether they be good or bad? If they make sorry work, shall not the governors who made them or suffer them to exist be blamed, rather than an unfortunate man who may seem to gain by the sorry work?

A GLIMPSE AT ITALIAN MIDWIFERY.

In another column we present our readers with a brief abstract of a work by Dr. Monteverdi (*Anglicè*, Dr. Greenhill), of Cremona, on the action of quinine and other preparations of cinchona on the organs supplied with unstriped muscles, and especially the womb. What we have quoted will no doubt be carefully considered by the Practitioner. In this place we cannot refrain from noticing the curious glimpses which Dr. Monteverdi's book gives of the actual practice of midwifery in Italy at the present time. We may observe in passing that Dr. Monteverdi is evidently a man of scholarly habits and great information, well acquainted with the writings of English and French Physicians from Sydenham and Morton down to West, Barnes, and Trousseau.

Let us take case the first of the cases which illustrate the efficacy of sulphate of quinine as a substitute for the ergot. Louisa Regonelli, aged 38, a seamstress, was in her first labour attended by a midwife, who on the *first* day had her bled, and on the *second* gave a dose of ergot. (We put the days in italics to make the exact lapse of time more evident.) These measures failed to finish the labour, and so, as the pains were becoming more languid, a Surgeon-accoucheur was sent for. Dr. Monteverdi, being summoned that night, made out that the cause of the delay was only that the pains were infrequent, short, very weak, and unable to move the head of the child, which was impacted in the pelvic cavity. The patient, who was easy, tranquil, and in excellent spirits, received with satisfaction the Doctor's announcement that he should wait till morning before taking the determination to relieve her, in case the labour should not be finished of itself ere then. On the morning of the *third* day the foetal head was found in the first position, the pains altogether languid; and so, with the consent of the excellent Dr. Anselmi, it was determined to extract the foetus with the forceps, it being deemed useless and hurtful to give a second dose of ergot, for the womb was contracted and painful on pressure. So the forceps was used, and a full-term foetus, well developed and already dead, was extracted.

The placenta was not extracted immediately after the operation, says Dr. Monteverdi, because the patient was exhausted, the womb sufficiently contracted, and there was no urgent symptom demanding it. So thirty-six hours passed, although the midwife pulled from time to time at the umbilical cord, and practised injections after the manner of Mojon. This must bring us to the *fifth* day. "In this state of things," says Dr. Monteverdi, "judging it dangerous to extract the placenta with the hand—forasmuch as the umbilical cord had been torn in the preceding attempts, so that there was no guide for the hand—the determination was come to to administer some remedy to excite the contractions of the womb." So the sulphate of quinine was given; but as this was the first time of trial in such a case, the Doctor prudently combined it with the

ergot, and divided a gramme of each into four powders, one to be taken every hour. Under the use of these substances some slight uterine contractions ensued, by which some fragments of placenta and clots of blood were expelled. "Having seen this happy result," says Dr. Monteverdi, "and finding the patient in a state of sensible amelioration, I administered on the following day (the *sixth*) a gramme of sulphate of quinine, of which a third part was to be taken every hour. Under the action of this drug the contractions of the womb were quickly renewed, and the remaining placenta separated and extracted easily by two fingers from the vagina, though it was in a state of incipient putrefaction. The dribbling of fetid matters, which had lasted two days, now ceased, the lochia appeared, and the patient left her bed in twenty days from the birth.

It may not be uninteresting to our Italian brethren if we point out the criticisms which arise spontaneously in the English mind on the perusal of these interesting details. Perhaps it is that the English are always in a hurry—they think illness the worst possible waste of time—and hence it is the custom, especially in parturition, to incur no unavoidable delay, and to treat the patient *cito*, as well as *tuto et jucunde*. Thus we have little doubt that if an English midwife had bled a woman of 38 in her first labour (without some special reason, of which a midwife would not be a fit judge) she would have been sent away with a flea in her ear; and if the ergot had been judged proper on the second day, it would have been supplemented with *brodo* and *vino generoso*. Then, when the Surgeon was called in at the end of the second day, he probably would have relieved the patient with his forceps at once, and so peradventure would have saved the child's life; for, after all, what is the use of obstetric science that only brings forth a stillborn child? Immediately after this, in Northern Europe, the placenta would have been gently extracted at once; for we believe that in this case, like many others, the longer you wait the worse the task becomes. Moreover, with the left hand steadying the fundus uteri from without, the Northern obstetrician would no more have hesitated to remove the placenta with his hand than he would have let it remain for the *mamma* to tug at the rotten cord. Thus, in all probability, without a grain of medicine, and without the risk attending the retention of a putrid placenta, the patient and Doctor would have been spared four days of suffering and fatigue and many others of weakness and danger.

In another case, of a seamstress, aged 23, labour began at the end of her first pregnancy with pains weak and slow. So the first day passed. Next day things were in the same state, except that the waters had escaped; so the midwife ordered her to be bled. But, says Dr. Monteverdi, this, instead of exciting, slackened the pains, which became more languid, and ceased towards evening. "Called to this young wife," says Dr. Monteverdi, "I ascertained by examination that the neck of the womb was perfectly dilated, and the head, presenting with the vertex, already descended into the lesser pelvis. In this condition it was clear that the birth would be safely and naturally effected when, with the return of uterine contractions, there should be sufficiently strong and prolonged pains. And forasmuch as the weak pulse pointed to a state of slight prostration of the forces, which had caused cessation of the uterine contractions, so I ordered the patient to take during the night some cups of broth and generous wine." In the morning—*i.e.*, forty-eight hours from the commencement of labour—Dr. Monteverdi found that the patient had slept some hours, and passed a quiet night, and the pains had returned, albeit very feeble and short. Then, he says, "finding the head in the same position, and the pains utterly insufficient to move it, I determined to give sulphate of quinine, instead of ergot, to reanimate the uterine contractions." So he gave twenty-five centigrammes (nearly four grains) of the sulphate. In an hour the pains

were a little more forcible, so a second dose was given; and in another hour a third; after which a well-developed living child was born, and followed by the placenta, the uterus contracting itself into the globe of safety (*globo di sicurezza*).

There are many points about these cases which seem strange to English eyes. Bleeding at the beginning of labour used to be performed here, and sometimes is so now, in the case of women of rustic habit, rigid fibre, and intensely violent and painful uterine contraction; although at the present day cooling and soothing remedies are far more frequently used. But if a midwife were to bleed a woman on the second day of labour, because the pains were few and feeble, she would run the risk of being sent to a lunatic asylum. We recognise the great dialectic ability and logical precision with which Dr. Monteverdi made and formulated his diagnosis and prognosis at his first visit, and we suspect that one of our working English Doctors would have turned up his sleeves and applied the forceps sooner than he could have reduced his thoughts into so symmetrical a shape. But every nation has virtues and defects of its own, and we are glad to know what others do, so that we may improve ourselves.

PROFESSOR HENDERSON, OF EDINBURGH.

THERE has recently passed away from among us a man of mark in his way, whose life is in many ways instructive. Dr. William Henderson was the son of the Sheriff Substitute of Caithness—that is to say, of the highest judicial authority resident in the county. He was born in 1810, and had his education in Edinburgh, partly at the High School, and afterwards at the University, where he also studied Medicine. He was an apprentice to Mr. Liston, and graduated in 1831. After graduating he spent two years in the Medical schools on the Continent—Paris, Vienna, Berlin—and returned to practise his Profession in Edinburgh a well-grounded man. Very early in his career he was appointed Physician to the Fever Hospital, and a little later to the Royal Infirmary, Edinburgh; and in 1842, after having been Pathologist to the Infirmary for some years, he was appointed Professor of General Pathology in the University. For two years longer he held on his way, working hard, and doing good work—investigating disease, and lecturing with much success. He was, indeed, the first to point out the distinction between typhus fever and relapsing fever—an epidemic of the latter raging in Edinburgh in 1843. But in 1844 the brilliant and promising career was abruptly eclipsed—Dr. Henderson embraced homœopathy; and though he continued to hold his chair, which was *ad vitam aut culpam*, he was compelled to relinquish his post of Physician to the Royal Infirmary, and his public career may be said to have ended; for, though he continued to lecture, he ceased to teach and to write, and though his private practice very greatly increased, he lost the position he had held in public estimation. Fierce were the debates of that time, but out of them all Henderson came with an unscathed personal character, if with a sad loss of Professional reputation for acumen; but he has ever been looked upon as the best of the homœopaths, and an honest man.

Sir James Simpson used to tell a curious story of Henderson's conversion to homœopathy. He had been induced by (it is said) Abercrombie to investigate the subject, and he had made certain researches which he mentioned in public as having struck him. Simpson had some time before that received from a well-known homœopathic chemist a case containing a set of phials filled with globules, which he had never used. These, he said, he should be glad to hand over to Henderson, and Henderson with pleasure accepted them. He made use of them, and was so struck with their effects, that he declared himself convinced of the truth of the homœopathic doctrines. Unfortunately, it turned out too late that he had unwittingly deceived himself; for the case with its phials had long been a plaything for Simpson's children, who used to

empty out the little globules into heaps, and fill the phials from these indiscriminately. We need hardly say that this was not known to Simpson when he gave Henderson the case, but it became known to him after, and he made Henderson aware of it. But Henderson had gone too far to recede, even if he desired to do so, and he became a declared practitioner of homœopathy.

The chair of General Pathology was strenuously assailed by such men as Syme and Christison, but it remains to this day to be filled by a worthy occupant—Professor Sanders. Of Henderson in this chair not much is to be said: his lectures were good, even eloquent; but they utterly failed to impress his hearers. He had no strong views to express, no clear and decided opinions of his own to teach. He could tell all about other people's views, but he left Hospital practice to any to have any of his own. Of all the teachers in the University he was the one whose individuality is most shadowy in the minds of his pupils, though had he continued to tread the path of 1842-44 things might have been very different.

In the winter of 1868 he suffered a good deal from obscure pains in the chest, which he attributed to rheumatism of the costal cartilages, but which were in reality the first warnings of the disease which has removed from among us a valuable life.

In the spring of 1869 he himself discovered the existence of an aneurism of the aorta. After submitting himself to an examination by Dr. Begbie, who was then alive, he resolved to retire from practice, which he did on the first day of June of that year—the last time he visited a patient.

From the spring of 1869 till July, 1870, he was confined in great measure to the house, but was able up to that time to see a few patients at his own house. From July, 1870, till near the close of 1871 he was confined entirely to his bed, but after that date was able to spend part of the day in the drawing-room. About the middle of last month cough came on, accompanied by purulent bloody expectoration. A few days before his death this ceased, but there remained great difficulty of breathing, and finally orthopnoea. On the morning of April 1 he became unconscious, and at twenty minutes to eleven he passed away.

His life is instructive; it teaches that money is not everything, and is not to be compared with the loss of Professional estimation.

MEDICINE IN VICTORIA.

WHATEVER may be the case with other professions and callings, it is pretty certain that Medicine does not occupy an enviable position in Victoria. More especially is this the case in Melbourne, where quarrels, lawsuits, and criminal proceedings with reference to Medical Practitioners take place. The disputes which arise—whether it be with regard to a “discovery,” a point of practice, or a question of etiquette—are carried on with a vehemence and asperity altogether unknown in the mother country. What, for instance, could have been fiercer and more unwarrantable than the attacks made upon Dr. Halford's “cure of snake-bite”?—what exceed in badness of spirit the evidence lately given on several trials, both in the civil and criminal courts? The question now attracting the attention of the Profession and laity of Melbourne is the formation of a committee by Government for “investigating the subject of diphtheria.” Here is the description the *Argus* gives of three out of four of these committeemen—Dr. McCrea, from his official position, being the fourth, and beyond cavil or objection:—“A homœopath, who even as a disciple of that schismatic school is not illustrious; a Geelong Surgical celebrity, who is not famous for the cultivation of Professional amenities; and a suburban Practitioner, who is known principally to the public as a justice of the peace in a local police-court.” The *Argus* then proceeds in a strain of ridicule and invective to denounce the formation of the committee, and declares it to be a job. It argues that if Government had

really been desirous of obtaining information on diphtheria, why not apply to the Central Board of Health or the Medical Society of Victoria. "The Chief Secretary," says our contemporary, "can hardly expect that out of such a singular trio there can be any outgrowth not suggestive of derision." This is speaking out pretty plainly, and perhaps to the purpose; but whilst we advocate to the fullest extent the liberty of the press in all matters relating to our Profession, we cannot help coming to the conclusion that a good deal of the ill-feeling and bitterness attending Medical quarrels and discussions in Melbourne arise from the very active part that political journals take in these matters—not so much as regards the present case, because that is a legitimate one for free comment, but those of a more purely Professional character. In some of the articles which have appeared in the Melbourne newspapers personalities have been indulged in, such as characterised the Medical press in this country in its worst and most objectionable times. Purely Professional disputes should be confined as much as possible to the Profession itself and their recognised organs of the public press. Nothing but scandal and ridicule can arise amongst the public from such articles as we have alluded to appearing in the newspapers. So long as these combats go on, the Profession must occupy a position in Melbourne far inferior to what it deserves. We should be glad if anything we say may convince our friends in the Far South that, however gratifying it is to give a "knock-down blow" to an opponent, every such blow rebounds to the injury of the Profession at large.

THE WEEK.

TOPICS OF THE DAY.

THE trial of Arthur O'Connor for trying to intimidate the Queen illustrates two things—one, the ease with which science can prove a man mad; the other, the difficulty there is to get unscientific people to accept its conclusions. We suppose this obstinate resistance of the unlearned springs from the old antagonism between science and credulity, only the development is in a new direction. We have been long told of faith making demands on assent which science would not or could not yield; but now it is science that asks for a submission which the weak vulgar, who only follow the dictates of common sense, obstinately refuse. Science, in the person of a distinguished alienist Physician, maintains that Arthur O'Connor is mad. Mankind, as represented by judge, jury, and Arthur O'Connor himself, are credulous enough to maintain that he is sane. The age, we must confess, is not yet sufficiently educated to pay proper respect to the dicta of scientific men. Who ought to know if Arthur O'Connor is mad if two alienist Physicians do not? and yet, lamentable to relate, we have not met a single person who does not think he thoroughly deserves his birching and imprisonment! People will admit that the boy has a weak chest, and is of a scrofulous constitution, and that his head-measurements are not up to the standard of the highest Aryan type, and they do not dispute that his great-uncle may have been insane; but somehow the stolid plain sense of the average Englishman refuses to be convinced that a lad is mad who never showed any symptoms of insanity previously to his crime, for which there was an avowed motive, who pleaded guilty, and who scouts the idea of his not being at the time and now perfectly aware of all he was doing, and of the consequences. With crass ignorance the public refuse to accept the enlightened teaching that if a man or a lad allows himself to listen to the dictates of inordinate vanity, thirst for notoriety, and political fanaticism, and is tempted to commit a foolish and wicked act, he is not responsible for it. Of course, transcendental psychology sees the whole matter in a different light, and will find in the conditions above enumerated all the proof of insanity it could wish. All we can say is, that the schoolmaster must be abroad for some generations to come

before the English mind will ascend to the exalted height from which mental pathology judges; and as we are members of society, and subjects of a Sovereign—both of whom require protection from fools as well as rogues—we are bound to confess that we are glad that the required mental development is not likely to take place in our time.

A case of accidental poisoning was investigated by Mr. Humphreys last week, which reflects but little credit on the discipline and management of the London Hospital. A child having a cough, her father applied at the London Hospital, where he saw *the porter*, who furnished him with a mixture, after taking three doses of which the child died with the symptoms of narcotic poisoning. The attention of the authorities of the London Hospital has been called to the case by the verdict of the coroner's jury, and we have no doubt that a stop will be put to consultations with the porter. The child's father is a shoemaker, and probably now regrets that he did not pay a small fee to a general Practitioner for advice and medicine, instead of asking for charity.

The English Conjoint Examination Scheme continues in its unsatisfactory and imperfect state. We hear of attempts in various quarters to render it a more comprehensive one, but we do not know that any decisive step has yet been taken. Those who are best informed in the matter believe that it cannot be done without fresh legislation; and it has yet to be proved how far those Bodies which have given in their adhesion to the scheme are legally justified in doing so by their charters. In Scotland the opposition to a Conjoint Scheme is by no means diminishing.

PATHOLOGICAL SOCIETY.

At the last meeting of this Society, the chairman announced that the first meeting in May would be devoted to a discussion on pyæmia. Dr. Burdon-Sanderson will commence the discussion, and will exhibit certain specimens, which we may say are of exceeding interest, illustrative of his views. Gentlemen who may desire to take part in the discussion are also invited to submit any specimens they may possess illustrative of their views to the meeting.

PUNISHMENT IN THEORY AND FLOGGING IN PRACTICE.

OUR readers may do us the honour to recollect that some time ago we favoured them with some essays on the nature of punishment, in which we laid down the principle that it should be—first, such as may reform the offender; secondly, such as may deter others from offending; and thirdly, that it should be frankly vindictive—that it should satisfy that inborn instinct by which we feel that a properly punished offender has got what he deserves, and deserves what he has got. So when the estimable Sheriff Sir John Bennett sent to our office the other day an order of admission to see certain criminals flogged at Newgate, we accepted the invitation as a means of studying in practice what had been before but the subject of inward cogitation, and we went. Punctually at ten o'clock we were ushered into a long whitewashed room, the chief piece of furniture in which was a huge black box with uprights so contrived as to hold the patient's legs and arms immovable. In one corner were two men stripped to their shirts; in another, a pale, scowling wretch, whimpering and protesting his innocence. Soon, however, was he confined in the black box, and the operator, poising his instrument scientifically, and giving it a preliminary flourish, began to lay on stripes in slow deliberate succession, whilst the worthy sheriff counted them, and gave the time with chronometric precision. As to the stripes, surgically speaking, we can only describe them as a compound of bruising, cutting, and tearing of the most horrible description; and, familiar as we were with Surgical operations before the days of chloroform, we believe that not the most serious and protracted, including amputation, trephining, lithotomy,

tooth-drawing, or all of them put together, were half so painful as flogging. As for the reformation of the offenders we have no evidence; but we could not help thinking what a pity it was that a thousand costermongers could not have been admitted to the exhibition, as we are sure that a thousand tongues would then have spoken of the possible inconvenience of beating a wife, or even of shoving her under the wheel of a cart.

BAD BEER AND WIFE-BEATING.

It is well known that "intoxication" is not a simple and uniform process, but that the precise character of it depends on the intoxicating agent. Good old wine will produce a good-tempered hilarity, whilst new, heady, ill-brewed, and ill-kept liquors produce stupidity or brutal violence. Now, with regard to beer, it must be remembered that its intoxicating power is far greater than can be accounted for by the mere alcohol it contains, and that cheap and coarse varieties of the hop—a plant nearly allied to the Indian hemp, or *bhang*—may be capable of producing a furious delirium, quite apart from alcoholic intoxication. A magistrate's clerk once told us that the worst assaults and crimes of violence in his district were committed by men who drank at public-houses supplied by one particular brewery. We know a publican, ordinarily a soft, easy-tempered man, but subject to occasional fits of intemperance, during which he gorged himself with new ale. The result was a compound of imbecile stupidity with fits of unreasoning brutal ferocity, of which his wife was the victim. This poor woman told the writer that she never went to bed during one of these fits without fear of her life; but that waking up one morning she discovered her husband leaning over her in what she hoped was a pensive and penitent attitude. "Well, my dear William," she said, "what are you thinking of?" "I was thinking," he replied, "that I hoped you might die in your confinement"! Query: Whether we can much blame the poor wife-beating costermonger, so long as a glass of bad beer is cheaper and more attainable than a cup of tea or coffee?

PRESTWICH ON THE CONTAMINATION OF WATER-BEARING STRATA.

IN the course of an admirable lecture delivered before the Geological Society of London, and published in *Nature*, Mr. Prestwich makes the following remarks on the contamination of wells:—

"With the art of well-digging it soon became apparent that, let the well be carried down but half-way to the level of ground-springs, it would remain dry, and that then, so far from holding water, any water now poured into it would pass through the porous strata down to the water-level beneath, keeping the shallower well or pit constantly drained. So convenient and ready a means of getting rid of all refuse liquids was not neglected. Whilst on one side of the house a well was sunk to the ground-springs, at a depth, say, of twenty feet, on the other side a dry well was sunk to a depth of ten feet, and this was made the receptacle of house-refuse and sewage. The sand or gravel acting as a filter, the minor solid matter remained in the dry well, while the major liquid portion passed through the permeable stratum and went to feed the underlying springs. What was done in one house was done in the many; and what was done by our rude ancestors centuries back has continued to be the practice of their more cultivated descendants to the present day, with a persistency in the method only to be attributed to the ignorance of the existence of such a state of things among the masses, and to the ignorance of the real conditions and actual results of perpetuating such an evil—an evil common alike to the cottages of the poor and, with few exceptions, to the mansions of the rich.

"Instances occur from time to time to point out isolated consequences of this pernicious practice, but I believe no one who has not gone into the geological question can realise its magnitude. It is not confined to one district or to a few towns or villages. It is the rule, and only within the last few years have there been any exceptions. . . . In villages and detached houses, great or small, it remains untouched and unchecked. Not a county, not a district, not a valley, not the smallest tract

of permeable strata, is free from this plague-spot. It haunts the land, and is the more dangerous from its unseen, hidden, and too often unsuspected existence. Bright as the water often is, without objectionable taste or smell, it passes without suspicion until corrupted beyond the possibility of concealment by its evil companionship. Damage, slight in extent, or unimportant possibly for short use, but accumulative by constant use, may and does, I believe, pass unnoticed and unregarded for years. Nevertheless the draught, under some conditions, is as certain in its effects, however slow in its operation, as would be a dose of hemlock. Go where we may, we never know when the poisoned chalice may be presented to our lips. . . .

"This also is only one form of the evil—it is that where the water-bearing strata are thin and the wells do not exceed a depth of thirty feet. . . .

"But even our deeper and apparently inaccessible springs have not escaped contamination. As before mentioned, the underground water will, when tapped by artesian wells, rise to or above the surface, according to the relative height of the surface of the ground at the well, and of the outcrop of the water-bearing bed or beds. . . . Further, it has been discovered that a well of this class can absorb a quantity of water equal to that which it can furnish; and as these wells give greater supplies than shallow wells, the absorbing wells of the same class are alike powerful in proportion to the others. The perverse ingenuity of man has here again taken advantage of these conditions to get rid of offensive waste waters by diverting them into such deep wells, whence they pass away in hidden underground channels, unseen and unsuspected, and mingle with those deep-seated water-sources feeding the artesian wells dependent upon them for their supply.

"In Paris, where there are several alternating beds of permeable and impermeable strata, and the depth to reach them is not very great, this system of absorbing wells connected with factories became, until regulated by the municipality, very common, to the great injury of many of the underground springs. . . . Our own system of surface-drainage is generally too good, and the depth to the lower water-bearing strata too great, to have rendered the use of such wells here equally advantageous; nevertheless, I have reason to believe that they do exist, and that the sources even of our deep well-water supply in the lower tertiary sands and in the chalk are thus to some extent polluted and injured.

"Nor do the great and perennial springs supplying our rivers altogether escape the evils arising from these obnoxious practices. On the high oolitic ranges and amongst the undulating chalk hills, the line of water-level is often so deep below the surface, that only in few cases are wells made—the population being generally dependent on rain-water for their water-supply. But this does not prevent the construction of dry wells for the disposal of sewage and refuse. It is true that the population of these hills is sparse—here and there a farm, a few cottages, and scarcely a village. Still, as the ground is everywhere absorbent, and there are no streams even in the valleys (I am now speaking of the higher districts), every dwelling contributes its quota; for the rain and all liquid matter absorbed in these strata necessarily pass down to the great underground reservoirs of water feeding the springs thrown out in the deeper river-valleys. In these cases, however, the thickness of strata through which any liquid has to pass before reaching the line of water-level is such as to produce a more or less efficient filtration and complete decomposition."

THE SURGICAL CONGRESS AT BERLIN.

WE have been favoured with the following extract from a letter dated April 14:—

"The Surgical Congress has just been held here (Langenbeck, President), in the Hotel Rome, from Wednesday to Saturday. Trendelburg gave a very good address on 'Tracheotomy,' and Busch 'On Cranial Fractures, with Depression.' Simon (Heidelberg) brought with him a rare case—fistula of the kidney. You could place your finger in the pelvis. Stilling, of Cassell, brought with him a large collection of microscopical preparations and drawings of the same to prove that the trabeculae of the corpora cavernosa and spongiosa were composed of unstriped muscle. Weggener (Virchow's assistant) was, however, very sceptical, and in no very measured manner expressed his opinions, much to the annoyance of Stilling, but yet with the secret (if not avowed) approval of very many members of the Congress. Weggener himself brought an elaborate report of experiments relating

to the influence of phosphorus on the growth of bone. Billroth made a good speech on the injection of tumours. In reference to a microscope, I am very well pleased with mine from Hartnack. Weggener strongly advises Benecke, a Berlin maker, who is cheaper than Hartnack. I believe that the English glasses are superior to the Continental, but that the superiority is not of any practical importance. I am inclined to think that the English stands are more convenient than the German, as here they do not care about a coarse movement, being content with the hand. The apparatus for work is cheaper in England than here, and better. With Hartnack I have all that is needful for pathological work. I paid him 73 thalers, and sent him 20 thalers more the other day for a No. 9 object-glass, so you see the cost is about £15. I think if you can pick up a second-hand microscope in England it would be better, and then, if you required it, you could get one of Hartnack's glasses adapted to it. Lawley, of Farringdon-street, has always on sale a collection of second-hand microscopes. The summer session will begin here about May 1."

QUININE COMPARED WITH ERGOT.

It is well known amongst practical men in England that sulphate of quinine has certain effects on the womb, of which it is well to be aware—for instance, that if given to young girls it is apt to make the menstruation painful and scanty. Dr. Angelo Monteverdi, of Cremona, has treated of this matter at length in a lately published treatise,^(a) of which the following are the conclusions:—Bark and its preparations act first on the sympathetic, then on the spinal nerves. Thus it produces contraction of the muscular fibres supplied by the great sympathetic, and especially of the womb, bladder, intestines, and bloodvessels. Its effects depend on the dose, and on the condition of the organs acted on. It may restore relaxed organs to their normal state of tone; or if the tone of these organs be already sufficient, it may induce morbid and excessive contraction. This is shown by its action on the pregnant womb, and especially during parturition. It may, administered imprudently, cause abortion; but in case of languid and feeble uterine contraction it may accelerate childbirth, and cause the normal expulsion of the placenta. Dr. Monteverdi believes it to be far preferable to the ergot, and less detrimental to mother and child. It takes the place of the ergot in all relaxed conditions of the womb—menorrhagia, amenorrhœa, and the like. It is the best preventive of puerperal fever, and the best remedy for its early stages. It is injurious in all cases of uterine excitation. These are the conclusions of Dr. Monteverdi, supported by many cases and by abundance of argument. Without doubt he demonstrates the effect of quinine on the womb; but he fails to show that for rapidity, certainty, and power of action it is at all comparable to the ergot as a parturient. Nevertheless, the hints here given, and especially on the possibility of causing dysmenorrhœa or abortion, are worthy the attention of the circumspect Practitioner.

THE PROPOSED NEW LAW OF LIBEL.

A BILL on this subject has just been introduced into the House of Commons by the Hon. Geo. Denman, Mr. Raikes, and Mr. Cross. The Bill proposes to add hard labour to the term of imprisonment, which may now be inflicted upon the publisher of any defamatory libel, if it be proved that he knew the libel to be false. Again, in the case of libelling with intent to extort money, the Bill proposes to add whipping, in case the offender be a male; and further, "whosoever shall accuse or threaten to accuse, or send, deliver, or utter, or directly or indirectly cause to be received, knowing the contents thereof, any letter or writing accusing or threatening to accuse any woman of unchastity, with a view to extort or gain by means of such accusation (letter or writing) any property, chattel, money, valuable security, or other valuable thing from any

person, shall be guilty of felony, and liable to the punishment of penal servitude for life, or imprisonment for two years with hard labour, with the superaddition of three floggings."

SOAP AND SKIN DISEASE.

A WRITER in *Nature* traces some cases of eczema to the use of soap made of putrid fat, whose ill qualities are hidden by perfume. Moreover, he says that such fat is often melted out of putrid bones, and that the soapmakers combine with the soap a large quantity of sharp angular fragments of bone. Thus the skin, and especially that of the face if the victim be a shaver, is both mechanically abraded and exposed to the absorption of the venomous products of putrefaction.

"I have," he says, "while using such shaving-soap thrice suffered from eczema of the face. On the first occasion I derived no benefit from treatment by the two most celebrated dermal Surgeons in London, and at last the disease went away of itself after giving up shaving for a time. I had by me a quantity of this brown soap, and through inadvertence took to using it again, for a time without effect; but when dry and hot weather came, with it came a recurrence of the skin disease, which also again, after some months of discomfort, went away. Curious to make sure whether or not the soap was the real cause, I a third time employed the soap deliberately to see if the eczema was due to it. I was in excellent health, and in about three weeks I found the disease re-established, so that I think the soap must be viewed as found guilty. Good white unscented curd soap is now my resource, and with no ill-effects."

"Sweet are the uses of adversity;" and the sufferer will be cheaply let off if he has learned at the expense of only three attacks of eczema and some fees to a "dermal Surgeon" that soap, having for its function the removal of dirt and smell, ought not itself to contain anything dirty or odoriferous. Sensible people use two kinds of soap—one called *Knight's pale primrose*, for the head, body, and limbs; the other a pure white-scentless curd soap, or else the white Castile soap of the Pharmacopœia, for the face (if the skin is too delicate to bear the yellow) and for the mouth. As for children with "bad heads," *Knight's pale primrose* cures cases rebellious to all the compounds of mercury, brimstone, zinc, and benzoin which are liberally dispensed at the skin Hospitals; but then it is so cheap and unpretending, and people feel quite offended at being told their children can be cured by a lump of pure yellow soap! We have made washing a science, and affirm that the right way is, to wash yourself sweet and clean first, then scent yourself if you please; but don't mix perfume with the soap. So, also, colouring matter. Why should soap be mixed with burnt sugar to make it brown? and what is the use of washing with a soap that stains the towel a light yellow? Pure white curd soap and precipitated chalk form the best dentifrice. If the breath lacks perfume, it is better to get the "Medical man" (or perhaps an "oral" or "guttural Surgeon") to look at the tongue and tonsils than to use a perfumed tooth-powder. There are, of course, purposes which are answered legitimately by medicated soaps. For instance, when sages or divinities of 50 are a little too plump and buxom, and liable to chafe, or when the skin of the feet is tender after walking, a little of Calvert's medical carbolic soap, or Wright's *sapo carbonis detergens*, acts as a fortifier to the too soft epithelium. Soap mixed with sand is sometimes useful to rub off thick and dirty cuticle; but these are exceptions. Sensible people generally use the plain, pure soap, and do not buy bad soap, worsened by colouring matter and scent, at a higher price.

AMERICAN MEDICAL DEGREES.

It has long been a scandal that so-called Medical degrees have been obtainable in America by persons altogether unqualified and quite uneducated. The evil has at length become so intolerable in one quarter, that the Government of Philadelphia have taken action on the subject. Bills have passed the Assembly, and now only await the Governor's signature to become a law, depriving the Eclectic Medical College of

(a) "Dimostrazione di una Virtù Medicamentosa della China." Cremona, 1870.

Philadelphia and the Philadelphia University of Medicine of their charters. The preambles to the Bills declare that these establishments "have for some time past been engaged in the unlawful sale and issuing of Medical diplomas to persons not qualified to receive them, in violation of the spirit and terms of their charters, to the gross detriment of the public interest, tending to bring the Medical institutions of the State into discredit, and endanger the public health, by permitting persons utterly unqualified to practise Medicine and to exhibit diplomas thus improperly obtained." It is high time that some others of the United States should follow the example set them by the authorities of Philadelphia. Throughout the States spurious diplomas are to be obtained by the payment of a small sum of money.

SMALL-POX JOTTINGS.

THE Medical report last week to the St. Pancras Vestry stated that "small-pox exhibited a slow but satisfactory decline."—Four new cases of small-pox were reported last week to the St. James's (Westminster) Vestry.—Two deaths from the disease occurred in Newington last week.—There were no deaths registered from small-pox during the past month in St. George's-in-the-East.—The Dublin Small-pox Committee continue to devote considerable time to their duties. Already the Committee have accomplished much. At a meeting held on Friday it was resolved that the clergymen of all denominations in the city should be *ex officio* members, as well as the chairman, vice-chairman, and deputy vice-chairman of each union, and all the members of the Public Health Committee of the Corporation.—The *Leicester Chronicle* says that there are 300 cases of small-pox at present under treatment in the town.—Two deaths were reported in Bermondsey from small-pox in the past fortnight.—Forty-nine deaths from small-pox occurred in London last week, thirteen of which were recorded in the special Small-pox Hospitals.—The disease is very fatally prevalent in Poplar; nine deaths were returned, four of which were unvaccinated cases.—Dr. Aldis, St. George's, Hanover-square, reports for the week ending the 13th inst. five cases of small-pox, four of which were sent to the Hospital.

SANITARY CONDITION OF ARISTOCRATIC MANSIONS.

THERE can be no excuse for the neglect of sanitary measures in the abodes of the wealthy; yet, according to Dr. Whitmore, the Medical Officer of Health for Marylebone, this neglect is by no means uncommon. He says in his last monthly report that his attention has been lately called to the condition of a highly rented house in one of the most respectable streets of the parish, which he could designate by no other term than disgraceful; but this, Dr. Whitmore says, is by no means an isolated case. He need hardly say that in these cases orders for sanitary work are promptly made upon the owners, and he personally took care that no unnecessary delay in carrying them out was permitted.

VACCINATION IN JERSEY.

THE Jersey "States" remain true to their colours respecting vaccination, and their motto is still "No surrender." Small-pox is rife in the island, and the Bill for rendering vaccination compulsory has been thrown out by the powers that be. At the same time they have, like the currier in the fable, compromised the matter, and have appointed a committee to consider and report upon the best method of carrying out the principle of vaccination on a voluntary basis. Verily, "there is nothing like leather."

FROM ABROAD.—THE FRENCH MEDICAL ASSOCIATION—M. GOSSELIN ON SURGICAL AFFECTIONS OF ADOLESCENTS—THE "AFFAIRE DOLBEAU."

THE French General Medical Association held its anniversary meeting on Sunday week, and, in spite of the perturbations of

every kind ensuing on late events, most of the local societies were represented by their respective presidents or by delegates. Those from Alsace and Lorraine, putting in their appearance in order to testify the love and attachment they felt for their mother country, and their hopes of future restoration to it, were received with a cordial enthusiasm amounting to an ovation. The first business devolved upon the Association was a consequence of becoming its own absolute master on the fall of the Imperial *régime*—the election of a President by universal suffrage. It was, indeed, only a confirmation, for the re-election of M. Tardieu had taken place a few weeks before. There was at first some opposition to the list of names proposed by the Council of the Association, as supposed to be the product of cliquism, and devolving too much power on the Paris Central Association. It is, in fact, one of the unavoidable necessities of all societies that those who are at all the trouble of displaying the necessity for them, getting them up, and seeing them through the difficulties of their early career, should retain a predominant power in their future working. The justice of their doing so seems to have been admitted in this case, for the names of various eminent persons selected as opponents were one after another withdrawn. M. Tardieu, in returning thanks in one of the happy addresses, displaying skill, tact, and just appreciation, for which he is famous, received immense applause when he "protested against the stupid kind of ostracism which too large a portion of the Assembly at Versailles had inflicted upon Paris"—a circumstance not without its political significance, when we remember that the audience was derived from all parts of France.

M. Brun, the Treasurer, gave a satisfactory account of the finances of the Association, stating that the Benevolent Pension Fund amounted to 215.00 fr. The Secretary, M. Latour, stated that the terrible events of last year, by throwing all France into trouble and confusion, prevented the local secretaries from furnishing their returns in time to allow of a complete display of the actual condition of the Association. But he was enabled to assure his audience as to the future of the institution, the information he is in possession of proving "that if, like everything else in France, it has felt the recoil of the public disasters, the Association, in imitation of France herself, is in train of recovery, and taking a new spring forward." Professor Jeannel, of Bordeaux, delivered an animated report in favour of the re-establishment of the *concours* for all Medical places and functions, but under broader and more intelligent conditions than have heretofore prevailed. A report by M. Guerrier, the legal adviser of the Association, relating to the difficult subject, "the illegal practice of Medicine," terminated the proceedings.

In a memoir read to the Académie des Sciences by M. Gosselin, on the "Surgical Affections of Adolescents," he sought to show the influence exerted by the age of the patient in the choice of the means of treatment.

"For determining this choice," he says, "I offer the following formula for our guidance, viz.:—'The special spontaneous surgical affections of young persons have a tendency to persist, increase, or relapse, as long as the period of adolescence lasts; but these tendencies are lost as soon as adult age is reached.' Thus—1. In *ingrowing nail* many are the remedies that have been recommended, and yet new ones are always being sought for, because, after using those hitherto employed, relapse has ensued. Now, most frequently this depends upon the fact that the subject, being still young, retains the special pathological aptitude through which the disease was originally produced. For my part, I have never had occasion to observe relapse after the 25th year, and from this I conclude that, while we should take every care to prevent the return of the disease, we must not expect a definitive cure as long as the patient has not reached his 23rd or 24th year.

"2. In *valgus douloureux*, which I have also named *tarsalgis*, I have established that the disease depends on a special arthrositeitis of the tarsus, developing itself as a consequence of the growth of this part of the skeleton; and that the chief indica-

tion consists in relieving the pain in walking and the concomitant contraction of the muscles of the leg, and thus preventing termination by muscular retraction, permanent valgus, and ankylosis. The best means for obtaining these results are rest, *inamovable* apparatus, and sometimes tenotomy of the lateral peronei and electricity. But as long as the patient remains young, relapse is not always avoidable. When it does occur we must return to the employment of the same means, and not conclude too hastily that the disease is incurable; for by persevering in the treatment until the subject has attained the adult age we may prevent the consecutive deformity and infirmity which would ensue if the affection were left to itself.

"3. In *acute suppurating osteitis of the epiphyses*, when this has not been intense enough to call for primary amputation or to cause death, and when it has terminated by necrosis of long duration, I recommend that consecutive amputation should not be too readily determined upon; for in such cases I have seen the necrosis terminate and a definitive cure ensue, when the patient, having reached his 25th or 26th year, has lost his predisposition to suppurative osteitis, which was a consequence of his age and an aberration of nutrition at the period of the juncture of the epiphyses.

"4. In *exostosis of the epiphyses*, or exostosis of development, my observations have taught me that the tumour ceases to grow and to be painful when the subject has once passed adolescence; and, as its removal is a dangerous operation, I advise temporising and leaving the affection to itself.

"5. In *subungual exostosis of the great-toe*—an affection too troublesome and too painful to allow of non-interference on the part of the Surgeon—the relapses which follow their employment constitute the objection to most of the measures that have been proposed for its removal. But here, as in in-growing nail, I have found that, although relapse occurred while the patient still continued young, it ceased when once adult age had been reached.

"6. In *large fibrous naso-pharyngeal polypi*, the dimensions of which do not allow of their being treated even in a palliative manner without a preliminary operation affording access to their seat of implantation, this consideration regarding age is of primary consequence. I reject the excision of the upper jaw because it endangers life and leaves a mutilation of the face without assuring in an absolute manner against relapse. I prefer M. Nélaton's procedure—an aperture in the velum and arch of the palate—contenting myself with palliative operations by excision and cauterisation, thus preserving the patient's life until the time when, being of adult age, he will in all probability have lost the disposition to reproduce the tumour."

The *Journal des Débats* publishes the following statement respecting Professor Dolbeau, which the *Gazette Hebdomadaire* regards as a quasi-official circular:—

"It will be remembered that at one of the latter sittings of the National Assembly the Minister of Public Instruction stated that Professor Dolbeau had demanded of the President of the Assistance Publique that an investigation should be made as to the occurrences which took place at the Beaujon Hospital when the Versailles troops entered Paris. The inquiry, which was conducted by a Commission, has now terminated its proceedings, having interrogated M. Dolbeau and all those able to speak to the facts. The minutes of the depositions have been forwarded to the Minister. All the witnesses agreed that M. Dolbeau had attended to all the patients, whether federals or not, with the greatest zeal. With regard to Bredon (whom he was reproached with delivering up) he had even manifested great complaisance, inasmuch as this man, in order to avoid the combat, had pretended to be worse than he was. When, therefore, the troops had occupied the Hospital, and room had to be made for the wounded who were on their way thither, Bredon and eight others were selected for discharge. An observation made aloud by one of the students caused M. Dolbeau to remark that the card which was presented to him for signature was not that of Bredon, but he only desired the Sister to see the matter rectified. On returning to the Hospital in the evening he learned that no such rectification had taken place, that the patient was still in the Hospital, and that the card could not be found. Finding no one from whom he could get any explanation, and believing in a kind of mute conspiracy, M. Dolbeau addressed himself to the officer on duty, and informed him of what had occurred. Bredon was taken into custody, but liberated next morning. A report having got about that this man had been shot, great excitement prevailed throughout the Hospital; but on the

truth becoming known, those who had taken part in it retracted their accusations. Moreover, Bredon has since been at the Hospital to ask for aid and to return thanks for the care that had been taken of him. The Commission dismisses the complaint against Professor Dolbeau, and comments upon the irregularities which explain the manifestation of his displeasure."

PARLIAMENTARY.—THE LICENSING BILLS—LOCAL TAXATION.

ON Tuesday, April 16, in the House of Lords,

The Earl of Kimberley introduced the Government Licensing Bill, when it was read a first time.

In the House of Commons,

Sir Massey Lopes carried his annual motion on local taxation, against the Government, by a majority of 100. The motion took the form of the following resolution:—"That it is expedient to remedy the injustice of imposing taxation for national objects on one description of property only, and therefore that no legislation with reference to local taxation will be satisfactory which does not provide, either in whole or in part, for the relief of occupiers and owners in counties and boroughs from charges imposed on ratepayers for the administration of justice, police, and lunatics, the expenditure for such purposes being almost entirely independent of local control."

On Wednesday, Sir H. Selwyn-Ibbetson moved the second reading of his Licensing Bill. The debate was adjourned.

POOR-LAW MEDICAL OFFICERS AS
MEDICAL OFFICERS OF HEALTH.

(By a Poor-law Medical Officer.)

It is a very old and lamentable fact that the Medical men who are entrusted to take care of the health of the poor are themselves poor and ill-paid. The office of Parish Doctor confers no dignity or Professional rank upon the holder, and, so far from being an introduction to profitable practice, it is a positive injury to Professional prospects.

Under these circumstances, any proposal that was likely to increase the salary, and at the same time add to the dignity, of the District Medical Officer would be hailed with satisfaction by the Profession; and such a proposal we were led to expect in Mr. Stansfeld's Public Health Bill.

In that Bill it is proposed to appoint the District Medical men Officers of Health for their respective districts; and we are of opinion that in that proposal lies the germ of a radical change for the better in the position of those gentlemen. In the future the art and science of preventing disease is destined to occupy a very prominent and important place, and it is by all means desirable that the Medical Profession should guide and direct this great movement.

District Medical Officers are brought into personal communication with cases of epidemic disease arising from culpable neglect of the most common sanitary laws; and while they are well aware that the cases of fever, for example, are produced by contaminated water or by the foul sewage gases, they have no power to compel owners of property to remedy the evil. Such a power it is proposed to confer on the District Medical Officers by Mr. Stansfeld's Bill, and we certainly were of opinion that such an accession of power and responsibility, if accompanied with equitable and liberal arrangements for remuneration, would be the means of elevating the Professional and social status of the parish Doctor. The Medical Officers themselves, however, are not of that opinion, and they have expressed themselves through numerous letters and petitions in terms of unequivocal condemnation of those provisions of the Act which relate to the appointment of Officers of Health.

The Medical Officers urge, firstly, that no provision is made in the Act for the payment for services as Officers of Health by boards of guardians; and their experience of those boards in the past justifies them, they say, in thinking it probable that they (the Medical Officers) would be saddled with onerous

additional responsibilities without any addition, or with a very inadequate addition, to their present salaries.

We scarcely think that these apprehensions are well grounded. No change in the way of adding to the duties of the Medical Officer can be made by the guardians without communication with the Local Government Board, and the drawing up of a fresh contract; and we have Mr. Stansfeld's personal assurance that he has no intention whatever of adding to the duties of the District Medical Officers without increasing their pay.

The second and most important plea of the Medical Officers is, that if appointed Officers of Health in their districts they could not discharge the duties without injury to their own private interests; that the owners of property are guardians, vestrymen, and private patients, and that to take the necessary steps as Officers of Health—to compel such persons to put their houses in order—would make enemies of them in the board-room and in society.

We cannot but regard this plea with sorrow. It is a confession of weakness—natural and true perhaps, but of doubtful wisdom. If Medical men feel themselves too weak for this great task, other and bolder men will take it up. It must be remembered that the education which fits a man for the curative treatment is not necessary for him who deals only with the prevention of disease, and while an Officer of Health must be a man of science, he need not be a registered Practitioner or have any Medical licence.

We would therefore suggest caution in rejecting what is really intended as a boon, and may, we think, if judiciously handled, tend to elevate the position of the Medical Profession, and especially of the District Medical Officers.

No doubt the scruples and hesitation of the unwilling must be regarded, and due provision made that every District Medical Officer who professes himself unwilling to incur the responsibilities of Health Officer must not be forced into such a position, nor have any alteration made in his existing contract for the curative treatment of the sick.

If, then, due provision is made by the Public Health Bill for the adequate remuneration of Health Officers, and protection for those of our Medical brethren who do not feel themselves strong enough for the place, we trust that a large number of District Medical Officers throughout England will accept the position of Health Officers, and with it the chief share in the great work of preventing disease.

NEW BOOKS, WITH SHORT CRITIQUES.

Consumption and the Air Rebreathed: being a Sequel to the Author's Treatise on Consumption. By HENRY MACCORMAC, M.D., Consulting Physician to the Belfast General Hospital, etc. London: Longmans. Pp. 150.

*** Dr. MacCormac is a learned man, and his views are supported by a host of authorities direct or indirect. These views are now tolerably well known—viz., that consumption only occurs under conditions which imply the necessity for breathing air over again. The carbonic acid is, in his estimation, the originating element. Now, whilst willing to admit that rebreathed air may be a cause of consumption, and that it is harmful in the extreme, we are hardly prepared to follow Dr. MacCormac in every particular. To his practical conclusions we cordially assent. Fresh air is undoubtedly a thing of the very utmost value, especially to those whose chests are naturally weak.

A Lecture on some Points for Comparison between the French and English Soldier. By Deputy Inspector-General C. A. GORDON, M.D., C.B., Officier de la Légion d'Honneur; late in special service with the French Army. London: Baillière, Tindall, and Cox. 1872. Pp. 30.

*** Our readers well know that Dr. Gordon had the high distinction of being accredited to the army within Paris during the German siege and bombardment. This opportunity was not thrown away on a man of his ripe experience and accurate powers of observation. This lecture will show how carefully he has scrutinised the whole status of the French soldier;

including the qualification of recruits, the length of service, the weight which the soldier has to carry, his social standing, education, food, and drill; and on all these points a fair comparison with the English soldier is instituted. The French soldier of the future ought to bless Dr. Gordon for pointing out so clearly the circumstances in which his food and clothing are ill adapted to sustain him in his work.

The Education of the Deaf and Dumb by means of Lip-Reading and Articulation. By W. B. DALBY, F.R.C.S., M.B. Cantab. London: J. and A. Churchill. 1872. Pp. 32.

*** A very clear and able exposition of the art of teaching deaf mutes to speak by imitating the lip- and breath-movements of their teacher, with the comparative disadvantage of teaching them to talk with the fingers only.

FOREIGN AND COLONIAL CORRESPONDENCE.

FRANCE.

PARIS, April 9.

ASSOCIATION AGAINST ALCOHOLIC DRINKS—NEW MEDICAL JOURNALS—THE ENGLISH HOSPITAL—REPAIRS IN PARIS—NEW LIGHT—MEDICAL MUTUAL AID SOCIETY—REOPENING OF THE MEDICAL SCHOOL.

In referring to the new association organised in Paris against the abuse of alcoholic drinks, I overlooked the fact that there was another which has been in existence for some time, and likewise opposes the abuse of tobacco. This was started by M. Jules Guérin, who about a year ago petitioned the National Assembly to adopt measures to put down the immoderate use of tobacco and alcoholic drinks, which he looks upon as a symptom of the degradation of the race. He proposes to levy heavy taxes upon these articles, but to diminish that upon wine, and would have done well to add, upon all *necessaries of life*. As for beer, the worthy *savant*, strangely enough, classes it among spirituous liquors, as he says it is in its way not less prejudicial to the health. "It alters the 'national character,'" he adds, "by rendering those who indulge in it heavy and stupid."

A great many new Medical journals are springing up in France—among them the *Journal d'Ophthalmologie* (monthly), having for its principal editor Dr. Galezowski. *L'Indépendance Médicale*, essentially a specialist organ, also published monthly, professes to propagate new ideas and new remedies in Medicine and Surgery; the principal editor is Dr. F. Moreau-Wolf, who styles himself "Professeur libre de Pathologie des Voies Urinaires." An introductory address in the first number, by Dr. Jules Chéron, justifies specialism as "nécessaire au progrès de l'art de guérir, car elle représente un puissant mode d'analyse indispensable à l'étude d'un domaine trop vaste que la division du travail peut seule permettre d'explorer." *L'Hospitalier*, a bi-monthly publication, is the special organ "des Sociétés de Secours aux Blessés et aux Victimes de la Guerre," and the principal editor is H. Renou.

There has been a series of popular Medical lectures in Paris. In the lecture-hall in the "Boulevard des Capucines," Dr. Blain des Cormiers entertained his hearers on "Les Maladies Régnautes" and "Les Maladies Professionnelles."

Sir Richard Wallace—"le grande bienfaiteur," as the French call him—who did so much to relieve the sufferings of Paris during the siege, seems indefatigable in his philanthropic efforts. He has founded just outside the fortifications at Neuilly a Hospital at his own expense, for the reception of poor British residents. It is designated the "Hertford Hospital," and Dr. Rose Cormack and Dr. Herbert are the Medical officers. I have paid frequent visits to this Hospital, which, although in every respect well suited for the purpose, is to be superseded by one more complete. In Sir John Cormack's Ward there were no less than four cases of bites and kicks from horses. As there were only twelve beds, this fact gives a hint of the composition of the English colony in Paris.

The "Galigani" Hospital at Neuilly—a similar institution to the above—has been reopened.

Sir Richard Wallace is, I understand, about to establish, at his own expense, drinking fountains in the most populous quarters of Paris; but, however well intended, they will, I fear, not take well in Paris, as the French are not generally water-drinkers. Nevertheless, let us have the fountains and be thankful.

The annual exodus for the provinces has already begun—rather earlier than usual—and several people are quitting Paris altogether, thoroughly disgusted with the internal state of affairs. While there is a great egress of Parisians, it would appear that there is a greater ingress of visitors, provincials as well as foreigners, the British being, as usual, the predominant element. But, wherever the people are gone, Paris seems as full as ever, and, owing to the increasing difficulties of free circulation, it is proposed to have subterranean boulevards in the most commercial quarters, which would not be a bad idea, as the number of accidents in the streets seems to be on the increase. Paris is beginning to look itself again, as the damage incurred by the double siege is being rapidly repaired, and many of the buildings that were burnt in the last agonies of the Commune have been set up again, with the exception of the larger edifices and monuments, which still remain to tell their sad tale. The French are generally very clever in all sorts of artistic work, and it is astonishing to see the manner in which the bullet-marks and other injuries inflicted by shells and the hands of the Vandals are being effaced. A peculiar cement is used, which dries up with wonderful rapidity, and assimilates itself with the hardest stone. Even the very trees that were so badly treated during the dreadful struggle between the Communists and the Versailles troops seem to be thriving again, and many that had their bark literally torn off, and were otherwise injured, are now flourishing as if nothing had happened to them, the wounds having been dressed with a substance composed of pitch—both not bad specimens of “plastic Surgery.”

The oxy-hydric light, lately experimented with for lighting up the boulevards, is spoken of as a success, and the company—the patented owners of the invention—offers to substitute this new gas for that now in use, at a saving of 20 per cent. The light produced is equal to that by the carburetted hydrogen, but is somewhat paler, and resembles more an electric light. This, I am afraid, would form a serious objection to its use indoors, as the flame is rather dazzling and trying to the eyes, as are all white lights; but in other respects it is less detrimental to the health. Moreover, the agents observe that, as the price will not exceed 10d. per cubic metre, it may with advantage be utilised for other purposes, such as for the rapid fusion of metals, the manufacture of certain chemicals, and for rendering the air of sick-rooms and Hospitals wholesome and sweet, thus insuring salubrity, cleanliness, and economy at a trifling cost.

The weather is still very variable, the mercury fluctuating between 45° and 55° Fahr. within doors—and this will account for the continued prevalence of pulmonary and throat affections; but we are as yet free from any epidemic, properly so-called. The mortality for the week ending April 5 amounted to 884, being somewhat in excess of that for the week preceding.

Interrupted by the painful circumstances of which Paris had been the scene for nearly two years, the annual meeting of the Association Générale de Prévoyance et de Secours Mutuels des Médecins de France took place at 2 p.m. on Sunday, the 7th inst., in the great amphitheatre of the Bureau Central, which is situated in the Avenue Victoria, being about the only part of the building that escaped the Vandalic fire of the Communists, who had their head-quarters in the Hôtel-de-Ville—within a stone's throw. The meeting was presided over by M. Tardieu, the elected President of the Association, assisted by the Baron Larrey and Dr. Horteloup, Vice-Presidents; Dr. Amédée Latour, Secretary-General; and Dr. Brun, Treasurer. After the preliminary business of the meeting, M. Tardieu, as eloquent, and M. Latour, as fluent as ever, spoke of the past and present history of the Association, and held out hopes of a bright future. The latter referred most feelingly to the painful events that France, and particularly Paris, had just gone through. “Let us all work for the common weal,” said he “and France will yet take its wonted place among the nations;” adding that, “although Alsace and Lorraine have been wrenched from us, the inhabitants of these lovely provinces will ever remain as they always have—our brothers and sisters’ by the more sacred and indissoluble bonds of consanguinity.”

The object of the Society is to succour those members and their families who, by advanced age, disease, or other calamity, may be reduced to a state of distress; to afford aid and protection to its members in every possible way; and to insure by its moralising influence the practice of the Medical art in a manner conformable to the dignity of the Profession. There is a sister society whose aims are almost identical, which was founded in 1833 by the late M. Orfila, but is confined to

Practitioners in the Department of the Seine, whereas that of the Association Générale extends throughout France and its colonies. It is anticipated that ere long the two societies will be amalgamated.

On Sunday evening a *soirée confraternelle* was organised at the Grand Hotel, at which there were a goodly number of the Faculty present, but nothing compared to what it used to be in former years. There were a great many provincial Practitioners, and a sprinkling of the notabilities of the Profession, among whom I noticed Ricord, Tardieu, Amédée Latour, Dr. Horteloup, formerly of the Hôtel-Dieu, and Dr. Béhier. Before the war a banquet used to be the order of the day, but it has been considered not quite the thing so soon after the disasters that had befallen the country. As it was, the *soirée* passed off most agreeably; there was no lack of refreshments, and owing to the admirable tact of Dr. Brun, the treasurer, the arrangements were all that could be desired, even for smoking, which, from the absence of ladies, was freely indulged in in the hall itself. It struck me, however, and others likewise, that the presence of an usher would be an improvement, so that one may know whom he is talking to, or whose acquaintance he may wish to cultivate.

April 16.

The distinguished Professor Richet has been promoted from the grade of Officer to that of Commander of the Legion of Honour, “for exceptional services, and for his devotedness to the sick and wounded during the siege and insurrection of Paris.”

You will have learned that the court of inquiry on Professor Dolbeau has ended in his acquittal. The Medical School was reopened yesterday, under certain restrictions, which had reference only to Professor Dolbeau's course. At three o'clock precisely, M. Dolbeau, who looked somewhat jaded, made his appearance in the amphitheatre, preceded as usual by the beadle. There was no demonstration of any kind, either for or against him. Some attempts had been made to create a sensation, but the would-be agitators, not finding themselves sufficiently strong to carry on the contest, took their revenge by leaving their seats in a noisy manner, and “sloped” out of the school-room. The lecture, however, continued uninterrupted, and M. Dolbeau on leaving was saluted by a few tame hisses, of which he took not the slightest notice. Thus ended this comico-dramatic affair. M. Dolbeau is comparatively young for a Professor, being only 42 years of age. He is an able lecturer, a profound scholar, and an accomplished Surgeon.

AMERICA.

PHILADELPHIA, March 16.

STATE MEDICAL SOCIETIES—PROTECTION AGAINST ACTIONS FOR MALPRACTICE—MEDICAL EDUCATION IN AMERICA—MEDICAL COLLEGES—DENTAL COLLEGES—FORTHCOMING MEETING OF THE AMERICAN MEDICAL ASSOCIATION.

The proceedings of State Medical Societies are interesting, as a reflection of the prevailing spirit and sentiment of the Profession as a mass. Most of these gatherings are held in the early summer months, when a convenient excuse may be made for temporary absence from the cares of practice at a season when pleasure trips are fashionable and desirable. Very few Medical men visit these conventions with any actual intention of presenting startling communications on interesting themes of pathology, or of bringing forward any measures for the improvement or benefit of the Profession; most of the work of conventions, as of committees, is in the charge of a handful of men, and the rest of the members are listeners to, or quiet seconders of, the acts proposed for their consideration and votes. The useful few who are the prominent movers of measures in these societies often effect a great deal of good by the recommendations they make for the Profession at large, and the good sense of the majority generally checks any tendency to injudicious legislation. When I use the word “legislation,” I do not mean to imply that the action of any Medical convention has the binding force of law, although usually graciously accepted by Medical men generally. The social aspects of these gatherings are not the least attractive features they offer.

I am led to make these remarks by the assembling of the “Medical Society of the State of New York” at Albany, about three weeks since, at their usual exceptional date of annual meeting. Among other important business transacted by it, was the adoption of a draft of a Bill to be presented to the Legislature for the protection of Physicians and Surgeons in cases of alleged malpractice. I do not know what safeguards

are thrown around the Profession in Great Britain in this respect, but hitherto in all our States science and skill applied to the cure of deformity or disease have been liable to punishment for malpractice, provided juries of ignoramus could be found to respond to the appeals of legal advocates of the plaintiff's efforts at extortion. Three recent cases occur to me at this moment, in which as many of our most respectable Medical men were exposed to annoying legal persecution; but in each instance the vindication was triumphant, and the example in its moral effect beneficial for future cases of a similar kind. Judges are scarcely ever so sympathetic on the plaintiff's side that they are blinded to the real merits of the controversy, but juries are not always so intelligent or so just. The difficulty in all measures that are intended to throw a safeguard around the members of the Profession is in the enforcement of them. When a State Medical Society recommends a law to a Legislature for its approval, it is a settled custom that these mere politicians throw every practicable obstacle in the way of its passage, and it is therefore very doubtful whether the Profession will succeed in securing the protection it solicits.

There is always a disposition manifested at these annual gatherings to produce in the community at large an improved knowledge of Medical matters. There is a tendency here, which may be greater or less than prevails abroad, even among those who are considered the most reputable of our citizens, to patronise quackery—in which I, of course, include a number of *isms*—and the task of correcting such false and baneful influences seems to be almost hopeless. The laws now in force to prevent unqualified Practitioners from pursuing their injurious practices are certainly thus far insufficient. They vary in different States, and in some have not been enacted at all. It is very problematical whether the plan recommended by Dr. Stephen Rogers, of New York City, at the recent meeting would, if adopted, be of permanent advantage to the public, while it would certainly lower the tone of the Profession. "Upon the assumption that a properly educated Physician will, in some form or other, do what appears to him appropriate in cases of disease and in wounds, let us," he says, "insist upon the education, and leave the collateral questions of therapeutical belief and faith to the conscience of the individual." But what will the qualification or training of a "properly educated Physician" be? Will the homœopath and the regular Physician agree at the outset what is to be the standard of "proper education"? If so, the millennium of peace and harmony is close at hand. Dr. R. thinks that all efforts for the protection of the Profession will not then seem like selfish plans for the advancement of those having a particular set of views; but it may naturally be asked, When such legislation has been effected by this combination of all shades of Medical belief, in what way would its provisions be carried out to accommodate the regular Practitioner at the top of the scale, and every possible gradation of irregular globule-vendor, pellet-dispenser, and water-cure enthusiast, down to the very foot of it? The Society seems to have listened to these recommendations, but not to have heeded them.

Some interesting papers were read at this meeting. Once in a while, as for three or four successive years recently, in the State Medical Society of Pennsylvania, some cause of wrangling, such as the woman question, comes in as a disturbing element, and when the members of the convention afterwards review their own proceedings they wonder at the trifling importance of their scientific labours, and find they have accomplished almost nothing worth reporting. At the New York Society meeting, Dr. T. Addis Emmet read an interesting paper on "Chronic Cystitis in the Female," especially that form of it which is consequent on vesico-vaginal fistula. When Dr. J. Marion Sims left New York City to go abroad nearly a dozen years ago—about the outbreak of our civil troubles—he established for himself a reputation in Paris in the performance of difficult Surgical operations on the sex, and in the treatment of the peculiar diseases to which it is liable, equal to that which he had left behind him in America. His assistant, Dr. Emmet, then, however, stepped into his place in private and public practice in New York, and having a mechanical genius, he soon added to the value and importance of the operations, and is now universally recognised as one of the very foremost authorities in vesico-vaginal Surgery in this country, and as Dr. Sims's legitimate successor.

The winter sessions of our Medical Colleges terminate usually with the month of February, and within a few days from the suspension of lectures hundreds of new aspirants for the popular favour and for the honour of a liberal profession enter the ranks, and become scattered at once broadcast over the land. The technical term "commencement," is universally applied in

this country to the graduation exercises of a college, inasmuch as the newly created M.D. on that day begins his career of Professional life. As you are doubtless aware, each graduate is a Doctor of Medicine; in other words, we have no classification of Physicians and Surgeons in those who study Medicine, but only in those who practise it. A student enters a Medical College, usually without foreseeing at first whether fate or his own taste may make him the one or the other, and, as a general rule, must practise all the departments of medical, surgical, and obstetrical science and art in the country town in which his abilities are henceforth to shine. In order to graduate, the Medical student has hitherto been compelled to attend the full courses of lectures on Anatomy, Physiology, Surgery, Obstetrics, Materia Medica, Practice of Medicine, and Chemistry, in addition to three years of study, and all the usual moral and other qualifications desirable and attainable. These are the solid and substantial branches, which are applied and amplified into various ramifications in different schools, in combination with clinical teachings in all their phases. When a student comes up for examination, the rule in most of the Colleges is that he must pass satisfactorily in at least five of the branches out of the seven before he can receive the degree. It is a defect in the system of Medical education in this country, that the Professors who have lectured to the young men during several months, and taken often a personal interest in their welfare, should also examine them at the end of the session. There is certainly a natural leniency and tendency to admit students to the degree on the part of these gentlemen, rather than an undue severity in refusing them admission into the ranks of the Profession. The graduation fee—thirty dollars usually—might, with the unprincipled Faculties of some of the minor schools, which border slightly on the confines of Professional dishonesty, operate as an incentive to reject only occasionally candidates for graduation, in anticipation of the pecuniary loss involved in such rejection. Such tricky colleges are very, very few, however, are frowned upon by all honourable men, and soon find their proper level, and meet with an early demise. There has always been a strong feeling in this country of opposition to examining boards, and one of the best reasons for such opposition has been the fear that political influence might lead to the appointment of irregular and incompetent men, who in moral and mental *status* might be greatly inferior to those who presented themselves before them for examination. As at present constituted, the college Faculties are far more reliable, and although from partiality or too generous consideration of the candidate's proficiency the Profession may thus receive sometimes an unworthy addition to its numbers, there is no doubt that the same thing would not only occur more frequently in any other mode of examining, but that many an excellently prepared student would suffer martyrdom at the hands of a Medico-political board of pretentious State examiners.

A year or two ago it was not an uncommon event, in the absence of all restriction to the contrary, for a student to complete his attendance on lectures and become an M.D. with almost lightning-like rapidity. In other words, he would attend a course of winter instruction in Philadelphia or New York—this being his first session of lectures—and then, after an interval of a week or two, go to some summer school elsewhere and graduate; thus, in less than one year, attending two full courses of lectures, and storing away an immense mass of undigested material. It was not unusual for these hastily prepared Physicians to come back again to their first love the following winter, and claim all the privileges of reduced fees, etc., generally accorded to third-course students and graduates of other schools. But this soon came to be regarded by the winter colleges as not only detrimental to the interests of the student himself, but an unfair method of depriving them of the full fees to which they were justly entitled. The general sentiment of the Profession, which aims unceasingly at a higher standard and greater completeness of education, has materially aided the faculties of the various schools to break down this deleterious system; and it is probable that in time the evil complained of may be done away with entirely. The summer colleges referred to generally give a full and thorough course of lectures, and do not have any winter sessions. All the larger Medical schools in the cities of the North give summer lectures also; but, unlike those just referred to, they are merely intended to occupy the time of the student during the warmer months with subjects that are auxiliary to the lectures of the winter, and count nothing towards graduation, the tickets of this series being separate and not receivable as evidence of attendance on a full course of lectures. The summer instruction thus acts as a feeder to that of the winter,

the student becoming sufficiently interested to enrol himself continuously as a member of the College.

The larger Medical schools generally average, under existing circumstances, about a hundred graduates every spring; some of them rising to a score more, others to as many less. Before the late rebellion the usual number varied from 200 to 250 in the most popular and populous institutions, on account of the great numerical strength of the representatives from the Southern States. In one year before the war the number of matriculates at the Jefferson Medical College of Philadelphia was 630, and between 400 and 500 of these were from the South. Many of them were second-course students who came to the North to complete their education, having already commenced it, during the previous winter, in some Medical school in their own section of country. In this way the list of graduates of the Northern colleges was enormously swollen. At the present time a few stragglers from the South visit us, but it would be safe to say that there are now less than ten where there formerly were a hundred. Of course, this state of things is of benefit to the Southern Medical schools by contributing to keep these young gentlemen at home, but not so much as might at first appear; for the blasting effects of the rebellion on the people of the South, around whose homes the terrors of war brought its terrible ravages and desolation, have been such that they have not yet been pecuniarily able to contribute the means for the education of their sons in the Profession. It is probable, however, that the North will never again recover its lost prestige as the centre of Medical instruction, so far as the South is concerned, until long hereafter, when all personal and political sectional animosity is forgotten and its traces for ever buried.

In addition to the purely Medical schools, we have in Philadelphia a college of pharmacy and two dental colleges, each of which sends forth at this season of the year its graduates to practice the specialities taught by them. The branches of instruction in all of these institutions include not only those absolutely and exclusively necessary to pharmacists or dentists, but also others which can be judiciously brought into connexion with them. For instance, in the dental schools, Chemistry, Physiology, Anatomy, and Surgery are combined with Mechanical Dentistry, Dental Pathology, and Therapeutics, etc. The result is that a much more accomplished class of dental graduates pass from their halls into practice in consequence of this addition of what might be called incidental branches of study. There are nine of these dental colleges in the United States, and it has been stated in one of our recent journals that no such institutions exist in Europe, although in England lectureships on Dental Surgery are attached to some of the Hospitals. The advantages of having special schools for these purposes have been signally manifested in this country, and their plan and objects might be very well imitated abroad. In the Pennsylvania College of Dental Surgery, which is a good illustration of this class of colleges, four hours are spent daily in actual clinical instruction, a large number of chairs being assigned for the use of the students in their performance of all the operations, and the practice of the various manipulations necessary in the treatment of the teeth. There is also a laboratory, in which are all the conveniences for the preparation of the metals, manufacture of teeth, etc., and in which also every process known in the Profession, which has any value to the mechanical dentist, is fully taught. The student is also required to go through all the essential steps connected with the insertion of artificial teeth, from taking the impression of the mouth to the entire construction of the denture, and its proper adjustment in the mouth of the patient. I have mentioned all these details to exhibit how thoroughly dentists may be educated in this country, if they only choose to avail themselves of the facilities offered them. It must assuredly be due to some innate fault in the moral or mental constitution of the individual, when with this groundwork of a full and complete education in dental science and kindred branches he fails to be a skilled, accomplished, and trustworthy practitioner of his art.

Very extensive arrangements are being made in this city for the next annual meeting of the National Medical Association, which holds its session here early in May. I shall be able in my next letter to enter more fully into details as to the nature of these preparations, and it is probable that unless some disturbing element, such as the woman or the negro, enters into the deliberation of the convention, its proceedings, business and social, will be very interesting. It is likely however, that the irrepressible advocates of colour and sex may endeavour to arouse the passions of the excitable, and to disturb the equanimity of the more placid delegates, by appeals on behalf of

the woman and the negro, and thus impede the otherwise smooth current of business. There is a disposition among the best men of the Profession to make these national meetings something more creditable than arenas for the solution of political or social problems, the discussion of which annually dims the lustre of this organisation. A very interesting feature of this year's meeting will be the exhibition of chemical and pharmaceutical preparations, apparatus, and appliances; Surgical and obstetrical instruments and appliances; optical, ophthalmological, and other instruments of precision; philosophical instruments and apparatus; anatomical and pathological specimens, models, and other means of illustration; books, prints, and other publications. Such a display has never before been attempted, and no better field could have been selected for it than Philadelphia, for so long the centre of Medical instruction on this continent. As the occasion will bring together an excellent representation of the leading Medical and Surgical intellects and active working men of the country, I hope at that time to be able to give you a sketch of those present and the services they then render which may be of general interest as exhibiting the Professional progress and status of the day.

The small-pox has not yet been "stamped out." In Philadelphia there were last week 120 deaths. It is universally believed that the extent of its ravages in New York is suppressed, and that the public is deceived as to its actual progress. I hope in a short time to be able to present to you some exceedingly interesting official data connected with this variolous epidemic of 1871-72.

GENERAL CORRESPONDENCE.

EXPERIMENTS IN CHOLERA.

LETTER FROM DR. JOHN PATTERSON.

[To the Editor of the Medical Times and Gazette.]

SIR,—The following experiments on animals with cholera-matter will, I think, be read with interest. Every care was taken to render the conditions as accurate as possible. The animals were seen at least twice in the day by myself or Dr. Zebrowsky, the Assistant-Surgeon, and their conditions carefully registered. The cholera-matter was from patients in deep collapse—the true rice-water motions—and was passed direct from the intestines into a wide-mouthed vessel and closely stoppered. The first experiments were performed with the fresh matter, the others with cholera-matter in a state of fermentation.

Series 1.—Experiment 1.—Two well-grown healthy young dogs were kept for forty-eight hours on simple food and pure water. November 17, 1871, at 10 a.m.: Twenty drops of fresh cholera-matter were injected into the cellular tissues of the back of the animals by the subcutaneous method. Same diet. 5 p.m.: No result. 18th, 10 a.m.: Repeated injections. 5 p.m.: Both animals well; no result.

Experiment 2.—A third dog, specially selected for his unhealthy-looking condition, was subjected to the same treatment. No result.

Experiment 3.—November 19, 9 a.m.: Injected four fluid drachms of fresh cholera-matter into the rectum of each dog. 5 p.m.: All well, though one looks dull and stupid. 20th: Repeated the injections of four fluid drachms. 5 p.m.: All well. 21st: This morning all the animals looked drooping, but it was discovered that they had not been supplied with water. After drinking freely they began to eat heartily. 5 p.m.: Motions somewhat liquid, but coloured and faecal-smelling. The cholera-matter was now freely sprinkled over their food for the night. 22nd: Motions still somewhat liquid, and a little bloody mucus was passed by one of the first two experimented upon; he had also tenesmus. The unhealthy-looking one is much improved in appearance. 5 p.m.: Food again sprinkled with cholera-matter. 23rd. All well. They remained under observation until the 30th, eating food charged with cholera-matter, when the experiments were discontinued. No result.

Series 2.—Performed with Cholera-Matter taken during Collapse, but allowed to Ferment.—January 21, 1872: The two healthy dogs had each twenty drops of the fermenting matter subcutaneously injected into tissue of back and loins. They were allowed to run about the yard and to eat freely. 22nd and 23rd: Operation repeated. No apparent change in health was observed. 24th: Active; but both have large hard and tender swellings over the seat of the injections, one apparently going on to suppuration. 25th

10 a.m. : Active, and eat well ; the phlegmon in one actively suppurating. 1 p.m. : Opened the phlegmon and let out about an ounce of fetid pus. 6 p.m. : Both active. 26th : Active and hungry ; the abscess opened is refilling ; the hard swelling in the other disappearing. 28th : Both dogs well ; the opened abscess healing ; motions of both natural.

Series 3.—Experiment 1.—January 29, 1872 : The stronger of the two dogs had a wire muzzle accurately fitted over his mouth. At the end of the muzzle a pad of cotton-wool was arranged. This was first steeped in fermenting cholera-matter, and was regularly three times a day resoaked in the fluid until February 4, being only removed at meal times. No result.

Experiment 2.—A young pup, feeding on milk, was similarly treated, and exposed to breathe the effluvia from January 28 to February 6. No result.

Experiment 3.—February 7 : This same pup was placed under the influence of chloroform. The femoral vein was exposed, and twenty drops of the decomposing cholera-fluid injected direct into the circulation. 8th and 9th : Very dull ; declined his food, but drank greedily of water. 10th : Is well, and eats ; motions natural ; was under observation for a week longer. No results.

Series 4.—Experiment 1.—January 23 : Three healthy rabbits had each twenty drops of the decomposing cholera matter injected subcutaneously. 26th : Injections repeated. No result.

Experiment 2.—January 27 : Injected three fluid drachms of the cholera-matter into the rectum of each rabbit. 31st : Injected again three fluid drachms, diluted with an equal quantity of water. February 2 : Repeated this last injection. 4th : Injection repeated. No result.

Series 5.—Experiment 1.—From January 19 to February 10, six healthy mice were exposed under inverted glass funnels to an atmosphere of fermenting cholera-matter, and fed with bread, meat, and barley soaked for two days in the same fluid—the true rice-water motions from cholera patients in stage of collapse. The air of the funnels was stinking. The animals were occasionally removed to an airy wire cage for a few hours, and fresh food given them. Under the funnels they drank freely of the cholera dejection and devoured the food soaked in it. Two died on the fourth day of their confinement. On both occasions fresh water had been forgotten, and the cold at night was severe. The symptoms of both were alike ; debility and horripilation ; but the motions were solid and natural. One was carefully examined after death. The intestines were filled with hard fecal matter. After this cotton-wool was supplied to the others, in which they immediately rolled themselves and seemed quite happy. Two of the mice were exposed to these concentrated conditions all the time, and two more half of it ; and from February 5 to 10 all four were kept together, feeding on food steeped in the cholera-matter, and breathing the impure atmosphere of the funnels. No result.

Experiment 2.—February 10 : The four mice had each eight drops of cholera-matter subcutaneously injected, and were put into an airy wire cage, and allowed pure food and water. They became very uneasy and irritable. At night they were well, but unfortunately they were not supplied with food. 11th, 9 a.m. : One was found in a wounded and dying state, and one was nearly all devoured ; his bones and a little bit of skin only remained. The other two were well and active, and the motions all hard and natural. These two and a newly caught one were again subcutaneously injected with ten drops of the cholera-matter. After three days the operation was repeated. They were under observation until the 20th, and were in good health. 22nd : Discontinued the experiments. No result.

In reference to my former communications on the treatment of cholera by subcutaneous injection of morphine, it has been asked if the treatment was applied at a late period of the outbreak, when the disease had probably lost its first virulent character. Certainly not. It was begun within the first six days. Moreover, the disease was as virulent towards the end as at first.

I am, &c.,

JOHN PATTERSON, M.D., L.R.C.S.,

Surgeon-Superintendent of British Scamen's Hospital,
Constantinople.

Constantinople, February 27.

“PITYRIASIS RUBRA.”

LETTER FROM DR. H. S. PURDON.

[To the Editor of the Medical Times and Gazette.]

SIR,—Seeing in one of the quarterly Medical journals a short time since that the disease known as “pityriasis rubra” or general dermatitis usually terminated fatally—a view held by

most authors—I should like to know if that is the received opinion. I have only met with three cases out of some 12,000 cutaneous diseases to which the term pityriasis rubra was applicable. My first two cases I lost sight of, so cannot say how they terminated, but the last one (a note of which may not be uninteresting) made a rapid recovery.

Mr. W. B., aged 40, married, of a good constitution, had an attack of rheumatic fever in Australia in 1865. Since his return to this country has been troubled more or less with rheumatic pains, but not latterly. During the autumn of 1871 felt out of health ; complained of loss of appetite, etc. A red-coloured blotch then appeared on chest, and in about two weeks had spread over the entire body. He had been treated with arsenic, mercury, iodide of potassium, sulphur, etc., for some two to three months when I was asked to see him. I found him anxious ; had a slight cough ; urine high-coloured from urate of ammonia ; skin of whole body red, dry, and covered by branny scales, which rapidly exfoliated. The hair was also falling out. Every day the bed was emptied of nearly a coal-bucketful of scales. The redness of the skin disappeared on pressure. The nails were easily broken, and of a dirty dry appearance. Without entering into further details I may say that the general symptoms were comparatively slight, compared with the extent of the disease. The treatment adopted was supporting diet, cod-liver oil, compound infusion of gentian and nitro-muriatic acid, and every second or third night a dose of compound jalap powder. Locally a liniment consisting of olive oil, lard, and oxide of zinc was smeared over entire body two or three times daily ; subsequently nitrate of silver in sweet spirit of nitre being used to stimulate the more obstinate places. Mr. B. was able to go out in about six weeks, and returned to his business in about ten weeks. I have lately seen him ; there are no symptoms of the disease returning. The palms of his hands are a little tender and hacked, for which I ordered him a pair of indiarubber gloves made by Wilmot, Holt, and Co. (Manchester and Belfast).

I am, &c., H. S. PURDON, M.D.,

Physician to the General and Skin Hospitals, Belfast.

5, College-square East, Belfast, April 9.

FAGGOT-VOTERS AT THE ROYAL ORTHOPÆDIC.

LETTER FROM MR. W. ADAMS.

[To the Editor of the Medical Times and Gazette.]

SIR,—Without desiring at present to make any observations upon the events which have recently occurred at the Royal Orthopædic Hospital, which have been warmly condemned by the Medical press and Professional opinion, and as to which I shall shortly ask for an authoritative judgment, I feel called upon to notice the statement made by Mr. Brodhurst, in a letter published in your journal of the 13th inst., that “prior to most of the annual and special courts, an active canvass for new governors has taken place.” I can only say that I have no knowledge of any such practice, and that on no occasion whatever, since my connexion with the Hospital, have I directly or indirectly been instrumental in making a single new governor for the purpose of voting at any annual or special court.

I am, &c.,

WM. ADAMS.

Henrietta-street, Cavendish-square, April 17.

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, APRIL 9.

T. B. CURLING, F.R.S., President, in the Chair.

CASES OF ABDOMINAL ANEURISM TREATED BY PROXIMAL AND DISTAL PRESSURE.

A PAPER, by Dr. WALTER MOXON, and Mr. ARTHUR E. DURHAM, was read, entitled “On a Case of Abdominal Aneurism cured by Compression of the Aorta.” The patient, a comparatively healthy-looking young man, 27 years of age, presented himself among Mr. Durham's out-patients at Guy's Hospital on August 2, 1871. On examination he was found to be suffering from an abdominal aneurism of considerable size, the pulsation and intumescence of which were manifest to the eye as well as to the touch. He was recommended for imme-

mediate admission, and was placed under the care of Dr. Moxon in the clinical ward. The aneurism could be distinctly felt over a space extending from rather less than an inch below the cartilages of the fixed false ribs above to a level with the umbilicus below, and from the right side of the median line across to about midway between the median line and the left border of the abdomen or rather further. Pulsation was full and strong, but could be controlled by careful and deep digital pressure. The patient was kept perfectly at rest in bed for eleven days, and on very spare diet. At 10.30. a.m. on August 14 (no food having been taken since the preceding evening) chloroform was administered, and Mr. Durham proceeded to compress the aorta on the proximal side of the aneurism by means of Lister's abdominal tourniquet. There was just room to get the pad of the tourniquet between the cartilages of the ribs and the aneurism. The tourniquet was screwed down very slowly, and carefully adjusted in position and direction until the pulsation of the aneurism as well as that of both femoral arteries was completely arrested. The lower extremities were enveloped in cotton-wool, and flannel and hot-water bottles were placed in the bed. The compression was absolutely maintained for ten hours and a half, the patient being all the time kept under the influence of chloroform. At the end of that period his general condition, as indicated by pulse and respiration, was such as seemed to render it undesirable to continue the treatment. The tourniquet was accordingly removed, and no more chloroform was administered. No pulsation of the aneurism nor of the femorals could be detected. A bright-red patch marked the spot where the pad of the tourniquet had compressed the skin. The lower extremities were cold, and marked here and there by purplish or livid patches, but they were in more favourable condition than they had appeared to be at an earlier period during the compression. In the course of a short time pulsation of the aneurism could be again detected; but the aneurism remained much smaller and harder than before the treatment. The patient passed a good night, and the next day had little or nothing to complain of except the exquisite tenderness of the skin at the compressed spot. There was no internal pain or tenderness, nor any indication whatever of mischief done to the visceral or other internal structures. It seemed remarkable that such severe treatment should be followed by so marked an absence of all serious disturbance, whether local or constitutional. No bad symptom of any kind arose. The aneurism gradually became firmer and smaller, and its pulsation less and less perceptible. At the end of rather more than a month, pulsation could no longer be detected. The femoral arteries, in which, as well as in the aneurism, pulsation had to some extent temporarily returned—had also ceased to pulsate; the aneurismal tumour gradually diminished in size; the patient recovered health and strength, and indeed was apparently in far better condition than he had been for a long time previously to his admission to the Hospital. He was presented for examination by the Fellows present. In commenting upon this case, the authors remarked that, so far as they were aware, it was only the second case of the kind upon record in which a similar method of treatment had been followed by similarly successful results. The first case occurred in the practice of Dr. Murray, of Newcastle (to whom they wished to ascribe all the credit of having initiated the method of treating abdominal aneurisms they had thus adopted). It appeared probable that in their case, as in that of Dr. Murray, the aneurism was connected with the aorta at or about, and probably involving, the inferior mesenteric. In such cases this method was most applicable. In another case, however, now under their care at Guy's Hospital, there was reason to believe that the aneurism was upon the superior mesenteric. Nevertheless, they hoped to succeed in applying this method, and with satisfactory result. Sphygmographic tracings were taken by Mr. Mahomed during an experimental attempt made by Mr. Durham to compress the aorta in the case referred to. Mere tracings showed in a most striking manner the effect produced upon the pulse at the wrist by compression of the abdominal aorta or immediately connected parts. In conclusion, the authors expressed their opinion that the method described should be carefully, but fully, tried in all cases of abdominal aneurism (few though such cases be) in which it may be found practicable to compress the aorta on the proximal side of the aneurism in such way and to such extent as to arrest its pulsation, and at the same time without the exercise of such force as might seriously damage the viscera or other internal parts. On anatomical grounds compression of the aorta on the distal side of an aneurism would not appear to offer promise of much success.

Mr. THOMAS BRYANT related a case of "Abdominal Aneurism

treated by Distal Pressure, with Remarks." The patient was one of Dr. Pavy's, who asked Mr. Bryant to see the case with a view to treatment. It was a man, aged 30, with an abdominal aneurism in the epigastric region the size of a fist. Distal pressure was determined upon, as no other treatment was applicable. It was applied by means of a Lister's abdominal tourniquet, with the patient under chloroform. It was kept up for twelve hours, then removed for twelve hours, and reapplied for four hours; the treatment being given up as the man's powers seemed failing. He died eleven hours after the removal of the clamp. After death peritonitis was found to have been the cause of death from the bruising of the bowel and peritoneum by the clamp. An aneurism of the cœliac axis was present, which was filled with a perfect clot, evidently of recent date, but ante-mortem. The post-mortem was made by Dr. Moxon, whose report was read. In his remarks, Mr. Bryant pointed out how the danger of peritonitis seemed to be one that appertained to the application of pressure by an abdominal tourniquet under all circumstances, and was to be accepted as a danger which should always be considered. He dwelt upon the pathological fact, which the preparation and drawing from it taken from the patient illustrated, that a large abdominal aneurism may undergo mechanical closure by a clot from the application of distal pressure for twelve or sixteen hours. The case suggested the value of other forms of practice upon the distal side of an aneurism which are based upon the same principle, such as the temporary occlusion of an artery by ligature, acupressure-pins, or other means; for if, he remarked, pressure for a few hours upon the afferent or efferent artery of an aneurism—sufficient to arrest the flow of blood through its channel—is enough to bring about the mechanical closure of a sacculated aneurism by means of a clot, and consequently its cure, surely the application of other means which are calculated to fulfil the same purpose may be employed to effect the same end. He then alluded to Hunter's, Astley Cooper's, and Travers's temporary ligatures, and to Lister's carbolised catgut ligatures, which he regarded as temporary ligatures. He went on to show how contused arteries often became occluded ones, and that this was probably from some detachment of the inner coats. He suggested the adoption of some instrumental means by which these results were to be secured—by which the inner and middle coats of an artery might be divided and allowed to recur without destruction of the external. He then alluded to the artery constrictor of Dr. F. Spiers, of New York, and showed the instrument, stating that his own experiment had gone to prove the truth of Dr. Spiers's statement. He believed that we had in this instrument an element of usefulness that wanted working out. He concluded by showing how successful the distal treatment of aneurism had been under certain circumstances, and expressed a belief that it was a form of practice well worthy of renewed attention in cases where all other forms of practice were inapplicable.

(To be continued.)

EPIDEMIOLOGICAL SOCIETY.

WEDNESDAY, FEBRUARY 14.

DR. EDWARD C. SEATON in the Chair.

A PAPER by JAMES CHRISTIE, M.A., M.D., Physician to the Sultan of Zanzibar, and to the Universities Mission, was read, entitled "Additional Notes on the Cholera Epidemics on the East Coast of Africa." In a previous paper read before the Society during session 1870-71, Dr. Christie had given an elaborate account of the prevalence of epidemic cholera on the East Coast of Africa. The present paper had for its object to correct certain dates in that paper, and convey additional information of the movements of the disease. The dates of the different recorded epidemics on the East Coast, are as follows:—First epidemic, December, 1836, to January, 1837; second epidemic, 1859 to 1860; third epidemic, 1865; fourth epidemic, 1869 to 1870. The chief interest of the present paper rested in the additional light cast upon the beginnings of the third and fourth epidemics. By carefully prosecuted inquiries among native traders on the mainland, it would appear that the epidemic of 1865 probably reached the East Coast from Berbera, on the south coast of the Gulf of Aden. The disease it is believed was introduced into Berbera about the same time that it was introduced into Makalla, on the south coast of Arabia. Makalla, it will be remembered, was the first definitely ascertained starting-point of the north-westward extension of the

epidemic of 1865. At the break-up of the Berbera fair, doubtless the malady followed the track of the great southern caravan route, across the Somali country to Gananah and Bardera, on the river Jubb. From Bardera, still following the trade route, cholera extended to Brava, on the East Coast, and thence it spread northwards to Merka and Mukdesha, and southwards as far as Mombassa. The fourth epidemic (1869-70) reached the coast from the interior of Africa. A large caravan which left Pangani for the Masai country in November 1868, reached its destination on the forty-ninth day of journeying, and then heard of a virulent disease which proved to be cholera, in the Somali country, to the north. The Masai had made a raid on the Somali, and the expeditionary party contracted the disease and brought it back with them into their own country. Subsequently the malady spread into the district intervening between the Masai and the East Coast, and appeared at Tanga and Pangani, and from these coast towns began that wide diffusion along the coast which Dr. Christic described in his first paper.

In the discussion which followed the first paper Mr. NETTEN RADCLIFFE suggested that the cholera prevalent in the Masai country at the close of 1868 and beginning of 1869 was the continuation of the epidemic of 1865-68 in Abyssinia, and which in 1868 was known to have spread into the Galla country, in the direction of Evarea, the great centre of commerce for this part of Africa and for the East Coast north of Zanzibar; and the further details given by Dr. Christie tend to confirm this suggestion.

OBITUARY.

GEORGE ANGUS, M.D.,

DIED on the 7th instant at 13, Golden-square, Aberdeen, in the 78th year of his age. He was the son of the late Rev. Mr. Angus, minister of Botriphny. He was educated at Botriphny parish school, studied at Marischal College, finished his Medical studies in London, and went out to Bengal in the Medical service upwards of fifty years since. Shortly after his arrival in that country he joined the army, then engaged in active service against the Pindaris; and a hard schooling it was, for there was much and harassing work for the army, both in the way of fighting and of exposure to climate at all seasons. It was during these campaigns that cholera first made its appearance as an epidemic in India, and proved far more deadly to friends and foes than a hundred hard-fought battles. On the restoration of peace, Dr. Angus was appointed to the Medical charge of a civil station, which he held till his promotion, in 1836, to the rank of Surgeon. He was nominated in the course of his service to several important appointments, and for some years was Secretary to the Medical Board in Calcutta, the duties of which post he discharged in such a manner as to gain alike the entire confidence of the Government of India and the members of the Board—the then regulators of the Medical affairs of the Presidency—and of all the members of his own Profession with whom he was brought in contact. For several years he held the important position of Garrison Surgeon at Allahabad, which brought him into connexion with persons of all classes. His hospitality and kindness became almost proverbial among the numerous strangers who passed through the station. His sound judgment and enlarged experience rendered his Professional services highly valued. On leaving the station the inhabitants of all classes presented him with a handsome testimonial of their esteem. On his promotion to the rank of Superintending Surgeon—now called Deputy Inspector-General—he was appointed first to Benares and afterwards to Cawnpore, and eventually retired from the India Service in 1854. Since then he has resided in Aberdeen, where his generous kindness of heart and happy genial disposition have endeared him to a large circle of warmly attached friends. Dr. Angus took no leading part in public affairs; still, within his own sphere he invariably acted with independence and energy. For two years he was President of the Medical Society. He was manager of the Royal Infirmary and General Dispensary, and was for several years a member of the Parochial Board of St. Nicholas Parish. He was ever ready to support every scheme which tended to improve the condition of his fellow-men. Though he has been declining for some time past, it was only within the last few weeks that any alarm was felt for him; and there are many, both at home and in India, who will lament his loss. Dr. Angus, we may add, was never married.

MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen having undergone the necessary examinations for the Diploma, were admitted Members of the College at a meeting of the Court of Examiners on the 16th inst., viz.:—

Alliott, Alexander John, B.A. Cantab., Eeles, near Manchester, student of St. Thomas's Hospital.
 Atkinson, John Charles, L.R.C.P. Edin. and L.S.A., Kew-green, of King's College.
 Bird, Cuthbert Hilton Golding, B.A. Lond., Brunswick-square, of Guy's Hospital.
 Birt, Ernest, Leamington, of the Birmingham School.
 Blake, Frederick George, Bristol, of the Bristol School.
 Coltart, William Wilson, Liverpool, of St. George's Hospital.
 Cooke, Thomas, L.R.C.P. Edin., Ashton-under-Lyne, of the Manchester School.
 Coote, Michael, M.D. Laval Univ. Quebec, of St. Thomas's Hospital.
 Curtis, Arthur, Alton, Hants, of University College.
 Dakeyne, Thomas Edward, Warslow, near Ashbourne, of the Westminster Hospital.
 Eady, George John, L.R.C.P. Edin. & L.S.A., Chertsey, of King's College.
 Emms, Alfred Wilson, Ilminster, of Guy's Hospital.
 Evans, Francis Morse, Norwich, of St. George's Hospital.
 Fayer, Edward, L.R.C.P. Edin., Henley-in-Arden, of St. Mary's Hospital.
 Hale, Charles Douglas Bowdich, Chepstow-villas, Bayswater, of St. George's Hospital.
 Hemming, John Lamond, L.R.C.P. Lond., Great Portland-street, of St. George's Hospital.
 Holmsted, Perryman Wakeham, Boeking, Essex, of the London Hospital.
 Jones, Henry William, L.R.C.P. Edin., Dyffryn, Merionethshire, of the Glasgow School.
 Lawson, Thomas Cornelius, Kidderminster, of University College.
 Lush, William John Henry, Yarmouth, Isle of Wight, of King's College.
 Morrell, Robert Baker, L.R.C.P. Edin., Moulsoford, Wallingford, of King's College.
 Purell, James George, L.R.C.P. Edin., Mottram, Cheshire, of the Manchester School.
 Shemilt, Geo. Richard, L.S.A., Tean, Staffordshire, of University College.
 Taylor, Charles Lamb, Newark, of University College.
 Ticehurst, Charles Sage, L.R.C.P. Lond. and L.S.A., Hastings, of Guy's Hospital.
 Tweedy, John, L.R.C.P. Lond., Stockton-on-Tees, of University College.
 Wardale, Joseph Augustus William, L.S.A., Newport, Isle of Wight, of University College.
 Williams, Henry, Nottingham, of Guy's Hospital.

The following gentlemen were admitted Members on the 17th inst., viz.:—

Bird, George Gwynne, Swansea, student of St. Mary's Hospital.
 Breeze, Richard Goodwin, L.S.A., Euston-road, of University College.
 Jackson, Francis Edward, L.S.A., Chertsey, of St. Bartholomew's Hospital.
 Mahomed, Frederick Henry Horatio Akbar, L.S.A., Brighton, of Guy's Hospital.
 Ridley, James Hutton Wilkie, Gateshead, of the Newcastle School.
 Young, Thomas Frederic, Liverpool, of the Liverpool School.

Two candidates passed the examination in Surgery, and, when qualified in Medicine, will be admitted Members of the College, and seven candidates were referred to their Professional studies for six months. A Primary or Anatomical and Physiological Examination will commence this day (Saturday).

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received Certificates to practise, on Thursday, April 11:—

Sankey, Julius Ottaway, St. Bartholomew's Hospital.
 Smith, Charles Wait, Jamaica, West Indies.

As Assistants in Compounding and Dispensing Medicines:—

Evison, William, South Lincolnshire.
 Henry, Edward Lawrence, Lewisham.

APPOINTMENTS.

* * * The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new appointments that take place.

BARRY, MICHAEL J., L.R.C.S.I., L.K.Q.C.P.I., L.M.K.Q.C.P.I.—Medical Attendant to the Royal Irish Constabulary.

BLAIR, ROBERT, M.B., C.M.—Senior House-Surgeon to the Preston and County of Lancaster Royal Infirmary, *vice* Arthur W. Smith, M.B. Lond., resigned.

BLYTHMAN, CLEMENT S., M.B., C.M., M.R.C.S. Eng.—Medical Officer to the Swinton District, Rotherham, Yorkshire.

BODMAN, JOSEPH BAKER, L.S.A.—Medical Officer of the Castor District, Peterborough (reappointment).

DICKSON, GEORGE TAIT, M.B., C.M.—Junior House-Surgeon to the Preston and County of Lancaster Royal Infirmary, *vice* Robert Blair, M.B., promoted to Senior House-Surgeon.

DIVER, THOMAS, M.D., M.R.C.S. Eng., L.S.A.—Medical Officer to the Railway District of Portsea, Hampshire.

GIBB, GABRIEL, M.D.—Medical Officer to the Parish of Row, Dumbartonshire.

MARSHALL, FRANK, M.R.C.S.E. and L.S.A.—Medical Officer and Public Vaccinator for District No. 1 of the Sudbury Union, Suffolk, and Medical Officer and Public Vaccinator for the Eighth District of Thingoe Union, *vice* Mr. E. S. Stanley, resigned.

NICHOLSON, DR.—Surgeon and Apothecary to Trim Gaol.

SMITH, WM. J., L.S.A.—Medical Officer to the Rawmarsh District, Rotherham, Yorkshire.

STOTHARD, W. J., L.R.C.P. Edin., M.R.C.S. Lond., L.S.A.—Medical Officer to the Camberwell Provident Dispensary.

SWAN, WILLIAM, M.B. Oxon, M.R.C.S. Eug.—House-Surgeon to the Seamen's Hospital, Greenwich.

NAVAL AND MILITARY APPOINTMENTS.

MEDICAL.—Patrick Heelau, Surgeon to the *Ganges*; Samuel Grove, Surgeon to the *Excellent*.

MEDICAL.—Surgeon-Major William Godfrey Watt, from the 3rd Dragoon Guards, to be Staff Surgeon-Major, *vice* Staff Surgeon James Landale, M.D., who exchanges; Surgeon James Hornidge Finmore, from the 45th Foot, to be Staff Surgeon, *vice* George Whitla, appointed to the 45th Foot; Assistant-Surgeon George Whitla, from the Royal Artillery, to be Staff Surgeon, *vice* William Thomas Paliologus, placed upon half-pay; Staff Assistant-Surgeon Arnold Royle retires upon half-pay; Staff Assistant-Surgeon James M'Cully, M.D., resigns his commission; Staff Surgeon John T. Acheson and Surgeon Thomas Jameson, M.D., have been placed on the Retired List.

BIRTHS.

BULLOCK.—On April 9, at Overtown House, Spring-grove, the wife of Henry Bullock, F.R.C.S., of a son.

GANGE.—On April 16, at Faversham, the wife of Frederick A. Gange, M.D., of a son.

JACKSON.—On March 13, at Allygurrh, North West Provinces of India, the wife of James R. Jackson, M.D., Civil Surgeon, of a son.

MORTON.—On April 16, at 1, Greville-road, Kilburn, the wife of Dr. T. Morton, of a daughter.

THORNE.—On April 10, at 5, Waterloo-place, Leamington, the wife of Frederic Thorne, M.R.C.S., L.S.A., of a son.

MARRIAGES.

BOWKETT—DAVIS.—On April 10, at St. Martin's-in-the-fields, Trafalgar-square, W.C., Thos. E. Bowkett, M.R.C.S. and L.S.A., East India-road, E., Surgeon to the Poplar Hospital, to Emily Eliza, twin daughter of George Davis, Esq., 32, Cranbourne-street, W.C.

BRAYE—CASE.—On April 11, at St. Nicholas Church, Great Yarmouth, Hardwick Hubert Braye, M.R.C.S., L.S.A., of 15, New-road, Commercial-road, London, eldest son of Hardwick Braye, Esq., of Hastings, to Anna Mary, third daughter of Philip Case, Esq., of Great Yarmouth.

DAY—SHEEPHANKS.—On April 13, at the Church of St. Michael and All Angels, Coventry, Francis Day, Surgeon-Major Madras Army, to Emily, youngest daughter of the Rev. T. Sheepshanks, Rector of St. John's, Coventry.

ELLIS—CHAPMAN.—On April 16, at St. James's, Piccadilly, J. Ellis, M.A. M.D., Surgeon Bengal Medical Service, to Rose, eldest daughter of the late Samuel Chapman, Esq., of Buenos Ayres.

GOODDAY—RICHARDSON.—On April 11, at Fenny Bentley, near Ashbourne, Derbyshire, Horatio George Goodday, of Havre-de-Grace, eldest son of Horatio Goodday, M.D., of Bayswater, to Jane, second daughter of the late Rev. Harling Richardson, Vicar of Onecote, Staffordshire.

HETLEY—BRNN.—On April 16, at the Church of the Holy Trinity, Whitfield, Northumberland, Frederick Hetley, M.D., of Norbury Lodge, Upper Norwood, to Mary Ann, second daughter of the late Thomas Benn, Esq., Captain R.N., of Greenbank, Cumberland.

KNOX—MOGG.—On April 9, at the parish church, Clifton, George Knox, Esq., Deputy-Commissioner of Delhi, eldest surviving son of the late Superintending-Surgeon George Knox, H.M. Madras Army, to Edith Mary, only daughter of Michael Mogg, Esq., of Clifton.

MEREDITH—MITCHELL.—On April 11, at St. Barnabas, Hornsey-road, James Meredith, of Kingtou, Herefordshire, to Winifred, eldest daughter of the late Thomas Henry Mitchell, M.R.C.S.E., of Holloway.

MOORHEAD—GILLMAN.—On April 11, at St. Thomas's Church, Dublin, William R. Moorhead, M.A., M.D., Benburb, county Tyrone, to Amelia Davis, only daughter of the late James Gillman, Esq., J.P., Oakmount, county Cork.

PAYNE—TILEY.—On April 11, at St. Mary's Church, Wallingford, Sydney Payne, only son of Robert Payne, Esq., J.P., of St. John's, Wallingford, to Marie Langley, eldest daughter of W. G. Tiley, M.R.C.S., and granddaughter of the Rev. John Langley, Rector of St. Mary's.

RAYNER—SLACK.—On April 11, at the Priory Church, Great Malvern, John Rayner, L.R.C.P., M.R.C.S., of Oakhayes House, Woodbury, Devon, to Susannah, eldest daughter of the late Rev. S. Slack, M.A., Oxon., formerly Head Master of the Grammar School, Bradford, Yorkshire.

SHORTTRIDGE—GARD.—On April 10, at St. Mary's Church, Glasgow, John Shortridge, son of S. Shortridge, M.D., Greenock, to Martha Sarah, daughter of W. G. Gard, Esq., Breaston, Derbyshire.

THOMAS—BANKS.—On April 10, at the Church of the Holy Trinity, Brompton, Edwyn Thomas, Esq., barrister-at-law, Middle Temple, to Francis Maria, only surviving child of the late William Houghton Banks, M.D., R.N., of Vernon House, Ryde, Isle of Wight.

DEATHS.

BARTLEY, CHARLOTTE O'HARA, widow of Alfred Collett Bartley, M.D., at Mitcham-green, on April 9, aged 76.

BICKERTON, THOMAS, F.R.C.S. Edin., L.S.A., at his residence, 82, Mount Pleasant, Liverpool, on April 13, aged 45 years.

COCKLE, ELIZABETH, of 9, Bolton-gardens, South Kensington, and Truro Lodge, St. Lawrence, relief of James Cockle, Surgeon, formerly of Great Oakley, Essex, at her residence in town, on April 5.

CRADDOCK, WM., M.D., of Dhurm-sala, Punjab, and of H.M. Bengal Army, on board the *Scotland*, off Cape St. Vincent, on March 30.

GUY, JOHN, M.R.C.S., at 13, Golden-square, St. James's, on April 7, in his 74th year.

HARVEY, JOSEPH ALFRED RADCLIFFE, M.D., R.N., at Melita, Merton-road, Southsea, on April 14, aged 49.

HOVELL, ARTHUR DENNIS DE BERDT, of New College, Oxford, and Lincoln's-inn, eldest son of Dennis de Berdt Hovell, Esq., at Five Houses, Clapton, Middlesex, after a short illness, on April 9, in his 21st year.

VACANCIES.

In the following list the nature of the office vacant, the qualifications required in the Candidate, the person to whom application should be made, and the day of election (as far as known) are stated in succession.

HAMADRYAD HOSPITAL-SHIP FOR SEAMEN OF ALL NATIONS.—Port of Cardiff. Resident Assistant Medical Officer. Candidates must be unmarried, and must possess a Surgical qualification. Applications, enclosing testimonials, to be forwarded to David Roberts, Secretary, 17, Church-street, Cardiff, on or before Tuesday, April 30.

DUNDEE ROYAL INFIRMARY.—A qualified Medical man, to act as Joint House-Surgeon. Further particulars may be learned from the Secretary, D. Gordon Stewart, Esq., solicitor, 18, Meadow-side, Dundee, to whom applications, with testimonials, must be sent on or before May 1.

ECHT, ABERDEENSHIRE.—Medical Officer to the Parish of Echt.

INFIRMARY FOR CONSUMPTION AND DISEASES OF THE CHEST, 26, MARGARET-STREET, CAVENDISH-SQUARE.—Visiting Physician. Candidates must be Members of the Royal College of Physicians, London. Testimonials to be sent to Francis Baily, Secretary.

KING'S COLLEGE.—Demonstrator of Practical Physiology.

MIDDLESEX COUNTY LUNATIC ASYLUM, HANWELL.—Medical Superintendent of the Male Department. Candidates must be Fellows, Members, or Licentiates of one of the Royal Colleges of England, Scotland, or Ireland, and duly registered in Medicine and Surgery. Copies (only) of testimonials, accompanied by a form (which will be forwarded on application), must be sent to Richard William Partridge, Clerk to the Visitors, on or before Saturday, May 4.

NAAS UNION.—Medical Officer for the Kilecullen Dispensary District. Applications, with qualifications required by the Poor-law Commissioners, and testimonials, will be received by R. West Manders, Esq., Hon. Secretary *pro tem.*, Dunshaue, Brannockstown, Newbridge, up to noon on April 26.

ROYAL ALBERT HOSPITAL, DEVONPORT.—Resident Medical Officer. Candidates must be unmarried, and duly registered Medical Practitioners. Applications and testimonials to be sent to the Honorary Secretary, Alfred Norman, Esq., endorsed "Application for Appointment," on or before Saturday, April 20. Canvassing is strictly prohibited.

ST. PETER'S HOSPITAL FOR STONE AND URINARY DISEASES.—House-Surgeon. Must be duly qualified. Further information may be obtained by addressing the Hon. Secretary, 54, Berners-street, W. Applications should be sent in on or before Friday, April 19.

SKIRLAUGH UNION.—Medical Officer for the District of Aldborough. Candidates must be duly qualified. Applications, with testimonials, to be forwarded to Thos. A. McCoy, Clerk to the Guardians, Beverley, on or before Thursday, May 2.

STAFFORDSHIRE GENERAL INFIRMARY.—House-Surgeon and Secretary. Candidates must appear at the Infirmary on Monday, April 22, at one o'clock. Candidates must be Members of one of the Royal Colleges of Surgeons of London, Dublin, or Edinburgh, and possess a qualification also in Medicine which will entitle to register. Further information may be obtained from the Secretary.

WALSINGHAM UNION.—Medical Officer. Must be duly qualified in accordance with the General Orders of the Local Government Board. Applications, with testimonials, to be forwarded to J. Wright, Clerk, Bridge-street, Fakenham, on or before Tuesday, April 30, and endorsed "Application for the Office of Medical Officer."

WANDSWORTH AND CLAPHAM UNION.—Medical Officer for the Eastern District of the Parish of Battersea. Applications and testimonials to be sent to John Sanders, Clerk to the Guardians, Union Offices, East-hill, Wandsworth, on or before Tuesday, April 30.

WESTBOURNE PROVIDENT DISPENSARY AND MATERNITY, 165, QUEEN'S-ROAD, BAYSWATER.—Honorary Dental Surgeon. Candidates must send in their applications, with testimonials, to the Hon. Secretary, at the Dispensary, on or before Saturday, April 20.

UNION AND PAROCHIAL MEDICAL SERVICE.

* * * The area of each district is stated in acres. The population is computed according to the census of 1861.

RESIGNATIONS.

Atherstone Union.—Mr. McBeath has resigned the Polesworth District; area 14,410; population 4649; salary £60 per annum.

Bideford Union.—Mr. Louis R. Cooke has resigned the Hartland District; area 21,953; population 2950; salary £37 per annum.

Congleton Union.—The Congleton District is vacant; area 18,079; population 19,119; salary £90 per annum.

Guildford Union.—The Woking District is vacant; area 8190; population 3819; salary £80 per annum.

Huddersfield Union.—Mr. J. Clough has resigned the Woodhouse District; salary £12 per annum. Mr. J. Mackintosh has resigned the Lindley-cum-Quarby District; area 2671; population 7660; salary £20 per annum.

Mere Union.—Mr. Wm. N. Marshall has resigned the Second District; area 16,156; population 3715; salary £105 per annum.

Newcastle-upon-Tyne Union.—The Sick District is vacant; area 176; population 16,145; salary £50 per annum.

Newent Union.—Mr. J. C. Cooke has resigned the Dymock District; area 13,624; population 3098; salary £55 per annum—and the Workhouse; salary £15 per annum.

Stafford Union.—The Stafford District is vacant; area 1282; population 11,075; salary £50 per annum—also the Workhouse; salary £35 per annum.

Stokesley Union.—The Hutton District is vacant; area 19,109; population 2405; salary £25 per annum.

APPOINTMENTS.

Alderbury Union.—Frederick C. Bennett, M.R.C.S., L.S.A., to the Workhouse and the Fourth District.

Berwick-upon-Tweed Union.—James Lambic, M.B. Glasg., L.F.P. and S. Glasg., to the Islandshire District.

Caxton and Arrington Union.—Henry F. La Touche White, L.R.C.S. Ire., L.K. & Q.C.P.I., to the First Caxton District.

Gainsborough Union.—Thomas Stones, L.R.C.P. Edin., L.R.C.S. Edin., to the Haxey District.

Portsea Island Union.—Thomas Diver, M.D. St. And., M.R.C.S. Eng., L.S.A., to the Railway District.

Settle Union.—Edmund Tatham, B.M. & M.C. Edin., to the Bentham District.

Stockton Union.—Finlay Munro, M.B. and C.M. Glasg., to the Norton District.

Windsor Union.—Wm. T. Drew, M.R.C.S. Eng., L.S.A., to the Second District.

THE PRINCESS ROYAL.—Dr. Gream has left London for the New Palace at Potsdam, to be present at the confinement of her Imperial Highness the Crown Princess of Germany, which is shortly expected.

DR. JAMES Y. TOTHERICK, having been appointed Physician to the South Staffordshire General Hospital, Wolverhampton, has been publicly presented with a gold lever watch, a purse of money, and a timepiece for Mrs. Totherick, of the value of £100, by his friends at Sudbury.

CAMBRIDGE MEDICAL EXAMINATIONS.—Intending candidates for examinations for Medical and Surgical degrees in the present term at the anatomical schools are required to signify the same on or before May 13. The first and final examinations for the degree of M.B. will begin on Monday, May 27, at 9 a.m. The second examination for the M.B. degree, and the examination for the degree of Master in Surgery, will begin on Monday, June 3, at 9 a.m.

MR. ROBERT W. KEATE.—The Queen has approved the appointment of the above gentleman to be Governor-in-Chief of the West African Settlements. It may not be generally known that the new Governor is a son of the late Mr. Robert Keate, Surgeon to St. George's Hospital, who filled the office of President of the Royal College of Surgeons of England in the years 1830, 1831, and 1839.

ASSOCIATION OF MEDICAL OFFICERS OF HEALTH.—At the next meeting of this Association, which will be held at the Scottish Corporation Hall, Crane-court, Fleet-street, on Saturday, April 20, at 7.30 p.m. (Robert Druitt, M.R.C.P., F.R.C.S., in the chair), Dr. C. J. B. Aldis will read a short paper "On a Sudden Outbreak of Small-pox in Belgravia in 1871, and on the necessity of Amending the 38th Section of the Sanitary Act, 1866"; and J. Netten Radcliffe, Esq., will read a paper, entitled "Cholera Prospects."

RADCLIFFE STUDENTSHIPS have been awarded to Mr. Francis J. Carey, of Guy's Hospital, and Mr. C. R. B. Keetley, of St. Bartholomew's Hospital, on the recommendation of Sir James Paget, D.C.L., Sir William Gull, D.C.L., and Dr. John Ogle, M.D.; and to Mr. Farington M. Granger, of the Hospital of Leeds, on the recommendation of Mr. T. P. Teale, M.A., M.B.

The Medical School in Paris was reopened on Monday, and Professor Dolbeau's lecture was delivered without disturbance. Sixty students attended.

The last returns of the Registrar-General on the public health show the following mortality in some of the large cities in England and on the Continent:—London, 25 per 1000; Portsmouth, 17; Norwich, 26; Liverpool, 26; Manchester, 30; Salford, 38; Oldham, 24; Newcastle-upon-Tyne, 26; Bradford, 28; Paris, 28; Rome, 40; Berlin, 33; New York, 33; Bombay, 25; Madras, 32.

The Commander-in-Chief on the East India Station reports that cholera has entirely disappeared from H.M.'s ship *Daphne* since her arrival at Trincomalee, and that she was released from quarantine at that place at the beginning of March.

A SUPERANNUATION of £35 per annum has been voted by the St. Marylebone Board of Guardians to Mr. Alfred Elkins, late Medical Officer of the St. Mary's District. Mr. Elkins had held the office for fifteen years.

VARIOUS cases of poisoning by vanilla lees which have taken place for some time past in Altona, Munich, Vienna, and other places are being discussed in the German newspapers. The poison in the vanilla, one Doctor says, is produced by the use of cashew-nut oil to besmear the vanilla pods.

PRESENTATION.—Mr. Wright Allen has been presented, by the Arnold United Independent Order of Odd Fellows, with a case of spoons and forks, accompanied by a suitable address.

PROFESSORSHIP OF CHEMISTRY AT OXFORD.—This important office is announced to be filled up in Act Term, and applications for the appointment are to be made to the President of Magdalen College, Oxford, on or before May 18. The electors are the Chancellor of the University of Oxford, the Visitor and President of Magdalen College, Oxford, and the President of the Royal Society, and of the College of Physicians, London. Mr. A. G. Vernon Harcourt, M.A. Christ Church, Oxford, Dr. Lee's Reader in Chemistry at that University, is spoken of as the probable successor of Sir Benjamin Brodie in this office.

THE PUBLIC HEALTH BILL.—On Tuesday, at the meeting of the Central Chamber of Agriculture, it was resolved to insist on the preservation of local self-government and such a degree of independence of local action as can alone insure the efficient administration of the law. As the provisions of this Bill do not apply to the metropolis, the local bodies of London will not be affected by its proposals.

INFANT MORTALITY IN NEW ZEALAND.—Infants born in Christchurch during the autumn very often die. Owing to the flatness of the site of the town, it is almost impossible to get a proper system of drainage, and the arrangements seem very bad, if you are to judge from the evil smells which are abroad in the evening. Children who are born on a station, or taken there as soon as possible, almost invariably thrive, but babies are very difficult to rear in the towns. If they get over the first year they do well, and I cannot really call to mind a single sickly or even delicate-looking child among the swarms which one sees everywhere.—*Lady Barker's "Station Life in New Zealand."*

THE RATIONALE OF A LARGE FEE.—Frederick Jäger, the celebrated oculist of Vienna, having operated with success for cataract on the old Servian Prince Milosch Obrenowitsch, received the princely fee of 2000 ducats, besides a present of a costly jewel for his wife. Some years afterwards he operated with equal success upon the other eye, for which, however, he received only 1000 ducats. Dining with the Prince some time afterwards, Jäger jocularly alluded to the difference of the two fees. "My dear Jäger," replied the old Prince, "it is natural enough that I should pay you the 2000 for a successful operation on the first eye, and only 1000 for that on the second; but if I had a third to be operated upon, I should most certainly have also given you 2000 ducats for the second operation."

EXAMINATION QUESTIONS.—The following are copies of the questions on Surgical Anatomy and the Principles and Practice of Surgery and Medicine submitted to the candidates at the Pass Examination for the Diploma of Membership of the Royal College of Surgeons, which was brought to a close on the 17th inst.:—1. How would you distinguish, Surgically, chronic induration of the breast from scirrhus? What are the microscopic appearances by which each is characterised. 2. Describe the operation of excision of the elbow-joint, and state under what circumstances it may be required. 3. What treatment should be adopted in a case of incised wound of the cornea with protrusion of the iris? Mention the consequences which may ensue, and the proper mode of dealing with them. 4. What are the causes which may impede the union of a fracture of a long bone? Describe the modes of treatment which might be resorted to in order to promote the cure of an ununited fracture. 5. Describe deligation of the right carotid artery in the first part of its course, giving the exact relations of the parts concerned in the operation. 6. Mention the different forms of nævus, and the appropriate modes of treatment. 7. Describe a case of paralysis of the facial nerve, and mention the causes upon which it may depend, and the treatment you would adopt for its relief. 8. What are the circumstances which would induce you to have recourse to thoracentesis in a case of effusion in the pleural sac? State how you would perform the operation, and the changes that would follow it, supposing the case to terminate in cure. 9. Write prescriptions in Latin in full, and the directions in English, for a diuretic mixture and a purgative powder, and give the compositions and doses of the following preparations in the British Pharmacopœia:—*Pulvis jalapæ compositus; mistura ferri composita; tinctura camphoræ composita; liquor morphinæ hydrochloratis.*

The Monthly Return of the Births, Deaths, and Marriages registered in the eight principal towns of Scotland, published by authority of the Registrar-General, states that during the month of March, 1872, there were registered in the eight principal towns of Scotland the births of 3425 children, of whom 1755 were males and 1670 females. Of these, 3156 were legitimate and 269 illegitimate, being in the proportion

of one illegitimate in every 12·7 births, or 7·8 per cent. of the whole as illegitimate. In Dundee, 5·5 per cent. of the births were illegitimate; in Perth, 5·6; in Greenock, 6·1; in Paisley, 6·2; in Leith, 6·5; in Edinburgh, 7·9; in Glasgow, 8·6; and in Aberdeen, 10·1 per cent. 2662 deaths were registered in the eight towns during the month, of whom 1311 were males and 1351 females. Allowing for increase of population, this number is 271 under the average for March during the last ten years. The annual rate of mortality was 22 deaths per thousand persons in Dundee, 23 in Perth, 24 in Paisley, 25 in Aberdeen, 28 in Leith, 29 in Greenock, 31 in Glasgow, and 35 in Edinburgh. Of the 2662 deaths registered, 1037, or 39 per cent. were of children under 5 years of age. In Perth, 12 per cent. of the persons who died were under 5 years of age; in Edinburgh, 29; in Aberdeen, 32; in Paisley and in Leith, 33; in Dundee, 40; in Glasgow, 45; and in Greenock, 46 per cent. The epidemic and contagious class of diseases proved fatal to 735 persons in the eight towns, and constituted 27·6 per cent. of the total mortality. In consequence, however, of the prevalence of small-pox, and also to some extent of scarlatina in Edinburgh, and of small-pox in Leith, this rate was exceeded in both of these towns, the proportion of zymotic deaths being 42·8 per cent. in Edinburgh, and 48·2 per cent. in Leith. Small-pox was again the most fatal of the epidemics, having caused 244 deaths, or 9·2 per cent. of the mortality. In Edinburgh this disease continued as fatal as during the previous month; but is on the decrease in Aberdeen, Leith, and Dundee, where respectively there were recorded 17, 37, and 24 deaths, against 30, 52, and 74 deaths during February. No deaths from small-pox were recorded in Paisley or Greenock. Hooping-cough was the next most fatal of the epidemics. Fever caused 81 deaths, or 3·0 per cent. of the mortality. Of these, 35 were tabulated as typhus, 37 as enteric, 7 as relapsing, 1 as simple continued, and 1 as infantile remittent fever. The month has been on the whole warm and dry, especially in the earlier part of the month, when the temperature was much above the average, and the rain extremely small; but this was modified by a change, in both respects, towards the end of the month, which was cold and stormy, with snow and rain. Still the mean temperature exceeded the average by 1·7°, and the quantity of rain was very nearly the same as the average. The mean temperature was greatest at Leith (43·2°), and least at Aberdeen (41·2°). The greatest amount of rain fell at Paisley (3·90 inches in 11 days), and the least at Aberdeen (2·28 inches in the unusual number of 29 days).

NOTES, QUERIES, AND REPLIES

Be that questioneth much shall learn much.—Bacon.

Dr. Junker's paper in our next.

Dr. Christie's interesting letter next week.

Dr. A. P. Stewart.—We are sorry that we cannot publish *Dr. A. P. Stewart's* letter this week.

Belfast.—*Dr. T. Reade's* interesting communication shall be inserted as soon as possible.

Midwives.—We have received a copy of the question proposed at a late examination of midwives by the Obstetrical Society, which are few and sensible.

Malaria.—The writers who deny its existence are Menzi and Oldham. For evidence of the sort you require consult Baudens. MacCulloch and La Roche are also well worth reading.

Dr. E. Symes Thompson will deliver the Gresham Lectures on April 25, 26, 27, and on May 30 and 31, at the Gresham College, Basinghall-street, E.C., at 7 p.m.

Ais.—In Copland's Dictionary, under the heading "Idiosyncrasy."

A M.D.—Yes, by ballot.

Liverpool.—The *Daily Courier* of Tuesday last contains a well-written and able article on "The Examination of Midwives," as published in a circular by the Obstetrical Society of London. The writer in the *Courier* advocates the establishment of these examinations, and points how they may tend, in more ways than one, to the public safety and public morality.

A Surgeon-Major writes (alluding to the cholera epidemic in Bombay)—"That the military cantonments in India are so frequently ravaged by cholera is due to the fact that their water-supply continues in its former filthy state. Thanks to the counsels of the late Lord Mayo, projects are now under consideration for remedying the defect. It was left for the practical mind of Lord Mayo to discover that reform of the water-supply was the most essential of all the sanitary improvements required in India."

Peregrinus.—*Dr. Velten*, late of Aix-la-Chapelle, has removed to Wiesbaden, where he will practise for the future.

Scarborough.—It is not necessary to enter into the controversy. It is quite certain, by whatever name the complaint may be called from which Miss Rose Constable suffered, the vaccination had nothing whatever to do with its cause or its progress. We think the plaintiff in the late action conducted himself with dignity and moderation, and that he is entitled to the respect of his Professional brethren and the public.

MR. BAKER BROWN.

A fund is being raised on behalf of Mr. Isaac Baker Brown, who is completely prostrated by paralysis. He is also in great pecuniary distress.

CORRIGENDUM.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.
SIR,—I regret to find an error in a letter of mine published in your journal of April 6—"In conclusion, I would mention that the window-tax did much to improve the ventilation of houses." It should be, of course, "the abolition of the window-tax did much to improve the ventilation of houses." I am, &c., D. OSBORN.

2, Anglesea-place, Southampton.

"THE MEDICAL DIRECTORY."

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.
SIR,—Your Reviewer has fallen into an unaccountable error. He says (p. 443), "It has always been a bore to turn to the Provincial Directory for a name which should have been included in the Metropolitan one, and we would strongly urge the editor of the old 'Medical Directory' to include within his metropolitan area all gentlemen practising within the twelve miles radius."

If your Reviewer will examine "The Medical Directory" for the present year he will find that the London portion of the work includes all gentlemen practising within the Metropolitan and Suburban Postal Districts.

We are, &c., THE EDITORS OF "THE MEDICAL DIRECTORY."

ENGLISH MICROSCOPES.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.
SIR,—I have only just read the article on foreign microscopes in the *Medical Times and Gazette* of March 30; and without any desire to depreciate the merits of the same, I must say that the statements of comparative cost and utility can only apply to some years back, and certainly not to the present time. The writer of the article cannot have recently examined the low-priced microscopes of some of the London makers, myself included, and I should have much pleasure in giving him an opportunity of testing the same, when I think he would admit that an Englishman can spend his money in his own country and reap certain advantages at the same time.

I refrain from more detail, so as not to advertise myself, but shall feel obliged by a notice of my protest. I am, &c., CHAS. COLLINS.

157, Great Portland-street, W., April 10.

PENSIONS TO POOR-LAW MEDICAL OFFICERS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.
SIR,—I saw in the Parliamentary news a few days since that the question was asked why Mr. Grubbe, of Warminster, did not have a pension. It appears that the matter was brought before the guardians, and that they rejected it by a large majority, saying they thought he was still fit to work. Do the guardians of unions generally only intend to give pensions to those who are hopelessly diseased, and who cannot do another day's work, and must die soon, after the same principle that they get rid of paupers? I should think twenty-seven years, or even twenty years, quite long enough for any gentleman to have served for a Poor-law Union, and if he has done his duty it is quite certain he has not made anything out of it. At the present time it appears that Poor-law Medical Officers are expected to work hard for the most absurd payment, to do all sorts of Medical charity that ladies and ratepayers wish them to do, and at the end they are to die broken down with hard work, and perhaps for the last few months of their life the generous guardians may give them a mite to keep them from starvation. I think *Dr. Rogers* has intended to do much for the Profession, but he and the Association have failed in not making the pension a first consideration. I believe now it is not too late to get *Mr. Stansfeld* to introduce a clause into his Bill to grant pensions out of the Consolidated Fund to Poor-law Medical Officers of twenty years' standing; and if they gave the whole of the paltry salary they now give them it would not be too much for a pension.

At all events, I hope *Mr. Stansfeld*, who appears kindly disposed, will not allow this session to pass without getting a Bill through the House,

empowering the Local Government Board to grant pensions to Poor-law Medical Officers of twenty years' standing, quite irrespective of age or ill-health, to be paid by the Government, and not by the guardians, but that if necessary every union should contribute a small sum towards the expense, which would really be a very small item; and I feel certain that no member of the Legislature with any kind or proper feeling would oppose it. I therefore hope that before Mr. Stansfeld's Sanitary Bill has become law an enactment will be passed granting Government pensions to the overworked, ill-paid, and snubbed Poor-law Medical Officer; and I think it is the duty of every one of them immediately and during the next week to petition Mr. Stansfeld on the subject.

Dr. Lush and Dr. Brady are always at their post, and I hope they will kindly use their influence and urge on the President of the Poor-law Board the necessity of the measure, as I am quite sure it will benefit the pauper as much as the Medical Officer, inasmuch as from my experience of what I have seen of the Surgeons of unions, they are not nearly so fit at 50 years of age to give the same attention to their patients as they were at 25; and as far as allowing men of very old age to attend paupers, the thing is preposterous—they cannot be attended to properly. I am, &c.,
Sloane-street, April 16. J. COLVILLE.

COMMUNICATIONS have been received from—
Mr. ERNEST MORGAN; Dr. PURDON; Dr. W. BRYCE; Mr. C. COLLINS; Sir JOHN BENNETT; Mr. H. OSBORN; Messrs. A. and C. BLACK; Dr. G. BUCHANAN; Dr. IMRAY; Mr. T. C. WHITE; Dr. FORBES WINSLOW; Mr. H. MORRIS; Mr. J. CHATTO; Mr. H. ARNOTT; Dr. SINGLETON; Dr. VINEN; Dr. STEVENSON; Dr. ALDIS; Mr. T. PIPER; Dr. N. GEISSE; Mr. FIDDIAN; Mr. J. COLVILLE; Dr. T. READE; Mr. CHURTON; Dr. MASSEY; Dr. A. P. STEWART; Dr. A. CHRISTIE; Dr. HERMANN WEBER; Mr. TEEVAN; Professor FLOWER; Mr. T. M. STONE; Mr. POOLE.

BOOKS RECEIVED—
Dimostrazione di una Nuova Importantissima Virtù Medicamentosa, del Dottore Angelo Monteverdi—Miller's Elements of Chemistry, part i.—Red-cross Operations in the North of France, 1870-72—The Provident System of Medical Relief impartially considered—On the Uses and Derangements of the Glycogenic Function of the Liver, by Dr. G. M. Smith—The Teeth and How to Save them, by Dr. L. P. Meredith—Cumberland and Westmoreland Lunatic Asylum Report.

PERIODICALS AND NEWSPAPERS RECEIVED—
Nature—Pharmaceutical Journal—Aberdeen Journal—Micrographic Dictionary, parts iii. to vii.—Scarborough Express—The Clinic—The Transactions of the New York Academy of Medicine, vol. iii., part 2—Philadelphia Medical Times—Liverpool Daily Courier.

APPOINTMENTS FOR THE WEEK.

April 20. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; King's, 2 p.m.; Charing-cross, 2 p.m.; Royal Free, 2 p.m.; Hospital for Women, 9½ a.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. Thomas's, 9½ a.m.

ASSOCIATION OF MEDICAL OFFICERS OF HEALTH, 7½ p.m. Dr. C. J. B. Aldis, "On a Sudden Outbreak of Small-pox in Belgravia in 1871, and on the Necessity of Amending the 38th Section of the Sanitary Act, 1866." Mr. J. Netten Radcliffe, "Cholera Prospects."
ROYAL INSTITUTION, 3 p.m. Mr. R. A. Proctor, "On the Star Depths."

22. Monday.

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; St. Peter's Hospital for Stone, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

ANTHROPOLOGICAL INSTITUTE, 8 p.m. Meeting.
MEDICAL SOCIETY OF LONDON, 8 p.m. Dr. Prosser James will show a new description of Spray Atomiser. Dr. J. Astley Bloxam, C.C., "On Cystic Disease of the Breast, with two Specimens in the Female and one in the Male." Dr. Semple, "On Diphtheria."

23. Tuesday.

Operations at Guy's, 1½ p.m.; Westminster, 2 p.m.; National Orthopædic, Great Portland-street, 2 p.m.; Royal Free, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; West London, 3 p.m.

ROYAL INSTITUTION, 3 p.m. Dr. Guy, "On Statistics, Social Science, and Political Economy."
ROYAL MEDICAL AND CHIRURGICAL SOCIETY, 8½ p.m. Dr. C. T. Williams, "On the Results of Warm Climate in the Treatment of Pulmonary Consumption as exemplified by an Analysis of 251 Cases."

24. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1½ p.m.; Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.; St. Thomas's, 1½ p.m.; Samaritan, 2.30 p.m.; King's College Hospital (by Mr. Wood), 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. George's (ophthalmic operations), 1½ p.m.

ROYAL INSTITUTION, 3 p.m. Meeting.

25. Thursday.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Royal Orthopædic, 2 p.m.; University College Hospital, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.
ROYAL INSTITUTION, 3 p.m. Prof. Tyndall, "On Heat and Light."

26. Friday.

Operations at Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.

CLINICAL SOCIETY, 8½ p.m. Dr. Tilbury Fox will exhibit a patient suffering from Lepra Anæsthetica. Dr. Anstie will read a paper on a "Case of Lepra Anæsthetica." Dr. Andrew, "On a Case of Unusual Daily Range of Temperature associated with Vegetations on Mitral Valve and Infarction of Spleen." And other Papers.

QUKETT MICROSCOPICAL CLUB, 8 p.m. Mr. J. G. Waller, "Observations on Fresh-water Sponges."

ROYAL INSTITUTION, 9 p.m. Prof. Blackie, "On the Genius and Character of the Modern Greek Language."

VITAL STATISTICS OF LONDON.

Week ending Saturday, April 13, 1872.

BIRTHS.

Births of Boys, 1334; Girls, 1240; Total, 2574.
Average of 10 corresponding weeks, 1862-71, 2104.7.

DEATHS.

	Males.	Females.	Total.
Deaths during the week	780	690	1470
Average of the ten years 1862-71	762.0	728.8	1490.8
Average corrected to increased population	1640
Deaths of people aged 80 and upwards	54

DEATHS IN SUB-DISTRICTS FROM EPIDEMICS.

	Popula- tion, 1871.	Small- pox.	Measles.	Scarlet Fever.	Diphtheria.	Whooping- cough.	Typhus.	Enteric (or Typhoid) Fever.	Simple continued Fever.	Diarrhoea.

METEOROLOGY.

From Observations at the Greenwich Observatory.

Mean height of barometer	29.972 in.
Mean temperature	51.4°
Highest point of thermometer	69.9°
Lowest point of thermometer	32.2°
Mean dew-point temperature	42.9°
General direction of wind	Variable
Whole amount of rain in the week	0.05 in.

BIRTHS and DEATHS Registered and METEOROLOGY during the Week ending Saturday, April 13, 1872, in the following large Towns:—

Boroughs, etc. (Municipal bound- aries for all except London.)	Estimated Population to middle of the year 1872.*	Persons to an Acre. (1872.)	Births Registered during the week ending April 13.		Deaths Registered during the week ending April 13.		Temperature of Air (Fahr.)			Temp. of Air (Cent.)		Rain Fall.

At the Royal Observatory, Greenwich, the mean reading of the barometer in the week was 29.97 in. The highest was 30.30 in. at the beginning of the week, and the lowest 29.61 in. on Friday at noon.

* The figures in this column are the unrevised numbers enumerated in April, 1871, raised to the middle of 1872 by the addition of a year and a quarter's increase, calculated on the rate which prevailed between 1861 and 1871. The population of Dublin is taken as stationary.

FLOUR.

HORSNAILL & CATCHPOOL, BULLFORD STEAM MILLS, ESSEX,

Continue to supply families in and around London with Flour, &c., of their own manufacture (warranted pure), carriage free. Whites for Pastry. Fine Households, specially recommended for Bread-making. Seconds. Wheaten Meal for Brown Bread. Rye Meal. American Hominy Meal. Pure Flour of Lentils. Scotch Oatmeal (fine) for Gruel; ditto (round) for Porridge. Scotch Brose Meal, &c., &c.

Address, Horsnail & Catchpool, Liverpool-road, London, N., for all information.

BOUDAULT'S PEPSINE.

In 1854, after many experiments, PEPSINE was obtained in a pure state by M. BOUDAULT, Chemist, and Dr. L. Corvisart.

Boudault's PEPSINE was honoured with two Reports at the Academy of Medicine, Paris, and with having its formula inserted in the New French Pharmacopœia.

The International Jury of the Universal Exposition, Paris, 1867, awarded to Boudault's PEPSINE the ONLY MEDAL given for PEPSINE and its preparations. (Silver Medal, 1868.)

Boudault's PEPSINE is the only one that has been furnished to the Hospitals in Paris since 1854.

PEPSINE Wine (Sherry), in bottles, 4/ and 8/. Dose—a tablespoonful before each meal.

PEPSINE Lozenges, in bottles, 4/. Dose—3 before each meal.

PEPSINE Pills, in bottles, 4/. Dose—3 before each meal.

Boudault's PEPSINE or Poudre Nutrimentive. Dose—15 grains; sold in 1-oz., 4-oz., 8-oz., and 16-oz. bottles.

HOTTOT BOUDAULT, 7, Avenue Victoria, Paris.

London: A. & M. ZIMMERMANN, 7, Fen-court, E.C.

May be obtained through all Chemists.

LIEBREICH'S CHLORAL HYDRAT.

To be obtained through all the Wholesale Druggists of the United Kingdom.

Sole Wholesale Agents, A. & M. ZIMMERMANN, 7, Fen-court, Fenchurch-street, E.C.

Natural Mineral Waters of Vals, Vichy, Carlsbad, Seltzer, Kissengen, Homburg,

PULLNA, FRIEDRICHSHALL, &c., direct from the Springs; also the Artificial Mineral Waters prepared by Dr. Struve and Co. at the Royal German Spa, Brighton; R. Ellis and Son, Ruthin; and the Natural Bromo-Iodine Water of Woodhall Spa, Lincolnshire.—Agents, W. BEST and SONS, 22, Henrietta-street, Cavendish-square, London, W.

HUBBUCK'S PURE OXIDE OF ZINC.

See *Pharmaceutical Journal* of May 1, 1856.

Sold in Stamped Boxes of 14 lbs. each, by the following Wholesale Druggists:—

Messrs. Baiss Brothers & Co.	Messrs. Geo. Curling & Co.	Messrs. Hearon, Squire, & Francis.	Messrs. Southall, Son, & Dymond.

IMPROVED ABDOMINAL BELTS.

Invented and manufactured only by SALT & SON, Patentees, Birmingham, Anatomical Mechanicians to H.R.H. the Prince of Wales.

PRIZE MEDAL, DUBLIN, 1865. | HON. MEN., PARIS, 1867.

MEDICAL OPINIONS.

“Mr. T. P. SALT, of Birmingham, forwards us a very good ABDOMINAL BELT. This gentleman, after reflecting upon the direction of the forces which exist in the fibres of the abdominal muscles, has constructed a Belt which artificially supplies all that is naturally required.”—*The Lancet*.

“We have lately had an opportunity of trying Mr. SALT's Belt in a case of enlargement of the abdomen from obesity, with the result of completely relieving many of the symptoms which had previously caused the patient pain and annoyance.”—*Medical Times*.

ORIGINAL LECTURES.

LECTURES ON
EXCISION OF THE HIP-JOINT.

By HENRY HANCOCK, V.P.R.C.S.E.,

Senior Surgeon to Charing-cross Hospital.

(Continued from page 427.)

WHEN the opening occurs in the groin, the existence or non-existence of perforation of the acetabulum may often be ascertained by the introduction of a probe slightly curved into the opening, and directing its point downwards and outwards. It may thus be passed through the perforation into the joint. At the same time we must not overlook the possibility of mistaking either disease of the sacro-iliac synchondrosis or pelvic cellulitis for disease of the hip-joint. I have seen two cases of this latter affection—"pelvic cellulitis"—which had proceeded to suppuration, and in both the matter had found exit by the anterior inferior spinous process of the ilium. In both the symptoms and progress so closely resembled caries of the hip-joint, that in both instances I was called in by the gentlemen in attendance for the latter complaint. Curiously enough, the patients assigned the same cause for the mischief. The one lady resided in the neighbourhood of Great George-street, Westminster, the other in Piccadilly, and they both ascribed the malady to having, shortly after a confinement, sat for some time upon a bench in the park. They were both taken with a chill the same evening, followed by pain in the groin and neighbourhood of the joint, fever, etc. When I saw the first of these patients—and the description of one will suffice for both—I found her propped up in bed extremely emaciated, perspiring profusely, and pulse considerably above 100. She could not straighten the limb on account of pain, neither could she bear the slightest movement from the same cause, the pain being referred to the inner side of the knee. There was an opening in the groin close to the anterior inferior spinous process, from which a continuous and profuse discharge was kept up. I at first thought that this was a case of hip-joint disease with pelvic complication, but by careful examination with a probe and of the joint under chloroform convinced myself that the joint was uncomplicated; and the patient's death shortly afterwards enabled us to ascertain the correctness of this view, the joint being found perfectly healthy, the deceptive symptoms being due to the mischief going on beneath the pelvic muscles.

The second lady, to whom I was called very shortly after the former, presented almost the identical train of symptoms. There was the opening in the groin, the inability to straighten the limb, the constant and intense pain in the knee, aggravated on the slightest movement, the emaciation, etc.; but the same absence of joint disease. From my experience of the former and the desperate condition of the present patient, I gave a very unfavourable opinion of the probable result of the case—in fact, I did not think it possible she could survive. This was twelve years ago, and I only saw the patient once. To my great surprise, a few weeks since she called upon me to consult me upon some other malady totally unconnected with the former, from which she had gradually but, after some months, completely recovered, no longer having any difficulty or pain in straightening the limb or in walking.

In some cases an abscess forms in the pelvis before actual perforation of the acetabulum occurs, though in all probability depending upon disease going on in that cavity. In such cases, should the connexion be clearly made out, and circumstances warrant operative interference, the floor of the acetabulum may readily be perforated by a trephine, and any amount of the acetabulum removed by a blunt-pointed meta-carpal saw. So, likewise, in those cases in which there is neither pelvic abscess nor perforation, but extensive disease of the acetabulum, I cannot see the objection to the operation. Here we have a patient actually dying; we know that an operation holds out the only chance of life. There never was a greater mistake than that made by Mr. Knox when he asserted that the pelvic portion of the hip-joint is beyond the reach of excision. Nothing can be more contrary to fact. The whole of the acetabulum is reached with the greatest ease, and may be removed without penetrating the cavity of the pelvis at all or injury to the parts contained therein. The whole operation is performed external to the obturator fascia and the levator ani muscle, and is consequently so far extra-pelvic;

and the operation is still more easily performed when pelvic abscess is present, for then the obturator fascia is not only detached from the bone and thickened, but there is usually a considerable space between the two.

I was led to the foregoing conclusions by the study of the following case, which most incontestably proves that if the regulations I attempted to combat in 1857, as now, were right, I was as indubitably wrong in even proposing, much less attempting, the operation. In fact, according to these laws, it ought never to have been attempted at all, as by so doing, not only was one, but the whole of them violated. The head of the bone was not dislocated; the acetabulum was extensively diseased and perforated, and there was pelvic abscess:—

Timothy D., aged 14, admitted, under my care, into the Charing-cross Hospital in July, 1856, with disease of the hip-joint. Five years before, observing a swelling in his groin, he attended the Middlesex Hospital, but got worse, and was made an in-patient. He remained there five months. Two years afterwards abscesses formed around the joint, and in the early part of 1855 he first came under my care, and remained in the Hospital three months, when he left apparently cured. He continued able to walk for ten months, when he was attacked with severe pain in his knee, which increased so much that, upon application, I at once admitted him into the Hospital. Shortly afterwards abscesses formed around the joint, opening behind the trochanter and also low down on the back of the thigh; and subsequently an abscess burst in the groin, and a probe introduced into this opening passed readily into the pelvis. He in the course of time became so emaciated and worn out with the profuse discharge, night-sweats, loss of appetite, etc., that it was evident he could not long survive if something was not done for him. Great prostration and cough supervened, and his sputa became streaked with blood. I therefore requested my then colleague, Dr. Wiltshire, to examine his lungs. He did so, and pronounced them free from any cause contra-indicating an operation. Having, as far as possible, ascertained that the disease was confined to the hip-joint and pelvis, I examined the inside of the latter with a probe passed through the opening in the groin, and directing it downwards and outwards discovered that the acetabulum was perforated. Under these circumstances I concluded that the pelvic abscess and the boy's condition generally were due to hip-joint disease, and that by removing the head of the femur and the floor of the acetabulum I might not only get rid of the diseased bone, but also, by affording a free and depending opening for the discharge of the matter, the abscess within the pelvis might be approximated to the condition of an ordinary abscess, and the patient by these means be afforded a chance of recovery. Having stated my views to my colleagues, Messrs. Canton, Hird, and Barwell, and they having acquiesced therein, on December 6, 1856, the patient being under the influence of chloroform, I performed the operation, making a crucial incision extending three inches in all directions over the great trochanter of the femur. The flaps having been reflected, a circular incision was carried round the head of the bone, which remained in its cavity, cutting through the glutei, the muscles inserted into the digital fossa, the pectineus, etc. Upon examination by the finger the neck of the femur was found to be so much involved in the disease as to necessitate its removal below the great trochanter, after which the head of the bone was removed without difficulty. When this was done the acetabulum was found to communicate by two openings at its deepest part with the abscess within the pelvis. With a metatarsal saw (blunt-pointed) I cut round the acetabulum, removing the whole of the diseased bone, and exposed the thickened pelvic fascia, leaving a large opening by which the matter from the pelvic abscess could escape. In this proceeding I used the metatarsal saw alone; I did not employ the gonge at all. The flaps were then brought together and secured by sutures, except opposite and below the opening in the acetabulum, where they were kept asunder by lint. Not a single vessel required tying. An interrupted splint was applied, as the leg could now be straightened without difficulty.

The operation was followed by almost instantaneous relief of his constitutional symptoms. His countenance very soon became cheerful and free from anxiety. His night-sweats ceased altogether two days after the operation. On the third day the wound in the groin was completely healed. The discharge from the wound made at the operation, for the first few days thin and abundant, gradually became thicker as it diminished in quantity, until at length it ceased entirely. On the fourteenth day after the operation he was able to sit up in bed with his knee straight, for the first time for nearly a year. In

three weeks he dressed himself, and sat in a chair by the fire. In five weeks he walked with a crutch and a stick. At the end of eight weeks he imprudently dispensed with both crutch and stick. Inflammation consequently set in, followed by abscess external to the pelvis. This, however, subsided, and he progressed steadily, daily gaining health and strength. At the beginning of April he walked in the park daily. In May, 1857, he went down to Ramsgate, and in the following July he returned to the Hospital with symptoms of phthisis; and he died twelve months afterwards—or nineteen months after the operation—of that disease.

On post-mortem examination, it was found that the head of the femur abutted against the sawn surface of the upper margin of the acetabulum. It was enclosed and shut into a cavity by a tough, fibrous capsule, which was deficient at the posterior part, whence pus escaped. The end of the femur was rounded off, and the extremity of the medullary tube was partially closed in by a thin plate of bone. The opening still remaining had jagged, uneven edges, and it seemed as though the osseous covering had at some former period been complete, and had subsequently yielded to the absorption produced by pressure at that part. The cavity which supplied the place of the acetabulum was roomy, and had a large perforation still patent. The upper part, against which the end of the bone had pressed, was covered by a thin but dense fibrous structure. At its back was a carious spot, about the size of a sixpence, the diseased action being quite superficial. A singular adaptation of parts, in order to compensate for the absence of the cervix femoris, was found in the bending inwards of the descending ramus of the pubes and the ascending branch of the ischium. The pelvic abscess was consolidated, and the iliac fascia was tightly stretched over the opening in the acetabulum cavity.

The post-mortem examination of a child operated upon by Mr. Holmes, who subsequently died of hepatisation of the lungs, presented somewhat similar features. All the viscera were found healthy with the exception of the hepatised lungs, which, however, contained no trace of tubercles. The new joint was buried beneath a dense fibrous cicatrix, separating it from the scar of the wound. The bones were surrounded by a complete capsule of fibrous tissue. The small trochanter was drawn up, and the truncated end of the femur pressed into the acetabulum by the tendon of the psoas muscle. The cavity of the acetabulum was much larger than usual. The end of the femur was rounded off, and coated by a substance resembling cartilage to the naked eye, but which proved to be fibroid tissue when examined under a microscope. The femur and acetabulum were firmly united together by bands of fibrous tissue.

In another case of Mr. Holmes's, the child was so worn down by emaciation that, though 6½ years old, the body after death weighed only twenty-one pounds and three-quarters. The limb operated upon was an inch and a half shorter than the other one. The acetabulum was found absorbed in its lower part, which had been made to communicate with the great sacro-sciatic foramen, so that the pelvis was perforated by a ragged hole the size of a florin. On the inner side of the pelvis was a large collection of pus between the iliacus internus muscle and the peritoneum, communicating with the exterior through the acetabulum, and round by the anterior inferior iliac spine. Beneath the glutæus medius was a large abscess communicating with the operation-wound, and reaching back as far as the spines of the vertebræ running along the crest of the ilium. The inner aspect of the os ilii was laid bare to a considerable extent. The right and left femoral, all the iliac veins in their upper parts, and the lower vena cava were occupied here and there by thrombi, which were very granular, laminated, variously coloured—strongly resembling an agate in some places on section—and nearly filling the vessel. The clots were not adherent, and the veins and cellular tissue around looked natural.

The late Mr. Jones, of Jersey, was the first Surgeon, I believe, who ever introduced his fingers through an opening in the acetabulum of a living man into an abscess situated within his pelvis; and although, as we have seen, the operation has now been performed several times in cases where the acetabulum had previously been perforated by disease, I find that my colleague, Mr. Barwell, was the first who ever systematically removed the head of the thigh-bone for hip-joint disease combined with abscess within the pelvis, and who, finding the floor of the acetabulum entire, applied the trephine, and removed the latter, with the express object of evacuating the abscess, giving the matter a free exit, and thus of saving the patient.

The two cases to which he applied this practice are well worthy of being recorded.

J. H., aged 16, came under Mr. Barwell's care September 14, 1864, very much reduced with long-standing hip disease of left side. There was a large abscess near the great trochanter, and an opening in the outer part of the groin below Poupert's ligament, which discharged freely. An operation was proposed on October 3, but the boy refused, and it was delayed until November 26, when it was considered necessary to save his life, the symptoms being urgent, and the discharge from his groin very copious. Mr. Barwell removed the head and neck of the femur, and trephined the acetabulum. The patient rallied for some days after the operation, but the discharge became very copious. On December 3 it had a fæulent odour, and a few days after that pus was found in his fæces. This subsequently increased in quantity; diarrhœa, which merged into dysentery, set in, and he sank, and died on January 14, 1865.

The next case was more satisfactory:—

L. N., aged 7, admitted May 10, 1865. Around his right hip was a large abscess, with sundry openings of sinuses. A probe passed along these towards the hip-joint detected rough bone. A sinus at the inner side of the thigh communicated with the inside of the pelvis. The thigh much adducted; the shortening was apparently two inches. The boy suffered greatly, and his health was much injured. He was operated upon on May 20. The head and neck of the femur were reduced to a mere tubercle, which still lay in the acetabulum; the remainder of this cavity was filled by florid soft granulations and pus. On passing the finger into it, a more solid material was felt, which, on being extracted, was found to be a portion of the articular cartilage from the head of the femur, with the articular lamella attached, and still very sound, being barely affected by fibrous degeneration—showing that the disease, commencing in the head of the bone, ran on to suppuration so rapidly as to detach the articular lamella before the ulceration of the cartilage could be effected. Finding the floor of the acetabulum carious, and being also aware of suppuration inside the pelvis, the trephine was applied, and a large opening established, through which pus flowed freely. Four days after the operation the discharge from the wound had suddenly and almost entirely ceased, and a more thin secretion replacing the healthy pus flow, the edges of the wound were separated and opened out by the finger, and a drainage-tube carried to the bottom of the wound, through which chlorated soda solution was injected twice daily. On the fifth day healthy discharge was partially, and on the sixth entirely restored. After a fortnight some pus found its way into the sheath of the rectus, and was evacuated in front of the thigh one-third down. The boy walked well, and without support, three weeks before leaving the Hospital, which he did in the first week of March, 1866.

Mr. Barwell, in sending me the above cases, lays great stress on the importance of watching for and preventing any sudden cessation of pus flow, as such an event, if it continues, is sure to be followed by osteo-myelitis, pyæmia, or both. He also draws attention to the importance of keeping the thigh much abducted. "The patient," he says, "was very quiet, and amenable to the required splint. In all cases of hip affection, adduction means apparent shortening; abduction, apparent lengthening. By this means I got the limb so placed that an additional sole three-quarters of an inch thick sufficed to fill up the inequality."

The operation has been required for necrosis following direct violence to the part. These are comparatively rare cases. Textor operated for this cause on July 31, 1834. The patient, a boy aged 7½ years, fell on his great trochanter. Within a few weeks a swelling and abscess formed, and on opening this the trochanter and part of the neck of the bone were found to be denuded. The incision already made being enlarged, a fracture through the cervix was found; and although the bones appeared to be necrosed below the lesser trochanter, the saw was applied above that process, in order to preserve the muscular attachments. Suppuration, bedsores, and gangrene ensued, and the patient died on the twenty-third day after the operation.

On May 1, 1865, I operated upon A. A., aged 6, for abscess and necrosis of the head of the thigh-bone. In February, 1863, when returning home from school, he was knocked down by a man running against him, and was trodden upon and kicked. Some few weeks passed before any particular notice was taken, when he complained of so much pain, and became so lame, that his parents took him to Guy's Hospital, where he became an in-patient, and attended off and on until February, 1865, when he was discharged as incurable.

He was brought to me, and admitted into Charing-cross Hospital on March 21. He was then suffering from symptoms

of advanced hip disease. There was an abscess near the trochanter, which had burst. He complained greatly of pain in the knee, especially when the limb was moved or shaken. His hauds were employed in steadying the limb, and he was very much emaciated, and very weak and feverish. I tried what rest, constitutional treatment, and extension of the limb would effect, but he gradually became so much worse that it was evident that he would sink if not relieved. Accordingly I made an incision four inches long over the trochanter, and a second at right angles towards the nates. When I opened the capsular ligament a quantity of matter escaped, and upon examining the part I found the neck of the femur rough, and the head of the femur broken into some six wedge-like fragments resembling the quarters of an orange more than anything else, entirely denuded of cartilage, and in a state of necrosis, lying loose in the acetabulum. I removed the neck of the bone, or rather its remains, by the bone-nippers; and having extracted the fragments of the head from the acetabulum, a further examination showed that cavity to be healthy. It was therefore left intact. He did not get on so quickly as some do, but eight months after the operation he was able to walk about the ward with the assistance of a small chair, which he pushed before him, and which I infinitely prefer for young children to the use of crutches. The child has done well since then. He has recently been under my charge again for an affection of the spine, and a small ulcer in the cicatrix; but he is very active indeed. The difficulty is to keep him quiet; and he now walks and runs about with the aid of a high-heeled boot, without requiring crutch, stick, or any other artificial support.

In a case related by Mr. Holmes in the *Lancet* of 1864, a small sequestrum, about the size of half an almond, was found embedded in the lower aspect of the neck of the bone.

In another case Mr. Holmes observes—"The operation was somewhat tedious in consequence of a rather odd mistake which I fell into. There was a large carious pit in the neck of the femur, surrounded by soft tissue; and on getting my finger into this I at first took it for the edge of the acetabulum, and spent a short time in vainly endeavouring to open it."

In a third case, wherein the hip-joint disease appeared to follow immediately upon an attack of scarlet fever, the neck of the bone was found separated by ulceration from the head. This separation had taken place about half an inch above the root of the great trochanter. There was a portion of the neck lying loose in the cavity of the joint; and the epiphysis of the head was separated from the shaft at the epiphysial line, and was lying loose and necrosed in the acetabulum.

In a case related by Dr. Donald Macgregor, of Glasgow, wherein discharge had gone on for several months, accompanied by hectic fever, prostration, and great emaciation, in cutting through the femur below the great trochanter the saw passed through a large abscess in the cancellated structure of the bone. The acetabulum was healthy; and the youth, aged 17, recovered.

Mr. Bowman, also, in the case of a girl 6 years of age, found the head and neck of the femur necrosed and loose, embedded in an excavation in the inner surface of the trochanter major. The acetabulum had partially disappeared. Mr. Bowman removed the fragment, and the child got well; and I find some twenty or more additional cases recorded, in which at the time of operation the head of the femur was found spontaneously separated from the rest of the bone.

Mr. Gant, who has met with great success in the performance of this operation (having had six consecutive cases, five followed by complete recovery, and one at present doing well), relates the following very interesting cases:—

A sailor, aged 26, when on board ship four years previously, fell from the masthead, a distance of thirty feet, upon his left hip. This was followed by severe pain and swelling, which were relieved by cupping, but he was not afterwards able to walk on that limb. A year afterwards he was sent to the Dover Hospital, where he remained for nearly three years; and during his residence there a series of abscesses formed about the joint, and discharged freely, but no dead bone ever came away. On March 28, 1864, he came under Mr. Gant's care; and on May 7 following Mr. Gant excised the head, neck, great trochanter, and one inch of the shaft—altogether four inches. On July 27 the wound was nearly healed. The patient was able to get about on crutches, and had become fat and cheerful.

In another case, that of a dairyman, aged 16, Mr. Gant removed five inches and a half of the femur, including the head, neck, and great trochanter. The patient recovered completely, becoming from a living skeleton a fat and healthy individual.

This, I believe, is the largest quantity of the femur which has ever been removed for disease of the hip-joint, the next in extent being the first by Sir Wm. Fergusson, in which he removed the head, neck, great trochanter, etc.—in all about four inches and a half.

(To be continued.)

ON THE VARIETIES OF FEVER WHICH FOLLOW SURGICAL OPERATIONS.(a)

By T. SPENCER WELLS, F.R.C.S.,
Surgeon to the Queen's Household and to the Samaritan Hospital.

LECTURE II.

GENTLEMEN,—In the last lecture (see *Medical Times and Gazette*, January 27) I related three remarkable cases where high temperature and other signs of fever were clearly due to inflammation and suppuration of ovarian cysts, or to decomposition of the fluid contents of these cysts, where the fever subsided almost immediately after the removal of the cysts, and the patients completely recovered. In all those cases the fever was of the type now commonly termed *pyæmic*. Lately we have had a typical example of what may be termed *uræmic* fever. The case was a very interesting one. A girl in her 16th year was sent to me by Dr. Wardell, of Tunbridge Wells, on account of an abdominal tumour. She was a fat, florid girl, and apparently in robust health; but her abdomen began to enlarge when she was about 12 years old, and went on increasing, not attracting any particular notice till May or June, 1871, when she was seized with some pain on the right side. This lasted only a few hours, and was followed by swelling, also on the right side, which disappeared after some days' rest, the general enlargement remaining. Dr. Wardell first wrote to me about her in October, 1871. A month later he wrote that the tumour was enlarging, and she was admitted here early in December. On December 15 the girth at the umbilical level was 35 inches, distance from sternum to pubes 15 inches, and from one ilium to the other, across the front of the abdomen, 15½ inches. Fluctuation was distinct all over the lower part of the abdomen, and the movement of a cyst was distinctly visible between the umbilicus and sternum—rising and sinking with the respiratory movements—the upper border of the cyst being about half-way between the sternum and the umbilicus. On both sides of the abdomen the sound was dull on percussion; so it was from below the pubes to within two inches of the umbilicus. From thence to the upper border of the cyst in the centre it was resonant or tympanitic, and on pressure with the fingers the peculiar gurgling and contraction of intestine could be felt. It was quite clear, therefore, that we had intestine adhering in front to the upper part of the cyst. Both loins and flanks were clear on percussion, the right more distinctly so than the left. The uterus was normal in size and situation. On the right side of the vagina a soft fluctuating tumour (the lower part of the cyst) could be felt just above the brim of the pelvis. The catamenia appeared when she was 14, and continued regular for four months, then ceased for four months, and since then have been regular, but rather excessive, lasting a week. There was some irritability of bladder. Very unfortunately, owing to a mistake, the urine was not examined.

The girl was kept in Hospital, and on January 23, 1872, the girth had increased to thirty-seven inches, and each of the other measurements showed an increase of about an inch. The presence of intestine in front of the cyst led to the suspicion of hydronephrosis; but the resonance of both loins, and the fact that the cyst could be felt by the vagina on the right side, almost negatived this suspicion, and it appeared more probable that we had to deal with a multilocular ovarian cyst, to which intestine adhered in front. I made an exploratory incision on January 24, and at once came upon the cæcum, its appendix, and the ascending colon, which had been pushed upwards and across the median line by the cyst, which was behind it. I saw at once I had to deal with a hydronephrosis; so, pushing aside the intestine, I tapped the cyst. Twelve pints of fluid escaped through the canula, and I then found that the uterus and both ovaries were healthy. A small cyst in each broad ligament I felt, but did not disturb. When the cyst was empty I fixed the opening in its

(a) Delivered on Wednesday, March 6, 1872.

wall to the abdominal wall by a harelip-pin, and then closed the wound by sutures.

The fluid removed from the cyst was clear, light yellow in colour, with a faint urinous odour, acid reaction, and specific gravity of 1006. On standing, a few flocculent clouds formed, and some red blood-corpuscles were deposited. On careful chemical examination, urea, urates, and chlorides were found in about the normal proportions of healthy urine. There were traces of uric acid. A very small amount of albumen and phosphates were detected, but no traces of sugar. On microscopic examination of the deposit, large numbers of red blood-corpuscles were seen, a few pus cells, some squamous epithelial cells, and granular cells, but neither tube-casts nor crystals.

Now comes the interesting part of the case in relation to fever. At two o'clock, half an hour before the operation, the temperature was about a degree *below* the normal standard— 97.4° . A good deal of pain followed the operation, and thirty-five minims of laudanum were given (twenty by rectum and fifteen by mouth), and a quarter of a grain of morphia was injected under the skin. In three hours the temperature had risen to 100.2° and the pulse to 104; in three hours more to 101.8° and the pulse to 140. After three hours more the thermometer marked 102.4° —a rise of 5° in ten hours, after simply opening the abdomen and emptying a cyst. I have removed many large ovarian tumours, after separating adhesions, tying bleeding vessels, cutting away omentum, securing the pedicle, and freely sponging the peritoneal cavity, without anything like such a rapid elevation of the temperature of the body.

Early on the morning after operation I found that the girl had passed a very restless night, but that she had slept at times, and only ten minims more laudanum had been given. The temperature at 3 a.m. was 101.8° , at 7 a.m. 100.6° , and at 9.30 99.8° ; the pulse being 116. The urine was pale and scanty, and examining it for the first time I found it loaded with albumen. She seemed better till the afternoon; then there was more pain, and fifteen drops of laudanum were given, the last opiate which was required. At 2 p.m. the temperature was 100.8° , at six it had risen to 102.6° , and at ten it was still 102.6° ; the pulse 136. She was lethargic unless roused, and fluid was evidently again distending the cyst; so I removed the silk which closed the opening in the abdominal wall around the pin which kept the opening in the cyst from sinking inwards, and inserted a glass tube. Three pints of urinous fluid at once escaped, resembling that removed at the operation. At midnight the temperature was 102.2° .

At four in the morning of the second day the temperature was 103° . At nine it was 104.2° , and the pulse was 140. There was a very free discharge through the glass tube—between two and three pints in twelve hours—and there was much less albumen in the urine. At 12 and at 4 p.m. the temperature was 104° , pulse 160. At six she was comatose and very restless; urine very scanty and albuminous; temperature 103.6° , pulse 128. Then I bled her from the arm to nine ounces, and sent the blood to Dr. Richardson. He told me afterwards that the specific gravity of the serum was normal, the clot and corpuscles also normal, that there was no excess of fibrine—in fact, nothing to distinguish it from perfectly healthy blood. At seven the temperature was 103.2° , and at eight 102.6° ; but at ten it reached 105.2° , and at midnight 105.4° , the pulse being fully 140. Free discharge continued through the glass tube. The head was placed on a pillow of iced water, and the body was sponged every three hours.

During the third day the state of uræmic fever and coma continued; the discharge was free, and the urine scanty and albuminous. The temperature, which had fallen in the morning to 103.6° , rose in the afternoon to 108.4° , and by ten at night to 110° . She lived through the night and up till noon of the fourth day after the operation, when she died; the temperature for several hours before death exceeding 111° . The thermometer used is only graduated up to 110° , but there is a space above fully equal to two degrees, and that was quite filled up by the mercury.

Surely this rise of temperature is quite wonderful. The girl weighed about 120 pounds, and we know pretty nearly how much water and fat that would represent. We also know how much heat is required to raise a pound of water one degree or ten degrees in temperature. Suppose this girl's body before the operation represented eighty pounds of water at 97° , and when she died the same amount at 111° —an average of about 103° or 104° having been maintained for four days—it would not be very difficult to calculate the amount of coal which would have been consumed in the production of this temperature, providing no cooling process had been going on. But here

natural and artificial cooling was kept up. The slow combustion of the constituents of the body under the influence of the oxygen introduced is constantly producing heat. The quantity of heat which a full-grown man gives off in half an hour would be sufficient to raise the temperature of his body nearly three degrees of Fahrenheit. If no heat were given off, his temperature would rise continuously in each hour between five and six degrees. The maintenance of the constant normal temperature of our bodies at between 98° and 99° depends upon the amount of heat produced by combustion and the amount given off by cooling processes being nearly equal. This girl's cooling processes were going on, and they were assisted by the application of ice to the head and sponging the body with cold water. The loss of heat must have been very great, and yet the temperature of the body kept rising. The production of heat must therefore have greatly exceeded the normal production. The tissues of the body must have been oxygenated or burnt up at an extraordinary rate, even supposing the cooling processes—the secretion of sweat, evaporation from the skin, secretion of urine, lung ventilation, bronchial elimination, etc.—were not as effective as usual.

Two very puzzling questions follow:—First, how did the operation check the elimination of urea in this girl, and lead to its presence in excess in her blood, or to the ammonia resulting from the decomposition of urea? and secondly, how does uræmia lead to fever heat or hyperpyrexia?

The first question is a difficult one. The post-mortem examination showed that the left kidney was almost useless—it was so small and so changed that it could scarcely have acted at all; and the right kidney was in great part converted into a cyst which held twelve pints of fluid. Why no symptoms of uræmia showed themselves before this cyst was emptied, why they came on almost immediately afterwards, and why they continued (although a free drainage of urinous fluid was kept up from the cyst) I cannot explain. It would be easily understood if the operation had led to any check in this secretion from the right kidney—the left kidney being useless—but there was no such check; and we are led to the suspicion that the opium which was given to relieve the pain, or possibly the chloro-methyl by which the anæsthesia was kept up, may have been the cause of the first stoppage in the elimination of urea, or else that some injury to the nerves of the kidney may have been the first step in the fever process.

Then, we ask, Why or how does the accumulation of urea or of ammonia in the blood lead to a rise in the temperature of the body?—and to explain this we are driven to the consideration of the influence of the nervous system upon the production and regulation of heat. Experimental researches upon the effects of removal of the brain or of the spinal cord, or of portions of one or both, show that the oxidation of the tissues and the evolution of carbonic acid—the regulation of the production of heat—are under the control of the nervous system. The arrangements for the regulation of the cooling processes depend more upon simple physical relations. In cold air or cold water more heat is given off, but as soon as the surface of the skin is cooled, evaporation is checked, the flow of blood to the skin is checked, and so is the secretion of sweat. In hot air the skin is moist, and evaporation rapid; thus high atmospheric temperatures become tolerable through free secretion from the sweat-glands and active evaporation.

A patient whose brain and spinal cord are supplied with blood charged either with urea, or with ammonia the product of the decomposition of urea, may be more or less in the condition of an animal whose brain has been removed. The regulation of the production of heat is lost; combustion goes on unchecked, and we may expect fever heat if the cooling processes do not keep pace with the excessive oxidation. If these cooling processes are also checked, of course the elevation of temperature will be more rapid and excessive.

APHASIA.—One man suddenly lost his voice three months previously, which he ascribed to a fit of anger and some unpleasant family matters. He recovered. Another appeared with slight paralysis of the right side, a third slightly affected on both sides, and a fourth with no paralysis. After recovering from typhus fever three years ago, and while engaged in settling up some accounts, into which an error had crept, the writer suddenly lost his power of uttering Chinese. His English was not affected. After perfect repose for two hours, the power of articulating Chinese returned.—*Report of the Peking Hospital, by Dr. John Dudgeon.*

ORIGINAL COMMUNICATIONS.

ON THE
AFFINITIES AND EVOLUTIONS
(CONVERGENT AND DIVERGENT)
OF THE
SUBCLAVIUS AND OMO-HYOID MUSCLES.

By J. BESWICK-PERRIN,

Demonstrator of Anatomy at King's College, London.

THE simple and average arrangement of the subclavius and omo-hyoid muscles would scarcely lead anyone to infer that there was a close affinity between them. It is from those eccentric and restless manifestations, not unfrequently met with in the human subject, which exhibit progressive grades from the simple condition described as average to that of a dual status of both muscles, that the kinship is evident.

The average subclavius is an unpretending muscle, simply stretching between the first rib and the collar-bone, partly filling up the subclavicular space. It plays its part in the economy of the body as an accessory depressor of the point of the shoulder. Many instances have been recorded by anatomists in which this muscle made a step beyond its usual clavicular limit on to the neighbouring pinnacle of bone—the coracoid process of the scapula. The stride is a simple one—important morphologically, useless functionally. This scapular attachment is the minor grade of parallel fission, which attains its ultimatum in the dual muscle, or so-called double subclavius. Intermediate between these *plus* and *minus* grades there are many stages met with. In the simple coracoid attachment there is rarely any connexion with the omo-hyoid muscle. But in all the specimens of double subclavius which I have met with, the additional muscle has been closely associated by its outer extremity with the scapular attachment of the omo-hyoid.

Specimen 1.—The subclavius apparently presented its normal arrangement. On sectioning and removing the middle third of the clavicle, I noticed a second muscle lying parallel to it. It was attached proximally by a long slender tendon to the cartilage of the first rib, closely associated with the tendon of origin of the average subclavius. As the tendon passed outwards, a distinct and increasing muscular belly was developed upon it, which terminated at the upper border of the scapula, where it joined with the posterior factor of the omo-hyoid, occupying an internal position to it. It attained to a corresponding width to the latter muscle.

The omo-hyoid presented its usual arrangement with the above exception, and an incomplete or transitional central tendon. Relatively this leads us but a short way towards a conception of the true signification of this additional subclavius; but in the same subject, and on the same side, there was an accessionary muscle, a quarter of an inch wide, which afforded the requisite information. It arose fleshy from the inner border of the first rib, close to its cartilage, being associated with the fibres of the additional subclavius. From this origin the muscle passed almost vertically upwards, approximating in its course to the thyro-hyoid, running parallel with the outer border of the latter muscle. It finally terminated in the upper and outer angle of the left ala of the thyroid cartilage, having the thyro-hyoid internal to it, and the anterior belly of the omo-hyoid in front of it. It was fleshy, and maintained an equal breadth throughout its whole extent.

The sterno-thyroid was average. At first sight this appears to be an additional sterno-thyroid; but it is not. I think the explanation of this is easy enough. The additional subclavius is the posterior belly, and this costo-thyroid muscle is the anterior belly, the two constituting an additional omo-hyoid muscle, whose central tendon is absorbed by an abutment on to the first rib. In confirmation of this view I met with, in another muscular male subject, on the right side only, a peculiar additional omo-hyoid. The average muscle presented its usual arrangement, except that it had the transitional central tendon. The second one arose by a narrow but distinct tendon from the upper border of the scapula, close to the supra-scapular notch, and slightly from its ligament, immediately adjacent to the average muscular scapular belly. The tendon crossed in front of the latter, and at an inch distance from its origin terminated in a muscle which ran internal and parallel with the average omo-hyoid. Beneath the sterno-cleido-mastoid it

spread out into a broad muscular sheet of fibres, in front of the common carotid artery and internal jugular vein, and was finally inserted into the middle third of the outer border of the sterno-thyroid. (a)

This is a very instructive specimen, and, *plus* a rib attachment, would simulate the first described specimen.

The third specimen occurred in a moderately muscular female, on the left side only. The omo-hyoid was single and average. The additional subclavius was present as above described, joining fleshy the posterior belly of the omo-hyoid about an inch from its scapular attachment.

The fourth specimen had a similar arrangement, and was found on the left side only in a male subject.

The fifth specimen is perhaps more interesting from a metamorphic point of view. It arose from the upper border of the clavicle, immediately internal to the anterior border of the trapezium, as a narrow fleshy band. This arched over the rest of the posterior triangular space, behind the platysma, over the clavicular and sternal factors of the sterno-cleido-mastoid, and, making a sudden bend downwards, terminated in a sub-fascial musculo-tendinous band of fibres in front of the manubrium sterni. This is merely a further aborted degradation of the anterior belly of the more complete muscle described.

The sixth specimen occurred in a muscular male on the right side only. It is the most peculiar muscle in the series. It arose from the upper border of the clavicle, external to the clavicular factor of the sterno-cleido-mastoid, as a small muscular belly, three-quarters of an inch long and two lines in width. A second belly arose, also from the upper surface of the clavicle, a little longer than the preceding, and situated between the clavicular attachments of the deltoid and trapezius. Between the two bellies was a short (half an inch) and free tendon. I found this muscle some time ago, but I had no idea of its relative value. I simply looked upon it as a curious specimen of a vagrant and rare specimen of a supra-clavicular muscle. But the omo-hyoid arose entirely from the clavicle, directly opposite the median tendon of this muscle, and this led me to observe more closely the attitude of the omo-hyoid in all the subjects which afterwards came under my notice. I have found many specimens of a dual distal attachment of the omo-hyoid—namely, to the clavicle as well as to the scapula. Some of these specimens have been noticed by Professors Turner, Wood, Macalister, and others. All these specimens indicate transitional stages of one, of two, omo-hyoid muscles. These seem to be undoubtedly abortive. Even the single average muscle evinces unmistakable signs of desertion from the scapula to the clavicle as a proximal nidus, and further of culminating into a more useful monogastric muscle, rather than an incomprehensible digastric one. (b)

ON LEPROSY.

By GEORGE GASKOIN, M.R.C.S.

As a London Practitioner moderately versed in dermatology I must confess at present no further acquaintance with the scheme drawn up for the Indian Government by Drs. Tilbury Fox and Farquair beyond what I find in your leader of February 10. I beg leave to contribute these few remarks to those set forth in that paper. Bateman has stated that leprosy (that is, elephantiasis Græcorum) was extensively prevalent in Europe during the middle ages, and especially subsequent to the Crusades. As far as my reading goes this seems exactly correct, though there may be some hesitation as to the latter point. Strong proof, I think, may be shown that leprosy was abundant before the date of the Crusades, and especially in the South of France. I think I remember there is even some small mention of it in the pages of Miss Strickland. When conversing on this subject with a contemporary *littérateur* who is supposed to have extensive or special knowledge on such subjects—M. Francisque Michel—this gentleman remarked to me that “so far from leprosy coming from the East, he could show proof that it was towards the East that patients in time past were directed for their cure.” The syllogism is imperfect. For my own part I can believe there was a recrudescence following on these wars in Egypt and Syria with the Saracens.

(a) On the same side of the body the subclavian artery gave off the posterior scapular from its third part, and the supra-scapular arose from the first part of the axillary.

(b) I have not attempted to quote from work done by others in this direction. This is merely a preliminary paper. In a future one probably I may embody some extensive, but at the present time incomplete, comparative researches on this subject, [as well as the observations of modern observers.

What is certain is that the intimacy and connexion between the races was sufficiently close, and the sojourn in these countries was long enough, for the diathesis to be acquired. The first Crusade was preached at Clermont, in Auvergne, and it is a matter of history that a large portion of the inhabitants, both peasantry and gentry, embarked in this wild and foolish expedition. A complete history of these people has fortunately survived in the interest which attaches to the Montgolfier family as paper-makers, aeronauts, and Protestants well known to fame. A large mass or group of these Auvergnats were swept into captivity and planted as a colony at Damascus, where they were taught or acquired some of the industries of the East. After a time, released from captivity, they returned to their province in France, and fixed at Clermont the art of paper manufacture, where it long remained—until the expulsion, in fact, of the Montgolfiers on account of religious opinion. By them it was carried into Holland. It is sufficient to have opened up this line of inquiry, without pursuing it further. The Auvergnats are of the lowest type of Frenchmen; but as to the amount of leprosy among them, and the share this disease may have had in their degradation, further details are desirable.

The observations of Dr. Farquair on the faulty character of rice and cereals in India appear to me of the highest possible amount of interest. I believe I am fairly interpreting the Medical mind of Italy when I say that, after long conjecture and debate, pellagra, an allied disease, is commonly referred, and by an assent almost universal, to the innutritious character of the maize-corn, a principal article of food among the Italian peasantry. To the physiologist some nice points remain; but, as far as the legislator is concerned, the consideration of leprosy would seem to merge into a larger question—that of food-supply and the physical well-being of the people. With fish it will be the same as with grain—it varies much in nutritious quality. Fevers in our fishing villages we know to be severe. But some kinds of fish may fairly rank with meat in respect to nutritive power. It is reckoned so abroad when used in the diet of soldiers. I cannot here refrain from quoting a living Portuguese Physician who has had remarkable experience in leprosy. Dr. Silva Beirão, in confuting the idea of fish producing the disease, instances certain monastic orders in Portugal who abstain from flesh religiously and altogether, but use fish as a principal article of food, “and yet,” he says, “they do not suffer from leprosy as those of the lower classes.” The reason of this is plain. The fish they eat is Newfoundland cod for the most part—a great mainstay of existence in Portugal, not less nutritious than meat. The disease of leprosy in some shape or form is so universal among underfed races that one may be excused from regarding it as the effect of so general a cause as innutrition. Its hereditary character, rather than the dread of contagion, seems to have led to the separation of the affected; and if attention were drawn to a higher scale of dietary in our colonies abroad, as has been the case in our madhouses at home, the result might prove advantageous as regards its prevention and cure.

SCROTAL ELEPHANTIASIS.

By J. FAYRER, M.D., C.S.I.,
Hon. Physician to the Queen.

AULAD A., a Mohammedan, said to be 41, but seemingly very much older, a resident of Moorshedabad, was admitted into the Medical College Hospital on October 2, 1871, with a scrotal tumour of great size.

He was a small man: height, 5 feet 1 inch; girth of chest, 32 inches; body moderately well-nourished, but his appearance was suggestive of fatty degeneration and of advanced age; his hair and beard were perfectly white; he had lost all his teeth; and his face, body, and limbs were covered with large patches of leucoderma. The tumour of the scrotum was similarly affected. His heart-sounds were normal, but rather feeble; his pulse steady, but wanting in force; his weight, 15 st. 8 lbs., or 218 lbs. He says the tumour commenced about twelve years ago with hydrocele, and that he has been subject to frequent recurrences of elephantoid fever, during each of which the tumour increased in size and became painful; but it is only during the last two years that it has attained its present great dimensions. Its measurements were as follows:—Round the neck, 17 inches; horizontal circumference, 51 inches; vertical circumference, from a line drawn round

the neck of tumour behind to a corresponding point in front, 61 inches; distance of meatus urinarius from symphysis pubis, 16 inches. When standing the tumour reached within two inches and a half from the ground. The legs were widely separated by the growth, which protruded backwards between them to a great extent. His general health was, on the whole, fair, his spirits good, and his anxiety to have the encumbrance removed great. He was most urgent in his solicitations for relief, and expressed his willingness to undergo the operation at whatever risk.

In order to improve his health and prepare him by good food and tonics, the operation was deferred until November 20. Early on that morning the tumour was suspended by pulleys, and ice applied, with the view of emptying it of blood as much as possible. At 9 a.m. the operation was performed in the usual way. The penis was exposed by laying open the sinus at the bottom of which it lay. A few sweeps of the knife, during which the hæmorrhage from large venous sinuses was excessive, sufficed to release it. The testes were then exposed by long and deep incisions. The left testicle was surrounded by an enormous hydrocele, the right by a comparatively small one. They were exposed and disengaged from the surrounding mass without loss of time and with little difficulty, but the hæmorrhage was severe. A few bold strokes with a large scalpel completed the removal, and the mass fell heavily on the floor. During the operation it had been raised or depressed, as circumstances required, by the pulleys and a canvas sling on which it rested. The vessels, which were very large and numerous, were then tied.

He became very low on the table, but rallied under the influence of stimulants, sinapisms, warmth, and the magnetic current, and was removed to the ward. He remained low; the pulse at times rising and then falling again. Reaction never perfectly set in, and he died at about 11 p.m.—fourteen hours after the operation. The operation was certainly a very formidable one, and in effecting it I received most able assistance from my colleague, Professor Cutcliffe.

There was no hæmorrhage after the operation, but the shock to the nervous system was more than he could bear. He was most carefully tended, stimulants were given, and warmth applied, but to little purpose. His bowels acted freely during the day. He took nourishment, but remained in a state of only semi-consciousness, opening his eyes when spoken to, but not speaking. His pulse gradually failed, and death occurred as I have before stated.

His weight after the operation was 108 lbs., that before it 218 lbs., so that 110 lbs. was the actual weight removed. The solid fibrous mass, after all fluid had drained away, was over 28 lbs. in weight. The weight removed was two pounds more than that which remained. Larger tumours have been removed with success, but I do not know that more than half of a man's weight has ever before been removed by a Surgical operation. I believe that, had his general condition been more vigorous, he would have done well.

The post-mortem examination was made at 9 a.m. of November 22. The body was that of a small, slightly made old man; the hair perfectly blanched; the teeth all gone. The body, head, face, limbs, and the tumour itself were mottled with patches of leucoderma. He was moderately well nourished and tending to obesity. The chest and abdomen were laid open. The lungs were healthy, but slightly emphysematous and hypostatically congested; the pericardium contained a quantity of serum. The heart was small, had some fat deposited externally, and was friable, being easily torn; it looked fatty; there were small fibrinous coagula in both ventricles. The liver, spleen, and kidneys were smaller than natural, and seemed to be fatty. The muscles generally looked feeble, pale, and flabby. There was a considerable layer of subcutaneous fat; the tissues generally seemed to be in a state of adipose degeneration. The arteries were healthy; the aorta was remarkably good. About the wound there was nothing peculiar. The testes were apparently healthy, though small; the cords were elongated and hypertrophied, with much gelatinous matter in their substance. The remains of the left tunica vaginalis were much thickened; it had contained an enormous amount of fluid. The right tunica vaginalis was also somewhat thickened, and had contained a certain amount of fluid. The mouths of many large vessels were apparent on the wounded surface. Dr. T. R. Lewis, Staff Assistant-Surgeon H.M.S., who was present at the operation, has most kindly made a microscopical examination of the organs as well as of the tumour. I append his report as follows:—

“Liver: The hepatic cells were no longer recognisable as

such. Their usual granular appearance had entirely disappeared, minute molecules of fat alone being seen. It was with difficulty that a tolerably normal cell could be picked out. Kidney: The cortical portion extremely fatty, and the lining epithelium of the tubules had degenerated into what appeared to be mere globular accumulations of oil molecules. Heart: The fibres had undergone extensive fatty degeneration; in fully one-half of the fibrillæ the transverse striæ had disappeared, or become so granular as scarcely to be visible. Muscle: The fragment forwarded (of the pectoralis major) appears to be healthy. Vessels: So far as I have hitherto been able judge, the two samples present a normal appearance; but as yet they are scarcely sufficiently cleared up by the glycerine to be able to pronounce more definitely. Should subsequent observation show that they are diseased, I will let you know."

Minute Structure of the Scrotal Tumour.

(Drawn by Dr. T. R. LEWIS, H.M.S.)

FIG. 1.

FIG. 1.—Microscopic appearance presented by a fragment after prolonged immersion in glycerine, showing areolar tissue (chiefly) in an hypertrophied condition. Magnified 300 times.

FIG. 2.

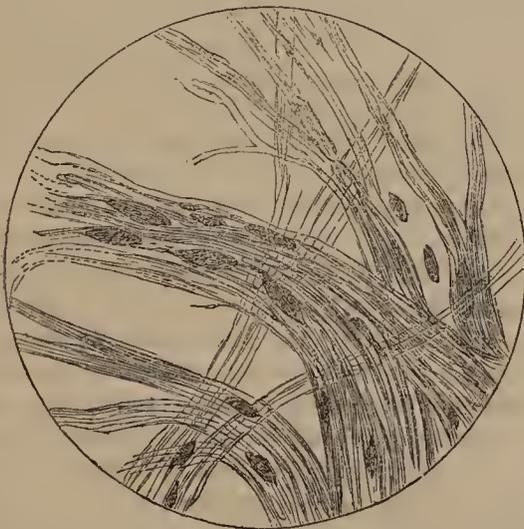

FIG. 2.—Appearance of another fragment stained in a solution of aniline and glycerine, dilute acetic acid being subsequently added. In the midst of the fibrous tissue the more or less transversely cut fibres of non-striated muscle are seen. Magnified 500 times.

The operation was performed in the presence of Dr. J. Campbell Brown, C.B., Inspector-General; Professors Chevers, Chuckabutty, and Cutcliffe; Drs. Lewis and Dobson, of H.M.'s British Medical Service; and others.
Calcutta.

THE engineer of the Lambeth Waterworks states that the Lambeth Company is carrying out works for forming a new intake from the Thames above Hampton, by which the water from the river Mole, objectionable during floods, will in future be avoided. It is expected that the works will be completed and opened in September next.

MEDICINE AND SURGERY.

BIRMINGHAM GENERAL HOSPITAL.

CASE OF RHEUMATIC PERICARDITIS AND PLEURITIS; A CASE OF DOUBLE PLEURISY: EACH WITH VERY SLIGHT RHEUMATIC DEVELOPMENT—MENTAL DERANGEMENT IN CHOREA.

(Under the care of Dr. RUSSELL.)

THE following two cases form a supplement to six cases I published in this journal (1870, vol. iv., p. 644) in illustration of the varying relation which subsists in different cases of acute rheumatism between the pyrexia, the inflammation of the joints, and the visceral inflammations which constitute a less constant factor in the disease. A similar case appeared from the pen of Mr. Gray, of Oxford, at page 40 of the next volume.

The cases need no comment. The combination of pericarditis with pleurisy in the first case indicates with much probability that the visceral inflammation had its origin in blood disease, even were there not other evidence to the same effect. The pleurisy in the second case being double, bears testimony of the like character. The first case, however, has a separate interest in relation to the development of chorea which it records, and particularly to the severe mental disorder which twice occurred. I would draw attention, likewise, to the light thrown upon the rheumatic element in my patient's family, and upon the presence of cardiac disease in her own person long after she had passed from under my notice on the occasion of her first attack. During that attack all information in this direction was of a negative kind. The bearing of this observation upon the presence of a cardiac bruit in cases of chorea and upon possible inheritance of rheumatic proclivities, will be at once obvious.

Case 1.—C. H. was first admitted on September 23, 1868. She was then 12 years old, and was suffering from a mild attack of bilateral chorea of three weeks' duration. The outbreak of chorea was preceded by headache, and was accompanied by painful swelling of the feet, attributed to a wetting. She was discharged cured in five weeks. It was affirmed that rheumatism was entirely absent from the family history; she herself had never had rheumatism other than the slight development just described. A slight prolongation of the first cardiac sound, which it was impossible to localise, was heard repeatedly, but entirely disappeared before her discharge; and six weeks afterwards the sounds of her heart were pure, and she was stout and fresh-coloured. Eighteen months subsequently (May, 1870) she returned, with renewal of the chorea of a month's duration. She looked delicate and pale, but the sounds of her heart were pure. Again she had a threatening eighteen months after, in last December. Nutrition had continued to decline; she had become very anæmic, and had not menstruated for four months. On this occasion I found a loud diastolic aortic bruit, with some effusion of fluid in the right pleural cavity. Shortly before this time her brother had been admitted into the Hospital, with symptoms of cardiac disease and a mitral bruit. The threatened chorea did not then take place, but two months afterwards her mother came to me to complain of her daughter's mental state. I then learned that nine months ago she had run away to London without money, to see the Queen married, as she said; she came back without a ticket, and was brought home by the railway officials. She continued strange for three months, going out in her night-clothes, putting on her father's dress, and getting the family into trouble by her tricks. She subsequently improved, but three weeks since she again disappeared for two days and nights, and was found in the privy of her own house, footsore and covered with mud, but unable to give an account of herself. She affirmed that she was to be married, and that the wedding-ring had been purchased. She came into the Hospital soon after (on March 13), with decided choreic development, which in three days assumed great violence, but with few traces of her mental disorder. Under the influence of chloral, continued every six and then every four hours, the movement yielded, and after the 20th rapidly subsided. On admission she had slight rheumatic inflammation in the knees, which speedily subsided. There was some fluid in the left pleura, and a slight pericardial rub. By the third day after

admission the pleuritic effusion had rapidly increased, and fluid was poured into the pericardium, reaching by the following day as high as the second rib, and crossing the sternum; the pleuritic effusion also filled the greater part of the left chest. From this date, however, recovery was rapidly effected, clearness being re-established over the pericardium and over the chest, except at the base, in two days. The improvement coincided with diminution in the severity of the chorea. The temperature in the axilla never rose above 101.6°, and only attained that elevation three times, on each occasion falling in the night to the normal line again to rise. The severity of the choreic symptoms prevented any special treatment for the visceral disease, excepting the administration of iodide of iron, with small doses of iodide of potassium. Fortunately the patient continued to take food freely throughout.

Case 2.—H. A., aged 15, had suffered from two attacks of acute rheumatism. He was admitted on March 20 with slight rheumatic inflammation in the right knee and elbow, and a threatening in the other joints. The joint affection speedily subsided, the muscles of the back, however, remaining stiff for a day or two. He was not brought under my notice until the 23rd, when I found effusion in each pleura to the middle of the dorsal region; the heart sounds were pure; the joint affection had receded. Removal of the fluid was effected as speedily as in the last case, for on the 25th the base only retained any degree of dulness. Thenceforward recovery was satisfactory. The temperature on admission was 102°; it retained this elevation for the next three evenings, falling in the morning to 100° to 99°, and at last to 98°; it then remained within normal range.

SATURDAY, APRIL 27, 1872.

DWELLINGS FOR THE WORKING CLASSES.

WHEN Lord Derby opened the new Hospital at Bootle a short time ago, he made of the occasion an opportunity for insisting on the necessity of educating the poor to appreciate and accept sanitary measures, pointing out that, without such education, sanitary legislation must be of little or no effect, for people cannot be made cleanly, or temperate, or moral, or lovers of pure air by law. We need not say that we fully agree with his lordship in taking the term "education" in its broadest,

fullest sense, and not as meaning merely instruction: we have frequently tried to enforce the same views in our own pages. And we would once more insist that the first and most paramount means of this desired education is a due provision of decent healthy dwellings. Of course we are not believers in the planting-out-in-the-clear theory, or in the wildly impracticable idea of making every man or every head of a family the owner of a cottage and a bit of land. Our demands, and those of sanitarians in general, are much more humble and much more practicable. We are content to ask that it shall be possible for the poor to obtain in cities and towns rooms in which human beings can live in decency and cleanliness if they wish it, and not be forced, even when earning fair wages, to herd together in dens in which a country squire would utterly refuse to kennel his dogs. The frightful overcrowding in our cities and towns, and even our villages, is one of the most crying evils of the day, and one fraught with the most disastrous results to the physical, moral, and intellectual health of the population. It would be the merest waste of time to place proofs of this before our readers. Every Medical Practitioner knows it but too well; our sanitary reports teem with proofs of it; our pages constantly contain illustrations of it. Only the other day we reported Professor Stokes's discourse on State Medicine, in which he speaks of the overcrowding and uncleanness of the poor in towns, "where poverty, neglect, and overcrowding so often make them foci of endemical disease," and of the deplorable social and physical condition of the poor in the country towns and villages. A short time ago, also, we quoted Professor Leone Levi's assertion that "the increase of drunkenness in Manchester during the last ten years was mainly due to overcrowding, that city being the most densely populated of the large towns"; and we believe that we may take it as universally admitted by all who have any real knowledge of the subject, that one of the chief causes of the vice of drunkenness, and all forms of brutality and vice, is the wretched state of the lower classes with regard to their dwellings. And this terrible source of evil, this overcrowding, is, alas! to be found everywhere—not only in the thickly populated parts, and overgrown and age-incrusted cities of the Old World, but from the New World also; and even from the young towns of our young colonies come the same cry, the same complaints of overcrowding, filth, vice, and disease. We cannot just now lay our hand on the sanitary reports from Melbourne to quote proofs of the existence of the evil there, but we may show how rampant it is in America. The valuable and admirably got-up reports of the Board of Health of the State and City of New York are full of it. In the "Report on Vital Statistics," which forms a part of the "Fourth Annual Report of the Metropolitan Board of Health of the State of New York," the evils caused by overcrowding are proved with a fulness and clearness that leave nothing to be desired, and are eloquently denounced; and the language of the New York reporter may be well and usefully borrowed, as depicting with equal truth the state of things here at home. Two forms of overcrowding are prevalent, the reporter observes, both of which are fatal. One pertains to the surface area, the other to the dwellings; bad as both forms are, the latter is much the more deadly of the two:—

"If the proximity of dwellings produces morbid mental and physical conditions, the proximity of families is still more demoralising and pernicious. The forced companionship of the old and young of both sexes, which may be seen in any of the more crowded tenement-houses, 'is not, nor can it come to, good.' . . . The want of accommodation for families arises from an increase of population without a corresponding increase in the number of dwelling-houses. This offers an inducement for the degradation of buildings that were intended and fitted out for a single family. Houses built for this purpose are let in floors; those intended to accommodate but one family on each floor are compelled to contain two; families who were once isolated find that they can save the rent by taking lodgers—and thus the process of agglomeration goes

on, until all the proprieties of life are violated, the pride of the family crushed, its sensibilities deadened. The people so housed huddle and herd together in a manner that may be described as far more bestial than human. . . . And this is one of the teachings of these statistics of the mortality of tenement-houses—namely, that overcrowding of the ground-space by dwellings, and overcrowding of dwellings by inhabitants, are the greatest social and sanitary evils against which the Board of Health has to make war. Other sanitary evils are limited in their operations, and affect but a few—they are local in their effects; these are general, and their effects are to be seen not only in the present, but they reach far into the future. The subject is one of vital interest, for the stability of the State, in the last analysis, depends on the purity of the home. In many of the houses whose vital statistics are the subject of this report a home is an impossibility. 'Home is the sacred refuge of our life;' but there is no such refuge in these crowded tenement-houses. The very instinct of domesticity, of privacy, of homelikeness would be crushed in anyone who would even make an effort to dwell in such untold filth and degradation. To children born and reared under such influences it is inevitable infamy. Life is too short to allow them to escape from the debauchery into which they are baptised at birth; and moral elevation, or an improved social standing, can rarely come to any family so environed and so housed. But when these dwellings are improved in their sanitary condition, the dwellers are also improved in a social aspect, and the physical view of the hygienist becomes at last the spiritual view of the philanthropist."

Take this quotation as a description of the overcrowding in our own cities, and of its disastrous and certain consequences, and who will say that the language is in any degree exaggerated, or the picture one whit overcharged? And is not the danger to the national healthy life from this condition of things greater with us than in the wider-spaced, far less fully peopled New World, and the difficulty of individual escape from its brutalising effects increased even to hopelessness? The facts of the matter are universally known and admitted; the inevitable consequences, if they are allowed to persist, are not disputed. Is anything being attempted to even lessen present evil, and to avert worse disasters in the future? Sanitary science can do, and even with its present imperfect help from the law does do, much to improve existing dwellings and lessen some of the dangers arising from them; but sanitary science cannot supply increased and ever-increasing accommodation—and this is *the* great need.

Something has been done, and more is being done, by private efforts. The Peabody Buildings, the Coutts Buildings, and the erections of "The Improved Industrial Dwellings Company" are an immense boon to those who are fortunate enough to obtain lodgings in them, and leave nothing to be desired in the way of healthy, cheerful homes. The Peabody and the Coutts Buildings must ever be looked at with all gratitude and praise as grand results of munificent and large-hearted philanthropy; but the work of Sir Sidney Waterlow and Mr. Allen, by means of the Improved Industrial Dwellings Company, must excite, we think, still greater interest and admiration as having proved that excellent homes, replete with all the improved sanitary arrangements, can be provided for the working classes at a profit. The Company has never paid less than 5 per cent. on its invested capital, and its dwellings are in constant demand. But, admirable as are these efforts to meet the dire want of which we are treating, they are utterly insufficient; they do little more, though this is a great deal, than show what can be and ought to be done. The want and its attendant evils are of gigantic, of imperial proportions, and demand the action of the Legislature. What has Parliament done in the matter? We were going to say it has done nothing; but that would be sadly untrue. It has done nothing to prevent or to remedy overcrowding, but it has done very much to cause and to intensify it. Parliament has not been slow to grant powers for the making of metropolitan improvements, by which thousands of the homes of the working classes have been swept away; but whenever it has been asked to require that at least

some new dwellings shall be erected in place of those ruthlessly destroyed, the narrow, poor knowledge and the unwisdom of the mere political economist have been used to denounce and reject the appeal; and consequently nearly every "metropolitan improvement" has increased the overcrowding, wretchedness, and disease in the dwellings of the poor. But we are delighted to see that a public body has at last determined on making an effort to prevent the poorer part of the population of the metropolis from being improved away. The Metropolitan Board of Works has, by a very large majority, resolved to introduce into the Improvement Bill of the Board now before Parliament a clause empowering the sale or letting of certain sites along the line of alterations, on the condition that industrial dwellings shall be built on them. It is stated that the works of the Board will turn 1457 persons out of their homes, and that the sites selected to be set aside for industrial dwellings will accommodate 3452 persons. We regard this as by far the greatest improvement ever attempted by the Board, and earnestly trust they may carry their clause through Parliament. There has never been the least difficulty in getting tenants, and good tenants, for well-constructed and healthy dwellings; but it has been most difficult to get dwellings for the tenants, while there are large cleared spaces in the City and at the East-end, on which healthy homes might be built, which would be occupied almost as rapidly as they could be opened. We fear that the huge evil of overcrowding and the dire want of healthy homes for the poor will never be fully met and grappled with till we have a Government of great statesmen instead of mere politicians, or till the subject is made a national demand or a party cry; but meanwhile the resolution of the Board of Works is a most hopeful sign, and is full of promise of some larger measure of relief than has ever yet been attempted.

THE CORONER'S COURT AND THE CAUSE OF DEATH.

COMPLAINTS are being constantly made, particularly in country districts, of imperfect and unsatisfactory inquests. It is frequently the case that the Coroner dispenses with Medical testimony, when such testimony is the only evidence on which a jury could arrive at an accurate knowledge of the cause of death and return their verdict accordingly. Competently conducted, and with a jury of ordinary intelligence, the Coroner's Court is a valuable institution; but it may be the reverse of these, and then it is likely to shield the wrong-doer and frustrate the ends of justice. Though not having reference directly to these remarks, but as an instance of how complicated and unsatisfactory an inquest may be, we may call attention to one held at Lincoln the week before last. The facts may be briefly stated. The subject of inquiry was a child 19 months of age, who, whilst on a visit to a village near Lincoln, was taken ill and vomited. This was attributed to the fact that the child had been eating plum cake and fried bacon. It came out, however, during the inquiry that a man who was employed at the house where the deceased child was taken ill had dropped from his coat pocket some white "stuff," which the man said was "mercury," and hoped the child had not touched it. This "stuff" was, no doubt, arsenic, as it will be proved in the sequel. The child was removed to its home at Lincoln, where Mr. Redman, a Surgeon, was summoned to attend it. As the parents refused to allow Mr. Redman to lance the child's gums, that gentleman declined to continue his attendance; another Medical Practitioner was sent for, but the child died before his arrival. Mr. Redman having been informed that the child might possibly have taken a poisonous quantity of mercury, ordered it to have white of egg and flour-and-water. He did not communicate his opinion of the nature of the disease to the parents. The child died in convulsions, having screamed a good deal before death. The Coroner was applied to to hold an inquest, but being informed that the Surgeon had

declined to give a certificate of death, in consequence of the parents refusing to act on his advice, he (the Coroner) declined to hold an inquiry. A certificate was afterwards brought to the Coroner, on its way to a burial club, and this document ran as follows:—"Primary cause of death was irritant poison; secondary cause, convulsions." Under these circumstances, an inquest was called, and a post-mortem examination ordered to be made. At the inquest the foregoing facts were elicited, and Dr. G. M. Lowe, who examined the body, deposed as follows:—

"The body was that of a fine healthy child, without any mark of violence on the surface, with the exception of a rosy rash on the thighs and arms. On examining the body I found the lungs were emphysematous, and the right side of the heart was engorged with black clotted blood. The œsophagus was removed and examined. The mucous membrane was found to be white, and not congested. The stomach was removed entire and preserved. The mucous membrane and the whole of the intestines were remarkably white, and free from any congestion. The mesenteric glands were greatly enlarged and matted together in a mass. The intestines were covered with a light-coloured fluid. The brain was perfectly healthy. I think, in all probability, the immediate cause of death was convulsions, on account of the state of the heart and lungs. As regards the cause of the convulsions, it may be an open question, as the child was cutting its teeth. If there had been any irritant poison taken, I should have expected to have found the stomach congested. There was no immediate evidence of poison, and there was quite sufficient in the state of the child to account for death. To the Foreman: I have not had time to analyse the contents of the stomach."

Mr. Redman fully concurred with Dr. Lowe's evidence, but would prefer having an analysis made of the contents of the stomach. The Coroner said he thought "that there was sufficient proof that the child had died from convulsions, and there was a sufficient cause for the same other than from poison"; still, if the jury wished it, he would adjourn the inquiry, in order that an analysis of the contents of the stomach might be made. The inquest was adjourned accordingly, and the contents of the stomach having been analysed, at the second meeting of the Court Dr. Lowe gave the following somewhat startling evidence:—"That arsenious acid was present in large quantities, both in the stomach and intestines." In summing up, the Coroner said the child might very possibly have died from an overloaded stomach, or from teething, or from cold from being taken out on such a day; but there was now no doubt that it died from arsenical poisoning. Verdict, "Accidental poisoning."

Now, this case is most instructive and suggestive. Had it not have been that the Burial Board insisted on a certificate being given them before the sum for which the child was assured was paid, no inquest would have been held. Having been held, and evidence given to show that the child died a natural death, the inquiry would have been abortive had not Mr. Redman requested that an analysis of the contents of the stomach should be made. But why was this analysis not made before? The summons Dr. Lowe received was no doubt an ordinary one, and directed that the "contents of the stomach should be analysed." Dr. Lowe's excuse was no answer to this requisition, and, as it was proved, his evidence was worse than useless without the analysis. The Coroner's suggestion after the poison had been detected was neither ingenious nor happy; it would have been far better had he acknowledged that the inquest had *fortunately* been complete, and the cause of death arrived at, rather than speculated upon what the child might have succumbed to.

We may gather from the facts disclosed by this inquiry how important it is that if an inquest is held it should be a searching and complete one. Cases will at once suggest themselves to the reader in which wilful poisoning, as well as accidental poisoning, may escape detection when the inquiry is incomplete. Rather let us have no inquest at all than one calculated to mislead, to shield the guilty, and be the fosterer of crime. If the Coroner's Court is to maintain a respectable

position as a court of inquiry, inquests must be conducted in a very different manner to what they are in some parts of the country. Medical evidence must not be suppressed or ignored. If a more satisfactory system cannot be carried out, then it is high time the "crown's quest" should be superseded by a more searching, more impartial, and, consequently, more satisfactory tribunal.

THE WEEK.

TOPICS OF THE DAY.

THE recent proceedings at the Royal Orthopædic Hospital can hardly be allowed to pass into oblivion. The charges publicly made against a gentleman, who has hitherto occupied a prominent position in the Medical Profession, are not of a character that they can be quietly forgotten. If the Profession of Medicine is to continue a body in any corporate sense, and especially if it is to continue a Profession for gentlemen, it must have a code of ethics which it cannot permit its leading members to infringe. It is, then, for the interest of the whole Profession that the recent proceedings at the Royal Orthopædic Hospital should be investigated and pronounced upon by some public body. Unfortunately, it seems that the Council of the Royal College of Surgeons—the body which of all others should be most anxious to uphold the standard of Professional honour and Professional morals, especially amongst its own Fellows—will not, or cannot, entertain the matter. We do not know whether it is beyond their legal powers; but as they have lately shown a disposition to stretch their legal powers to the utmost limit in other directions, it seems a pity that they should not assume the existence of a little more elasticity where the honour of certain of their Fellows, and indirectly of the whole Profession, is so deeply implicated. Several other bodies have been mentioned as affording suitable Courts of Appeal. These are the General Medical Council, the Royal Medical and Chirurgical Society, and the Medical Teachers' Association. It is for the sake of all parties—accused and accusers—that we urge the necessity of a public Professional inquiry. We repeat that it is not merely in the interests of Mr. Brodhurst or of Messrs. Tamplin and Adams, but of the staff of every Hospital in the kingdom and of every Medical man holding a public appointment, that we ask for an investigation. We have received two letters on the subject. One from Mr. Tamplin, in which, in answer to Mr. Brodhurst's statement, published in this journal of April 13—that, "prior to most of the annual and special courts, an active canvass for new governors has taken place"—he states that "he has been connected with the Royal Orthopædic Hospital from its foundation—thirty-four years since—and that he is not aware that such a practice has ever been followed." He concludes his letter thus: "It is to be regretted that Mr. Brodhurst himself voted, on the occasion of the annual court, in favour of the report of the Committee, containing a censure upon Mr. Adams and myself, and which compelled us to tender our resignations." The other letter, also in answer to Mr. Brodhurst's letter, is from Lord Abinger. We regret that its length prevents our publishing the whole of it; but the following extract will suffice to support our assertion that, in Mr. Brodhurst's own interests, the whole matter demands a full inquiry:—

"His (Mr. Brodhurst's) first statement is inaccurate. I never was in a small minority on the Committee of Management. I resigned the chairmanship for a reason quite unconnected with the case of the Surgeons, and a deputation, headed by a relative of Mr. Brodhurst's, requested me to reconsider my determination. To Mr. Brodhurst's second statement a stronger word should be applied. He says that 'prior to most of the courts of the Royal Orthopædic Hospital an active canvass for new governors has taken place.' I have inspected the last subscription-book of the Hospital from its commencement in September, 1859—a period of nearly thirteen years—and I do not find the slightest indication of any active canvass,

or of any canvass whatever; the largest number of male governors at £1 ls. entitled to vote has never exceeded six during the month previous to the date at which the annual court has been held, the average number being from three to four. Mr. Brodhurst's next statement is that at the special court his friends made votes for him. This I have no doubt is true; but the question turns on his having manufactured votes at the annual court, and not at the special court. It was at the annual court that the condemnation was passed on his senior officers, and it was at that court that every vote was made by Mr. Brodhurst, or with his knowledge, amounting in number to thirty-two, at which packed meeting the censure on the two senior Surgeons was carried; and I ask Mr. Brodhurst to deny it if he can that he voted himself for that censure, and by the action of his feet betrayed a most demonstrative satisfaction when the result of the vote was announced from the chair."

The authorities of Glasgow are fortunate enough to possess a Medical Staff of the Sanitary Department of the Board of Police, presided over by Professor Gairdner as chief Medical Officer. The services which this staff of Medical men has rendered the city it is not easy to over-estimate. We will only mention the comparative immunity of Glasgow from cholera in 1866, when Liverpool, Hull, and Leith, and many other seaports, were severely visited, as an illustration of the debt which Glasgow owes to its sanitary administrators. The Committee of the Board of Police, we are now told, have recommended that the present Medical staff be superseded by a sanitary Medical officer, who shall be precluded from engaging in private practice, and who shall be paid £600 per annum, being £140 less than the salaries of the present staff, which amount to £740. If there were any positive advantages to be gained by discarding a tried and efficient body of public officers, we should hold that the public good has paramount claims. But any advantages are hypothetical, and the whole proposal has too much the aspect of a miserable short-sighted economy to recommend it. The Glasgow authorities will certainly find that a studied disparagement of past Medical services is not likely to conduce to future efficiency; and if they discard their present staff with cholera threatening our shores, they may regret before long that they have staked the health of their community on an uncertain venture.

We would call especial attention to the paper on the probabilities of a cholera visitation in the present year, by Mr. Netten Radcliffe, read before the Association of Medical Officers of Health, which we publish in another column. Mr. Radcliffe—who has the best claim to be heard on this matter (for it is in no small degree to his exertions that the immunity of last year can be traced)—tells us that there is no ground for excessive anxiety, if only local authorities can be induced to take precautionary measures in anticipation of the evil. The possibility of their not doing so he as clearly admits. That the law is inefficient which should enforce precautions is also undoubted; yet, as Sir C. Adderley told the House of Commons on Wednesday, the Government go on postponing week after week, and day after day, all attempt to have their Bill made into a really useful law. The Ballot Bill takes the place of the health of the people, and cholera may sweep away its thousands whilst our legislators are squabbling whether Brown shall see Jones's name on a voting paper. Meanwhile, we have not settled what we are to do with the excreta of our towns, which most of us believe to be one channel through which the poison of cholera is especially conveyed. We thought we had done the right thing when we put some check on its being allowed to pollute our rivers, and had proved that its natural destiny was the soil. But now we are told by such an authority as Dr. Letheby that sewage farms on the irrigation principle are apt to become stinking morasses, and to spread dysentery and typhoid far and near. If this be true, it follows that, if the sewage be allowed to pollute the water-supply, cholera will attack us; if it be poured on the earth we shall have to encounter typhoid and dysentery. Mr. Radcliffe speaks hope-

fully, and relies upon the powers given by the Sanitary Act of 1866 and on Orders of Council. These may check to a certain extent the introduction and dissemination of cholera; but we must recollect, as he has reminded us, there is such a thing as "regional diffusion," and that cholera may burst out at different foci without apparent migration.

PROCEEDINGS OF THE ROYAL COLLEGE OF SURGEONS.

The following is an abstract of the unconfirmed minutes of the quarterly Council on the 15th inst. :—

The report of the Jacksonian Committee was read, and the Council approved of the subject proposed by the Committee for the Jacksonian Prize for the year 1873—viz., "Ununited Fractures"—and no award having been made for the Jacksonian Prize for the past year, the dividends were directed to be invested and added to the principal of the fund.

The usual honoraria for their lectures were voted to Professors Wilson and Flower.

The Council resolved, on application from Dr. Wadham, Dean of St. George's Hospital Medical School, to recognise the Dental Department of St. George's Hospital under paragraph 10 of the Regulations relating to the Diploma in Dental Surgery.

The following motion by Mr. Erichsen, seconded by Mr. Hilton, was carried, viz. :—"That a report be prepared by the Court of Examiners and presented to the Council at its meeting in May next, of the number of candidates who have been rejected at the respective 'Primary' and 'Pass' Examinations for the Membership during each of the three Collegiate years from July, 1868, to July, 1871, stating the number who have been rejected and who have passed from each school; and that till the Council otherwise direct a similar report be presented to the Council each year at its quarterly meeting in July."

Moved by Mr. Gay, seconded by Mr. Simon, "That the report referred to in the foregoing resolution be for publication;" and the votes of the Council having been taken on the motion, a majority was against the same.

Mr. Robert Marshall Allen, of Brackley, Northamptonshire, Surgeon 3rd Dragoon Guards, was admitted a Fellow of the College, his diploma of Membership having date June 26, 1810.

The President appointed Monday, May 15, as the date of the ordinary meeting of Council in that month.

THE VENTNOR CONSUMPTION HOSPITAL.

The biennial dinner in aid of the funds of this institution was held at Willis's Rooms on the evening of Monday, the 22nd inst.; the Bishop of Winchester in the chair. A large company of ladies and gentlemen sat down, and in the course of the evening subscriptions to the amount of £2500 were announced. Moreover, a friend of the charity had promised to build one of the remaining blocks or cottages if another would undertake to build the last. The challenge was taken up by Mr. Leaf; so that the Hospital will now be completed on the original plan. We would beg leave to direct the attention of our Medical brethren to this Hospital: as a winter residence for consumptives it is in the best spot in England. Moreover, it is intended for a class not altogether destitute, but who can afford a small weekly payment to the funds of the institution.

SEA-WATER IN LONDON.

It is difficult to overrate the value and importance of a constant supply of sea-water to London, particularly when it can be obtained at a low price. We are happy to state that there is now a Bill before Parliament, virtually unopposed, which will empower a company to bring the water from the sea at Brighton to the West-end of London, where a constant supply will be delivered. The company is restricted to very moderate prices, so that the water will be within the reach of most Londoners.

SURGICAL SOCIETY OF IRELAND.

THE closing meeting for the session of 1871-72 was held in the Albert Hall of the Royal College of Surgeons, Ireland, on Friday evening, April 19. A numerous gathering of the members assembled on the occasion. Several communications of interest were made, including a paper by Dr. B. Francis McDowell on Laryngo-Tracheotomy; one by Mr. H. G. Croly on Reduction of Dislocation of the Head of the Femur on the Dorsum Ilii by Colombat's Method—the so-called "osteostreptic manipulation"; and a report of a case in which Pyæmia ensued after Self-mutilation, occurring in the practice of Mr. Richardson. The President, Dr. Wharton, also delivered a valedictory address, in which he reviewed the labours of the Society during the past session. He paid a feeling tribute to the memory of his late colleague Robert St. John Mayne, who a few months back had fallen a victim, at an early age, to the prevailing epidemic of small-pox. After thanking the Society for the honour they had conferred upon him in electing him as President, Dr. Wharton declared the session closed.

CONVERSAZIONE AT STEEVENS'S HOSPITAL, DUBLIN.

A VERY pleasant *réunion* took place on the evening of Saturday, April 20, within the walls of this venerable institution. The occasion was that of the annual distribution of prizes at the close of the winter session. The leading members of the Profession, the *ex officio* governors of the Hospital, and a large number of eminent men received invitations, and many were present to partake of the hospitality of the Medical Committee, who were the hosts for the evening. Many experiments in electricity and chemistry were performed under the direction of Dr. Cameron, and several very beautiful microscopical specimens were shown by Drs. Robert McDonnell and Bookey. The Cusack Medals were awarded to the following pupils of the school connected with the Hospital:—Messrs. Leonard H. Kellett and R. McVittie; while certificates of honour were granted to the most distinguished and industrious members of the clinical and school class.

MR. ROBERTSON GLADSTONE AND HABITUAL DRUNKARDS.

A VERY practical result has followed Mr. Robertson Gladstone's recent proceedings in relation to drunkards. It will be remembered that Mr. Gladstone, who is a town councillor and magistrate for Liverpool, determined to publish the names of those who were locked up for drunkenness on the Saturday night, but who were for the most part discharged before Monday morning upon the responsibility of the inspector on duty, and who did not therefore appear before the magistrates, and thus escaped publicity. It is now found that many of such are actually in the receipt of outdoor relief as paupers. It is needless to add that the ratepayers have since benefited by the removal of all such names from the list of recipients of such assistance.

ARMY SURGEONS.

IN the last number of the *Army and Navy Gazette* some sensible remarks are made on recruiting the Medical Service of the Army. We quite agree with our contemporary, and trust that the authorities of the War Office will, before it is too late, open their eyes to the real position of the question. What really seems to be urgent is not so much to facilitate the retirement of Surgeons of twenty years' standing, as to hold out an inducement to the best men from the different Hospitals and Schools to enter the service, by furthering the position of its members. This may be effected, as is proposed for the combatant branches of the army, by the prospect of rank, by an increase of emoluments, and by the promise of honorary distinctions now so sparingly bestowed. At present, the inducements for the higher class of Medical students to prepare for a military

career are but very small, and none but those with a love for the military service think of entering the army in preference to undertaking civil practice.

SMALL-POX JOTTINGS.

THERE were twenty-four cases of small-pox in the workhouse Hospital at Sheffield last week, which was a decrease of three as compared with the week before. The returns for the same period for the borough show eleven fatal cases of small-pox—a lower number than has been returned in any week since the middle of October last. Six of these were stated to be unvaccinated cases, while the others were not stated as to vaccination. —In Poplar, last week, twelve deaths from the disease were reported, and eleven new cases brought under notice. In the same period thirty-seven persons were vaccinated at the public stations. There were at that time fifteen small-pox patients in the Infirmary, North-street, under treatment.—It was reported to the Metropolitan Asylums Board, on Saturday, that in the Hospitals under their control there was a continued diminution of small-pox cases.—Fourteen fresh cases of the disease were reported last week at Wakefield, and there were eight cases in the workhouse Hospital.—Small-pox is at present prevalent at Bombay. Monday's *Bolton Chronicle* states that the order for the Duke of Lancaster's Own Yeomanry to assemble at Lancaster on May 10, for permanent duty, is cancelled in consequence of a serious outbreak of small-pox at Lancaster.—Forty-eight fatal cases of small-pox were reported last week in the metropolis; in the two previous weeks they had been sixty-five and forty-nine.—In the Holborn district during the past fortnight three fresh pauper and five other fresh cases of small-pox were reported; three of these occurred in registered lodging-houses. They were all slight cases, after vaccination.—Eight fresh cases of the disease occurred in the past fortnight in the Whitechapel district, and two deaths.—Dr. Aldis reports two cases, last week, in the district of St. George, Hanover-square, which were sent to the Hospital.

SICKNESS AMONG PAUPERS.

FROM a return just issued, relating to the Medical poor relief it appears that taking the total number of paupers in receipt of relief on the same day—December 18, 1869—as 998,964, the proportion of sick to the whole number was 15.34 per cent., or between one-sixth and one-seventh of the whole. The proportion varied much in the indoor and outdoor paupers, the former being 29.5 per cent., and the latter 12.7 per cent., or about one-third and one-eighth respectively.

WOMEN-STUDENTS IN EDINBURGH.

THE *Scotsman* understands that the managers of the Royal Public Dispensary, Edinburgh, have granted three of the women Medical students permission to make arrangements with the Medical Officers of the institution for instruction.

FROM ABROAD.—DR. BOWDITCH ON INTEMPERANCE IN NEW ENGLAND.

THE question of intemperance has now become one of the most engrossing topics of the day, not only in this country, but in France; and the Legislatures of both countries have before them more or less coercive measures. That of France especially, coming fresh to the work, and not yet damped by previous disappointment, seems to entertain a sanguine expectation in the efficacy of severe penal enactments as a repressive agency that certainly will not be shared in this country. It is highly instructive to turn to an important paper from the pen of a veteran reformer, Dr. Bowditch, which, under the title of "Intemperance in New England: How shall we Treat it?" was read before the Boston Society for Medical Observation, and is published in the *Boston Journal* of March 21.

The idea of writing the paper suggested itself to him

while preparing "a chart illustrative of certain cosmic and social laws regulating the prevalence of intemperance over the globe," and the materials for which were derived from a correspondence carried on between the Massachusetts State Board of Health (published in their third report, just issued) and American Ministers and consuls in foreign countries and other persons of note. While preparing it, he obtained also some important information as to the operation of preventive legislation in Boston, and it is to facts of this latter kind he now chiefly draws attention. He observes that there are thousands of persons in New England who, while utterly abhorrent of intoxication, feel disinclined to assent to the doctrines of those who defend total abstinence from, or of those who defend a free sale of, intoxicating drinks, and are little satisfied with the results of the procedures of either party. Notwithstanding all efforts, drunkenness has increased, at least among the lower orders in large centres of business—the police of Boston declaring that there is a "steady increase of intemperance compared with the increase of population . . . it having increased in fourteen years 175 per cent. in spite of law." During the year when licences were issued there were fewer arrests for drunkenness than when complete prohibition was sought to be carried out.

While, however, intemperance has remained unchecked in its onward progress in Boston, "in the estimation of many a good effect has been produced in some of the smaller towns of the State, where the people have decided by vote that no liquors shall be sold. Such towns have occasionally become real asylums for the salvation of drunkards." In other medium-sized towns, however, in which the prohibitory law was in full operation, drink can be obtained at every corner, and drunkenness was never more rife. According to Dr. Bowditch's personal experience, drink can be obtained with every facility in Maine by all who wish for it.

"Surely," he says, "there never was a greater attempt of a whole people to hoodwink itself, as it were. Such promulgation of law, and at the same time such utter and open daily, and I might say hourly, contempt for it, tend to lower the political morality of each citizen consenting thereto, to corrupt the whole community, and, in fact, to bring all law into less repute among the masses of the people. Nothing, surely, can be more fatal to the best interests of a republic than such a state of things, however caused. . . . As we learn from Boston that when there was the least law there were least arrests for drunkenness, and when some relaxation of law allowed the use of milder liquors there was less intoxication than before, we have a right to ask whether similar results would not follow further relaxation, and whether the permission to sell light ales and beer and light wines would not, under certain very general rules, really be a promotion of temperance."

The following are the results of the investigations by Dr. Bowditch of the returns already alluded to:—

1. Stimulants of some kind are found to exist, and to be used at times to excess, in every quarter of the globe. An instinct so universal cannot be annihilated; and we can only curb it by reason or by law, if it transgress the bounds of social life.
2. Intemperance is very rare between the isothermal lines of 77° F. north, and south of the equatorial isothermal 82.4°. It gradually increases on going northward (and southward probably) between 77° north and south and 50° isothermal lines, which is the area of the natural growth of the grape-vine. It becomes very rife above 50°; and, moreover, it is of a coarser, more brutal character than in either of the two previously named areas.
3. Intemperance produces little or no crime at the equatorial area, rarely in the middle area; whereas it is the great provocative of crime above 50° F.
4. Race has immense influence on the prevalence of intemperance. For example, the English race has entailed on this nation the incubus of two centuries of drunkenness, inherited from one generation to another. England now overshadows Ceylon in the tropics, and Australia in the grape region, with these same habits, thus overriding all climatic law—at least for a time, till reason and conscience and wise laws can restrain it.
5. In Europe and in other grape-growing areas of the earth, mild wines are used freely from babyhood to old age, and they do not seem to produce a nation of drunkards.
6. Similar remarks may be made on lager beer and its effects.

7. On the contrary, ardent spirits dwarf intellectually, morally, and physically the nation that uses them to excess.
8. Hence we should not classify all liquors as equally prejudicial to man; on the contrary, admitting a human instinct, we should allow the reasonable and free use of some stimulants, and discourage others.
9. We should in this country cultivate everywhere the grape vine, and permit the use of lager beer. We should open our ports to a free trade in mild 'unfortified' European wines, doing everything we can to restrain the use of ardent spirits, and closing 'grog shops.'
10. Moral suasion and education as to the horrors of intemperance have been too much neglected of late, in our pursuit of law as a preventive of intemperance.
11. Inebriate asylums should be established for the reformation of dipsomaniacs; and repeated drunkenness should be punished as a crime.
12. The sellers of liquor to a known drunkard should be signally punished.
13. All adulterations of liquor should be punished signally and promptly, as a high crime against society.
14. It would be the greatest blessing to the community if, by large co-operative work, 'Holly Tree Coffee-houses' could be everywhere opened. These could be placed side by side with the 2000 grogshops that now disgrace our city. Our correspondence proves that a great gain for temperance would be the result of such a movement."

PARLIAMENTARY.—PUBLIC HEALTH IN RURAL PLACES BILL.

In the House of Commons on Wednesday, April 24,

Sir H. Selwyn-Ibbetson withdrew his Public Health in Rural Places Bill, and gave notice of some amendments which he intended to propose on the Government measure, enabling local committees in rural districts to take the initiative in sanitary matters, with the view of relieving Boards of Guardians, who had already too much to do, and of giving greater elasticity to the system.

In the course of a short debate that followed, Sir C. Adderley reflected strongly on the Government policy, inasmuch as after the whole course of procedure on the subject of the public health during the last three years, and the terms in which sanitary measures were referred to in her Majesty's speech, the Government postponed their measure week after week, and night after night, in order to proceed with a measure of infinitely inferior importance.

MORE NOTES ON WINE.

THE appearance in the *Times* of April 18 of an admirable article on the chemistry of wine prompts us to say a few words on the subject. It is no small indication of a change in the public taste and intelligence that the leading journal boldly makes the distinction between pure wine and adulterated, and unhesitatingly puts into the latter category much of that which passed as "wine" with our ancestors, and does so still with ladies of a certain age, country clergymen, and others whose brains and stomachs have long passed the stage when they seek for anything new. Wine (says the *Times*) should be the pure fermented juice of the grape, and if so should be of "moderate alcoholic strength." On the other hand, what passes for "wine" has often had its alcoholic strength almost doubled. Besides this (says the *Times*) it should be "distinctly acid in its character," from the presence of the acids of the fruit out of which it was made. On the other hand, much of the liquid which does duty for "wine" is boasted by its vendors as being "perfectly free from acidity," which pure wine never is. One of the commonest methods of depriving wine of its natural acidity is the use of gypsum, or sulphate of lime, which unites by double decomposition with the tartrate of potass naturally present in the wine, precipitating tartrate of lime, and leaving sulphate of potass in solution, which is bitterish and sickly, and if it does no great harm cannot do good. Acids in some shape, nevertheless, are universal articles of diet, demanded by the appetites and instincts of man, and sanctioned as medicines by the experience of Physicians. Our own belief is that men in good health, who take muscular exercise, and, above all, who perspire freely, are much the better for acids; and, with regard to many others, that the appetite for acids and power of taking them is an index to the state of general health. The only legitimate way of lessening the percentage of acid in wine is to keep it, and let the tartar

precipitate itself. We are glad to see that the *Times* critic dis- countenances all attempts to make, to imitate, or to tamper with wine by chemical processes. He shows that some wine merchants of Spain and Germany have characters to retrieve, and meanwhile draws attention to the markets of Hungary and Greece, "where wine is too plentiful to render adulteration profitable, and where the fermented juice of the grape may still be obtained in its purity, with the wholesome and pleasant subacid freshness of its youth, and with a capacity to develop fragrant ethers in its progress towards a glorious old age."

We say "Amen" to all this. Believing that the way to put down the stupefying use of spirits is the use of wine, we delight in the evidence which is given by the press, as well as by her Majesty's Customs, of the increasing importations. Mr. Shaw, who writes incessantly to the *Times* in favour of letting in the highly brandied wines of Spain and Portugal at a shilling duty, to compete with the purer wines of other countries, is obliged to confess that the tide goes against him. From 1856 to 1859 Spanish wine constituted about 40 per cent. of the total quantity imported; so it does still; but Portuguese, which from 1856 to 1859 formed 30 per cent., now forms barely 20 per cent. of the whole consumption, whilst the importation of French wine has risen from 8 to 27 per cent. Yet, when all is said, the total consumption per head of the population, which was one bottle and a half in 1856-59, was only three bottles in 1871. Wine, then, however slowly, is coming into greater use, and light wine is supplanting port and the "heavies."

The *Times* justly points to the wines of Hungary and Greece. The former have from their intrinsic merits obtained a high place in the Physician's dietetic list. Carlowitz is become almost as common as cod-liver oil in the treatment of the phthisical. And we now find that this is no new discovery. Five years ago, when we were writing on the subject, people wondered with a half-shudder at the notion of getting good wine from Carlowitz or Szamorodny; but lo! a little research shows that our ancestors knew all about them, although the art of prescribing them was like that of fresco or Venetian glass—a dropped art—till its modern revival, in which we claim to have had a share. Friedrich Hoffman, the great Professor of Medicine at Halle—the man from whom Cullen derived his inspiration—he who invented that *liquor anodynus mineralis*, which we call compound spirit of sulphuric ether, that boon to the asthmatic and hysterical—was quite as enthusiastic about Hungarian wines as we are.

Greek wines need not our pen to tell of their ancestry. The vines grow on a volcanic soil, which Mother Earth has, as it were, prepared as a fit cradle for them; they bask in the most glorious sunshine—in fact, come from a land where "only man is vile." Since their importation they have gained wonderfully in softness and refinement. The St. Elie is remarkable for developing that flavour which distinguishes the Amontillado sherry, and which the ablest chemists believe to depend on a production of aldehyde. The Keffesia, red and white, has more of the characters of Burgundy. A bottle of Noussa, which we have, as we write, unearthed from a cellar where it has been these three years, is a remarkably good wine—soft, subastringent, no predominant acidity, good flavour, clean taste—quite a wine for a gentleman. The Patras is lighter, and like hock. But of all these wines it must be said that they are full of vinous properties, acidity included; they are not thin and watery, but well calculated to excite the appetite; and he that can eat a salad may drink St. Elie. As with the Hungarians, so with these, we find a *catena* of authors from Homer down to Edmond About, who, by a series of "undesigned coincidences," have shown that the Grecian wines have had a constant succession of worshippers, though, like the Hungarians, their *cultus* had passed out of view till revived by the reduction of the wine duties. Sir Edward Barry, M.D., F.R.S., in his "Observations on Wines" (London, 1775), says of them—"As from their peculiar fine flavour they are not easily adulterated, they are seldom imported."

Amongst French wines, we may bring to our readers' notice a pale amber light Gauphine, the product of the viticultural skill of our *confrère*, Dr. D. Dulac, of La Gauphine, near Béziers, l'Hérault. Dr. Dulac is well known at the tables of many members of our Profession, who drink his marvellously cheap and invigorating red Gauphine. The white Gauphine ought to have great vogue amongst the middle-classes; and there is a higher, older quality of the red (*haute Gauphine*), which is not expensive, but very clean, hearty old wine.

Hungary, Greece, and France can boast an ancestry. But now we must plead for a country whose place on the map 200

years ago was a great blank, labelled *Terra Australis Incognita*. During the last ten years the three great Australian colonies have raised their production from 444,917 gallons (a) to 1,933,403 in 1870, and if they do but keep clear of the *oidium* and other scourges, will probably increase at the rate of 1,000,000 gallons *per annum*. Thus they will supply their own great and growing communities, and export largely, as we hope, to the mother country. Nay, more, there is India. We hope the day is not far distant when *Auldana* and *Bukkulla* will be handed round at Government House at Calcutta and Madras, instead of the hock and claret now sent round from Europe.

Of the Australian wines at present on sale in London we know three stocks: one is the *Tintara*, from South Australia, grown by our *confrère*, Dr. A. C. Kelly, and now sold by Mr. P. B. Burgoyne at The Tintara Office, 50, Old Broad-street, E.C. It is an economical wine, calculated to please those whose conversion from the "drugged ehalice" of port is not complete, and—as we said of it two years ago—is "robust and satisfying."

The next is the *Bukkulla*, red and white, which are amongst the many kinds of wine cultivated by Mr. John Wyndham, of Sydney, New South Wales. A Frenchman who visited us a short time ago pronounced the white *Bukkulla* simply perfect—a wine of exquisite finish; the red is a good stout, full-bodied, nutritious wine, and both (bottled in Australia) are to be had of Messrs. David Cohen, 19, St. Helen's-place, E.C.

Again, whoever has assisted at a wedding at St. George, Hanover-square, may remember a small street at the back, called Mill-street, once famous for an oyster-shop (in the days when oysters yet existed), and a place where the race of flunkies imbibed the spirituous whilst their betters were drinking in the spiritual. In that street is the *Auldana* office for the sale of the wines of Mr. Patriek Auld, from his vineyards in South Australia. Some of the white muscatel *Auldana* is truly superb, and in the fulness of its flavour reminds one of the old Dry Ruzster. The Red or Ruby *Auldana* is a very fine wine: well matured, generous, not like claret of which you should drink a bottle, but telling in a single glass; albeit a wise man will empty a bottle, if he has a friend to help him. We may say that all these Australian wines are at prices much below their merits.

The wise Physician is he who prescribes judicious change of air, water, place, occupation, food, and drink. Life is kept up by the conversion of matter; but matter, to be converted, must first be assimilated, and both palate and stomach require the stimulus of change to keep them vigorously at work. Hence, another wine, even of the same sort, may spur a flagging appetite, especially if rational curiosity adds its charms; and the Physician who is treating chronic disease, whose patient's appetite is worn out on one wine, may make his choice from the great variety—Greek, Hungarian, and Australian—which we have ventured to point out. Even the most bigoted old stomach, which looks askant on claret and hock as sour inventions of the enemy of souls and bodies, if it can be beguiled into one trial, will generally be tempted to go on, if the choice was a lucky one.

DR. LETHEBY'S ANNUAL REPORT FOR 1870-71.

Four subjects are saliently noticed in Dr. Letheby's report—(1) Census facts, (2) the mortality and sickness, (3) the water-supply, and (4) the record of sanitary work.

1. As to the Census—"In the year 1851 the population of the City of London rose to 129,171. This is the largest population of the City during the present century, and it is perhaps the densest on record, for it is in the proportion of nine persons to every house, or 180 persons to an acre. In 1861 the number of the population fell, according to the Registrar-General's Returns, to 112,063 persons, which is at the rate of 8.4 persons to each inhabited house, or 155 persons to an acre; and then, at the census of 1871, the number of the resident inhabitants in the City was returned at only 74,732, which is less than six-tenths of the population of 1851. It must not be forgotten, however, that the census of the City was taken at a time when the number of the population was at its very lowest; for at midnight on Sunday, in the early part of April, the City

(a) See Ridley's Wine Circular for April 12, 1872; also the Statistical Register of South Australia for 1870.

is to a very large extent deserted. . . . But in point of fact, the day population of the City cannot be less than a quarter of a million; for, to say nothing of the 509,611 persons who, at the day census of 1863, were found in the City as clients and customers, there were 170,133 merchants, shopmen, clerks, and others engaged in the City warehouses and shops. These, with the 74,732 who sleep in the City at night, make a total of 244,865 persons as the resident day population of the City."

2. As to the mortality, especially from small-pox—"The chief feature in the table of causes of death is the large mortality from small-pox—a mortality which has been only once exceeded since the year 1848. . . . The disease, at intervals of about every two years, acquires epidemic violence, and becomes alarmingly fatal, and then declines for a couple of years. Taking, for example, the two years successively, from 1849 to 1871, it will be seen that the number of deaths in each of the biennial periods is as follows:—50 in 1849-50, 137 in 1851-52, 24 in 1853-54, 91 in 1855-56, 20 in 1857-58, 107 in 1859-60, 8 in 1861-62, 66 in 1863-64, 37 in 1865-66, 49 in 1867-68, 5 in 1869-70, and 88 in 1871—the average annual mortality of the epidemic periods being 49, and of the alternating years only 12. This condition of things is not peculiar to the City, but is common to the whole metropolis, and to every large town in England, although the intervals of the epidemic are not in all cases the same. . . . It is also worthy of note that the proportion of cases in which vaccination had been performed has been steadily advancing during the last twenty years; for, according to the returns of the Small-pox Hospital, Upper Holloway, it appears that during the sixteen years which terminated with 1851, the average number of vaccinated cases was only 53 per cent. of all the patients admitted, whereas in the epidemic years of 1854, 1855, and 1856 it amounted to 71 per cent.; in 1859-60, it was 78 per cent.; in 1862-66, it was 81 per cent.; and in 1871, it was 91.5 per cent. These facts are suggestive of two things, namely:—1st, That vaccination is often imperfectly performed, and therefore fails of its prophylactic power; and 2nd, That even when it has been well performed in infancy, the effect of it is weakened by time."

3. As to the water-supply, it is well known that while some high authorities who watch the quality of the water with unceasing vigilance are apt to describe its condition in the darkest terms the facts permit, and to present to the public mind the totals of impurity in colossal figures, others treat the matter more calmly—they pooh-poo the twenty grains of chalk, or thereabouts, which all Thames water contains, and do not alarm themselves about moving organisms. Dr. Letheby is one of the latter school, and makes light of the turbidity caused by occasional floods:—"The turbidity has been at all times due to the presence of a very small quantity of finely divided clay in which there was occasionally a trace of vegetable tissue; and no doubt it had been caused by the heavy floods of the river. Although perfectly harmless, a slight turbidity of the water is sure to command attention, and may easily be made the subject of popular clamour."

4. Dr. Letheby is very emphatic on the necessity of a well-organised system of sanitary inspection and government for the port of London; and it is to be hoped that Mr. Stansfeld will put the nineteenth section of his Public Health Bill into good working order and get it passed. "At present, the small area of the port of London—extending from the Tower to the Temple—is the only part of the port which is systematically inspected in accordance with the thirty-second section of the Sanitary Act, 1866. This is manifestly an inconsistency; for, as I gather from a report by Mr. Harry Leach, the Resident Surgeon of the Seamen's Hospital, there are about 25,000 vessels entering the port of London yearly, besides about 2300 sailing barges, and nearly 4000 dumb barges, which belong to the Thames. These represent a floating population of about 15,000 persons, which are at present almost entirely without sanitary supervision; and that they require it is shown by the results of the inspections of vessels within the limited area of the City. . . . Fever and scurvy and epidemic diseases are very prevalent in the vessels which trade with this port, and are referable to defective sanitary arrangements. And not alone do they affect the floating population, for they are generally the means whereby certain forms of zymotic disease are imported into this country." There are thirteen nuisance authorities in the area of the port of London, besides the Conservators of the Thames and the Commissioners of Customs and Board of Trade. These should be reduced to one; and of all possible units, Dr. Letheby argues that the Conservators of the Thames would be the most efficient.

An account of the mortuaries established for the reception

of the dead of all classes, and of convictions for selling unsound meat, and other sanitary work, concludes Dr. Letheby's very practical and interesting report.

ON THE RELATIVE

POWERS OF VARIOUS SUBSTANCES IN PREVENTING THE APPEARANCE OF ANIMALCULES IN ORGANIC FLUIDS. (a)

By JOHN DOUGALL, M.D. Glasgow.

THREE series of experiments were made—one with vegetable, and two with animal matter—of which the following are a few of the more important details:—

Sixty-seven substances were selected for trial, consisting of irritant, narcotic, and narcotico-irritant poisons; also several others, whose sensible properties or alleged antiseptic powers recommended them as worthy of experiment. Nitrate of ammonium and spirits of nitric ether were added for contrast. Sulphite of soda, perchloride of iron, and one or two other such bodies were unintentionally omitted. To three drachms of a solution consisting of one part of the substance to be tested in 500 parts of water was added one drachm of a filtered infusion of hay, of the strength of half a drachm of dried hay to a fluid ounce. This mixture was put into a phial. Where the substance was volatile the phial was kept closed, otherwise it was left open.

The *modus operandi* with the animal substances was similar, the only difference being that human urine was substituted for infusion of hay in one set of experiments, and a mixture of beef-juice and egg-albumen in another; while only half a drachm of the latter mixture was added to three drachms and a half of the test solutions. Three blank experiments were first made—*i.e.*, three phials were filled respectively with water and infusion of hay, water and urine, and water with juice of flesh and egg-albumen only—in order that any contrast in the growth of animalculæ in the simple and supposed preventive solutions might be noted. All the phials, when filled, were placed in a medium temperature of about 60° Fahr., and exposed to a moderate light. In two to six days the microscopical examination of each series, with a magnifying power of 700 diameters, was begun and concluded. The simple solutions were found teeming with bacteria, vibriones, monads, amœbæ, torulæ, etc. The results of the examination of the various test-solutions were necessarily of two kinds—life or no life—the one or the other being inferred from the presence or absence of moving bodies only.

In those cases where motion was perceived, the phials were refilled with stronger solutions; conversely, weaker solutions were tried, and, after being allowed to stand as before, were again examined microscopically, and the process repeated till a point was gained where none, or only the faintest movement, was perceptible. Thus the strength of the solution was ascertained, and its preventive power noted—*i.e.*, the quantity of the foreign substance in the mixture in which no animalculæ were observed after the lapse of six clear days.

The substances used have been classified into fifteen groups, according to their chemical relations, placing the group that shows the highest average preventive power "first" on the table, and the one that shows the lowest "last." The various substances have also been tabulated in their respective groups on the same principle.

The Metallic Salts, from their showing the highest average preventive power, form *Group I.* Sulphate of copper here has not only the highest individual average, but its three preventive points, in the three solutions, are very much higher than those of any other substance in the group. Nitrate of silver, on the other hand, exhibits the lowest individual average. This is undoubtedly to be attributed to its peculiar property of being decomposed by the combined action of light and organic matter, and further, in the urinous solution, by the chlorides present.

In *Group II.*—the Organic Acids—"benzoic" has the highest, and "acetic" the lowest average preventive power. Of the seven members composing this group, carbolic acid occupies the fifth place.

Group III. Salts of the Alkaline Earths.—Here chloride of aluminium is "highest" (I do not refer, of course, to the commercial liquid chloralum, which, however, has been included), and a sulphurous-smelling fluid, said to be bisulphite of lime, "lowest." Were it not for the extremely high pre-

(a) Paper read before the Association of Medical Officers of Health.

ventive point (1 to 2000) of the chloride of aluminium in the hay column, this group would occupy a comparatively subordinate position.

The average of *Group VIII.*—Inorganic Alkaline Salts—would be “extremely low” were it not for that of the bichromate of potassium, which has the “very high” average of 1 to 900. The salts of soda and Condry’s fluid are all blank in the urine and albumen columns, except the borate of soda, which, however, has a merely nominal preventive power.

Group X. The Aromatic Oils—viz., oil of caraway, cassia, and peppermint—are inert in the urinous and albuminous solutions, but show good averages in hay.

Group XIII. Animal Substances.—Here the extract of cantharides shows three entire blanks, while the tincture of musk is blank in the urine and albumen columns.

Group XV. The Poisonous Vegetable Extracts—viz., extract of aconite, belladonna, Calabar bean, digitalis, lobelia, tobacco, and curara—show blanks in all the columns; which is not surprising, seeing that their aqueous solutions, *per se*, soon teem with life.

Premising that an infusion of hay is poorer in organic matter than urine, and that the latter fluid is less rich than albumen, it appears from the experiments that the germ-generating or developing force is strongest where the organic matter is richest, and weakest where the organic matter is poorest. Hence the “quantity” of the “preventive” substance requires to be proportioned to the “quality” of the “organic.” Many of the bodies experimented with merit special observation, but only a few can be noticed.

First, as to carbolic acid. If germs are the cause or even indicative of putrefaction, then this substance is a very mediocre antiseptic, being surpassed as a preventive by nearly thirty of the commonest bodies. Its toxic power on microscopic organisms is also considerably exceeded by even a greater number of the same bodies, and its vapour at ordinary temperatures under usual conditions has absolutely no effect in arresting putrefaction and the appearance of bacteria, vibriones, penicillium, etc. These results, whatever may be alleged to the contrary, I have disinterestedly, carefully, and repeatedly confirmed. It is remarkable in proof of the foregoing, that all well-known disinfectants, as sulphurous acid, nitrous acid, permanganate of potassium, bisulphite of lime, protosulphate of iron, chloride of zinc, chloride of aluminium, chlorine, bromine, and iodine decompose sulphuretted hydrogen, while carbolic acid does not. Chloride of lime, hard soap, chloralum, and common salt are low preventives. The hyposulphite, borate, and sulphate of soda are useless as such. Chlorate of potassium, so much used as a gargle in stomatitis, diphtheria, etc., where it is held to act by destroying certain fungi or germs of specific poison, has not only no preventive power, but actually accelerates decomposition. Caustic potash has the minimum of preventive power—1 to 10. Such a mixture is highly caustic; still it was necessary to use it of such strength, as at 1 to 25 bacteria and vibriones were abundant. At 1 to 10, though no life be present, nor, indeed, could possibly be, the mixture is nevertheless very putrid—an obvious proof that organisms are not the cause of putrefaction. *A strong solution of beef-juice may be made putrid almost instantly by adding caustic potash.* Bichromate of potassium stands very high.

Dr. A. Smith shows, in a table of experiments in his work on disinfectants, “to determinethe amount of each of fourteen of the most energetic antiseptic bodies necessary to prevent the evolution of sulphuretted hydrogen in a mixture of equal parts of blood and water,” that all of them, in from six to ten days, had evolved more or less of that gas except the one containing bichromate of potassium. It is strong proof of the decided and valuable antiseptic powers of this salt that the same result should be gained by two different observers using two different tests—*i.e.*, the evolution of sulphuretted hydrogen, and the appearance of animalculæ—and the one also being unaware of the results obtained by the other. Observing the low power of potash and the high power of bichrome, it seemed certain that the former weakened the power of the acid of the latter.

Chromic acid *per se* was therefore tried, and found to have a preventive power surpassing all the others, its average being 1 to 2200, while that of carbolic acid is only 1 to 266. These results were subsequently confirmed, though not so strikingly, by a number of comparative experiments with the two acids on fresh and putrid blood, muscle, pus, urine, and on faecal matter. The coagulating power of chromic acid in albuminous solutions has been compared with that of most metallic salts, acids, etc., and found to exceed them all—*e.g.*, it has about ten times the power of carbolic acid, fifteen times that of nitric

acid, twenty times that of bichloride of mercury, and 150 times that of chloralum.

The following arrangement exhibits, in juxtaposition, the antiseptic and disinfectant properties of chromic acid and carbolic acid:—

<i>Chromic Acid.</i>	<i>Carbolic Acid.</i>
Free from smell.	
Strong affinity for water.	Weak affinity for water.
Hardens animal matter.	Slightly volatile.
Combines with ammonia.	
Decomposes sulphuretted hydrogen.	
Oxidises organic matter.	
A powerful germicide.	A weak germicide.
A strong preventive of animalcules and fungi.	A moderate preventive of animalcules.
A powerful coagulator of albumen, gelatine, and mucus.	A strong coagulator of albumen.

LOSTORFER’S SYPHILITIC BLOOD-CELLS: PROFESSORS WEDL AND STRICKER; WAR IN SCIENTIFIC CIRCLES.

DR. LOSTORFER’S corpuscles seem to have become a standing article in the Medical Society of this town, having caused the formation of two parties violently opposed to each other. At the head of the one Professor Stricker has been placed, against his own inclination; whilst Professor Wedl has voluntarily undertaken the lead of the other. It will be remembered that in a recent meeting of the Medical Society Dr. Lostorfer came forward with the discovery of corpuscles peculiar to the blood of syphilitic patients, by means of which the diagnosis of syphilis may be made by the microscope. This discovery, if true, would have been of the utmost importance, giving a positive basis to the much-discussed question of the relation of microscopic growths to contagious and infectious diseases. Everybody was struck with the novelty of the discovery; and it cannot be said that those who have worked in the same direction as Lostorfer did have listened to Lostorfer’s lecture without feelings of jealousy. The first who stepped forward to oppose the new theory was Professor Wedl, whose work on pathology has been published by the New Sydenham Society. We are, however, sorry to say that this renowned worker came forward too hastily—neither sufficiently furnished with facts to oppose Lostorfer, nor even acquainted with Lostorfer’s investigation: nay, he had not even seen the corpuscles in question, but had them described by two of his disciples. Standing on such loose ground, he nevertheless denounced Lostorfer’s corpuscles to be nothing but fat-cells, which are squeezed out from the skin when the blood is drawn for microscopic investigation. He further urged that these corpuscles may be seen a few hours after the preparation is made, and particularly when water is added to the blood. To this Professor Stricker simply replied very clearly, that if a man of Professor Wedl’s renown assures us he has seen fat-cells, there can be no doubt that it was so; but in the present instance it evidences simply that Professor Wedl has seen fat-cells, and not Lostorfer’s corpuscles. Dr. Lostorfer has expressly stated—and we have communicated in this journal—that the corpuscles only after the fourth day assume such a size as to become visible under the microscope; that they disappear at once if water is added to the blood—so that an object is at once rendered useless if by some chance or accident water had been admixed with it. If, therefore, Professor Wedl had done all which Lostorfer has strongly advised to avoid, he had of course no chance whatever to see the corpuscles in question. At this point the discussion became hot. Dr. Neumann, the well-known dermatologist, supported Professor Wedl; and when Professor Stricker again replied he made use of the expression that one must be a well “rubbed-up” microscopist (*ein geriebener Microscopiker*) in order to repeat Dr. Lostorfer’s investigations. From this moment the signal was given for *guerre à outrance*, and, what is more peculiar, from this moment Dr. Lostorfer, the original investigator, was put aside, and Professor Stricker made responsible for the investigation of the former—thus, as I said, involuntarily placed at the head of one of the opposing parties. This was the first evening of the great

battles. Skirmishing, however, has been going on continually in all the Vienna medical journals; and at every meeting of the Medical Society a paper-war was kept up, Professor Wedl complaining, by letters sent to the Society, of Dr. Auspitz, the secretary, having been biassed by party feelings in framing the report of the discussion, and also accusing Professor Stricker, the editor of the Society's journal, of likewise being partial in performing his duty. To these accusations Professor Stricker and Dr. Auspitz have responded, eliciting again written replies from Professor Wedl, each new letter being more excited, more deviating from the original question, and becoming more personal, and even offensive. Under such circumstances it is evident that the Society's meetings are not always of a very agreeable character. But the war has already produced some good—namely, whether Dr. Losterfer's teachings be true or not, they have induced the microscopists to again pay attention to the investigations of blood, which have been neglected in the last two or three decennials. One of the best experienced blood-investigators, Professor Stricker, is already at work, which he has been forced to assume. From what we have heard of his recent investigations, one thing seems certain—namely, that something has been discovered by Dr. Losterfer which hitherto has not been known in blood. The corpuscles, according to Professor Stricker, exist decidedly; they are of a round shape, grow evidently, but form no projections (as described by Dr. Losterfer) giving to the observer the impression of projections if a smaller corpuscle is adjacent to a larger one. Whether or not the corpuscles are peculiar to syphilitic blood Stricker has not yet made out. If I am well informed, we may expect the publication of Professor Stricker's researches in a short time. Whilst in the one camp preparations are thus made for a new battle, Professor Wedl's army is likewise busy to meet the enemy's movement, or, if necessary, to open the hostilities. Dr. Neumann, we hear, has likewise been engaged in the solution of the important question, and the result of his researches, I hear, we shall read in one of the next impressions of the *Wiener Wochenschrift*. In conclusion, it may be mentioned that whilst the minds of Medical men are heated by Dr. Losterfer's discovery, Dr. Salisbary is preparing a paper for Dr. Hallier's *Journal of Parasitology*, in order to claim the right of priority of Dr. Losterfer's discovery.

THE BOOTLE HOSPITAL; LORD DERBY ON PREVENTIVE MEDICINE; ABUSES IN SELECTING HOSPITAL PATIENTS AND HOSPITAL OFFICERS—MR. LOWNDES ON MEDICINES.

ONE of the earliest acts of the recently incorporated borough of Bootle was to build a public Hospital, and on the 10th inst. the Earl of Derby, who had given the site and laid the foundation-stone, formally opened the building. In his address on the occasion, he drew attention to the rapid growth and wide spread of a belief in the importance of preventive Medicine, and remarked it as an especially honourable feature in the Medical Profession that workers in that field have never been rare among its members; and that while, on the one hand, no class of society has so freely given its time and care for the relief of suffering among the poor, so, on the other hand, no set of men have so habitually looked beyond the mere temporary relief of existing evils or so strenuously asserted the doctrine that prevention is better than cure. He pointed out so clearly the necessity of an education of the people in sanitary knowledge—if sanitary laws are ever to be really efficacious—that I shall not apologise for quoting his words at some length. "I am deeply convinced," said Lord Derby, "that no sanitary improvement worth the name will be effected, whatever Acts you pass or whatever powers you confer upon public officers, unless you can create a real and intelligent interest in the matter among the people at large. In the first place, you cannot get laws effectually put in force where they interfere with the profits or convenience of individuals unless they are supported by opinion. In the next place, whatever administrative measures can do for the public health—and they can do a great deal—they can never supersede the necessity for personal and private care. It is no good providing pure water for drinking if those who are meant to consume it prefer less innocent fluids, and a great deal of them. It is no good

setting up public baths and washhouses if people do not care to use them; though let me say, in passing, I think the want of such institutions on an adequate scale is one of the chief defects of our great towns. It is no good purifying the atmosphere from smoke and foul vapours—though that is one of the objects which in these parts we ought to keep most steadily in view—if when people have got clear air they will not let it into their houses. The State may issue directions, municipal authorities may execute them to the best of their power, inspectors may travel about, Medical authorities may draw up reports, but you cannot make a population cleanly or healthy against their will, or without their intelligent co-operation. The opportunity may be furnished by others, but the work must be done by themselves. That is why, of the two, sanitary instruction is even more essential than sanitary legislation. For if, in these matters, the public knows what it wants, sooner or later the legislation will follow; but the best laws in a country like this are waste-paper if they are not appreciated and understood." In the latter part of his address, Lord Derby said—"There are only two dangers which an institution like this has to guard against. One is that its gratuitous benefits should be taken advantage of by a class of patients who can afford to pay for the help they get. The remedy is care and honesty in the distribution of letters of admission. The other danger is that the appointments should be given away by personal favour or liking, or to the candidate who is most active in his canvass. Now, that is—to put it plainly—a matter of life and death. Whoever votes for putting A instead of B in a post of that kind, knowing or believing A to be the less competent of the two, is morally responsible for whatever injury to life and health may ensue; and it is not the slightest diminution of that responsibility that he has been flattered or talked over into giving his vote, or, as very often happens, that he has given it, without inquiry, to the first person who asked for it." It is greatly to the credit of Bootle that her Hospital is opened free of debt.

At a very numerously attended meeting of the Liverpool Medical Institution on the 11th inst., Dr. Cameron, the President, in the chair, the following motion was introduced by Mr. F. Lowndes, and after a long and interesting discussion was carried, with only one dissident:—"That the meeting approves of the scheme for the examination of midwives recommended by the Obstetrical Society of London, and strongly advocates its adoption, with such modifications in detail as local circumstances may require, believing that a uniform and higher standard of qualification will improve the position and usefulness of midwives, and secure for them the confidence of the Profession and the public."

GENERAL CORRESPONDENCE.

THE POISONING CASE AT THE LONDON HOSPITAL.

LETTER FROM MR. W. J. NIXON.

[To the Editor of the Medical Times and Gazette.]

SIR,—With reference to a paragraph on accidental poisoning in your impression of this date, I much regret that the information on which you have acted did not give a correct version of the facts. They are simply these:—A porter of this Hospital applied for and received from one of our dispensers some ordinary cough linctus, as if for himself, having previously derived benefit from its use. It was given to him, just as medicine would be given in a druggist's shop to any servant in his employ, and the dose was duly noted on the bottle. Influenced, however, by motives of mistaken kindness, the porter gave it to a friend, and by that friend it was administered to his own child. For the ultimate result, lamentable as it was, I leave to your sense of justice to decide whether the Hospital, its discipline and management, are in any way responsible.

I am, &c., W. J. NIXON,
House-Governor and Secretary.

London Hospital, Whitechapel-road, E., April 20.

A COMPLAINT ANSWERED.—In reply to a complaint from the Chairman of the Managing Committee of King's College Hospital, Dr. Evans, the Officer of Health for the Strand district, states that last year the District Board of Works provided an ambulance for the conveyance of persons suffering from infectious diseases, and that no application has up to the present time ever been made for the use of the district ambulance by the authorities of that institution.

NEW BOOKS, WITH SHORT CRITIQUES.

Sciatica, Lumbago, and Brachialgia: their Nature and Treatment, and their immediate Relief and rapid Cure by the Hypodermic Injection of Morphia. By HENRY LAWSON, M.D., Assistant-Physician to St. Mary's Hospital, and Lecturer on Physiology in the Medical School. London: Hardwicke. Pp. 200.

*** The greater portion of this very excellent volume having appeared in our columns, we shall be spared the task of doing more than expressing an opinion as to the nature and quality of its contents. It has been said that one fact is often worth a bushel of opinion; and in this book one fact certainly stands out in such bold relief that what remains is paled before it. This fact was Dr. Lawson's own suffering from sciatica, so severe that nothing but death seemed to promise relief until the hypodermic injection of morphia was tried. Instant relief was obtained, and the assiduous use of the same remedy completed the cure. Naturally enough, Dr. Lawson clings to the remedy which has effected so much for himself, and is, we fear, as a consequence, inclined, not perhaps to overrate the value of morphia injection, but to undervalue other measures of treatment; for as, undoubtedly, neuralgic pain arises from more than one cause, our duty is to ascertain as far as we can the nature of that cause, and if we can remove it. It cannot be said that injection of morphia answers to any one of these demands, however valuable a remedial agent it may be, and we are quite willing to admit what Dr. Lawson claims for it; yet it is only treating a symptom, though a terribly severe one. Therefore we would counsel the Practitioner whilst using Dr. Lawson's method to try to go a little beyond him in ascertaining the true cause of the neuralgic pain. But as a good practical book with an idea in it we can commend Dr. Lawson's to the Medical world.

Transactions of the Obstetrical Society of London. Vol. XIII., for the year 1871. London: Longmans. Pp. 335.

*** Year by year this Society is gathering together stores of knowledge and the results of ripe experience, and embodying them in these *Transactions*. Its reputation is spread abroad wherever the obstetric art is studied—an art which itself has done much to redeem from the position of obscurity to which it had been discarded by other branches of the Profession. Among the most interesting communications are those by Dr. Playfair, "On Irritable Bladder in the latter months of Pregnancy"; Dr. Braxton Hicks and Dr. Phillips, "On Mortality after Obstetric Operations"; Dr. Graily Hewitt, "On the Vomiting of Pregnancy"; Dr. Meadows, "On Pelvic Hæmatocele"; Dr. Tilt, "On Uterine Inflammation"; Dr. Braxton Hicks, "On the Contractions of the Pregnant Uterus during Pregnancy"; Dr. Konrad, of Pesth, "On Prolapse of the Genital Organs"; Dr. Snow Beck, "On the Structure of the Uterus during Pregnancy," etc., etc. We congratulate the Society on the increasing interest taken in its work on the Continent; for London, mainly owing to its labours, is rapidly becoming a valuable and well-worked field of gynecological study.

Gutch's Literary and Scientific Register and Almanac for the Year 1872. London: Virtue.

*** Though "Gutch" has reached us late, and though his fame is, we confess, new to us, we feel bound to say a word on his behalf. His work contains the most extraordinary amount of information on almost every subject under the sun we have seen. We cannot, of course, vouch for its accuracy, but its extent is something wonderful. Talk of a man being a "walking dictionary," that would be nothing to being a living Gutch. Soberly, the work contains information on almost every subject, and what it gives is well selected.

Griffith and Henfrey's Micrographic Dictionary. Third edition. Parts III. to VII. London: Van Voorst.

*** We have already pointed out to our readers that a re-issue of this very valuable work is going on, and that it is brought within the reach of all by the price of each number being fixed at half-a-crown. We take leave again very earnestly to commend it. Its excellences are not half wide enough known, and we know of no work so valuable to the man of cultivated scientific tastes as a book of reference and a working manual in minute natural objects. Take one thing: we don't know of any work so useful on cryptogamic botany.

It is expected that the Halifax Small-pox Hospital will be opened at the beginning of next month. No Medical officer has yet been appointed for the borough.

REPORTS OF SOCIETIES.

ASSOCIATION OF MEDICAL OFFICERS OF HEALTH.

SATURDAY, APRIL 20.

Dr. DRUITT, President, in the Chair.

An abstract of a paper by Mr. F. W. LOWNDES, of Liverpool, was read on Medico-Legal Evidence and on Infanticide. He aimed at the prevention rather than the punishment of crime, and desired greater efficiency and stringency in the registration of births, living or still; and that the practice of midwifery by women should be encouraged by the Legislature. Thus he hoped to render self-delivery and concealment of birth more difficult, whilst he trusted to improved moral and social conditions for the prevention of unchastity. An elaborate table of coroners' inquests on children at Liverpool was appended, by which it appeared that 127 bodies of infants had been found in Liverpool in the last three years, on which inquests were held; with verdicts of wilful murder in twenty-eight cases, neglect twenty, stillborn thirty-three, the remainder "found dead" or "no evidence."

Dr. ALDIS read a paper entitled "On a Sudden Outbreak of Small-pox in Belgravia, and the necessity for amending the 38th section of the Sanitary Act, 1866," as follows:— "I received a letter from a lady residing in Wilton-crescent, stating that a death from small-pox had occurred at a milk-seller's in Motcomb-street on May 23, 1871. Mr. Charles Hunter, Surgeon, of Wilton-place, complained to me on June 5 'that he had been called to six or seven patients within the last week in the immediate vicinity of the milk-seller's shop—three for certain, who were regularly served from the shop—the milk being furnished by the mother and son, both covered with small-pox.' I went to the house on June 6, and ascertained the following facts:—Two sons aged 19 and 11 years, with a daughter of 13, were attacked with small-pox about the second week in March; the second son, aged 17, was taken ill in the latter part of March, the mother also about the middle or the latter end of April, and another son, aged 15, on May 3, who died May 23—so that six in family had suffered, besides a servant, who left her situation on account of the infection in the house, but was afterwards attacked and removed to the Hospital, from which she was taken on June 9 to a convalescent asylum. The mother, who presented marks of small-pox on her face, told me that she had been well about a month, and served customers with milk during that time when her husband was from home. She also admitted that her eldest son sold milk shortly after his illness. I called upon a gentleman at No. 3, Wilton-place, on June 7, who frankly told me that the butler was removed ill with small-pox to Highgate on June 1, after having waited at dinner, on May 30, upon the occupier of the house (a lady) and another lady, both of whom took the complaint. The family were supplied with milk from the same shop. The butler died in the Hospital on June 7. It was believed that the disease had nearly ceased about the middle of May, but a boy was attacked on the 24th, at No. 4, Motcomb-street, and a man in Kinnerton-street was sent to the Hospital on the 26th. A boy came to be vaccinated by Mr. Hunter after buying milk from the milk-seller's son while recently marked with small-pox. A lad belonging to Lady Essex's stables in Belgrave-mews North had been served at the shop in Motcomb-street by one of the sons on the morning of the brother's funeral. A woman living in Kinnerton-street went for milk and sent for it by a strange girl; the former was taken to the Hospital. The small-pox seems then to have rapidly increased in this particular neighbourhood, the focus being the milk-seller's house, round which it radiated. Under these circumstances, I took out a summons at the Westminster Police-court, on June 13, with a view of ascertaining the opinion of the magistrate upon the 38th section of the Sanitary Act. Mr. Woolrych said it was lamentable to hear what had taken place, but the section of the Act applied only to what took place out-of-doors, and not in a shop, where people went to make purchases of their own accord. It was a great pity that the Act did not go a little further, so as to meet such cases, for it was hard for persons to go to a shop, and, being unaware of a dangerous disease being in the place, to carry the infectious complaint home to their households. In consequence of this decision appearing in the

newspapers, I received a letter from Mr. E. Turner, M.P., inquiring into the facts of the case, which I forwarded to Mr. Bruce, who, in reply to a question in the House of Commons from Mr. Turner, said that he thought the Act might be very usefully amended and enlarged, so as to include shops. No alteration, however, has been made in the Act, and tradesmen are at liberty to sell milk or any other article, while suffering from small-pox, with impunity."

Mr. NETTEN RADCLIFFE read a paper, entitled "The Prospects of Cholera," and based upon the information which has been obtained concerning the prevalence and progress of the disease since the autumn of 1869. At that period cholera reappeared in the city of Kieff, after having been entirely absent for more than twelve months. It spread to the surrounding places, and in the course of a year it invaded nearly every part of Russia in Europe, extending along lines of railway and other channels of human intercourse. It was conveyed from St. Petersburg, by passengers, to railway stations in the provinces, insomuch that it was found necessary to make arrangements at some of the larger stations for the reception of any cases that might occur among the persons waiting or arriving there. From Russia the disease was carried both by land and sea, by railway passengers *via* Königsberg, and by steamers or other ships to various ports on the Baltic, whence again it was conveyed in at least two instances to Hartlepool, and in one to Nova Scotia. It was taken also from Odessa to Constantinople, where it occasioned a great mortality. Coincidentally with the presence of the disease in Russia, it prevailed also in the Pashalik of Bagdad, and followed the lines of caravans through Central Arabia, by way of Medina and Mecca, until it reached Gonfudah and other ports on the Red Sea. He then came to the question, What is the prospect of this country suffering from or escaping an epidemic during the present year? This question may be regarded from two distinct points of view—first, with reference to the phenomena of the recent diffusion of cholera on the Continent and in Arabia; secondly, with reference to the conditions existing among ourselves. As far as regards the first branch of the subject, he remarked that the circumstances of the recent diffusion approximate very closely to those of 1852-55. Then, as now, the early cases appeared at first to have been due to recrudescence of a preceding and unexhausted epidemic; but it is probable that in both the phenomena of recrudescence masked the more important presence of fresh migrations of cholera into Europe from India by way of Persia. The outbreak of 1852-55, not only in Europe but in other parts of the world, was one of the most extensive on record; and, assuming a parallelism between the initial phenomena of development and progress of that outbreak and those of the outbreak of 1869-71, it may be inferred that the future course of the latter will be somewhat similar, as regards magnitude, to the course of the former. The probability that the diffusion of 1869-71 was essentially a true migrating epidemic of cholera is increased by the consideration that, during its progress in Europe last year, cholera became largely diffused in the Pashalik of Bagdad, and spread thence into Eastern and Northern Arabia, and to the eastern shore of the Red Sea. Further, there has been only one instance in Europe, that of 1859, of the occurrence of what has been aptly termed by Indian Physicians a "regional diffusion" of the malady. In that year cholera, apparently first showing itself in an active form in Hamburg, and prevailing there with considerable severity, broke out at various points of Western Europe, from Helsingfors to Southern Spain, and extended also into Morocco. Numerous cases were imported from the Continent to this country; but with the exception of the three slight outbreaks at Wick, Glass Houghton, and on the Itchen at Southampton the disease did not extend. Assuming that the recent diffusion may be of a similar character to that of 1859, it would be impossible to forecast its future; but the extent and universality of its prevalence in Russia, as well as the other considerations which have been mentioned, appear almost to shut out the hope that it may prove to be regional only, and support the view that it is part of a general, and as yet uncompleted, diffusion. On the whole, therefore, a comparison of the events of 1869-71 with those of previous outbreaks in Europe renders it probable that there will be a further extension of the disease in the course of the present year. The diffusion of cholera in Arabia, and its presence on the east coast of the Black Sea, should give rise to serious disquietude; for in this direction Egypt is threatened with the disease, and through Egypt the basin of the Mediterranean and the whole of Southern Europe. Great danger was apprehended from the assemblage of pilgrims at

Mecca in March, but it is now reported—I trust accurately, although no official confirmation of the report has been received—that this year's pilgrimage has passed without an outbreak, notwithstanding the asserted presence of the disease in Mecca earlier in the year. Concerning the state of this country I would observe that all previous diffusions of cholera have been heralded by lesser outbreaks in the years preceding them. Last year there was no outbreak of cholera in England, but whether we may hope to escape in like manner during the year to come is a matter on which I will not venture a prediction. With regard to the conditions favourable to the development and propagation of the disease, I think it may be said that its too probable invasion of England may be contemplated without any excessive anxiety if only local authorities (and upon the "if" must turn the whole gist of my remarks) can be induced to take precautionary measures in anticipation of the evil. Speaking generally, the greater or less improvements which were carried out, either in the water-supply or in the abatement of nuisances, in the principal cholera-fields of previous epidemics, between 1854 and 1866, have been continued since the last-named period; and the conditions which chiefly favour the development and propagation of cholera never existed among us to so small an extent as at the present time. At no previous time has the water delivered by the companies been comparatively so pure, neither have the arrangements for the removal of nuisances from the metropolis or for dealing with infectious diseases been more completely organised. The amended sanitary law of 1866 gave to local authorities largely increased powers with regard to the abatement of nuisances and to the provision of Hospital accommodation for cases of infectious disease, so that such authorities are now placed, with reference to cholera, in a position which they have never before held. The law now empowers them to take all essential precautions for the protection of the populations under their control, and throws the entire responsibility of taking these precautions upon them. Nay, more—the Sanitary Act gave further powers for meeting an epidemic of cholera, as soon as certain sections were put in force by an Order in Council, which order was duly issued on July 29, 1871. Whether, therefore, we regard the general sanitary state of the kingdom, or the state of the law in respect to infectious diseases, the threatened invasion of cholera may be contemplated with less dread than in the case of any previous epidemic.

Inspector-General MURRAY had been led by his observations in India to believe that the epidemic of last year was only one of the stages of the ordinary progress of the disease from India to Europe, and he cited some curious examples of the way in which the rate of progress of cholera was accelerated by a railway—now, in fact, it travelled at the same pace as the travelling public.

Dr. DE RENZY, Sanitary Commissioner of the Punjaub, said: I entirely agree with Mr. Radcliffe that there are no solid reasons for regarding the late epidemic in Russia as a recrudescence of the epidemic of 1865. On that hypothesis the epidemic would have appeared simultaneously, or nearly simultaneously, over large tracts of country where the cholera was lying dormant from the previous outbreak. But this was not the case. On the contrary, the disease spread gradually from Kieff as a centre, following, as has ever been its custom, the main arteries of commerce, and especially affecting those regions traversed by railways. The facts which Mr. Radcliffe adduces to connect the epidemic in Kieff with that in Persia are of great interest. They go far to show that cholera is not bound to any particular atmospheric highway, as some people imagine, but that it is always ready to avail itself of any new facilities for diffusion that modern civilisation may open to it. The doctrine of recrudescence is, I believe, of Indian origin. It originated at a time when we had very little exact information about cholera, before any attempt had been made to tabulate the deaths caused by the disease among the native population. But now, as our knowledge of the facts becomes more precise, much of the mystery that formerly enveloped the disease and added to its terrors has disappeared. Already it is seen that the disease never appears with explosive suddenness, as was once supposed. It spreads gradually, like other epidemic communicable diseases. The opinion that the cholera virus is disseminated in great atmospheric waves is confronted by unanswerable objections furnished by our experience in India. The atmospheric currents must be the same now as they were a hundred years ago. And yet there can be no doubt of the fact that cholera epidemics are becoming much more frequent in the upper provinces. Two illustrations of this fact will suffice. In the first forty-four years of this century Umritsur, the great com-

mercial centre of the Punjaub, suffered from three epidemics. Since the annexation of the province—less than thirty years—it has suffered from six epidemics. Again, Peshawur remained entirely free from the disease in the long interval from 1805 to 1857. Since 1858 the valley has been visited by four terrible epidemics. In the last two—those of 1867 and 1869—the losses of the British troops were awful. In 1869 H.M.'s 36th Regiment lost no less than 15 per cent. of its strength in thirty days. The atmospheric currents being the same as they were formerly, we must look elsewhere for an explanation of the great increase in the frequency of epidemics. It cannot be said that the sanitary condition of the province is worse than it was, for the native cities, though they are lamentably deficient in sanitary arrangements, are incomparably cleaner than they were, and the people better off in every way. Of all the changes wrought in India by British rule, there is none so remarkable as the improvement in the facilities for intercourse between the different provinces and the extent to which the people avail themselves of those facilities. Calcutta and Lahore, only twenty years ago separated by a five months' journey, are now within as many days; and tens of thousands of people who never thought of leaving their villages, now travel largely on business or pleasure or devotion. This is the true explanation of the greater frequency of cholera in Upper India. The facilities for the importation of the cholera virus from its endemic home in Bengal are enormous, compared with what they were. Natives have frequently complained to me that British rule was bringing cholera among them so often—a circumstance which they attributed to the displeasure of the Deity at the sacrilegious custom of cow-killing. When I explained to them the influence of railways in spreading infection, and asked them whether they would unmake the railways for the purpose of being free from cholera, they admitted that they could not get on without railways: they had become necessary to their existence; and they expressed the hope that Government would be able to remove so unlooked-for a result of the opening of their great highways. There is one expression in Mr. Radcliffe's paper to which I strongly object. He speaks of "cholera travelling," implying that the disease is capable of automatic motion. Now, I maintain that there is no reason for supposing that the disease is endowed with any such power. On the contrary, every year's observation confirms the opinion that it is incapable of motion, and that when cholera travels it is invariably carried by man—his clothes, his goods, or merchandise. I must also take exception to one statement made by my old chief, Inspector-General Murray, who has said that cholera often appears in gaols and cantonments whose sanitary condition is perfect. If we admit the truth of this statement, how can we do battle with the disease with any earnestness of victory? We must abandon the soul-inspiring hope of delivering the people of India from the misery and degradation which this cruel pestilence inflicts. But I hope to convince you that Dr. Murray is mistaken. In most respects Indian gaols and cantonments are in a much better sanitary state than any English towns. The soil is dry—I speak of the upper provinces—the ground-surface clean, the house accommodation good and not overcrowded, the inhabitants well-fed and well-clothed. There are no towns in England that will bear comparison in these particulars with our great military cantonments of Peshawur, Meean Meer, or Umballa; and if the conditions I have mentioned comprised all that is necessary for the protection of communities against epidemics, Dr. Murray's statement would be undeniable. But there is one all-important point in which Indian gaols and cantonments are sadly defective. There are very few indeed in which the water-supply is not exposed to the grossest pollution. Peshawur derives its water-supply from open gutters, flowing by roadsides, fifty-two miles long, and open to every sort of pollution. If the people of Belgravia were dependent for their water-supply upon an open gutter flowing along the edge of the flagway, you, gentlemen, would not take a very sanguine view of their chances of escaping cholera or other epidemics diffusible through water that might visit the metropolis. And yet this is the actual condition of Peshawur. Is it strange that the place has been a pest-house; that it is hardly ever free from some destructive epidemic? At Meean Meer the supply was taken from wells, but within 100 feet or so of the wells deep trenches were cut, thirty feet deep, almost down to the water-level—and these trenches were the latrines of the troops. In 1861 the troops lost just one-fourth of their strength from cholera; and after that warning the trenches were cleared out and filled up, and privies on the dry-earth system constructed. The system of water-supply, however, continued very defective. The water was raised by Persian

wheels, and stored in a reservoir placed on a mound six feet above the level of the ground, near the well-mouth. This reservoir, which is only about eight feet square by four feet deep, is covered with planks laid loosely over it. The natives use the wells as places of rendezvous for chat in the cool of the evening, and the dust from their feet and shoes falls into the tank. I do not know of one great military station the water-supply of which is not grossly defective; some are worse than others, but all, without exception, are in a most dangerous condition. With these facts before you, gentlemen, I think you will agree with me that, so far as Indian experience goes, there is no reason to despair of our ability to control the ravages of cholera in that country as you have controlled them here. I cannot conclude without saying that when I urged upon the late Earl of Mayo the supreme importance of undertaking at once the reform of the water-supply of Indian cantonments, his Lordship expressed his belief that that reform would do more than all other contemplated reforms together to relieve our soldiers from the scourge of cholera and the other epidemics that debase and impoverish India.

Dr. BUCHANAN recalled to the meeting the time, not so far distant, when the propagation of cholera was supposed to be due to all manner of cosmic, atmospheric, or other vaguely described and incomprehensible influences, and congratulated his hearers on having now reached a solid basis of fact and knowledge, upon which further observations might be built with security.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, APRIL 9.

T. B. CURLING, F.R.S., President, in the Chair.

(Continued from page 474.)

ON taking the chair, the PRESIDENT announced that the Council had duly considered the proposal to place a bust of her Majesty in the rooms, and had come to the conclusion that it was not advisable to carry out the scheme.

Mr. J. ASTLEY BLOXAM also brought forward a case of Aneurism of the Abdominal Aorta at its bifurcation, and involving the left common iliac, treated by pressure of the abdominal aorta, and which was followed by embolism and death. The case was under the care of Sir James Paget, Bart., at St. Bartholomew's Hospital in the year 1870. The patient, aged 29, was admitted on February 23. He had suffered with pain in the back and loins for eighteen months, and occasionally he had numbness in the lower extremities after running. When admitted, the tumour presented the following appearance:—It was irregularly oval, with its long diameter directed towards the left common iliac, equally firm all over, and pulsating very forcibly in all directions. Pressure was applied, with the aid of chloroform, two inches above the umbilicus, no less than four times within a period of twenty-four days, on the following dates:—March 4, for two hours and twenty minutes; 8th, for one hour and thirty minutes; 14th, for four hours; 21st, for six hours. In each period it was especially remarked by Sir James Paget and all present how immediately the circulation was affected by the pressure. At the last operation the pulse became almost indistinguishable at the wrist, and remained so for hours, and on all occasions the arterial circulation seemed to have contracted to its greatest extent, and at the same time became exceedingly rapid, and at times intermittent. After the 21st, the last date on which the pressure was applied, he had frequent attacks of vomiting, and retched up a little blood, and appeared in a moribund condition up to the 25th, when he rallied a little. At this period he complained much of pain over the seat of pressure, became rapidly emaciated, and died on March 29, eight days after the last application of the pressure. At the post-mortem, local peritonitis had taken place about the pancreas and spleen, and an abscess had formed in the gastro-splenic omentum. The superior mesenteric artery was found for more than an inch flattened out, of a dark purple colour, its coats infiltrated, and on opening it, on the internal coat were clots of blood, firmly adherent; but a channel existed through the artery. The arteries to the spleen and pancreas were branches of it, and it appeared to Mr. Bloxam that the breaking-up of their structure into abscesses might be the result of emboli, as several were detected along the main trunk of the superior mesenteric. The aneurism itself had eroded the bodies of the lumbar vertebræ, and was full of laminated clots. Mr. Bloxam

simply drew attention to the peculiar condition of the circulation when pressure was applied over or near the semilunar ganglia.

Mr. WOOD wanted a more detailed account of the condition of the duodenum where it crosses the aorta, as there it was most likely to meet the pressure. He thought they must not attribute the whole of the clot to the pressure, for some of it seemed to have been exposed to the wash of the blood after its removal in the specimen shown. He also thought the formation of the clot might in part be due to the inflammation of surrounding tissues, which in one case was shown to be present. He considered the second case alluded to by Mr. Durham more likely to be, from its mobility, an aneurism of one of the branches of the aorta rather than of that vessel itself. The cases justified his previous opinion of Lister's instrument—that its use was not without risk from various causes. He thought distal pressure should only be had recourse to when proximal was impossible; but then it ought to be tried. Pressure had failed, in his hands, in curing aneurism.

Mr. T. SMITH thought that credit ought more distinctly to be given to Dr. Murray, to whom was due the introduction of the practice, and who certainly was the first to cure an abdominal aortic aneurism so. He found this plan to be both practicable and safe. These cases clearly showed that sudden stoppage of the blood was possible, and even beneficial in such trunks as the aorta. In the case alluded to, arteries after a time freely sprang up in places even where it is generally supposed that there are no vessels. The papers of that night showed when and how to apply pressure. He could see that in Sir James Paget's case the treatment was too severe and too continuous. The pulse, too, altered as in Mr. Bryant's case, probably from pressure on the solar plexus.

Dr. BARCLAY said he had recently seen two cases of abdominal aneurism in St. George's Hospital. One was no case for interfering with, as it was extending into the chest. The pain from erosion was very great, and the patient died by rupture into the pleura. In the other the aneurism was freely movable in the abdomen; it was probably, therefore, an aneurism of a branch of the aorta. The patient had albuminuria when he came in, but it disappeared. He tried Murray's plan. They could arrest pulsation by digital pressure, but the patient could not bear chloroform, so that had to be given up. Two days after they tried ether, but they could only keep it up for two hours, and the aneurism was unchanged. They also tried pressure without chloroform, but could obtain no useful result.

Mr. HAWARD considered the collapse in this case to be due rather to the pressure of the tourniquet than the ether. If the pressure was relieved, the faintness got better, but it returned when the pressure was renewed.

Mr. BARWELL thought he felt the femoral pulsating in Mr. Durham's patient (who was present). Ten hours under chloroform was an exceptional period for a man to bear. He thought the pressure might be made intermittent.

Mr. CROFT thought the pad might be made, by a little ingenuity, so as to do no harm to the bowels.

Mr. DURHAM, in reply, said he considered much was due to letting the man alone for a time after the first attempt. Repetitions were dangerous without a long rest. He also used slow pressure at first, and moulded away as well as he could the parts from beneath the pad. He also applied the pressure as high as possible.

Mr. BRYANT considered that his case proved fully that as perfect consolidation could be procured by distal pressure as by proximal. He thought there was no evidence of "wash" in his specimen.

After a few words from Mr. BLOXAM, the meeting adjourned.

After the meeting,

Dr. DOBELL exhibited two instruments, having for their object to reduce the intra-vesicular pressure in the chest, and that resulting from it on the surface of the diaphragm, and to effect a more complete change in the reserve air of the lungs, and thus indirectly of the residual air, in cases of emphysema, chronic bronchitis, carbonic acid poisoning, and the like. The first instrument was invented by Dr. Berkart, and consists of a set of inspiratory and expiratory valves communicating between an orinatal mask and an air-pump. Dr. Dobell's instrument is of simpler construction than an ordinary respirator, and, though not so large, somewhat resembles it in shape. It is made by Maw, and is called a "Residual Air-pump." That of Dr. Berkart is manufactured by Hawksley, and is called an "Expirator."

OBITUARY.

THOMAS BICKERTON, F.R.C.S., L.S.A.

THE Medical Profession of Liverpool have sustained a very serious loss in the death of Mr. Thomas Bickerton, and the numbers who attended his funeral prove that the loss is one not felt by the Profession only. Mr. Bickerton was born in Warrington, and after having served an apprenticeship to Mr. Ellis Jones, of Liverpool, then one of the Honorary Surgeons to the Northern Hospital, spent a session at the Liverpool Royal Infirmary School of Medicine. He then went to Glasgow, where he completed his curriculum, working throughout with great steadiness and zeal. As a proof of the diligence with which he prosecuted anatomy, it is only necessary to mention that in the latter period of his course he filled the post of prosector, one which is always assigned to those students who are possessed of the best practical knowledge of the subject. After obtaining his diplomas he undertook a voyage or two to Australia, and at the conclusion of these settled down in practice in Liverpool. With a great aptitude and skill in general Surgery he had always displayed a marked predilection for ophthalmic practice, and, on the resignation of Dr. Neil some fourteen years ago, was appointed Assistant-Surgeon to the Liverpool Eye and Ear Infirmary. Two years later, when Mr. Poole resigned, he became full Surgeon, and up to a few weeks of his lamented death continued to discharge the duties of his important post with a zeal, energy, and success which are very rarely equalled. The brilliance and success of his operations on the eye early brought him into repute, and secured for him a large and lucrative ophthalmic practice, while the invariable amiability of his disposition insured his being thoroughly liked both by his patients and Professional brethren. As well as being Surgeon to the Eye and Ear Infirmary, and in possession of a large general Surgical practice, he was Consulting-Surgeon to the North Western Railway Company's Northern Division—a post which, until the last year or two, when rearrangements were made by the Company as to its Medical service, gave him abundant employment; and, as if all this could not satisfy his love of work, he was Major of the 1st Lancashire Artillery Volunteers.

The occasion of his early death—for he was only 45—was peculiar. Some three years ago he was thrown from his carriage, and sustained a severe, but, as it seemed to be, superficial injury to one knee; and after a short confinement to the house, resumed his work with unabated vigour. Beyond a little stiffness, and an occasional slight pain, no inconvenience whatever was experienced from this accident until about four weeks ago. On the Monday he was at the Eye Infirmary, did his work just as usual, and in the course of the day actually walked several miles. On the Tuesday morning he appeared to be in his usual health, which was that of a robust, powerful man. On the afternoon of that day, however, he began to suffer from pain and swelling in the knee, and as these increased towards the evening he requested the advice of Mr. Hakes, Surgeon to the Royal Infirmary. There was doubt at first as to the character and extent of the mischief. Constitutional disturbance, however, was very great, and by Saturday the symptoms had become so alarming that Mr. Bickersteth saw him in consultation with Mr. Hakes; and on the following day (Sunday) a free incision was made into the joint, evacuating a very large quantity of fetid pus. It now became apparent that the patella was extensively necrosed, and that there was other mischief besides that in the joint. In the upper and outer third of the thigh a large abscess had formed, which required a separate opening for its evacuation, and two subsequent incisions were rendered necessary into or near the joint by the disorganised condition of the tissues and consequent sloughing and suppuration. It is not wonderful, under these circumstances, that when he was able to bear amputation—which for a week or two could not be thought of, in consequence of his extreme prostration—secondary hæmorrhage occurred. On the second day after the limb was removed by Mr. Hakes, hæmorrhage occurred from the femoral, not at the original point of ligature, but so as to require another site to be tied. Two further slight hæmorrhages from smaller vessels at two subsequent periods so exhausted his strength that he died at half-past two on Saturday morning, the 13th inst.

Mr. Bickerton was a Fellow of the College of Surgeons of Edinburgh, and L.S.A. of London. He was twice married, and leaves a widow and six children (four of whom are by his former wife) to deplore their loss.

JOHN CROUCH, F.R.C.S., ETC.

MR. CROUCH died on the 13th inst. at Chippenham, at the age of 62 years. He was first a pupil at the Winchester County Hospital, then was further educated at Guy's and St. Thomas's. He was in general practice for several years at Castle-Carey, Somerset, and subsequently at Mitcham, in Surrey. Whilst in full practice incipient symptoms of paraplegia developed themselves, and gradually incapacitated him, and he was struck down in the very prime of life and in the zenith of a useful career. He was formerly House-Surgeon to the Winchester Hospital. Contributions: "A Successful Case of Ovariectomy by a large Abdominal Section," *London Medical Gazette*, 1849; "On Ovariectomy, with a Table of all the Cases recorded in England previous to 1849," *Provincial Medical and Surgical Journal*; "A Successful Case of Parturition in a Patient who had previously undergone Ovariectomy by a large Incision," *Medical Times and Lancet*, 1851, and *Medical Chirurgical Transactions*, 1852; and other cases of ovariectomy in *Lancet*, 1854-59, and *Association Journal*, 1854.

ROBERT VENABLES, M.A., M.B. OXON., ETC.

THIS venerable Physician died on the 15th inst. at his house on Blackheath-hill, at the advanced age of 88. He was in practice for many years in London, and at one time prepared candidates for passing examinations of the Medical Colleges. He for a long time past has been gradually retiring from active practice. He was educated in Dublin, and was a man of good abilities and varied acquirements. He was Physician to the Royal Kent Dispensary, Greenwich-road; Member of the West Kent Medico-Chirurgical Society; H.P. Royal Artillery. Author of—1. "On Dropsics;" 2. "Diabetes;" 3. "On Cystic Oxide Calculus, and the Properties of the Urine in this Diathesis;" 4. "On Siliceous Gravel and on Carbonate of Lime," *Journal of the Royal Institution*; 5. "Elements of Urinary Analysis;" 6. "On Cholera;" 7. "Organic Diseases of Liver," *Cyclopædia of Practical Medicine*.

GARRETT DILLON, M.D., M.R.C.S., ETC.

WHO had been for many years retired from practice, died on the 17th inst., at Bryanston-street, in the 80th year of his age. In the early stages of the Medical reform question Dr. Dillon took a prominent part. He was a man of ability and great energy, and addressed an audience with fluency and effect. Being independent of his Profession, he was careless as to the obtaining of practice, and, consequently, was never much occupied in it. He was a genial, warm-hearted man, an excellent companion, and a staunch friend.

MEDICAL NEWS.

UNIVERSITY OF DURHAM COLLEGE OF MEDICINE, NEWCASTLE-ON-TYNE.—The following gentlemen passed the primary examination for the Licence in Medicine at the examination held on April 15 to 18:—

Callcott, James T. | Kowell, Geo., M.R.C.S. | Wilson, Chas. W.

Two candidates failed to satisfy the examiners.

UNIVERSITY OF ABERDEEN.—At the late Medical Graduation Term the following candidates, after the usual examinations, received Degrees in Medicine and Surgery:—

THE DEGREE OF M.D.

Clark, Thomas Edward, M.R.C.S., L.S.A., Clifton.
Pearson, Thomas Robert, M.R.C.S. Eng., L.R.C.P. Ed., Shotley Bridge, Durham.

At the same time the following gentlemen received promotion to the Degree of M.D.:—

Anderson, Alexander Thomas, M.B., C.M., Wigan.
Blacklock, Arthur Woolsey, M.B.; C.M., Brighton.
Blake, Edward Thomas, M.B., Reigate.
Catto, Robert, M.B., C.M., Portsoy.
Gillies, John, M.B., Milksham, Wilts.
Hutchison, George Wright, M.B., C.M., Belford Hospital, Fort William.
Lawrence, Alexander, M.B., C.M., County Asylum, Chester.
M'Rae, Alexander Edward, M.B., C.M., Fetterearn.
Morison, George, M.B., C.M., Huntly.
Munro, Alexander Begg, M.B., C.M., St. Helen's, Melrose.
Newth, Alfred Henry, M.B., Hayward's-heath, Sussex.
Ross, Walter, M.B., Trinity College, Glenalmond.
Thomson, George, M.B., C.M., Oldham, Lancashire.
Thomson, John William, M.B., C.M., Brechin.
Timmins, John A. J., M.B., C.M., Wellington.
Waterworth, Edward Allan, M.B., Newport, Isle of Wight.
Williams, Albert, M.B., C.M., Sydenham, Surrey.
Willcock, Richmond Colts, M.B., C.M., Aberdeen.

THE DEGREE OF M.B.

Campbell, William, Kinellar.
Carless, William, Stroud, Glos.
Cushny, William Alexander, M.A., Fochabers.
Elliott, Frederick William, M.R.C.S. Lond., London.
Farquharson, Patrick Davidson, New Deer.
Footner, Edward, M.R.C.S. Lond., 91st Highlanders.
Forsyth, Alexander, Aberdeen.
Garden, Robert John, Aberdeen.
Gibb, Robt. Shirra, Cults, Aberdeen.
Gibbes, Cuthbert Chapman, Plymouth.
Gosse, Charles, M.R.C.S. Lond., South Australia.
Inglis, James, Aberdeen.
Knowles, W. Bisset, Aberdeenshire.
Law, James, Aberdeen.
Lawrence, Alfred E. Aust, Bristol.
Low, David, Skene.

Lyon, John, Peterculter.
Macdonald, John Davidson, M.A., Clatt, Aberdeenshire.
MacKenzie, Duncan J., Ross-shire.
Mitchell, Andrew, New Deer, Aberdeenshire.
Parkinson, John Taylor, M.R.C.S. Ed., Yorkshire.
Pringle, John, Torwoodlee.
Reid, James, M.A., Ellon.
Reid, James Alexander, Kildrummy, Aberdeenshire.
Rennie, Thomas, Inverurie.
Robertson, George James, Daviot.
Smith, Geo. Washington, Methlick.
Stephen, James, M.A., St. Cyrus, Kincardineshire.
Tytler, Peter, Midmar.
Wright, Francis James, L.S.A., Preston, Lancashire.
Wyness, Jas. Davidson, Aberdeen.
Welford, Geo. Edward, Sunderland.

THE DEGREE OF C.M.

Campbell, William.
Carless, William.
Clark, Thomas Ed.
Cushny, William Alex.
Farquharson, Patrick D.
Forsyth, Alexander.
Garden, Robert John.
Gibb, Robert Shirra.
Gibbes, Cuthbert C.
Gosse, Charles.
Inglis, James.
Knowles, William B.
Law, James.
Lawrence, Alfred Ed. A.
Low, David.
Lyon, John.

Macdonald, John D.
Mackenzie, Duncan J.
Mitchell, Andrew.
Parkinson, John Taylor.
Pearson, Thomas R.
Pringle, John.
Reid, James.
Reid, James Alexander.
Rennie, Thomas.
Robertson, George James.
Smith, George Washington.
Stephen, James.
Tytler, Peter.
Welford, George Edward.
Wright, Francis James.
Wyness, James Davidson.

Of the above-mentioned candidates, Alexander Forsyth, Robert John Garden, David Low, James Reid, Thomas Rennie, and Peter Tytler received their degrees in Medicine and Surgery, with highest academical honours; George James Robertson, his degree in Medicine, with academical honours.

At the same time Alexander Burrell, George William Fowler, Walter Gawen King, Francis Ogston, David Aikman Patterson, and Robert William Reid were certified as having passed all the examinations, and are entitled to receive degrees on their attaining the necessary age; and the following were declared to have passed part of their examinations:—

Aldridge, Charles.
Allardyce, James.
Anderson, Alexander.
Arthur, John Findlay.
Burness, Alex. Geo.
Busfield, Harcourt M'Leod.
Cantlie, James.
Davy, John.
Donald, William.
Ewart, Alex. Barelay.
Hall, John George.
Hallett, Henry Arthur.
Hanson, Hargreaves H. H.
Hoole, Pemberton Abel.
Keith, Alex. C.
Lawrance, Patrick Jas.
Lechler, Henry Martin.

Lumsden, Jas. P.
Mearns, William.
Milne, Robert.
Moir, Forbes F. M.
Napier, Alex. D. Leith.
Napier, Thos. Wm. Adam.
Newcombe, Chas. Fred.
Oakes, Charles.
Reid, George.
Rigby-Hughes, John.
Rowan, Robert K. O'Neill.
Skene, Thomas Alex.
Swaine, Charles L.
Thomson, John.
Wadd, Thos. Herbert.
Wardrop, Douglas.

The next Professional examination for degrees in Medicine commences on Saturday, July 27.

KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.—At the monthly examinations held on April 8, 10, and 11 last, the Licence to Practise Medicine was granted to the following successful candidates:—

Cormack, John Claude.

Applications, enclosing testimonials, to be forwarded to David Roberts, Secretary, 17, Church-street, Cardiff, on or before Tuesday, April 30.
- INFIRMARY FOR CONSUMPTION AND DISEASES OF THE CHEST, 26, MARGARET-STREET, CAVENDISH-SQUARE.—Visiting Physician. Candidates must be Members of the Royal College of Physicians, London. Testimonials to be sent to Francis Baily, Secretary.
- KING'S COLLEGE.—Demonstrator of Practical Physiology.
- MIDDLESEX COUNTY LUNATIC ASYLUM, HANWELL.—Medical Superintendent of the Male Department. Candidates must be Fellows, Members, or Licentiates of one of the Royal Colleges of England, Scotland, or Ireland, and duly registered in Medicine and Surgery. Copies (only) of testimonials, accompanied by a form (which will be forwarded on application), must be sent to Richard William Partridge, Clerk to the Visitors, on or before Saturday, May 4.
- ROYAL ORTHOPÆDIC HOSPITAL, 315, OXFORD-STREET.—Two Surgeons and two Assistant-Surgeons. Candidates must be F.R.C.S. Applications, with testimonials, to be sent to Benjamin Maskell, Secretary, on or before May 1.
- SALOP AND MONTGOMERY COUNTIES AND WENLOCK BOROUGH LUNATIC ASYLUM.—Assistant Medical Officer. Candidates must be duly qualified. Applications with testimonials to be sent to Mr. De Courcy Peele, Clerk to the Visitors, Shrewsbury, on or before April 30.
- SKIRLAUGH UNION.—Medical Officer for the District of Aldborough. Candidates must be duly qualified. Applications, with testimonials, to be forwarded to Thos. A. McCoy, Clerk to the Guardians, Beverley, on or before Thursday, May 2.
- TEWKESBURY UNION.—Medical Officer to the Forthampton District. Candidates must be duly qualified. Applications and testimonials to be sent to George Badham, Clerk to the Guardians, Tewkesbury Union, on or before April 30.
- UNIVERSITY COLLEGE HOSPITAL.—Resident Medical Officer. Applications and testimonials to be sent to John Robson, B.A., Secretary to the Council, on or before May 18.
- WALSINGHAM UNION.—Medical Officer. Must be duly qualified in accordance with the General Orders of the Local Government Board. Applications, with testimonials, to be forwarded to J. Wright, Clerk, Bridge-street, Fakenham, on or before Tuesday, April 30, and endorsed "Application for the Office of Medical Officer."
- WANDSWORTH AND CLAPHAM UNION.—Medical Officer for the Eastern District of the Parish of Battersea. Applications and testimonials to be sent to John Sanders, Clerk to the Guardians, Union Offices, East-hill, Wandsworth, on or before Tuesday, April 30.
- WEST BROMWICH DISTRICT HOSPITAL.—House-Surgeon. Candidates must be doubly qualified. Applications and testimonials to be sent to P. D. Bennett, Honorary Secretary, West Bromwich, on or before May 6.

UNION AND PAROCHIAL MEDICAL SERVICE.

. The area of each district is stated in acres. The population is computed according to the census of 1861.

RESIGNATIONS.

- Aysgarth Union.—Mr. J. A. Harrison has resigned the Hawes District; salary £30 per annum—also the Workhouse; salary £10 per annum.
- Chertsey Union.—Dr. T. A. Chaldecott has resigned the First District; area 10,000; population 6583; salary £80 per annum—also the Workhouse; salary £50 per annum.

APPOINTMENTS.

- Clifton Union.—Henry Grace, M.R.C.S. Eng., L.R.C.P. Lond., L.S.A., to the Sixth District.
- Foleshill Union.—Edward W. Orton, M.R.C.S. Eng., L.R.C.P. Edin., to the Bedworth District.
- Leeds Union.—Charles Jack, M.D. and C.M. Univ. Glasg., to the Headingley-cum-Burley District.

Penkridge Union.—John C. Blackford, M.R.C.S. Eng., L.S.A., to the Workhouse.

Portsea Island Union.—Thos. P. Simpson, M.D. St. And., M.R.C.S. Eng., L.S.A., to the Workhouse.

Selby Union.—Alex. C. Gray, M.D. and C.M. Univ. Glasg., to the Workhouse and the Selby District.

Sudbury Union.—Francis Marshall, M.R.C.S. Eng., L.S.A., to the First District.

Toxteth Park Township.—Albert E. Carter, L.R.C.S. Ire., L.R.C.P. Edin., to the First District.

DR. WILLIAM CRADDOCK, of the Bengal Army, died on March 30, on board the *Scotland*, off Cape St. Vincent.

TYPHOID fever is prevalent at Mountain, Queensbury.

THE *Sindian* says that almost every family in Kurra-
chee is attacked with measles; and fever and other maladies, brought on by the sudden change of the season, prevail to a great extent.

THE HISTORICAL SOCIETY will meet in the Scottish Corporation-hall, Crane-court, Fleet-street, London, on the evening of Friday, the 26th inst., at half-past seven o'clock. The Council will meet at seven o'clock precisely. B. G. Jenkins, Esq., will read a paper, entitled "A Chapter in the History of Cholera, founded on a Communication to the Russian Imperial Academy of Sciences, and now under the consideration of the Medical Council of the Minister of the Interior."

ST. GEORGE'S HOSPITAL MEDICAL SCHOOL.—The "William Brown Exhibition" of £40 per annum for three years, to the student showing the best general fitness for the exercise of the Medical Profession, has been awarded to Mr. Francis M. Evans. Mr. W. Wilson Coltart, the second in order of merit in the competition, has been presented with a special prize by Mrs. Brown, the founder of the Exhibition, in acknowledgment of the excellence of his examination. The "Henry Charles Johnson Memorial Prize" in practical anatomy has been awarded to Mr. E. J. Spitta, and the Honorary Certificate to Mr. W. A. Frost.

EXAMINATIONS IN ANATOMY AND PHYSIOLOGY.—The following were the questions submitted to the candidates at the primary examination for the diploma of Membership of the College of Surgeons on Saturday last, viz.:—1. Describe the boundaries of the posterior mediastinum, and its contents, in their relative position. 2. Describe the structure of veins, and the forces by which the venous circulation is carried on. 3. Describe the ligaments of the hip-joint; and mention the muscles in contact with its capsule. 4. Give an account of any experiments with which you are acquainted, illustrating the influence of the pneumogastric nerve upon the action of the heart. 5. Describe the ligaments connected with the clavicle, and mention the parts which pass beneath it in their relative position. 6. Describe the ciliaris muscle and its action.

THE NEW STRASBURG UNIVERSITY.—The lectures are to commence on May 1 and terminate on August 15. The following are the courses to be delivered:—1. Professors Oscar Schmidt (from Graz)—Introduction to Zoology and the Natural History of the Lower Animals, with zootomical and microscopical practice. 2. Waldeyer (Breslau)—Osteology and Syndesmology, General Anatomy, and the Anatomy of the Brain and Spinal Cord. 3. Hoppe-Seyler (Tübingen)—Physiological and Pathological Chemistry (with a private laboratory Medico-chemical course) and Dietetics. 4. Schmicdeberg (Dorpat)—Materia Medica and Therapeutics. 5. Von Recklinghausen (Würzburg)—Special Pathological Anatomy and Physiology, with demonstrations and microscopical practice. 6. Leyden (Königsberg)—Diagnosis, Clinical Medicine, and Diseases of the Kidneys. 7. Lücke (Bern)—Clinical Surgery, Operations, and Diagnosis of Tumours. 8. Gusserow (Zurich)—Midwifery and Diseases of Women. 9. Laqueur (Lyons)—Ophthalmology. 10. Kraft-Ebing (Stephansfeld)—General and Clinical Psychiatry. Seven of the former Professors of the Faculté de Médecine will terminate their annual courses in the French language. Besides the above lectures, others will be delivered on Botany, by Du-Bary (Halle) and Von Solms-Laubach (Halle); on Chemistry, by Bueyer (Berlin); and on Physics, by Kundt (Würzburg).

LIFE INSURANCE.—Our Profession is just now appealed to for help by several of its members whom misfortune and sickness have struck down, and by the widows of others who, after having benefited Medical science and the public, have left behind them no ostensible reward of their labour. We hope that these appeals will meet with all the success they deserve; but we should gladly see amongst all ranks of our Profession a little more prudence and forethought in the management of the ordinary business of life. We know how difficult it is for men engaged in ministering to the wants of others to find

time to attend to their own. As we have recently observed, early life-insurance offers the only hope of providing for a family in case of death which many Medical men can entertain. We would, therefore, repeat our counsels to young men entering on practice to insure, and insure early, but not too largely, and let the premiums be so arranged as to cease at 60. To the offices whose names we have before mentioned, as those in which many Medical men are interested, we would add the Prudential, whose prospectus seems to offer considerable advantages. We are glad to see that the habit of life assurance is making way amongst workpeople and *employés*. For this class of persons the Royale Belge Life and Accident Assurance Company seems to be especially intended.

PYÆMIA.—The number of the *New York Medical Record* for April 1 contains a long and elaborate essay on the "Pathogeny of Pyæmia and Septicæmia," from the pen of Dr. Mary Putnam, one of the lecturers of the Women's Medical College of the New York Infirmary.

THE EARLIEST ENGLISH DENTISTS.—Professor Oliver Wendell Holmes, in an eloquent and amusing introductory address delivered to the students of the Dental Department in Harvard University (reported in full in the *Boston Journal*, February 29), observes:—"It is a long interval from Galen to the middle of the seventeenth century. But I had not found any other traces of a special dental profession until I came upon the following, which looks very much as if it referred to such specialists. In the diary of the Rev. John Ward, vicar of Stratford-on-Avon from 1648 to 1679, is the following:—"Upon a signe about Flect Bridge this is written: Here lives Peter de la Roch and George Goslin, both which, and no other, are sworn operators to the King's teeth.'"

NOTES, QUERIES, AND REPLIES

He that questioneth much shall learn much.—*Bacon.*

Mr. A. B. Steele is thanked. But we had received notices of the deceased *confère* from three other sources.

F. S.—For a very good, long-established, and lucrative practice, say two years' income; but the price must vary with locality, rate of fees, length of introduction, and whether a death vacancy or no.

Ishmael.—First, Epsom salts with iron and sulphuric acid, *omni mane*; secondly, Calvert's carbolic soap. Address, "The Registrar of the General Medical Council, Soho-square."

Consul, Venezuela.—It is not held to be wrong to vaccinate during the incubation of small-pox. The vaccine disease will run its course side by side with the variolous, and will probably favourably modify the latter. This is not a new discovery.

MEDICAL CONGRESS AT LYONS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I should feel obliged if you would announce in your journal that I have been authorised by the president to receive the names of members of the Profession in England who are willing to support the Congress by becoming *membres-adhérents*. This entails no pecuniary contribution. I shall forward such names to Lyons, and they will be printed in the lists in due course. The questions to be discussed have already been announced in your journal. I am, &c., PROSSER JAMES.

18, Dover-street, Piccadilly, W., April 23.

Wenham Lake.—The Company get their ice from a lake in Norway. It is brought in large blocks to the Surrey Docks, and stored in the Surrey end of Waterloo-bridge. In the Strand premises these blocks are sawed and planed into the shape of pyramids one sees at table. There can be no question of the extreme purity of the ice.

Cundurango.—The American Surgeon-General's Circular, No. 3, dated Washington, August 31, 1871, gives one of the reputed cases of cure of cancer by this drug, and describes it as a commercial speculation—not as a remedy for cancer. Surgeon Basil Norris, U.S.A., speaks with approval of the compound of bromide of potassium, acetic acid, and water as an external soothing application, as recommended by Dr. Osborne, of Southampton.

A QUERY.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I am desirous for important reasons to ascertain the name of the Medical man who, in July, 1869, on the night of the debate in the House of Lords on the Irish Church Bill, was called in to attend the late James Earl of Kingston, at Claridge's Hotel, on the occasion of a sudden attack of illness. If you would kindly insert this communication in your valuable paper one of your numerous readers may be able to give me the information required. I am, &c., HENRY WHITE.

7, Southampton-street, Bloomsbury, W.C., April 24.

P.S.—Mr. James Startin has suggested my writing to you on the subject.

Dr. C. Clark (Brighton, Victoria).—The letter has been received with much pleasure. We are glad that our old friend and contributor appreciates the articles to which he refers. His communication will probably be further alluded to on a future occasion.

The "Social Science and Joint Committee's" Opposition to Mr. Stansfeld's Bill.—We have received a letter from Dr. A. P. Stewart, in which he points with commendable pride to the "thought, time, and self-denying labour" which these bodies have expended in devising a perfect scheme of sanitary organisation, and claims for its "deliberate and collective opinions" some degree of respectful attention—in fact, Dr. Stewart regards any opposition to their opinions or movements as a "public wrong," an "inuedo," "simply ridiculous," etc. Let us substitute the Royal Sanitary Commission, or the Local Government Office, or any other body who have spent "thought, time," etc., in exciting sanitary measures. Why does not Dr. Stewart think them above criticism? Or why cannot honourable men criticise each other's opinions without intermixture or suspicion of personal disrespect?

Poor-law Medical Officers as Medical Officers of Health.—We would respectfully call Dr. Stewart's attention to the following passage in the memorial of the Joint Committee to Mr. Stansfeld:—

"That the Poor-law Medical Officers, being necessarily dependent for success in private practice on the goodwill of their neighbours, many of whom are interested in the very abuses which it would be their duty to denounce if they were appointed *sole* Officers of Health in accordance with the provisions of the Public Health Bill, protest against being burdened with duties and responsibilities for the right discharge of which they feel that their position disqualifies them; though as *assistants* to responsible Medical chiefs, their services would be both willingly rendered and of the highest value."

The very function which the Poor-law Medical Officers shrink from undertaking is that which would be laid on them by this proposal. It is the first step—the pointing out the black spots: the houses where fever and diarrhoea prevail from defective drainage and polluted water—which must fall to the lot of the Poor-law Medical Officer; and it is this denunciation which is more odious than the measures it leads to.

PILES AFTER LABOUR.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—For "piles" say congestion and bruising of the rectum. The piles are a mere accident of a temporary injury. Ice, or iced water, is the remedy used by Yours, &c., A. B.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—In reply to the question of "R. E. P.," though I know of no means of averting piles after labour, except emptying the large gut, and afterwards giving good diet, yet he will probably find the anguish of which he speaks (and which generally depends upon inflammation of the piles, with great tenseness and tenderness) relieved by lead and opium lotion—sixty minims of liq. plumbi diacet., and the same or a larger quantity of laudanum, in half a pint of rain-water. This lotion is used until the swellings are no longer tender to the touch, when the ointment of gall and opium usually completes the cure.

In the inflamed state of piles the lotion always gives immediate relief. It should be constantly applied, not quite cold, and to the piles only. Pier-road, Erith, S.E. I am, &c., T. CURTON.

A Competitor.—It will be seen in a report of the proceedings of the last meeting of the Council of the College of Surgeons, published in another page, that of the six essays sent in for the Jacksonian Prize none were deemed worthy of the prize. "Ununited Fractures" is the subject for the prize of 1873.

An Inhabitant of Poplar.—We think it not creditable to those interested in the important district of Poplar that they have not the spirit to maintain a small Hospital in that locality, where accidents are of frequent occurrence, and the nearest Hospital—the London—being a considerable distance off. Under the circumstances it would be far better for the Governors of the Poplar Hospital to accept the offer to purchase the building for a convalescent home.

THE BAKER BROWN FUND.

This fund is being raised on behalf of Mr. Isaac Baker Brown, who is paralysed, and in great pecuniary distress.

Fifth List of Subscriptions.

£ s. d.		£ s. d.	
Amount previously advertised	... 284 16 0	Dr. Rd. Neale, Boundary-road, St. John's-wood	... 2 2 0

Rev. W. H. L. Cogswell	... 1 1 0		

The Treasurers are Dr. Forbes Winslow, 23, Cavendish-square, and Dr. Charles Cogswell, 47, York-terrace, Regent's-park, to whom subscriptions may be sent.

Lex.—There must, we think, be an error in the report of the proceedings. The coroner has no legal power to order a Medical witness to make an analysis of any preparation under the ordinary summons issued under the provisions of the Medical Witnesses Act. The Medical Practitioner is, however, bound to comply with the requirements of the summons; and where it states that he is to make a post-mortem examination of the body, and analyse the contents of the stomach, and give evidence thereon, he is liable in default of so doing to a penalty of £5. There is no fund provided by law for the payment of analyses of anything not contained in the body of the deceased person. It is, however, in the power of the Home Secretary to order such payments out of the public purse.

PAYMENT FOR PRESCRIPTIONS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Will you kindly say in your next Answers to Correspondents whether a general Practitioner acts correctly, and in accordance with the custom of the Profession, in charging a fee when applied to for a prescription for a patient who has been under his care (in the case in point the maid of a wealthy lady), he having been paid for his previous attendance and the medicine then furnished?

General Practitioner, when requested to give a prescription, has hitherto charged for it either one guinea or half a guinea, according to the social position of the patient; but it is now suggested to him that this is an unusual demand to make.

* * * We should say—charge for the prescription as for a visit.

COMMUNICATIONS have been received from—

Dr. BEIGEL; Dr. J. W. MOORE; Dr. GAIRDNER; Mr. E. MORGAN; Mr. F. H. HEMMING; Dr. NEILD; Mr. E. F. TURNER; Mr. A. B. STEELE; Mr. METCALFE JOHNSON; Mr. HENRY THOMPSON; F. S.; Mr. W. W. REEVES; Dr. H. ROOKE LEY; Dr. ARMSON; Mr. T. SYMPSON; Dr. S. DREW; Mr. W. J. NIXON; Professor BRAZIER; MESSRS. BLACKWOOD; Mr. WRIGHTMAN; Mr. VINCENT JACKSON; Mr. HENRY WHITE; Dr. PROSSER JAMES; ISHMAEL; MESSRS. BOOKS RECEIVED—

Cases from Practice, with Clinical Remarks, by Staff Assistant-Surgeon W. Curran—Medical Education in America, by Dr. Henry J. Bigelow—On the Antagonism between the Actions of Physostigma and Atropia, by Dr. T. R. Fraser—On Feeling Ill, by Dr. W. A. Johnson—Introduction to the study of Biology, by Dr. H. Alleyne Nicholson—On Winter Cough, by Dr. Horace Dobell—Vital Statistics and Meteorological Report of the Borough of Salford, 1871—Annual Report of the Surrey County Lunatic Asylum.

PERIODICALS AND NEWSPAPERS RECEIVED—

Nature—Dublin Journal of Medical Science—Lincoln Journal—Pharmaceutical Journal—The Clinic—Australian Medical Journal—Glasgow Herald—Melbourne Argus—American Journal of Medical Science—Birmingham Morning News—The Free West.

APPOINTMENTS FOR THE WEEK.

April 27. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; King's, 2 p.m.; Charing-cross, 2 p.m.; Royal Free, 2 p.m.; Hospital for Women, 9½ a.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. Thomas's, 9½ a.m.

GRESHAM COLLEGE, 7 p.m. Dr. E. Symes Thompson, "On Doses of Medicine."

ROYAL INSTITUTION, 3 p.m. Mr. R. A. Proctor, "On the Star Depths."

29. Monday.

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; St. Peter's Hospital for Stone, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

MEDICAL SOCIETY OF LONDON, 8 p.m. Dr. Sansom, "Some New American Preparations derived from Petroleum." Dr. Semple, "Specimen and Case of Disease of Right Portion of Heart." Dr. Chapman, "On the Treatment of Diabetes." Mr. Thomas Bryant (President), "On Skin-grafting."

30. Tuesday.

Operations at Guy's, 1½ p.m.; Westminster, 2 p.m.; National Orthopædic, Great Portland-street, 2 p.m.; Royal Free, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; West London, 3 p.m.

ROYAL INSTITUTION, 3 p.m. Mr. E. B. Tylor, "On the Development of Belief and Custom amongst the Lower Races of Mankind."

May 1. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1½ p.m.; Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.; St. Thomas's, 1½ p.m.; Samaritan, 2.30 p.m.; King's College Hospital (by Mr. Wood), 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. George's (ophthalmic operations), 1½ p.m.

OBSTETRICAL SOCIETY, 8 p.m. Dr. Newman, "On a Case of Delivery per Vias Naturales, in which the Cæsarian Section had formerly been performed. Dr. Squarey, "On the Cases of Three Sisters in whom the Uterus and Ovaries were Absent." Dr. Braxton Hicks, "On the Structure of the Human Placenta." And other Papers.

ROYAL INSTITUTION, 2 p.m. Annual Meeting.

SOCIETY OF ARTS, 8 p.m. Meeting.

2. Thursday.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Royal Orthopædic, 2 p.m.; University College Hospital, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

HARVEIAN SOCIETY, 8 p.m. Mr. George Eastes, "Use and Abuse of Alcohol in Health and Disease."

ROYAL INSTITUTION, 3 p.m. Prof. Tyndall, "On Heat and Light."

3. Friday.

Operations at Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.

MEDICAL SOCIETY OF LONDON, 8 p.m. Meeting of Council.

ROYAL INSTITUTION, 9 p.m. Mr. Wm. Spottiswoode, "On Optical Phenomena produced by Crystals when submitted to Circularly Polarised Light."

VITAL STATISTICS OF LONDON.

Week ending Saturday, April 20, 1872.

BIRTHS.

At the Royal Observatory, Greenwich, the mean reading of the barometer in the week was 29.74 in. The highest was 30.11 in. on Sunday, the 14th inst., and the lowest 29.30 in. at the end of the week.

* The figures in this column are the unrevised numbers enumerated in April, 1871, raised to the middle of 1872 by the addition of a year and a quarter's increase, calculated on the rate which prevailed between 1861 and 1871. The population of Dublin is taken as stationary.

ORIGINAL LECTURES.

LECTURES ON THE
COMPARATIVE ANATOMY OF THE ORGANS
OF DIGESTION OF THE MAMMALIA.

DELIVERED AT THE ROYAL COLLEGE OF SURGEONS OF ENGLAND IN
FEBRUARY AND MARCH, 1872,

By WILLIAM HENRY FLOWER, F.R.S.,
Hunterian Professor.

LECTURE IV.

(Continued from page 453.)

ALL the monkeys hitherto spoken of have exactly the same dental formula as Man—viz., *i.* $\frac{2}{2}$, *c.* $\frac{1}{1}$, *p.* $\frac{2}{2}$, *m.* $\frac{3}{3}$, total 32. The next family, the *Cebidæ*, have an additional premolar above and below, the formula being—*i.* $\frac{2}{2}$, *c.* $\frac{1}{1}$, *p.* $\frac{3}{3}$, *m.* $\frac{3}{3}$, total 36. They are all inhabitants of South or Central America. Like most of the Old World monkeys, they appear to be very mixed or indiscriminate feeders, chiefly subsisting on various kinds of fruits, but also partaking at times of insects and other small animals.

One of the most characteristic forms, and perhaps the most elevated in the scale, is the genus *Ateles* or Spider Monkey, distinguished by the slenderness of the body, the great spider-like length of the limbs, the strong prehensile power of the tail, and absence of thumbs on the anterior extremities.

Of the viscera of one of these, the black-handed spider-monkey (*Ateles melanochir*), the Museum contains several preparations, from a specimen recently received from the Zoological Society's Gardens. It was a nearly adult female, all the permanent teeth being in place, except the last molars. The length from the nose to the root of the tail was twelve inches, the length of the tail twenty-two inches.

As in all the other American monkeys there are no cheek-pouches. The lining membrane of the lips and cheeks are smooth. The palatal ridges are about eight on each side, not meeting in the middle line, irregular and sinuous, and not strongly developed. The posterior edge of the soft palate is thickened and forms a broad arch, without any appearance of uvula.

The tongue is rather lancet-shaped and pointed at the apex. The lateral group of linear follicles at the base of the palato-glossal fold is very distinct and large. The papillæ generally are small and soft. Of circumvallate papillæ there are only two, situated side by side, close to the middle line opposite the attachment of the palato-glossal folds. The frænum is attached very near (three-tenths of an inch) to the apex of the tongue, which has a strong median groove below. The sublingual papilla is rather small, soft, thick, and pointed, with a slightly bifid apex.

The parotid and submaxillary glands are largely developed, coming in contact with each other for a considerable space. The sublingual gland forms a longitudinal prominence on each side of the floor of the mouth beneath the tongue, its anterior extremity extending into the sublingual papilla.

The stomach still greatly resembles that of man in form, but is, perhaps, rather longer and more slender, and the *antrum pyloricum* is more developed. It is much curved in its long diameter, the anterior surface being convex and the posterior concave, as was noticed in the gibbon. The great omentum was drawn up close to the lower border of the stomach, so that when the abdominal cavity was opened it did not cover the intestines. Its anterior layer depends from the stomach, and its posterior layer returns behind that organ without involving the greater part of the transverse colon, though attached to its right end at the junction with the ascending colon, as in the *Cercopithecidæ*.

The small intestines are ninety-five inches in length, or about eight times that of the body. There are no valvulæ conniventes, but Peyer's patches are numerous and large, especially in the lower half of the intestine; about twenty-five, of various sizes, were counted in all. The large intestine, without the cæcum, is seventeen inches long, loosely suspended throughout, except at the right superior bend, where its peritoneal connexions attach it to the duodenum and right end of the stomach. It gradually diminishes in calibre from the upper to the lower end, and is not so long or tortuous as in the smaller Old World monkeys, and is very little sacculated, except at its commencement. Single dark-coloured closed follicles, and small groups

of two to four similar follicles, are sparingly scattered on its mucous surface.

The cæcum (Fig. 16) is three inches and a half long when undistended, of pretty nearly equal thickness throughout, and with a rounded apex. When filled with water or air it became curled in a half-circle, being kept in this position by a pair of peritoneal folds—one passing on each side of the entrance of the ileum, and extending close to the apex of the cæcum, which they cause to bend very abruptly. In addition to these there is a small median fold or frænum passing from the convex or free border of the ileum to the concave border of the cæcum, corresponding to the single fold observed in the Old World monkeys. The cæcum is not sacculated, the lateral longitudinal muscular bands of the colon (which are by no means well marked) only commencing but a little way from the ileo-cæcal junction.

FIG. 16.

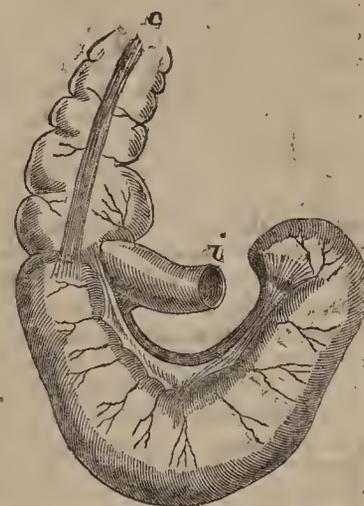

FIG. 16.—Cæcum of black-handed spider-monkey (*Ateles melanochir*): *c* colon, *i* ileum.

The liver (Fig. 17) is larger from before backwards than transversely, in accordance with the elongated compressed form of the abdominal cavity. It is very symmetrically divided into the four principal lobes. The umbilical fissure (*u*) is short, extending not a fourth of the distance from the free edge to the posterior border above, and being partially bridged below.

FIG. 17.

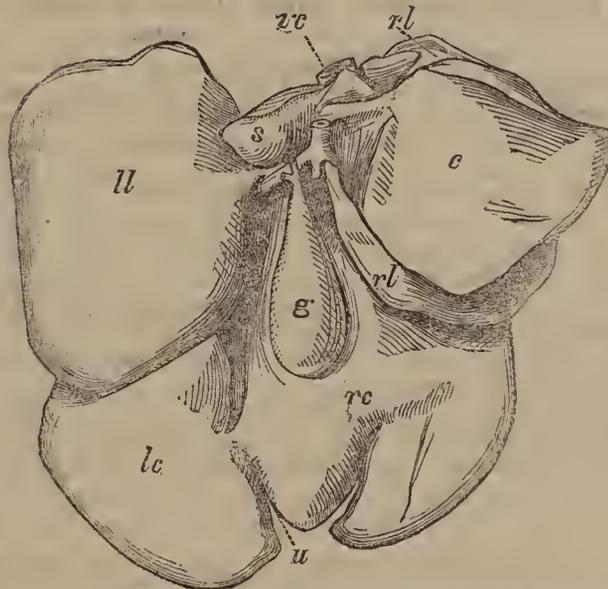

FIG. 17.—Under surface of the liver of the black-handed spider monkey (*Ateles melanochir*): *u* umbilical fissure, *vc* vena cava, *ll* left lateral lobe, *lc* left central lobe, *rc* right central lobe, *rl* right lateral lobe, *s* Spigelian lobe, *c* caudate lobe, *g* gall-bladder.

The two central lobes (*lc* and *rc*) have very rounded external borders; the right is slightly larger than the left, and has a notch at its free edge, near to the fundus of the gall-bladder. The two lateral fissures extend to one-third of an inch from the posterior border. The lobes (*ll* and *rl*) they cut off, are subtriangular, smaller than the central lobes, and the right smaller than the left. The Spigelian lobe (*s*) has a considerable-sized tongue-shaped process projecting forwards and to the left, and a small process to the right overhanging the base of the caudate lobe. The latter (*c*) is very large, being about the same size as the right lateral lobe, beyond which its pointed apex projects. By this character the liver is easily distinguished from that of any of the Old World monkeys. The vena cava is superficial, separating the Spigelian from the posterior border of the right lateral lobe. The gall-bladder (*g*) is pyriform, sunk in a depression on the lower surface of the right lateral lobe, near its central margin, and not reaching its free border by about an inch.

The common Capuchin monkey (*Cebus capucinus*) may be taken as another type-form of this family. In a specimen lately (February 17) received from the Zoological Gardens the lips are thin, the lining membrane of the cheeks smooth, and

though they are lax and extensible, they form no distinct pouches. There is no median frænum to the lower lip, but a distinct one to the upper. The palate has eleven pairs of symmetrical, much-curved ridges, not extending across the middle line; posteriorly the ridges become less developed and irregular. The palato-glossal folds are sharply defined, meeting above in a regular arch, leaving a small crescentic faucial aperture. The soft palate is continued some little distance behind the palato-glossal folds, and has a rudimentary uvula. The tongue is narrow, and rounded in front. The fungiform papillæ are large, and scattered evenly over the surface; the filiform are long and soft; and the circumvallate papillæ are three in number, and have the usual disposition.

The parotid gland is of moderate size, of a flattened roundish form, altogether below the meatus auditorius externus, and with a distinct lobule projecting forwards over the masseter, from which the duct proceeds. This terminates by a simple orifice which will readily admit a bristle, rather further forward than in man, being opposite the interspace between the first and second premolar teeth. The submaxillary gland is of an elongated oval form, extending from beneath the angle of the jaw nearly half-way down to the sternum, occupying the "anterior triangle" of the neck, and in contact with the parotid above; posteriorly it is partially divided into an outer (larger) and an inner (smaller) lobe; in front several small partially detached lobules are clustered round the commencement of the duct. The latter runs forward in the usual course, and opens on the under surface of the flattened heart-shaped sublingual papilla, which is but slightly bifid at the apex. The sublingual gland consists of a number of delicate lobules lying just beneath the buccal mucous membrane, in contact with the anterior half of the duct of the submaxillary.

The stomach is more globular in form than in the spider monkey, the cardiac and pyloric orifices more approximated, and there is no distinctly marked pyloric compartment. The great omentum has the usual arrangement found in animals of this group, its posterior or deep layer involving the right third of the transverse colon and the upper half of the ascending colon. The small intestine is fifty-eight inches in length, or rather more than four times the length of the body (from mouth to anus was thirteen inches); the large intestine, including cæcum, only eleven inches in length. The duodenum forms a large loop to the right, supported by a loose mesentery before it crosses the spine, beneath the ascending colon. Peyer's glands are numerous and large throughout the small intestine from the duodenum downwards, and in the lower part of the ileum very long, and following each other with scarcely any interval. The cæcum is placed on the right side, nearly midway between the diaphragm and pelvis, simple, two inches long, of even width, with a blunt rounded extremity, and sharply curved, being retained in that position by a single median peritoneal frænum, without the lateral bands noticed in the spider monkey. The colon is comparatively small and simple, having no distinct longitudinal bands or sacculations, and the ascending, transverse, and descending colons are each nearly straight (without sigmoid flexure), and attached by a loose mesocolon throughout.

The pancreas is much like that of man, consisting of a principal narrow elongated part, reaching transversely to the spleen on the left, with a considerably developed process running down from the right end along the inner curvature of the duodenum. The duct joined the bile-duct to enter the duodenum rather less than an inch from the pylorus. I could find no second pancreatic duct.

The liver occupied considerably more of the right than the left side of the abdominal cavity. It is wider transversely than from before backwards, differing in this respect from that of *Ateles*. The umbilical fissure is well marked, and divides it into two segments, of which the right is considerably the larger. The lateral fissures do not extend quite to the posterior border. The lobes progressively decrease in size from the right lateral to the left lateral. On the under surface the left lateral has two small tongue-like accessory lobules near its inner border. The Spigelian lobe is long and pointed, and directed to the right, lying alongside of the caudate, which is smaller relatively than in *Ateles*, its apex not quite reaching the lateral margin of the right lateral lobe. The gall-bladder is deeply embedded in a fossa on the under surface of the right central lobe, near its left margin, so that the edge of the left central lobe overlaps it. The apex does not extend to the free edge of the lobe by half an inch, and there is no trace of a cystic fissure.

Another characteristic and well-known genus of this group is *Mycetes*, containing the howling monkeys, remarkable physi-

ologically for their stentorian voices, and structurally for the extraordinary modification of their vocal organs, especially the great drum-like expansion of the basi-hyal bone. These animals, natives of the tropical Brazilian forests, are very intolerant of confinement, and have in but few instances survived the voyage across the Atlantic; hence not many opportunities have occurred of examining the visceral anatomy of recent specimens. Fortunately, two adult specimens, which lived for a short time in the Zoological Society's Gardens, and were dissected here, and from which several preparations were made for the Museum, will enable me to furnish some information on this point.

With regard to the stomach, Cuvier says, (a) "Celui des *alouattes* a des parois épaisses et musculuses au cardia et au pylore, une forme globuleuse dans son grand cul-de-sac et cylindrique dans sa partie pylorique. J'ai même trouvé dans une espèce quelque traces de boursoufflures le long de la grande courbure, qui le rapprochent un peu de celui des semnopithèques."

In both the specimens of *M. seniculus*, the stomach (one of which is preserved in the Museum) was perfectly simple, without any trace of sacculations. Its form is very much that of the human stomach, but rather elongated, the cardiac pouch being more developed. The *antrum pyloricum* is also more dilated, and marked off by a distinct constriction from the rest of the cavity. When moderately distended its greatest length was 7.5 inches, and its greatest thickness 3.8 inches.

The small intestine had, as usual, no valvulæ conniventes, and the Peyer's patches were small and not numerous. The colon had only one broad longitudinal muscular band, exactly opposite the attachment of the mesocolon. The cæcum was very different from that of *Ateles*, being very capacious and comparatively short, in the form of an obtuse rounded cone, curved towards the side of the ileo-cæcal valve. Its length when distended was 2.5 inches, and its width at the commencement 2.2 inches.

The liver resembles that of *Ateles* in general characters, but the central lobes are much smaller, their sides being more parallel, and not expanding towards the anterior or free part. The left is considerably smaller than the right; the umbilical fissure extends nearly half-way between them. The cystic notch is very small, and close to the umbilical. The lateral lobes are both relatively larger than in *Ateles*, and the same may be said of the caudate and Spigelian lobes, which otherwise have the same general shape.

Certain other monkeys of this family, sometimes called Sakis, are united to form the genus *Pithecia*. They are smaller than the howling monkeys, but in some respects not far removed from them. A nearly adult female of *P. monachus*, dissected at the College in 1862, (b) measured eleven inches from the nose to the root of the tail.

The tongue, from the base of the epiglottis to the tip, is 1.4 inches, and its breadth nearly uniformly half an inch, its sides being nearly parallel, and the tip truncated. The sublingual papilla is fleshy, except towards the end, and sharp-pointed; free to the extent of a quarter of an inch, and fissured in the middle line at the tip.

The stomach is simple, and of a more globular form than in the higher monkeys, the cardiac and pyloric orifices being much approximated; the pyloric portion somewhat lengthened and tubular. The small intestine, from the pylorus to the ileo-cæcal valve, measures fifty inches, and is of the uniform diameter of four-tenths of an inch. Peyer's patches (the largest one and a quarter inch long) are scattered at tolerably regular distances all along the canal. There are no valvulæ conniventes. The common bile-duct and pancreatic ducts enter the posterior part of the duodenum half an inch from the pylorus.

The large intestine, from the ileo-cæcal valve to the anus, is twenty-two inches long, nearly an inch in diameter at the commencing, but rapidly diminishing to the same calibre as the small intestine, but slightly increasing again towards its termination, scarcely showing any tendency to sacculation. The cæcum large and long, being four inches and a half in length, and of greater calibre than the large intestine, from which it is distinctly marked off by a deep constriction passing obliquely round the gut, but slightly diminishing in size as it approaches its terminal end, which is obtuse and rounded. It presents a tolerably uniform curve, almost a semicircle in the same plane.

The liver has the four principal lobes very distinct. Both

(a) "Leçons d'Anatomie Comparée," 2nd edition, tome iv., part 2, p. 29. 1835.

(b) See *Proceedings of the Zoological Society*, 1862, page 326.

lateral lobes are larger than the central lobes. The caudate lobe is of remarkable size, larger than the right lateral, of quadrate outline, with a narrow base by which it is attached to the Spigelian lobe, and a pointed apex at the opposite end connected by a strong diagonally running ridge. The Spigelian lobe has a prominent rounded extremity to the left, and a small tongue-like process to the right, lying over the base of the caudate lobe. The vena cava runs superficially in its fossa. The gall-bladder is broadly pyriform; it is rather loosely attached to the under surface of the right central lobe, but its apex does not reach the free border by a considerable distance.

It will be observed that all the members of this group in which I have been able to describe the liver, agree in the depth to which the lateral fissures cut up the organ into its four principal lobes, and also in the great development of the caudate lobe, which is the principal character by which they can at once be distinguished from the Old World families, and which, as might be expected, appears to increase in size in descending the scale from the higher to the lower forms.

The last division of the *Simiina*, or true monkeys, constitutes the family *Hapalidæ*, comprising a number of elegant and delicately made animals of diminutive stature, like the last all inhabitants of the South American forests, but distinguished from them by their dentition, for with the same number of premolars (viz., 3), the posterior true molar is absent, and the total number of teeth is thus reduced to that of the Old World monkeys, though differing in kind; the dental formula being $i. \frac{2}{2}, c. \frac{1}{1}, p. \frac{3}{3}, m. \frac{2}{2}$, total 32. The cusps of the teeth are more sharply pointed, in accordance with their more insectivorous diet. The family is divided into two genera—*Midas* and *Hapale*—chiefly distinguished by the arrangement of the lower incisor and canine teeth. The former contains the largest members of the group, among which the pinche (*M. adipus*) may be described as an example, as an opportunity of examining one has recently occurred.

The specimen was an adult male, measuring from the nose to the root of the tail eight inches. The mouth shows no trace of cheek-pouches. There is a distinct, short, but thick, conical uvula, showing that this organ does not so much betoken approximation to the genus *Homo* as is sometimes thought. The tongue gradually tapers from just in front of the attachment of the palato-glossal folds (which is its widest part—four-tenths of an inch) towards the rounded apex. The length from epiglottis to apex of tongue is nine-tenths of an inch. The dorsal surface has a median furrow posteriorly, and the under surface beyond the frænum (which is half an inch from the tip) is deeply grooved in the middle line. There are three large circumvallate papillæ—one median behind, and two lateral in front. The fungiform papillæ are large and regularly scattered over the anterior two-thirds of the dorsum. The filiform papillæ are thick and short, and covered with hardened epithelium. The group of vertical slit-like follicles on each side of the base near the junction of the palato-glossal folds are very conspicuous. As in other monkeys, there is no trace of a median internal fibrous support or "lytta." The sublingual papilla is firm in texture, a quarter of an inch long, with a median ridge on its upper surface, tapering, and slightly cleft at the apex, with its lateral margins indented.

The salivary glands, especially the submaxillary, are very largely developed, almost resembling those of the true Insectivora. The parotid is a triangular mass, between the hinder edge of the masseter muscle and the meatus auditorius externus, broadest and thickest behind and below, where it runs in deeply behind the angle of the jaw. The duct leaves its anterior and upper narrow and thin extremity, and passes forward across the masseter muscle just below the level of the zygoma. The greatest diameter from above downwards of the parotid is six-tenths of an inch, and it is five-tenths of an inch across at its lower part.

The submaxillary fills the whole of the anterior triangle of the neck, only covered by the platysma, and making a visible prominence beneath the skin; below it almost meets its fellow across the middle line, about half-way between the angle of the jaw and the top of the sternum. It is six-tenths of an inch in length, and four-tenths of an inch in its greatest thickness, rounded in front, and with a straight posterior border resting on the anterior edge of the sterno-mastoid muscle. There is a small accessory lobule at the upper end, just under cover of the angle of the jaw, and about as large, in proportion to the surrounding parts, as the whole gland in man. The duct runs forward in the usual course, and opens on the sublingual papilla, about one-twentieth of an inch from its apex, and less than that distance from the middle line. The sublingual glands are comparatively rudimentary—a mere thickening

of the mucous membrane on the side of the ridge which continues the margin of the sublingual papilla backwards—of the size of a split grain of rice.

The abdominal cavity is long and narrow, and laterally compressed. The stomach is of an elongated oval form, but differs from that of man and the higher monkeys in the position of the cardiac orifice, which is situated far more to the right, or nearer the pylorus than usual—in fact, about midway between the two ends of the oval—so as to leave a very projecting cul-de-sac or fundus.

The small intestine is twenty-four inches in length, or only three times the length of the body; it is wide at first, and gradually diminishes in calibre as it approaches the ileo-cæcal valve. The duodenum, as usual, passes first to the right, then downwards and to the left, being closely connected with the front of the vertebral column as it passes across it, but soon becomes free and attached by a loose mesentery.

The colon (excluding the cæcum) is ten inches in length. It is disposed very much as in man, but the ascending and descending portions are longer in proportion to the transverse, and there is no sigmoid flexure, the descending colon passing insensibly into the rectum. The cæcum and ascending colon are very free, their mesocolon being only a part of the mesentery which supports the small intestines. The transverse colon at the right end is closely connected to the duodenum and to the stomach by the great omentum. The descending colon has a mesocolon, about three-quarters of an inch in breadth, connecting it to the front of the bodies of the lumbar vertebrae. Three longitudinal bands are present, but not very distinct, and the sacculi are very feebly marked. The cæcum is one inch in length, narrower than the ascending colon, with a rounded apex, and curled in a half-circle.

The most remarkable feature in the liver is the great size of both lateral lobes as compared with the central, each being fully twice the size of the combined central lobes. The lateral fissures are very deep. The umbilical fissure divides the triangular median portion, formed of the combined central lobes, very unequally, the left central being much larger than the right; but as the left lateral is rather smaller than the right lateral, the two main segments of the liver are very nearly equal. The right central lobe is so small that it is entirely excluded from the anterior border, and the right lateral and the left central come in contact (in the natural position of the liver) for some distance in front. The caudate lobe is tolerably large (though much smaller than the right lateral), broadening to the free end, where it is hollow, to receive the right kidney; it passes by a broad base into the Spigelian lobe, which has a small conical prominence pointing upwards and to the right. The vena cava is completely bridged over, so that the Spigelian, caudate, and right lateral lobes are connected superficially over it. The gall-bladder is small, and only attached by its neck to the base of the right central lobe, close to the umbilical fissure, which is not bridged on the lower surface.

Daubenton (Buffon, vol. xv., p. 102) notices the absence of gall-bladder in a member of this family (*Hapale jacchus*); but this was probably an individual variation, as in numerous specimens that have been subsequently dissected by various anatomists this receptacle has always been found.

It was decided, at a meeting held at Owen's College, Manchester, on Friday, to raise a fund of £10,000 in addition to another sum of £10,000 given by Miss Brackenbury for the erection of a suitable Medical school and the endowment of chairs in connexion with Owen's College.

ACUPUNCTURE.—No treatment could be more irrational than the indiscriminate use of the needle in all cases of disease, by the Chinese Doctors as well as by quacks. Expertness in this and in feeling the pulse constitutes the skilful Physician. The worst results from this practice have frequently to be chronicled in our Hospital note-book. One came with sup-puration of the entire arm and inflammation of the elbow-joint, who had been punctured eight days previously for cholera; and another with the same condition of the leg. The former, after his cure, wished to present me with the most valuable thing he had, and worth a considerable sum of money. From its rarity and supposed efficacy, it is highly valued by the Faculty and the public. The *keu pau*, for such it was, is a canine calculus, held in higher esteem than the same article in the cow, called bezoar (*nieu hwang*). The offer of this rare medicine was declined with thanks.—*Report of the Peking Hospital, by Dr. John Dudgeon.*

ORIGINAL COMMUNICATIONS.

ON THE USE OF THE TRACHEAL TAMPON.

By F. JUNKER, M.D.,

Late Physician to the Samaritan Free Hospital, London.

LAST autumn I had the opportunity of seeing Professor Langenbeck, at Berlin, perform several extirpations of extensively diseased superior maxillary bones, in which he adopted Dr. Trendelenburg's plan of plugging the trachea through the tracheotomy wound as a preliminary operation. It was the first occasion on which Professor Langenbeck had resorted to this method, which, however, had been practised in different cases before. Having thus tested its advantages during and after the operation, he commented on it by declaring that in future he would not perform any operation on the face, in which inspiration or deglutition of blood may be apprehended, without using Dr. Trendelenburg's instrument.

The description of the operation of plugging the trachea, the cases which call for it, and correlative comments, will constitute the substance of this paper. In writing it, I shall largely draw from Dr. Trendelenburg's own papers, which he read before the Medical Society at Berlin in 1869 and 1870, and add such remarks as my limited observations on this subject and my experience of diseases of the air-passages and of the operation of tracheotomy might suggest.

Before, however, fully entering on my task, I propose to give a short statement of Professor Langenbeck's operations as far as they bear on the subject of this paper.

The first case in which this celebrated Surgeon used the trachea-tampon was operated upon on November 23, 1871. The subject was a young woman who was suffering from a large recurrent tumour of the size of a cocoa-nut, arising from and involving the whole superior maxillary bone, without, however, perforating the periosteum of the orbital surface. The disfiguration of the face and displacement of eye, nose, and mouth were proportionate with the size of the degeneration. Tumours, but not of the enormous bulk of the present one, had been removed on several previous occasions, the last not many months ago. I regret that, having lost my memoranda on this case, I must write from recollection; I abstain, therefore, in order to avoid unintentional errors, from entering more into the details of the history and of the nature of the disease, which, however, are irrelevant to the purpose of these lines.

Professor Langenbeck commenced the operation by performing tracheotomy above the thyroid gland, the patient having been brought under the influence of chloroform previously. This done, Dr. Trendelenburg introduced his instrument and made the tampon-canula safe, through which the narcosis was continued during the whole time taken up by the removal of the tumour with the superior maxillary bone. The patient being under deep anæsthesia, and the entry of blood into the trachea being prevented, nothing interrupted or interfered with the speedy performance of the operation. The hæmorrhage having been completely stopped, and the wound effectually cleansed from blood and clots, the plastic part of the operation was terminated. The cavities caused by the loss of substance were plugged with dossils of lint moistened with carbolic oil, the threads of which were passed through the nostrils. Now the tampon was removed and a common tracheotomy tube introduced. The patient breathed quietly during the whole operation, and continued so afterwards. She slept soundly during the following night. The highest temperature after the operation was 104° F., but on the fifth day she was perfectly free from fever. The lint-dossils were removed on the 26th (third day after the operation), the sutures on the 25th and 28th (second and fifth days), and the tracheotomy tube on the 28th (fifth day), after which the edges of the wound were drawn together with strips of gauze painted over with collodion to secure their union. The progress of the recovery continued as satisfactory as can be expected in cases of this nature.

The second case, in which Professor Langenbeck operated in a similar manner, was that of an elderly man with a tumour of still more gigantic dimensions, and involving besides the right superior maxillary bone, also the posterior nares and the fauces of the corresponding side. The tumour having already perforated the skin of the cheek, to which it was firmly united, had to be removed with its integument, and a plastic operation therefore become necessary, in order to cover the extensive loss

of substance. For this purpose the skin was taken from the right temple and the forehead. In this operation, also, the tampon-canula proved its efficacy by thoroughly excluding the entry of blood and carbolic water (with which the wound was irrigated) into the trachea, and permitted the uninterrupted continuance of the narcosis, which was the more important as the actual cautery had to be applied to the deep-seated portion of the degeneration, which could not be removed with the knife. The other features of the case were similar to the first mentioned, and the progress was satisfactory.

Dr. Trendelenburg,^(a) to whom Surgery is indebted for this important new method, is of opinion that the plugging of the trachea ought to be an auxiliary and preliminary to all operations in the larynx, as well as those in the buccal and pharyngeal cavities, in which inspiration of blood may be apprehended.

Cases are on record in which patients have died even during the operation, through suffocation from blood flowing into the bronchi; and it has happened in the practice of some of the most eminent Surgeons that they had been obliged to perform tracheotomy and suck out the blood from the air-passages, often with but negative results, in order to save the life of the patient.

According to Lücke's and Hueter's statistics,^(b) deaths from pneumonia, pulmonary œdema, bronchitis, and gangrene of the lungs constitute more than one-third of the fatal cases after resection of the superior and inferior maxillary bones. This proportion will be still increased if the deaths from meningitis after perforation of the skull in deep-seated tumours and from delirium tremens are deducted; and it will become evident that nearly one-half of the deaths after the above operations resulted from secondary acute diseases of the lungs and bronchi. The causes of these fatal results are twofold: Inspiration of blood during, and entry of saliva and pus into the trachea after, the operation. The first occurs more frequently in resection of the superior maxillary bone and extirpation of the tongue, the second more often after resection of the inferior maxillary bone.

During the resection of the superior maxillary bone the head of the patient is more reclined, and the blood finds easily its way from the nasal fossæ and posterior nares into the larynx, which can only be imperfectly protected by sponges. In resection of the inferior maxillary bone the danger of inspiration of blood is not so great. After the removal of the body of the bone, however, when the attachments of the tongue are separated, the deglutition of the saliva will be impeded, and its entry into the larynx facilitated.

In such operations it has been the common practice to commence under the administration of an anæsthetic, and to stop the latter after the external incisions have been made—a method which is fraught with much pain to the patient and considerable inconvenience to the operator. But even these preventive measures will not guard the patient completely against the dangers of blood passing into the lungs in cases of profuse hæmorrhage and great excitement. The dangers of bronchitis, and pneumonia, arising from coagulated blood in the air-cells, are increased and assisted by the circumstance that the lungs will be exposed during the following days to the irritating influence of the breath, contaminated by its passage over suppurating and unclean wounds.

Professor Langenbeck adopts the following method of preventing the descent of pus into the trachea in resection of the superior maxillary bone:—He stitches the mucous membrane and the periosteum of the hard palate of the side operated on, when the latter could be preserved, to the mucous membrane of the cheek, thereby separating the nasal from the buccal cavity and facilitating the deglutition of fluids. This method, however, can find only a very limited application, and in very extensive resections, after which the deglutition is either impeded or for some time rendered altogether impossible, every means hitherto adopted have failed to prevent the flow of blood or secretions into the trachea. For this purpose Professor Nussbaum, of Munich, places pieces of linen soaked in oil over the epiglottis, which, however, it is difficult to keep *in situ*, and which, therefore, will not offer the same protection as Dr. Trendelenburg's method, which I shall describe further on, and which has since been also adopted by Professor Nussbaum.

The results arising from the flow of secretions and fluids

(a) Dr. Trendelenburg is Assistant-Surgeon to the University Klinikum at Berlin, and also Lecturer on Surgical Diseases of Children and on Diseases of the Bones and Joints.

(b) Beitrag zur Lehre von den Resektionen. Archiv. f. Kl. Chirurgie, iii. Die Resektionen, 1862-1865, im Kgl. Klinikum ausgeführt. Ebendas. viii.

into the trachea are the more dangerous as a complete cleansing of the buccal cavity and a perfect disinfection of the secretions can barely be accomplished. Strong solutions of carbolic acid cannot well be applied in the buccal cavity, and frequent syringing with chlorine water and Condry's fluid will not prevent offensiveness of breath. The patient becomes tormented and worn out by the continuous desire to swallow, which he cannot satisfy. A mass of pus and saliva will accumulate behind the tongue in the region of the epiglottis, which tends to prevent the passage of air through the glottis, and renders the reclination of the head impossible. The patient is obliged to pass night and day sitting up in bed in stooping posture, in order to let the fluids, which he cannot spit out—the movement of the lips being too painful—drain off along the back of the tongue and dribble over the pendent lips. Notwithstanding all endeavours to ease this posture of the head by supporting it with cushions and slings, the patient will become exhausted from want of sleep. The fluids, which he is afraid of expectorating by any effort of clearing his throat or coughing, will finally find their way into the trachea without impediment.

Two objections may be raised against the plugging of the trachea, or against the introduction of an impermeable plug within the trachea:—(1st) The great irritability of the mucous membrane lining the trachea, and its intolerance of foreign bodies which have accidentally entered into it; and (2nd) its great tendency to inflammation after such mechanical insults. But there exists a great difference between the effects caused by an instrument carefully introduced through the tracheal wound, of convenient shape and exerting an equal pressure on the walls within the trachea, and those excited by a foreign body which accidentally finds its way through the irritable glottis. The latter is generally irregular, angular or pointed in shape, and loosely moves within the windpipe, and by dropping upon the bifurcation brings on a violent effort of coughing. Thus it is jerked upwards to the spasmodically closed rima glottidis, and again falls against the point of the bifurcation. In this manner, occluding every outlet, it rebounds between the two most sensitive portions of the trachea, like an elastic ball between two walls, until either suffocation takes place or it becomes impacted within one of the bronchi or in one of the sinuses of the larynx. Each inspiration during the spasmodic closure of the glottis causes an ever-increasing rarification of the air within the trachea, and consequent hyperæmia of its lining membrane, which, by the repeated contact with the irregularly shaped foreign body, becomes injured. A severe catarrh of the air-passages is the natural result of such attacks of dyspnoea. Different symptoms will arise when the foreign body becomes impacted soon after passing the glottis. In the latter case there may be no cough or dyspnoea at all, the catarrh may come on very gradually, and the body may remain impacted unnoticed for weeks and months.

Physiology fully bears out these observations. Experiments on animals have demonstrated that the slightest irritation of the inferior surfaces of the vocal cords and of the mucous membrane, as far downwards as the cricoid cartilage, as well as of the bifurcation of the trachea, causes most violent coughing; whilst the whole tract of the mucous membrane between these two parts and that of the bronchi exhibit comparatively little irritability. In children, after tracheotomy in cases of diphtheria, a feather may be introduced into the windpipe for the purpose of clearing away the mucus and diphtheritic pseudo-membranes without causing cough, except when touching the bifurcation or glottis.

The sensibility of the mucous membrane of the trachea rapidly decreases after this operation, as may be frequently observed. A striking instance of the truth of this fact is afforded by the case of a young woman whom I had the opportunity of repeatedly seeing at the University Klinikum at Berlin. She was herself able to introduce a bougie into the larynx and trachea without experiencing pain or irritation. This patient, when 19 years of age, had tracheotomy performed below the thyroid gland in June, 1869, on account of chronic laryngostenosis. Extensive ulcerations of the epiglottis, stridor, and asphyxia had rendered the operation unavoidable. The power of deglutition of solids was unimpaired, but the act of drinking caused a sensation of choking and coughing. The canula was worn until October, when dyspnoea came on again to an alarming degree. It was suspected that ulcerations from pressure of the canula were the cause of this, and tracheotomy was performed by Professor Langenbeck above the thyroid gland, in order to place the canula into a healthy part of the trachea. The tube, however,

could not be passed on account of a stricture of the trachea below the new incision. A minute examination could not be made immediately after the operation, owing to hæmorrhage, which was arrested by plugging the wound with lint. The swelling of the neck, which was considerable during the following days, subsided sufficiently by December 6 to permit careful examination. In order to carry it out under chloroform without danger, Dr. Trendelenburg introduced a small catheter, armed with a tampon, through the old incision, it being impossible to pass the tampon-canula through the callous borders of the fistula on account of its length and curvature. The inflation of the plug caused slight irritation, giving rise to coughing, evidently from its pressure on the ulcerated and tender mucous membrane of the trachea. The anæsthetic was administered through the catheter by means of a funnel-shaped apparatus. A strong callous thickening of the mucous membrane between the primary and secondary incision was discovered. This caused so narrow a stricture that only a very thin bougie could be introduced. A No. 12 bougie, however, could be passed upwards into the larynx. After several attempts to divide the stricture by means of delicate curved bistouries had failed, the trachea having been carefully plugged below the stricture, the latter was treated by Dr. Trendelenburg in the same manner as in the case of the *boutonnière*. The incision was 6·7 centimetres in length, extending from the crico-thyroid membrane to the lower fistulous opening, dividing the anterior wall of the windpipe and the isthmus of the thyroid gland. Owing to the hæmorrhage which followed, the plug was left in during the next twenty-four hours, so that the entry of blood into the bronchi was rendered impossible. The tampon was borne without inconvenience; there was no cough, no irritation or pain below the wound, and the power of deglutition remained unimpaired. Since this time bougies had been passed regularly twice a day, and the patient has herself learned the use of the instrument.

After several unsatisfactory attempts at plugging the trachea above the canula after tracheotomy with sponges, indiarubber balls, etc., Dr. Trendelenburg succeeded in devising an apparatus in which both plug and canula are combined. (c) The tampon consists of a delicate double-walled indiarubber tube of about 3·4 centimetres in length. The walls of this tube are united at their extremities, so as to form a cavity, which is inflated by means of a small tube opening into the external wall. The internal wall closely embraces the vertical portion of the tracheotomy-canula. This tampon, when inflated within the trachea, thoroughly plugs the space between the canula and the windpipe. By letting out the air, the plug again collapses, and the expanded external wall approaches the internal wall. A small indiarubber balloon, with an ivory nozzle, fits into the inflating tube. After inflation, the tube itself is closed by means of a small metal clamp.

The point of the canula is furnished with a raised shoulder of about one millimetre in thickness. A similar shoulder exists above the plug, so that the latter is firmly retained between these two shoulders. By this arrangement the tampon is prevented from slipping when passing through the wound.

(To be continued.)

TRANSMUTATION OF QUOTIDIAN MALARIAL AGUE INTO SYPHILITIC QUOTIDIAN AGUE.

By THOMAS READE, M.B.T.C.D., M.R.C.P. Lond.,
L.R.C.S. Dub.

THIS case was entrusted to my care in the year 1837, and was the first incident which guided me to the study of an unacknowledged form of disease—syphilitic diseases of the nervous system.

Before I narrate the incidents connected with the patient's record and my own intervention in the disease, I beg to refer to the mind and belief existing in the highest range of Medical men, and participated and followed with universal consent by all regular Surgeons and Physicians throughout the empire. The judgment to which I allude was the authoritative dogma, "That constitutional syphilis left the brain intact and uninjured"—by consequence, the whole nervous system in union with or taking its origin in the brain.

Fully impressed with the certainty and stability of this

(c) This apparatus may be obtained at Messrs. Krohne and Sesemann, surgical instrument makers, 8, Duke-street, Manchester-square, W.

credence, I was summoned, in the year 1837, a distance of about twenty-two miles, to visit a gentleman, aged about 32, reduced to a most abject state of bodily prostration. At the time of my arrival at his residence he was confined to bed. He related to me that for eleven years he had been quartered with his regiment in the Ionian Isles, and enjoyed excellent health. About ten to eleven months before I saw him he suffered an attack of ague, a common effect of the malaria of those isles. It became quotidian, and resisted all treatment. Then he was invalided and sent to England on sick leave. When in London he went through the usual inquiries of Medical boards. Physicians saw him in London, but no benefit. He moved to Dublin—to Belfast—seeing Medical men in each place. Deriving no benefit from any advice, he came to the abode of his family, where I was summoned. He was confined to bed, undergoing eighteen hours of fever between cold, hot, and sweating stage every day—six hours' pause alone for rest and food. With such an adverse balance, his existence was almost marvellous. Nearly all substance had been removed from those parts of the body usually covered with flesh. He had been muscular—in fact a fleshy man.

My first examination led to the exploration of the abdomen for the regular, if not ordinary, structural changes concomitant upon protracted ague, such as are met with in cases from America and the fenny districts of England, but very rarely in Ireland, especially in Ulster. The liver and spleen participated in the general diminished bulk. The omental and tegumentary fat on the belly had disappeared. I could lay my fingers into all the forms of the bodies of the lumbar vertebræ. The abdominal aorta was as palpable as in the last stages of phthisis. He told me he could not stand or walk, on account of swellings at his ankles. I probably expected dropsy at the first. No such thing. Each internal malleolus had thrown out a firmly resisting tumour of the periosteum. On the os frontis was a tumour soft and fluctuating, the size of a large half-walnut, which had been opened in the Ionian Isles by a Surgeon, but had filled since. There was a similar one on the occiput.

My examination being concluded, I announced to him that no trace of malarial ague existed, but a positive certainty of syphilis. This imputation he repudiated with the strongest assertions of its impossibility. I said "I will act under your assertion, but *not* according to my own conviction." I ordered twenty-grain doses of quinine in the pause of the six hours, and diet as generous as he could swallow. This treatment was not without relief for some days, but he then sank back into the previous prostration. I now advised his removal to the town of my residence, which was accomplished in two days, resting on the road. I then commenced, under my daily observation, the effect of arsenic, which I gradually advanced to ten drops of Fowler's solution three times a day. This also, like the quinine, mitigated his attacks; but he became so much worse that I removed him to a seaport town, where there was admirable accommodation for an abode. This was a complete failure, although a district more free from malarious miasma does not exist. On the fourth morning of my visit, after three nights of torment and without sleep, he refused all food. The catastrophe was drawing hopelessly to a few days' distance, when he made to me the following revelation:—"I wish to tell you something which came into my head during the miserable watches of the night. Just at the time I began to be unwell and out of sorts, I changed my lodgings in the island. I had, unfortunately, made some amatory indications to my landlady. Being accepted, they were followed up by a very reluctant amour. I was now daily visited by a Surgeon of one of the regiments on account of my shake. After some days, I asked him to examine a small sore in the pubic region. He touched it with nitrate of silver. This ministrations closed the history of the sore. There never was again any visit with reference to it (the sore)." He added, "I know it can have no reference to my present state, but I thought it right to mention that which only came to my memory last night." I replied, "That information is to me absolutely conclusive, and on it I will immediately act." I summoned his servant, and gave him exact instructions for rubbing in fifteen grains of mercurial ointment on the inside of each thigh on alternate nights. He slept throughout the third night, and ate a fair breakfast next morning. Fourth night sixteen hours' sleep, followed by an insatiable desire for food. The nodes on the malleoli were so relieved that he walked in his room.

The fifth day from the mercurial inunction found him free from all intermittent febrile action, which never returned. He suffered from many of what have been called the accidents of tertiary syphilis for a year, which yielded principally to hydriodate of potash. The fluctuating effusions of the pericranium

were rapidly absorbed. I made no reference to this case in 1847 or in 1852.

I considered, in the cases of syphilitic meningitis, I had strained my credit for correct observation sufficiently. For many years after 1852, men honestly told me they believed I had been mistaken, as they had seen no cases to sustain mine; consequently, I waited the growth of knowledge on this subject before I reported a case of such extreme interest, and so far apart in physical and descriptive demonstration, but in essence identical with the cases previously published—all being products of the syphilitic poison, and cured or abated by the same specifics.

Belfast.

REPORTS OF HOSPITAL PRACTICE

IN

MEDICINE AND SURGERY.

MIDDLESEX HOSPITAL.

OPERATIONS ON WEDNESDAY, APRIL 24.

There is always an abundance of important and instructive material for the Surgeon as well as for the Physician in the wards of this Hospital, but on Wednesday last, on a visit to the operating theatre, we had the opportunity of witnessing operations upon four cases which presented features of very considerable interest. For notes of these we are indebted to the individual courtesy of the respective Surgeons, as well as to the remarks which fell from them in addressing the students and visitors in the theatre:—

Case 1.—Excision of the Hip-joint for Disease of Five Years' standing.

The first operation was the excision of the head of the femur in a delicate strumous-looking lad, much emaciated, with a large head and waxy-looking skin, aged 11 years. The commencement of his illness dated back five years, when he injured his right hip-joint by falling upon it when jumping from a cart. He had been in University College Hospital, and in the Children's Hospital, Chelsea, and has been unable to walk since August, 1870. On his admission, on February 27, 1872, under Mr. Hulke, there was some swelling and tenderness about the joint, pain (referred to the knee-joint), and a sinus discharging pus on the front of the thigh. For a short time he obtained relief and seemed to improve by extension of the limb, but latterly he had been declining in his general health. In performing the operation, Mr. Hulke (as he usually does in excising the hip-joint) made a semi-lunar incision above and posterior to the great trochanter. This he commenced at the mid spot of an imaginary line from the anterior superior spinous process of the ilium to the top of the trochanter, and then continued it above and afterwards along the posterior margin of the great trochanter. This incision was from three to four inches in length, with its concavity looking downwards and forwards. After the soft parts had been separated from the trochanter, and the capsule of the joint laid open, Mr. Hulke made the necessary movement of the limb for turning out the head of the bone. Although no unusual degree of force was used, the femur gave way, snapping in sunder between the hand grasping the bone and the knee-joint. This was temporarily set in two side-splints, and the operation proceeded with without any difficulty, by sawing through the bone immediately below the great trochanter, and then removing it with a pair of Lion forceps. On looking at the portion of the bone excised, it was seen that the cartilage had been completely removed by ulceration, leaving softened carious bone projecting into the joint. Around the margins of the head little papillæ of new bone were studding the surface. Mr. Hulke remarked that these no doubt had been thrown out during the time of the patient's improvement, and had given rise to the greater fixity of the limb at the time when hopes of anchylosis were entertained.

Case 2.—Hard Cancer of the Breast—Excision.

The second operation was the removal of a scirrhous tumour from the right breast of a woman, aged 45, under Mr. De Morgan's care. In his remarks Mr. De Morgan stated that the growth had been noticed between five and six months, that pain soon afterwards was suffered, and was most intense during any movement of the arm. Her general health previously had been good, and there was no history of injury to the

breast nor of cancer or phthisis in her family. The tumour was fairly well circumscribed, very hard to the touch, of the size of a walnut, and was situated at the outer side of the breast. The skin over it was faintly dimpled by adhesion, but everywhere over the breast the skin was of very unusual thinness, and the breast-tissue remarkably abundant in quantity. This gave rise to a difficulty in the operation, as extreme care was required in dissecting the integument off from the glandular tissue. After the excision of the breast was completed, the edges of the wound were brought together by carbolic silk sutures, and the whole dressed with Lister's gauze and protective. The section of the tumour confirmed the diagnosis of hard cancer. It presented the well-known firm yellowish-white striated and concave surface, passing indistinctly into the surrounding breast-tissue; here and there were extended across it some lactiferous ducts distended with semi-solid secretion.

Case 3.—Extirpation of Tumour from the Antrum of Highmore.

This was a man, aged 65, who was admitted into the Middlesex Hospital, under the care of Mr. Lawson, on March 18, 1872, suffering from a tumour of the upper maxilla. The man stated that the growth first showed itself about four months ago, since which time it has steadily increased. On his admission there was a soft, elastic swelling about the size of an egg over the left upper maxilla; there was a bulging between the lip and alveolus, corresponding to the canine tooth, but there was no protrusion of the palate or closure of the left nostril. An exploratory incision made through the protrusion in the mouth found the antrum filled with a soft growth, which broke down under the finger, and had very much the appearance of recurrent fibroid. The whole of the anterior wall of the antrum was absorbed. Two or three days after his admission an erythematous blush attacked the face, the skin over the tumour became shining and red, then ulcerated, and the tumour from within the antrum burst through. All swelling and œdema of the surrounding tissues now subsided, but the tumour grew with great rapidity, and in another fortnight presented a prominent fungating surface, from which there was a constant discharge. The growth was so rapid that there was a visible increase from day to day.

As there was much of the skin now involved Mr. Lawson decided to try to extirpate the disease partly by cutting and partly by caustics. He accordingly first excised all the diseased structure from the antrum, then freely applied the actual cautery, and lastly lined the walls of the cavity with the chloride of zinc paste spread on pieces of lint. A subcutaneous injection of morphia was then given.

Case 4.—Amputation through the Condyles for Chronic Synovial Disease of the Knee-joint.

This patient was a strong and otherwise healthy man, aged 35, under the care of Mr. Lawson. He had been discharged from the Royal Artillery on account of an accident to his knee-joint three years ago, when he received a blow on the knee while at gun exercise, and soon after the joint became so painful and swollen that he was unable to work, and was under Surgical treatment for three months. He remained pretty well from this time till a short while before Christmas, when the joint again commenced to swell. It was not very painful, but he was unable to walk upon it. Lately it has been contracting, and on admission (March 15, 1872) the leg was bent at an angle to the thigh; the knee was much enlarged, and measured fourteen inches and three-quarters, as against eleven inches and three-quarters on the opposite side; there was much wasting of the muscles of the leg and thigh. No fluctuation was detectable, but everywhere a doughy, gelatinous feeling was given. The movements were very limited, and the patella was fixed to the front of the condyles of the femur.

Mr. Lawson amputated through the condyles, employed Teale's flaps, torsion for the popliteal artery, and lint dipped in carbolic oil for the stump.

On examination of the joint after removal, the disease was found to be chiefly seated in the synovial membrane, which was everywhere soft, pulpy, and vascular, and in some places readily breaking down into small gelatinous masses. The crucial ligaments were considerably destroyed, especially the anterior—the portion of this attached to the tibia alone remaining, and this was soft and pulpy, like the synovial membrane. The extreme margins of the articular cartilages were ulcerated, and in the outer articular facet of the tibia was one small spot where the cartilage was nearly ulcerated through, and the bone beneath for about one-eighth of an inch was

soft and carious, approaching nearly to the condition of a small abscess. The bones elsewhere were healthy.

Mr. Lawson stated that the case was one altogether favourable for excision of the knee-joint; but as the nature of the two operations had been explained to the patient, he, being anxious to be about again as soon as possible, preferred amputation to excision. A subsidiary consideration also had some influence—namely, as the man was an invalided soldier, who had met with his injury while on duty, he would obtain a pension for life if his leg were lost to him by amputation, but only for a few years if it were preserved by excision.

GUY'S HOSPITAL.

OPERATIONS ON APRIL 26.

[For the following notes we are indebted to Mr. Higgens.]

Case 1.—Chronic Inflammatory Enlargement of the Testicle—Removal.

This patient was a healthy adult, 35 years of age. The body of the left testicle was enlarged to about the size of a goose's egg; it was irregular in outline and soft in some parts. The disease had commenced five months previously after a blow. A puncture had been made at one of the soft points, but only blood escaped. Mr. Bryant stated that he had some doubts as to the nature of the swelling, whether it was simple inflammatory enlargement or a malignant growth, but that as the testicle was only a useless encumbrance he had determined to remove it as a matter of expediency. A longitudinal incision was made over the tumour, which was then turned out without difficulty. The spermatic cord was secured by a whipcord ligature passed round the whole of it. The wound was closed by silk sutures. On section the enlargement was found to be of a simple inflammatory character.

Case 2.—Amputation at Knee-joint for Epithelioma of the Leg.

Male, aged 30, suffering from epithelioma of the leg. On the front of the leg was a large ulcer, measuring four inches and a half in length by three and a half in width, the edges raised, everted, the surface foul, and covered by offensive discharge. The disease had developed itself on the seat of an injury received twenty years ago. Mr. Bryant first cut a posterior oval flap of medium length, including only the skin; next an anterior flap rather longer, consisting also of skin, the patella being removed. He then divided the soft parts at the back of the joint vertically; the joint was then opened from the front, and the limb removed. The vessels were secured by torsion, the flaps brought together by silk sutures, a piece of dry lint applied, the limb firmly strapped to a short back-splint, and the whole enveloped in a fold of cotton-wool secured by a bandage.

LONDON HOSPITAL.

CASE OF DISEASE OF THE BRAIN—LEFT HEMIPLEGIA—MENTAL AFFECTION.

(Under the care of Dr. HUGHLINGS-JACKSON.)

A PATIENT, 56 years of age. His mind is much impaired, but he has mind enough to frame delusions. A recent fancy is that he wishes to be killed. The most striking feature in his case has been an inability to recognise places and persons. At one time he did not know his own wife; he gave his watch away, and having wandered from home was unable to find his way back. But at the present time he is better, and can name things he sees in pictures, and can read. There seems now to be only a general imperfection of mind, hebetude, and slowness. His wife reports that he has called things by wrong names. Such blunders may arise either from non-recognition of the thing to be named, or from inability to find the name of it.

He has recovered from left hemiplegia—a symptom which, in the vast majority of cases, points to disease of the right side of the brain. In many cases of left hemiplegia there is no striking mental affection. But this patient's palsy was of the rarer kind, in which the leg is more affected than the arm. Trousseau has spoken of the evil omen of cases of hemiplegia in which the leg suffers more than the arm—or, rather, of cases in which the arm recovers, the leg remaining paralysed. He appears to refer—in part, at least—to mental affections. Dr. Hughlings-Jackson supposes that the lesion in his patient is in the right posterior lobe. As there has been severe carache of the right side, and as there is deafness of that side, the lesion is possibly cerebral softening or abscess from plugging of veins. The hemiplegia came on after the

But even if the language were clear as crystal, the things which the scholar has to learn of are to him the vaguest abstractions and nonentities. The ideas of abstract carbon, of oxygen, of chemical affinity, of the production of heat and force, of nitrogen, are most difficult to conceive; but then in treating of physiology we have not these elements merely, but their most complex compounds. Moreover, the ideas of quantity and bulk which are used in physiological teaching are inconceivable; the untutored mind can form no conception of blood corpuscles $\frac{1}{5000}$ th of an inch in diameter. Without a microscope these things are myths—and how are microscopes to be multiplied for the million?

We are very familiar with the working of a national school, in which the master, encouraged by a Privy Council regulation which allowed physiology to be taken up as an extra subject, set to work with Huxley's "Lessons in Elementary Physiology," a work "intended to serve the purpose of a text-book for teachers and learners in boys' and girls' schools." The structure of the mammalian frame and its various tissues and the chief organs were taught from the book, and shown by means of dead rabbits and such other specimens as came to hand. The boys are of a class far above those in ordinary schools, for most of them become upper servants, lawyers' clerks, and shopmen. In due time the examination came. Some very simple questions were asked on the tissues, the circulation, and so forth; but the answers were so ridiculous that we don't like to quote them. Thus a great deal of time had been worse than wasted. A friend of ours soon afterwards visited the school, and condoled with the master on his failure, and, being interested in education, asked leave to hear the first class read. A reading lesson was chosen from one of the reading-books most in use—it was the story of a tame lion. The boys read pretty fluently, and at last came to a sentence with the words, "when he had completed his ablutions." "Stop!" said our friend. "Tell me, my boy, what do you mean by 'when he had completed his ablutions'?" The boy did not know—nor the next; but a sharp lad below held out his hand in sign that he had an answer ready, and so, being told to speak out, said, "When he'd done his dinner, sir." These were the boys who had been studying elementary physiology!

As things are now, we believe the best plan is to teach such palpable facts as can be vouched for by the senses, and let the science alone till the scholars shall have learned its language, and something of the chemical and physical forces. To attempt to teach physiology without these is like the Laputan plan of beginning to build a house at the top.

COOKERY BOOKS.

We have before us three cookery books—one, very cheap and compendious, written by a Physician who appears to have lived some time in America, (a) and who has written a book in which he professes to tell people how to live on sixpence a day; the others, (b) works of some pretension, intended for people who not only *feed* but *dine*. The second on our list is intended for people who have large incomes, or who would be thought to have them, and teaches the uninitiated how to order a dinner at a Parisian restaurant. Moreover, it is said to be written by the joint labour of a cook and a Doctor, and aspires at the union of feminine delicacy with manly philosophy. The third (c) professes to be written with a view to "extending culinary instruction to the smallest kitchen of the most modest housekeeping." But it might certainly be used as a manual by the *chef* of a duke, a banker, or a brewer. The English

(a) "How to Cook." By T. L. Nichols, M.D., Author of "How to Live on Sixpence a Day." London: Longmans. 1872.

(b) "Wholesome Fare; or, the Doctor and the Cook: a Manual of the Laws of Food and the Practice of Cookery." By Edmund S. and Ellen J. Delamere. London: Lockwood and Co.

(c) "The Household Cookery Book. Practical and Elementary Methods." By Urbain Dubois. London: Longmans.

and the flavours are alike Gallican, and the bills of fare for dinners, with the wine for each dish, are worthy of the *Trois Frères*. We will begin with Dr. Nichols's, and may say that without doubt it contains many recipes that may be useful to young housekeepers, and there are many sensible remarks in it; but it is sadly contaminated by Purist and Rationalistic errors.

To begin. The first thing a Physician would desire to see in a cookery book is a good method of preparing beef-tea; a thing which is food and remedy in one, and on which the life of a patient more often depends—in fever, exhaustion, and hæmorrhage—than on almost anything else. Now, we look at Dr. Nichols's book, and with a shudder read what follows:

"*Beef-tea*.—Cut a pound of beef into small dice, which put into a stewpan with two small pats of butter, a clove, a small onion sliced, and two saltspoonfuls of salt. Stir the meat round over the fire for ten minutes until it produces a thickish gravy, then add a quart of boiling water, and let it simmer at the corner of the fire for half an hour, skimming off every particle of fat; when done pass through a sieve. If wanted plain, omit the vegetables and clove; the butter is taken out in skimming; pearl barley, vermicelli, rice, etc., may be served in it if required. A little leek, celery, or parsley may be added."

Where the author can have lived, or what kind of diseases he has been in the habit of treating, is a mystery; but we gratefully believe that there is no workhouse or Hospital in England where such a mess would be given to the sick under the name of beef-tea. This liquid ought to be a simple solution in water of all that water will dissolve of the constituents of muscular fibre; and if prepared in perfection, should also contain in the form of sediment all those albuminous portions which are soluble in cold water but coagulated by heat. For this purpose the flesh should, to begin with, be finely minced, and infused in cold soft water. We need not repeat Liebig's directions, which ought to be like household words, but may say that to begin by cutting the meat into lumps and frying these in butter with clove and onion is enough to make Mrs. Gamp turn in her grave. So much for beef-tea.

In the next place, the author sets out with that cardinal wrong proposition which is the source of most of the absurdities in books of medicine and cookery. He affects to reason *à priori*, forgetting that every true Physician and cook must confess himself empiric, and ought to argue from the results of experiment. "A healthy gastronomy must be founded upon a sound physiology," etc., etc., says our author, just as some Physicians say that successful treatment must be based upon sound pathological principles! If they would but rub their eyes, they would see that sound physiology and pathology must agree with what has already been taught by successful cookery and treatment.

The next point on which cookery and dietetic writers are delirious is brown bread. They wish us to go back to the coarsest unbolted wheaten meal, forgetting that it would be utterly indigestible and pernicious to a majority of town-people. It may be used as a medicine against constipation, and possibly against bone-softening; but as a general diet it is impossible.

Their next maniacal attack is against suppers. Of course a heavy indigestible meal may be worse in the evening than at noon—it is good at no time; but common sense shows that people who are obliged to work hard and eat little all day are infinitely the better for a good nutritious meal in the evening, whether it be called dinner or supper. Invalids who act by the advice of Dr. Nichols, and abstain from supper, although they dine early, are often kept awake by flatulence, sinkings, and cold feet; and we affirm from positive experience that where no supper is taken a dose of "ginnums and water" is often the substitute.

In the next place, these maniacs rave against all fat articles of food. Pie-crust, which in a respectable house is a nicely made biscuit-like or flaky compound of the finest wheaten flour and the purest butter, offering a resemblance as a solid to that

milk which the purists take as a type of all food, is universally condemned. "All greasy food," says the oracle before us, "is to be avoided. Fats—and especially animal fats and fats exposed to much heat—are very difficult of digestion, clog the liver, and overload the whole glandular system." Pork in any form is worse than doubtful; salmon, mackerel, and eels, etc., are also tabooed by Dr. Nichols.

We wonder that even people so hoodwinked as cookery and diet scribes cannot see how utterly false and mischievous are these dicta—mischievous, that is to say, if they were acted upon, which, thanks to common sense, they are not. The practical Physician knows that fat in some shape is the only means of combating some of the direst diseases; and if cod-liver oil seem the fat of Medical predilection, others answer the same purpose, though not so well. But if cod-liver oil may be taken by the spoonful, why may not oily fish and pork be eaten? The common tirade, too, against salted and smoked meats may be answered by saying that they are relishes. Half an ounce of ham may enable an invalid to eat five or six ounces of bread, which otherwise he would loathe.

In the next place, there is the thoroughly unpractical nature of many of the rules laid down. "Our food," says Dr. Nichols, "should be pure, healthy in its own character, free from noxious adulteration, adapted to the requirements of the human system, bland, unirritating, not too concentrated in nutriment, nor heterogeneous in mixture," etc. What human being was ever the better for platitudes like these? How is a poor devil to know whether his food is heterogeneous? Is veal-stuffing heterogeneous? Is Dr. Nichols's beef-tea heterogeneous? If not, what is? So, when the author says "No hard work, mental, or physical, should be done for at least half an hour before a meal and an hour after, . . . no cold bath should be taken either soon before or after eating," how can a family at the seaside put this rule in force if they want a dip before breakfast and a good healthy walk after it?

The more ambitious work, by Edmund S. and Ellen J. Delamere, which we have included in this notice is free from some of these faults. The formulæ for beef-tea are good, though what Liebig taught is ascribed to a Mrs. W—, and to two or three Physicians whose modesty, we are sure would not allow them to claim what they never invented. Both books concur in condemning the exaggerated nonsense talked about essence of meat, as though 100 grains of nutriment could be more than 100 grains anyhow, or as if the juice of meat could be a substitute for the substance. Dr. Delamere's work takes cognisance of the dietetic value of fat, and is enthusiastic in praise of the flesh of the pig. "The Doctors waste their breath with preaching that his flesh is indigestible, heavy, and laxative. . . . Everything belonging to the pig is good." Dr. Delamere evidently surveys man and food from a higher and more generous standpoint than Dr. Nichols—in fact, he runs into the opposite extreme of giving formulæ too complicated, expensive, and impracticable. For instance, Brillat Savarin has a well-known recipe for the concoction of a restorative soup, and he makes his recital piquant after his own fashion by introducing the case of a too obsequious husband in a state of complete exhaustion, from a cause that may be guessed at. His soup is made out of vegetables fried in butter, an old cock, suga candy, and powdered amber. Now, we know well enough that it is only the French who believe that exhaustion can be cured by sugar, and the notion of the virtues of amber belongs to the past generation; so what are we to think of the practical experience and common sense of people who reproduce this foolish and troublesome formula, and call it the "Elixir of Life"?—or of the chemical skill of a person who ascribes the virtues of the soup to the meat being more highly charged with caloric! Cookery books are sometimes given to young ladies on their marriage, and it is quite possible some young wife may ask what it is that Edmund S. and Ellen J. Delamere give cautions about at the end of their

description of the elixir. Why did not they give us Brillat Savarin's piquant story of the young couple who had up a cold poulette and wine at two in the morning?

To cook food is an art learned from experience—to reason on organic chemistry pertains to a science that is fluctuating; and surely, when we seek books to learn how to cook, we don't want to be dosed with second-hand scraps of popular food lectures. In fact, just as a treatise on anatomy and pathology would be disgusting at a dinner-table, so disquisitions on chemistry, the exploded twaddle about *heat-producing* and *flesh-forming* articles of food, dissertations on intestinal worms, and quack recipes—"Hooping-cough simply and quickly Cured," "How to Cure Chilblains," etc.—are out of place in a cookery book.

We have left ourselves but little space to notice M. Urbain Dubois. This artist does not give us a receipt for beef-tea but his soups are as numerous as our English religions. His stock-pot, or *pot-au-feu*, made with five pints of water to a pound of meat, with vegetables, and five or six hours' simmering, is doubtless an excellent prescription for a clear and abundant broth which need not be very "succulent," but would hardly do for the sick. His prescription for pectoral broth made with a fowl—the body-bones, pinions, *paws*, and crop, all well cleansed—with marshmallow or althéa-root and pearl-barley, might be worth trying. The fowl is to be covered with three or four quarts of water, and is to be boiled for three hours.

We may conclude with a suggestion which we humbly venture to think would tend to the infinite advantage of the civilised world. It is that, when the Ballot Bill is settled, a measure shall be introduced into Parliament for the erection of an Institution for the especial treatment of persons afflicted with those theories which lead to the exanthematisation, or blossoming-out, or eruption of "Popular Treatises on Diet," "Remarks on the Classification of Foods," etc., etc. The patients admitted should dine at a common table; we should place a distinguished member of the Poor-law Medical Service at one end of the table, and a distinguished Coroner at the other. The inmates should order the dinner in turns, and have full scope for putting their peculiar theories into practice; and they should not be allowed to leave the walls till they had come to a state of unanimity as to the theoretical value and the best practical mode of dealing with food.

THE WEEK.

TOPICS OF THE DAY.

THE favourers of the woman's franchise agitation met with a serious check in the House of Commons on Wednesday last. Honourable members who had voted for Mr. Jacob Bright's Bill last year have discovered since that time that the whole agitation is fictitious, that it has been raised and kept up by a few foolish, conceited, querulous women and womanly men for their own purposes, and that it is by no means in favour with the great mass of the sex itself—nay, that it is utterly repudiated by those who most adorn, by their virtues and influence, our English homes and hearths. We have no doubt that, could the woman-Doctor outcry be submitted to the same test, it would be proved to be in reality as utterly contemptible. It may be quite true that half a dozen or half a score of women whom circumstances may exclude from family life want to be Doctors, but we utterly deny that there is one in ten thousand of English women who would prefer a woman to attend them, or who would feel anything but dislike for one of their sex who had gone so far to unsex herself as to dissect the human body in company with men. The fact is that these women-questions have had their origin in the same pestilential moral atmosphere which has produced those pleasant flowers of free love, easy divorce, and abortion-mongering which threaten to reduce American society to a far worse state than Roman was in the time of Juvenal, and compared with which the

rough virtues of our Teutonic forefathers before the introduction of Christianity constituted a golden age.

The length to which fanaticism will carry a party was never better exemplified than by the following quotation from a recent article in favour of female franchise in the *Fortnightly Review*, quoted by Mr. Bouverie in Wednesday's debate. Surely the article must be grave irony. If not, the writer had better turn his attention to enlisting some of our surplus female population for the service of the King of Dahomey—

"Some women are allowed, under the pressure of necessity, to teach, or to write for the press, or, if they have very great energy, to profess Medicine; it only remains to allow all who have the necessary material inducement to enter the Civil Service (where Mr. Gladstone is evidently prepared to let them have clerkships cheap), the army, the navy, the universities, and any other learned or lucrative profession they may fancy."

The writer went on to say—

"Undoubtedly when women have seats in Parliament and on the bench they will also hold commissions in the army, and it may even be surmised that the profession of arms will be rather a favourite with them than otherwise; for military glory has more in common with the aims which they have hitherto encouraged to pursue than any inducements held out by learned or commercial careers. The few cases on record of women who have disguised their sex in order to enter the army offer no criterion as to the number who would do so when the necessity for secrecy was removed. The contrary assumption is so much the creation of habit that it is scarcely possible to argue either for or against it. The physical strength of women is the principal difficulty contemplated, but it is obvious, quite apart from the effect of education or training, that the women of some races are taller and stronger than the men of others; and if that consideration appear too remote, it could easily be ascertained how many maids-of-all-work in London work harder than a dragoon. But it is supposed that women will be particularly influenced by the reluctance which we all feel at the prospect of slaughtering our fellow-creatures. Similarly it was held quite recently that they could not—it is still thought in some circles that they should not—cut off babies' legs. Now, to shoot an invader, who may be out of sight, and to cut off a baby's leg are both painful Surgical operations, which no right-minded person would perform except for the benefit of the infant or the fatherland; but there can be no question as to which of the two is most trying to the nerves and harrowing to the sentiments. Unless antiquity—as is possible—was quite mistaken as to the natural instincts of the female sex, it will prefer the science of destruction to the art of healing."

Professor Odling, F.R.S., Professor of Chemistry at the Royal Institution, and Vice-President of the Chemical Society, and Mr. Vernon Harcourt, Lee's Reader of Chemistry at Christ Church, are amongst the candidates for the Professorship of Chemistry at Oxford, vacant by the retirement of Sir Benjamin Brodie.

Dr. Alfred Carpenter, of Croydon, has published a letter in the *Times* of Tuesday last, in which he contradicts the statements recently made as to the bad effects of the Croydon sewage farm on the health of the neighbourhood. He writes—

"Will you allow me to state the following statistical facts, which speak for themselves, and do not require opinions or theories to support them? They have been obtained from the reports of the registrar of the sub-district in which the farm is situated, and which district is in close proximity to three sides of it, the fourth side being the town of Croydon itself. It includes also the Beddington Female Orphan Asylum. The births during the year ending April 1, 1872, were 97, giving a birth-rate of about 33 per thousand; and the death-rate during the same period has been 9 per thousand only. The deaths registered have been 27, and do not include a single case of fever. I have given the statistics for the year just ended, as that is the first time the births have been reported. They have reference to a district in which a large sewage farm has been in operation for nearly twelve years; and, after such evidence, I trust we shall hear no more of the assumed unhealthiness of sewage farms."

A telegram published in the *Times* of Thursday announces the safety of Dr. Livingstone. He is said to be with Stanley,

but the name of the place is unintelligible. The news comes from a native source *via* Zanzibar.

We publish in another column a list of subscriptions for the purpose of raising a fund as a provision for the widow of the late Dr. Day, of Torquay, formerly Professor in the University of St. Andrews. Dr. Day's services to Medicine render this case an exceptional one. He was prevented by many years of ill-health from making anything more than a very insufficient provision for his wife and family. During this time our readers were indebted to his perseverance and indomitable energy for some of the most valuable scientific articles which have appeared in our pages. We trust that they will supplement the fund that has already been raised for maintaining in a modest independence the widow of so excellent a Physician and praiseworthy a man.

PATHOLOGICAL SOCIETY OF DUBLIN.

THE thirty-fourth annual session of this Society was brought to a close on Saturday, the 27th ult. The specimens presented on the occasion were numerous, and of peculiar interest. They included a case of idiopathic endo-pericarditis, shown by Dr. Johnston; an enormous round-celled sarcoma engaging the right kidney of a boy only 5 years of age, exhibited by Dr. Evelyn Little; the dissection of the very rare luxation of the sternal end of the clavicle upwards, forwards, and inwards, detailed by Dr. Robert W. Smith; a case of general mollities ossium by the same distinguished Surgeon and pathologist; four urinary calculi removed by crushing, presented by Mr. G. H. Porter, Surgeon to the Queen; an example of abscess, resulting apparently from old encysted hydrocele, brought forward by Dr. Barton; a large intestinal cyst which resembled ovarian disease, exhibited by Dr. James Little; and a remarkable specimen of glioma of the brain submitted by Dr. Evelyn Little. In this last case paralysis of the third, fourth, fifth, sixth, and seventh nerves of the affected side had existed during life. The President, Mr. Joliffe Tufnell, delivered a short but impressive address, in the course of which he announced with regret that there had been no competition for the gold medal annually given by the Society for the best essay on a subject of Surgical or Medical Pathology. There was present a very large assemblage of members and of students, by whom the President's remarks were received with rapt attention.

WHAT IS TO BE DONE?

SMALL-POX is rampant in some parts of Ireland, and is spread to a fearful extent by the refusal of persons affected with the disease to go into Hospital. What is to be done in such a case? We cannot fine the person who so refuses as we can the father of a child who refuses to have that child vaccinated. We understand from the *Cork Examiner* that the eminent firm of Sir John Arnott and Co., brewers, of that city, have resolved upon taking a decided step to counteract the hostility alluded to. A list of the *employés*—about 152—has been supplied to the Medical Officers of the different dispensary districts, with a request to report to the firm each case where there is a refusal to send a small-pox patient to the Hospital. This refusal will be visited by the immediate dismissal of the offender. "This," says the *Examiner*, "seems a very rigorous course, and we would much prefer that the people were made to accept voluntarily the aid; but when it is remembered that every small-pox patient kept in a poor, ill-ventilated dwelling is spreading a deadly poison round, the time seems to have come for very strong measures, even measures so strong as this. We cannot afford to have the disease spread amongst us to gratify any prejudices." We agree with our worthy contemporary, who has thorough Irish humour as well as thorough Irish sense. We might ask the *Examiner*, if we wished to be critical, what he means by "the people being made to accept

voluntarily”? But it is, no doubt, an Irish phrase well understood in Cork. At all events, it is as easily understood as Lord Castlereagh “turning his back upon himself,” or “standing prostrate in the presence of his sovereign.”

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.

THE annual general meeting of the above Society was held in the Council-room of the Royal Medical and Chirurgical Society, 53, Berners-street, on Friday, April 26. Mr. Charles Hawkins, V.P., was in the chair. The Secretary informed the meeting he was desired by the President, Dr. Burrows, to express his regret at not being able to take the chair, unavoidable absence from town being the cause. From the statement of the affairs of the Society, it appeared that the available receipts for the past year amounted to £2936 13s. 8d., the grants to £2606, the expenses to £247 10s. 6d., and the total expenditure to £2853 10s. 6d., leaving a balance of £83 3s. 2d. in favour of the Society. During the year 9 new members had been elected, 17 had died, and 10 had resigned or ceased to be members; the number of members at the end of the year being 411—a decrease of 18 on the previous year. Four widows and 7 children had been added to the list of recipients of grants, and 4 widows and 14 children had died or become ineligible for relief; the number on the books being 55 widows and 43 children. Information had been received by the acting treasurer that the Society would benefit by two legacies—one of £200 stock, duty free, left by Mrs. Ann Hammond; the other of £500, duty free, from Mrs. Jane Lyon. The meeting was special to consider the proposed repeal and alteration of some of the by-laws. It was resolved that by-law 15, imposing a fine on members remarrying, should be repealed; also that by-law 68 should be repealed, and a new by-law be enacted in its place, viz.:—“In case of life members it shall not be necessary for such members to have lived two years after having paid a life subscription to render their widows and orphans eligible for relief.” A vote of thanks to the Royal Medical and Chirurgical Society for their kindness and liberality in granting accommodation to the Society, rent free, was carried unanimously. A requisition was signed by seven members for a special general meeting, to confirm or not the repeal of the by-laws and the new by-law as resolved at the meeting. The proceedings terminated by a vote of thanks to the chairman.

SEA-WATER IN LONDON.

BESIDES the proposal to which we referred last week for bringing sea-water to London from Brighton, we understand that a plan has been set on foot for conveying it in lighters from a point sufficiently beyond the mouth of the Thames to secure freshness. The supply thus obtained will be delivered into floating baths situated at convenient and accessible points on the river, and it is anticipated that a salt plunge will be obtainable at so low a rate as sixpence; the water, nevertheless, being entirely changed every other day. The cost of delivering sea-water in this manner into baths situated in the London district is estimated not to exceed 1s. 3d. per thousand gallons.

MORTALITY IN HOLLAND.

WE give elsewhere a table, with which our correspondent has favoured us, of the vital statistics of twelve of the largest towns in Holland during the year 1871. It will be useful to compare it with our own Registrar-General's tables for the English towns. The enormous mortality from fever and small-pox are most striking, but it is said that typhoid is more prevalent in the towns under 10,000 inhabitants, and this is ascribed by Dr. Egeling, the Medical Inspector, to frequency of dung-yards in close proximity to the houses.

DIGESTION OF CALOMEL.

IN his recent lecture on “Diet and Medicine,” Dr. Symes Thompson showed that some drugs undergo a process of solution within the body analogous to that which food passes through under the influence of the digestive juices. With the assistance of Professor Heaton he demonstrated Tuson's experiment on calomel. In one vessel (α) calomel and hydrochloric acid were placed, and in another (β) calomel, acid, and pepsine. After digestion for two or three hours at the temperature of the blood (care being taken that the heat should not rise above 140° Fahr.), the contents of both vessels were thrown on filters. The filtered liquid from the second (β) gave a black precipitate with sulphuretted hydrogen, showing that pepsine had rendered the calomel soluble, while the liquid from the first (α) was unaffected by the gas. This experiment has served to remove much of the difficulty previously felt of accounting for the effect of a salt insoluble in acid, and is of value as showing why calomel does not produce its characteristic effects in cholera and other conditions in which the digestive powers are in abeyance, or when the active ingredients of the gastric juice are wanting.

DR. BRISTOWE ON “PREVIOUS SEWAGE” IN THAMES WATER.

DR. BRISTOWE, the able Medical Officer of Health for Camberwell, has issued a report on the water supplied by the Kent, the Southwark and Vauxhall, and Lambeth Water Companies, in which he follows the consolatory guidance of Letheby, Taylor, Whitmore, and Major Boulton, instead of the alarmist tone of Dr. Frankland.

“It must not be presumed,” he says, “that the organic matters which are detected in river water come to us in the form in which they first reach the river; it is not the organic matter as it lies on our fields, or as it leaves the pans of our water-closets, which reaches us. Its large dilution by the running oxygenated water into which it passes effects the most important chemical changes in it; so that before long, that which was sewage is no longer sewage, but merely the inert chemical derivatives of sewage—it is no more sewage, in fact, than vinegar (which has been formed from beer) is beer, or than sugar (which has been formed out of starch) is starch still. Dr. Frankland (than whom there is no more determined opponent to the employment of Thames water for drinking) fully recognises this fact, and nowhere ventures to call any portion of the organic matter found in the waters supplied by our Thames Water Companies, sewage: he ventures only to designate a portion of it as ‘previous sewage or animal contamination.’ Many chemists believe, and I believe also, that he exaggerates the proportion of organic matter due to this cause, and yet he says of it—‘by gradual oxidation this animal contamination has been, so far as analysis can show, converted into innocuous inorganic compounds, before the water was submitted to investigation.’ You will clearly understand, therefore, that even that water which you were receiving from the Southwark and Vauxhall and the Lambeth Companies, in January and February last, imperfectly filtered though it was, and containing as it did an exceptionally large quantity of organic and other matters, was still not in any proper sense of the term ‘merely extensively diluted sewage,’ and that still less were you then ‘simply drinking the sewage matters poured into the river by all the town and farm drains along its banks.’ You were drinking a small amount of organic matter (roughly speaking, perhaps, one grain in 100,000 grains) dissolved in the water, of which a small percentage was doubtless traceable to sewage, and might be said to be due to ‘previous sewage contamination,’ but which was, I repeat, in no sense ‘sewage.’”

A DANGEROUS OPERATION.

A CASE which excited considerable interest was heard at the Sheriffs' Criminal Court, held at Dundee on Monday. A Surgeon was charged with having pulled out a boy's tooth against his will. He pleaded guilty. It was explained that a number of boys had annoyed the Doctor, and that he seized one of them, took him into his house, and extracted one of his front teeth against his will. The Sheriff fined the accused £1 or seven days. The fine was paid.

SMALL-POX JOTTINGS.

DR. A. SPEEDY, in his report last week to the Board of Guardians at the North Dublin Union, says:—"I have revaccinated 1400 persons during the past eight months, a very large proportion of whom had good marks of primary vaccination; yet in these individuals excellent vesicles were formed. Among the above no cases of small-pox have occurred. In a Hospital where there is a class of sixty-five pupils attending, all except five were revaccinated, and these five contracted small-pox; all the others escaped. In Cork-street Hospital there have been 500 cases of small-pox. One of the Physicians informs me that on careful examination he found that not one of these persons had been revaccinated. In the Hardwicke Hospital there have been 600 cases of small-pox, and I find that in this institution there were a few cases of small-pox occurring in those who have been revaccinated. Although revaccination in these cases did not actually prevent the persons being attacked with small-pox, yet it had the effect of modifying the disease; and these particular cases were of a very mild character. There are always a large number of the military stationed in the Royal Barracks, which are in my district. There have been only four or five deaths from small-pox among them, and any cases are generally very mild. You are doubtless aware that all recruits are revaccinated, and this I contend is the reason they escaped so well."—Last week the Medical Officer of Lambeth reported that small-pox had appeared at the "Cripples' Home."—There were no deaths from small-pox last week in the Mile-end Old Town district.—Only one death from the disease had occurred in the past fortnight in the Limehouse district.—Small-pox is reported to be on the decrease in Kensington. During last week there had been only one fresh case, and no deaths.—Dr. Aldis, St. George's, Hanover-square, reported last week two cases of small-pox, one of which was sent to the Hospital.—Forty-one persons died from the disease in the metropolis last week. In the two previous weeks the deaths had been forty-nine and forty-eight.

SMALL-POX IN DUBLIN.

It has been estimated from sufficiently reliable data that between 7000 and 8000 cases of small-pox have already come under notice within the seven dispensary districts of the City of Dublin. The number of deaths, judging from the Registrar-General's returns, has already considerably exceeded 1000. To meet the distress entailed on the poorer classes by the continued severity of the epidemic, a sum of about £4000 has been collected, and the influential committee, whose selection was announced some three weeks back, are daily engaged in distributing small sums of money amongst the most necessitous of the numerous applicants for relief.

THE MIDDLESEX HOSPITAL CLUB.

The annual dinner of this Club was held at Willis's Rooms on Tuesday, April 30, when the lecturers and members of the Medical and Surgical staff, and a large number of gentlemen who received their Professional education at the Middlesex Hospital, met together under the presidency of Mr. Campbell De Morgan, F.R.S., lately the Secretary. Speech-making is, as a rule, tabooed by the Club, but the usual loyal toasts were given from the chair, and, subsequently, "Prosperity to the Middlesex Hospital Club." The healths of the Chairman (proposed by Mr. Oscar Clayton) and of the Honorary Secretary (Mr. Nunn) were drunk with full honours and with much enthusiasm. The *esprit de corps* of this Club has from its foundation been considerable, and members must be glad to feel that this character is still thoroughly sustained by their old institution, which was never in a more flourishing state than now.

A WOMAN-DOCTOR'S THOUGHTS ON WOMEN-DOCTORS.

EXPERIENCE bears out our observations on women-Doctors. The following is a plain outspoken narrative, and is from the pen of a lady-Doctor to the *New York Evening Mail*:—

"If the girls were to know my experience," she says, "not one in ten thousand of them would ever attempt to be a Doctor; for I have studied Medicine and some branches of Surgery, graduated with honours seven years ago, practised for five years, and was successful, so far as restoring my patients and building up a large practice may be considered success. But as for collecting bills and getting fees proportionate to the time and services rendered, I was no more successful than most Practitioners; and though I am now healthy and strong I could not compete with young men in the Medical Profession, because of inability to bear overwork and exposure to bad weather, night air, etc. Men who take reasonable care of their health are always well enough to visit a patient; but this is not true of women until they are fifty years old, and never will be true of them at an earlier stage while the human race continues. Having almost killed myself, and known two other lady-Physicians to quite kill themselves by attending to a large Medical practice, I have already given up the Profession two years since, and will never resume it."

The writer thinks even the forlorn hope of authorship preferable to the lancet.

FINES FOR NEGLECT OF VACCINATION.

OPPONENTS of vaccination have shown much zeal and courage, if not much discretion, in their proceedings in the law courts. It has been resolutely asserted by some of their legal friends that a man could not be punished twice for the same offence; and they have accordingly brought a case before the judges of the Queen's Bench. On Thursday an application was made to set aside the conviction of a man who had been twice fined for refusing to have his child vaccinated, on the ground that the offence was one and the same, and that he could not be convicted twice; but the Court held that this view was altogether untenable, Mr. Justice Blackburn stating it might as well be contended that because a man had been fined yesterday for beating his wife, he could not be fined for beating her to-day. Of course this decision will be regarded as most unjust and tyrannous by Mr. Jacob Bright and his friends.

MR. AYRTON ON BATHING.

MR. AYRTON is well known for his politeness and urbanity. He is not always happy, however, in the mode in which he exhibits them. He has not enlarged views on social or sanitary matters, as the following will show:—A deputation waited on him last week, with the view of obtaining permission for the inhabitants of Battersea to use the ornamental waters in the park for the purpose of bathing, on the ground that it would promote the health and cleanliness of the poorer classes. Mr. Ayrton said—"If a man desired it he could keep himself clean without public baths. He had only to buy himself a tub for two or three shillings, and have a bath at home." One of the deputation here observed that there was often a deficiency of water in dwelling-houses; upon which Mr. Ayrton remarked, "That was a reflection on the vestry, whose duty it was to see that there was a sufficient supply."

TESTIMONIAL TO A SURGEON.

It is with pleasure we notice the recognition, by a number of his friends and patients, of the valued services as a Medical Practitioner of Macclesfield for upwards of half a century, of Mr. Frederick Francis Lallemand, F.R.C.S. Last week this gentleman was presented with a gratifying token of their affectionate esteem for him, in the form of an address accompanied by a gift of 300 guineas. The address, which was handsomely illuminated on vellum, with the names of every individual subscriber appended, was as follows:—"Presented, with a purse containing 300 guineas, to Frederick Francis Lallemand, F.R.C.S., by a number of his friends and patients

in testimony both of the high esteem in which they hold his personal character as a Christian and a gentleman, his honour and integrity in every relation of life; and also of their strong appreciation of the eminent qualities which have distinguished him in the exercise of his Profession for upwards of half a century in this town, his unremitting attention and sympathy in time of sickness, and his readiness at all times to minister gratuitously to the relief of pain among the suffering poor."

CEREBRO-SPINAL FEVER.

DR. A. W. BARCLAY, in his report to the Chelsea Vestry, states there is among the deaths one "alleged to be due to cerebro-spinal fever, a disease which may or may not become epidemic among us, but well recognised in Germany and Poland, where it is said to take its rise." Dr. Barclay also stated, in reply to questions, that there had been fourteen deaths from this disease in New York in the past fortnight, where it threatens to become epidemic. The case in Chelsea was the first he had heard of in the metropolis, and he had never met with a case in his private practice. The disease was an inflammation of the brain and spinal cord, together with disturbance of the blood, which produced black spots in different parts of the body. The disease was spreading very extensively in various parts of Germany and Poland.

THE NEW SYSTEM OF MEDICAL RELIEF.

WHATEVER other advantages or disadvantages it may have, the new system of Medical relief commends itself to the ratepayers on the score of economy. Dr. Wood submitted to the St. George's-in-the-East Board of Guardians last week a return of the extra outdoor Medical relief for the corresponding quarters of this and last year. Under the old *régime* the cost of the relief for the first quarter of last year was £212 5s. 10d.; for the corresponding quarter of this year under the new *régime* the cost had been £10 3s. 7d.—thus showing that by the new arrangement a saving of about £800 per annum would be effected. In reply to an observation, that perhaps some of the cases were merely transferred to the infirmary, Dr. Wood stated that there were quite as many cases in the infirmary last year as this.

COOMBE LYING-IN HOSPITAL, DUBLIN.

THE annual meeting of the guardians and directors of this institution was held on Wednesday, April 24. The report was read by Dr. Ringland, sen., one of the masters of the Hospital. From a statistical summary of the practical benefits conferred on a very poor and dense population by this institution, one of the most venerable of the charities of Dublin, it appears that during the year ended February 29 last 342 cases of labour and 55 chronic cases were admitted within the walls, 1209 labour cases were attended at the patients' own homes; the extern dispensary patients numbered 3340; and the cases prescribed for amounted to 10,580. The Hospital thus afforded relief, through the wards, extern midwifery, and dispensary, to as many as 15,526 poor women or children.

FROM ABROAD: DR. BULKLEY ON CLINICAL THERMOMETRY—TEACHING OF HYGIENE IN FRENCH SCHOOLS—PROFESSOR ZEISSL ON THE TREATMENT OF BUBO.

DR. BULKLEY read, at a recent meeting of the Medical Society of the County of New York, an elaborate paper on "Clinical Thermometry," being a systematic record of experience during three years in the New York Hospital; a regular register of the temperature, pulse, and respiration having been kept in 337 cases. Forty or fifty of the most interesting of these were given in detail, with diagrams showing the curves of the three signs. "Each diagram was the record of an actual case, and faithfully exhibited every failure of observation. There were no typical curves made up from the generalisation of

many cases, as in Wunderlich's book." The following are the chief points which Dr. Bulkley considers established:—

1. The body heat is maintained in health, under all conditions, at the uniform standard of 98.4° F.
2. Any constant deviation from this denotes disease.
3. A return to, and continuance at, this standard marks the termination of disease.
4. A single high temperature is important.
5. The changes of temperature in diseases follow definite and known courses.
6. Variations from these typical ranges of temperature in disease are significant, as indicating a disturbing cause.
7. An irregular course is more unfavourable than a uniformly high range of temperature.
8. Different temperatures characterise different diseases and various days of the same disease.
9. Although a high temperature indicates a more severe attack, no heat under 109° can be considered surely fatal.
10. The daily study of the pulse and respiration in connexion with the temperature is of great assistance.
11. When the temperature and general symptoms agree, but the pulse disagrees, the two former are to be relied on.
12. When the pulse and general symptoms agree in indicating unfavourably, the temperature cannot be relied on, if contradictory, unless the improvement in temperature is marked and persistent.
13. When the pulse and general symptoms agree in a favourable indication, a high or rising temperature should arrest attention.
14. All other means of investigation should be used in connexion with the temperature to obtain the greatest benefit from the latter.
15. The continuous daily record of the three vital signs here represented, in the way exhibited, affords much aid in the diagnosis, prognosis, and treatment of disease, by the presentation to the eye of its history in these respects.
16. The systematic record of these three points may assist in determining at some future day the vexed question whether the type of disease is changing, by preserving pictures which can easily be compared."

When the Académie de Médecine paid its New Year's-day visit to the Minister of Public Instruction, and in its address recounted what it had done during the last year, it dwelt upon public hygiene as a subject which had occupied much of its attention. M. Jules Simon, having the full confidence becoming a Minister in the power of instruction, and the unbounded receptivity of French boy-nature, at once pricked up his ears. "Hygiene!" he exclaimed; "an idea just occurs to me, gentlemen, and a capital idea it is, too! We must have hygiene taught in our lyceums and colleges. Do you prepare me a programme of lectures to be delivered to the scholars by the Physicians attached to these establishments." Nothing loth, the Academy appointed a committee *ad hoc*, consisting of MM. Bergeron, Colin, Delpech, Guérard Jolly, and Vernois. In February, M. Vernois, reporter, laid the programme before the Academy for its approval. It consisted of a scheme for eight lectures or "conferences," and when we consider that these are to be addressed to lads of the same age as those who frequent our public schools, and who are already overburdened with work, it is a somewhat astounding production. The following are the chief subdivisions:—1st lecture: The influence of atmospheric agents on the health; the principal changes in the air; climates; epidemics. 2nd: The conditions of salubrity and causes of insalubrity of habitations; clothing in relation to age, climate, and season. 3rd: The nature and quality of alimentary substances in relation to ages, temperaments, professions, and climates; adulterations of food; regimen. 4th: Potable waters and their purification; the various forms of fermented drinks. 5th: Hygiene of the senses; sleep and waking; intellectual and manual labours. 6th: Exercise and repose; gymnastics. 7th: Virulent, contagious, and parasitic diseases of man and animals—itch, tinea, rabies, charbon, glanders, etc.; the principal poisons and their antidotes; alcohol; tobacco. 8th: Popular errors and prejudices relating to health; treatment of accidents, such as drowning, asphyxia, hanging.

At a recent discussion upon this report, the Academy struck out the seventh and eighth lectures, on the absurdity of their being delivered to schoolboys being exposed by MM. Chauffard, Bouillaud, and others. M. Bouillaud advised the Academy

to at once tell the Minister that what he sought for was a mere Utopia; but it was resolved to forward the programme of the first six lectures with the Academy's approval. It has been well observed that the best way of teaching the pupils hygiene will be to improve the faulty hygienic conditions of their school-rooms and modes of study and recreation—which, indeed, have been often pointed out as urgently calling for reform.

"The principle that hygiene shall be taught to the pupils in secondary schools being thus determined on," says M. Dechambre (a strong opponent to the visionary project), "it now only remains to apply it in the best possible manner. For our part we remind conscientious Professors that their first duty will be to imperiously recommend to their pupils—(1) to only accept a dietary which according to their humble judgment is sufficiently wholesome and substantial; (2) to refuse to sleep in low and crowded dormitories; (3) to apportion their intellectual occupations to the capacity for work with which nature has diversely endowed them, in order not to expose themselves to those obstinate headaches which are of such frequent occurrence; (4) to interpose a long interval between their reports and the resumption of their studies; (5) to take plenty of exercise in the open air, etc. If the Professors believe that they should abstain from offering such good councils, they may be assured that the pupils will give them to themselves after they have profited by some of the lectures conformable to the programme on 'alimentary substances and drinks, the principal changes in the atmosphere, habitations, intellectual labour, exercise, and repose.'"

In a paper published in the *Wiener Med. Wochenschrift*, March 9, Professor Zeissl, of Vienna, describes the great advantage which he has derived from what he calls the "abortive and methodical treatment" of bubo and other acute and subacute glandular enlargements of the groin and thigh. "Everyone," he observes, "who has had much to do with such is well aware of the difficulties and sometimes even dangers which they may give rise to, and cannot but be anxious for a means which may prevent their suppuration and its tedious consequences." Engaged in Hebra's division of the Hospital for more than twenty years, Dr. Zeissl was always on the lookout for some such means, and had often, both in private and Hospital practice, derived remarkable benefit from the application of the acetate of lead, as recommended by Bchrend and Cooper. In 1869 he was appointed to take charge of the syphilitic wards in the Hospital, some of which had a bad reputation (of late much redeemed) for their sanitary conditions. He soon found that such conditions told sadly on open buboes, which became frightfully gangrenous. The proximity of these wards to the dead-house seemed one cause of their insalubrity; and in order to avoid the contact of wounded surfaces with the infected atmosphere, the experiment was tried of opening and discharging buboes under water, and then closing them with a gypsum bandage. In some cases primary union took place, but in many others the cavity filled again, and the skin covering the abscess became so thinned, in spite of all preventive measures, that at last it had to be opened over a considerable extent, either by cutting instruments or caustics. Every attention to cleanliness and ventilation, etc., the application of carbolic acid according to Lister's and other plans, all failed to secure the prompt healing of such ulcers.

The author undertook no operation upon these inflamed glands without fear and trembling, so that at last he resolved to treat the buboes with lead, which he had found so useful in private practice, and only opening them quite exceptionally. This treatment has now been pursued during two years in the following manner:—When, on first seeing the patient, hope may still be entertained of preserving the skin intact, it is carefully cleansed from all adhering dirt and plaster, and depilated. The patient then goes to bed, and a compress which has been soaked in a solution of basic acetate of lead is applied to the tumour, wetting it as often as it becomes dry. Even at the end of three or four days the skin covering the enlarged gland feels thicker and firmer—tanned, as it were. The fluctuation, which on close examination was at first per-

ceived, either has gradually disappeared altogether or become much less perceptible; and on pressing the tumour with the fingers it is found already to impart a doughy feeling. If the fluctuation on the commencement of the treatment is very plain, or becomes so, a puncture in a perpendicular direction by a pointed bistoury should be made into the thinnest portion of the skin, taking care that the puncture does not become an incision, and is only large enough to secure the gradual and continuous discharge of the pus, which should be aided by moderately firm pressure by means of a compress soaked in the lead, and over which a roller is applied. The bandage also brings the excavated skin into contact with the underlying parts, and favours their union. The replacement of the purulent contents which first flow out after a few days' application of the bandage, by a more serous lymph-like fluid, is always a favourable circumstance. Care must be taken to prevent any of the linen used in the dressing entering into the aperture, as repeated irritation of this kind may easily convert the simple puncture into an ulcer. If the swelling consists of the (so-called) multiple bubo, and a spontaneous rupture has already taken place at one or more points, the following iodine plaster may be advantageously substituted for the lead compress:—Plumb. iod. ʒj., ext. bellad. ʒij., emp. diach. c. ʒj., ung. elemi q.s. ut f. empl. molle. As long as only a thin lymph-like fluid is discharged through the puncture or spontaneous apertures, and no symptoms of renewed inflammatory action are present, and still more if erysipelas be prevalent, we should abstain from any removal of the skin. But if one or more sources of pus lie deeply under the fascia superficialis, the cavity of the abscess should be laid open, employing the Vienna paste or the knife, with the usual precautions. In many cases a simple incision of the skin will suffice; and the author has met with others in which the excavated skin occupied several inches in extent, conveying the impression that it must perish, and yet the lead application has preserved it and led to its solidification.

In this way, in now more than 100 cases of indolent or acute buboes, whether arising from infection or from mere catarrh, the author has succeeded in preventing suppuration and in obtaining, very often without any puncture, absorption of their contents in the course of from six to ten weeks. Gangrenous glandular tumours are now of the rarest occurrence in the Hospital, if they have not been admitted when already in that state. Just as rare now are those deep ill-conditioned sores, burrowing under fasciæ and sheaths of vessels, with all their dangerous consequences. The dressers and nurses now have to spend much less time over these cases. Professor Zeissl, therefore, is very anxious to make his mode of treatment more known—not that he believes he has made any discovery, for the same means have been employed by Wallace, Cooper, and others. One peculiarity he claims is that of not confining the treatment to mere indolent bubo, but of employing it also in the acute and subacute venereal bubo.

CHOLERA IN INDIA.

It would appear, from the reports received lately from India, that cholera is somewhat increasing. The *Homeward Mail* says that the 22nd Bengal N.I. was attacked on its way to Calcutta, and that one or more deaths occurred in the train before it reached Mirzapore. Cholera, it is also stated, has made its appearance in Indore, and is very bad below the ghauts, on the Khandwa road. Mhow is carefully watched to prevent the disease being carried into that station.

PUNISHMENT FOR DRUNKENNESS IN RUSSIA.—All persons found drunk in the public streets, whatever their position in life may be, are apprehended, and next day are forced to do a day's sweeping in the streets. Strangers are not exempted from this regulation of municipal police.—*Pressé Belge*, April 21.

HOLLAND.

BIRTHS AND DEATHS IN TWELVE OF THE GREATEST TOWNS IN 1871.

TOWNS.	Population January 1, 1871.	Births (with stillborn).	Deaths (with stillborn).	Deaths in 10,000 inhabitants.	Ages at Death.				Causes of Death.															Deaths in 10,000 Inhabitants.					
					Stillborn.	Under 1 year (with-out stillborn).	1 to 5 years.	5 to 20 years.	20 to 65 years.	65 and upwards.	Typhus and typhoid.	Small-pox.	Scarlatina.	Measles.	Angina membranacea.	Angina diphtheritica.	Hooping-cough.	Diarrhoea and cholera nostras.	Atrophy, debility, tabes mes., 1 to 14 years.	Phthisis, 14 to 65 years.	Marasmus senilis, 65 years and upwards.	Acute dis. of resp. organs.	Chronic ditto, except phthisis.	Puerperal dis-eases.	Accidents.	Other diseases.	Unknown.	Typhus and typhoid.	Small-pox.

REVIEWS.

Anæsthesia, Hospitalism, Hermaphroditism, and a Proposal to Stamp out Small-pox and other Contagious Diseases. By Sir JAMES Y. SIMPSON, Bart. Edited by Sir W. G. SIMPSON, Bart. Edinburgh: A. and C. Black. 1871.

Clinical Lectures on the Diseases of Women. By Sir JAMES Y. SIMPSON, Bart. Edited by ALEXANDER R. SIMPSON, M.D. Edinburgh: A. and C. Black. 1872.

THESE two volumes, which complete the posthumous edition of Sir James Y. Simpson's works, are of equal, but of different interest. That which contains Simpson's writings on Anæsthesia is of the utmost value as a record of a very important passage in Medical history. The "Clinical Lectures on Diseases of Women" is a book of no less mark, but its excellence is that of a repertory of practical facts, and of the teaching of an undoubted master in obstetrical and gynecological Medicine. The one will be referred to by the Medical historian, the other by the bedside student and teacher. With the limited space at our disposal we can only indicate some of the matters which are to be found between the covers of these volumes. But doing this we shall perhaps confer a greater benefit on the reader than if we attempt an abstract of the whole. At least, this will be the case if our brief notice induce him to become the possessor of Sir James Simpson's works. In this age of newspapers and magazines, reviews are apt to take the place of the books themselves. In the majority of cases the readers are gainers by this arrangement, but in the present they would be greatly losers.

The collection of papers on Anæsthesia opens with one of Simpson's pleasant Medico-archæological essays on its ancient history. It is far too much the habit of the Profession as writers on their own craft and learning to ignore all that has preceded the present era. This is one of the great reasons of the ephemeral value that pertains to Medical literature. A Medical author, as a rule, acknowledges no debt to his predecessors, and need expect nothing from posterity. Hence the Profession is constantly being surprised by discoveries which are at least new to the discoverer, and which may continue to be discovered for the benefit of many future generations. This fault was not chargeable on Simpson. Original and intelligent observer as he was, he was no less attached to ancient lore than to modern science; and the facility with which he blended the two together makes him one of the most attractive of Medical essayists. The curious will find a half-hour's treat in the out-of-the-way learning brought to bear on the subject—in the story of the intoxicating fumes of the Massagetæ and the somniferous sponge of Hugo of Lucca, and the mandragora of Dioscorides and Pliny, and the stone called by the ancients *nephtis*; the herb named archimenides, which, being given to criminals, sets them to sleep, "and in their sleep the confession of the fact may be drawn from them much better than by any torture and rack." One prescription in the sixteenth century to annul the sufferings of parturition, Sir James tells us, was to hang the husband up in the next room by his feet till the labour was accomplished!—a preventive measure, certainly. But, leaving these curiosities, we come on the Bigelow controversy, which it will be remembered

originated from an extempore speech made by Simpson when he returned thanks to the Lord Provost of Edinburgh for the honour of a burgess-ship bestowed on him by the citizens. Simpson, it appears, did not recount the American claims to the discovery of anæsthetics on this occasion, and was seriously called to account for the omission by Dr. Jacob Bigelow, of Boston. The correspondence is doubtless fresh in our readers' memory, for it took place as late as 1870. It will therefore be sufficient to say that Simpson fully and most readily acknowledged the priority of Wells with nitrous oxide gas, although he got the hint from Sir Humphry Davy, and that of Morton with sulphuric ether; whilst he very naturally defended himself from any imputation of unfairness in not giving the full history of anæsthetic discovery in a speech extemporised in answer to one made by a civic functionary.

The second part of the volume is perhaps the most curious, historically, of any, containing as it does, Simpson's defences of anæsthesia in midwifery and Surgery from religious and other objections. Since December, 1847, when his defence of his discovery from religious objections appeared, what a change has taken place! It is almost inconceivable now that such an answer should ever have been necessary. But it is no less true that Simpson had to brush up Hebrew, and to quote Gesenius, in order to stem the tide of fanatical opposition to his great discovery. Chloroform was affirmed to be "a decoy of Satan, apparently offering itself to bless woman; but in the end it will harden society, and rob God of the deep, earnest cries which arise in time of trouble for help." This was a clerical view of anæsthesia in midwifery. But the Medical opposition which the new practice met with is, from our present standpoint, no less extraordinary. Simpson records that one of the most famous of living Physicians read a paper before a London Professional Society in 1847 on the injurious effects of ether inhalation, and ended his communication with queries as to the *desirability* of removing pain. Mr. Bransby Cooper afterwards affirmed as his opinion "that pain was a premonitory condition, no doubt fitting parts the subject of lesion to reparatory action, and therefore he (Mr. Cooper) should feel averse to the prevention of it." This referred to Surgical practice. In obstetrics the objections were no less curious. One leading obstetrician charged chloroform with inducing patients to commit various indecencies under its influence, and, by omitting the word "old" in an account of a post-mortem examination, gave (no doubt unintentionally) currency to the idea that chloroform inhalation might cause adhesions of the pericardium.

The other chapters on anæsthesia are on the Nature and Power of various Anæsthetic Agents—including chloroform, chloride of hydrocarbon, nitrate of ethyle, benzin, aldehyde, bisulphuret and bichloride of carbon; on the Applications of Anæsthesia in Surgery, Medicine, and Midwifery; and on Local Anæsthesia. These articles, varying in their date, and some of them supplemented by the labours of Snow, Richardson, and others, are of different value; but apart from their intrinsic scientific worth they have a peculiar interest as embodying the opinions of the discoverer of chloroform, and the great developer and improver of the anæsthetic art. The rest of the volume contains the papers and statistics on Hospitalism—work which we believe is destined to bear good fruit in the future—the exhaustive and very curious paper on Hermaphroditism

published in the "Cyclopædia of Anatomy and Physiology," and the Proposal to Stamp out Small-pox communicated to our own columns in January, 1868. Utopian as the last may appear to some, it no doubt maintains the only philosophical and satisfactory mode, in the present state of our knowledge, of combating contagious disease when it makes its appearance. How far isolation may be possible must be determined by circumstances. That it is incompatible with the liberty of the subject may be true, but it is the only proceeding compatible with the safety of a community. Vaccination, when small-pox has made its appearance, is a very valuable adjunct for the protection of a population, but it will not prove sufficient to stamp out the disease without perfect isolation of the sick. This is the gist of Sir James Simpson's argument, and it has been amply confirmed during the present epidemic. We shall conclude our notice of these valuable books in an early number.

(To be continued.)

FOREIGN AND COLONIAL CORRESPONDENCE.

FRANCE.

PARIS, April 23.

THE ASPIRATOR IN SURGERY: RELIEVES RETENTION OF URINE; MAY SUPERSEDE THE LANCET—M. BÉHIER ON THE EFFECTS OF CORROSIVE POISON ON THE ŒSOPHAGUS—A PAINFUL REMEDY—M. RICHEL'S CLINICAL LECTURES—THE CONCOURS FOR THE AGGREGATION—CONDITIONS REQUISITE FOR OBTAINING THE "M.D. PARIS."

M. LABBÉ, a young Surgeon and *agrégé* (sub-professor), has been doing wonders with the capillary or aspiratory trocar—the instrument patented by Dieulafoy, of Paris. M. Labbé informed me, while on a visit to the Hôpital la Pitié, that he had, the previous evening, punctured the bladder above the pubis of an elderly gentleman who was suffering from retention of urine resulting from an enlarged prostate. This was done with the above-named instrument, and 700 grammes (about 22 ounces) of urine were drawn off at one sitting. Several ineffectual attempts had been made to introduce a catheter, which ended in making a false passage towards the rectum. M. Labbé prefers Dieulafoy's trocar to the other methods in vogue, as being perfectly innocuous, the wound healing immediately. He had performed the same operation several times—both in his nosocomial and private practice, and intends submitting his observations to the Academy of Medicine. A very interesting thesis has been written on the subject by Dr. J. Watelet. In the case under notice, M. Labbé was to relieve the bladder in this way once or twice in the twenty-four hours, according to the urgency of the symptoms; and that he will repeat daily until the wound in the urethra is healed, when he will resort to other means for the removal of the cause of the retention of urine. I may here observe that many Surgeons already predict one great disadvantage in this new method—not to the patients, but to the future generation of Surgeons—as catheterism, which even nowadays is so little confided to students, would run the risk of being altogether put aside. This capillary or aspiratory trocar, intended at first only as an exploring instrument, was not much larger than an ordinary urethra-syringe. This was gradually increased in size, and was then employed for emptying large abscesses and cavities containing liquid. M. Collin, successor to Charrière, has still further improved the instrument, in such a way that it may be used not only for emptying abscesses and cavities, but for washing out or injecting these, and it is of a size containing from 120 to 160 grammes that these operations may be performed without deranging the instrument. This new trocar is, I think, destined to render great service both in Medicine and Surgery; and it struck me that it would be preferable to the ordinary lancet in venesection, as the risk of air entering the vein is *nil*, in which case the needles would of course have to be made a little thicker, so as to have a good and uninterrupted flow, and the ligature above the elbow may be dispensed with.

Since the reopening of the School of Medicine yesterday week, the clinical lectures have also been resumed. M. Béhier, Professor of Clinical Medicine at the Hôpital-Dieu, in his first lecture enlarged upon the advantages of paracentesis in purulent or other collection of fluid in the chest, and spoke in great favour of the capillary trocar. He entertained his hearers with a most interesting case, of which the following is a summary:—

A patient, who is still to be seen in his ward, was admitted about the middle of February last, reported to have swallowed some corrosive substance. The man, who is about 28 years of age, being an engraver, had a quantity of different acids in his possession, and after some family quarrel determined to put an end to himself, and swallowed about half a small wineglassful of a mixture of pure nitric and sulphuric acids, having previously mixed the draught with his finger. As he was in great agony Medical aid was immediately sought, and he was attended by a Practitioner in the neighbourhood, who administered an emulsion of milk and carbonate of magnesia in the proportion of thirty grammes to a litre. He was then taken to the Hospital, where this treatment was continued for some time. The learned Professor entered into the *modus operandi* of this mixture, which, for obvious reasons, was to be preferred in these cases to the simple watery solutions of other alkalies. The patient was admitted with the usual symptoms of corrosive poisoning, vomiting being the most urgent, the matter rejected being tinged with blood. This has continued up to this date with gradually diminished intensity, for the relief of which, and for the burning in the throat and stomach, morphia was epidermically employed. Deglutition is still extremely difficult, the patient being unable to swallow anything but liquids. He takes nothing but milk, and for the stricture of the œsophagus, one of the usual consequences of this form of poisoning, an œsophagus tube was attempted to be passed, but failed; and now a medium-sized gum-elastic catheter is daily introduced, not for injecting food, but simply to keep the passage patent. M. Béhier was afraid the time had not yet arrived to try dilatation, as the cicatrices would not be sufficiently strong to resist the slightest force. The patient is gradually wasting away, and must soon die from starvation unless more solid food be taken or administered in any other way. I must not forget to mention that the forefinger of the right hand, with which the patient mixed the fatal draught, was simply vesicated, and that very superficially, and is now well.

M. Béhier is one of the most practical Physicians of Paris, and a very agreeable and able lecturer; but, as he himself exclaimed at the bedside of a patient in the female ward, to whom a day or two ago he applied the actual cautery for an arthritic affection of the knee, he would make but a poor Surgeon, as he was not constituted for one. I noticed that while he was branding the poor creature, who stood it most bravely, he became ghastly pale, and almost let the heated iron drop from his hand.

On Saturday M. Richet, who has succeeded M. Laugier, deceased, at the Hôpital-Dieu, began his course of clinical lectures with the past history of this ancient Hospital, and by paying a just tribute to the memory of those of its deceased officers who by their talent and skill had earned a world-wide reputation. His remarks were confined to his more immediate predecessors in the chair of Clinical Surgery; and, commencing with Desault, he spoke in the most eulogistic terms of Dupuytren, Roux, and lastly of Laugier, of whom he gave a biographical sketch. He here also mentioned the name of Bichat, who, though not a Surgeon, had rendered as much service to Surgery as he did to Medicine by his well-known writings. Laugier, he continued, became Professor by competition, which, although it did not always produce the best men, ought to be encouraged as an incentive to those who aspire to a certain position; and even when they fail they create a name for themselves—for example, Lisfranc.

After this introductory lecture, M. Richet made a few remarks on a case of amputation he was about to perform on a patient who was suffering from disease in the ankle-joint, which, he said, was of a strumous nature, involving the astragalus and the articular portion of the tibia. There were sinuses leading in all directions, from which issued a sanious discharge, which was draining the man's constitution. He was afraid, from the patient's appearance and a cough, that there were tubercles in the lungs, but could detect none of the usual physical signs. M. Richet attributed the cough to the irritation set up by the disease. The patient, who was a young man of about 28, and of a delicate frame, was then placed upon the operating-table, and having been chloroformed, amputation was practised immediately above the malleoli. An anterior and posterior flap were formed, the latter a little longer than the former, which M. Richet preferred to the other methods, as it afforded a better covering to the sawn ends of the bones. The arteries having been tied, the stump was then put up with straps, and the whole covered with cotton wadding. The patient is doing well.

The *concours* for the *agrégation* (sub-professorships) began

on Friday, April 19, and the following is a list of the candidates, with the subjects of examination affixed to their names:—M. Laborde, *De la Malignité*; Bergeron, *Affections Catarrhales Aiguës*; Beaumetz, *Myélite Aiguë*; Gouraud, *Des Crises*; Damaschino, *Etiologie de la Tuberculose*; Hayem, *Hémorrhagies Intra-rachidiennes*; Duguet, *Apoplexie Pulmonaire*; Lancereaux, *Parallèle de la Maladie Expérimentale comparée à la Maladie Spontanée*; Dieulafoy, *De la Contagion*; Fernet, *Du Tremblement*; Rathery, *Pathogénie de l'Œdème*; Rigal, *Pathogénie des Névralgies*; Lépine, *De la Pneumonie Casécuse*—all most interesting subjects, which will be submitted in the form of theses and discussed publicly among the candidates themselves in the above order, in the great amphitheatre of the school, and in the presence of a board of examiners composed as follows:—M. Tardieu, President; MM. Hardy, Gubler, Vulpian, Jaccoud, Chauffard, and Roger, members.

It may not be uninteresting to your readers to know the conditions under which the Sub-Professorship of the Faculty is obtained in France:—

The subjects of examination, which are written on slips of paper and put into an urn, are chosen by the candidates themselves, who, being Doctors of Medicine or Surgery, should inscribe their names two months at least before the day fixed for examination, with a statement of their services and the works of which they are authors, depositing a copy of each in the secretary's office. There are two series of examinations to which the candidates are subjected—*épreuves préparatoires* and *épreuves définitives*. The former consists of a written composition on a subject in anatomy, the same being addressed to all the candidates; then each in his turn is to deliver a lecture extempore on a Medical or Surgical subject, according to his candidation, which lecture should last at least three-quarters of an hour, to prepare which the candidate (shut up in a room) is allowed only an hour. Here those who have failed to satisfy the examiners are rejected, and those left are allowed to proceed with *les épreuves définitives*, which consist of a clinical lecture, also extempore, to be delivered by the candidate, which, as in the first instance, should last at least three-quarters of an hour, followed by a thesis, which is discussed as above described. Thus, you see, the test for the Sub-Professorship is rather a severe one, and its owner now becomes eligible for the office of Professor, which, however, he can only obtain by vote among the other Professors, and he must have distinguished himself as an author or in some remarkable manner. You are aware that it is in contemplation to restore the *concours* system for the Professorship, which was abolished under the Empire; but the subject is still in abeyance, as there are arguments for and against it which I cannot enter into here.

The Paris M.D. seems very much sought after just now by British subjects, as I am told that applications are daily received for information as to the conditions of the examination. I happened to be in the Secretary's office one day, when the Dean came in with one of these letters, and he gave orders once for all that an answer be sent to all foreign applicants to the effect that they will be exempted from the preliminary examinations called *de fin d'année*, but that they will have to pass the other five called *examens de réception pour le Doctorat*, of the subjects of which, with your permission, I hereby submit an outline for the information of intending candidates:—(1) Anatomy and Physiology, with Dissection; (2) Medical and Surgical Pathology, with Operative Surgery on the Dead Body; (3) Natural History, Physics, Chemistry, and Pharmacology; (4) Hygiene, Forensic Medicine, *Materia Medica*, and Therapeutics; (5) Clinical Medicine and Surgery, and Obstetrics (partly written and partly *viva voce*)—to be wound up by a thesis, printed at the expense of the candidate, on a subject chosen by himself in Medicine or Surgery, and on which he will be examined. The whole should be passed in French at different periods, at the convenience of the candidate. The fees amount to 1272 francs and 50 centimes, or about £51 in English money. I heard the Dean say that, as far as in him lay, he would prevent foreigners obtaining permission to practise on French territory without passing the required examination, as being altogether unjust to other parties.

It is, perhaps, not generally known that M. Jules Simon, the present Minister of Public Instruction, is a Doctor of Medicine as well as an academician, and that many of the higher appointments, even non-Professional, are held by Medical men; the present Director-General of Posts is a Doctor, and the Chamber of Deputies count twenty-seven—a thing never before known in the history of other Governments.

The weather is still chilly and inclined to rain, and although Paris keeps free from epidemics, pulmonary and throat affections continue to be the prevailing diseases. Measles are also some-

what on the increase, the disease affecting adults as well as children. The trees are covered with leaves, and the market is full of fresh vegetables; asparagus in abundance, and cherries and strawberries already grace the fruit-stalls.

A subscription dinner was given by some members of the Faculty on the 19th inst., to celebrate the anniversary of the inoculation of cow-pox in the human subject, which was for the first time practised in Paris on April 19, 1800.

M. Sédillot, the eminent Surgeon and Professor of the Faculty of Strasburg, offers himself as a candidate at the Academy of Medicine, in lieu of M. Laugier, deceased.

AUSTRALIA.

MELBOURNE, VICTORIA, January 2.

THE VAN HEMERT CASE—THE DIPHTHERIA COMMISSION—SPIRITUALISTS IN VICTORIA—THE MELBOURNE HOSPITAL—VICTORIA HEALTH OFFICERS—VICTORIA MEDICAL BOARD.

The Profession in this colony has been stirred to its greatest depths for some weeks, in consequence of the verdict given in a trial in the Supreme Court, on November 20, 1871, against Mr. Van Hemert, a Surgeon in extensive practice at St. Kilda, near this city. The action was brought by an old woman, aged about 60, named Turner, and the circumstances were briefly these:—On October 11, 1870, she experienced a fall, and Mr. Van Hemert was called in to attend her. He found a good deal of contusion, and some extravasation of blood about the knee, but no evidence of fracture. He attended her for about six weeks, and repeatedly examined the limb, always with the same negative result as regarded any injury to the bone. On November 15 evidences of intra-capsular fracture of the neck of the os femoris showed themselves, and a splint was applied, which the patient obstinately removed several times; and on the 19th she insisted upon calling in another Medicalman. Mr. Van Hemert was dismissed, therefore, and a Mr. Crooke was consulted, and he brought with him Mr. Beaney, who has recently been notorious by the publication of two books on Syphilis and Spermatorrhœa, and their advertisement throughout the colonies. These declared that the fracture occurred at the time of the accident, and that, as it had not been then discovered, the patient had in consequence been crippled. The action followed as a matter of course. At the trial, both recognised authority and personal testimony were brought to show that fractures of this description were frequently difficult to discover, and that they were nearly always productive of permanent lameness. Nothing, in short, could be clearer than that all the circumstances pointed to the possibility of an incomplete intra-capsular fracture on October 11, and its completion, and therefore recognition, on November 15. But the judge, unfortunately, informed the jury there was no need for the patient to have been of necessity crippled. The jury decided, therefore, for the plaintiff, with damages £230, which, with expenses, brought up the sum to about £400. A meeting of the Medical Society was at once called to consider the case, and a series of resolutions agreed upon expressive of sympathy with Mr. Van Hemert. A few days later a larger meeting of the Profession was held, and active steps were taken to organise a subscription to reimburse Mr. Van Hemert for the expense to which he had been subjected. No question ever occasioned such unanimity in the Profession in this colony as the case of *Turner v. Van Hemert*, and it has proved for once that there is an exception to the adage of Doctors disagreeing. The sympathy with Mr. Van Hemert, however, is by no means of a merely personal kind. It is simply the expression of a protest against an injustice from which any member of the Profession at any time may suffer.

As to the part taken in this action by Messrs. Crooke and Beaney there is but one opinion. They are condemned, as a matter of course, on all hands. Nobody, however, is very much surprised.

The Committee of the Melbourne Hospital have agreed to recommend to the contributors the appointment of two additional Assistant-Physicians, and it is probable that the recommendation will be adopted. Already several candidates are prospectively in the field, and the most likely of these are Dr. O. V. Lawrence, who for some time has been the Senior Resident Medical Officer of the Hospital, and Dr. Wigg, the Pathologist and Curator of the Museum. It is likely that they will both be successful.

At the Geelong Hospital some curious changes have been made by the Committee. They have appointed their Non-

resident House-Surgeon—who up to the date of this change has been absurdly styled “Resident”—the Non-resident at a salary of £300 a year, with unlimited liberty to practise privately, and they have given him an Assistant Resident at £200 a year, who is also to do the dispensing, but who on no account is to engage in private practice. They have in fact altered their regulations to suit their circumstances, as it seemed impossible to change their circumstances to suit the regulations. Meanwhile another of the honoraries has resigned, and it is said the remaining one contemplates taking a like step; so that Mr. Reid will really be what he has always aimed at being—the autocrat of the place.

Of other recent appointments the following may be taken as a summary:—Dr. Haig has been appointed one of the Physicians to the Alfred Hospital; Dr. Neild, Consulting-Physician to the Children’s Hospital; Mr. James, Consulting-Surgeon to the same charity; Dr. Fishbourne, Resident Surgeon to the Ararat Hospital; and Dr. Lawrence, Demonstrator of Anatomy in the Medical School of the University.

The Medical Society has recently revised its rules, and a somewhat important change has been made in the rule defining the functions of the Committee, which has been constituted a sort of court of ethics, to which all questions relating to matters of this kind are to be submitted. As such cases are constantly arising, it is felt that this change is one out of which much benefit may come.

February 1.

A considerable ferment has been occasioned in the Profession here in consequence of the appointment of a Commission by the Government to investigate the subject of diphtheria. Now and then, in certain of the up-country districts, the disease shows itself somewhat severely. The general mortality from diphtheria, however, is not excessive, and it is the rule for the disease to yield to well-directed treatment. But because a few alarmists have worried the Government, and written sensation letters and paragraphs in the newspapers, a Commission has been granted. The majority of the men who have been appointed upon it, however, even if the Commission had been required, would have been fatal to its utility. Instead of picking out the few scientific men there are in the Profession, the Government have selected them according to any principle but that of eligibility, and they have capped the climax of unreason by including in the number a homœopath, one Dr. Günst, who has a hydropathic institution, and who publishes, at fitful intervals, a homœopathic journal, in which he abuses the Profession generally, and gives extracts from European homœopathic literature. It appears that this man, who apart from his homœopathy is but a shallow creature, has worked himself into favour with one of the members of the Government; ergo his appointment. The homœopaths consequently have raised a loud cry of exultation, and as the Government lately subsidised their dispensary, they are in high spirits at the declared progress of their system. I think I mentioned, in a former letter, that two of the newspapers in this city were homœopathy-bitten, so that the doings of the Hahnemannian disciples in this part of the world are extensively made known. It is only right to state that Dr. Motherwell and Mr. Wilkins, who were nominated on the Commission, have declined to act in consequence of the inclusion of Dr. Günst in it. And speaking of the support given by the newspapers to homœopathy, I am reminded of some remarks in your issue of November 11, relative to the opinion of the *Melbourne Herald* on Medical coroners. In explanation of the foolish virulence which characterised the observations in the *Herald*, it is only right to tell you that, at the time those remarks were published, the editor of that paper was a homœopath, who, having applied to the Medical Board to have registered a more than questionable American diploma, and having been refused, and subsequently having been prosecuted and fined for practising without a licence, took to abusing, individually, the members of the Board. Of this body Dr. Youl, the city coroner, is an active member, and against him and Dr. McCrea, our most efficient chief Medical officer, the silly spite of this disappointed homœopath was continually directed—“Hence these tears.” It is generally admitted that the rule of Medical coronerships in Victoria has been an undoubted success. Now and then an incompetent Medical witness, who finds his ignorance exposed, commences to exclaim against Medical coroners; but the lay-public, in the main, cordially approve of them. And to show what very incompetent Medical witnesses are to be found in this part of the world, it has twice happened of late for such witnesses, in describing the appearances in an autopsy of a new-born child, to speak of a “large morbid growth” behind the sternum! They had made the acquaint-

ance for the first time in their lives of the thymus gland! It may be reasonably asked, Who but a Medical coroner, in such a case, could detect the ignorance of the witness?

Another little ferment in the Medical world just now is the allegation that two of our leading Medical men, who have spiritualistic proclivities, treat their patients according to the instructions obtained from mediums. A bookseller, who deals largely in spiritualistic literature, and who was formerly a grocer, is, it is said, making a fortune by his professed ability to diagnose disease by the examination of a patient’s hair. That an ex-grocer and present bookseller should be an impostor and quack-salver is nothing so wonderful; but that this man should be consulted by two leading Physicians is a little startling. I myself know of no facts in proof of this allegation; but that it should be the current topic of conversation is suggestive of some basis of truth for it, and I am bound to confess, also, that it is generally believed. A rather good story was lately in circulation about this bookseller-medium. The hair of a delicate young man, suffering from aneurism of the aorta, was sent to him for examination. The hair was very fine and silky, and the medium pronounced it to be that of a woman suffering from uterine disease!

Mr. Girldstone, the city Health Officer, has initiated a movement for the establishment of a Health Officers’ Association. The project has been warmly taken up, and it promises to be a success. Such an association is much needed here, where sanitation is a subject in almost everyone’s mouth, from the comparatively imperfect provision there is in respect of hygienic needs.

At the annual meeting of the contributors of the Melbourne Hospital on the 31st ult., it was decided to increase the staff by the appointment of two additional Assistant-Physicians. I think I previously mentioned that this alteration was in contemplation, and that several candidates were already in the field. Of these, by far the most likely are Dr. Lawrence, the present Senior Resident Physician, and Dr. Wigg, the Hospital Pathologist. The resident staff has just undergone some change by the election of Drs. Gillman and Hinchliffe in place of Drs. Moloney and Lyttleton, who were somewhat hastily dismissed by the Committee.

March 1.

The Diphtheria Commission, of which I made mention in a previous letter, has at last been gazetted. It consists of Dr. McCrea, the chief Medical Officer, who sits unwillingly upon it, but who has no option in the matter on account of his official obligations; Dr. Günst, a homœopath, hydropath, etc.; Dr. Lloyd, a suburban Practitioner, whose claim to be a scientific commissioner is derived from the circumstance of his being the principal conductor of a Medical publication; and Mr. David Boswell Reid, the anomalous House-Surgeon of the Geelong Hospital. To complete the absurdity, it is said that the secretary to this precious Commission is to be a person named Hickson, a homœopath, who has been twice prosecuted for practising without a licence, but who has an American degree which the Medical Board has long refused to register. With Dr. McCrea much sympathy is felt, for he has long been the object of abuse both of Lloyd and Hickson, the latter person having been for some time connected with the *Herald*, an evening journal, the proprietors of which permitted this man to gratify his personal spite by writing abusive articles against Dr. McCrea, as President of the Medical Board. Dr. Günst being a homœopath, and the proprietor of a hydropathic Hospital, it is not surprising that Dr. Motherwell, Dr. Day, Mr. Wilkins, and Mr. Thompson should have refused to be associated with him. The respectable portion of the Profession are unanimous in the feeling that the Government have offered a marked affront to them in the appointment of this Commission. There never has at any time been any need for such an inquiry, and if there had been they have gone the wrong way about to effect it.

There has been another disturbance at the Melbourne Hospital in connexion with the resident staff. Dr. Bradford, one of the House-Physicians, having submitted a doubtful epileptic case to the galvanic battery test, was accused of cruelty, and the matter made the subject of inquiry by the Committee. After a prolonged investigation it was decided that, though Dr. Bradford had not acted improperly in using the galvanic battery, he had not comported himself with becoming dignity in using vehement language to the persons who accompanied the epileptic. As these persons were women, and as they gave the freest possible licence to their tongues, the temptation to use powerful terms of remonstrance with them was very considerable. One of the women told Dr. Bradford that, being the paid officer of a public charity, he was only a pauper hin-

self, and therefore the servant of the patients. Human nature is hardly equal to feminine objurgations of this kind.

The Health Officers of the colony have organised themselves into an association. At the last meeting, Mr. Girdlestone, the City Health Officer, read an instructive paper pointing out the defects of the Health Act. It is felt that if only the objects of this association are properly carried out very much good will result; for though we have a Health Act fairly framed to meet public requirements in respect of hygiene, there is very little real desire on the part of the authorities to carry it out. The position of Health Officers, moreover, is in every way objectionable. They are underpaid and overworked, and a great deal of responsibility cast upon them, and yet they are continually blamed because the purposes of the Act are defeated. The wonder is that such an association, therefore, has not been organised long ago, and much is expected from the movement.

A vacancy has occurred in the Medical Board through the death of Dr. Stewart, and some curiosity is felt as to who will be selected in his place. The last two vacancies were filled up with a ludicrous defiance of the claims of the leading members of the Profession, and entirely from political or personal motives; and it is by no means unlikely that this rule of political eligibility or personal friendship will again be observed. To those who know of what materials Australian Governments are composed, this preposterous ignoring of the rights of the really eligible is not surprising. The same spirit of contempt for what is deserving of recognition was observed some time ago, when the vacancies in the Board of Health had to be supplied. The choice, in one instance, fell upon a Medical man whose recommendation consisted in the circumstance of his having a great many club-patients, and in having been several times insolvent. At least, there was nothing else to entitle him to conspicuous recognition.

GENERAL CORRESPONDENCE.

THE ROYAL OPTHOPÆDIC HOSPITAL.

LETTER FROM MR. B. E. BRODHURST.

[To the Editor of the Medical Times and Gazette.]

SIR,—In commenting upon my previous letters, Lord Abinger has failed to understand the statement they contained. Upon March 13 the annual court of the Orthopædic Hospital was immediately followed by a special court. It was to this special court alone that I referred as that in contemplation of which the thirty new governors were made whose subscriptions were forwarded to the secretary by me. I had nothing whatever to do with making the eighty-one new governors who, Lord Abinger says, were added immediately prior to the second special court, held on April 8, when his lordship tried, unsuccessfully, to reverse the previous vote. I see, however, that amongst those new governors appear various members of his lordship's own regiment and of his club.

With regard to my personal action at the courts, I did not vote at either of them, although both Mr. Tamplin and Mr. Adams did. It is almost too ridiculous to deny that I "betrayed satisfaction by the action of my feet"; but it is not true, and I do deny it, as his lordship has thought it worth while to make the statement, and you have allowed it to appear in your columns.

It is naturally a source of satisfaction to me that Lord Abinger's opinion of my "Professional capacity" should be such as to lead him to be willing to concur in my appointment as full Surgeon to the Hospital, though the value of this testimonial is, perhaps, somewhat diminished by the mistake his lordship evidently makes of thinking that my promotion would make any change in the nature of either my duties or my relation to my patients.

Grosvenor-street, May 1.

I am, &c.,

B. E. BRODHURST.

GENERAL PRACTITIONERS AND CHEMISTS.

[To the Editor of the Medical Times and Gazette.]

SIR,—I think young men who are entering the Profession ought to think carefully of the future status which may be their lot—that is, supposing that they propose to live by their Profession soon, and to join the great mass of general Practitioners, and not to enter the army or navy or official life, nor yet to join the throng that hangs on to every Medical school in the hope of lectureships and consulting practice.

The British public, for all minor and incipient maladies, has

the custom of going for advice to some Practitioner who will supply them with the requisite medicine at one transaction. In every community, too, the vast majority abhors the payment of fees, and likes credit till next Christmas. On these grounds the old Surgeon-apothecary or general Practitioner, with a surgery to which access could be had without the trouble of ringing at a private entrance, had a large and lucrative business; and let it be observed that, in law and physic alike, it is the many little cases that pay far better than the stupendous cases with their enormous labour and anxiety which no money can compensate.

Now, I think young men ought to be aware how much of this general practice has passed into the hands of the chemists. In London, the gentleman who was once general Practitioner now prescribes; and the nobleman, if he pays for the Medical attendance of his servants, now sends them to the chemist for advice as well as medicine. "Why," says he, "should I pay two people for doing what one can do very well?" The chemists, nothing loth, undertake the treatment of minor Medical and Surgical cases. But it may be said, they dare not come out and visit! Wait a few years, and we shall see who will dare hinder them. All the maxims of free traders will be invoked against such a mischievous (?) restraint of liberty.

A consulting Physician in London receives letters from a chemist in the country about a patient under the chemist's care; and I can't see what difference there is between such a consultation and one with a general Practitioner.

It would seem as if the apothecaries, in their anxiety to raise the status of their licentiates, had really begun to make them unfit to live; just as we are told some thoroughbred colts have legs so long and necks so short that they cannot crop the grass.

Whilst the general Practitioner is thus supplanted by the chemist from below, see how he is treated by the Hospital people above him. I was amused at reading the other day an account of the speeches at a meeting on behalf of one of the largest Hospitals and Medical schools, boasting that persons in middle life could receive better Medical attendance at the Hospital gratis than they could from their own Practitioner whom they pay. A general Practitioner, who lives near a large Medical school, where his son, a youth of 21, is an advanced pupil and dresser, was telling me that when his patients were dissatisfied with himself—a well educated man of thirty years' experience—they could go and be advised by his stripling of a son!

I am, &c.,

FIFTY-FIVE.

London, April 27.

OBITUARY.

WILLIAM EDWARD MASFEN, M.B.,

WAS born in 1831, and was the third son of the late Mr. John Masfen, of Stafford, who was for many years one of the leading Practitioners in the county. Dr. Masfen having passed through the routine of apprenticeship with his father, and at the county Infirmary, went to London and entered King's College, where, as a student, he had a very successful career, obtaining many prizes and distinctions—amongst others the Warneford Prize for Divinity, and a scholarship in Comparative Anatomy. Before leaving King's he held the appointment of House-Physician at the Hospital, under the late Dr. Todd. He passed the College and Hall in 1852. He graduated at the University of London in 1853, distinguished himself by obtaining the University Scholarship in Medicine and the gold medal in Surgery and Midwifery. On the death of his father in 1854 he succeeded to his practice, and at the same time was appointed Surgeon to the General Infirmary, which post he held to the time of his death, having been for about two years Senior Surgeon. Dr. Masfen was a sound and painstaking Practitioner, and, in addition to natural abilities of a high order, he had an exceedingly well-disciplined and regulated mind, and the methodical manner in which he could arrange his ideas enabled him at all times to express himself in a clear and lucid manner. In addition to his Professional attainments, Dr. Masfen excelled in the contributory sciences, and was a man of great and varied accomplishments. He was deservedly esteemed, his uniform courtesy and kindness being evident to all; but his liberal charity to the poor was probably only known in a great measure to the recipients themselves, as nothing was more distasteful to him than ostentation in any form. The funeral took place on Friday se'nnight. The shops were partially closed, and the blinds of the windows of private houses drawn down along the line of route, and the streets

were filled by respectful and evidently sympathetic spectators. It is seldom a funeral in Stafford has called forth such a mournful interest. The funeral itself was of an unostentatious character, the deceased's partner (Dr. Cookson), Mr. Weston, the officiating priests, etc., and his immediate relations being alone invited. As a mark of respect, however, the mayor, the magistrates, Medical men, ministers of religion, and a large number of the gentlemen of the town, and members of the Earl St. Vincent Lodge of the London Order of Odd Fellows, joined the procession. The Rev. J. Nary delivered the funeral discourse, which was listened to with sorrowful attention by a large congregation. He alluded in feeling terms to the sad event which had called them together that day, and to the many good qualities of the deceased, particularly instancing his kindness to the poor. He said that he was foremost in every good work connected with the church at Stafford, of which he had been the mainstay, and he looked around in vain for one to fill his place. At the conclusion of the service the procession proceeded to the cemetery, where the remains were lowered into the grave with the usual ceremony, the choir singing the Psalm "De Profundis."

SAMUEL BROWN, F.R.C.S., etc.,

OF Lewisham, was born on May 3, 1805, and died on April 21, 1872, in his 67th year. He was the eldest son of Mr. Samuel Cowper Brown, Surgeon, of Lewisham. He was educated at Mr. Walpole's school, Greenwich, which at that time had a great celebrity; and in 1821 was apprenticed at the College of Surgeons, and entered as a student at the united Hospitals of St. Thomas's and Guy's. He was dresser to Sir Astley Cooper, and a favourite clinical clerk to Dr. Bright. After obtaining his diploma, he joined his father in practice in the year 1828, and when Mr. Brown, sen., retired in 1835, he associated with himself his brother, William Henry Brown, who continued in partnership with him till his death in 1865. Mr. Brown was a man of great physical and mental energy, in spite of frequent attacks of gout. These became more severe after his brother's death, and about two years since it was found that he was suffering from albuminuria, and shortly afterwards he became the subject of epilepsy from uræmic poisoning, which compelled him to relinquish the active duties of his Profession. As may be supposed, this was a great trial to one of his energetic temperament and active turn of mind. He continued to take a warm interest in all that was going on around him, and only two hours before his death, when he was scarcely able to articulate, he inquired of a Medical friend, who called to see him, as to the condition of a mutual acquaintance who had been suffering from pleurisy. The immediate cause of his death was congestion of the lungs of a few days' standing. Mr. Brown kept himself *au courant* with the progress of Medical science, and was never so happy as when he had about him younger men who were actively employed in scientific pursuits. He was a man of considerable ability, and fair Surgical skill. A former rival Practitioner in his neighbourhood has often spoken to the writer of this notice of the skill and neatness with which he had several times seen Mr. Brown operate for hernia. His social qualities were much esteemed. He was very hospitable—in fact, more so than his means warranted; but he had a most kindly disposition, and entered heartily into the enjoyment of those around him. He was always a welcome visitor at the United Hospitals Club, of which he was for some years a member. The remembrance of "Old Sam Brown," as he was familiarly called, will not quickly pass away from a large circle of patients and private and Professional friends.

GEORGE ODLING, M.R.C.S., L.S.A.,

OF Sydenham-road, Croydon, Surrey, was born at Tetney, in Lincolnshire, the seventh son of a well-to-do farmer. He studied at the Borough Hospitals, and afterwards practised for many years in the Borough, where he was well known as an observant, skilful man. On the establishment of the Metropolitan Police Force he was appointed Surgeon to the M Division, and held the office until his retirement from practice about fourteen years ago. He was also Surgeon to the Licensed Victuallers' School at Kennington. Throughout life he enjoyed uninterruptedly good health until within the last few months, when symptoms of cardiac disease manifested themselves. He died rather suddenly, at Worthing, on the 26th inst., aged 77. He has left a widow and two children—a daughter (married), and a son, William Odling, M.B., F.R.C.P., F.R.S.

ALEXANDER BROWNE,

SURGEON on half-pay, 37th Foot, died on the 15th ult. at Langlands, Kirkcudbrightshire. He entered the service in June, 1825, became Surgeon in November, 1839, and retired on half-pay in August, 1850.

MEDICAL NEWS.

UNIVERSITY OF ST. ANDREWS.—The following gentlemen, having passed the requisite examinations, obtained the degree of Doctor of Medicine on April 24 last:—

Clarke, John J., M.R.C.S. Eng., Surgeon H.M. Indian Army, Edinburgh.
Finch, Thomas, M.R.C.S. Lond., Torquay.
Franklin, Edward J., F.R.C.S. Edin., Surgeon-Major R.A., Woolwich.
Gibson, John H., M.R.C.S. Eng., L.S.A., Hull, Yorkshire.
Hebblethwaite, James E., M.R.C.S. Eng., L.S.A., Bawtry, Yorkshire.
Mayer, John, F.R.C.S. Lond., Inspector-General Indian Army, London.
Perkins, Samuel S., M.R.C.S. Lond., L.A.C., Exeter, Devonshire.
Saunders, George, C.B., L.R.C.P. and S. Edin., Deputy-Inspector of Hospitals, H.M. Army, London.
Stretton, William H., M.R.C.S. Eng., L.S.A., Beverley, Yorkshire.
Veale, Thomas S., M.R.C.S., L.S.A., Surgeon H.M. Indian Army, Epsom, Surrey.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—At the ordinary quarterly meeting of the College on Thursday, April 25, the following Member was admitted Fellow:—

Wade, Willoughby Francis, M.D. Dub., 24, Temple-row, Birmingham; and the following gentlemen were admitted Members:—
Cole, Thomas, M.D. Lond., L.R.C.P., 17, Paragon, Bath.
Farquharson, Robert, M.D. Edin., Junior United Service Club, S.W.
Grigg, William Chapman, M.D. Edin., 6, Curzon-street, Mayfair, W.
Laking, Francis Henry, M.D. Heidelberg, L.R.C.P., 13, Addison-road, Kensington, W.
Winslow, Henry Forbes, M.D. Lond., Sussex House, Hammersmith, W.

The undermentioned gentlemen, having conformed to the by-laws and regulations, and passed the required examinations, were granted Licences to practise Physic, including therein the Practice of Medicine, Surgery, and Midwifery:—

Allwood, John Philip, M.R.C.S., The Dispensary, Macclesfield.
Arthur, Joseph, M.R.C.S., 14, Commercial-place, Commercial-road, E.
Boon, Alfred Pearl, M.R.C.S., St. Mary's Hospital.
Domville, Edward James, M.R.C.S., Devon and Exeter Hospital, Exeter.
Ewart, William, M.R.C.S., St. George's Hospital.
Harrison, Richard, M.R.C.S., Mabe House, St. Lawrence-road, Nottingham, W.
Lammiman, Cleland, M.R.C.S., 106, Cannon-street-road, E.C.
Pitts, Henry Yate, M.R.C.S., Raikes House, Walton, Liverpool.
Roche, Eleazer Birch, M.R.C.S., 21, St. Stephen's-road, Lewisham, S.E.
Young, Adam, M.R.C.S., Seamen's Hospital, Greenwich, S.E.
Coltart, William Wilson, who passed his Examination in Medicine, July 24, 1871, and has obtained a recognised qualification in Surgery.

The following candidates, having passed in Medicine and Midwifery, will receive the College Licence on obtaining a Qualification in Surgery recognised by the College:—

Dundas, George Albert, Guy's Hospital.
Fagg, Thomas Henry, 4, Talbot-road, Bayswater, W.

Mr. Harry Davis, of University College Hospital, passed his Primary Professional Examination.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen having undergone the necessary examinations for the diploma, were admitted Members of the College at a meeting of the Court of Examiners on the 30th ult., viz.:—

Addis, Philip, Gloucester-crescent, N.W., student of University College.
Bailey, John Andrew, Bushey, Herts, of Guy's Hospital.
Chicken, Rupert Cecil, Nottingham, of Guy's Hospital.
Cleghorn, George, Caleutta, of St. Thomas's Hospital.
Drew, Charles Wallace, Exeter, of the London Hospital.
Floyer, Blaise Bernard, L.S.A., Floore, Northamptonshire, of the Middlesex Hospital.
Galabin, Alfred Lewis, M.A. Cantab., Camberwell-grove, of Guy's Hospital.
Goldsmith, Septimus Jesse, Brixton, of St. George's Hospital.
Hutchings, Robert Huntriss, L.R.C.P. Edin., Southsea, Hants, of Guy's Hospital.
Laver, Arthur Henry, Rayleigh, Essex, of St. Thomas's Hospital.
Maybury, Aurelius Victor, Frimley, Surrey, of St. Thomas's Hospital.
Newman, Alfred Samuel, Birmingham, of the Birmingham School.
Parkes, William Edmund, L.S.A., Birmingham, of the Birmingham School.
Ritchie, James, Edinburgh, of the Edinburgh School.
Thomson, William, M.B. Edin., Charles-street, Grosvenor-square, of the Edinburgh School.
Underhill, Arthur Stafford, M.B. and M.C. Trin. Col. Dub., Tipton, Staffordshire, of the Dublin School.
Wright, Francis James, L.S.A., Preston, Lancashire, of St. Thomas's Hospital.

The following gentlemen passed on the 1st inst., viz.:—

Cave, Alfred, L.S.A., Newport, Isle of Wight, student of the London Hospital.
Chilcot, James, L.S.A., Southsea, of University College.
Critchett, George Anderson, B.A. Cantab., Harley-street, of the Middlesex Hospital.

Dixon, John Francis, Bournemouth, of St. Bartholomew's Hospital.
 Groves, Matthias, Radipole, near Weymouth, of St. Bartholomew's Hospital.
 Hacon, Walter Edward, Mare-street, Hackney, of Guy's Hospital.
 Hawthorn, William Thomas, L.S.A., Uttoxeter, Staffordshire, of the London Hospital.
 Knott, Charles, Portsmouth, of Guy's Hospital.
 Morris, Sydney, Hayes, Kent, of St. Bartholomew's Hospital.
 Oates, James Pimlott, L.S.A., Stourbridge, Worcester, of the Birmingham School.
 Pitts, Robert Zaccheus, L.S.A., Hingham, Norfolk, of the Middlesex Hospital.
 Price, Hugh Pughe Jones, L.S.A., Iron Works, Dowlais, Glamorganshire, of the Manchester School.
 Roberson, Edward, Tytherington, Gloucestershire, of the Charing-cross Hospital.
 Sparrow, Robert Launcelot, Dublin, of the Dublin School.
 Thompson, Francis Henry, L.S.A., Tenbury, Worcestershire, of St. Thomas's Hospital.
 Williams, Benjamin Harvey, Haverfordwest, of Guy's Hospital.

The following gentlemen were admitted Members on the 2nd inst., viz. :—

Baldock, Alfred, L.S.A., Upper Holloway, student of St. Bartholomew's Hospital.
 Dundas, George Albert, St. George's-road, S.E., of Guy's Hospital.
 Fosbroke, George Haynes, L.S.A., Bedford, Redditch, of the Westminster Hospital.
 Harris, John Delpratt, L.S.A., Exeter, of St. Bartholomew's Hospital.
 Kinson, Joseph, L.S.A., Croydon, of Guy's Hospital.
 McCammon, James, M.D., Kingston, Canada, of Guy's Hospital.
 Wall, Abiathar, L.S.A., Bayswater, of St. Bartholomew's Hospital.

Five candidates passed the examination in Surgery, and when qualified in Medicine will be admitted Members of the College; and eighteen candidates having failed to acquit themselves to the satisfaction of the Court of Examiners, were referred to their Hospital studies for six months.

The next primary or anatomical and physiological examination for the diploma of Membership takes place this day (Saturday).

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received Certificates to practise, on Thursday, April 25 :—

Goodchild, Nathaniel, Kentish Town-road.
 Lyle, Henry Bowden, Graham-road, Hackney.

The following gentlemen also on the same day passed their Primary Professional Examination :—

Nunez, Daniel, Guy's Hospital.
 Williamson, George Edward, London Hospital.

At the Preliminary Examination in Arts held at the Hall of the Society on April 26 and 27, fifty candidates presented themselves, of whom twenty-three were rejected, and the following twenty-seven passed and received certificates of proficiency in general education :—

FIRST CLASS (IN ORDER OF MERIT).

First—James Herbert Simpson. | Second—William Saunders.

In the Third Division—

Battle, William Henry. | Hoppus, John Devenish.
 Ellis, Philip Mackay. | Rowland, Alice M.
 Griffin, Arthur Edward.

SECOND CLASS (IN ALPHABETICAL ORDER).

Badcock, George Sainthill.	Lawson, Ella.
Bax, Ernest Belfort.	Money, Angel.
Bentham, Edward Cooper.	Phillips, Stephen Thomas.
Boyd, Robert John.	Platt, Adrien Pigot.
Buckley, Herbert.	Roberts, Walter Reginald.
Dent, Francis Alfred.	Robinson, Ernest Laurie.
Gilbert, Philip Francis.	Smith, Henry Phillips.
Hope, Edward.	Tyrrell, Walter.
Isbell, Richard Woodward.	Watkins, Sydney.
Lavies, J. W. Y. H.	Williams, Chas. Godfrey Hugh.

Of the fifty candidates, nineteen had been previously rejected, and of those nineteen, thirteen have again failed to pass the examination.

APPOINTMENTS.

* * * The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

ASHBY, A., F.R.C.S.—Assistant-Surgeon to the Royal South Lincoln Militia, *vice* G. W. Shipman, promoted.
 ELLIOTT, WILLIAM HAMILTON, A.B., M.B., L.R.C.S.I., L.M.—Medical Officer to the Coolock and Drumcondra Districts, North Dublin.
 GREAVES, C. H., M.R.C.S. Eng., L.S.A.—Medical Officer to the Stafford Union.
 OLDHAM, C. J., F.R.C.S.—Assistant-Surgeon to the Central London Ophthalmic Hospital, *vice* W. Fairlie Clarke, M.R.C.S.
 PEARCE, W. HENRY, M.R.C.S. Eng., L.S.A.—House-Surgeon to the Rotherham Hospital.
 WALKER, ALEXANDER, M.A., M.B., C.M.—Medical Officer to the Parish of Echt, Aberdeenshire.

NAVAL APPOINTMENTS.

MEDICAL.—Matthew Coates, Surgeon, to the *Cambridge*; Dr. J. W. Fisher, Assistant-Surgeon, to the *Ganges*, for service in the *Liberty*.

BIRTHS.

ADAMS.—On April 23, at Barnes, Surrey, the wife of James Adams, M.D., of a son.
 DE FABECK.—On April 27, at 28, Nelson-street, Edinburgh, the wife of Wm. F. De Fabeck, Surgeon 6th Regiment Madras N.I., of a daughter.
 PAYNE.—On April 27, at Wimbledon, the wife of Charles Henry Payne, M.D., of a son.
 SCOBELL.—On April 25, at Plympton St. Mary, the wife of Thomas E. Scobell, M.R.C.S. Eng., of a son.

MARRIAGES.

BISHOP—PIDCOCK.—On April 24, at the parish church, Watford, Herts, Thomas Bishop, Esq., of Bramcote, Notts, to Georgina Ehreita, only surviving daughter of the late John Pidcock, M.D., of Watford.
 BRODIE—JOHNSON.—On April 23, at the parish church, Sturry, David Brodie, M.D., of Columbia Lodge, Liberton, Edinburgh, to Martha Grove, eldest daughter of George Richard Johnson, Esq.
 GULSTON—MCWILLIAM.—On April 24, at St. Michael's Church, East Teignmouth, John Reynolds Gulston, Esq., of the Inner Temple, and of East Cliff, Teignmouth, to Frances Pemberton Deas, fifth daughter of the late James Ormiston McWilliam, M.D., C.B., F.R.S., F.R.C.P., R.N., late Medical Inspector of her Majesty's Customs, London.
 HENDERSON—PHILIP.—On April 25, at the British Consulate, Leghorn, Robert Charles Henderson, Esq., merchant, Leghorn, to Anna Marie Louise, eldest daughter of the Rev. H. Philip, M.D., D.D.
 OWEN—TURNER.—On April 23, at St. James's, Bermondsey, the Rev. John Stanley Owen, curate of Stepney, to Emily, second daughter of William Hall Turner, M.R.C.S. Eng., L.S.A., of 33, Bermondsey-square.
 PARSONS—BARTLETT.—On April 23, at the Minster, Wimborne, Frederick James Parsons, L.R.C.P. Edin., M.R.C.S. Eng., L.S.A., of Yeovil, to Mary, eldest daughter of the late Thomas Bartlett, Esq., of Closworth, Somersetshire.
 SAYER—RICHARDS.—On April 30, at St. Giles's-in-the-Fields, William Feetham Sayer, Esq., of 86, Alexandra-road, South Hampstead, eldest son of Edward Sayer, Esq., of Oak Lodge, East Finchley, to Angelina, fourth daughter of Samuel Richards, M.D., of 36, Bedford-square.
 TURNER—SHACKLE.—On April 27, at St. Martin's-in-the-Fields, Francis S. Turner, of Manor-road, New Cross, second son of the late J. S. Turner, M.R.C.S.E., of Woolwich, to Fanny, third daughter of W. Shackle, Esq., of The Hollies, Iver, Bucks, late of The Woodlands, near Romford.

DEATHS.

BLECKLEY, JOHN MOLLAN HAMILTON, eldest child of Staff Surgeon T. M. Bleckley, M.D., LL.B., Secretary to Inspector-General of Hospitals, at Simla, Punjab, India, on March 15, aged 4 years and 2 months.
 BODEN, ROBERT, M.R.C.S. Eng., L.S.A., at his residence, Smalley, near Derby, on April 21, aged 74.
 CARR, FRANCES REBECCA, the beloved wife of J. K. Carr, M.D., Surgeon-Major Royal Artillery, at 14, Victoria-terrace, Exeter, the house of her father, Major John Bent, on April 26.
 CHARLTON, HENRY BERNARD, third son of Edward Charlton, M.D., of 7, Eldon-square, Newcastle-on-Tyne, at Bath-terrace, Plymouth, on April 24, aged 2 years and 7 months.
 FERRIS, HENRY JAMES, Assistant-Commissary, eldest son of George Thomas Ferris, M.R.C.S. Eng., Inspector-General of Hospitals, at Stonehouse, Plymouth, on April 28.
 KNIGHT, MORRISON, M.D., at Gladesville, near Sydney, New South Wales, one of the Medical staff on duty at the Hospital for the Insane at that place, on February 23.
 ODLING, GEORGE, M.R.C.S., of Sydenham-road, Croydon, at Worthing, on April 26, aged 77.
 ROSS, Mrs., widow of the late Dr. Andrew Ross, late E.I.C.S., at 49, Colville-gardens, Notting-hill, on April 24, aged 69.
 WATSON, ROBERT MATHER, M.R.C.S., L.S.A., J.P., at Stoke, Devonport, on April 16, aged 70.

VACANCIES.

In the following list the nature of the office vacant, the qualifications required in the Candidate, the person to whom application should be made, and the day of election (as far as known) are stated in succession.
 ASHTON-UNDER-LYNE DISTRICT INFIRMARY.—House-Surgeon. Candidates must possess both a Medical and Surgical diploma. Applications and testimonials to be addressed to "The President of the District Infirmary," and forwarded to H. T. Darnton, Esq., Honorary Secretary, Ashton-under-Lyne, on or before May 11.
 DERBY COUNTY LUNATIC ASYLUM, MICKLEOVER.—Assistant Medical Officer. Candidates must possess both a Medical and Surgical diploma. Applications and testimonials to be sent to John Barber at the Asylum.
 GREAT NORTHERN HOSPITAL.—Ophthalmic Surgeon. Candidates must be F.R.C.S. Applications and testimonials to be sent to G. Reid, Secretary, 46, Great Coram-street, W.C., on or before May 16.
 GUILDFORD UNION.—Medical Officer and Public Vaccinator. Candidates must be duly qualified. Applications and testimonials to be sent to Mark Smallpeice, Assistant-Clerk, Guildford Union, on or before May 9.
 INFIRMARY FOR CONSUMPTION AND DISEASES OF THE CHEST, 26, MARGARET-STREET, CAVENTISH-SQUARE.—Visiting Physician. Candidates must be Members of the Royal College of Physicians, London. Testimonials to be sent to Francis Baily, Secretary.
 ISLE OF MAN GENERAL HOSPITAL AND DISPENSARY.—Resident Medical Officer. Candidates must be duly qualified. Further information may be obtained by applying to the Honorary Secretary, E. L. Watts, Esq., Douglas, Isle of Man, to whom testimonials must be sent on or before May 7.
 KING'S COLLEGE.—Demonstrator of Practical Physiology.

MIDDLESEX COUNTY LUNATIC ASYLUM, HANWELL.—Medical Superintendent of the Male Department. Candidates must be Fellows, Members, or Licentiates of one of the Royal Colleges of England, Scotland, or Ireland, and duly registered in Medicine and Surgery. Copies (only) of testimonials, accompanied by a form (which will be forwarded on application), must be sent to Richard William Partridge, Clerk to the Visitors, on or before Saturday, May 4.

NORTH RIDING INFIRMARY, MIDDLESBOROUGH-ON-TREES.—House-Surgeon. Candidates must be Fellows or Members of one of the Royal Colleges of Surgeons of the United Kingdom. Applications and testimonials to be sent to the Secretary, on or before June 12.

SHEFFIELD GENERAL INFIRMARY.—Assistant House-Surgeon. Candidates must be Members of one of the Royal Colleges of Surgeons of the United Kingdom, or L.F.P.S.G. and L.S.A., or L.R.C.P.L. Applications and testimonials to be addressed to "The Medical Staff of the Infirmary," care of the Secretary, on or before May 16.

UNIVERSITY COLLEGE HOSPITAL.—Resident Medical Officer. Applications and testimonials to be sent to John Robson, B.A., Secretary to the Council, on or before May 18.

WEST BROMWICH DISTRICT HOSPITAL.—House-Surgeon. Candidates must be doubly qualified. Applications and testimonials to be sent to P. D. Bennett, Honorary Secretary, West Bromwich, on or before May 6.

WESTHAMPTON UNION, SUSSEX.—Medical Officer. Candidates must be duly qualified. Applications and testimonials to be sent to R. G. Raper, Clerk to the Guardians, at the Office, West-street, Chichester, on or before May 17.

WESTMINSTER UNION.—Medical Officer. Candidates must possess both a Medical and Surgical degree. Applications and testimonials to be sent to the Union Office, Poland-street, Oxford-street, on or before May 15.

UNION AND PAROCHIAL MEDICAL SERVICE.

. The area of each district is stated in acres. The population is computed according to the census of 1861.

RESIGNATIONS.

Alton Union.—Dr. Hammond has resigned the Third District; area 14,588; population 3340; salary £100 per annum.

Belper Union.—The Smalley District is vacant; area 9258; population 4974; salary £27 10s. per annum.

APPOINTMENTS.

Bramley Union.—Alfred Rickards, L.R.C.P. Lond., M.R.C.S. Eng., to the New Workhouse.

Chesterton Union.—Patrick J. Molony, B.M. and M.C. Trin. Col. Dub., to the Fourth District.

East Ward Union.—Robert Buntine, L.F.P. and S. Glasg., for the Brough District.

Kingston-on-Hull Incorporation.—Daniel Gibson, M.R.C.S. Eng., L.S.A., to the West District.

Kingston (Surrey) Union.—Other W. Berry, M.R.C.S. Eng., L.S.A., to the Upper Wimbledon District. Edward Johnson, L.R.C.P. and L.R.C.S. Edin., to the Lower Wimbledon District.

St. Austell Union.—George C. Birt, L.F.P. and S. Glasg., L.S.A., to the Second District. Thos. J. Hill, M.R.C.S. Eng., L.S.A., to the Grampound District.

Thingoe Union.—Frank Marshall, M.R.C.S. Eng., L.S.A., to the Eighth District.

INSPECTOR-GENERAL MUIR, C.B., has been recalled from India, where he has been filling, during five years, the position of principal Medical officer of H.M.'s forces, to assume the duties of head of the sanitary branch of the Army Medical Department in London.

DR. B. G. DARLEY, having served as Medical Officer to the Coolock Dispensary District, North Dublin Union, for thirty-five years, has been granted the highest superannuation allowed by Act of Parliament.

THE death is announced of Mr. Dudley Doran from typhus fever, taken in discharge of his Medical duties at the Meath Hospital.

THE Glasgow Chamber of Commerce have resolved to petition Parliament against the Public Health Bill, on the ground that its provisions, were they applied to Scotland, would "seriously injure productive industry and make it impossible to carry on many of the productive operations of the country."

TESTIMONIAL.—Nearly £400, in amounts varying from half a crown to twenty pounds, has been already subscribed for a public testimonial to Dr. Evan Pierce, of Denbigh.

GREAT MASTODON.—The remains of a mastodon have recently been discovered in a swamp near Otisville, Orange County, New York. Nearly all the bones have been dug out, and the skeleton, when put together, will be fourteen feet high and twenty-five feet long. The contents of the stomach were also discovered, and found to consist of very large leaves and long blades of strange grass from one inch to three inches wide.

MR. HAVILAND'S DISEASE MAP.—At the *conversazione* of the Royal Society held at Burlington House on the 27th ult., under the presidency of the Astronomer Royal, Mr. Alfred Haviland exhibited a coloured map of the geographical distribution of typhoid and other fevers in England and Wales, reduced from the large chart which illustrated his lectures during the winter session at St. Thomas's Hospital.

BRODERIP SCHOLARSHIPS.—Two scholarships, of the annual value of £30 and £20 respectively, tenable for two years, have been founded by the Governors of the Middlesex Hospital, for the encouragement of the study of Medicine and Surgery, in memory of the late Francis Broderip, Esq., a munificent benefactor to the Hospital. These scholarships will be open to competition, at the end of each winter session, amongst the general Students of the Hospital who shall have completed their third year of study at the Medical College. The successful candidates will be required to attend and work at the Hospital for a fourth year, during which period they will be eligible for the various resident appointments.

MIDDLESEX HOSPITAL ENTRANCE SCHOLARSHIPS.—Two scholarships, of the annual value of £25 and £20 respectively, will be offered for competition at the commencement of the winter session 1872-73. Each scholarship is tenable for two years, provided the scholar conducts himself satisfactorily. These scholarships are open to all gentlemen who commence their Medical studies in October, 1872. Successful candidates will be required to become general students of the College. The examination will take place on September 27 and following days, and the result will be declared on October 5. The following are the subjects for examination:—Latin, Greek, French or German, mathematics, natural philosophy, chemistry, botany, and zoology. Candidates will be examined in any three of the above subjects they may select; but only one modern language and two out of the last three subjects are permitted.

PRESENTATION OF AN ADDRESS TO PROFESSOR TUSON.—The other day an address by the students attending the class of Practical Chemistry at the Royal Veterinary College, of which the subjoined is a copy, was presented to Professor Tuson:—"To Richard V. Tuson, Esq., F.C.S., Professor of Chemistry and Materia Medica in the Royal Veterinary College. —Sir,—We, the undersigned students of the Royal Veterinary College, beg to acknowledge most heartily the efforts you have made to facilitate the acquirement of a practical knowledge of such a difficult subject as chemistry. While our opportunities for studying this important science were confined to those afforded by attendance on lectures only, the facts and principles of this branch of the curriculum were retained in the memory with extreme difficulty; but since we have had the privilege of working with our own hands in the laboratory, we find that we make greater and more rapid progress, and that we can more thoroughly appreciate the value and practical utility of chemistry to everyone desirous of following the profession of veterinary medicine on sound and rational principles. We also beg to congratulate you on your being the first to establish a course of laboratory instruction in the oldest and principal veterinary college in this country; to thank you most sincerely for the sacrifice of your valuable time which you have voluntarily and gratuitously made for our benefit and advancement; and to hope that you may long be spared to participate in that in which you have manifested such a deep interest—*videlicet*, the education and elevation of the social status of the veterinary student." (Here follow the signatures of seventy-seven students.)

ZYMOTIC DISEASES.—In his Quarterly Report the Registrar-General writes:—"The annual death-rate from small-pox in England and Wales during the first three months of this year was, as before stated, equal to 1.3 per 1000 of the estimated population, against 1.1 in the last quarter of 1871. In the eighteen largest English towns, the 2585 fatal cases were equal to an average annual rate of 1.6 per 1000; while in fifty other large towns 1296 deaths from small-pox occurred, or equal to 2.1 per 1000. In England and Wales, exclusive of these sixty-eight large towns, which are now estimated to contain a population of 8,893,299 persons, the deaths from small-pox last quarter were therefore 3839, or equal to an annual rate of nearly 1 per 1000 of a population of rather more than 14,000,000. The following are a few of the highest death-rates from small-pox per 1000 persons living during last quarter:—among the eighteen largest cities and boroughs, 13.5 in Norwich, 9.3 in Wolverhampton, 7.7 in Nottingham, and 7.0 in Sheffield; among the fifty other large town districts, 12.8 in Northampton, 9.8 in Newport (Monmouth), and 8.6 in Dover; in other town registration sub-districts, 24.0 in Bideford, 15.2 in Tredegar, 14.9 Bridport, 14.5 in Bishop Auckland, 14.0 in Cadoxton, 13.5 in Radford, 12.8 in Castleford, 12.4 in Malton, 12.0 in Yeovil, and 11.9 in Llantrisant. With regard to the distribution of the fatal cases of the other zymotic diseases, it may be briefly remarked that measles was proportionately most prevalent in London, Staffordshire, Lanca-

shire, and the West Riding of Yorkshire; the districts of Bolton and Cardiff showed excessive numbers. Although the deaths from scarlet fever were less numerous than in recent quarters, the disease was more or less epidemic in many parts of Staffordshire, Lancashire, the West Riding of Yorkshire, Durham and South Wales; Wolstanton, Stoke-upon-Trent, Bury, Burnley, Todmorden, and Whitehaven were among the districts which suffered from exceptional prevalence of this disease. The deaths from hooping-cough were exceptionally high last quarter, and the disease was especially fatal in London, Liverpool, Manchester, and West Bromwich. The death-rate from fever was considerably lower than in recent corresponding quarters, but, as usual, showed an excess in the manufacturing districts of Lancashire and Yorkshire; in Nottinghamshire the deaths from fever had considerably declined from the high number returned in the last three months of last year, but they were again excessive; the fatality from fever was exceptionally high in the borough of Sunderland and in Strood (Kent), Whitchurch (Hants), Radford, Yarm, and Llanelly sub-districts. A considerable reduction in the death-rate from fever has occurred in recent years, and has been especially conspicuous in London. There is little doubt but that this result is directly due to an increased efficiency in sanitary supervision. When the whole country shall have been brought under the organised control of sanitary authorities we may hope for a still more strongly marked decline in the fatality from zymotic diseases. So long, however, as the appointment of Health Officers, even in large towns, is optional, and so long as rural districts are not formed into organised sanitary districts, it is almost futile to hope for a more rapid decrease of the waste of life from these causes which is continually occurring around us."

MEDICAL STATISTICS OF PARIS FOR THE QUINQUENNIAL PERIOD 1865-69.—Those of our readers who are interested in the subject will find an elaborate statistical and nosographical analysis of the above period, from the pen of M. Ely, a very able statistician, in the *Gazette Hebdomadaire* for March 15 and April 5 and 19.

CRIMINAL ABORTION IN CHINA.—M. Martin, Physician to the French Legation at Peking, states that strangers remark innumerable small bills which are pasted on the walls of Peking and other large towns. These, when translated, are frequently found to relate to "infallible drinks for overcoming obstructed menstruation"—an adroit mode of describing abortives. The police do not interfere with the sale of these; but when persons seek to purchase them the seller informs himself of their names and addresses. Every seller has his own secret remedy; but in Peking the *pediculus bovis* and a species of leech dried and reduced to powder and applied to the cervix uteri are the favourites. Instruments are very rarely used. The seller apprises the mandarin of the locality of the purchase that has been made, and he institutes his inquiries, not with the view of preventing the abortion, but of ascertaining the circumstances which have rendered it desirable. The pregnancy may have arisen from illicit relations, and adultery is a capital crime in China; or a girl, escaping from the surveillance of her friends, may have become the victim of violence, and here it is also the business of justice to protect the honour of the domestic circle. But if it is only a married woman who, pregnant by her husband, wishes to disembarass herself of the inconvenient results, the law is satisfied and does not interfere. How the case is viewed by public opinion there is no means of judging, the numerous works on moral philosophy all being silent on the subject.—*Gazette Hebd.*, April 5.

NOTES, QUERIES, AND REPLIES

He that questioneth much shall learn much.—*Bacon.*

Dr. C. J. B. Williams's next lecture on "Success and Failure in Medicine" is in type, and shall appear next week.

The late Dr. Bell, of Amoy.—A fund is being raised for the benefit of the widow of the late Dr. Bell, who acted as Medical missionary in China, and afterwards practised in New Zealand. We will give fuller particulars next week. The fund is raised and managed by John P. Coldstream, Esq., 5, St. Andrew's-square, Edinburgh.

A National Medical Council.—Several voices are raised in behalf of the establishment of a National Medical Council, not merely to take charge of the education and registration of the members of our Profession, but to guide the Government in all questions of hygiene and Medical policy at home and abroad, civil and military. "An Army Surgeon" writes—"There should be a Medical Council of some kind to advise Government

upon all questions of a national character, and of such a council I would allow the Director-General to be a member. I would leave him despotical enough with regard to the authority he might exercise upon his *own* dependents and subordinates, but I would relieve him as soon as possible from any power to control Medical science or the Medical and Surgical practice of his subordinates."

It must never be forgotten that one man often does a thing right out, whilst a council ponders, and weighs, and doubts, and deliberates till the time for action is gone by.

Dr. A. P. Stewart.—In the *Medical Times and Gazette* for April 13, 1872, the following paragraph was published respecting Mr. Stansfeld's Public Health Bill:—

"Two deputations have made a visitation on Mr. Stansfeld respecting it—one of the body of philosophers who issue from the Social Science Association, and who dwell chiefly on the theoretical and administrative features of the Bill. The objection to Dr. Rumsey's schemes is that they are too elaborate, exclusive, expensive, and technical to be accepted by a practical country. As studies of that theoretical perfection which philosophers desire, they are perfect; and it is something to have a high standard set up, though it may be unattainable. The other deputation (of Medical Officers of Health) avoided all theoretical questions, and seemed animated with the desire to push through what promises to be a very valuable Bill."

Thereupon Dr. Stewart sent us the letter which follows:—

"Sir,—In your notice (April 13) of the deputations to Mr. Stansfeld in reference to the Public Health Bill, you have (I am sure unintentionally) done great injustice to the Joint Committee, of which I have the honour to be one of the secretaries. That body, composed of above fifty members of the British Medical and Social Science Associations, has, during the last five years, bestowed upon the whole question of sanitary organisation an amount of thought, time, and self-denying labour that ought to secure for its deliberate and collective opinions some degree of respectful attention. Its 'collective opinion' I say—for, with the exception of two (or at most three) distinguished and generally esteemed members of it, all are agreed as to the principles which should guide them in the discharge of the duties assigned to them; its 'deliberate opinion' I say, because not a report or memorial has been adopted without being subjected for weeks to the most searching criticism—"proofs" having been issued to every member, and returned by many with annotations and suggestions more or less elaborate. To represent such men as blindly following the lead of any one man, however eminent—and nothing less is implied in describing the proposals of the Committee as 'Dr. Rumsey's schemes'—is a great public wrong. But when I state that among this flock of sheep who meekly or mechanically follow the bell-wether are such men as Arldge, Edward Ballard, Baylis of Birkenhead, William Budd Burke of Dublin, Edwin Chadwick, William Clode, Davies of Bristol, Dyke of Merthyr, Falconer, William Farr, Gairdner, Hastings, Alfred Hill of Birmingham, Holland, Edward Jenkins, Liddle, Michael Morgan of Manchester, Philipson of Newcastle, Ransome of Bowdon, Tindal Robertson of Nottingham, Strange of Worcester, Tremeneere, Tyacke of Chichester, Washbourn of Gloucester, Thomas Webster, and Edward Wilson of Cheltenham, the *inuendo* becomes simply ridiculous. Those who are familiar with the history of sanitary effort during the last quarter of a century will be inclined to accept these names as a guarantee that any proposals seriously put forth by them are *not* 'too elaborate, exclusive, expensive and technical to be accepted by a practical country.' Without some such machinery to carry them out as is recommended by the Joint Committee, the 'practical' suggestions of the Metropolitan Medical Officers of Health, and any number of Acts embodying them, will be (as heretofore) a dead letter. Provide a thoroughly effective agency of enlightened administrators, and of well-trained and independent executive officers, and the practical results will follow as a matter of course. No such effective machinery is provided by the Public Health Bill, hence our earnest endeavours to amend its administrative provisions. I am, &c., A. P. STEWART.

"Grosvenor-street, W., April 17."

We did not think Dr. Stewart's letter required publication, but we inserted the following note in the *Medical Times and Gazette* for April 27:

"The 'Social Science and Joint Committee's' Opposition to Mr. Stansfeld's Bill.—We have received a letter from Dr. A. P. Stewart, in which he points with commendable pride to the 'thought, time, and self-denying labour' which these bodies have expended in devising a perfect scheme of sanitary organisation, and claims for its 'deliberate and collective opinions' some degree of respectful attention—in fact, Dr. Stewart regards any opposition to their opinions or movements as a 'public wrong,' an 'inuendo,' 'simply ridiculous,' etc. Let us substitute the Royal Sanitary Commission, or the Local Government Office, or any other body who have spent 'thought, time,' etc., in excogitating sanitary measures. Why does not Dr. Stewart think them above criticism? Or why cannot honourable men criticise each other's opinions without intermixture or suspicion of personal disrespect?"

Hereupon Dr. Stewart sends the following note:—

"Sir,—After the notice to correspondents in your last issue, I must claim, as a simple act of justice, the publication *in extenso* of my letter, that your readers may judge for themselves whether I gave expression to any such sentiments as those indicated in the said paragraph.

"April 30.

I am &c.,

A. P. STEWART."

We would willingly do anything to gratify so honourable and justly esteemed a Physician as Dr. Stewart, and we willingly shall abide by the verdict which any unbiased person may give on the matter. Nay, we would appeal to Dr. Stewart's own sense of honour, and ask him by what right he puts a gloss of his own upon our plainly expressed opinion, and uses the most unjust and offensive term *inuendo*, and then complains of being hurt when his own sentiments or those of his friends are subjected to criticism!

THE MRS. DAY FUND.

Executive Committee: Benjamin W. Richardson, M.D., F.R.S., F.R.C.P. (Chairman); Professor Bell, M.D. St. Andrews; J. Matthews Duncan, M.D., F.R.C.P., Edinburgh; Professor Eichen, London; Inspector-General Gordon, M.D., C.B., Dover; S. Day-Goss, M.D., London; Sir James Paget, Bart., F.R.S., London; J. Lockhart Robertson, M.D., F.R.C.P., London; R. H. Semple, M.D., London; E. Sieveking, M.D.,

F.R.C.P., London; Sir Thomas Watson, Bart., M.D., F.R.C.P., London; A. Wynn Williams, M.D., London. *Hon. Treasurer:* J. H. Paul, M.D. *Hon. Secretary:* Leonard W. Sedgwick, M.D.

JOTTINGS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—In 1757, ninety-one years after the Plague, at Eyam some labouring men digging potatoes came upon what appeared to be linen, which they immediately buried. All sickened with typhus; three died; the disease spread, and seventy people in the parish fell victims. Reading and thinking over this, an unwelcome tap on one's venerable shoulder was experienced, and the everlasting inquiry again reiterated—How is poor Mrs. Rogers? What is the matter? What is your opinion? Heaven knows the work to-day has been anxious enough—the modest income (heavily saddled with many deductions) fairly earned—why not a little peace? One statesman said life would be very tolerable but for the amusements; another, who had just been addressing a lady rather *décolletée* and old as his bosom friend, remarked that receiving deputations constituted his relaxation; and, to descend from great people to small, my recreation consists in writing to the *Medical Times and Gazette*. There is one great advantage in attending those persons whose relations, friends, and chance acquaintances cannot pester you morn, noon, and night with idle questions about one particular patient when many others are weighing sorely on the Professional mind. There is no escape, either at the Boat-race, the "Sublime Society of Beefsteaks," or at ordinary meals. The fate of nations depends upon how they are fed, remarks Brillat Savarin; even a dog is worthy of his dinner. Lately more than fifty cases of measles, greatly complicated, have been on the list, all turning out well, giving far less trouble than the single case of Mrs. Rogers; not that she is to blame—a nice, gentle, amiable creature, very ill indeed, suffering from gastric fever during early pregnancy, besides neuralgia and obstinate vomiting (the latter condition, by the way, greatly benefited by Chapman's spinal ice-bags). A good mother, a large room, and a trained nurse combine to counterbalance a nervous husband; and, above everything, the patient, taking a bright view, and fully understanding that the Physician corresponds to the captain of a ship tossed by the storm or approaching the rocks, obeys implicitly. Mrs. Price writes to-day, asking what to do with her baby, who, refusing all artificial food, prefers that which not enriches him yet leaves her poor indeed. A story is going about that Mrs. Wilkins, on her second honeymoon, nursed her first husband's child. (Holding up his hands, Dominie Sampson ejaculates "Prodigious!") Also, an eight months' child, six weeks old, refusing the breast and the bottle, takes kindly to beef-tea! Just now, astatic patients, rigidly keeping Lent, are suffering from neuralgia, relieved by a good dinner and a bottle of port. A woman states that, after each of her six labours, for weeks she experiences a feeling of hatred to everyone excepting the infant; and that, as a rule, she cannot put her hands into cold water without exquisite agony, only relieved by stroking velvet. Another, that (confined at ten o'clock on a Sunday night) she was naturally delivered by a midwife of a boy, and twenty minutes after of a girl—one placenta, two cords. On the Wednesday after she gave birth to a putrid male foetus (separate cord and placenta), none of her children surviving. By several Medical men enormous bursters about the knees and elbows are attributed to muscular strain during labour. Coincidentally, a few days ago, another woman considered squinting due to the same cause. Lately, a patient suffering from pneumonia in the eighth month of eighth pregnancy gave premature birth to three girls footling at half-hour intervals, the children surviving three days. Amongst savages there is a great objection to twins—an implication of infidelity—one father, one child. Talking of savages, a cannibal was asked if he knew a certain Medical man, who was missing; he replied that he did, intimately—in fact, had eaten him. February 27 will long be remembered in connexion with a case of puerperal mania, which prevented my witnessing the Thanksgiving ceremonial. Captain Binks of the Horse Marines, in a gold-laced jacket, plumed busby, embroidered sabretasche, and mounted on a well-gingered charger, looked splendid with his long sword, saddle, and bridle. Little did the admiring crowd imagine that for hours this gallant officer had to endure the agonies of a distended bladder. In the crowd there were two deaths and 227 accidents, including the crushed babies of mothers who agree with Lord Amberley as to the limitation of families, and the man who dislocated his jaw agape with admiration at the loyal and reckless-of-expense decorations at the *Lancet* office. At dinner the other night, a strong-minded lady, covered with diamonds, said, "Look at my husband, who has been ill—three Doctors, two nurses, ninety tins of essence of beef, pounds of ice, dozens of champagne; I assure you, Mr. Smith, that man cost me £300." Dr. Ollapod doubtless would have replied, "Thank you, madam; I owe you one." In some book there is a story of a field preacher, who, taking as his text, "Although, after my skin, worms destroy this body," etc., divided his sermon into three heads—"First, The diagnosis, pathology and treatment of skin-worms; secondly, What they done; thirdly, What the man saw after he was eaten up." Please excuse a little levity. The fact is, I write in high spirits—delighted, after thirty-three days' hard battle with the case of puerperal mania, to find the patient, who for many nights required constant restraint, and whose

screams and yells were frightful to hear, is getting better, mentally as well as bodily. Every remedy was tried, including repeated scruple doses of bromide of potassium, henbane, chloral hydrate, opium, etc., by the mouth; but the hypodermic injection of morphia alone was of service, acting splendidly, although one night four grains had to be administered. Turpentine enemata, too, the constant application of ice to the shaved head, a diet mainly consisting of milk, and the amount of wine never exceeding five ounces a day, all helped. Even now we are scarcely out of the wood, but gradually she is improving. Her mother and her grandmother died insane after delivery.

I am, &c., A GENERAL PRACTITIONER.

COMMUNICATIONS have been received from—

PERIODICALS AND NEWSPAPERS RECEIVED—

Nature—Pharmaceutical Journal—Transactions of the Odontological Society, vol. iv., No. 6—The Clinic—Monthly Microscopical Journal—Science Gossip—New York Medical Journal—Food, Water, and Air—Medical Press.

APPOINTMENTS FOR THE WEEK.

May 4. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; King's, 2 p.m.; Charing-cross, 2 p.m.; Royal Free, 2 p.m.; Hospital for Women, 9½ a.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. Thomas's, 9½ a.m.
 ROYAL INSTITUTION, 3 p.m. Mr. R. A. Proctor, "On the Star Depths."

6. Monday.

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; St. Peter's Hospital for Stone, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

ANTHROPOLOGICAL INSTITUTE, 8 p.m. Meeting.
 MEDICAL SOCIETY OF LONDON, 8 p.m. Annual Oration (by Mr. F. J. Gant, F.R.C.S.) and *Conversazione*.
 ROYAL INSTITUTION, 2 p.m. General Monthly Meeting.

7. Tuesday.

Operations at Guy's, 1½ p.m.; Westminster, 2 p.m.; National Orthopædic, Great Portland-street, 2 p.m.; Royal Free, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; West London, 3 p.m.

PATHOLOGICAL SOCIETY, 8 p.m. Discussion on the subject of Pyæmia introduced by Dr. Burdon-Sanderson; after which the following Specimens will be exhibited:—Dr. Moxon, "Lymphoid Cancer of the Small Intestine." Mr. Hulke, "The Parts after Operation for Cancer of the Penis." Mr. Gay, "A Cyst; Sequestrum from the Tibia." Dr. Crisp, "Disease of the Cerebellum; Intussusception in an Infant." Mr. Arnott, "Multiple Exostosis." Dr. Hawkes, "An Intracranial Tumour." Dr. T. Sutton Townsend, "Ossified Aneurism of the Left Ventricle of the Heart."

ROYAL INSTITUTION, 3 p.m. Mr. E. B. Tylor, "On the Development of Belief and Custom amongst the Lower Races of Mankind."

8. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1½ p.m.; Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.; St. Thomas's, 1½ p.m.; Samaritan, 2.30 p.m.; King's College Hospital (by Mr. Wood), 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. George's (ophthalmic operations), 1½ p.m.

EPIDEMIOLOGICAL SOCIETY, 8 p.m. Mr. R. Lawson (President), "On the Influence of Fever in Checking the Advance of Cholera."
 SOCIETY OF ARTS, 8 p.m. Meeting.

9. Thursday.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Royal Orthopædic, 2 p.m.; University College Hospital, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.
 ROYAL INSTITUTION, 3 p.m. Prof. Tyndall, "On Heat and Light."

10. Friday.

Operations at Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.

CLINICAL SOCIETY, 8½ p.m. Dr. Burney Yeo, "Case of Paralysis of the Senses of Smell and Taste following Concussion of the Brain." Dr. Greenhow, "Case of Progressive Muscular Atrophy." Dr. Baumler,

"Case of Enteritis." Dr. Broadbent, "Left Hemiplegia, with Convulsions and Coma."
 QUEKETT MICROSCOPICAL CLUB, 7 p.m. Extra Meeting, for Conversation and Exhibition of Objects only.
 ROYAL INSTITUTION, 9 p.m. Mr. Nevil Story-Maskelyne, "On Meteoric Stones."

VITAL STATISTICS OF LONDON.

Week ending Saturday, April 27, 1872.

BIRTHS.

Births of Boys, 1167; Girls, 1149; Total, 2316.
 Average of 10 corresponding weeks, 1862-71, 2163.5.

DEATHS.

PART VIII.

CHRONIC CONSOLIDATION OF THE LUNG FROM PLEURO-
PNEUMONIA.*Terminations by Expectoration, Absorption, and Loose Adhesion. Cacoplastic Deposits. Condensation of Lung, with Dilatation of Bronchi. Signs and Symptoms like those of Phthisis—Cases, Fatal; Anatomical Characters—Recoveries. Different views on Origin and Nature of Chronic Consolidations of the Lung.*

I HAVE mentioned that the solid products of inflammation of the lung and its membranes vary in their amount, in their nature, and in their results. In the case of simple inflammation in previously healthy subjects, under judicious treatment the inflammatory deposit in the tissues of the lung is gradually dispersed, partly by absorption and partly by expectoration, the matter of which contains it either in a fibro-albuminous form or disintegrated in pus corpuscles.

[Note added in 1872.—Recent observations have given a better understanding of the processes by which inflammatory products are formed and dispersed. Not only is there exudation of an enriched and fibrillating liquor sanguinis from the blood-vessels, but the bioplasm itself, in the form of amœboid sarcophytes, migrates and multiplies, as do also the germinal nuclei of the cells of the adjoining connective and other tissues. When healthy inflammation subsides, all these products are resolved or dispersed, some being absorbed into the lymph-streams of the lymphatics, others being thrown off on adjacent mucous surfaces in the form of mucus or pus-cells, which are only modifications of the original sarcophytes—the latter elimination being aided by the chemical and physical change of the material from viscid and colloid to diffuent and fatty. Thus pneumonia ends favourably with opaque, ripe, or “concocted” expectoration, which afterwards gradually gives place to the natural mucous secretion. The case of predominant suppuration is not an equally favourable one, as it involves a hyper-oxidation of the plasma which carries the solvent process too far for the integrity of the tissues. But this is not under our present consideration.(a)]

The lymph thrown out by inflammation on the pleura is also partly absorbed; but generally enough remains to form bands of adhesion between the pulmonary and costal pleura; and as the lung recovers its expansibility these adhesions are so much stretched and loosened by the respiratory movements as not to impede them in any material degree.

It is different when, either from the unhealthy state of the blood, or from the long continuance of the inflammation, the inflammatory deposit, either in the lung or on the pleura, is deteriorated in quality. It is then less capable of absorption when the quantity is small, or of organisation when more abundant; and it is apt to remain obstructing the textures, or clogging and binding down the membranes, to the permanent injury of the functions of the part. Thus, after prolonged inflammation the lung may remain consolidated, and more or less impervious to air, especially in the lower and middle lobes. In this case the side remains more or less dull on percussion, chiefly behind, with little or no breath movement or sound, and sometimes with loud tubular sounds of breath and voice to a very remarkable extent. These loud bronchial sounds are caused, not merely by the increased density of the lung conducting the sounds to the surface, but also by the dilatation of the bronchial tubes themselves.

It is nearly thirty years since I pointed out this as the most common origin of dilatation of the bronchi, yet even now it scarcely seems to be generally understood.(b) Yet the process

(a) See Chapter vii. (“On the Nature of Pus and Suppuration”), “Pulmonary Consumption,” etc., p. 50.

(b) Some time after I had published this explanation, Dr. Corrigan, of Dublin, described a similar condition under the term “Cirrhosis of the Lung.” He considered the deposit to be a peculiar tissue like that affecting

is simple enough. In cases of prolonged pleuro-pneumonia, after the absorption of the effused fluid, the inspiratory forces tend to draw air into the lung; but, as this cannot penetrate into the condensed tissue, it presses on the walls of the tubes, and expands them to far beyond their natural dimensions. The membrane lining these dilated bronchi is often in an unhealthy state, secreting more or less mucopurulent matter, which in some instances becomes offensive in consequence of being retained through want of power of expectoration, which is lost because it depends on the act of expelling air from the vesicular tissue beyond, which is now condensed, and receives no air. Dilatation of the bronchi after pleuro-pneumonia is liable to be mistaken for phthisical lesions. Deficient motion, dulness on percussion, sometimes with the cracked-jar noise, loud bronchophony, or even pectoriloquy, with cavernous breathing, or gurgling if there be liquid in the tubes, form a close resemblance to the physical signs of tuberculous cavities. To these are added cough, opaque expectoration, and shortness of breath; and the likeness is sufficient to deceive many ordinary observers. The distinction lies chiefly in the situation and extent of the consolidation, and in the absence of the tendency to spread to other parts which exists in phthisis. Pleuro-pneumonia usually affects the lower half or two-thirds of the lung, the base being quite dull, and the common site of dilated bronchi is at or below the scapula; whereas the lesions of phthisis usually commence at or near the apex, whilst the lower parts of the lung are less affected and more pervious. In the simply inflammatory consolidation of the lung there is more complete and general dulness, contraction, and often hardness of the affected parts, which feel like unyielding wood as the fingers strike them. This may also occur in connexion with masses of tubercles, or the cavities which they produce, for the reason that here also there is often some of the same hard contractile deposit; but in this case it is more partial, and differing in the situation as just mentioned. There is also commonly a disproportion between the physical signs and the emaciation and other general symptoms which occur in phthisis. Dilated bronchi, although causing such marked signs, are attended with much less wasting and disorder of the general health than tuberculous lesions. Again, for the same reason, dilated bronchi may exist for many years in persons with tolerably good health; or at least there is not the same tendency to spread and invade other parts that we find in phthisis. In fact, one is a local disease; the other constitutional as well as local.

The distinction may therefore be sufficiently marked in many instances; but I must not omit to point out that there are cases in which one set of lesions passes into the other. A person with dilated bronchi ultimately becomes phthisical. The chronic consolidations left by pleuro-pneumonia are commonly more or less *cacoplastic*. If they do not degenerate further they only partially cripple the organs by their density and contraction, and, if extensive, may cause increasing vascular obstruction and end in emphysema or dropsy. But these deposits are liable to further degeneration into *aplastic* matter, which, in its nature and tendencies, is not to be distinguished from yellow tubercle. It is under circumstances which deteriorate the general health that this degeneration is apt to occur; and then we find not only the condensed lung softening into cavities, but grey tubercles are formed in other parts, showing that the disease has now become general.(c) But we have here to do only with the contractile consolidations, and have now further to add a few examples illustrative of the subject. The first two are some of the earliest instances in which I discovered this affection.

Case 1.—Edward P., aged 17, admitted to St. George's Hospital November 20, 1837. After exposure, took cold last April, and has since suffered from increasing shortness of breath, weakness, and loss of appetite and flesh; little pain or cough, and no expectoration. In July legs began to swell, and since the abdomen, which is now large and fluctuating. Lips livid; veins in neck distended; pulse 130; urine scanty. Whole

the liver; and, strangely enough, ascribed the dilatation of the tubes to the contraction of this tissue around them. Assuredly this contraction would have just the opposite effect were it not for the pressure of the air drawn into the tubes by the inspiratory effort. This pressure is the efficient cause of the bronchial dilatation. I have endeavoured to show that the contractile property is common to cacoplastic deposits in many organs. (“Principles of Medicine,” third edition, p. 463.)

(c) *Footnote added in 1872.*—The subject of chronic consolidations and contractions of the lung has attracted much attention since these lectures were delivered, and has received valuable contributions from Dr. Andrew Clark and others; but I have met with no facts which invalidate the views which I have here, and long before, held on the subject, and which are more fully developed and applied in our recent work on “Pulmonary Consumption,” etc., particularly in chapter viii.

right side contracted and dull, except an obscure tubular stroke in mammary region. Loud diffused bronchophony in parts, pectoriloquous in all anterior upper regions; coarse crepitus below. Respiration puerile, without bronchophony, on left side. Diagnosis: Condensed lung and dilated bronchi from pleuro-pneumonia. Died on December 19, after increased dyspnoea and dropsy of legs and abdomen. Right pleura everywhere most firmly adherent by tough fibro-cartilaginous matter, in parts a quarter of an inch thick. Lung contracted, quite solid, hard and heavy, of dark reddish colour; chief bronchi generally dilated and empty. Left lung much congested, and some bloody serum in left pleura. Pericardium universally adherent by dense tissue a quarter of an inch thick, and much bloody serum in abdomen. Liver large, with thick false membrane on upper surface; the under surface studded with numerous hard semi-transparent bodies, of sizes from a pin's head to a small pea, adhering to peritoneal covering. Several similar bodies on left pleura and between the lobes of the lung.

Case 2.—Anna B., aged 54, admitted into St. George's Hospital June 13, 1838. Three months ago caught a severe cold, followed by pains in the chest, and has ever since suffered from increasing shortness of breath. Lately the pain and difficulty of breathing have prevented lying down. Cough without expectoration; palpitation; legs œdematous; urine scanty and high-coloured; pulse 100. Left front of chest collapsed, motionless, and quite dull. Loud cavernous breath, and perfect pectoriloquy down to fourth rib, under which heart in contact with walls. Less dulness and some vesicular breath below axilla and in posterior region. Stroke clear and breath puerile in right chest. Short fling with both heart-sounds. Dyspnoea increased, and she died on the 19th. A pint of clear serum in lower part of left pleura. Lung compressed, and strongly adherent to upper front of chest. Lower lobe less compressed, and contained some air, but upper lobe quite dense, of a slate colour, with whitish bands pervading it. In it were three tubular cavities of the size of fingers, which on examination proved to be dilated bronchi ending like the fingers of a glove. Some traces of circular fibres and lining membrane. The pulmonary tissue around and beyond quite dense and grey. Right lung generally healthy, but some indurated grey masses near apex. Dilated hypertrophy of both sides of the heart, and some thickening and rigidity of aortic valves.

With these tragic but instructive terminations of Hospital cases let us contrast the results of private practice, some permanently successful, but others showing eventually the same fatal tendency.

Case 3.—A hale, florid-looking old gentleman of 70 consulted me in December, 1848, on account of cough with opaque expectoration, and pain in the right side, from which he had suffered more or less since an attack of inflammation eight years previously. The cough never quite left him, and was occasionally severe and accompanied with copious expectoration of heavy opaque matter, like that of phthisis. In the right side, at and below the scapula, there were dulness, pectoriloquy, cavernous breath, and occasionally gurgling; and to a less extent the same signs were on the left side also. With generous but careful living, often aided by cod-oil and varied tonics, this gentleman retained his good looks and tolerable health, only having occasional attacks of increased cough and expectoration, but rallying well from them, till 1862, when his legs began to swell, and, together with the infirmities of age, the respiratory organs became more embarrassed, and he died at the age of 84. Thus life was prolonged in considerable comfort for fourteen years, notwithstanding the ugly aspect of the case; not a bad example of a *minor success* in diagnosis and practice. After death both lungs (but chiefly the right) were found extensively adherent and partially consolidated in their lower and middle portions, and in these the bronchi were largely dilated to from three to six times their natural dimensions. The consolidation was tough and firm, and of a dark-reddish colour, almost black in parts—not at all like tubercle in any of its forms.

Case 4.—A gentleman, aged 24, since an attack of inflammation three or four years before, had cough and expectoration, varying very much in amount; and in 1853 I found dulness and large tubular or cavernous sounds at and below the right scapula. Under careful treatment and avoidance of fresh cold, he gradually lost the cough and expectoration. I saw him again in 1858, when he was quite well, except shortness of breath from an occasional cold; but the bronchophony and dulness were still there, and from their stability I regarded them as caused by dilated bronchi.

Case 5.—About twenty years ago I was consulted by a gentleman, aged 40, of sedentary habits, who had, during two or three years, repeated attacks of inflammation of the lungs and pleura, and still suffered much from short breath, cough, and mucopurulent expectoration. The whole left side was dull, motionless, and contracted, and presented to the ear a most noisy bronchophony over a great extent. The vocal vibration was so strong in the side that it could be felt by anyone walking arm-in-arm with him. The consolidation and contraction of the lung in this case were so extensive, and interfered so much with respiration and circulation, that dilatation of the heart and general anasarca gradually ensued, and the patient died in about three years. The whole of the left lung and the lower lobe of the right were found in a state of tough dark-reddish consolidation, with many dilated bronchi but no tubercles. Pleuræ firmly adherent everywhere.

A late eminent ophthalmic Surgeon had a very similar affection following pleuro-pneumonia, after which he convalesced, but he was permanently short-breathed; and had he, as advised, withdrawn from all exertion and excitement, he probably might have lived for years. He died suddenly at a public auction, where he had gone to bid for an estate.

The following cases show the more successful results of careful management:—

Case 6.—A gentleman, aged 43, consulted me in May, 1855, having short breath, cough, and much loss of flesh and strength, after an attack of inflammation in the left chest three months before. The whole left side was much contracted, motionless, and dull. No vesicular breath-sound could be heard in any part; but loud bronchial voice and whiffing in the mid-regions posteriorly. The heart was drawn higher up and further to the left than usual. There were no moist sounds, and the expectoration had ceased. The treatment ordered comprised cod-liver oil with a nitric acid tonic; night and morning frictions with a stimulating liniment containing iodine; good but regulated diet, with a little stimulant; gentle exercise in the open air, in carriage, on horseback, and on foot, gradually increased. In two months all cough and pain had ceased and there was great improvement in flesh and strength; but the condensed lung was little changed, and the breath, though better, was still short on exertion. However, he considered himself sufficiently well to fulfil his engagement to be married, which had been postponed by his illness. A year after he continued in fair health, and then I found some vesicular breath in the upper third of the left lung, the lower part still remaining collapsed and impervious. I have not seen him since, but heard of him as quite well and active in 1861.

Case 7.—A gentleman, aged 39, whose grandmother died of phthisis, consulted me on September 19, 1856. Two months before, after much exertion, was laid up with a feverish attack, which was called gastric, but it was attended with cough and expectoration, once bloody; and the cough has continued with opaque sputa, loss of flesh, and night sweats. Defective motion, and hard dulness of whole right chest, most marked in central and upper parts, where are large loud tubular sounds and strong vocal vibration. Some crepitus in lower parts, but no vesicular breath-sound. To take cod-liver oil in mixture of sulphuric acid and orange infusion. He passed next winter at Rome with little improvement, the emaciation, cough, and expectoration continuing. State of lung much the same: extensive consolidation, with loud tubular sounds, but no softening. The winter of 1857-58 was spent at Nice; and during this year a gradual improvement took place in flesh—9 lbs. were gained—and cough and expectoration ceased. Still much dulness, with tubular sounds, but more motion, and some vesicular breath. October 4, 1859: Last winter at Rome, with more strength and activity. Has since gained much flesh. Motion and sound on percussion in right chest much improved. Dulness and tubular sounds still at and above right scapula. To take iodide of potass, quinine, and nitric acid. December 6, 1860: Generally well, except occasional pain in right chest. Movement and stroke-sound of right chest still not equal to those of left; but good vesicular sounds in most parts; tubular at scapula. 1866: Quite well in health; still some tubular sounds and dulness in upper right. 1871: Continues well.

Case 8.—A gentleman, aged 32, who had lost a brother and sister from consumption, consulted me January 25, 1855. Since an attack of left pleurisy, a year before, had suffered from short breath, weakness, and occasional pain in left chest, but no cough or expectoration. Whole left side of chest contracted and quite dull, with only weak breath in upper portion, and loud tubular voice and expiration in central parts. Heart felt over large space in contact with chest-wall. Had tried cod-liver oil, but, as it caused diarrhoea, gave it up. To take oil

with tannic acid and orange mixture, and use an iodine liniment on chest. In May he was much improved in flesh, but not in strength or breath. Less dulness, but no more breath. To take iodide of potass and liquor potass and sarsa. During the summer was at Ems, where the waters proved strongly diuretic, and his strength and breath improved, but he has now slight cough. Further diminution of dulness, and slight return of breath-sound and movement. The improvement gradually went on during the following year, when he had a succession of boils, for which he was ordered chlorate of potass with nitric acid and quinine. In 1857 the chest continued to improve, but, being thinner and weaker, he was again ordered the oil with quinine, which was taken for some months with benefit, and resumed in 1858, on account of cough and yellow expectoration, but no crepitus or sign of cavity. In the last examination—March, 1859—there was weak breath-sound and clearer percussion in left chest. Still tubular at left scapula. This patient was reported as improving in breath and well in health in 1861. Not since heard of.

Note added in 1872.—Some cases exemplifying the transition of inflammatory consolidation of the lung into phthisis are omitted, as abstracts of these have since appeared in our work on "Pulmonary Consumption"; cases 29, 37, and 40 are especially referred to. Besides Sir D. Corrigan and Dr. Andrew Clark, whose views respecting chronic consolidations of the lung have been alluded to, several other writers have given descriptions of these changes in the pulmonary structure, in various ways interpreting their nature and origin. The views taken are principally of two kinds, one after the example of Sir D. Corrigan, ascribing the pulmonary induration to the growth of a new tissue in the lung, which he called cirrhosis, and to which he imputed the paradoxical property of dilating the bronchi and obliterating the air-cells. This tissue, of fibroid structure, is supposed to spread in bands through the lung texture until it converts it into a tough solid mass. The other is the view originally held by Andral and Chomel with regard to these chronic consolidations: that they are the result of an inflammatory process. This view I made more applicable by showing how the inflammatory obliteration of the air-cells of the lung by pleuro-pneumonia caused the dilatation of the bronchi by expending the inspiratory forces on the latter; and I further proved its connexion with the cacoplastic and contractile formations of phthisical and serofulous subjects. These two opposing views are strongly represented in the recent volume of the "System of Medicine," edited by my friend and former pupil Dr. Russell Reynolds, in the elaborate articles of Dr. Wilson Fox and Dr. Bastian. Under the diverse titles of "Chronic Pneumonia" and "Cirrhosis of the Lung," the two Professors at the same college describe the same disease, exemplified by the very same cases, and yet arrive at totally opposite conclusions as to its nature. Such incongruity in an educational work, however interesting and exciting it may be to the clever controversialist, must prove perplexing to the student and to the young Practitioner.

Although Dr. Wilson Fox makes no allusion to my long-published views on the subject, he has adopted very similar opinions; and, referring to his article for further details, I will briefly mention the chief reasons which originally led me to conclude that these chronic consolidations are chiefly due to inflammation.

In not a few instances the affection can be traced to an inflammatory attack which had occurred months or years previously. This was the case in all the eight examples which I have recorded above, and in some of those cited by Drs. Fox and Bastian; but the previous history of several is imperfect, and latent forms of inflammation, which are common enough, might probably have occurred in those cases in which no former attack is noticed.

But it is in their anatomical characters that these pulmonary consolidations exhibit the most striking proofs of their inflammatory origin. In their situation, affecting principally the lower and middle lobes, and in most instances limited to one side, like pneumonia and pleurisy; in the redness of the consolidation, if not too chronic, resembling hepatitis or carnefication; in the almost constant co-existence of strong pleural adhesions, often thick, dense, and cartilaginous, like the deposit in the lung tissue—we find, it seems to me, conclusive evidence of an inflammatory origin. The remarkably dense and thick adhesions (stated by Dr. Bastian to have been present in twenty-two out of thirty cases) are further proofs of the share which the pleuritic products have had in modifying the condition of the lung: first by effusion (liquid and solid), subsequently when the liquid was absorbed, by the solid lymph agglutinating and contracting—all tending to compress and

obliterate the alveolar texture, its place being occupied by collapse of the walls, by dilatation of the bronchi, or by both. Simply pneumonic consolidations, if of a contractile tendency, may lead to dilatation of the bronchi without any pleural affection; but such cases are exceptional. The rule is, that contractile disease involving a large part of the lung has its origin in pleuro-pneumonia.

It would take too much space to describe minutely the pathological nature of these cacoplastic consolidations of the lung. They are variously combined with hyperplasiae of the elementary structures of the lung, especially the alveolar and the connective tissues; but their chief material consists of the fibrinous exudation from inflamed vessels, which in such cases predominates over the corpuscular matter, and therefore tends to form a dense fibroid solid, disposed to contract or wither, but little, if at all, to soften or cascade. I have discussed their nature and their relation to tubercle and other phthineplasms in the fourth, eighth, and tenth chapters of our recent work on "Pulmonary Consumption."

(To be continued.)

INTRODUCTORY LECTURE
TO THE COURSE
ON PSYCHOLOGICAL MEDICINE.
DELIVERED AT KING'S COLLEGE, LONDON.
By EDGAR SHEPPARD, M.D.,
Professor to the College, and one of the Medical Superintendents of
Colney Hatch Lunatic Asylum.

GENTLEMEN,—This is a new chair, and I am a new professor. The Council of King's College, following the example of other metropolitan schools, have in their wisdom thought fit to institute psychological teaching; and, honouring me as an old student of this place, and one largely familiar with insane life, they have charged me with the responsibility of leading you within the precincts of that domain which is peopled alike by the wildest and the happiest, the tamest and most mournful, of mankind.

Now, you will naturally expect that I should seek to magnify the importance of that which I am about to bring under your notice, and which is the subject of my specialty. But really I have no desire to do anything of the kind. You will hardly expect me, at all events, to *under-rate* it. For who can lightly estimate that which is of such stupendous interest, as embracing the higher part of man's nature? Whether we are descended (as some suppose) from simian conformations, or (as the majority of men think) there is an impassable gulf, which time and development can never bridge over, between those odoriferous travesties of humanity and ourselves, it is equally certain that the breath of life has been breathed into us by Omnipotence, and we are supposed, in contradistinction from all other living creatures, to be bound for a larger and more enduring destiny beyond the confines of this world.

To have this higher part, then, deranged, "out of gear," and not perfectly *d'accord* with its surroundings, must of necessity be a very serious matter. It is my province to speak to you of these things; and the problem which I have to solve is—How shall I best fulfil the mission which is involved in my acceptance of this Psychological Chair? Not, as it seems to me, by giving you a long and elaborate course of lectures upon mental science—upon what the metaphysicians term "inner consciousness" and "spiritual essences." The tendency of the age is, unquestionably, to undue amplification. My error, at least, shall not be in this direction. For I have before me the large number of lectures which you have been called upon to attend and digest; the immense demands which have been made upon your time and your energies; the varied character of your pursuits and studies. And I do not think I shall be doing justice to you if I extend this course beyond seven or eight lectures. Therein I shall give you a general outline of insanity, a simple classification, a sketch of the most important forms, and the treatment of disease. For more than this, according to your several tastes or future intentions as to practice, you will consult the recognised text-books.

From this my intention you will gather that I regard the measure of my usefulness to you as not lying in the number of my words, but in the subjective force and vigour which I can bring to the portraiture of disease, as also in the spirit in which you receive my utterances. Nor shall we be without objective help and assistance. The Visiting Committee of Colney Hatch Asylum, whose Physician and servant I am, have

allowed me, under certain restrictions, which I will explain to you at the end of this lecture, to give you an insight into asylum life and practice, and to illustrate my teaching here by the variety of maladies to be met with there. I have pledged myself that you will not abuse this privilege. Of course you will not. You are gentlemen, and students of King's College.

This first lecture will be general in its scope, and as comprehensive as I can make it without touching upon any of the special forms of insanity.

1. AS TO THE PREVALENCE OF INSANITY.

Now, by the last Official Report of the Commissioners in Lunacy it would appear that the number of lunatics, idiots, and persons of unsound mind in England and Wales was close upon 57,000; the ratio per 1000 of the population being $2\frac{1}{2}$. Ten years ago the ratio was not quite 2 per 1000. This is the "nearest available approximation to the truth" upon official registrations and returns. Yet still it is a debatable and disputed question as to whether insanity is or is not on the increase. Drs. Maudsley and Robertson are on the negative side; but I cannot help thinking there is some fallacy in the statistics which lead to such an inference, and I am disposed to give an affirmative adherence to the proposition. Apart from statistical evidence (which is often very untrustworthy), our inclination to one side or the other will be much coloured by the meaning which we attach to that conventional term "civilisation." If it implies all that our optimists say it implies—the practice of all the virtues and a greater capacity for all that is good and noble—then you will be disposed to hold to the opinion that insanity cannot be on the increase. But there is another side to the picture. To me, as I view "this vast rolling vehicle the world, the end of whose journey is everywhere and nowhere," "civilisation" may but express wear and tear, and high pressure. And the product of these is deterioration of nerve-tissue and general impairment of our material organisations. You yourselves are sufficiently acquainted with all that is going on about you to have learned that civilisation is really a term singularly inexact and indefinite, and admitting of great latitude of interpretation. It involves an improvement, no doubt, of the social wheat; but there is to be considered also its inevitable correlative—a frightful multiplication of the social tares. If our schools and seminaries, and Hospitals and churches have multiplied, so also have our casinos and gin-palaces and betting-rings; the whole area of speculation is a hundred-fold enlarged; all the energies of life are multiplied and intensified; and men shriek at each other on the Stock Exchange who used to converse in quieter and less "civilised" times.

2. PREDISPOSING CAUSES OF INSANITY.

From what I have observed of insane etiology I have come to the conclusion that a great many seemingly small and trivial circumstances go towards conditioning a disturbance which ultimately eventuates in disease. Some of these circumstances are unavoidable. For instance—if nature has given you a pair of "bandy legs" you must put up with them and make the best of them; but by provoking the ridicule of your school-fellows they may be a constant source of irritation, and so endanger the integrity of your intellectual tenement. If one has a squint, or a halting gait, or a tendency to blush unduly, he is equally exposed to derision; and it is not everyone who can bear it with philosophy and indifference. Others of these hindrances to smooth sailing are not imposed by nature, but by the thoughtlessness and vanity of your nearest relatives, who, acting with the best possible intentions, or with no intentions at all, bring about the most disastrous results. If I call my son Pisistratus and my daughter Penelope I am doing them an injustice to which they can have no claim at my hands. The patronymics of many of us are sufficiently hateful and hurtful, without further invitation of the Church's aid to produce nominal disfigurement of individual men. Many a boy at a public school has been ruined by the bantering and bullying to which his name has exposed him. The neurotic diathesis (of which you will hear so much before you have done with insanity) is evoked and developed by the petty teasings of tailless tyrants; but the tyrants were stimulated into action by the thoughtlessness of loving parents and guardians.

You may call these things trifles, but indeed they are not so; and if you have brothers and sisters marrying, or intend some day yourselves to marry, a wise reflection upon the possible results of eccentric nomenclature may preserve you and your children from much unnecessary sorrow.

It is known to you that the great secret of successful horticulture lies in ascertaining the treatment required by different plants—their temperature, their atmospheric surrounding as

regards moisture and light, and the nature of the soil which they can best utilise and appropriate to their individual needs. Now just the same care and judgment are required in that social garden which we call the world. The natures of the young must be studied—their parental antecedents (where practicable), their proclivities, their temperaments, their habits, their talents, their aptitudes. Without this study there can be no educational success that is not empirical. The present Bishop of Exeter, and the present Master of University College, Oxford, are noble instances of what can be achieved by force of character and discernment in the culture and training of individual minds. I say it as a layman, and as an alienist Physician, that no one can overestimate the obligations which the age is under to those who have so nobly sustained the previous reputations of Rugby and Marlborough. Such men raise up a barrier against the *neuroses* by co-ordinating and blending into harmonious working the "morality of clean blood" and the morality of the Christian life.

And if this study and this discernment are so essential with natures which, however different, are supposed to be up to a healthy standard, how much more are they required where there is any tendency to run into the morbid and abnormal. The potentiality of example is great; and it is our first duty as Physicians and philosophers to counsel the removal of young persons from all those surroundings which are favourable to the development of latent mischief, as in the case of a bad ancestral type.

I have written elsewhere, and I here repeat—"A nervous child should be placed in a strong-minded family; that is, with those who have the *will* in complete domination, never allowing themselves to be betrayed into doubt or vacillation. The melancholy should consort with the cheerful; the unduly hilarious with the more sober-minded and sedate; the wandering and vacant should be won to interest by comparatively sensational modes of placing things before them, their perceptive and reflective faculties being alike encouraged; above all, the timid and introverting, having exaggerated religious feelings, should be placed with one of the school which is muscularly Christian and philosophically Socratic. These adjustments of individual temperaments are the basis of true education, both in those who have and those who have not passed the line of mental integrity; and society owes all her well-being to their observance. Each plant to its own peculiar soil: thus only can we discern its capacity for growth and beauty."

Believe me, these things are worth considering. To neglect them is to repudiate the basis of a true and lucid psychology; to study them is or should be the power to prevent evil.

In some cases, indeed, your knowledge will only be a power to modify or temporarily suspend the inevitable. In a large number of persons the hereditary law is so overpowering and impervious that there is no alternative but to yield to its behests. "Multitudes of human beings (says Dr. Maudsley) come into the world weighted with a destiny against which they have neither the will nor the power to contend; they are the step-children of nature, and groan under the worst of all tyrannies, the tyranny of a bad organisation." Against such a state of things you are powerless. And this sense of powerlessness must in the very nature of things lessen your estimate of individual importance. The units, it would seem, are nothing; the totality is everything.

"And the individual withers,
And the world is more and more."

Now, where this bad organisation involves what Dr. Anstie calls the active or dormant hereditary neurosis, or what we term the insane temperament, the future of its subjects cannot be very bright or cheery. There is about them a want of uniformity; their cranial development is not always satisfactory; the features are irregular, one part of the face being bright and expressive, another part very much the reverse. They are given to facial twitchings, an occasional squint, convulsive movements of the limbs; all the actions are ungainly, and lack that muscular co-ordination which is the life of symmetry. In early life they may have stuttered, or had occasional fits; and it is somewhat singular that they may have been unusually stupid or unusually precocious. By only "thin partitions" are the two states separated. Those who are charged with any form of neurosis are easily tilted off their equilibrium; eager, excitable, impetuous—they are constantly throwing off electric sparks. They jump and dance rather than walk through life. The puberty of these creatures is premature; the sexual appetite is strong, and they are given to habits of self-abuse, initiated either by bad example or the innate impulses of an erethistic temperament. Anyhow, the

effect is to aggravate their morbid condition. Happily the power of propagation is not commensurate with the intensity of their lust, and there is a tendency in all faulty organisations to die out and become extinct. I need scarcely tell you that intermarriages with such should in every way be discouraged. It is a dreadful calamity—the repetition of an insane or a neurotic temperament. The young men and women of our day (and I suppose it has been the same in every day) are too much given to marry without inquiry as to the healthy antecedents of those with whom they ally themselves. Mothers naturally enough conceal their daughters' ailments, and a man finds, when it is too late to turn the discovery to advantage, that he has plunged into the arms of hysteria (which is a neurosis), or leagued himself with an indolent and flatulent female addicted to rhubarb and red lavender. But there can be no excuse for you, as physiologists and men of science, getting into this sort of trouble. You would not buy a horse without a warranty, or attempt to breed cattle without starting with a healthy stock. Be cautious and intelligent observers, and your eyes will soon light upon something which will indicate to you safety or danger. I do not ask you to receive as wisdom the satire of Leibnitz, who said—"Marriage is a good thing, but a wise man ought to consider of it all his life." But I do ask you to take advantage, during your pupilage at King's College, of the suggestion of Balzac, who said—"Every man should have dissected at least one woman before he marries."

If a faulty organisation is a desperate, I need scarcely tell you that a sound organisation is a splendid heritage. It is the greatest of natural gifts, for which one cannot be sufficiently thankful to one's ancestors. The somatic integrity of some is so great and continuous that they resist everything in the shape of morbid processes. Like the son of Peleus, they have been dipped in some sanitary Styx, and washed with invulnerability.

3. THE HEREDITARY NATURE OF INSANITY.

This question has already been incidentally touched upon in our remarks concerning temperaments and education. Esquirol has remarked that of all diseases insanity is the most hereditary, and that it is more frequently transmitted through the mother than the father. No doubt a check will be put upon this tendency by the strong-minded women who, dissatisfied with their natural position, are now striving to make themselves men. The worst evil I can wish those ladies is that their ovaries may become shrivelled, and that they may be compelled to shave. Anyhow, the more frequent transmission through the maternal channel will more than justify the remarks which I made just now as to a prudent selection from the many candidates for the nuptial bed who will in due course present themselves to you.

4. PREVALENCE IN THE TWO SEXES—AND IN TOWN AND COUNTRY.

There has been a great difference of opinion as to whether insanity is more frequent in the male or in the female, and the large aggregation of women in our different asylums has led to a belief that they are more obnoxious to mental alienation than ourselves. But a source of fallacy is obvious; *existing* cases do not represent *occurring* cases. Women do not die and do not recover as we do; hence they accumulate. It is pretty certain that the *occurring* cases in the two sexes are about equal; perhaps an excess slightly obtains in the males. Insanity occurs more frequently between the ages of 30 and 40 than any other decade. It is more frequent in the summer than in the winter months, and among the agricultural than the town populations. Regarded superficially the latter circumstance is somewhat puzzling, and in contradiction to what one would naturally expect. The vices and the wear and tear of great cities, with all the attendant evils of dense gregariousness, would seem to invite disease in a larger ratio than in the country. But I take it, as a rule, an agricultural is worse fed than a town population. The cold and comfortless apathy, due to imperfect nutrition, of many of our farm labourers and their families is probably owing to this fact. The glorious hills, and the sunny valleys, and the invigorating air are not advantages sufficient to compensate for the loss of that which supplies nerve and muscle, animal heat, and vital energy. Children half-clothed are turned into fields to frighten crows from sunrise to sundown, a hunch of bread being their only sustenance, and they never get really warm from November to June. Animal food is unknown to them as an article of diet, though fat hogs and fatter yeomen are about them everywhere. Starved and stunted and congealed, they cannot learn; but they live to marry and be given in marriage, and repeat themselves in even a less promising form—if that were possible.

No doubt the form of insanity to which the agricultural labourer is liable is of a less acute kind (dementia and imbecility) than that of the busy artizan.

5.—THE EXCITING CAUSES OF INSANITY.

The causes—the exciting causes—of insanity are, I need scarcely tell you, very varied, and are comprised under two heads—physical and moral—of which the latter are by far the most productive. But it is not always easy to define with anything like accuracy the factorship of mental disease; and it is only right I should tell you that my experience of asylum statistics is that they are utterly unreliable. Let me illustrate this unreliability, and point out the reason of the same.

An insane person, who may have been ill six months, is taken to the workhouse. He is kept there for a few days, when, being found unmanageable, he is transferred to the county or borough asylum, on the certificate of the Medical officer whom the attesting magistrate may happen to call in. In this certificate a statement is required as to the duration and the cause of disease; and without any inquiries being made on these important matters, the *duration* is commonly dated from the day of the patient's admission into the workhouse, while the *cause* is written down as "unknown." The mistake is obvious to the experienced alienist, and our accuracy is at once confirmed on the patient's friends visiting him at the asylum.

I have over and over again admitted patients far advanced in general paralysis, the duration of whose malady has been certified as seven days. We have no power to alter the record, and it goes, with many other lies, to make up our statistics, which are really nothing more or less than formulated falsehoods.

In another way, though to a less extent, and in a less culpable (because partly unavoidable) manner, the element of unreliability is introduced in connexion with causation. As thus:—

A man holding a good situation, upon which his family is dependent, from some cause or other loses it. No longer a bread-winner, he desponds—becomes the subject of melancholia, and is certified as insane from a *moral* cause: loss of employment. But the loss of employment had already involved a diminished supply of food before the insanity manifested itself, and thus physical privation may have led to his despondency, and been the real factor of his disease. Probably both causes contributed to his unhappy condition, but the exacting requirements of tabulation render imperative our adoption of the physical or moral columns in our statistical return.

Again, a man loses his wife or child. In a month he is insane, and his insanity is assigned to a *moral* cause. But it comes out that the loss led him to drink inordinately; the *physical* element is overlooked, and we write down *moral*. Probably, as in the previous case, both causes had their share in bringing about the mental derangement which has now resulted in loss of liberty. So that the etiology of insanity is beset with difficulties and complications, which limit the exactness of our knowledge, and demand the calmest judgment of the observer.

It is obvious that anxiety and losses, and trouble of every kind, must play a very conspicuous part in the factorship of insanity. Undue pressure put upon the ideational centres in the shape of study is also one of the causal phenomena (it really may be considered partly physical and partly moral), of which we must not lose sight. It is said that the competitive examinations now everywhere established in the public service are telling disastrously upon some of the finer-strung natures. It might be found on investigation that they are of the dormant, if not active, neurotic temperament.

Much evil has been thoughtlessly effected by *fright*. Impress, I beseech you, upon all young persons in whom you are interested the folly and wickedness, even in play, of terrifying their schoolfellows and companions. I am sorry to think that some even of our teachers and preachers need a lesson and a warning upon this subject. Children have been stricken into dementia by the sudden jump from behind a door of a concealed playmate, or startled into epilepsy by an unexpected scream, or thrust into the outer darkness of confirmed melancholia by the "rockets and blue-lights" of a fiery preacher. The transition is natural to *religion* as another fertile cause of insanity. There are some I know (and they belong to a theological school which I need not particularise) who affirm that it is impossible for religion to produce mental aberration. Of a truth, I know not why that which contains the largest controversial element of things known to men, and which has produced more bitterness, cruelty, and bloodshed than anything else in the world, should not derange the world. The fact that it can do, and has done, these things, and yet, pointing with the eye of faith to the untried and unseen, give to millions

unmeasured consolation, is alone evidence of its extraordinary power both for good and for evil.

I should be sorry for you to misunderstand anything which I say upon this very difficult and delicate subject. I should wish you to regard it in a calm and philosophical and unprejudiced spirit; and you will then be led to acknowledge that some minds are so constituted, having such inherited proclivities or acquired tendencies, that, put religion before them how you may, they are certain to make shipwreck of it—the magnitude of its teaching is too much for them. There are others who are repelled by a creed which bristles too formidably with shafts and arrows, but are to be won by gentleness and conciliation. It is the doctrines of “verbal inspiration of Scripture,” and “election,” and the “personality of the devil,” which are so fatal to the young and the sensitive and the uneducated, of whom I see so many. I could name, if I chose, more than one Nonconformist preacher known for their power to “stain the imaginations of young children (as Mr. Lecky expresses it) by ghastly pictures of future misery,” to whom I am indebted for instructive cases of religious mania. These “foolish and abominable denunciations” (as Dr. Conolly called them) achieve incalculable mischief, and consign many nervous and impressionable subjects to a misery as hopeless even in this life as has been charitably predicted for them in the next.

(To be continued.)

ORIGINAL COMMUNICATIONS.

A CASE OF MEDULLARY TUMOUR OF THE FEMUR, WITH REMARKS.

By F. A. BULLEY, F.R.C.S.,

Consulting Surgeon to the Royal Berkshire Hospital, Reading.

ANN M., aged 48, was admitted into the Royal Berkshire Hospital, April 23, 1867, on account of a large, somewhat globular, elastic swelling, occupying the lower part of the left femur. The integument covering the enlargement is tense and shining, with two or three large tortuous distended veins ramifying over it in different directions. The circumference of the largest part of the swelling, which is just over the centre of the condyles, measures $20\frac{5}{8}$ inches, whilst that of the sound limb at the same part is fourteen inches. The lower part of the tumour seems to terminate somewhat abruptly opposite the articular surfaces of the condyles, the knee-joint and the upper extremity of the tibia being apparently unaffected by the disease. She suffers a great deal of pain in the part, especially at night, and she has not been able for a long time to support her weight upon the limb. The disease had commenced about six years before, when, after a slight accident, she began to feel uneasy sensations about the knee-joint, and some little stiffness in walking; but there was no perceptible swelling of the part until within the last three years, when it began to enlarge, and as it had then become very painful, she was admitted into the Hospital, whence she was discharged, after five or six weeks' treatment, with but slight relief to her symptoms. Shortly after this she had a severe attack of jaundice, when the swelling and pain and the general uselessness of the limb increased so much that she became unable to move it forward in going upstairs or even in walking upon crutches. From this time she became quite unable to put her foot to the ground, and the enlargement gradually increased to its present dimensions, the pain towards the last becoming almost intolerable. Her general health had become much impaired through the constant pain, and she had got very thin from the loss of appetite, which had latterly almost entirely left her. She had formerly enjoyed good health, and before the commencement of her present complaint was a robust and hearty-looking woman. Her parents and family generally had been particularly free from malignant disease of any kind.

May 3.—Ten days after her admission the limb was amputated. The inguinal glands were quite free from disease when the operation was performed. On sawing through the bone just clear of the enlargement, the medullary cavity appeared to be more capacious than ordinary, and was filled with the same kind of morbid deposit as was found to constitute the bulk of the tumour, of which, indeed, it seemed to have formed a part, and evidently extended for some further distance up the bone of the stump. The stump healed kindly, the cicatrisation being only a little delayed by the gradual dissolution and discharge of the deposit which had been left in the medullary

cavity of the bone. As soon as this had been completely discharged and its place occupied by healthy ossific matter, the wound of the integuments rapidly healed, her appetite had returned, and, as she shortly afterwards appeared to have recovered in every respect her former good health, she was discharged from the Hospital, five weeks after the amputation of the limb.

Examination of the Amputated Limb.—The tumour was composed entirely of a homogeneous unlobulated mass of yellowish brain-like matter, somewhat firmer and more compressed than ordinary brain, and having numerous bloody points upon its divided surfaces. In one part of it was a small clot of coagulated blood, round which the morbid deposit had become condensed, so as to form a cyst resembling in appearance an ordinary apoplectic cyst in the brain. The diseased mass completely occupied the condyles of the femur, the cancellous structure of which had entirely disappeared, as well as about five inches of the adjoining shaft of the bone, the portion removed by the saw (about three-quarters of an inch) remaining embedded in the tumour where the shaft had abruptly terminated. The immediate covering of the tumour was composed of the stretched and hypertrophied periosteum, strengthened in parts by thin flat scales of bony matter in its substance. Over the articular surface of the outer condyle the cyst was thicker than elsewhere, being formed by the undestroyed cartilage of the part; but over the inner condyle the cartilage had disappeared, the enclosing membrane of the tumour being here nothing more than the capsular ligament of the joint somewhat thicker than natural, and having a more bulged, elastic feeling than the other parts of the cyst. The crucial ligaments had lost their femoral attachment, and lay loose in the joint, and the alar ligaments, as well as the capsular, were thickened and softened, with other marks of progressive disorganisation of the joint, but with no appearance of pus in its cavity. The heads of the tibia and fibula were quite free from disease.

Remarks.—It is now nearly five years since the operation and there has not been the slightest perceptible symptom of a return of the disease either in the stump or in any other part of the body; it may therefore be fairly presumed that the malady had a strictly local origin, and was not the result of any pre-existing cancerous cachexia of the system, or from any hereditary predisposition to malignant disease on the part of the patient.

Judging from the examination of the tumour, and the absence of cartilage or other characteristic cells in its structure, I could not help thinking that the morbid deposit had commenced in the medullary cavity of the bone, and that, owing to some peculiar disturbance or loss of balance between the secretory and absorbent functions of the part, through the injury received, the natural medullary secretion had become deposited in excess, and thus by its subsequent eccentric expansion and pressure had caused the absorption of the lamellated structure of the shaft at first, and afterwards of the cancellous texture of the condyles; until at length, by additional deposit, it got altogether out of the influence of the absorbent system of the part and constituted a tumour, which, although apparently composed only of the natural secretion of the part in excess, was insusceptible of absorption and could only have been removed by amputation.

Thus much for what may perhaps be considered a non-malignant affection of the parts; but there are other morbid enlargements in this situation, such as the osteo-sarcoma and fungoid growth originating in the bone, from which the innocent disease is not easily to be distinguished, especially in the earlier stages; and as they are all equally, during every part of their progress, unamenable to local remedial means, and as, in fact, amputation seems to be the only remedy in extreme cases, whether malignant or not, the principal consideration would be as to how far the operation might be expected to afford permanent relief to the patient. To illustrate this point, Sir B. Brodie has recorded the case of a patient whose limb had been amputated for encephaloid disease of the bone, who four years after the operation was in perfect health; and Mr. Stanley, in his treatise on diseases of the bones, has given an account of a case of the same kind of disease originating in the head of the tibia, where the patient at the end of two years had had no return of the disease. Other instances, however, have been recorded of directly opposite results, and in the seventeenth volume of the *Medico-Chirurgical Transactions* may be found a case, under the care of Mr. Lawrence, of an encephaloid tumour originating in the head of the tibia, in which, the patient dying after the amputation of the limb, encephaloid deposits were found in the bone

and the inguinal absorbent glands; and other similar instances have been recorded by Surgical writers on the subject.

It would appear from these and other instances that some amount of doubt must always exist as to the remote effects of amputation in diseases of this kind, and, such being the case, it would seem only reasonable to give the patient the benefit of the doubt, provided there should be no particular implication of the absorbent glands, nor the constitution broken down by such an amount of general cachexia as would be almost certain to be followed by the reappearance of the disease, either in the part or in some one or other of the internal organs of the body; in which respect a tumour in this situation might perhaps be regarded in the same light as some other questionable growths in external parts of the body, of which the exact nature is often only revealed by the reappearance of the disease, or otherwise, after their removal by operation.

ON PYURIA IN YOUNG CHILDREN, WITH AN ILLUSTRATIVE CASE.

By ROBERT C. R. JORDAN, M.D.

THE passage of large quantities of pus with the urine is far from infrequent in young children, and many cases have come under my notice amongst the little patients at the Birmingham Children's Hospital. No case of idiopathic cystitis has, however, fallen under my care at any time; so that the very existence of such a disease in the young seems to me doubtful. The pus appears to depend always on some impediment to the passage of the urine, or on local irritation to the organs themselves, produced by the presence of a foreign body. In either case a certain amount of urine is retained, which, becoming ammoniacal, either causes or else increases the irritation. The commoner sources of such discharge may be classed thus:—

A. INTERNAL—

Stone in the bladder.
Stone in the kidney.

B. EXTERNAL—

Congenital phymosis.
Hypospadias.

Rarer cases of either class—such as, for example, tubercular deposit in the kidney, and consequent abscess—are not noticed in the table. If there be impediment it reacts backwards, and the sequence is usually as follows:—First, hypertrophy of the bladder occurs; and if this cannot overcome the obstruction, then discharge of pus, produced by the irritation of the decomposed urine; next comes dilatation of the ureters; and, finally, cystic degeneration of the kidneys, with abscess and death. The primary cause is almost always Surgical, and the treatment (when it can be of any avail) is Surgical also.

The following case which lately came under my care well illustrates these points:—

W. M., aged 6 years, was admitted into the Children's Hospital, Birmingham, in February, 1872. He was sent to me from the Surgical department by my colleague, Mr. G. Elkington, as he felt that the time for Surgical interference was gone. He had been sounded of course with care, but no stone detected. There was no phymosis, but he had slight hypospadias. The orifice of the urethra was on the inferior surface of the glans instead of at the apex; but there was no difficulty whatever in passing a sound into the bladder. The quantity of water passed was very small, and laden with pus; it became more and more scanty until the suppression was almost complete; and after being in Hospital about ten days, the boy lapsed into coma, and died. During the forty-eight hours immediately preceding his death he only passed three ounces of water, or rather of pus, with a very little urine with it.

Unfortunately there was great difficulty in obtaining a post-mortem examination, and for this reason the urethra could not be examined. The following was the condition of the other parts:—The body was not deficient in fat, and the organs were generally healthy, and without albuminoid infiltration. The bladder was hypertrophied, and its coats considerably thickened. Both ureters were enlarged and dilated until they quite equalled the small intestine in calibre. Of the kidneys, the right was hollowed out into a mere collection of cysts, the cortical part not being thicker than the partition-wall between these. It was filled with pus, and in its posterior wall were two orifices which communicated with an abscess in the psoas muscle; but there was no pus outside its sheath. In the left kidney the same process of disintegration had gone on as on

the right side, but not to quite so great an extent; and there was still a very thin layer of cortical portion, which, scanty as it was, must have been the only portion of either kidney capable of secreting. The large cysts and pelvis of this kidney were full of pus, and there was also a communication with the psoas, which was, however, so firmly adherent to it all round that a small encysted abscess was the only result. The renal arteries were enlarged and thickened; the supra-renal bodies seemed healthy.

This case teaches its own lesson, which is, that wherever the slightest obstruction exists to the free passage of urine in a child, Surgical interference should be promptly resorted to. Had early measures been taken in such a case as this, no doubt the fatal result might have been prevented. Even so simple a cause as congenital phymosis may lead to death. Every impediment—even the simplest—ought to be attended to as early as possible.

REMOVAL OF THE LOWER LIP FOR EPITHELIOMA—CHEILOPLASTIC OPERATION.

By J. FAYRER, M.D., C.S.I.,
Hon. Physician to the Queen.

SIETANATH, a Hindoo blacksmith, aged 58, was admitted into the Medical College Hospital, Calcutta, on May 1, 1871, with an ulcerated epithelial growth involving the centre of the lower lip. It was indurated, nodular, and ulcerated, made its first appearance five years ago, and had been growing rapidly during the last six months. There were no glandular complications, but a portion of the centre of the lower alveolar process and gum were affected, and the incisors were partly displaced. His health being otherwise good, the diseased parts were removed on May 10.

The entire lower lip was removed by a V-shaped incision extending from the commissures of the lip to the point of the chin; portions of the alveolus and gum, with part of the frænum linguæ, were also taken away. The incisions were prolonged from the point of meeting at the chin in a curved direction downwards, outwards, and then upwards as far as the masseter on either side. The flaps, being dissected away from the bone, were then brought forwards and upwards until the first two incisions formed the margin of a new lip, the flaps being united by three horsehair sutures in the central line, and leaving a triangular gap over the chin to be closed in by granulation and cicatrisation. Union occurred rapidly, and he was doing well until the 16th, when he had a severe attack of erysipelas of the face and scalp. From this, under the influence of purgatives, quinine, tr. ferri. muriatis, and plenty of wine and nourishing diet, he recovered, and union was not disturbed. His recovery was somewhat delayed. Cicatrisation of the lower part of the wound was not complete until July 21, when he was discharged.

The lower gum and teeth were well covered by the new lip, and the triangular gap had contracted to a small scar. The lip was adherent to the jaw, and its margin cicatrised satisfactorily.

THE GERMAN ARMY.—The establishment for 1873 includes 1672 Surgeons.

CARIES.—We have each year to report numerous cases of caries, and that principally of the left lower jaw. This tendency to caries may often arise from their unwillingness to part with decayed teeth. As pointed out in last report the Chinese part with portions of their body very unwillingly, from the fear of disfiguring them and being obliged to enter the other world maimed and imperfect, thus dishonouring those who gave them being. We forgot, then, to mention this additional circumstance when speaking of eunuchs, that individuals becoming such, and without a home or relations, roast and eat the parts there referred to, for fear of their going amissing by being obliged to carry them continually about with them till death. Decayed teeth are attributed by the Chinese to worms, supposed to be lodged in them. In one man the entire lower jaw, nearly perfect, was removed. His appearance was most peculiar before the operation. A boy appeared with exfoliation of nearly the entire skull; and a man, with the frontal bone entirely black and exposed.—*Report of the Peking Hospital, by Dr. John Dudgeon.*

REPORTS OF HOSPITAL PRACTICE
IN
MEDICINE AND SURGERY.

GUY'S HOSPITAL.

THREE CASES OF LACERATED PERINEUM.

(Under the care of Mr. BRYANT.)

Case 1.—Fracture of the Pelvis—Laceration of the Perineum—Protrusion of Intestine (large and small) with the Uterus and Bladder through the Perineal Wound—Recovery.

MARTHA B., aged 4, was admitted into Martha Ward, Guy's Hospital, under the care of Mr. Bryant, having been sent up to him from Wales, with a note from Mr. Hugh Bennett, who saw her after the accident, fourteen months previously. The injury was caused by a two-wheeled cart carrying a ton of coal passing over the child's pelvis. When seen half an hour subsequently, the bladder, uterus, rectum, and small intestine were protruding from the lacerated perineum, having been "pulped" out by the abdominal pressure. Some part of small intestine protruded between the protruding rectum and coccyx. The parts were reduced as well as they could be, and the perineal wound stitched up. Although some prostration followed, the child's life was saved. At the time of the accident there was likewise a lacerated wound upon the right crest of the ilium. Two weeks after the accident the perineum partially gave way, and the parts protruded as seen when admitted. Between three and four months after the accident three pieces of bone came away—one through the wound over the ilium, one in front of the protruding gut, and the third behind. After seven months the child was able to leave her bed and to walk. The descent of the bowel, however, prevented her going much upon her legs; it used to descend as low as her knees when walking.

On Admission.—The pelvic bones are clearly separated for about two inches; the bowel is protruding for about two inches. The posterior commissure of the vulva is completely gone with the perineum, being represented by a deep fissure in front of the protruded gut. In front of this, again, the labia minora and clitoris may be seen just to the left of the middle line, between the widely separated labia. Looking at the child from behind, the pelvis is clearly widened. The buttocks are flattened, and the knees abducted and everted. The urine constantly dribbles away. There is some power over the motions.

On April 30 Mr. Bryant attempted to bring the divided borders of the perineum together, and succeeded with the aid of quill sutures; but the parts subsequently gave way, and no good result was obtained.

Case 2.—Lacerated Perineum into Rectum—Prolapsus Uteri—Cured by Operation.

Ellen J., aged 47, was admitted into Guy's Hospital, under Mr. Bryant's care, on June 3, 1871. She was a married woman, and had had five children. She received the injury for which she was admitted during her first confinement twelve years ago. For many months she had been able to do very little, on account of the "falling of the womb." She had no control over her motions on admission. Most complete laceration of the perineum was seen, with the loss of one inch of recto-vaginal septum. The womb appeared externally.

On June 22, with the patient under chloroform, Mr. Bryant operated, taking away a good inch of mucous membrane from the sides of the perineum, paring the free border of the recto-vaginal septum, and dissecting off a column of mucous membrane from the posterior wall of the vagina from the septum upwards. He then brought the parts together with the quill suture, using gut. He put in also some superficial sutures of silk. On the sixth day the sutures were removed, Mr. Bryant fearing the parts were about to slough; but in this fear he was wrong, for good repair took place at the posterior part and in the recto-vaginal septum. Mr. Bryant thought that a second operation would be required to make a longer perineum to support the uterus.

The patient left the Hospital on July 12, to return in a few months when stronger.

She was readmitted on October 27, 1871, and on Mr. Bryant making an examination he said nothing more was needed; all the parts had contracted up so well that a good perineum existed. The patient had full control over her motions, and very slight prolapse of the uterus.

Mr. Bryant pointed out that no ease proved better the value of delay before operating a second time in these cases than this.

Case 3.—Lacerated Perineum—Operation—Recovery.

[Reported by Mr. CARTER.]

Fanny B., aged 28, was admitted into Guy's Hospital, under Mr. Bryant's care, on May 10, 1871, with a lacerated perineum through sphincter. It took place during her first confinement in November, 1868, the child being hydrocephalic. She has had no power in retaining her motions since then.

On May 15 Mr. Bryant operated, the patient being under chloroform. He pared the edges of the perineum freely, as well as the anterior border of the recto-vaginal septum, taking away some of the mucous membrane of the vagina in front of the septum. He brought the parts together with the quill suture, using silkworm gut as sutures. Opium was given subsequently. On the eighth day the sutures were removed, complete union having taken place. On the eleventh day the bowels acted, and the woman left with a good perineum on June 7, well able to retain her motions.

ST. GEORGE'S HOSPITAL.

CASES UNDER THE CARE OF DR. JOHN W. OGLE.

Supposed Swallowing of a Farthing—Glass Bead passed per Anum.

THE following is the case of a child, aged 4, who was supposed to have swallowed a farthing several days previous to admission. The mother at the time had made vain attempts to get out the farthing, and the child had taken no food, excepting milk and tea, since the event. The child was healthy in appearance. Pressure outside the neck seemed to occasion pain. For a day or two still the child only took liquid food. After this, as nothing had been given to him excepting soft pudding and bread, he began to eat solids, and soon ate like other children. The probang was avoided, and it seemed as if the unwillingness to swallow solids was the result of pain occasioned by rough treatment on the part of the mother in her attempts to recover the farthing supposed to have been swallowed. The stools were daily watched, and after a few days a large glass necklace bead was found in the evacuations. The child after this went home quite well.

Supposed Swallowing of Money—Uræmic Coma.

The patient, a waterman, past middle-age, got wet in a state of intoxication. Violent dyspnoea and shivering came on, and he was brought into Hospital with broncho-pneumonia. At this time the urine was free from albumen. He asserted that his illness was the result of some money which he had swallowed hurriedly to avoid his wife stealing it from him. Consolidation of the lung on one side followed, and some effusion into the pleural sac. All this cleared off, and he was convalescent, when his feet and ankles began to swell. This led to the urine being examined, and it was found to be loaded with albumen. In spite of treatment, coma and insensibility, lasting for two or three days, set in, from which he recovered under the use of a blister to the nape of the neck and croton oil. Afterwards he became quite convalescent, and all œdema left him. By degrees the albumen in the urine diminished so that scarcely a trace was left. Later on it increased, and he had again threatenings of head symptoms, which were relieved by elaterium and jalap purges. Eventually he left quite well, excepting that the slightest trace of albumen existed in the urine. At no time were casts of uriferous tubes discerned by the microscope.

Acute Rheumatic Fever.

This case commenced by pain and tenderness and swelling of the left temporo-maxillary articulation. On recovery, the lymphatic glands of the right side of the neck swelled and formed a large indurated mass. Under iodine, it was greatly reduced on her quitting the Hospital. In connexion with this case, Dr. Ogle mentioned certain cases of permanent immobility of this articulation resulting from rheumatism.

Itch Cured by Peruvian Balsam.

This was the case of a child affected by well-marked itch about the fingers and elbows. A German Physician had lately visited the Hospital, and spoke of the cure of this disease by the balsam; and, at the suggestion of Mr. Claridge, the House-Physician, Dr. Ogle gave it a trial. The daily rubbing of the affected parts night and morning sufficed, in four or five days, completely to cure the patient.

Suicidal Tendency from Cerebral Congestion.

A young man of healthy appearance, in whose family was no hereditary taint, had become, as he said, "queer in the head," and tormented by the idea that he must commit suicide. There appeared reason to think that unwonted venery had been given way to. On admission the head was hot, and pain in it was complained of. The face was red; and the eyes rather suffused. He was freely purged, low diet was ordered, and ice, followed by evaporating lotions, applied to the head. After some days he quite recovered, and there was no return of his mental disturbance.

Almost Total Blindness—Intracranial Tumour or Deposit (?).

The patient, a woman—Anne S.—aged between 45 and 50, suffering from much pain in the head, has been almost entirely blind for several months. The muscles of the face and limbs act naturally, as also those of the eyeballs. There is very slight divergent squint with the left eye. The eyes were examined by Mr. Carter by the ophthalmoscope, and atrophy of the optic nerve was found, obviously the result of neuritis. The retinal veins were not only winding, but beaded as if varicose from past distension. The urine is free from albumen and sugar, and no syphilitic history is traceable. The loss of vision only came on gradually after the cerebral symptoms had existed some time. There has been no double vision. Under the use of bromide and iodide of potassium and blisters to the neck the pain has ceased, and she says she can distinguish the outline of objects sometimes which she could not previously do; the power of vision, however, is obviously but little improved.

GERMAN HOSPITAL, DALSTON.

IDIOPATHIC (RHEUMATIC) TETANUS.

(Under the care of Dr. HERMANN WEBER.)

From the notes kindly furnished by Dr. Port, the Resident Medical Officer, we learn that H. S., aged 35, a well-nourished and muscular man, a labourer in a gas factory, began to feel stiffness in the jaws on January 22; a few days later stiffness in other parts (especially the thighs) supervened, and he was obliged to remain in bed. On January 29, when admitted into the German Hospital, he was in profuse perspiration; the jaws could only be opened far enough to admit a spoon; the muscles of the neck, back, and lower extremities were especially stiff, while those of the arms still allowed a tolerably free movement. In addition to this constant stiffness he had painful attacks of spasms, occurring especially at night, during which attacks he had twice bitten his tongue. The intellect was quite free; the urine scanty, acid, free from albumen. Pulse 78; temperature 98.4° F. (36.9° C.) Treatment: Subcutaneous injection of one-sixth of a grain of morphia; fluid food.

January 31.—No marked change. Temperature 99° to 99.6° F.; pulse under 90; respirations 32 to 36 (irregular). The perspiration continues. The face has an anxious expression, the muscles of the lips being contracted, leaving a roundish opening. At night sleepless. Treatment: Subcutaneous injection of one-fourth of a grain of morphia twice a day.

February 2.—The symptoms are rather aggravated. The arms are likewise affected, but less so than the legs. Abdominal muscles rigid; nights sleepless; retention of urine since yesterday. He has occasional attacks of general spasm, with violent shaking of the whole body, during which the back is somewhat arched, opisthotonus-like. During the attack he gives about every forty seconds a single loud hoarse cough, with rather abundant thin muco-purulent expectoration. The perspiration, constantly profuse, is during the attack increased to that degree that it runs from the forehead and face in large streams. Pulse during the attack 85 to 88; irregular. Respirations 30 to 34; very irregular. The attack lasts from four to six minutes, immediately after which the pulse is only about 60, from which number it gradually rises again to between 80 and 90. There is scarcely any pain during the intervals. Treatment: Instead of the morphia injections, thirty grains of hydrate of chloral three times, afterwards four and five times, per day.

Under this treatment the nights became better, the attacks milder, the perspiration diminished, and the expression of his face and the general health improved. The pulse, however, became weaker, and he continued to require the catheter.

On the 12th the chloral was left off, in order to test its share in the treatment. The attacks became immediately increased in severity; the nights sleepless, the perspiration profuse, and the secretion of urine very scanty. From the 14th the chloral

was resumed and led to rapid improvement; the stiffness of muscles likewise gradually diminished, and in the beginning of March he regained the power over the bladder, and was able to walk and to masticate.

The temperature after the 17th was never above 99.5°; it in general was under 100°, but on the 16th it reached 102.8° Fahr. The evening temperatures were always higher than those of the morning.

Dr. Hermann Weber remarked that it was rather difficult to demonstrate to which of the heads of idiopathic tetanus this case was to be assigned, but that he regarded it as rheumatic. Rheumatic fever, he said, was a most general affection at the time, occupying every third bed in the Hospital. The perspiration was much the same as in rheumatic fever, and the man's occupation exposed him to high temperatures, frequently alternating with cold draughts in the passages. He had, besides, met with another case of idiopathic tetanus, in which the alliance of the disease to rheumatic fever appeared to him as much as certain, as the patient, a lad aged 21 years, had previously suffered from rheumatic fever, without affection of the heart, while endocardial affection supervened during the course of the tetanus. As to treatment, the chloral had a decidedly favourable effect in half-drachm doses three to five times during the twenty-four hours, for the first improvement manifested itself soon after the administration of this medicine; the omission of the chloral during several days was attended with a recrudescence of all the symptoms, and the resuming of it was again followed by rapid improvement.

EDINBURGH ROYAL INFIRMARY.

RECURRENT ABSCESSSES OF LABIA MAJORA.

(Under the care of Dr. MATTHEWS DUNCAN.)

[Reported by Dr. J. R. HARDIE.]

B. J., aged 22, has been married for four months, and came into Ward XVI., December 20, 1871, complaining of frequent gatherings in the private parts. The first time that she noticed anything the matter was four years ago, when, after a fall off a ladder, an abscess formed in the left labium. Since then the abscesses have recurred eight or nine times, always at the same place, and without apparent cause. When left to themselves they have burst and healed up well; when opened with a lancet they also terminated quickly and well. On examining patient, an abscess is seen occupying the left labium—about the middle of its longitudinal direction. It is about the size of a walnut; not tender to the touch.

December 21.—Patient says the abscess burst to-day.

23rd.—No mark or trace of it could be detected.

25th.—Dismissed.

With this form of abscess of the labia—so far as can be judged from what has been written concerning it—the Profession do not appear to be very familiar. There is still great room for enlightenment with regard to it, its history being but imperfectly understood, and its preventive treatment (which would appear to be the treatment chiefly aimed at—in fact, the treatment) being in its infancy or still unborn. It is characterised by the formation of consecutive abscesses, which follow one another sometimes very rapidly, at others not so quickly, a considerable interval elapsing between their appearance. In some cases, before one abscess has burst or been artificially evacuated, another is in the process of formation. It matures and bursts; and this may go on until the patient has been the victim of ten or twelve, or even more of them. In others an interval of a few months may elapse between their formation. That the fall had any closer relation to the appearance of the first abscess than coincidence of time seems doubtful, since after the removal of the supposed cause the supposed effect was still apparent. Considerable pain generally attends their onset and maturation, which is only alleviated on the advent of suppuration.

The treatment to be adopted is that for the same disease occurring in other parts—namely, poulticing and evacuation locally, with the employment of any general remedies which the circumstances of the case may require; but, as has been already pointed out, what is greatly desiderated is some method of treatment which can either prevent the disease coming on at all, or cause it to abort when it has set in.

It is to be noticed as remarkable how little trace of the disease is left after evacuation, either natural or artificial;—so much so, that to one who had not seen the abscess before bursting its previous presence might appear questionable.

The following is an account of the autopsy of a case of Malignant Disease of the Ovary, under the care of Dr.

and a judge"; but almost every Practitioner whose name is appended to the "Manifesto" did in reality sustain these two characters—"two gentlemen at once." For it cannot be denied that many of these advocates of temperance are, and have been, in the habit for years past of stimulating with "intoxicating" spirits in cases of low fever, or depression following severe injury, and in most cases where the condition of the system called for support. Indeed, it would be criminal in them to withhold this means of sustaining life, when such means are demanded by nature, spite of the theories of half-crazed total abstainers, and the objections and denunciations of "temperance" advocates.

It is not our intention to go into "argument" as to the "wording" of the document in question. Without hair-splitting, and viewed merely by the light of common sense, the "Manifesto" is a denunciation of the members of the Medical Profession for their encouragement of the vice of intoxication. The offenders, however, may pride themselves on the fact that their accusers do not charge them with wilful and corrupt encouragement of intoxication. No, they are too charitable and polite to do this. On the contrary, they are convinced that drunkenness as fostered by Medical Practitioners is due to the carelessness or ignorance of the prescribers. If the Manifesto means anything, it means this. A grosser (but we believe unintentional) insult was never offered to intelligent members of an honourable and learned Profession. The reaction, however, has commenced, and is still going on. Discussions are constantly taking place in all gatherings of Medical gentlemen, whether over the dinner-table, in societies, or elsewhere; and it is not too much to say that the Manifesto is generally denounced as an attack upon the Profession. But the evil which this "Manifesto" has inflicted upon Medicine in the eyes of the public cannot be overrated: it has tended to lower the faith of the public in legitimate practice quite as much, if not more, than "homœopathy" or any other quackery. The reason of this is obvious. The charge against the Profession is made by nearly 300 of those who claim, and not without good cause, to be the "heads" of Medicine and Surgery.

"If," say the public, "the great mass of our Medical attendants deserve such a reproof from their 'betters,' how can we trust them?" The public has, however, we should hope, too much sense to regard the "offenders" in one light only. How many men, and women too, can point to their Medical advisers as their saviours from habits of gross intemperance! By precept, by example, by carefully and gradually reducing the amount of stimulus, how many a drunkard has been saved and reclaimed by his "Doctor"! If that Doctor, in the pursuit of his practice, finds occasion to stimulate as a means of curing disease or of saving life, we should not hold him guiltless if he withheld the required assistance. We say, on the contrary, that his neglect of the use of "alcohol," when alcohol was required, would be little short of a criminal act, and might be "murder" by omission—in the eyes of equity if not of the law.

In the whole discussion of the subject of intemperance it is to be regretted that the question has been taken up by the "societies" on either side as a party question.

"They give up to party what was meant for mankind."

Yes, it is a subject which cannot fairly or satisfactorily be discussed in this one-sided and unsatisfactory manner. Drunkenness is unquestionably to be denounced in unmeasured terms by all right-thinking people; but "temperance"—and by this we mean the moderate and wholesome use of "wine"—is not only not to be condemned, but is, as a general rule, beneficial to health and longevity. In these days of harass, competition, and the "wear and tear" of life, there is little that is "natural." If it be natural to drink only water, so it is equally natural to live as our first parents did in Paradise—feed on herbs and dispense with clothing. The mistaken enthusiasts who condemn the abuse with the use of wine are not open to argument.

They assume a position and hold it, fortified by their own self-conceit, in a citadel of prejudice, guarded by ignorance. In saying what we have said in defence of our Professional brethren, we desire to be understood as objecting to "overstimulation," even in disease, if such is ever resorted to. It may be in some few instances, and in these perhaps from ignorance. But we are firmly convinced, from a long and extensive acquaintance with the Surgeons in general practice in this country, that as a body they are not open to the grave charge made against them by the three hundred. On the contrary, we assert, without fear of contradiction, that they are too well informed, too intelligent, too conscientious to fall into such a mistake. It must be recollected that the progress of knowledge, the improvement in Medical education, the increase of severity in the examinations by our qualifying bodies, have had the effect of raising the Surgeon in general practice to a position very different indeed from what it was a quarter of a century ago. It is not too much to say that the "village doctor" of the present day is a man equal to something more than the "common exigencies of his Profession." He may not be so "acute," "subtle," or "microscopic" as some of the leading "specialists," but he takes a broad view of humanity in its healthy and diseased states, and as a Practitioner is as safe—nay, safer, if not so "brilliant"—as the man who confines his study to one organ at the expense of all the rest. We have spoken severely, and we intended to do so, of the "Manifesto." It originated in a *ruse* and is worded in a most objectionable manner. It is a blunder as to the influence it has exerted on the "cause" for which it was framed; it is erroneous as to its statements and inferences; and it is gravely offensive to many thousands of men as able and as worthy to "stand erect" as any of the three hundred who have needlessly called the conduct of their brethren into question.

THE WEEK.

TOPICS OF THE DAY.

WE hear that a Bill will before long be introduced into Parliament to enable the Apothecaries' Society to take part in a Conjoint Examining Board for England.

The death of Mr. Dasent is only one of a long list of fatalities that lie at the door of the University of Oxford. Our old Universities, and the colleges in connexion with them, have enormous revenues, which they are supposed to expend—and great privileges and rights which they are supposed to exercise—in maintaining the education of the better classes of English society. They receive large sums for the maintenance of the young men whom they educate; and yet it is marvellous how indifferent the authorities show themselves to their safety and physical well-being. In this matter of bathing, Sandford Lasher—the pool where Mr. Dasent was drowned—is well known to be a magnificent bathing-place, only it is excessively dangerous. It attracts to it all the best swimmers in the University during the bathing season, and yet the University authorities have taken no pains to provide assistance on the spot in case of accidents. A couple of men and a boat with a rope would have saved Mr. Dasent's life, and would have preserved to the country one of the most promising scholars in the University.

Under the heading "Layers of Infection," the *Pall-mall Gazette* extracts from the report of the City Officer of Health for Manchester some facts relating to the number of coats of paper found on the walls of houses infected with small-pox in that city. On the walls of one cottage fifteen coats were found. But it is not only in cottages or in Manchester that old papers are left on walls. Most of us have seen in respectable houses in London layer after layer of paper stripped off servants' bedrooms which we have recommended to be cleansed after scarlatina and other infectious diseases. The practice of whitening sepulchres is not confined to Palestine.

As we anticipated, the charge of manslaughter preferred against George Hurry, one of the "Peculiar People," was withdrawn from the consideration of the jury by Mr. Serjeant Ballantine, the leading counsel for the prosecution. Such a charge could not be sustained unless the death could be directly connected with the neglect to provide Medical assistance. To establish the charge of manslaughter such neglect must at least conduce to the death; and as Mr. Ryley, a Surgeon at Woolwich, very properly said in giving evidence, "he would, of course, not say that the child would have survived if he had been called in." The defendant was, however, convicted of a misdemeanour in having neglected to provide Medical assistance and advice for his child while suffering from small-pox. But even this seems a very questionable offence in the eye of the law, and Mr. Justice Byles expressed himself willing to reserve the point of illegality for the decision of the Court of Criminal Appeal. There being no desire to press harshly on the defendant, a person of exemplary character, he was eventually discharged upon his own recognisances of £50 to come up for judgment if called upon, which, as the judge said, would probably never be the case if he did not misconduct himself in future. The point of law will not therefore have to be argued, and the question still remains doubtful, whether such neglect constitutes an offence known to the law. Common sense and morality, a consideration for the health of the community, and a humane protection to infancy should of themselves suggest that such neglect should be specifically rendered criminal by some short Act of Parliament, and the question set at rest as to the relative duties in this respect of parents or those *in loco parentis* towards children as well as to the community at large.

We are informed that circumstances have occurred which have induced Mr. Holmes Coote to withdraw his name from the list of candidates for the post of Surgeon to the Orthopædic Hospital.

We are informed that 57 deaths took place in Dublin last week from small-pox, and that during the three previous weeks the deaths from the same disease were 83, 52, and 60—a mortality which would be represented in London by 830, 520, and 600. Meanwhile, the Corporation have provided no Convalescent Hospital, and are now only proceeding to borrow money for the purpose. By the time they have got their Hospital we may hope that the want may cease to be felt.

Sir William Jenner will preside at the distribution of prizes in the Faculty of Medicine at University College on Thursday, May 16.

THE EXHIBITION OF THE ROYAL ACADEMY, 1872.

The Exhibition of the Royal Academy is open for the season, and we may be allowed to jot down a few of the points of interest for Medical readers. Amongst the busts in the vestibule we cannot fail to recognise John Flint South (by H. Weekes), beaming with shrewd, quaint *bonhomie*. Near him is Sharpey, by Thornycroft, looking the incarnation of solid, dignified good sense; his portrait, too, by J. P. Knight (No. 167), in Gallery No. 3, represents him with left hand raised in the act of teaching with weight and earnestness. Both are public monuments, worthy of the man and of the institution for which they are designed. Professor Owen's bust, by M. Wagnmüller, almost exaggerates the light of self-consuming enthusiasm which beams from those features. No. 431, in Gallery No. 5, is the portrait of Erasmus Wilson, by S. Pearce, draped in his robes as Professor of Dermatology at the Royal College of Surgeons; a good portrait, with thoroughly calm and gentlemanly expression. No. 554 is the portrait of Sir James Paget, by Millais. It represents this great Surgeon standing as he taught in the theatre of St. Bartholomew's, with the black diagram-board behind him, and a bone just to indicate the subject of his teaching. To say that

it is full of earnestness and vigour would not be half the truth; the fact is, it is too full—painfully full; and the degree in which mental tension is expressed deprives the portrait of that air of repose which is essential to a perfect work of art. [So we said on a first view; second impressions force us to say that it is a powerful portrait, beaming with conscientious earnestness.] No. 638, by Richmond, is a bright, clear, intellectual presentation of Richard Quain, Esq.; and 952, by Macbeth, the powerfully drawn clear Scottish face of Arthur Mitchell, M.D., one of H.M.'s Commissioners for Lunacy in Scotland. No. 299 will bring to our readers' recollection that Sir Henry Thompson, if he were not a great Surgeon, might rank as a great painter. No. 1529 is a model of the statue of Dr. S. T. Chadwick, by Birch, to be erected in bronze for the town of Bolton: his features plain and thoughtful, and the whole figure worthy of a great Physician and philanthropist. No. 1481 is the prize medal of the Army Medical Department in memory of the late Director-General Thomas Alexander, whose effigy occupies the face of it. No. 1474, a bust with good square-cut Irish features, represents the late Dr. Barter, the promoter of Turkish baths. We must add that the features of Dr. Lockhart Clarke, the investigator of the spinal cord; of Dr. Joy, who we believe contributed several articles to the "Cyclopædia of Practical Medicine"; of the late Dr. Finch, Dr. Hadaway, and Dr. Greenhow (of the Middlesex Hospital), are all represented in monumental marble or in the preliminary clay. Some of them, at least, are faithful likenesses.

IMPORTANT DECISION.—LANGAN *v.* THE GREAT WESTERN RAILWAY COMPANY.

This case, recently adjudged by the Court of Queen's Bench, Westminster, raised a question of very great importance, not only to the public generally, but to the Medical Profession especially. The question was as to the liability of railway companies for necessary aid to sufferers in railway accidents. The case arose out of an accident which occurred at the Horsley-fields Junction, in the county of Stafford, in December, 1870, and the action was brought by the landlady of the "Durham Ox," at Horsley-leath, to recover from the Company £109 for board and lodging of three persons injured on that occasion. When the accident happened, the station-master at once appeared to assist the sufferers, and three of them were removed to the plaintiff's inn. The inspector, whose duty it was "to attend to accidents," assisted at the removal, and the Company's Surgeon was sent for, who attended the three sufferers at the plaintiff's house for some weeks, as they were not in a position to be removed. One of them asked who was to pay, and the inspector said the Company would see to that. Accordingly, they received] all proper nourishment for a month, and the bill came to the sum claimed. The case was tried at the Stafford Assizes, before Mr. Baron Pigott, who, upon the authority of *Cox v. Midland Railway Company*, quoted in "Weightman's Medical Practitioner's Legal Guide," as having decided that a station-master had no authority to pledge the credit of the Company by sending for a Surgeon, directed a nonsuit, the correctness of which was now disputed. The remarks of the judges are well worthy of consideration.

The Lord Chief Justice (Cockburn) said that this was a case of agency from necessity. He would not carry the case of "*Cox v. Midland Railway Company*" one iota further. What was to be done with wounded passengers in a railway accident? Were they to be left to bleed to death or to die of their wounds? Their lives might depend upon their having prompt Surgical aid and continued care and attention. And although he knew that Medical men in a case of emergency never waited to think who was to pay them, it was too much to expect continued care and attendance unless they were paid. The authority in every such case must depend upon the circumstances, and this case differed materially from that cited. . .

The "inspector of accidents" had, by virtue of his authority, a discretion to exercise with reference to sufferers. The plaintiff's claim, therefore, was sustained.

Mr. Justice Hannen said that the case cited only decided that a station-master had not necessarily, and as incident to his office, authority to send for a Surgeon; but here the officer who pledged the credit of the Company was one whose duty it was to attend to accidents and see to the persons injured.

Mr. Justice Quain said that he concurred. The officer here was one whose special duty it was to look after the sufferers, and he had authority to order them what was necessary.

This case, therefore, although relating to an innkeeper's bill, really decides that an "inspector of accidents" has authority to send for Medical attendance, and can pledge the credit of the company; and it would also seem that "the authority" of even a station-master must, to repeat the words of the Lord Chief Justice, "depend upon the circumstances" of the case. For there may be no "inspector of accidents" at the particular station; prompt Surgical attendance may be required, and yet the company's Surgeon may not be within call, and in such case the services of one on the spot may be secured. On the whole, the present case may therefore be considered both a more mature, and certainly a more righteous decision, than its predecessor.

THE WOMEN-STUDENTS.

THE Senatus of the Edinburgh University recently decided by a majority to defend the action of declarator brought against them by the women-students, and they have now given in their answers. Six of the professors (Bennet, Lorimer, Calderwood, Masson, Charteris, and Hodgson) have, however, declined to be parties to the defence of the action, and have entered a minute giving at length their reasons for such refusal, the last being that they would "individually feel ashamed of appearing as defenders in such an action."

MEDICAL SOCIETY OF LONDON.

THE annual oration of this Society was delivered by Mr. F. J. Gant, F.R.C.S., on Monday last, May 6, at the rooms of the Architectural Society in Conduit-street. The orator chose for his subject "The Aspects of Modern Surgery as a Science and an Art"—a theme which seemed to be specially appropriate on the occasion of the celebration, within one year, of the Society's centenary. Having traced the development of scientific Surgery from the Hunterian conception of biology, and the subsequent alliance of physics and chemistry—the latter sciences having been chiefly cultivated in the Continental schools of Germany and France—Mr. Gant approached pathology, as the more immediate ground of modern Surgery as a science. Standing, as it were, at the bedside, he expounded the various directions of inquiry which had thence arisen in the clinical investigation of disease—with regard to diagnosis; in the laws relating to the operation of diseases, and the prognosis of their further vital history; in their course, terminations, and consequences. These aspects of modern Surgery, and of Medicine collaterally, were abundantly illustrated and enforced by the observations of distinguished clinical Surgeons and Physicians, past and present.

Turning to the practice of Surgery as a scientific art, the leading features which had marked the progress of modern treatment were singularly interesting. The known resources of nature in the cure of disease and the repair of injury; preventive Medicine and Surgery, especially respecting infection or contagion, and the doctrine of antisepticism; the rise of conservatism in Surgery, and thence the rigid check imposed on the reckless amputations and mutilations formerly practised; the more recent relation of "excisional Surgery" to the natural cure of joint disease by ankylosis; plastic Surgery for the repair of deformities and malformations; the

guidance of pathology in the design and performance of Surgical operations; and the introduction of anæsthetics, to complete the beneficent no less than the artistic character of modern Surgery. These, and other large topics, were handled with much force and skill.

Amongst the many interesting objects exhibited at the *soirée* after the oration were the original drawings of the late Mr. John Leech; by Dr. Crisp, casts of the brains of various animals; by Mr. Hogg, the finer nerve-fibres of the cornea of the frog; by Dr. Sansom, an American preparation derived from petroleum, called "cosmaline;" by Messrs. Savory and Moore, pharmaceutical preparations; microscopes, photographs, Surgical instruments, etc.

THE JACKSONIAN PRIZE.

AGAIN we have to record the melancholy fact that out of six essays sent in to compete for the Jacksonian Prize of the College of Surgeons, not one was deemed worthy of receiving an honorarium of about fifteen pounds. Such an abortive result as this can only be explained by one of three reasons. Either the candidates failed to come up to the required standard of excellence; or they neglected to show sufficient originality and comprehensiveness in detailing their observations; or, what is more probable, they overshot their mark, as did poor Price, by including in their essays matter not strictly appropriate to the subject in hand. We very much regret such an unsatisfactory termination to the labours of these six gentlemen, because we are of opinion that a verdict like this tends to discourage gentlemen of standing in the Profession from competing for these prizes. Certainly, as far as the candidates are concerned, it ought to be the rarest possible thing that when several compete no award should be made. It was a practical subject—"The Treatment of Wounds after Operation, including the Arrest of Hæmorrhage, Primary and Secondary"—and the essays ought to have been good.

ELECTION OF MEDICAL OFFICERS TO CHARITIES.

A resolution of considerable importance to the Profession was passed at the last meeting of the Council of the Charity Organisation Society. It was to the following effect:—

"That, in the opinion of the Council, the system of periodical contested elections by the whole body of the subscribers is open to much objection in its application to Hospitals and orphanages; and that it would be more conducive to the object of such institutions if the selection of the persons to be benefited were made after full investigations of comparative claims by a committee elected according to such conditions as would secure a real representation of the subscribers."

The system of election of Medical officers to our charitable institutions which at present prevails is open to the gravest objection. It is one not calculated to the selection of the best men for the vacant offices, and it is derogatory to the candidates themselves. It is difficult to conceive anything more humiliating to an educated gentleman than for him to go eap in hand to the governors of a Hospital to solicit their "votes and interest." The labour of such a proceeding is often very great, and the electors have really no proper means of arriving at a just estimate of the candidate's fitness for the office he seeks to obtain. In some institutions, even at the present time, the vicious system prevails of "making votes" at the last moment to carry in a particular candidate. We look with shame and dismay at the late meeting of the Governors of the Orthopædic Hospital, as an instance in which governors permit themselves to be made to serve the purposes of an individual. If the resolution of the Council of the Charity Organisation Society can be carried out, it will confer an immense benefit on the public and the Profession.

CONVICTION UNDER THE MEDICAL ACT.

THE Medical Act would appear to be more effective than is generally supposed, when care is taken to select cases for

prosecution under its provisions. There can be no doubt that there is a multitude of cases similar to that of "Dr. Andrews," and it is to be hoped that the successful issue of this case may induce parties to prosecute whenever an infringement of the Act can be clearly proved. On Tuesday last an appeal—Andrews (appellant) *v.* Styrap (respondent)—was heard in the Court of Exchequer; it was an appeal from the conviction of the magistrates of Shropshire. The appellant had been practising as a Physician in Shrewsbury, describing himself on his cards as "M.D.," and having a brass plate on his hall-door with the same initials upon it. Upon this he was prosecuted before the magistrates, which resulted in a conviction of an offence under the statute of the 20 and 21 Vic., 1843, and a penalty of £20. It was contended, in support of the appeal, that the conviction was bad, as there was nothing to show that the appellant had wilfully and falsely styled himself a Doctor for the purpose of deceiving the public; that he had obtained a diploma from a German College of Physicians, and he believed himself fully authorised to practise in this country; and that to establish the offence it was necessary to show that he had "wilfully and falsely" styled himself a Doctor for the purpose of obtaining those objects. Evidence was given in support of the conviction, and the Court gave their unanimous judgment, confirming the conviction, declaring that there was evidence to prove that the appellant had been guilty of "wilful falsehood," and expressing their approval of the measures taken by the American Government in conjunction with us to put a stop to this traffic in false diplomas.

WHAT NEXT, AND NEXT?

IN an old Bill of Sir Andrew Agnew for preventing Sunday work, the provisions were carried to an extent that rendered the measure ridiculous and impracticable. In a popular song of the time—one of Hudson's—amongst other things mentioned was—

"Women taken in labour on Sunday
Must put off the hard work until the Monday."

Even the wags of the period, however, did not venture to suggest a "day of rest" for the poor Doctor—that was beyond the imagination of the most imaginative and suggestive. But now there seems something approaching, at all events, a release from labour for even the hard-worked Medical Practitioner. It is stated that the Doctors' coachmen in Edinburgh are organising against the imposition of Sunday labour. If the effort be successful, the horses of course must rest. If the horses, why not their masters, as well as their drivers?

HEALTH OF MANCHESTER.

IT is remarkable how slow are the improvements in some large towns for the purpose of lessening disease and mortality. The authorities of Manchester appear to have been very energetic in removing nuisances. Mr. J. Leigh, the Officer of Health, states in his report that the number of deaths in the city averages 9526, "more than two-thirds of which occur from infectious diseases in children under 10 years of age," and he offers some observations upon the best method of removing some of the causes of this excessive mortality. A large number of cellar dwellings have been closed during the year, and the Health Committee, after having closed 2400 of these places, are now able to announce that at the present time, with the exception of a few temporarily occupied by very old people, it may be said that there are no cellar dwellings in Manchester.

TROUBLES IN PARIS AND THE DOCTORS.

THE ferocity displayed by the opposing troops in the struggles around Paris during the civil war was all but unparalleled in history. Even in the most savage warfare the persons of the "Doctors" are, as a rule, held sacred. Not so, however, in the civil strife of last year. Attention has been drawn by a Paris journal to the fact that several Surgeons belonging to Val-de-Grâce were summarily executed by the Versailles

troops in endeavouring to protect a number of wounded insurgents near the Place St. Sulpice. The Government, it would seem, has attempted to hush up the affair; but the Dolbeau scandal has aroused some of the intractable students, and a private inquiry into the matter has commenced. MM. Fano and Ferreogobi, two well-known Surgeons, who had disappeared since the repression of the insurrection, are stated to have been among the victims.

SMALL-POX IN DUBLIN.

DURING last week 415 applications for relief were entertained by the Mansion-house Relief Committee, which met every day. At the meeting of Wednesday week, Dr. Evory Kenedy brought under notice the propriety of communicating with the Public Health Committee of the Corporation as to what steps had been taken towards providing a convalescent home for small-pox patients. Accordingly a deputation from the Relief Committee waited on the Public Health Committee on Thursday, when it was ascertained that the latter body had secured a suitable site, on which it was intended forthwith to erect a permanent structure as a Convalescent Hospital for city patients. Pending the completion of this building, a temporary arrangement has been made to accommodate some sixty convalescents in a house close by one of the metropolitan Hospitals.

THE "PECULIAR PEOPLE" AND THE SPREAD OF SMALL-POX.

THE Grand Jury at the Central Criminal Court, on Wednesday, annexed to the indictments a presentment in which they stated that the case of the "Peculiar People," who ignored the application of Medical science in cases of sickness, appeared to call for attention on public grounds; as, while the local authorities were bearing the expense of providing Medical officers for the purpose of attending to sanitary matters and making use of disinfectants, the "Peculiar People" did not appear, even in the case of small-pox, to call in Medical assistance or take means to prevent the spread of the disease, and such a practice as that was dangerous to the public at large. The Grand Jury expressed a hope that some action would be taken to provide a remedy in this matter.

SMALL-POX JOTTINGS.

DURING the past fortnight four cases of small-pox were reported to the Newington Vestry.—The deaths in East London from small-pox in the past week were six, of which four occurred in the Poplar Union.—Benjamin Pritchard, a potter, was last week fined 5s. by the Hanley magistrates for going about the town before he was thoroughly recovered from the small-pox. His defence was that the Medical officer never came near him, and he had therefore left the small-pox Hospital. He was ordered to return to the Hospital, and remain there till he received a certificate of convalescence.—The new Hospital at Halifax for the reception of small-pox patients was opened last week.—The return of small-pox cases in the Aberdeen Small-pox Hospital shows, for the week ending Monday last—total number of cases admitted since opening, 189; new cases admitted on Monday last, 2; number of patients now in Hospital, 20; total discharged recovered, 137; total dead, 32. The fatal cases of small-pox in the metropolis, which in the four previous weeks had gradually declined from sixty-five to forty-one, rose again last week to sixty-two.—In Edinburgh the disease is still on the decline. Thirty-eight cases were admitted into the Small-pox Hospital last week, thirty were discharged cured, and ten died.—In Plumstead East sub-district there are living about fifty of the "Peculiar People," among whom small-pox is raging severely. Three deaths occurred from the disease during last week.—Small-pox still lingers at Norwich. Since the disease first appeared in Norwich, 536 deaths have occurred from it.—Dr. Aldis, St. George's, Hanover-square, reported last week one case of small-pox, which was removed to the Hospital.

FROM ABROAD: M. OLLIER'S DRESSING BY OCCLUSION INAMOVIBLE

—DR. VOGT ON ERGOTINE INJECTIONS FOR VARICOSE VEINS—

M. VERNEUIL ON PRECOCIOUS ERYSIPELAS.

IN relation to the *pansement ouaté* of M. Alphonse Guérin, to which we lately adverted (*Medical Times and Gazette*, April 6, page 406), M. Viennois, in continuation of a former paper describing the isolating mode of dressing (*Medical Times and Gazette*, December 30, page 804) adopted by M. Ollier, furnishes in the *Gazette Hebdomadaire* for March 29 an account of the *occlusion inamovible* adopted by the Lyons Surgeon. Applied to large wounds in general—wounds of joints and those succeeding operations—it possesses, he observes, not only the advantages justly claimed by M. Guérin for his *pansement ouaté*, but also other special advantages, which are only attainable by the absolute immobility of the wound. Having now observed this plan applied to more than forty cases, M. Viennois is enabled to state that its adoption has entirely changed the prognosis of some wounds when treated in infected localities. Hospital Surgeons are now able to obviate the accidents which have hitherto excited their terror, and have often prevented their performing even the most rational operations in Hospitals.

Occlusion inamovible depends upon two essential principles—(1) occlusion by means of cotton, as practised by M. A. Guérin, preserving the wounds from infecting germs; and (2) complete, absolute, and permanent immobility of the wounded region by means of a silicated bandage, enveloping all parts the movements of which might in any way influence the divided tissues. The value of the first of these has been amply shown by the admirable success obtained by M. A. Guérin during the siege of Paris; and for the second M. Ollier prefers the silicate of potash to any other solidifying agent, by reason of its convenience of application and its lightness. It is much easier manipulated than plaster, and secures immobility just as well. When there is reason to suspect abundant production of pus or serosity, the layer of silicate may, after its desiccation, be perforated at several points, in order to allow of evaporation, without penetrating the wadding envelope which it surrounds. The immobility is not impaired, and the cotton remains dry beneath. M. Ollier was induced to recommend these perforations, as he found, in consequence of the moisture from want of evaporation, the skin near the wound became macerated and excoriated. The *occlusion inamovible* will hereafter much influence Surgery on the battle-field, as, with abundance of cotton and the silicate, most of the early dressings can be performed, while in wounds where immediate intervention is dubious and after amputation, transport is greatly facilitated.

Immobility seems especially advantageous in calming pain, limiting suppuration, and preventing subcutaneous detachments. Some wounds and stumps when they are only enclosed in masses of cotton and supple bandages still continue painful; but as soon as a silicated bandage has been added, and has dried, they cease to be so. For this to be so, the bandage must be well applied, and embrace a sufficiency of the body to secure immobility. Thus, in amputations of the arm, the shoulder, and in those of the leg the pelvis, has to be comprised; and even in amputations of the hand and foot the corresponding portion of the trunk must be embraced. M. Ollier is so convinced of the importance of immobility that, when congestive or articular abscesses have to be opened, he first applies the silicated bandage, employing Dieulafoy's aspirator for their discharge. Every attempt must be made to prevent the removal of the silicated bandage during ten days, by which time an ordinary wound may have a layer of granulations. It may then be advantageously changed to prevent maceration of the tissues. The medium time for its renewal after amputation is three weeks. Owing to the swelling of the limbs which follows excisions for chronic diseases, occlusion is not favourable in these cases, a silicated bandage largely fenestrated being preferable. One of the most remarkable circumstances in the

occlusion inamovible is the great diminution, or even complete absence, of suppuration.

Dr. Paul Vogt, Assistant-Surgeon in the Out-Patient Clinic at Greifswald, encouraged by the benefit which Langenbeck and others have derived from treating small aneurisms by hypodermic injection of the solution of ergotine, determined upon trying it in varicose veins of the lower extremity. Hitherto, as the various attempts at obtaining a radical cure of this affection by producing obliteration of the veins over a certain extent has led to evils and dangers out of proportion to the affection itself, he has confined himself to palliative treatment. He refers (*Berlin Kl. Woch.*, March 4) to a case in which an extensive varix which had occupied the leg for years yielded in the course of a week to two ergot injections (ext. sec. cornut. two parts, to sp. vini and glycerine of each seven parts), this being replaced by a hard, circumscribed infiltration, which eventually subsided. In various other cases as remarkable results have followed.

In explanation of the action of the ergot, Dr. Vogt believes that the following points are worthy of consideration:—1. From clinical and experimental observation the ergot injection produces contraction of the muscular coats of the vessels—chiefly of the arteries. Through the contraction of the calibre of the arteries thus produced (especially operative on those of medium calibre which are rich in smooth muscular fibre), less blood is carried into the veins, this lesser quantity being propelled with greater velocity. 2. The ergot also acts upon the muscular coat of the veins; for although this after years of persistent dilatation may have disappeared in many places, yet in others it is always still present. When, indeed, the varices have not been of prolonged duration, that a considerable elasticity of the walls of the veins persists is shown in puerperal women, who often prior to delivery have varicose veins as thick as the finger, which only a few days after that event entirely subside. 3. It is possible that some effect may be exerted by the direct compression produced on the varix by the infiltration-swelling which results.

Whether the favourable results which in all these cases have been so striking will prove definitive cannot be decided, as sufficient time has not elapsed to allow of the cure being regarded as radical. At all events, so simple and harmless a method is well worthy of further trials; and Dr. Vogt has derived good results from its employment in other forms of phlebectasis, in varicocele, hæmorrhoids, and certain forms of angioma.

At the meeting of the Société de Chirurgie on April 24, M. Verneuil introduced the subject of "The Causes and Mechanism of Precocious Erysipelas." He observed that numerous had been the discussions on the causes of erysipelas; for some, even at the present day, it is an exanthem, and for others a primarily local disease. According to some it may arise spontaneously, while others deny that it ever can do so—these last maintaining, and in M. Verneuil's opinion justly, that it has always been preceded by a prior accident or by a traumatism. He does not enter into the question of contagion, merely stating that there is a variety of erysipelas in which the patient gives himself the disease by a kind of auto-inoculation. This variety of traumatic erysipelas is marked by its precocity—that is, by its following the traumatism very speedily, sometimes coming on the same evening, or the next day after an operation. This is an exceedingly important characteristic, quite adverse to the idea of contagion, which could not operate so rapidly. When erysipelas supervenes after the removal of tumours, operations, etc., it does so about the fifth or sixth day, and in these cases it is to be observed that the incisions have been made in healthy tissues. On the other hand, precocious erysipelas appears after small operations performed on parts in a state of suppuration—*c. g.*, after exploration of a bony fistula, extraction of a splinter, or making a counter-

opening for drainage. M. Verneuil has even seen a patient who had erysipelas each time his fistula was explored. The removal of the most recent crust covering a wound may excite it.

"In all these cases of precocious erysipelas there is, on the one hand, a traumatism, and on the other a centre of suppuration, the one dependent upon the Surgeon, the other upon the patient. There takes place here, in fact, something analogous to inoculation; for it is just as if the Surgeon took pus on his lancet from the patient in order to inoculate him with it—for we open largely a series of lymphatic vessels in a place close to another which is yielding pus or septic matters. Absorption takes place, and there is produced erysipelas or angioleucitis, or rather both the one and the other. The more I see, the more I am persuaded that erysipelas and angioleucitis are in nowise different, there being the same commencement with an enormous increase of caloric, the same fever, and the same course. But I only mention this by the way, drawing from it the practical conclusion that this septic erysipelas can be prevented. Holding the conviction which I have just explained, I have pursued the practice of cauterising or touching with tincture of iodine all incisions which I practise in suppurating lesions; and this is a precaution, to the efficacy of which I do not hesitate to attribute a great value."

M. Desprès had long held and published the same opinions, believing that erysipelas is not contagious, and that it is really an affection of the lymphatics. As to its contagion, no proof whatever has been advanced; for it will not suffice to say that it is so because patients in the vicinity of each other contract it. In this way menstruation itself might be said to be so, for many women have this come on earlier when they enter a Hospital where other women are menstruating. When the lymphatic vessels have been opened, we may have sometimes angioleucitis, and at others erysipelas, or both at the same time. M. Chassaignac observed that angioleucitis and erysipelas are entirely distinct. The former is a phlegmasia of the sub-epidemic network, giving rise to red traces, the network being separated by lozenges of healthy skin. There are also the engorged glands, in which the inflamed vessels terminate. In erysipelas we have a uniform colour, with festooned edges, but without regular lines. It may commence by the hand, mount up the arm, and redescend to the hand, which is not the case with angioleucitis. In angioleucitis there are never phlyctenæ, which are present in most cases of erysipelas. In erysipelas there is a serious general condition, while in angioleucitis the patients sometimes clamour for food. Still, it is possible that the two affections may coexist. M. Chassaignac believes in spontaneous erysipelas, and refers to a case in which the disease has attacked the face in three successive years. He also believes that it may be propagated by contagion. M. Blot believes in the distinction between angioleucitis and erysipelas, and could not agree with M. Verneuil that the latter is always preceded by a lesion of the mucous membrane or skin. He referred to the case of an infant, kept most scrupulously clean, in whom this appeared in the back, where no lesion whatever could be discovered. In spontaneous erysipelas of the face, the eruption on the lips is preceded by general symptoms for three days—a condition very analogous to that in eruptive fevers. He is much disposed to believe the same thing takes place in traumatic erysipelas. M. Le Fort, while inclining to M. Desprès' belief in the identity of erysipelas and angioleucitis, believes that the question of contagion must be answered in the affirmative. M. Verneuil, in reply to M. Blot, observed that the initial lesion, whence erysipelas springs, may be a mere microscopic wound. In one of his own cases a patient had what seemed to be a spontaneous erysipelas of the face, until it was recollected that the evening before he had epistaxis, which of course implies lesion of a vessel. The initial lesion may not always be detectable, but since this has been more sought for negative facts have become more and more rare. In 999 times out of 1000 the erysipelas can be referred to such lesion. In M. Trélat's opinion, erysipelas must be regarded as an infectious disease, of which

angioleucitis must be looked upon as constituting one of the pathological elements.

PARLIAMENTARY.—THE GOVERNMENT LICENSING BILL—EPPING FOREST—LONDON WATER SUPPLY.

ON Thursday, May 2, the Intoxicating Liquors (Licensing) Bill was read a second time in the House of Lords.

On Friday, in the House of Lords, the Bill for preserving Epping Forest was read a second time.

Mr. Kay-Shuttleworth asked the President of the Board of Trade what had been done by the London water companies, the Board of Trade, and the metropolitan authorities respectively, under Sections 17 to 22 of the Metropolitan Water Act (1871), regarding regulations as to fittings; and how soon those regulations would be in operation, so that application might be made for a constant supply.

Mr. Chichester Fortescue said the metropolitan water companies had complied with the requirements of the Metropolitan Water Act of last session by submitting a set of regulations, which they had all agreed upon, to the Board of Trade and to the different metropolitan authorities. Until confirmed by the Board of Trade, however, these regulations were of no force whatever, and an inquiry must first be made by the Board of Trade, at which the metropolitan authorities and the metropolitan water companies themselves would have a right to be heard.

REVIEWS.

Red-Cross Operations in the North of France, 1870-72. Printed for the Boulogne English Committee for Aid to the Sick and Wounded in War, by Spottiswoode and Co. London. 1872. Pp. 215.

NINE English residents at Boulogne were formed into a committee, with a French Secretary, at the end of August, 1870, and were at once adopted as a branch society by the gentlemen who had established themselves as a national committee at St. Martin's-place. This book is the account of their stewardship. The active work of the branch was carried out by three soldiers—Colonel Cox, Lieut.-Colonel Berington, and Captain Uniacke—with the assistance of six temporary volunteer convoy agents, four of whom were also members of the British army, three "Drs." (one a M.R.C.S. and L.S.A. of 1869, and two whose names do not appear in the "Medical Directory"), and sixteen ladies. The reports of the gentlemen named, which are included in the book, are straightforward and sensible productions, and show that the writers did their best to carry out the duties that they had undertaken, without fear or favour. So much can scarcely be said for the rest of the work. That excessive self-consciousness and attitudinising for applause which are so common among people who set themselves up as benefactors appear to have found their way by some unlucky accident into the Boulogne committee-room. "They can only talk of England's bounty and sympathy;" "Dressed in England's shirts;" "One is so proud of one's Queen and country;" "Would I not leave the things? Certainly not, *ma sœur*; I am here to bestow England's bounty, and no one else shall give it;" "Proof that the labours of our Society have touched chords of generous sympathy in many a French heart, which will not easily cease to vibrate;" "The purest pleasure and self-congratulation at having been privileged to become, in the hands of Providence," etc.; "La conduite du peuple Anglais est au-dessus de tout éloge et digne d'admiration du monde entier;" and a variety of similar expressions, would perhaps have looked better in a French than in an English report. That such expressions should occur in the letters of good people, whose enthusiasm at the moment of writing outruns their judgment, is natural enough; but to publish them deliberately after a year's interval is scarcely compatible with due self-respect.

The amount of Medical and Surgical work done by the English in the district between Boulogne and Paris appears to have been somewhat minute. Except at Villers-Bretonneux, where some hundreds of wounded were left badly provided for after the battles near Amiens on November 27, at Querrieux on December 23, 1870, and at St. Quentin at the end of January, 1871, the three young Surgeons with the party had little opportunity of gaining experience otherwise than as distributors of stores. Nevertheless, the mere fact of having been eye-witnesses of what was going on in France at that time will

have given them a store of recollections which may be of great value in after life.

Many questions have been raised as to the usefulness of the Red-Cross Society and the results obtained by the expenditure of the contributions of the English people. It cannot be denied that the American Sanitary Commission succeeded better. But it could hardly be expected that the small knot of gentlemen who volunteered themselves suddenly at the outbreak of the war as a committee to collect subscriptions—labouring as they already were under the disadvantage of some fanciful notions about a semi-religious order—should not fail when the unexpected liberality of the public put them in possession of sums of which they had never dreamt, and when their plaything apparatus of “prior,” “brotherhood,” and “chapter-room” was called upon to carry out a work for which common sense and skill in organisation were imperatively required. A flagrant instance of the results of attempting to administer France and Germany from a committee-room in St. Martin’s-place occurs in this report. A “regularly authorised member of the Society” had been to the Crown Prince of Saxony near Paris, and had promised a supply of stores. These were sent by direction of the London Committee to Dammartin from Amiens, a distance of some seventy miles, through a population of excited French, within nine days after the surrender of Metz; and this notwithstanding the objections of the English officers on the spot, who saw the danger of the proceeding, and notwithstanding the fact that an English depot existed at Meaux, a town within the German lines at less than one-fifth of the distance (pp. 9, 51, 67-70). Thus, to fulfil the pledge ignorantly given by a starring committeeman, Colonel Berington and Captain Uniacke were put in danger of their lives among a howling mob at Amiens; and everyone who has seen a savage and frightened mob—especially in France—in war time can appreciate the danger. Moreover, when this risk had been safely passed through by dint of considerable tact, courage, and self-command—“We were most fortunate,” say they; “but in every village we might have been stopped, and it only required one Frenchman to have raised the cry that we were taking provisions to the Germans to have had our waggons destroyed. We were very near it sometimes.” But this convincing proof of bad management was scarcely needed; it was impossible to expect anything else from a fortuitous group of amateurs without experience. It is to be hoped that in case of another great war public opinion will enforce a better administration of any new fund that may be created, as well as of the £70,000 which the St. Martin’s-place Committee have hoarded from the sum subscribed in the last one.

The estimation in which such an organisation holds our Profession may be understood from the chief agent at Amiens asking leave to keep a young Doctor there, who chanced to come by that way, with this remark:—“A Doctor would be useful to us about the medicines, and this young man appears very desirous of making himself useful in any way.” It does not seem to have occurred previously to the gallant colonel who asks the question, nor to the Committee who appointed him, that he might not find himself as thoroughly at home with the pestle and mortar as with the sword. To trust in the Committee, and keep your powders dry, appears to have been thought a sufficient qualification for a temporary great medicine man. Those who think that the civilisation of Europe is not sufficiently far advanced to allow Medical aid in war to be made an international affair may possibly be right, though events seem rather to tend in the opposite direction; but it is at all events certain that no plans of the kind will succeed thoroughly which do not avail themselves of the freemasonry which exists among members of our Profession in all civilised countries. The initiative—in fact, the duty of determining what kind of help is required, and where—must rest with men experienced in the Medicine and Surgery of war, who must see the need with their own eyes; while the different and equally necessary duty of conveying stores to the spots where they are wanted cannot rest in better hands than those of the gentlemen who worked so conscientiously and bravely in France in the winter of 1870-71. Then the home committees would be able to limit themselves to their proper function of collectors and transmitters, and would not have to issue orders in the dark, nor be driven to any more sensational absurdities like patting two combatants on the back and giving them a “tip” of £20,000 a-piece in order to get rid of the money for which they were unable to find a use.

The report of the Boulogne Committee does not furnish any new hints for practice. The area for which they acted was so little involved in the track of the war that they had not, it appears, seen a hospital-train till the end of February, 1871,

though the Germans had been using them nearly half a year. But it is clear, notwithstanding the slight tendency to over-colouring shown in the book, that the energy and goodwill of the agents of the branch (two of whom contracted small-pox in the discharge of their duty) produced considerable results in the relief of suffering, and may have tended towards the much-to-be-desired neutralisation of everything relating to Medicine in war. The sum expended by the branch was about £4000, besides goods collected or sent from England in kind.

NEW BOOKS, WITH SHORT CRITIQUES.

Annuario delle Scienze Mediche, riassunto dalle più Importanti Pubblicazioni dell' Anno. Per i Dottori P. SCHIVARDI e G. PINI. Anno ii., 1871. Milano, 1872. 12mo, p. 376.

* * * A small book, teeming with information, and containing abstracts of the books or memoirs of nearly a thousand writers and workers. It is a capital index to the progress of Medicine and the allied sciences during 1871. Amongst English authors we find the names of Clifford Allbutt, W. Cholmeley, Cumming, Marcet, Meadows, and “*l'illustre chemico*, Richardson.” Notices of W. D. Moore, T. H. Tanner, Edwin Lec, Sir James Clark, and W. Clements, of Shrewsbury, are found in the “*Neerologia*.”

FOREIGN AND COLONIAL CORRESPONDENCE.

AUSTRIA.

VIENNA, May 1.

THE RESULTS OF PROFESSOR STRICKER'S INVESTIGATIONS ON THE NATURE OF DR. LOSTORFER'S CORPUSCLES.

THE last two meetings of the Vienna Medical Society were crowded with members and visitors anxious to listen to Professor Stricker's discourse on the much-discussed question of the so-called syphilitic corpuscles of Dr. Losterfer. In the last meeting we noticed amongst the visitors Mr. Jonathan Hutchinson, of London, and Dr. Bumstead, the well-known writer on syphilis, of New York. Professor Rokitansky presided, and Professor Stricker commenced his lecture, declaring that he has undertaken the investigation in order to gain information; firstly, on the nature of the corpuscles discovered by Losterfer; and, secondly, on the question of their being characteristic to syphilis.

The experiments were commenced with the blood of three syphilitic male patients, in all of whom the corpuscles became visible in great quantities after some days' germination. Thus material was sufficiently furnished for the solution of the first question. But there was a preliminary question to be solved first—namely, whether or not the corpuscles of Losterfer may not be found in fresh blood. Before entering into that question, the lecturer considered it necessary to describe his method of preparing and preserving his objects.

If objects are prepared for the mere purpose of being examined fresh and with high magnifying powers, they ought to form as thin a stratum as possible. This is best obtained by well cleansing and drying both the object-glass and covering-glass, and by bringing the latter into contact with the blood of a small wound in such a manner as to leave on the glass only a very small drop. By putting now the covering-glass quickly on the object-glass, the small drop turns into a stratum sufficiently thin for examination; if not, a slight pressure on it suffices to produce the desired effect. As the examination is always effected by means of immersing-lenses; as it is, further, important to observe the edges of the covering-glass as far as possible—overflowing of the water necessary for immersion rendering the object useless—it may not be amiss to mention that only a very small drop of water is put on the covering-glass, by means of a pipette, both ends of which are drawn out into capillary tubes.

The appearance of fresh blood is various. In some persons the blood shows nothing but normal elements—namely, red blood-corpuscles, white corpuscles, and minute granules devoid of any colour. Very often, however, small colourless lumps may be seen of the size from a nucleolus to the average magnitude of a nucleus of a white blood-corpuscle. To these granules our attention is particularly drawn if we work with very high powers.

It is not necessary to enter into a description of these bodies.

Suffice it to make the general remark, that many of them have the appearance of pieces of young cells, whilst others make the impression of crossing-points produced by coagulation. Such points are particularly produced where the blood stratum is somewhat thicker, and on spots containing no blood corpuscles, but being traversed by fine filaments. It may be supposed that the filaments, as well as the crossings or ramifications, consist of fibrine. The lumps, having the shape of pieces of white blood-corpuscles, are, like the latter, polymorphous, and only rarely spherical. Besides the elements just described, fresh blood of some persons contains other very minute granules in active undulation. They can be defined by Hartnack's No. 10a immersion, and it is not to be decided whether the undulation is that of Brown, or whether we have some organisms before us. The fact is, however, worth while mentioning, in order to draw attention to the question of the possibility of the existence of very minute lower organisms in the circulating blood of healthy persons. Fresh blood, however, contains also, though rarely, bodies of which it is very difficult to say whether they are accidental admixtures or whether they have already been in circulation. They are generally of spheroid shape, have dark contours, and are characterised by their being of a very dark hue when accurately focussed with very high powers (Hartnack No. 15).

The aim of germination for the lecturer's purpose consists in preserving good objects, accessible to air, as long as possible. This end is arrived at by the objects being put in some space where, on the one hand, they are prevented from exsiccation, and, on the other, protected from the accession of evaporated water. For this purpose they are placed in a camera exhibiting a comparatively small surface of water in respect to the cubic space of the camera. This exsiccation-glass affords room for a small stand to contain about a dozen objects, which, if provided with tickets, permit the placing of preparations of different individuals into the same glass and on the same stand. For the purpose of germination the preparations are not made so thin as described above. Before the object is prepared Professor Stricker forms on the object-glass two small ridges of wax, so as to support the covering-glass. After the preparation has been made he presses the covering-glass on these ridges until the rouleaux assume a reticulated arrangement. The meshes of that net, filled with plasma (plasma-islets), contain germinating-spaces exceedingly suitable for our purpose.

(To be continued.)

GENERAL CORRESPONDENCE.

LATENT MALARIOUS DISEASE.

LETTER FROM DR. CHRISTIE.

[To the Editor of the Medical Times and Gazette.]

SIR,—I wish to mention a case of long continuance of malarial poison in the system before development, which appears curious. I must state that I have for six years practised Medicine close to Washington, America, on the eastern branch of the Potomac river, where remittent and intermittent fever in all their varied forms prevail so extensively that some years not one in ten escapes the malady. The manner of seizure and its effects vary infinitely—a single type case of ague, with a cold stage, hot stage, and sweat, may be all the inconvenience one may feel during an epidemic; while another, apparently under precisely the same exposure and conditions, may, by repeated attacks, be rendered so anæmic and ill that to a casual observer he would appear in the last stage of phthisis. Intermittent attacks of any kind, of diarrhoea, vomiting, headache, without fall or rise of temperature, is the way some are affected, while others are sometimes seized with a sudden and violent attack of general *malaise*, in which it would be impossible to say in what part of the body most discomfort is felt, each organ asserting its claim to bearing the palm in that respect. Were it not for quinine, which many keep in their houses, deeming it as much a necessary of life as salt, I think many populous parts of the States would be uninhabitable. But with regard to the case I began about: I left Washington the night of March 22 in strong health, sailed on the 23rd from New York for Liverpool; once during the voyage feeling ill, the possibility of malaria entered my mind, but a little hot brandy-and-water quickly dissipated the feeling and idea; landed on April 5, and reached London the same day. On the 7th, while in a Turkish bath, I suddenly became quite ill, came home, and was unable to sit up. After a couple of days' illness, I began quinine; thirty

grains in twenty-four hours put me on my feet. Had I not taken this my recovery would have been postponed. The malaria was doubtless carried in the system from March 22 to April 7, sixteen days before making its appearance.

I am, &c.,

ARTHUR CHRISTIE, M.D.

9, Stanhope-street, Hyde-park-gardens.

PRACTISING CHEMISTS.

[To the Editor of the Medical Times and Gazette.]

SIR,—Your correspondent, "Fifty-five," in his letter concerning chemists who practise as Medical men, has the following words:—"But it may be said, they dare not come out and visit. Wait a few years, and see who shall dare hinder them." Those who think that chemists do not dare now to visit, and visit too as regularly and openly as any qualified and registered Medical man, are greatly in error, for I myself know those who are largely employed by both rich and poor, and who attend all cases of minor disease, though they are wise enough to refuse to undertake any case that threatens danger, thus avoiding all risk of exposure by an inquest. They carry stethoscope, pocket-thermometer, pocket-case of instruments, ostentatiously use all the most modern aids to diagnosis, and are looked upon by the multitude as at least equal in science and skill to the qualified Practitioners of the district. The comparatively few and far between dangerous cases, with, as your correspondent says, "their enormous labour and anxiety which no money can compensate," thus fall to the qualified Practitioner who can give a certificate in case of death, while the many slight cases which ought to help so largely to make up the Practitioner's income fall into the practising chemist's hands, who is always fawning and obsequious, and who, professing to make no demand beyond that for Medicine and cab-hire, is regarded as a generous man who gives his time and skill gratis, while the qualified man is one who, with no greater advantages but the power of giving a certificate, demands money for that which the other gives freely. The double gratification is thus enjoyed by an "enlightened public," of patronising a deserving and "good-hearted" man and of saving its own pocket. Consequently, when danger compels qualified attendance, it grumbles and grudges and delays payment as long as it can; the Medical man being fortunate if all the while the chemist is not in back-door attendance, criticising his treatment, and altering it from time to time according to his "better judgment." I know that this often happens in regard to one of the chemists whom I have now in my eye.

As to "waiting a few years" before anyone dare hinder this irregular practice, I would ask you, Sir, who dares, or rather who has the power to hinder it now, for I know no law by which I, and those circumstanced like me, can protect ourselves. If there be any method, present or prospective, by which we can now, or may in future be able to do so, I, and I am sure many others, will be much obliged by your pointing it out. I enclose my card.

I am, &c.,

May 6.

FIFTY-FIVE NO. 2, AND A CONSTANT READER.

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, APRIL 23.

T. B. CURLING, F.R.S., President, in the Chair.

A PAPER by Dr. C. THEODORE WILLIAMS was read, "On the Results of Warm Climates in the Treatment of Pulmonary Consumption, as exemplified by an analysis of 251 cases." The author, after dwelling on the difficulties involved in the selection of proper climates for consumptive patients, enumerates three grounds for forming an opinion. First, the alleged immunity from phthisis of certain localities. Second, the existence in certain localities of atmospheric conditions the reverse of those under which the disease was contracted. Third, the ascertained results of certain climates on similar cases. After pointing out objections to the "immunity" found arising from diversity of the climatic conditions accompanying it, he discusses the second, or "contrast" ground of selection, and in order to explain it, the causation of phthisis is considered and shown to be probably twofold: first, inflammatory—that is, influences which excite or keep up inflammatory affections

of the lungs, such as great variations of temperature, a combination of cold and damp, etc.; second, septic—that is, influences which blight and corrupt the bioplasm of the blood or lymphatics, such as foul air, bad nourishment, the combination of warmth and damp, etc. The differences in the type and distribution of phthisis arising from each of these causes are pointed out as indications in climatic treatment, dryness and warmth being desirable in consumption of inflammatory origin, and dryness and purity of air for consumption of septic origin. The far greater importance of the third or “fact” ground is then dwelt on, and, after regretting the paucity of published information of this character, and especially of statistics, Dr. Theodore Williams furnishes, from the practice of Dr. C. J. B. Williams and himself, a statistical account of 251 cases of consumption who passed periods varying from one to eleven winters in warm climates out of the United Kingdom. Sex: 190 were males and 61 females. Age: The average age at the onset of the disease was among the males 29·04, and among the females 23·39; nearly half the number of both sexes being attacked between 20 and 30. Predisposition: Family predisposition was present in 52 per cent., and hereditary in 27·8 per cent. Origin: 11 were cases of scrofulous phthisis, in 55 the disease had an inflammatory origin, in 41 a catarrhal, and in 2 a syphilitic; 2 cases followed on asthma, 6 were instances of hæmorrhagic phthisis, and 130 of chronic consumption. Hæmoptysis existed in 62½ per cent. in varying amounts. State of lungs: At the time the patients quitted England 61 per cent. were in the first stage, 21½ per cent. in the second, and 17½ per cent. in the third stage. Sixty-seven per cent. had one lung alone affected, 33 per cent. both lungs. A comparison is then made between these cases taken separately and 1000 cases of which they form a part; and it is shown that in the “climate” patients the disease was more advanced, but at the same time more local in its character. The climates of which a trial was made were classified as follows:—1. Moist temperate, as Pau, Bigorre, and Rome. 2. Dry climates of the Mediterranean, including the Riviera, Malaga, Algiers, etc. 3. Very dry climates of Africa, including Egypt, Cape of Good Hope, and Natal. 4. Moist Atlantic, as Madeira, the Canaries, and the West Indies. 5. Miscellaneous, including India, the Andes, New Zealand, etc. 6. Sea voyages. The average of winters passed abroad by each patient was 2½; and of eighteen patients who took voyages, the average number of voyages per patient was 2½. The results of the climate on the *general* condition of these patients were that 65 per cent. were more or less improved, 6 per cent. remained stationary, and 29 per cent. became worse. The *local* effects on the lungs were, that in 43½ per cent. cure or decrease of the disease took place, in 14 per cent. it remained stationary, and in 42 per cent. it increased either in the way of advance or extension, or of both. The influence of the various groups of climates is next considered; and from the results of a table it is shown that the *moist* climates, temperate or warm, yielded a percentage of “improved” varying from 50 to 55, of “stationary” varying from 4½ to 14¼, and of “worse” from 32 to 45; also that the *dry* climates yielded percentages of “improved” varying from 58 to 65, of “stationary” from 20 to 25, and of “worse” varying from 10 to 21; and that of the patients who took sea voyages, 89 per cent. improved, 5½ per cent. remained stationary, and 5½ per cent. became worse. The marked difference in the effects of the dry and moist groups gives rise to an inquiry as to whether it might not be accounted for by difference in the class of cases sent to each group of localities. This results in the conclusion that, except as regards the Pau cases, which were slightly more unfavourable than the rest, there was no important difference; and the natural inference is, that the less favourable progress of the patients was owing to some element in the moist climates themselves. The leading meteorological features of the climates of Pau, Rome, and Madeira are then sketched, the effects of each pointed out, and their less favourable results attributed to their moister and less stimulating character. With reference to the question whether or no certain forms of consumption derive special benefit from any particular climate, the author deduces from fifty-five cases of phthisis of inflammatory origin who wintered in various warm or temperate localities, that a dry climate is more favourable than a moist one for the treatment of this form of the disease; and as regards phthisis of catarrhal origin the deduction from forty-one patients is that “warmth and equability of climate are more important than dryness for patients of this description.” Forty of the climate cases died, and 202 were living at the last report. Among the former the average duration of life was eight years, and among the latter about nine years, which, when compared with the average of

life among patients who did not go abroad, showed a slight extension of duration. The effect of cod-liver oil in prolonging life is demonstrated by the instances of thirteen patients, who, though they had the full advantages of climate, either omitted oil or took it irregularly. Among these, who are all dead, the average duration was four years eight months and a half.

Dr. WILSON FOX, professing his inability to grapple with the vast array of figures presented to the Society, was fain, by a comparison of the thousand cases brought before the Society some time ago by Dr. Williams with those now before him, to come to the conclusion that climatic results are *nil*, inasmuch as no single climate exhibits a result equal to all the cases quoted collectively. He also referred briefly to the fact that many cases of phthisis, apparently hopeless, live on in London year after year, and asked the author if cases of septic and inflammatory origin can be accurately distinguished, and if so, how?

After some brief complimentary observations by Dr. DOBELL, Dr. HERMANN WEBER expressed his belief that mountain air most benefited cases of the inflammatory type, and that early hours and quiet habits had also much to do with success of treatment.

Dr. HEYWOOD SMITH quoted personal experiences of a winter on the Riviera in proof of the opinion enunciated by Dr. Williams, that a high and dry was better than a moist climate.

Dr. LEARED had arrived at the conclusion, from personal experience, that climatic laws with reference to phthisis were empirical, and quoted Iceland as a country in which phthisis is unknown, but where the houses have no ventilation; and Palestine, part of which is below the level of the sea. He asked the author how, during life, the particular variety of phthisis could be accurately determined?

Dr. SUTRO and Dr. DOUGLAS POWELL made brief observations, and

Mr. CHARLES BROOKE remarked that there were two distinct climates in Natal, the contrast between the coast-line, in which the rainfall was enormous, and the plateau being very striking.

Dr. C. J. B. WILLIAMS replied to so much of Dr. Wilson Fox's criticisms as referred to the inflammatory, catarrhal, and septic varieties, and remarked that by the inflammatory type were meant those cases that commenced in a distinctly acute attack, whether pneumonic, pleuritic, or pleuro-pneumonic, and that subsequently drifted into phthisis. He believed that Madeira was particularly suited to cases of phthisis aggravated by frequent catarrhs; that though statistics on this as on all other Medical subjects ought to be received with caution, he could point out many cases benefited by residence in particular places.

Dr. C. THEODORE WILLIAMS expressed his obligations to the Fellows of the Society for their able but commendatory criticisms of his paper, and, in reply to Dr. Wilson Fox, explained that the classification of the states of the climate patients at last report differed materially from that used for the 1000 cases included in his paper of last year. In the former, the report, which was noted under the terms “much improved,” “improved,” “stationary,” and “worse,” referred to the patients' condition at the close of one or more winters spent abroad. In the latter, the report, under the terms “well,” “tolerably well,” and “invalid,” applied to the patients' condition at the end of the entire treatment, which extended over many years, the average being eight. The duration of the climate cases was greater than the duration of the patients who did not go abroad, though the difference was small; but it should be remembered that the average number of winters spent abroad was only two and one-third; and also that the influence of the less favourable climates was taken into account. With reference to cases of inflammatory origin, Dr. Theodore Williams had, in a former paper, decisively proved by statistics that they had a longer average duration than the rest. In reply to Dr. H. Weber, he stated that the distinction between septic and inflammatory cases had been arrived at from observation of the out-patient department of the Brompton Hospital, confirmed by Guilbert's researches in Peru, and that some of Dr. Weber's own cases showed the benefit of mountain air in phthisis of septic origin. The benefits of cold pure air might be highly advantageous to invalids strong enough to take exercise sufficient to keep them warm, but many consumptive patients, and especially ladies, were unable to do this, and for them the combination of warmth with purity of air was desirable. After replying to Drs. Leared, Heywood Smith, Powell, and Dobell, Dr. Theodore Williams thanked the latter for the complimentary way in which he had spoken of the labours of Dr. C. J. B. Williams and himself, and, in conclusion, remarked that it would have been impossible for him to frame

the present statistics had not Dr. Williams's notes been most carefully kept.

At the conclusion of the meeting Dr. DOBELL exhibited a Bed invented by him for patients with severe heart disease. The bed had been constructed by Mr. Heather Bigg. Many chronic cases of heart disease passing through a stage in which the patient is unable to lie down or even to lean back beyond the perpendicular line without distress or danger, coupled with the difficulty of finding any support for the head and elbows in front which shall not continually slip away when the weight of the patient is thrown upon it, this couch has been devised to meet these requirements, and to support the head and arms in a position favourable for obtaining a certain amount of comfort and a passing chance of sleep.

THE PATHOLOGICAL SOCIETY.

TUESDAY, APRIL 16.

Mr. J. Wood, President, in the Chair.

THE CHAIRMAN announced that, on the first meeting in May, Dr. Sanderson would commence a discussion of pyæmia, and would illustrate his subject by specimens.

Mr. RIVINGTON exhibited a specimen of Bloody Tumour connected with a Nerve. The patient was a female, and in her axilla was a good-sized tumour, nearly as large as a cricket-ball. It was of nearly two years growth, and had been painful for five weeks. He tapped it, and blood came away. The tumour was then removed, and was found to be made up of cysts containing blood-clots. It was connected with the musculo-spiral nerve; but there was no paralysis. It was not an old aneurism. (Referred to Morbid Growth Committee.)

Dr. BROADBENT exhibited some Eyes the subject of Retinal Hemorrhage in Bright's Disease. The patient was a female, aged 50. Some months ago she had a sudden fit of fury, and at intervals from that time suffered from fits beginning in one leg and ending in a regular epileptic seizure. Her mental powers were feeble, and she could walk if led by the fingers. She had albuminuria and a dilated heart. She was attacked by pneumonia, and died not long after. During life the retina was elevated and vascular, and in it were seen a number of hæmorrhages. He thought there might be a cerebral tumour, but there was not; only a contracted kidney.

The same gentleman also showed Eyes from a case of Meningitis. There was injection of the commissure and optic nerves, with some elevation of the disc. The girl had been ill a fortnight. In the Hospital she seemed stupid, lay on her back, and was partly paralysed. She died twenty-four hours after admission.

Dr. MURCHISON related the case of a girl, aged 22, who had Scarletina followed by Dropsy. A fortnight after she had convulsions and impaired sight. Her eyes were examined by the ophthalmoscope, and signs of hæmorrhage were found.

Dr. THOROWGOOD exhibited a specimen of Stricture of the Oesophagus from a man, aged 64, who had complained of vomiting and what seemed dyspepsia. He used to bring up a quantity of pieces of meat after his food. He had not been long in the Hospital when he died suddenly, after sucking an orange. There was a pouch just above the stricture, and this was filled with bits of orange. There was no other disease. In answer to a question whether this pressed on the trachea, the gentleman who made the post-mortem examination said it did not.

Dr. LANGDON DOWN exhibited some specimens of Abscess in the Liver from a man who had never been abroad. For three months he had suffered from swelling in the side, and had had ulceration of the stomach. Six months before the man had suffered from dysentery, and he thought the abscesses might be secondary. He drew off a quantity of fluid by the inspirator, but pleurisy followed, and he died. There were large abscesses surrounded by pultaceous matter, and the colon was covered with ulcers of various sizes. It was not common to find such an amount of disease originating in England.

Mr. RIVINGTON had recently seen a case of abscess of the liver pushing the heart over to the left. The man had been in India.

Dr. GALTON said that in China he had two cases of abscess of the liver perforating the lung and ending in recovery.

In reply to Dr. Cayley, Mr. RIVINGTON said the evidence of the nature of the disease in his case was an opening in the side, whence issued pus and liver-tissue.

Dr. PAYNE exhibited a specimen of an unusually large

Tumour growing within the Heart. It was nearly as large as a billiard-ball, and almost filled the right auricle. Continuations of the same growth were traced in the superior vena cava and some of its branches. There was, besides, a tumour in the anterior mediastinum; and this appeared to be the primary seat of the growth, which might thus have extended into the thoracic veins, and thus into the heart. All these growths, though eminently malignant in their mode of growth, were in structure of the lymphatic or lymphadenoid type. The remarkable point in the history was that both the patient and his friends traced the symptoms of cardiac obstruction from which he suffered to over-exertion on one particular occasion.

Dr. POWELL asked if he referred to tumours in the anterior mediastinum or to those originating in the glands in the posterior mediastinum. Their anatomical character was strikingly different—those originating in the glands were apparently cancerous; those in the anterior mediastinum were lymphadenomatous.

Mr. HULKE said that out of twelve malignant tumours of the anterior mediastinum which he had seen, not a single one was anatomically cancerous. All were lymphadenoma.

Dr. KELLY showed a Heart covered in certain parts with Vegetations. The child was 9 years old, and had been healthy till the end of last month, when chorea set in, and all the limbs were jerky. There were signs of fever, but the heart's sounds were normal. The temperature went up to 106°, and the child died comatose. There were rows of vegetations in the mitral and tricuspid valves, but only on the auricular side. The right lung was hepatized, and the liver fatty; there was no embolism. The membranes of the brain were healthy, and no plugs could be found. The corpora striata were soft—more so in parts; the vessels were fatty, and there were numerous small hæmorrhages. Generally when there was high temperature in heart disease there were plugs to be found, but not so here.

Dr. BROADBENT said there were few deaths from chorea without hearts such as this. The changes in the corpora striata were of great importance.

Mr. DURHAM exhibited a specimen of Intussusception of the Bowel. The patient was a male, passing slimy motions streaked with blood. Obstruction in the bowel was diagnosed, and they could feel a tumour in the rectum resembling an invaginated gut. Constipation was absolute. They tried injections, but could get nothing to pass. Colotomy was performed, and a quantity of fæces removed, but the patient had erysipelas, and died. The upper part of the rectum was invaginated into the lower. Just at the bend was a growth of a villous kind, which was probably the cause of the invagination.

Dr. BRISTOWE exhibited the Brain of a Female, aged 42, who suffered from Right Hemiplegia after a fit. She was aphasic, but was beginning to understand words when she had a recurrence of the attack. Then amnesia existed to some degree. Suddenly she had something like a fit, but there was no paralysis. Her feet became cold and livid—the left first and most—and she died. The left corpus striatum was found completely destroyed and collapsed. In the heart was a softening clot; in the right lung was a gangrenous abscess; in the aorta was a clot extending downwards from the renal arteries.

Dr. BROADBENT said this was the only case he had heard of where there was merely lesion of the corpora striata, and yet loss of speech followed for so long a time. The change in the character of the loss of speech was very important.

Dr. BRISTOWE next proceeded to show a specimen of Obstruction of the Bowels from a man aged 23. Seven or eight months ago he had obstruction, with pain; and this time he was admitted to the Hospital with pain, sickness, and constipation. His bowels had not been open for three weeks. The pain was paroxysmal. Opium and warm baths at first did much good, but by-and-by the bowel swelled up to an enormous size. With enemata a little fæces came away, but not much. To relieve the distension, he punctured the bowel. Very little air escaped, and a little fæces. Peritonitis and death followed shortly. There was no inflammation near these spots, but there was perforation of the ileum near the cæcum, and the extravasated fæces had caused the peritonitis and death. The stricture was at the junction of the transverse and descending colon. It was caused by a colloid growth, and was quite impermeable. There were a few ulcers in the cæcum and ileum nearly perforating the gut, and one had gone through.

Dr. MURCHISON said he had seen a case where puncture had done great good. The patient was a lady, who was much distended, partly from flatus. Sir James Paget sanctioned the proceeding. Air passed out, and no fæces. There was great relief, but the patient died a week after.

Mr. Wood had punctured the bowel for accumulation of gas,

much to the relief of the patient. In one case it did not reaccumulate till death.

Mr. CROFT related the following case of Osteo-Sarcoma of Femur:—J. R., aged 18, in May, 1871, was the subject of a tumour as large as a fist on the front of the lower third of the left tibia. It had been growing seven months, and appeared to be an osteo-sarcoma. The limb was amputated no higher than the tubercle of the tibia, at the desire of the friends. On section, the tumour was of a graduated ruddy colour, was very vascular, and consisted of a soft structure, supported by a reticulum containing osseous spicules. The reticulum was composed of fibres and spindle-shaped cells, and in many places presented growths of bone, including canaliculi. The alveoli contained cells and nuclei of various forms—round, ovoid, polygonal, and even caudate. These all were multinucleolated, and many cells were multinucleated. The surface of the tibia was eroded, and the growth had invaded the medullary structure. The patient quickly recovered from the amputation, and returned to his employment. Four months after the operation he noticed that the knee had begun to swell. On March 15, 1872, he was readmitted into St. Thomas's Hospital with a knee-joint nineteen inches and five-eighths in circumference. A femoral gland was as large as a small egg. He was suffering severely, and the growth was increasing rapidly. On April 3 amputation at the hip-joint was performed, and the enlarged glands were dissected out. The patient had made an excellent recovery from the effects of the operation. On examination of the limb the tibia was found to be quite free from the disease. The joint had not been invaded. The growth appeared to have sprung from the condyloid extremity of the femur. Mr. Stewart, curator of the museum, had injected the tumour, but only partly succeeded—sufficiently to show great vascularity. Colour of section varied from greyish-white to chocolate. Septa radiated from a small centre of cicatrix-like fibrous texture, forming a reticular structure. The stromal tissue and the cells and nuclei in the alveoli were composed of elements similar to those found in the first tumour. The same sort of osseous deposits were also observed. The gland tumour was soft and brain-like on section; it yielded a juice rich in round and ovoid nuclei, containing several nucleoli. After hardening in chromic acid, this manifested a reticular structure, which consisted of connective tissue. Mr. Croft drew attention to the fact that the growth had not recurred in the stump of the bone on and in which it had been situated. He thought the character of the stroma and the cell-shape distinguished it from encephaloid cancer.

CLINICAL SOCIETY OF LONDON.

FRIDAY, APRIL 12.

Sir WILLIAM GULL, Bart., President, in the Chair.

A PAPER by Dr. COCKLE and Mr. CHRISTOPHER HEATH was read, "On a case of Aneurism of the Arch of the Aorta treated by Ligature of the Left Common Carotid Artery." The patient (who was brought before the Society) was a man, aged 48, a farm labourer from Cambridgeshire, who came under Dr. Cockle's care in January, 1872. He had experienced pain in the right side of the head, neck, shoulder, and chest, for four or five years, attributed to rheumatism. In April, 1871, he noticed a pulsating swelling in the hollow of his neck, and was in Addenbrooke's Hospital for two months without relief. After Christmas, 1871, he was compelled to give up work, from the increasing pain in the shoulder and neck. He presented marked symptoms of aneurism of the ascending and transverse portions of the arch of the aorta. There was displacement of the right sterno-clavicular articulation, with projection of the right and upper portion of the sternum; and the episternal notch was filled by a pulsating swelling. There was a strongly heaving and expansile impulse over the whole of the swelling, and marked dulness on percussion existed over the whole area of the tumour. No bruit could be heard, but a double concussion-shock was felt. The respiratory murmur was feeble or absent over the upper portion of the right lung. The heart-sounds were dull and muffled, but without appreciable murmur. There was no cough or difficulty of deglutition. The left radial pulse was decidedly feebler than the right; and the left pupil was much dilated, and the left eye congested. On exertion, he complained of shortness of breath, palpitation, and pain. Mr. Heath tied the left carotid artery above the omo-hyoid on February 26, 1872. Carbolised catgut was used for the ligature, and the wound was covered with cotton-wool. No constitutional disturbance followed. Within forty-eight hours

the patient could lie and sleep on his right side, which he had been unable to do before. The left pupil became natural, and the congestion of the eye disappeared. On the eighth day, when the dressings were removed for the first time, the wound was found completely healed by first intention. Since the operation, the condition of the patient had in every way improved, the chest having become flatter, and the heaving impulse greatly diminished. The patient was free from all pain or inconvenience. He was brought before the Society before returning to the country, and the authors proposed to report upon his condition at a later period.

Dr. ANSTIE showed some tracings of the pulses before and after the operation. These showed decided improvement in the left pulse. The aneurism had probably partially consolidated, but it was still felt to beat in the neck. There was a tangible difference between the two pulses.

Dr. ANDREWS asked if rest and diet had been tried. He could not understand how ligature of the carotid could affect an aortic aneurism, though confinement in bed might.

Dr. ANSTIE said he was inclined to believe the carotid was affected as well as the aorta.

In reply to Mr. Barwell, Mr. HEATH said he acted on no very definite principle, but experience abroad had shown the practice to be successful. He had already tried ligature of both the carotid and the subclavian with success. He this time tied the branch of the vessel next beyond the affected spot—that is, in this case, the left carotid—and the result had surpassed his expectation. The patient had been for some months in Addenbrooke's Hospital, and did no good.

The PRESIDENT asked Dr. Anstie and Mr. Barwell, as a committee, to report on the case. Professor Humphry might also be asked to look after him. He considered there was something more than mere mechanical effect.

Mr. GANT related a case of Spontaneous Gangrene of Both Feet in a messenger-boy, aged 16, who, when he was about 7 years old, had a decidedly bluish aspect, was always breathless, and complained of feeling cold even in warm weather. The boy himself stated that he had suffered from shortness of breath, with occasional dyspnoea, ever since he could remember; otherwise the boy's general health had remained unaffected. Latterly he had been much exposed to cold during very severe weather. After a day's exposure, during the night, when in bed, his feet "burned very much"; and the next morning the great toe and two adjacent toes of both feet were nearly black, and quite insensible. In this state he walked to the Royal Free Hospital. After admission, gangrene progressed until it reached the dorsum of both feet, presenting to some extent the appearance of senile gangrene. But the livid blueness and œdema of both legs up to the knees contrasted with the pale, shrunken condition of the legs as observed in senile gangrene; and the gangrene itself, at this early stage, was more succulent or moist than dry. Pulsation was quite free in both the tibial arteries of the feet. A physical examination of the chest was made by Dr. Cockle. The heart's action was feeble but regular, and unaccompanied by any appreciable murmur. Pulsation could be readily seen in both carotids, and a diffuse forcible pulsation in the external jugular veins. Pulse at the wrist 27 per minute, small, feeble, irregular. The only pulmonary signs were emphysema, and slight bronchitis at the bases of both lungs. Respiration was oppressed—16 per minute. The temperature in the axilla was—morning 103·8°, evening 101·6°. The urine was scanty and high-coloured, with a copious deposit of greyish-brown lithates and of albumen. The patient was lethargic, dull of understanding, and he spoke with a stridulous voice and broken articulation. Occasionally, when the heart's action became very feeble, and dyspnoea very urgent, fits of unconsciousness occurred, accompanied on one such occasion with epileptic convulsive movements of the upper limbs and face, this state lasting two hours. A line of demarcation having formed on the dorsum of the feet, Mr. Gant performed double amputation by modifications of Chopart's and Hey's operations. Both stumps united soundly in a week. But the cardiac and pulmonary conditions recurred at intervals with increasing severity; and in a fortnight the patient sank into a state of coma, and died quietly. The post-mortem examination showed that the heart in its right half was the seat of disease, the origin of which would seem to have been at a very early period of life. The right auriculo-ventricular opening was enlarged sufficiently to admit two, or even three fingers; but the three segments of the valve were healthy; the auricular cavity was dilated and distended with blood to more than twice its natural size; the wall of the auricle, not thickened in any part of its extent, was, between the muscoli pectinati, reduced to a membranous state; the foramen ovale was entirely closed;

the right ventricular cavity was also somewhat enlarged, and equally distended with blood, but the wall was not hypertrophied. The pulmonary valves were quite healthy. On the left side of the heart no morbid condition was discovered, either as regards the cavities or the valves. Recent pericarditis had occurred. Both lungs were emphysematous, but the texture generally was much congested, and the bronchial tubes were engorged throughout with frothy mucus. Recent pleurisy had taken place on both sides of the chest. The abdominal viscera generally were much congested, and the liver and kidneys considerably enlarged by interstitial deposit, passing into fatty degeneration. The brain exhibited marked venous congestion. Mr. Gant was disposed to draw the following two conclusions:—1. That the gangrene of both feet, depending evidently on systemic venous congestion, was caused by the enlarged state of the right auriculo-ventricular opening; and the accompanying dilatation of the auricle and ventricle, being thus essentially cardiac, although the immediate and exciting cause might have been exposure to cold. 2. That the immediate cause of death was pericarditis, pleurisy, and more particularly capillary bronchitis.

The PRESIDENT said there was not much to discuss in this case, it was so complete clinically. The patient was so weak there was hardly likely to be a bruit.

Dr. BROADBENT thought it rare that from simple feebleness of the right heart such a train of symptoms should flow. He thought the kidneys the origin of the gangrene—perhaps, too, of embolus in the lung.

In reply to Dr. Cholmeley, Mr. GANT said there were no changes in the vessels in the limbs.

Dr. BROADBENT related a case of Tumour of the Pons Varolii and Medulla in a man, aged 46, with a syphilitic history and aspect, who, while cutting grass in the sun, was suddenly seized with giddiness, and suffered afterwards from pain in the head, vertigo, double vision, and facial distortion. He entered the Hospital six weeks after the attack, and was then found to have slight weakness of the right limbs; marked paralysis of the left side of the face, of the kind seen in hemiplegia, and not involving the orbicularis oculi, as in Bell's paralysis; lateral deviation of both eyes to the right, with double loss of vision; sensation over the area of the right trigeminus; difficulty of deglutition, and indistinct articulation, the voice also having a nasal twang, due to partial paralysis of the soft palate. The ophthalmoscopic signs were negative. There was no albuminuria, and no heart disease. The diagnosis given was tumour in the pons and medulla. He remained under treatment for about three weeks, taking iodide of potassium in doses gradually increased to sixteen grains three times a day. The headache from which he continued to suffer on admission was greatly relieved, and he walked much better. At the end of this time he insisted on leaving the Hospital, and a week later he was found one morning dead in his chair, having got out of bed in the night to smoke. The only morbid appearances discovered were two small tumours just beneath the floor of the fourth ventricle, near the median line—one in the lower half of the pons, the other near the lower end of the ventricle. The tumour in the medulla undoubtedly gave rise to the dysphagia, and was the cause of the sudden death, as it was in close relation with the nuclei of the glosso-pharyngeal and pneumogastric nerves. The question of greatest interest was, whether the tumour in the pons could have given rise to the paralysis in the left side of the face and the lateral deviation of the eyes to the right, as well as to the anaesthesia of the right side of the face and head. Had the paralysis simply been of the sixth and seventh nerves, from lesion involving their common nucleus, there would have been no difficulty; but both the facial and ocular paralysis were such as is met with in hemiplegia, and, if caused by the tumour in the pons, could only be due to interruption of the fibres which connect the nucleus of the sixth and seventh nerves with the corpus striatum of the opposite side immediately after their decussation. No lesion was discovered, by most careful search, either in the crus or corpus striatum; and the author was inclined to believe that the explanation given above was the true one, and the more so because the lateral deviation of the eyes, usually a fugitive phenomenon, was here persistent.

Dr. BUZZARD said the lateral deviation of the eyes to the right was interesting; and, as it turned out, there was nothing the matter with the spot usually connected with the lesion—viz., the corpora striata. Perhaps the condition was one rather of spasm than paralysis. Irritation of the corpora quadrigemina produced that, especially irritation of the nates. There was something of the kind in unilateral epilepsy. Was there anything wrong with the corpora quadrigemina?

Mr. CARTER asked if the direct or indirect method of using the ophthalmoscope had been used. He was quite sure the former was the better for such purposes.

The PRESIDENT said the case was interesting physiologically, especially with regard to the decussation of fibres. We did not know well the conditions of the deposit of syphilitic matter in the nervous system.

Dr. BROADBENT said the indirect plan of using the ophthalmoscope had been used. There were no changes of importance. Lateral deviation might be due to spasm, but certainly, too, to paralysis. Here it was undoubtedly paralytic. The corpora quadrigemina were unaffected.

OBSTETRICAL SOCIETY OF LONDON.

WEDNESDAY, APRIL 3.

J. BRAXTON HICKS, M.D. F.R.S., President, in the Chair.

The following gentlemen were elected Fellows of the Society:—J. R. Bosworth, M.R.C.S., Sutton; C. E. Buckingham, M.D., Boston, U.S.; C. P. D. Chittenden, L.R.C.P., Lee, Kent; Thos. Savage, M.D., Birmingham; and A. W. Tomkins, M.D., Leamington.

Dr. AVELING exhibited his Apparatus for immediate Transfusion, which he has now modified by adding a tap at each end of the tube close to the nozzles. He had performed the operation successfully a few days previously. Dr. Aveling believed that the methods of preventing coagulation adopted when the mediate mode of transfusion was used were the cause of needless deterioration of the blood and of unnecessary delay.

Dr. BARNES suggested that instead of filling the syringe and tube with warm water it would be better to use a solution of phosphate of soda. In reference to the defibrination of blood in transfusion he would observe that, however carefully the filtration might be performed, it was still to be feared that in the filtrate some fibrine might coagulate and act as minute emboli.

Dr. PLAYFAIR had found no difficulty in defibrinating the blood, and he considered defibrination to be the best means of retaining the blood fluid. In his own case a gravitation instrument had failed to act satisfactorily, probably because there was not sufficient force to overcome the resistance of the venous wall on the nozzle of the instrument.

After some remarks by the President, Dr. ROUTH proposed a recommendation to the Council of the Society to appoint a Committee to report generally on the operation of transfusion.

Dr. CLEVELAND also hoped the Society might be enabled to give directions for facilitating the operation, and referred to a fatal case he had seen in consultation, in which, had it not been for the uncertainty of the operation, transfusion would probably have been performed, and perhaps a life saved.

The recommendation was carried unanimously.

Dr. HEYWOOD SMITH showed a modification of his Angular Scissors. The small scissors had curved blades, and when bent forwards would be useful for the removal of polypi, and bent backwards for cutting the sutures after the operation for vesico-vaginal fistula.

Dr. HALL DAVIS communicated a case of Inversion of the Uterus. The case came to the Middlesex Hospital ten months after labour. The patient was very prostrate from hæmorrhage. Ordinary efforts at reduction having failed, and the patient being much too weak for endeavours by sustained elastic pressure during consecutive days to effect reduction, the everted organ was removed by the single-wire craseur. The patient was discharged convalescent on the thirty-third day. The inverted organ, which was exhibited, was much involuted; it contained parts of the ligaments, but not the ovaries.

Dr. BARNES read a paper "On the Essential Cause of Dysmenorrhœa, as illustrated by cases of Menstrual Retention." The author sought, by comparison of different cases of dysmenorrhœa, to discover a common essential cause. Having discussed the question of "irritable uterus," and adverted to the evidence accumulated since the time of Gooch and Ferguson in proof that cases of neuralgic and constitutional dysmenorrhœa were being gradually transposed under closer clinical analogies to the class of obstructive dysmenorrhœa, the author stated the proposition that the essential condition of a large proportion of cases of dysmenorrhœa was really retention of menstrual fluid. He illustrated this by several cases typical of various kinds of obstruction, and especially by some of congenital or acquired stenosis and atresia of the genital canal. For example, one was that of a healthy woman

who never suffered dysmenorrhœa until after a severe labour, which was followed by sloughing of the vagina and gradual atresia by cicatricial contraction. As the constriction advanced dysmenorrhœa become more and more severe, until, the vagina being completely obliterated, the phenomena of complete retention ensued. When the vagina was restored by operation, the dysmenorrhœa was cured. So in cases of imperforate hymen there was dysmenorrhœa from retention. Some points in the history of this affection were discussed. The term "amenorrhœa" usually applied was bad; menstruation went on; it was occult and painful. The sources of danger and the modes of operating were considered. The cases of dysmenorrhœa from flexion and from stenosis of the os internum and os externum uteri were compared with those of complete atresia of the vagina, the common condition being in all retention of menstrual fluid. Other illustrations were adduced to show that retained fluid or clots in utero caused symptoms similar to those of dysmenorrhœa. The effect of stenosis and atresia in producing retrograde or ascending dilatation of the genital canal was shown, and the mechanism by which retained or injected fluids found their way through the tubes was attributed to the contractile efforts of the uterus excited by the pressure of the retained fluids. One condition submitted was that if the most common essential condition of dysmenorrhœa was retention of menstrual fluid, search must be made for the cause of the retention in order to remove it. This conclusion was as logical as the necessity, always recognised, of giving exit to the menstrual accumulation in cases of complete retention from imperforate hymen. Dysmenorrhœa was incomplete retention. The indication was the same, only less imperative.

Dr. PLAYFAIR believed that clinical facts were not in accordance with a theory so seductive from its simplicity as that advocated by the author. He had no wish to throw the least doubt on the mechanical theory as explanatory of a large number of cases, but he believed that cases existed far more frequently than Dr. Barnes allowed where no obstruction could be found. He referred especially to the cases of so-called congestive dysmenorrhœa, and to those usually included under the class of ovarian dysmenorrhœa.

Dr. SNOW BECK said that nearly all acquired, as distinct from congenital, alterations of the uterine organs from a state of health were attended with more or less increased pain during menstruation; and some affections of the neighbouring organs gave rise to a similar increase of pain. He had no hesitation in expressing his belief that obstruction to the exit of the menstrual flow formed but a small proportion of the cases attended with increase of pain during menstruation, and that treatment directed essentially to this object would in the large majority of instances be attended with unfavourable results.

Dr. ROGERS also believed that dysmenorrhœa was not a disorder depending solely on obstructive causes. Many cases of dysmenorrhœa were cured before the theory of obstruction was first acknowledged. Many of the cases depended on ovarian, rectal, or purely neuralgic disorders. One cause of dysmenorrhœa—fundal endometritis—had been specially described by Dr. Routh.

Dr. TILT thought the most frequent cases of obstructive dysmenorrhœa were those in which the obstruction was clearly of a spasmodic nature. He had repeatedly met with cases in which dysmenorrhœa was intense, although the cervical canal was perfectly free, and the discharge of a florid colour and without clots. The dysmenorrhœa in such cases sometimes depended on chronic inflammation of the menstruating surface, sometimes on morbid ovulation and subacute ovaritis, whereas in exceptional cases the complaint could only be considered a neuralgia of the menstruating womb.

Mr. SPENCER WELLS believed a very large proportion of cases of true dysmenorrhœa depended on mechanical impediment to the free escape of the menstrual fluid, and to be curable by removal of the obstruction. Sympathetic pains in the breasts or elsewhere, and nervous symptoms common at the menstrual period, should not be confounded with true dysmenorrhœa. He narrated cases in which severe obstructive dysmenorrhœa had been cured by replacement of the flexed uterus, by dilatation of the cervical canal, and by opening a closed vagina.

Dr. BARNES then replied.

OVARIOTOMY.—In the *Berliner Klinische Wochenschrift* for February 26 and March 4 Professor E. Martin relates seven cases of ovariectomy performed by him during 1870-71. Four of these were successful. He terminates the paper by some practical remarks derived from a consideration of these cases and his numerous prior operations.

OBITUARY.

THOMAS EDWARD BEATTY, M.D.

It is with no ordinary feelings of regret that we announce the death of one of the worthiest of our brethren in the sister country. Full of years and of honours, Thomas Edward Beatty has passed from amongst us after an illness of but a few days' duration. Indeed, so brief was that illness, that many will hear of it only at the same time with the announcement of its fatal termination. So lately as April 17 last, Dr. Beatty in his wonted health and vigour took the chair at a meeting of the Medical Society of the College of Physicians in Ireland. Two nights afterwards, at the Surgical Society of Ireland, he spoke on the treatment of diffuse cellulitis in the region of the neck. Alas! but one short week later the earliest symptoms of this same affection showed themselves in his own person, extreme asthenia supervened, and on the morning of Friday, May 3, the kindly, genial spirit took its flight from earth. Born almost with the present century, Thomas Beatty at the age of 14 entered Trinity College, Dublin. Four years subsequently he graduated in Arts, having already followed in the footsteps of his father, Dr. John Beatty, in choosing Medicine as a profession. In 1820 he proceeded to the degree of Doctor of Medicine at Edinburgh, and the following year joined the Royal College of Surgeons, Ireland. In 1824 he became a Fellow of the College, and entered upon the active pursuit of his Profession, his tastes leading to the closer study of obstetrics and gynecology. In due time he was chosen Master of the South-Eastern Lying-in-Hospital, an institution which for many years did good service among the poorer inhabitants of a thickly populated district in Dublin. The chair of Medical Jurisprudence at the College of Surgeons was also conferred upon Dr. Beatty. In 1832 the subject of this notice aided in founding the City of Dublin Hospital, of which he became a trustee, and to which he was attached as Consultant in Midwifery until his death.

Beatty now began to reap the reward of untiring assiduity, thorough uprightiness of character, and conscientious discharge of duty. It was his good fortune to enjoy the confidence of a wide circle of patients, and his Professional brethren were not slow to recognise his worth. In 1850 he was honoured by election to the Presidentship of the Royal College of Surgeons in Ireland. A similar dignity was conferred upon him by the Dublin Obstetrical Society, and in 1859 he was chosen to preside over the celebrated Pathological Society of that city. But this was not all. In 1864, the King and Queen's College of Physicians, of which corporation he had become a Fellow two years previously, made Dr. Beatty their President, his eminence as a Physician being thus recognised as his Surgical attainments had been many years before by the College of Surgeons. At this time, too, the University of Dublin granted the degree of Doctor of Medicine *honoris causa* to their distinguished alumnus. Well might the recipient of all these favours at the hands of his brethren exclaim (in the preface to his well-known work), "The many evidences of the esteem of my brethren in both branches of our Profession, with which I have been honoured, might well satisfy the most soaring ambition, and afford grounds for the deepest thankfulness, which I now desire to express; and again I repeat that my cup of Professional honours is full, even to overflowing."

Of the work to which these words are prefatory we need here say but little—it is too well and widely known and appreciated; suffice it to remind our readers that "Contributions to Medicine and Midwifery" are to all time the witness of the industry, the research, and the varied attainments of their author.

His writings, many of which in a revised form were republished in the work to which we have just referred, appeared at intervals from the year 1830. Among the most remarkable of them was an account of a case of abdominal aneurism which terminated fatally in 1829. Dr. Stokes, in his work on "Diseases of the Heart and Aorta," says of this communication—"Our knowledge of the diagnosis of this affection may safely be said to date from the year 1830, when Dr. Beatty, of this city, published his accurate observations on a single case of the disease."

It remained that a yet more general tribute should be paid; and accordingly, on the occasion of the visit of the British Medical Association to the Irish metropolis in 1867, Dr. Beatty was called upon to preside over the Midwifery Section of the meeting. His modest, brief, and interesting address to the Section is still fresh in the memory of many of our readers.

So far, we have dwelt merely on the Professional character

of him we mourn. Those who have had the good fortune to be brought into personal relations with Thomas Beatty, will understand how hard it is to have lost one whose sterling qualities of heart and hand, whose happy disposition, genial humour, and unflinching allegiance, surrounded him with a host of friends. Truly we "shall not look upon his like again."

On Tuesday morning last, all that was mortal of Thomas Beatty was laid in the tomb, and the sad occasion was taken advantage of by a vast number of friends to do honour to his memory. The procession included a large body of students; the Fellows and officers of the two Colleges in their robes; the Governor, Presidents, and Court of the Apothecaries' Hall; the members of the Order of Friendly Brothers of St. Patrick; many masonic brethren; members of the Royal Irish Academy; several Fellows of Trinity College; and almost the whole Medical Profession of Dublin and its vicinity.

ALDERMAN LAURENCE SPENCER, M.D. ABER.,
F.R.C.S. ENG., ETC.,

DIED at his residence, Winkley-square, Preston, on the 1st inst., in the 61st year of his age. He was a native of Burnley, and, after being educated at the Burnley Grammar School, came to Preston when he was 13 years of age. He was apprenticed to the late Mr. John Gilbertson, father of the present Dr. Gilbertson and Mr. Alderman Gilbertson. In 1834 he proceeded to London, where he became a Licentiate of the Apothecaries' Company and a Member of the Royal College of Surgeons. Subsequently he became a Fellow of the Royal College of Surgeons, a Licentiate of the Royal College of Physicians, Edinburgh, by examination, a "Doctor of Medicine" of King's College, Aberdeen, and a Fellow of the Obstetrical Society. He was twice president of the Lancashire and Cheshire branch of the British Medical Association, and was placed in the commission of the peace for the county of Lancaster. His practice in Preston commenced in 1835, and he was one of the most successful Practitioners in that part of Lancashire. He delighted to undertake difficult cases, and he attained a degree of proficiency rarely equalled and scarcely ever excelled. He was kind and genial with his patients, tender-hearted to a degree, and he seldom left a sick-room without the subject of his visit feeling the most perfect confidence in his skill. In November, 1841, he was elected a Councillor for Fishwick Ward, and was re-elected in 1844. In July, 1857, he was chosen Alderman, and maintained that position up to the time of his death. In 1857, and again in 1870, he was Mayor of the borough, and held the office with becoming dignity. He took a very active interest in the management of the water-works, and had the honour, as Chairman of the Water Committee, of cutting the first sod of the Hodder Valley Extension (now in progress) and the Grimsargh Reservoir in 1857. He has spent a most useful life in the service of the town of his adoption, and his removal from it will create a void which it will be almost impossible to fill. To the sick poor that loss is irreparable. The deceased gentleman was married, in 1834, to the eldest daughter of the late Thomas Barton, Esq., of Malton-le-Dale, the issue being four sons and two daughters, all of whom are living. The eldest son (Mr. W. H. Spencer) is a Surgeon practising in Preston; the second is a solicitor in the town; the third is the first Miller Exhibitioner and a Graduate of the University of Cambridge; and the fourth is completing his studies for the Medical Profession. His wife died in December, 1869.

JAMES HALL PARK, M.D. EDIN., L.R.C.S., ETC.,

DIED a fortnight since at Broughty Ferry, Dundee, and his remains were interred in the cemetery at Barnhill on the 30th ultimo. The funeral was intended to be quite private, but in addition to all the Doctors in the village, and the clergymen of the Free Church, the officers of the 3rd Forfarshire Volunteer Artillery (of which Dr. Park was Surgeon)—who had expressed a wish to be present—along with a few of the Coast Brigade of the Royal Artillery, followed. Dr. Park, after studying at the High School of Edinburgh, entered the University, and passing successfully through all the Medical classes, took his degree of M.D. and L.R.C.S.E. in 1857. In 1855, being in the last year of his Medical studies, in compliance with a request from the Government, backed by the strong recommendation of Dr. Millar (at that time Professor of Surgery), he along with some other Medical students volunteered to serve as Hospital dressers in the war that was then waged with Russia. Accordingly he joined the fleet that proceeded to the Baltic under the command of Admiral Dundas, and was present in the *Pembroke* Hospital-ship, at most of the naval engagements that season,

for which services he obtained a medal. After graduating, the following year, he was preparing to enter the navy—for which the Government offered inducements to those youths who had already served their country—when a circumstance occurred which entirely changed his prospects in life. Some severe cases of typhus fever broke out in Broughty Ferry, and the two senior Physicians, Drs. Gordon and Henderson, in the exercise of duty, caught the infection. At the request of the late Dr. Langlands, brother-in-law to Dr. Gordon, Dr. Park generously consented to take Dr. Gordon's practice pending the fever, but both these Physicians succumbed to the disease. At the request of many, Dr. Park consented to commence practice in Broughty Ferry, and was soon thereafter appointed Physician to the Monifieth Parochial Board, and Surgeon to the garrison at Broughty Castle. The effects of a severe cold, caught nearly seven years ago, never left him, and he passed the winter of 1870-71 at Bournemouth. He returned in June last year, with little or no abatement of his disease, and in the autumn went out to Calcutta. He returned in the beginning of March much worse, a new form of disease having set in, and seven weeks after he died. During the latter days of his life, though frequently severely tossed with affliction, he retained his intellectual strength, and was able to prescribe for himself to the last. His kind friends, Dr. Begbie, of Edinburgh, and Dr. Nimmo, of Dundee, and his assistant, Mr. Stewart, saw his case was hopeless, and he met their decision with the calmest fortitude. He has left a widow and five children.

R. M. WATSON, M.R.C.S., L.S.A.,

OF Devonport, was born in 1801, at Woolwich. In 1810 he entered the navy, where he remained seven years; but, as was usual at that time, he lived on shore, receiving the customary education. He then retired from the navy, and began studying Medicine; he entered at St. Bartholomew's, and passed in 1827. He immediately after commenced practice at Devonport, where he practised until his retirement in 1847. His practice was at no time a remunerative one, although at the earlier part of his career his work was very heavy, and the poor always found him ready to help in their hour of need. Whatever he undertook he did thoroughly and conscientiously. He never wrote any book, but he must have been a laborious and diligent student of current literature and scientific subjects even to within a few years of his death, as testified by many manuscript notes found among his papers. About 1847 he began to take an active part in the public affairs of his borough. He was elected Mayor in 1856 and 1857, made a borough magistrate in 1859, and a county magistrate in 1860. He was thoroughly beloved and respected by his fellow-townsmen. He died on April 16, at Stoke, aged 70, and was buried at the cemetery, Mayor and Corporation following, and very many friends sending their carriages.

JOHN HERBERT PATTERSON, M.D. GLASG., M.R.C.S., DEPUTY INSPECTOR-GENERAL OF HOSPITALS AND FLEETS, died at Bournemouth on the 1st inst. The deceased officer, who had received a medal and the Order of the Medjidie of the fifth class for his services, became an Assistant-Surgeon in the Royal Navy in 1838, Surgeon in 1845, and Deputy-Inspector on the retired list in 1868.

BOWYER VAUX, F.R.C.S.,

FORMERLY one of the Surgeons of the General Hospital, Birmingham, died on Saturday, May 4, aged 90, at Teignmouth, South Devon, where he had resided for the last seventeen years. Within a few months of the resignation of his father, Jeremiah Vaux, who had filled the office from the establishment of the institution, he was elected one of the Honorary Surgeons of the Hospital, and resigned in 1843, having held the appointment for thirty-five years.

NEW INVENTIONS.

NIGHTINGALE'S INVISIBLE RESPIRATOR.

(Charles Nightingale, 17, Sackville-street, Piccadilly, London, W.) "KEEP your mouth shut" is the well-known advice which Mr. Catlin gives with such emphasis and point. Mr. Nightingale gives us an instrument by the aid of which it can be done. This is described as an "invisible respirator and mouth protector, inducing natural respiration, for protecting the teeth, throat, lungs, etc., against cold, damp, fog, or noxious influences." It is a curved metallic shield fitted to the front teeth, and intended to induce the wearer to keep the mouth

shut and to breathe through the nose, and to warm the air before any of it reaches the teeth. It is ingeniously designed, but we must not anticipate the verdict which experience only can give.

GRANULAR EFFERVESCING "IRON AND ARSENIC" SODA AND MAGNESIA WITH BISMUTH; AND BISMUTH WITH IRON AND STRYCHNINE.

(*Young and Postans, Analytical and Pharmaceutical Chemists, 35, Baker-street, London, W.*)

In proportion as Medical Practitioners are giving up the preparation of their own medicines, we find gradually introduced a series of handy ready-combined preparations, which need no further "dispensing," and which the patient can easily administer to himself in the proper dose. The above preparations belong to this class. They are all in the "granular" form, and effervesce readily when mixed with water. They are as little physicky or siekly as possible. The iron and arsenic is a good compound; it dissolves readily, forms a clear pinkish solution, and looks nicer, and tastes quite as nice, as some champagne. The other preparations answer well to their titles. They are all instalments of a great change impending over pharmacy, which we believe will cause nausea to be no longer associated with the idea of the "Doctor's shop."

MEDICAL NEWS.

ROYAL COLLEGES OF PHYSICIANS AND SURGEONS, EDINBURGH—DOUBLE QUALIFICATION.—The following gentlemen passed their first Professional examinations during the April and May sittings of the Examiners:—

Bennett, William, Clonakilty.	Leader, Nicholas, Cork.
Davies, James H., Llandilo.	Marsh, Herbert Elliott, Lancaster.
Espagnet, Marc Edouard Tursand, Mauritius.	Page, Frederick M., Corfu.
Keir, William Ingram, Musselburgh.	Pollard, Clement, Taunton.
	Stevenson, John, Edinburgh.

And the following gentlemen passed their final examinations and were admitted L.R.C.P. Edin. and L.R.C.S. Edin.:—

Allin, William Briggs, Torrington.	Mackenzie, Alex., Kelso.
Anderton, William, Lancashire.	Mackenzie, Lawrence Storrar, Liverpool.
Bernard, Gerald, Portsmouth.	Masterton, John, Edinburgh.
Berry, William, Lancashire.	Murphy, John Joseph, county Carlow.
Blyth, Charles, Suffolk.	Orr, Hugh, county Cavan.
Chaffey, Elswood, Canada.	Quarry, Charles, county Cork.
Corbett, Michael, county Cork.	Rowan, Thomas, county Down.
Dixon, Joseph, Cumberland.	Smith, Charles Edward, Essex.
Gilligan, William Arthur, Bradford.	Smith, George Cockburn, Winchester.
Hawkes, Alfred Edward, Northamptonshire.	Wood, William John Haram, Boston.
Hunter, Christopher, county Tyrone.	
Kenny, Maurice Aloysius, Limerick.	

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen passed their primary examinations in Anatomy and Physiology at a meeting of the Court of Examiners on the 7th inst., and when eligible will be admitted to the pass examination:—

Bacon, Alfred P., student of the Leeds School.
 Clare, John, of Guy's Hospital.
 Darker, Frederick W., of St. Thomas's Hospital.
 French, Peter, of the Dublin School.
 Haden, Arthur C., of University College.
 Heale, Alfred L., of the Westminster Hospital.
 Hughes, P. Walter, of the Liverpool and Edinburgh Schools.
 Jones, T. Cattell, of Guy's Hospital.
 Lee, Edwin, of the Leeds School.
 Lendon, Edwin H., of University College.
 Morton, Richard J., of Guy's Hospital.
 Newington, A. S. L., of University College.
 Parson, Henry, of St. Thomas's Hospital.
 Powell, Howell M., of Guy's Hospital.
 Price, Robert J., of University College.
 Priestley, Clement E., of St. Thomas's Hospital.
 Ross, George H., of University Collge.
 Scott, Jeremiah, of the London Hospital.
 Smith, William, of the Manchester School.
 Smith, William, of the Sheffield and Glasgow Schools.
 Tamplin, Charles H., of St. George's Hospital.
 Worthington, Walter M., of the Birmingham School.

The following gentlemen passed on the 8th inst., viz.:—

Barrow, John, student of St. Bartholomew's Hospital.
 Collins, Charles E., of University College.
 Crouch, Edward T., of Guy's Hospital.
 Deardon, John A., of the Manchester School.
 Draper, Matthew R., of the London Hospital.
 Dixon, Thomas A., of St. Bartholomew's Hospital.
 Eastall, Henry F., of Guy's Hospital.
 Fowler, Breame W., of St. George's Hospital.
 Haines, Edmund, of St. Bartholomew's Hospital.
 Hind, Henry J., of Guy's Hospital.
 Howell, Bruce K., of St. Bartholomew's Hospital.
 Hutchings, Edward J., of Guy's Hospital.

Hutchinson, Joseph, of the Manchester School.
 P'anson, Welby, of St. Bartholomew's Hospital.
 Landon, Arthur J., of St. Bartholomew's Hospital.
 Nadin, Joseph, of St. Bartholomew's Hospital.
 Powell, Richard, of St. Bartholomew's Hospital.
 Richards, George P., of the Dublin School.
 Roe, Leyland F., of the Manchester School.
 Smith, Arnold A., of the Sheffield School.
 Steavenson, William E., of St. Bartholomew's Hospital.
 Sykes, William, of the Sheffield School.
 Treharne, John L., of Guy's Hospital.

The following gentlemen passed on the 9th inst, viz.:—

Byrne, John J., student of the Manchester School.
 Deeley, Ambrose W., of the Manchester School.
 Emmerson, William L., of the Westminster Hospital.
 Farfan, Joseph V., of St. George's Hospital.
 Garrett, Charles F., of the London Hospital.
 Hoffmeister, John B., of St. Bartholomew's Hospital.
 Hughes, Lewis J., of the Dublin School.
 Kershaw, Alfred, of the Manchester School.
 Moore, George E., of King's College.
 Smith, John P., of St. Mary's Hospital.
 Smith, Rev. William, M.A. Trin. Coll. Dub., of the Liverpool School.
 Tatham, G. George, of the Manchester School.
 Wallis, Kenneth S., of the Manchester School.

Forty candidates out of the ninety-eight examined having failed to acquit themselves to the satisfaction of the Court of Examiners, were referred to their Anatomical and Physiological studies for three months.

ROYAL COLLEGE OF SURGEONS, EDINBURGH.—The following gentlemen passed their first Professional examinations during the March and April sittings of the Examiners:—

Greene, John Joseph, Dublin.	Whittington, Thomas Price, South Wales.
O'Callaghan, John, county Kerry.	

And the following gentlemen passed their final examinations and were admitted Licentiates of the College:—

Adams, George Norris, Southampton.	Harris, Alfred Charles Edward, Cawnpore.
Aubrey, Richard, Somerset.	Lucas, John Cutchick, Calcutta.
Bailey, James Buttersby, county Cavan.	Murdoch, Robert, Ayrshire.
Cluxton, Frederic Charles, Ontario.	Norris, Henry Lee, jun., United States.
Cunningham, William Love, Beith.	Stewart, Henry Ward, Woolwich.
Fleming, John, county Derry.	
Fraser, John, Ontario, Canada.	

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received Certificates to practise, on Thursday, May 2:—

Delamotte, Peter William, Swanage, Dorset.
 Jenkinson, Harold, Ramskill, Yorkshire.
 Stickland, Samuel, Hawkhurst, Kent.

As Assistants in Compounding and Dispensing Medicines:—

Garratt, Arthur, Market-street, Guildford.
 Richards, James Griffiths, Crumlin, Monmouth.

The following gentleman also on the same day passed his Primary Professional Examination:—

Davies, John Hopkyn, Middlesex Hospital.

APPOINTMENTS.

* * * The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

BROWNE, WILLIAM HENRY, L.R.C.P. Edin., L.R.C.S. Edin., Medical Officer to the Aldborough District, Skirlaugh Union, Yorkshire.

CHAMBERS, E., M.R.C.S. England—House-Physician to St. Bartholomew's Hospital.

HOPKINS, FREDERICK FRAZER, M.R.C.S. Eng.—Resident Surgeon to Birmingham General Dispensary, *vice* Mr. J. H. Kenny, resigned.

MACKENZIE, DUNCAN JOHN, M.B., C.M.—Assistant House-Surgeon to the Leith Hospital.

ALLAN, RICHARD, L.F.P.S.G., L.R.C.P.E.—Medical Officer to the Dal-mellington Union, Ayrshire.

ANDERSON, WILLIAM, R.N., L.R.C.S.—Medical Officer to Kilmaurs Union, Ayrshire.

THOM, GEORGE S., M.R.C.S., L.S.A.—Resident Medical Officer to the Royal Albert Hospital, Devonport, *vice* M. M. Moore, Esq., L.R.C.P., M.R.C.S., resigned.

WALKER, GEORGE CHARLES, M.D.—Physician to the Bootle Borough Hospital.

WHITE, FREDERICK, M.R.C.S., Surgeon to the Eye and Ear Infirmary, Liverpool.

NAVAL AND MILITARY APPOINTMENTS.

MEDICAL.—Dr. Fleetwood Buckle, Assistant-Surgeon to the *Dart*; John M. Hunter, Surgeon, additional, to the *Duke of Wellington*; Charles J. Fennel, Surgeon to the *Duke of Wellington*; and Charles P. D. Chittenden, Assistant-Surgeon to the *Hercules*.

MEDICAL DEPARTMENT.—Staff Surgeon-Major William Godfrey Watt, to be Deputy Inspector-General of Hospitals; Staff Surgeon Thomas George Fitzgerald, having completed twenty years' full-pay service, to be Staff Surgeon-Major, under Article 342 of the Royal Warrant of December 27, 1870; Assistant-Surgeon Henry Carden Herbert, M.D., from 40th

Foot, to be Staff Surgeon, *vice* Staff Surgeon-Major John Rambaut, M.D., who has retired upon half-pay; Staff Assistant-Surgeon Williams Leaven White, M.B., resigns his commission.

BREVET.—Apothecary William Wilson, Bengal Medical Establishment, to have the honorary and local rank of Assistant-Surgeon.

BIRTHS.

DUNCAN.—On May 2, at 139, Buckingham Palace-road, the wife of H. M. Duncan, M.D., M.B., M.R.C.S., of a son.

GRAY.—On May 1, at 45, St. Giles's, Oxford, the wife of Edward B. Gray, M.D., of a son.

HUNTER.—On May 1, at 18, Abereromby-place, Edinburgh, the wife of James A. Hunter, M.D., of a daughter.

INGLIS.—On May 7, at Devon House, South Penge-park, S.E., the wife of Walter W. Inglis, M.D., of a son.

INKSON.—On April 5, at Nynce Tal, the wife of James Inksou, M.D., Staff Assistant-Surgeon, of a son.

MARSHALL.—On May 7, at Holly House, Mortlake, the wife of W. Marshall, M.D., of a son.

MUMFORD.—On April 29, the wife of William Lugar Mumford, M.D., of a daughter.

PRENTIS.—On April 6, at Goruckpore, India, the wife of Surgeon Charles Prentis, B.M.S., of a daughter.

ROGERS.—On April 11, at No. 4, Marine-lines, Bombay, the wife of A. M. Rogers, Presidency Surgeon, of a son.

MARRIAGES.

MOORE-SHIRLEY.—On April 30, at Moreton-in-Marsh, Gloucestershire, John New, second son of George Moore, L.R.C.S., L.S.A., to Annie, younger daughter of the late John Shirley, Esq., of Moreton-in-Marsh.

ROE-VERDON.—On April 27, at the parish church, Eccles, near Manchester, Edwin Hodgson Roe, M.R.C.S., The Poplars, Patricroft, to Annie, only daughter of the late Rev. William Verdon, B.A., incumbent of St. John's, Pendlebury, and sister of Richard Verdon, M.A., Fellow of St. John's College, Cambridge.

SMITH-SHAW.—On April 30, at St. George, Tombland, Norwich, W. Arnold Smith, M.D., Surgeon 2nd Madras Light Cavalry, to Charlotte Sutton, eldest daughter of Commander Charles Shaw, Royal Navy.

WADES-BAXTER.—On May 7, at St. Paul's, Knightsbridge, John Wades, M.D., Hanley, Staffordshire, to Sarah, daughter of the late Charles Fletcher Baxter, Esq., of Oxford.

DEATHS.

BARFOOT, CLARISSA, the beloved and deeply regretted wife of Edward Barfoot, M.R.C.S. Eng., L.S.A., at Freshwater Villa, Surbiton, Surrey, on May 4.

BROWN, JAMES LUNDIN, M.D., suddenly, at Malvern, on May 2, aged 44.

COOKE, T. WEEDEN, M.R.C.S. Eng., L.S.A., at his residence, Upper Berkeley-street, Portman-square, on May 7, aged 56.

DUNN, CHARLES, M.R.C.S. Eng., L.S.A., late of Fareham, Hants, at Ramsgate, on May 4, aged 40.

HODSON, MARY BEATRICE (Daisy), eldest child of Thomas Hodson, M.R.C.S. Eng., L.S.A., Ingatestone, Essex, on April 28, aged 6 years.

PATERSON, J. H., M.D., Deputy Inspector-General of Hospitals and Fleets, at Bournemouth, on May 1.

SPENCER, LAURENCE CATLOW, M.D., J.P., at his residence, Winckley-square, Preston, Lancashire, on May 1, in the 62nd year of his age.

VAUX, BOWYER, F.R.C.S. Eng., formerly one of the Surgeons to the Birmingham General Hospital at Teignmouth, on May 4, aged 90.

WATSON, CLARA LINDSAY, only daughter of Staff Surgeon Watson, at Manchester, on April 25, aged 22 months.

VACANCIES.

In the following list the nature of the office vacant, the qualifications required in the Candidate, the person to whom application should be made, and the day of election (as far as known) are stated in succession.

ASHTON-UNDER-LYNE DISTRICT INFIRMARY.—House-Surgeon. Candidates must possess both a Medical and Surgical diploma. Applications and testimonials to be addressed to "The President of the District Infirmary," and forwarded to H. T. Danton, Esq., Honorary Secretary, Ashton-under-Lyne, on or before May 11.

BRADFORD INFIRMARY.—Senior House-Surgeon. Diplomas and testimonials to be sent to Mr. C. Woodcock, at the Infirmary, on or before May 22.

CENTRAL LONDON SICK ASYLUM DISTRICT.—Assistant Medical Officer for Highgate Infirmary. Candidates must possess a double qualification, according to the Regulations of the Local Government Board. Applications on a printed form, which will be provided, with not more than four recent testimonials, to be forwarded to the Committee, at the Asylum, not later than twelve o'clock on Thursday, May 16.

DERBY COUNTY LUNATIC ASYLUM, MICKLEOVER.—Assistant Medical Officer. Candidates must possess both a Medical and Surgical diploma. Applications and testimonials to be sent to John Barber at the Asylum.

GREAT NORTHERN HOSPITAL.—Ophthalmic Surgeon. Candidates must be F.R.C.S. Applications and testimonials to be sent to G. Reid, Secretary, 46, Great Coram-street, W.C., on or before May 16.

INFIRMARY FOR CONSUMPTION AND DISEASES OF THE CHEST, 26, MARGARET-STREET, CAVENDISH-SQUARE.—Visiting Physician. Candidates must be Members of the Royal College of Physicians, London. Testimonials to be sent to Francis Baily, Secretary.

KIDDERMINSTER INFIRMARY.—House-Surgeon and Secretary. Applications and testimonials to be sent to the Chairman of the Managing Committee, on or before May 16.

MIDDLESEX COUNTY LUNATIC ASYLUM, HANWELL.—Medical Superintendent of the Male Department. Candidates must be Fellows, Members, or Licentiates of one of the Royal Colleges of England, Scotland, or Ireland, and duly registered in Medicine and Surgery. Copies (only) of testimonials, accompanied by a form (which will be forwarded on application), must be sent to Richard William Partridge, Clerk to the Visitors, on or before Saturday, May 4.

NORTH RIDING INFIRMARY, MIDDLESBOROUGH-ON-TEES.—House-Surgeon. Candidates must be Fellows or Members of one of the Royal Colleges of Surgeons of the United Kingdom. Applications and testimonials to be sent to the Secretary, on or before June 12.

SHEFFIELD GENERAL INFIRMARY.—Assistant House-Surgeon. Candidates must be Members of one of the Royal Colleges of Surgeons of the United Kingdom, or L.F.P.S.G. and L.S.A., or L.R.C.P.L. Applications and testimonials to be addressed to "The Medical Staff of the Infirmary," care of the Secretary, on or before May 16.

UNIVERSITY COLLEGE HOSPITAL.—Resident Medical Officer. Applications and testimonials to be sent to John Robson, B.A., Secretary to the Council, on or before May 18.

WESTHAMNETT UNION, SUSSEX.—Medical Officer. Candidates must be duly qualified. Applications and testimonials to be sent to R. G. Raper, Clerk to the Guardians, at the Office, West-street, Chichester, on or before May 17.

WESTMINSTER UNION.—Medical Officer. Candidates must possess both a Medical and Surgical degree. Applications and testimonials to be sent to the Union Office, Poland-street, Oxford-street, on or before May 15.

UNION AND PAROCHIAL MEDICAL SERVICE.

** The area of each district is stated in acres. The population is computed according to the census of 1861.

RESIGNATION.

Altrincham Union.—The Workhouse Medical Officership is vacant; salary £50 per annum.

APPOINTMENTS.

Atherstone Union.—John A. Lycett, M.R.C.S. Eng., L.S.A., L.R.C.P. Lond., to the Polesworth District.

Barrow-upon-Soar Union.—Wm. Paulson, L.R.C.P. Lond., to the Rothley District and the Workhouse.

Glanford Brigg Union.—Wm. Richardson, L.R.C.P. Edin., L.R.C.S. Edin., to the Messingham District.

Newport Pagnel Union.—George N. Swinson, M.R.C.S. Eng., L.R.C.P. Edin., to the Eleventh District.

Rotherham Union.—Wm. J. Smith, L.S.A., to the Rawmarsh District. Clement S. Blythman, M.B., C.M., M.R.C.S. Eng., to the Swinton District.

St. Thomas Union.—Wm. John Land, M.R.C.S. Eng., L.S.A., to the Littleham District.

Tendring Union.—Saml. N. Squire, M.R.C.S. Eng., L.S.A., to the Elmstead District.

Torrington Union.—Lewis R. H. Rouse, M.R.C.S. Eng., to the Shebbear District.

York Union.—James F. Henderson, M.D. & C.M. Univ. Aber., to the Fourth District.

MR. GEORGE W. JOTHAM, jun., has been appointed Honorary Surgeon of the Kidderminster Infirmary.

DR. STRANGE has been appointed Honorary Physician to the Worcester County Gaol, in the room of the late Dr. Williams.

The new Infirmary at Kensington will be opened early next month.

A NEW dispensary is to be erected in the Liverpool-road, Islington, on the site of the old workhouse.

The Vaccination Officers of Newtown, not considering a shilling for each successful vaccination sufficient, memorialised the Board of Guardians for one-fourth of the fines for the neglect of parents, etc., which the Guardians acceded to.

The Committee of Management of the West London Hospital, at a meeting held on the 6th inst., resolved that one of the new wards be named the "W. L. H. Ward," in recognition of two donations of £1000 each, one received in 1871 and the other in 1872.

WE regret to record that Dr. J. L. Brown, of Malvern Wells, while walking on Thursday week on the line of railway at Great Malvern, was overtaken and knocked down by a luggage train, the wheels of the trucks literally cutting his body in two. The guard of the train saw Dr. Brown on the line, but had not time to stop the train. At an inquest held on Saturday on the body, it appeared that the deceased was at the time greatly depressed in consequence of the death of his wife and child, and he fell between the trucks after throwing away a pipe he had been smoking. Dr. Brown was in his 44th year.

ROYAL COLLEGE OF SURGEONS.—The lectures for the present year will be resumed on Monday, the 3rd proximo, by Professor Holmes, F.R.C.S., who will deliver six lectures on the "Surgical Treatment of Aneurism in its various forms," to be followed by Dr. G. M. Humphry, F.R.S., who will commence his course of lectures on "Human Myology" on the 17th proximo. These lectures will be delivered on Mondays, Wednesdays, and Fridays, at four o'clock.

FEES OF OLD AND YOUNG PRACTITIONERS.—The Medical Association of Liège and Belgium has lately established a minimum tariff of fees to be adopted by all its members. This, of course, has often been done elsewhere, but not frequently with much success. One point, however, which the Association insists upon (and which other similar bodies would do well to note) is the extreme injustice of senior members of the Profession who have made their way and are

in easy circumstances continuing to charge the same fees as those who are just entering it.

ROYAL INSTITUTION OF GREAT BRITAIN.—At the general monthly meeting, on Monday, May 6, 1872, Sir Henry Holland, Bart., M.D., D.C.L., F.R.S., President, in the chair, the following Vice-Presidents were nominated for the ensuing year:—The Marquis of Salisbury, the Earl of Rosse, General Sir Edward Sabine. William Spottiswoode, Esq. the Treasurer. John Erie Erichsen, Esq., Charles Howard Esq., John Saunders, Esq., George Noble Taylor, Esq., were elected Members of the Royal Institution. John Tyndall, Esq., LL.D., F.R.S., was re-elected Professor of Natural Philosophy.

MEATH HOSPITAL, DUBLIN.—**DISTRIBUTION OF PRIZES.**—On Thursday, May 2, Dr. Stokes, Regius Professor of Physic in the University of Dublin, Senior Physician of the Hospital, and Mr. Porter, Surgeon to the Queen in Ireland, Senior Surgeon of the Hospital, distributed the Medical and Surgical prizes awarded at the examinations held at the termination of the winter session. The prize of ten guineas presented by Dr. Hudson, President of the King and Queen's College of Physicians, for six Medical cases—three of acute and three of chronic diseases—observed in the Hospital, and to be accompanied by commentaries, was divided between Mr. Charles Alexander McMunn and Mr. Henry Mallins. At the *vivâ voce* Medical examination Mr. H. Mallins obtained the first, Mr. Archibald Adams and Mr. Charles Alexander McMunn the second prizes. The first Senior Surgical prize was awarded to Mr. Marcus Given, the second to Mr. Archibald Adams. The first Junior Surgical prize was obtained by Mr. Cuthbert Fitzsimon, the second by Mr. John Middleton. Dr. Stokes complimented the Medical prizemen in eloquent and graceful terms upon the extent and variety of the information and practical knowledge they had proved themselves to be possessed of, and congratulated them upon the extent to which they had cultivated the physical sciences accessory to Medicine. Mr. Porter spoke in the highest terms of the distinguished answering of the Surgical class, and expressed the marked approbation with which he and his colleagues had witnessed the diligence and attention of the Surgical pupils throughout the past session.

COMPOSITION AND QUALITY OF THE METROPOLITAN WATERS IN APRIL, 1872.—The following are Dr. Letheby's returns to the Association of Medical Officers of Health:—

Names of Water Companies.	Total Solid Matter per Gallon.	Oxygen required by Organic Matter, &c.	Nitrogen.		Hardness.	
			As Nitrates &c.	As Ammonia.	Before Boiling.	After Boiling.
	Grains.	Grains.	Grains.	Grains.	Degs.	Degs.
<i>Thames Water Companies.</i>						
Grand Junction	18.41	0.117	0.149	0.004	14.6	3.8
West Middlesex	19.20	0.075	0.135	0.001	15.1	4.1
Southwark & Vauxhall	18.83	0.155	0.141	0.003	14.8	3.9
Chelsea	17.87	0.188	0.139	0.004	14.3	3.6
Lambeth	17.93	0.151	0.138	0.005	14.4	3.6
<i>Other Companies.</i>						
Kent	26.63	0.011	0.165	0.000	20.0	5.8
New River	18.63	0.079	0.148	0.001	15.0	3.8
East London	19.13	0.056	0.146	0.002	15.3	4.0

Note.—The amount of oxygen required to oxidise the organic matter, nitrites, etc., is determined by a standard solution of permanganate of potash acting for three hours; and in the case of the metropolitan waters the quantity of organic matter is about eight times the amount of oxygen required by it.

The water was found to be clear and nearly colourless in all cases but the following, when it was more or less turbid—namely, in those of the Grand Junction, Southwark and Vauxhall, the Lambeth, and the Chelsea Companies.

The average quantity of water supplied daily to the metropolis during the preceding month was, according to the returns of the Water Companies to the Association of Medical Officers of Health, 102,857,846 gallons; and the number of houses supplied was 493,978. This is at the rate of 31.5 gallons per head of the population daily. The last official return from Paris stated that the average daily supply per head of the population was 26.8 gallons; but this includes the water used for the public fountains, and for the ornamental waters in the Bois de Vincennes and the Bois de Boulogne.

NOTES, QUERIES, AND REPLIES.

Be that questioneth much shall learn much.—*Bacon.*

Dr. A. P. Stewart.—We think the controversy may cease. Dr. Stewart has had the opportunity of showing wherein he thinks we committed a public wrong, and withdraws a word to which we objected; so the matter may rest.

J. R.—We should be sorry to advise you to speculate. We have no faith ourselves. As for hearing the *truth* about schemes of the sort, whom are we to get it from?

Long Forceps.—There will be a meeting of the Midwifery Board on Wednesday, the 22nd instant, for the examination of candidates for the Licence in Midwifery of the College of Surgeons. See our advertising columns.

M.D., Btenheim.—Miss Hill, who supplanted Sarah, Duchess of Marlborough, was married to Mr. Masham privately, in the apartments of Dr. Arbuthnot, one of the Physicians of the Household.—*Stanhope's "Queen Anne."*

Post-mortem Examination of William III.—In his "History of England," Earl Stanhope states that the demeanour of William was certainly in no common degree dry, forbidding, and austere; that he never appeared quite at ease or quite to his advantage except on a day of battle. There, and there alone, the hero was fully manifested. For this coldness and reserve there might be, perhaps, in some degree a physical cause assigned, as, when his body came to be dissected in the presence of ten Physicians and four Surgeons (the most eminent of their day), they state at the conclusion of their joint report—"It is very rare to find a body with so little blood as was seen in this." The report is given at length in the "Complete History of Europe for 1702," p. 76.

The following is circulated by John P. Coldstream, W.S., 5, St. Andrew's-square, Edinburgh, to whom communications may be addressed:—

"Appcal on behalf of Mrs. Henrietta Mary Bell, daughter of the late William Turton, Esq., solicitor, Stoke-on-Trent, and widow of the late James Bell, Surgeon, formerly of Amoy, China, and latterly Physician and Justice of the Peace in Port Albert, New Zealand.

"Mrs. Bell has been left a widow with eight children, the eldest of whom is 11 years old, and their only means of support is £16 per annum, derived from property in New Zealand left by her late husband. Mr. Bell was educated in Edinburgh, and during his College career associated much with the students of the Edinburgh Medical Missionary Society, was favourably known to many of its Directors, and was instrumental in promoting the interests of the dispensary connected with that Society. In 1857, after having taken his diploma, he was requested by Dr. Hirschberg, Medical missionary at Amoy, to assist him in his work in that city; and he laboured there with much usefulness till the failing health of his wife compelled him to abandon his work in China and return to this country. After being engaged in practice for some time in Devonshire, he emigrated to New Zealand with his family, and was useful in promoting the welfare of the emigrants in Port Albert, where he settled in practice. He continued to reside there till his death, which occurred in August, 1870, after two days' illness, and by the discharge of his duties as a Medical man, a magistrate, and coroner, he won the entire respect and affection of all those with whom he came in contact. The *New Zealand Herald*, in noticing his death, stated that as a Medical man his services were always rendered wherever required, and in many cases without fee or reward; that as a settler his loss would be severely felt, as he had always taken a leading part in all public business from the commencement of the settlement, and was generally selected to occupy the chair at public meetings; that in him every one of the settlers had lost a friend; and that it would be impossible to name another person whose loss would be so generally felt. After Mr. Bell's death, Mrs. Bell continued to reside a short time in the colony; but in consequence of depreciation in the value of land and stock, she was obliged to abandon her intention of remaining there for the support of her family; and after realising her husband's estate, it was found that there would not be a larger sum at present than £16 a year for her own and her family's maintenance. On her return to this country, Mrs. Bell was kindly received by her husband's relatives, who care for her and her children according to their ability. A sister of Mr. Bell has taken one child; but this and the promise of the father of Mr. Bell, who is 82 years of age, to give a home to Mrs. Bell during his life, is all that can be done by them. Applications are about to be made to two of the public Hospitals of Edinburgh for the admission of other three of the children. From the youthful age of her remaining children, who require much attention from their mother, Mrs. Bell finds it impossible to procure a sphere in which she could earn a proper livelihood for her family. In these circumstances Mrs. Bell most reluctantly made known her position to a few of her late husband's friends in Edinburgh, who, after consultation, with the knowledge and approval of herself and her friends, now submit her case to the public, in the belief that they do not appeal in vain on her and her fatherless children's behalf. It is hoped that at least £1000 may be raised to be invested for behoof of Mrs. Bell during her life, and thereafter divided among the children."

THE BAKER BROWN TRUST FUND.

This fund is raised on behalf of Mr. Isaac Baker Brown, who is paralysed, and in great pecuniary distress.

CORRIGENDUM.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—In the obituary notice of Dr. Masfen in the *Medical Times and Gazette* of last week it is stated that in 1853 Dr. Masfen obtained the Scholarship in Medicine on his graduating M.B. at the University of London. Dr. Masfen obtained the University Scholarship in Surgery, but the Scholarship in Medicine was gained by Yours, &c.,
BUCHANAN WASHBURN.

OLD TIMES.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.
 SIR,—“I stood by a pretty young maid, whom I did attempt to take by the hand, but she would not; and I did perceive that she had pins in her pocket with which to prick me if I should touch her again, and was glad that I spied her design.” Thus writes that old rascal, Pepys, who dropped into St. Dunstan’s Church to hear an edifying discourse one Sunday evening. Taking up another ancient book, the following story appears very good:—A certain regiment was drawn up for General’s inspection—never mind when, never mind where—every man as rigid as the gendarmes in *Geneviève de Brabant*, everyone present with an exception. The colonel fumes, the adjutant raves; where is the Surgeon? where’s Doctor James? the service is going to the devil! At the last moment, slowly and solemnly, up drives a one-horse shay, from which emerges a gentleman, military as to trousers, but otherwise clad as a general Practitioner. With the rapidity of lightning, resembling Shaw, the Life Guardsman, in the circus, flinging aside the coat and hat, he assumes the scarlet tunic, the black belt, the cocked hat, and buckles on a trusty Toledo. The plot thickens as a regimental saddle appears; the venerable steed taken out of the shafts, and instantaneously converted into a war-horse, inclined to sniff the battle afar off. The Assistant-Surgeon, very much against the grain, was directed to hold the charger’s head, to give his superior officer a leg up, at the first blast of the trumpets to keep an eye on Rosinante, and should there be any firing, to cling to the bridle “like grim Death.” All passed off well; no one turned turtle; the programme was reversed; the old nag, stripped of his trappings, sorrowfully reverted to former degradation, doubtless on the way home moralising on the vanity of greatness, as well as the mutability of human affairs.

Quer people our ancestors!

Your obedient servant,

D. I. G.

APPOINTMENTS FOR THE WEEK.

May 11. Saturday (this day).

Operations at St. Bartholomew’s, 1½ p.m.; King’s, 2 p.m.; Charing-cross, 2 p.m.; Royal Free, 2 p.m.; Hospital for Women, 9½ a.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. Thomas’s, 9½ a.m.
 ROYAL INSTITUTION, 3 p.m. Mr. R. A. Proctor, “On the Star Depths.”

13. Monday.

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark’s Hospital for Diseases of the Rectum, 2 p.m.; St. Peter’s Hospital for Stone, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

14. Tuesday.

Operations at Guy’s, 1½ p.m.; Westminster, 2 p.m.; National Orthopædic, Great Portland-street, 2 p.m.; Royal Free, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; West London, 3 p.m.

ROYAL INSTITUTION, 3 p.m. Mr. E. B. Tylor, “On the Development of Belief and Custom amongst the Lower Races of Mankind.”

ROYAL MEDICAL AND CHIRURGICAL SOCIETY, 8½ p.m. Mr. Jeremiah McCarthy, “On some Renal Calculi of unusual shape in the Left Kidney of a Woman who died of Cancer of the Uterus;” “On a Case of Intestinal Obstruction, Artificial Anus made in Small Intestine, etc.” Mr. R. Hamilton, “On the Synovial Membranes in Pyæmia.” Dr. Wm. Murray, “On some further Attempts to Cure large Internal Aneurisms.”

15. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary’s, 1¼ p.m.; Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew’s, 1½ p.m.; Great Northern, 2 p.m.; St. Thomas’s, 1½ p.m.; Samaritan, 2.30 p.m.; King’s College Hospital (by Mr. Wood), 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. George’s (ophthalmic operations), 1¼ p.m.
 SOCIETY OF ARTS, 8 p.m. Meeting.

16. Thursday.

Operations at St. George’s, 1 p.m.; Central London Ophthalmic, 1 p.m.; Royal Orthopædic, 2 p.m.; University College Hospital, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.
 FARVEIAN SOCIETY, 8 p.m. Clinical Meeting. Presentation of a Testimonial to Mr. J. B. Curgenven, late Hon. Secretary.
 ROYAL INSTITUTION, 3 p.m. Prof. Tyndall, “On Heat and Light.”

17. Friday.

Operations at Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.
 ROYAL INSTITUTION, 9 p.m. Professor Abel, F.R.S., “On the more important Substitutes for Gunpowder.”

VITAL STATISTICS OF LONDON.

Week ending Saturday, May 4, 1872.

BIRTHS.

Births of Boys, 1219; Girls, 1121; Total, 2340.

Average of 10 corresponding weeks, 1862-71, 2116 6.

DEATHS.

At the Royal Observatory, Greenwich, the mean reading of the barometer in the week was 29.95 in. The highest was 30.27 in. on Tuesday morning, and the lowest 29.35 in. at the end of the week.

* The figures in this column, excepting those for London and Dublin, are the unrevised numbers, enumerated in April, 1871, raised to the middle of 1872 by the addition of a year and a quarter’s increase, calculated on the rate which prevailed between 1861 and 1871. The London population is now based upon the number enumerated in April, 1871, as revised at the Census Office; this revision added 2456 (principally shipping population) to the unrevised number published in the preliminary Census Report. The population of Dublin is taken as stationary.

ORIGINAL LECTURES.

LECTURES ON THE
COMPARATIVE ANATOMY OF THE ORGANS
OF DIGESTION OF THE MAMMALIA.

DELIVERED AT THE ROYAL COLLEGE OF SURGEONS OF ENGLAND IN
FEBRUARY AND MARCH, 1872,

By WILLIAM HENRY FLOWER, F.R.S.,
Hunterian Professor.

LECTURE V.

THE animals commonly known as Lemurs, from the island of Madagascar, and certain nearly related species from the African continent and the southern parts of Asia, constitute a well-defined group of mammals, which were formerly associated with the monkeys in the order Quadrumana. As a more complete knowledge of their organisation has been gradually attained, the interval which separates them structurally from the monkeys has become continually more evident; and since they cannot be placed within the limits of any other of the previously constituted orders, it has been considered advisable by some naturalists to increase the number of ordinal divisions for their behalf, and to allow them to take rank as a distinct group, related to the Primates on the one hand, and to the Carnivora and Insectivora on the other. (a) The whole group, whether we regard it as a sub-order or an order, is naturally subdivided into three sections or families—(1) the *Lemuridae*; (2) the *Tar-sidae*; and (3) the *Chiromyidae*. The first family contains the large bulk of the animals belonging to the group, each of the others being constituted for the reception of a single species.

The several genera constituting the *Lemuridae* may be grouped into four sub-families—(1) the *Indrisinae*; (2) the *Lemurinae*; (3) the *Nycticebinae*; and (4) *Galaginae*. I will first describe the digestive organs of one of the last-mentioned group—the grand galago (*G. crassicaudata*)—having lately had an opportunity of dissecting a recent specimen, and because it is (in many respects) a good representative of the whole order. I must premise that the lemurs resemble the smaller monkeys in their food, being usually omnivorous, though some (as the present example) feed chiefly on insects or small vertebrates, while others make fruit and other vegetable substances their principal aliment. We shall find some corresponding modifications in their digestive organs.

The animal I have just mentioned was an adult male, and twelve inches in length from the nose to the root of the tail. The muzzle is moderately elongated, but less fox-like than in the true lemurs. The hard palate has six very strongly marked ridges, extending from side to side, with indented margins. Those near the front, which are the most prominent, form single wide arches; near the back the arches become double by an indent in the middle, most marked in the last but one, the extremities of which are opposite the posterior molars. The inferior surface of the velum palati is thickened in the middle line so as to form a rudimentary uvula. The tongue is long, narrow, pointed, and extensile. There are three large circumvallate papillae, having the usual disposition, situated far back, the anterior pair being opposite, or slightly behind, the attachment of the palato-glossal folds. Round-headed fungiform papillae are scattered irregularly all over the dorsum, among the smaller conical papillae, which are thick at the base, and have a finely denticulated apex directed backwards. On the under surface of the tongue, projecting forwards from the frænum, which is placed rather far back, is a peculiar organ called the "sublingua." It is tongue-shaped, flat, rather more than half the breadth of the tongue itself, consisting of stiff fibrous tissue covered with mucous membrane, with a median ridge above and below passing into the frænum. Its edges turn up and its apex slightly down, to adapt it to the form of the under surface of the tongue, against which it lies. At its free anterior extremity it terminates in a series of fine but stiff-pointed denticles, placed side by side, giving it the appearance of a comb. In the natural position

this organ lies upon the floor of the mouth, with its pectinated apex applied to the base of the upper or internal surface of the six narrow, elongated, recumbent, anterior lower teeth so characteristic of the lemuroid animals; and as I particularly noticed in this specimen, when the mouth was first opened, and before the sublingua was disturbed, the sharp anterior prolongations lay in, and exactly fitted, the grooves between these teeth. One was median (rather smaller than the next), and lay between the central incisors; the next was between the first and second incisors; then between the second incisor and the canine was a large bifid one; and two or three small ones at the edge rested on the outer side of the canine. When the tongue was gently drawn forwards the sublingua came with it, each point retaining its position in relation to the teeth, and seeming most perfectly adapted to sweep over and keep clean the upper surface. There can be little doubt (if any function can ever be inferred from structure) that this must be their purpose. The breadth of this organ is three-tenths of an inch, its length from its inferior frænum six-tenths; superiorly it is free to the extent of four-tenths of an inch.

The sublingua of the galago must not be confounded with the salivary papilla situated on the frænum below the tongue in apes, as I believe has commonly been the case, for the latter structure is also quite distinct, well developed, and situated below the sublingua. It is soft, fleshy, triangular, flattened at the extremity, and bifid; the ducts of the submaxillary glands open upon it, close to the middle line and a short distance behind the apex. These glands are rather large and firm in substance, eight-tenths of an inch in length and five-tenths of an inch in greatest thickness, of a sub-crescentic shape, their concavity being adapted to the form of the rounded angle of the jaw, on which they rest. The duct leaves the middle of the anterior or hollow side of the gland and runs forward, having the usual relation to surrounding structures to terminate as above mentioned. In the anterior half of its course the well-developed, elongated, and flattened sublingual gland lies to its outer side. The parotid gland is rather small and thin, composed of loose lobules, situated below the auditory meatus, and passing a little way up in front and behind it; it comes in contact with the submaxillary below. Its greatest extent from before backwards is eight-tenths of an inch. The duct has a straight course across the masseter, and ends in a small slit-like orifice in the cheek opposite the anterior part of the first upper true molar. At the angle of the mouth, between the anterior edge of the masseter and the mucous membrane, is a distinct gland about the size of a hemp-seed; but I was unable to find a zygomatic gland in the situation indicated in *Tarsius* by Burmeister.

On opening the abdomen, the omentum was seen hanging from the lower border of the stomach, about half-way down to the pubis, and almost entirely confined to the left side, containing reticulated layers of fat. The superficial part of the right half of the cavity was occupied by coils of large intestine, presently to be described. The cæcum lay in the right iliac fossa, with the apex downwards and in the pelvis. The small intestines appear chiefly on the left side. The stomach is simple, oval, with a very large projecting fundus, the œsophagus being placed much to the right, and very near the pylorus. The pyloric portion is short, and can hardly be said to be distinct from the rest of the cavity. The duodenum is loosely attached by its mesentery, and has the usual course. The small intestines have much the same calibre throughout, and, after making many coils, end by ascending to join the colon in the middle of the right side of the abdomen. The mesenteric arteries form anastomosing loops. The cæcum is two inches long, thicker at the base than any other part of the intestines, but gradually narrowing to a rounded apex. It has a slight and simple curve in one plane towards its attached or mesocæcal border; a longitudinal muscular band passes along the middle of the opposite border, by which it is slightly puckered up into transverse sacculations.

The colon is quite simple, without longitudinal bands or sacculations, of about the same diameter as the small intestine. It is long, and takes a very peculiar course—first ascending to the under surface of the liver, then running forwards and downwards nearly half-way across the abdominal cavity, turning sharply upwards on itself again to the upper right corner of the cavity, then descending below the bend of the last coil, ascending again to the under surface of the stomach, and passing backwards and then downwards to form the simple descending colon, which ends in the rectum without sigmoid flexure. It is easy to show by their peritoneal attachments that the ascending and descending colons have the usual course,

(a) See Gratiolet, "Plis Cérébraux," 1853; J. Victor Carus, "Handbuch der Zoologie," 1868; Alph. Milne-Edwards, "Observations sur quelques points de l'Embryologie des Lémuriens, et sur les Affinités Zoologiques de ces Animaux" (*Annales des Sciences Naturelles*, October, 1871).

and that it is the transverse portion which is greatly elongated and developed into a loop coiled upon itself. (See Fig. 18.)

FIG. 18.

FIG. 18.—Diagram of the position of the abdominal alimentary canal in *Galago crassicaudata*. The greater part of the small intestine has been omitted; *d* duodenum, *i* ileum, *cm* caecum, *r* rectum.

of the lobe as in most mammals, but is turned upwards into the substance of the liver, and appears at the bottom of a cleft in the middle of the upper or diaphragmatic surface of the lobe. (b)

The sub-family *Lemurinae* consists of the genus *Lemur* and a few nearly related forms, all inhabitants of Madagascar. In

FIG. 19.

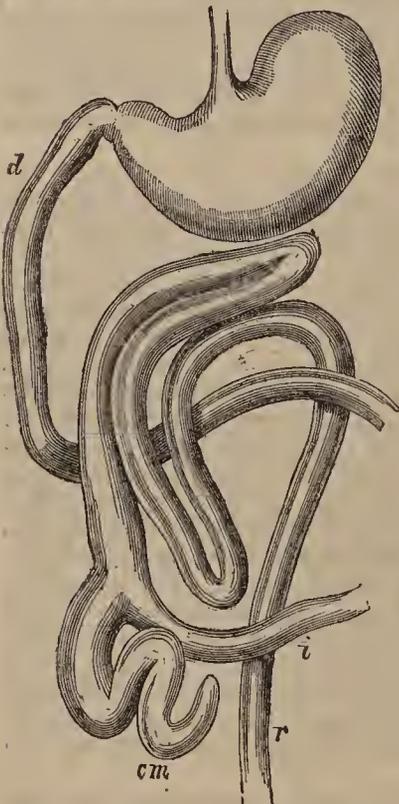

FIG. 19.—Diagram of the arrangement of the abdominal alimentary canal in *Lemur flavifrons*, the greater part of the small intestine being omitted; *d* duodenum, *i* ileum, *cm* caecum, *r* rectum.

The liver occupied rather more of the right than the left side. Its left lateral lobe overlaid but did not quite conceal the stomach. The umbilical fissure is of moderate depth, dividing the central portion of the liver into two lobes of very unequal size, the right being more than twice the size of the left. There is no cystic notch on the edge of the right central lobe, but a fissure in the middle of its upper surface corresponds to the fundus of the gall-bladder. The lateral fissures are very deep, and the two lateral lobes of semilunar form, the left being the largest. The caudate lobe is triangular and of moderate size, its apex just reaching to the free border of the right lateral. The Spigelian lobe is divided into two conspicuous tongue-shaped processes, which overlay the portal fissure. The vena cava is bridged over by hepatic substance as it runs between the Spigelian and right central lobes. The gall-bladder is small and buried in the right central lobe. Its fundus is not placed near the free edge of

the lobe as in most mammals, but is turned upwards into the substance of the liver, and appears at the bottom of a cleft in the middle of the upper or diaphragmatic surface of the lobe. (b)

The muzzle is more elongated and narrow than in the galago; the gape is wide. The fibrous sublingua is much less developed, (d) being of a narrow lancet-shape, with a strongly marked longitudinal median ridge on its lower surface, and a less marked ridge close to it on each side; the anterior terminations of these ridges form the trifid apex of the body. It is free from the tongue for a quarter of an inch, and its point reaches to four-tenths of an inch from the tip of that organ. Below it lies the flattened and laterally expanded leaf-like salivary papilla, bifid in front, and with notched edges. The salivary glands resemble those of galago, but are proportionately rather less developed.

The stomach is rather more elongated than that of galago; the duodenum takes a wider sweep, and descends further down the abdomen before it crosses behind the colon. The caecum is considerably longer, and curled in a sub-spiral

manner; and the colon is folded in a somewhat different manner, as will be best understood by a reference to the diagram (Fig. 19). The small intestines in *Lemur flavifrons* measured forty-four inches, the large (without caecum) twenty-five inches, and the caecum seven inches; the animal from tip of nose to root of tail being fourteen inches. In a specimen of the ring-tailed lemur (*L. catta*), the convolutions of the colon presented a similar arrangement.

In the liver (Fig. 20) the umbilical fissure extends nearly

FIG. 20.

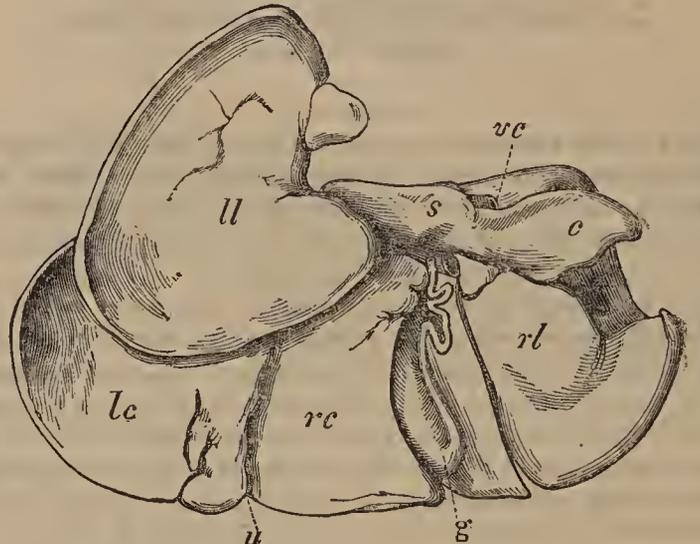

FIG. 20.—Under surface of the liver of *Lemur flavifrons*: *ll* left lateral lobe, *lc* left central lobe, *rc* right central lobe, *rl* right lateral lobe, *s* Spigelian lobe, *c* caudate lobe, *vc* vena cava, *g* points to the neck of the gall-bladder.

half-way from the free to the attached border, and there is a well-marked cystic notch. The left lateral fissure completely cuts off the left lateral lobe from the rest of the organ, leaving a connexion only by the vessels and capsule; while the right lateral fissure on the upper surface is scarcely deeper than the umbilical fissure. The Spigelian lobe (*s*) has no tongue-shaped projection, and the caudate (*c*) though distinct and pointed, is very small compared with the right lateral, the hollow for the reception of the right kidney being chiefly excavated in the latter.

In *L. mongoz*, Hunter observes, "the gall-bladder lies in a sulcus of the liver, contrary to the common manner, for the fundus lies forward or towards the diaphragm, and is in view upon the convex side of the liver; from thence it passes down between the flaps of the liver, and is seen through its whole length; and when got as low as the lower edge of the liver, it turns up upon the posterior or concave side in a contorted manner, becoming smaller and degenerating into the cystic duct, which joins the hepatic duct at the vena portae. There is a small hepatic duct that enters the cystic duct before the large hepatic duct enters. The common duct enters the

FIG. 21.

duodenum about three inches from the pylorus." This very peculiar position of the gall-bladder, which was partially indicated in galago, is characteristic of all the species of the genus *Lemur* which have been examined, as well as *Microcebus*.

(b) For visceral anatomy of animals of this genus see Andrew Smith, "Zoology of South Africa" (*G. moholi*); Peters, "Reise nach Mozambique" (*G. crassicaudata*); Hoekema Kingma (*G. peli*).

(c) These observations apply especially to *Lemur flavifrons*.

(d) Hunter, in his account of the dissection of *Lemur mongoz*, notices that "the tongue has a part underneath, in shape like that of a bird's tongue."—"Essays and Observations," vol. ii., p. 29.

Among the true lemurs, the principal known deviation in the digestive organs from the type above described occurs in the largest species, the Ruffed Lemur (*L. varius*), in which the cæcum is greatly developed, attaining a length of thirteen inches, and is coiled in a regular, spiral manner (see Fig. 21). (e)

The visceral anatomy of no member of the sub-family *Indrisinæ* having hitherto been described, the following information is derived from an imperfect specimen of *I. brevicaudatus*, in rather bad condition in the Museum stores. The structure of the alimentary digestive organs would indicate an animal of more vegetable-eating habits than the other members of the family.

The length of the animal is about twenty-two inches. The tongue is long, narrow, and with an obtuse point at the apex, being less truncated than in lemur. It is two inches and a half long, and seven-tenths of an inch broad at the widest part. The dorsal surface is covered with a very close-set soft velvety pile of small papillæ, apparently all of one kind. There are two small circumvallate papillæ, three-tenths of an inch apart, just in front of the attachment of the palato-glossal folds. Behind them the surface is almost smooth, and hence very different from that of lemur. The sublingua is narrow, especially towards the apex, which is one-fifth of an inch from the tip of the tongue, and free for a very small space (not one-twentieth of an inch). It has a well-marked median ridge below, with a groove on each side. Its apex has a median point, and a smaller one on each side, as in lemur. The whole of the free surface of this organ is covered with fine, stiff, filiform papillæ. The tonsils are a very prominent, horizontal, oval mass, two-tenths of an inch long, projecting very freely; their surface covered with conspicuous round and oval orifices. In front of each are two or three much smaller similar follicular masses, projecting freely from the mucous membrane of the fauces—supplementary tonsils, in fact. The submaxillary glands are oval or subtriangular in form, not large for the size of the animal, seven-tenths of an inch in principal diameter. The parotid glands are not preserved with the specimen.

The stomach is very short and globular, with a small fundus, and a large and distinct pyloric cavity folded back on the lesser curvature, so that the œsophageal and pyloric orifices are nearly approximated. The pyloric orifice was surrounded by a very strongly developed muscular ring. The position of the intestines had been so much disturbed before my examination that I cannot describe it accurately; but the important fact to be noticed is their extraordinary length, and especially that of the cæcum, which recalls that of the grass-eating rodents. The small intestine was about 130 feet in length, or six times the length of the animal; the colon eighty inches, and folded backwards and forwards many times, but not sacculated; and the cæcum forty-four inches and of great capacity, being considerably wider than any other part of the intestinal canal, and slightly sacculated at its commencement, though gradually narrowing to a blunt apex. The stomach was empty, but the intestines contained a brown pultaceous mass, in which all the particles which had any definite form were of vegetable structure; no traces of insects were found. (f)

It is curious that the branches of the mesenteric artery distributed both to the large and small intestines run as in the pig, in perfectly straight lines, without forming arches or loops as in the true lemur.

The liver differs chiefly from that of lemur in having the caudate lobe either aborted or coalesced with the right lateral—a very rare condition. The Spigelian lobe has a well-developed triangular projection. The gall-bladder has its neck at the free edge of the liver, and its fundus turned backwards into the substance of the right central lobe, appearing in a cleft on its upper surface; but it is not so sharply bent, and does not reach so near to the posterior edge of the liver, as in the lemur. The duct is not contorted; it enters the duodenum one inch and a quarter from the pylorus.

The *Nycticebinæ* are a group of small, slow-moving, arboreal, short-tailed, nocturnal, insectivorous or carnivorous lemur-like animals, represented by two principal forms from the south-east of Asia, and two from the West Coast of Africa.

(e) For the visceral anatomy of *Lemur* see Daubenton (Buffon, vol. xiii.), (*L. catta*, *mongoz*, and *varius*); Hunter, "Essays and Observations," vol. ii.; Martin, *Proceedings of the Zoological Society*, 1831, p. 58 (*L. varius*). For *Microcebus*, Martin, *Proceedings of the Zoological Society*, 1835, p. 125 (*M. murinus*); Peters, "Reise nach Mozambique" (*M. myoxinus*).

(f) Since the above was written M. Alphonse Milne-Edwards has been so good as to send me a lecture on the lemurs, published in *La Revue Scientifique* for September, 1871, in which the simple form of the stomach and the enormous size of the cæcum of the *Indrisinæ* are mentioned. The large intestine is said to be of great length, and coiled upon itself so as to form two regular and superposed spirals, recalling its condition in certain herbivores, as the sheep.

The Asiatic species were divided into two genera, *Nycticebus* and *Loris*, by Geoffroy St. Hilaire, but were united by Illiger under the generic name of *Stenops*; hence there is considerable confusion in the nomenclature of the animals of this group.

The common slow-lemur (*Nycticebus javanicus*) has been the subject of several anatomical monographs, in one of which, by the two eminent Dutch anatomists, Schroeder van der Kolk and W. Vrolik, it is stated that, "Les sous-maxillaires sont très-grandes, et montrant une singulière disposition dans leur conduits excréteurs, qui se réunissent de chaque côté en un tube commun, et se dirigent en arrière, pour s'insérer dans la membrane muqueuse de la bouche, un peu au-dessus de l'os hyoïde. C'est une disposition tout-à-fait anormale des conduits salivaires qui nous paraît pleine d'intérêt." As this is accompanied by a figure of the parts described, comes on such very high authority, and has been frequently repeated in subsequent works, I was of course desirous to verify its correctness, and have consequently dissected two specimens of *Nycticebus* belonging to each of the two best known species, *javanicus* and *tardigradus*; but in both the ducts of the submaxillary glands have precisely the usual arrangement, running forward under cover of the ramus of the mandible, passing first beneath the digastric, and then the mylohyoid muscle, being crossed by the gustatory nerve, and opening on the salivary papilla beneath the sublingua. A preparation demonstrating the relations of the salivary glands and ducts of one of these animals has been placed in the Museum.

The sublingua is largely developed and pectinated at the extremity, much as in galago. The disposition of the alimentary canal also much resembles that of galago, the transverse colon forming a very long loop, which descends in front of the coil of the small intestines nearly to the pubis, and is folded back on itself in the same manner; but the coils are more parallel and closely adherent to each other. The cæcum is longer than in galago, capacious and slightly sacculated at the commencement, but is so contracted in its terminal third that it has been described as a vermiform appendage. In an animal the length of which was nine inches, the small intestine measured twenty inches, the colon and rectum twelve, and the cæcum three. The liver much resembles that of galago, but the gall-bladder is larger; its neck is in the normal situation, but its fundus appears in a notch on the upper surface of the right central lobe.

The slender lemur (*Loris gracilis*), from Ceylon, though resembling the last in many particulars of its structure, differs notably from it in the arrangement of the alimentary canal, the colon simply ascending on the right side, crossing to the left, and descending to the rectum, without any of that remarkable elongation and folding of the transverse colon found so generally in the animals of this group. The cæcum is rather shorter than in *Nycticebus*, narrowest at the base, and widening towards the blunt rounded apex; the stomach is very globular; the fissures of the liver are deeply cut, and the lobes very pointed; the gall-bladder nearly globular, and normal in position.

The digestive organs of the two African species—*Perodicticus potto* and *P. calabarensis*—closely resemble those of *Nycticebus*, though the cæcum of the latter is proportionally shorter. (g)

Tarsius is a very strange little animal, remarkable for the singular structure of its hind feet and the enormous size of its eyes. It inhabits some of the islands of the Indo-Malayan Archipelago, and is said to feed chiefly upon lizards. Burmeister has given an excellent account of its anatomy, (h) the principal points in which I have been enabled to verify upon specimens in the Museum. In common with all the other members of the group it has a sublingua beneath the tongue, but in a much more rudimentary condition than in the others, consisting of a median ridge and two lateral smaller ridges, but attached to the tongue almost to the very tip. The bifid salivary papilla is situated below this, and much further back. In the abdominal viscera this animal differs from the true lemurs in the comparative shortness of the colon; for, while the small intestine measures ten inches, the colon (without cæcum) is

(g) For visceral anatomy of the *Nycticebinæ* see "Recherches d'Anatomie Comparée sur le Genre *Stenops*, d'Illiger," by J. L. C. Schroeder van der Kolk and W. Vrolik, in *Bijdragen tot de Dierkunde*, part i., Amsterdam, 1848-54. Daubenton (Buffon, vol. xiii.), (*Loris gracilis*). Hunter, "Essays and Observations," vol. ii. (The animals are not correctly identified in the published edition; the first and the third described are *Loris gracilis*, the second is *Nycticebus tardigradus*.) Van der Hoeven and Van Campen, *Ontleedkundig onderzoek van den Potto van Bosman* (Kong. Akad. van Wetenschappen, Amsterdam, 1859), *Perodicticus potto*. Huxley (*Proceedings of the Zoological Society*, 1864, p. 314), *Perodicticus (Arctocebus) calabarensis*.

(h) Burmeister, "Beiträge zur näheren Kenntnis der Gattung *Tarsius*." Berlin. 1846.

but two, and is very simple in its arrangement, commencing on the right side, just below the hypochondriac region, and passing across to the left, and then descending in a straight course to the rectum. The cæcum is one inch long, gradually tapering to the apex, and folded in a spiral manner. The liver is remarkable for the great size of the left lateral lobe, which is larger than all the rest of the organ put together, semi-circular in form, very thin, and envelopes the anterior and upper surface of the stomach; there is no umbilical fissure. The gall-bladder is broadly pyriform; its fundus turned towards the free edge of the liver, and lodged in a wide cystic notch. The Spigelian lobe is large and multifid; the caudate narrow and pointed.

There is one other very aberrant form still belonging to this group—the aye-aye, or *Chiromys*, of Madagascar—the teeth of which are modified so as to resemble those of the Rodents, in which order it was placed until its structure and affinities were thoroughly understood. Its anatomy has been fully described in two recently published memoirs,⁽ⁱ⁾ and the Museum contains preparations of the viscera of an animal which died in the Zoological Gardens in 1867. It is interesting to find in this aberrant member of the group, that though the lower teeth have quite a different arrangement from those of the typical members, the sublingua is still present, though greatly modified. As the teeth are but two, and of large size, with a median groove between them, this organ is broad and lancet-shaped, with a single median hard ridge or keel, terminating in a point in front, very little of which is free, and without any lateral denticulation. The stomach is sub-globular; the colon conforms with the general character of the order in forming a long loop near its commencement; the cæcum is small and contracted towards its termination; the gall-bladder is quite normal in its position and arrangement of its ducts; the caudate lobe of the liver coalesces with the right lateral, as in Indris; the left lateral lobe is large, and of the crescentic or semi-circular form so common in the order.

An interesting discussion has taken place as to the habits and food of this singular animal, upon which, however, the structure of the digestive organs throws little light.

CLINICAL LECTURES ON INTESTINAL OBSTRUCTION.

By THOMAS BRYANT, F.R.C.S.,
Surgeon to Guy's Hospital.

LECTURE IV.

ON LUMBAR COLOTOMY FOR THE RELIEF AND CURE OF RECTAL OBSTRUCTION AND DISEASE.(a)

GENTLEMEN,—I have selected the operation of lumbar colotomy—that of opening the colon in the right or left loin—as the subject of to-day's lecture, not only because I know it to be well worthy of your attention, but because I believe it has not yet found its true place in Surgery. It is admitted among the justifiable operations in exceptional cases, to be performed when all other means have failed to ward off death and give relief, but under no other circumstances; as an operation for any curative purpose it is hardly recognised. When successful also it has generally been believed that the condition of the patient is so miserable—that the escape of fæces and wind from the artificial wound causes so much distress and discomfort—that life at such a price is hardly worth having; that at the best it may prolong life, but with a local discomfort that is almost unendurable. Yet I think I shall be able to show you that the operation deserves far higher claims upon our attention than these; that it not only is a most valuable means of prolonging life and relieving pain; that when successful the artificial anus is not such a source of local discomfort as you might believe; and that, as a curative agent, it bids fair to be of great and undeniable value. I propose, therefore, to consider the operation in two points of view—first, as an operation of expediency to prolong life and relieve pain; and, secondly, as a curative agent. As an operation of expediency, it may be called for under any circumstances in which some chronic obstruction in the large intestine exists: whether the obstruction be due to the presence of some tumour pressing

upon the bowel—that is, to some outside influence—or to some stricture contracting the calibre of the bowel from some inside influence. As a curative agent, it may be performed for severe examples of ulceration of the rectum, which in a pathological sense are curable, but if left alone will go on to cause stricture; or for complications of ulceration of the intestines, in which the ulceration has perforated the bladder, and produced a recto-vesical fistula. I propose to consider it, first, as an operation of expediency—where there is obstruction of the large intestine, and other means have failed to give the necessary relief; and more particularly with reference to tumours. Now, I must ask you to recall to your minds some of the cases I have related in my former lectures, of intestinal obstruction produced by tumours so occluding the rectum or colon as to produce complete mechanical obstruction. The first case I will recall is one you will remember in which a cancerous tumour was present, hanging from the promontory of the sacrum into the pelvis, and so completely occluding the rectum—the case of Mrs. M., aged 46, that I saw in consultation with Mr. Phillips, of Leinster-square. She had suffered from chronic obstruction to the bowel for months, and had been under the care of my colleague Dr. Owen Rees and Dr. West. For one month before I saw her she had been the subject of constipation, and for ten days vomiting and tympanitis existed. Lumbar colotomy was performed with relief, but she died on the third day, on the patient suddenly lifting herself in bed to have the draw-sheet changed.

At the post-mortem examination we found that this cancerous mass hanging over the promontory of the sacrum had on that sudden movement burst, and discharged itself into the peritoneal cavity, producing the collapse and death of the patient. In that case the operation, although unquestionably it would not have saved her life, would have prolonged it and rendered the remainder of it much more comfortable. I do not know that I could have given you a better example of the class of cases which we are now discussing. In the second case we got a better result. It was caused by a growth inside the bowel. A young lady, only 18 years of age, had insuperable constipation for seven weeks, during the whole of which time nothing whatever passed per rectum. Enemata had been given her, both by the nurse and by a skilled Surgeon; but they returned always as they had been sent up—not a trace, not a smell of fæcal matter came down, and no wind. Owing to the obstruction she vomited, but this never went on to stercoraceous vomiting. She had been in the hands of several Medical men; a Physician-accoucheur had seen her, and could find nothing uterine. I examined her and could find nothing whatever beyond the constipation. I examined the rectum most thoroughly, and could find nothing. And this young lady, only 18, had mechanical obstruction clearly of some kind, completely shutting up the bowel. From the distension of the bowel it looked as if it were the large intestine. I thought I could trace the upper part of the large intestine very much distended. I say "thought" because there is oftentimes great fallacy here; you are very liable to come to a wrong conclusion upon that point. It is very difficult to tell whether the bowel you see distended is large or small intestine. The constipation having been of some weeks' standing, and all remedies having failed to give relief, I felt that life could only be prolonged or saved by an operation. This I did by opening the colon in the right loin. A quantity of fæces came away. The operation was performed in September of last year; now she is up and about. All the fæces pass through the artificial anus. She takes her food as well as any of us. But lately, during the last month or six weeks, she has complained of a bearing-down pain about the pelvis. I have had the opportunity of making two examinations of this patient since, and on both occasions I found clearly a tumour coming down into the pelvis—so clearly that, on passing the finger into the rectum, one could easily imagine the finger was in the vagina, and felt a polypus coming down from the uterus. I only hope this may force its way down lower, and that it is a fibrous polypus. Pathologically we know such things do exist. Should it come down and be within the means of Surgical treatment, we may remove it, and save the life of the patient. This, then, is a case of a tumour in the intestine itself producing mechanical obstruction, and necessitating such an operation as I have performed. In another case a hydatid tumour completely blocked up the pelvis, and produced obstruction of the rectum and also of the urethra. In that case I was consulted for the retention of urine. I relieved it by means of an incision, letting out a quantity of hydatids; but the man died from the constipation: the intestine burst, sloughed from over-distension. These are three good examples of obstruction

(i) Owen, "On the Aye-Aye," *Trans. Zool. Soc.*, vol. v. (1862), p. 33. Peters, "Über die säugethier-gattung *Chiromys*," *Abhand. Königl. Akad. der Wissenschaft, zu Berlin*, 1865.

(a) Reported by Mr. Henry Clarke (student).

from tumours occluding the large intestine, in which colotomy saved or might have saved life. Never hesitate, therefore, when you get such cases of intestinal obstruction as I have related, to perform such an operation. Do not wait until the patient is moribund before you perform it; colotomise, with the hope of such success as the history of these cases would seem to warrant.

We will now proceed to consider colotomy for the relief of some organic disease of the rectum, and, using a general term, say for stricture of the rectum—recognising the fact that we may get stricture from cancerous disease (either carcinoma or epithelioma), from syphilitic disease of the rectum, or from simple ulceration, in the same way as you may get in other parts syphilitic, cancerous, or simple ulceration. In a large number of cases there is no doubt this structure of the rectum is caused by cancerous disease. In many it is the result of syphilis; in a few of simple ulceration. You will find no better example of the (syphilitic?) form than in the patient in Astley Cooper ward now under care. This is the history of the case as given by the reporter, Mr. Lubbock:—

(I need hardly tell you in passing that any attempt to dilate a stricture by a bougie when ulceration has taken place is utterly futile; it is a direct irritation to the patient, it excites the breaking-up of the material, and therefore rather hastens the end than retards it.)

Stricture of Rectum—Vaginal and Ischio-Rectal Faecal Fistulae.
(Reported by Mr. MONTAGUE LUBBOCK.)

Eliza O., aged 29, admitted into St. George's Hospital on February 28, 1872, under Mr. Bryant, from Stoke, Suffolk. Patient has led a healthy life until her third confinement, four years ago, which was protracted, and the child was delivered by means of instruments after having been dead for three weeks. She laid up for fourteen days, and upon getting up found a discharge coming from the vagina, and was obliged to wear a cloth, as the faeces continually passed from the bowel into the vagina. Two years and a half ago she went to St. Bartholomew's Hospital, where an instrument was passed up the bowel, but which did not stop the passage of the faeces from the bowel into the vagina. Patient has been married nine years, and has been confined six times, always going the full time, and three of the children being born alive and three dead.

1st child	born about 7 years ago,	alive,	died after 5 weeks.
2nd	" "	6 "	" " dead.
3rd	" "	5 "	" " dead.
4th	" "	4 "	" " dead.
5th	" "	2 "	" " alive, died after 3 months.
6th	" "	1 "	" " alive, has had snuffles, but no eruption on the skin. Patient says that her husband is a labourer enjoying good health, and never to her knowledge having suffered from sore throat, eruption on the skin, or other syphilitic symptom.

On Admission.—March 1. Patient is a well-nourished person, having the appearance of being in good health, but complaining of the passage of faecal matter by the vagina. Superficially examined by Mr. Rendle: About the anus are several elevations, some having openings which discharge a thin purulent matter; soft parts around thickened. The parts being tender, no further examination was made.

4th. Mr. Bryant, upon examining the patient, found the skin near the anus riddled with fistulous openings, three existing on the right side of the anus, and four on the left, and by which passed a thin purulent matter. There were numerous outgrowths about the anus; and these symptoms led Mr. Bryant to suspect the existence of a stricture of the rectum. Upon introducing the finger per anum a stricture was felt about one inch above the anus, and the obstruction was so complete that no passage could be felt by the finger. Mr. Bryant was of opinion that the nature of this stricture was decidedly syphilitic.

Now, there is a case that is worth looking at. If you examine the patient locally, the first point which declares itself is a faecal discharge from the vagina; there evidently is some communication between the rectum and vagina. On examining the anus, four or five anal fistulous openings are visible, communicating with the bowel, through which faeculent fluid oozes; some fleshy anal outgrowths are likewise present. Whenever you look at a patient and see such a condition as that, you may safely say there is a stricture above it. You would not get all these symptoms except from the presence of some obstruction higher up in the rectum. These fistulae, anal and vaginal, are merely the means nature is adopting to get rid of the faeces somehow or other. On passing the finger into the anus we found the rectum perfectly occluded; no orifice could

be made out to get the tip of the finger into. Within an inch of the anus it came to a cul-de-sac and would go no further, though no doubt with a probe we might have found some little aperture of communication with the upper bowel still left. So this poor creature had gone on for years with this condition of matters. It had been recognised for two years and a half, but the stricture must have existed before that—no doubt for many months, if not for years—although it was made manifest in her first pregnancy, the pressure of the child's head having broken down the tissue and produced the recto-vesical fistula. In this case I have very little doubt as to the stricture being syphilitic; the history of the case fairly indicates it. Six infants born at the full time—four dead, the other two only born alive; and in the last child you see we get another symptom, the snuffles, which you know is a common consequence of hereditary syphilis; and although by itself it is not sufficient to establish the syphilitic nature of the disease, with the other points in the case it renders it very probable.

Having given you a fairly typical case of stricture of the rectum, although of a syphilitic form, I propose now to make a few brief remarks upon the subject of stricture as a whole.

In the majority of cases this is caused by cancerous disease; in many it is the result of an inflammatory process, simple or syphilitic, from the cicatrization of deep-seated and extensive ulceration; in others it is due to the contraction of inflammatory material poured out external to the bowel in the submucous tissue. In exceptional instances it may be caused by contraction of the parts external to the bowel, after pelvic cellulitis; and Curling quotes a case where it was the direct result of an injury.

In all these conditions the calibre of the intestine is gradually or rapidly encroached upon, till at last complete obstruction takes place. The stricture may appear after death as an annular contraction of the bowel, with adventitious material in the submucous tissue, and hypertrophy of the muscular coat, looking very like a scirrhus pylorus; or as a thickened, ulcerated, irregular mass of cancerous material, infiltrating all the tissues of the bowel, although rarely extending beyond two or three inches in length. The bowel above the stricture as time goes on will become dilated, and at a late stage it may rupture, ulceration of the colon being a very common consequence of its over-distension. Below the stricture there will often be found pedunculated fleshy or cancerous growths. It has been already pointed out that fistulae—vaginal, cutaneous, or vesical—often coexist with stricture; abscesses and haemorrhoids are also occasionally met with.

Stricture of the bowel, taken as a whole, is twice as common in women as in men—my note-book revealing the fact that of forty-eight consecutive cases thirty-two were in this sex. Syphilitic stricture seems to be the more common in women; cancerous stricture in men. Curling, out of sixty-seven cases of reputed cancer, gives forty-four as found in the male sex.

The approach of this disease is very insidious, whatever may be its origin or nature. *Constipation* is the one general early symptom, and it is not till some ulceration has commenced, either at the seat of stricture or above it, that others appear—such as *diarrhoea* with lumpy stools containing mucus, pus, or blood; straining at stool, and a sensation of burning in the part afterwards; with at last a complete stoppage of the bowel—abdominal distension and dyspeptic symptoms being constant accompaniments. An examination with the finger carefully introduced into the rectum will, as a rule, at once reveal the true nature of the case; for about two inches up the bowel the narrowing will usually be felt with or without new tissue infiltrating the part of ulceration. In exceptional cases the stricture is beyond the reach of the finger; but under these circumstances it may at times be brought within its reach by pressing with the free hand upon the abdomen above the pelvis. When the stricture is an annular one it is probably cicatricial or fibrous—possibly cancerous.

When epithelial or positively cancerous, the seat of stricture will be infiltrated with a nodular irregular mass of new tissue, probably breaking down and ulcerating. Sometimes this mass can be felt externally at the brim of the pelvis over the left iliac fossa. I have felt this clearly on three occasions.

When syphilitic, the ulceration will probably extend upwards from the anus, and anal integumental outgrowths will frequently exist.

In ordinary cases of cancerous stricture there is an inch or more of healthy rectum between the anus and the stricture. In exceptional and very extensive disease the anus will be involved.

In advanced cases the anus will appear patulous, and on separating the buttocks a red brickdust-coloured faeculent discharge may run out; wind will also pass without effort.

To flat tape-like or figured faeces, as given by authors as characteristic of this disease, I, with Curling, do not ascribe much importance—for such a condition of motion is very usual even in a state of health when the bowels are irritable, and many other conditions of the pelvic parts may give rise to the same thing; but when a patient never passes a well-formed motion, large or small, the case looks suspicious. On the other hand, when a large well-formed stool is occasionally seen, the probabilities of a stricture existing are very slight.

The examination of a rectum the subject of ulcerative disease with a tube, flexible or otherwise, requires the greatest care, for perforation of the bowel is very prone to occur.

In those cases of stricture of the bowel, therefore, where ulceration exists, and the hope of doing good by dilatation has passed—when relief can only be given by sedatives, and life cannot long be sustained—the operation of colotomy is of great value. It gives comfort to a degree that sometimes astonishes, and always gratifies. On convalescence or recovery it is not found to be practically associated with such inconveniences as Surgeons of old have theoretically surrounded it. It prolongs life, and adds materially to its comfort; and little more than this can be said of most operations. But it must not be postponed till the powers of life have become so exhausted as to render the chances of recovery from the operation poor, or till the large intestine has become so distended as to have become damaged or inflamed. It should be undertaken as soon as it is clear that the local disease has passed beyond the power of local treatment with any prospects of good, and the general powers of the patient are beginning to fail—as soon as the local distress finds no relief from palliative measures, and a downward course with unmingled anguish is evidently approaching. The difficulties of colotomy are not great, nor are its dangers numerous. When unsuccessful it has been usually made so from the delay in its performance—from the want of power in the patient, or secondary effects of the disease in the abdominal viscera. When most successful it gives immediate relief to most of the symptoms, and makes life worth having; when least so, by lessening pain it renders what remains of life endurable. I have performed this operation for stricture of different kinds on ten occasions, and have never regretted it.

(To be continued.)

THE ALLIANCE BETWEEN PYÆMIA AND TUBERCULOSIS.

In our article on the discussion on Pyæmia at the Pathological Society of last week we took occasion to remark that we had pointed out the alliance between pyæmia and tuberculosis some years ago. The same facts have since been brought before the Profession by other writers, and by none more clearly than by Dr. C. J. B. Williams in his recent work on "Pulmonary Consumption," from which we extract the following passages:—

"It is impossible to avoid seeing the close analogy which the process of tuberculation bears to suppuration. When Mr. Simon's experiments on the production of tubercle in the rabbit were discussed at the Pathological Society in the spring of 1867, my opinion was asked whether the experiments did not prove the specific nature of tubercle. My reply was in the negative, and that I believed that it would be found that tuberculation bore more analogy to suppuration, and that acute tuberculosis had its parallel in pyæmia."—Dr. Williams on "Pulmonary Consumption," 1871, p. 87.

"Take the parallel case of pyæmia, or hospital fever. Wounds and suppurating sores of all kinds have little tendency to infect the system, so long as cleanliness and free ventilation carry off decomposing matters, and supply abundance of pure air for the active performance of the purifying processes of respiration and sanguification; but in close habitations, with an atmosphere tainted with foul effluvia, every sore becomes both an inlet and a source of poison, which is spread by proliferating and septic pus-cells throughout the body. This is a rapid and more acute form of cachæmia. That inducing tuberculosis is more chronic, probably arising from a less potent septic power in connexion with humidity of air; and operating on a less active bioplasm, it palsies and coagulates the lymphatic sarcophytes, which, aggregating in little nodules, form spots of degenerating and decaying matter in scattered points of the adenoid tissue of the lungs and other organs."—*Ibid.*, page 103.

ORIGINAL COMMUNICATIONS.

CLINICAL OBSERVATIONS ON SOME FORMS OF ENLARGEMENT OF THE PROSTATE GLAND

IN CONNEXION WITH DISEASES OF THE URINARY ORGANS.

By RICHARD QUAIN, F.R.S.,
Emeritus Professor of Clinical Surgery in University College.

THE most instructive study of disease is obviously that which is strictly practical—carried on by personal observation, or, as it is termed, "clinical"—as by teacher and pupil observing the same cases: the one in order to teach, the other to learn. Recorded facts, the written representatives of observation, have, nevertheless, intrinsic value to those who have not been clinically connected with them, provided such persons have been prepared by knowledge gained in personal observation of facts in some degree analogous. Plainly, it is by means of such records only that the results of observation can travel beyond the sphere of the observers.

Some important parts of practice are seldom sufficiently illustrated in clinical teaching; for instance, maladies of long duration. They are little seen in the Hospital, and, when seen there, they do not remain long enough for the observation of more than a few incidents in their history. Moreover, such cases—examples of chronic disease—are not infrequently best observed among persons who are never inmates of a Hospital—whose position in life is above that of the class from which Hospital patients are derived. And it is so because such persons often remain more or less under observation, or accessible to observation, during the whole progress of the disease; whereas Hospital patients pass away after the cessation of the emergency which required a sojourn in Hospital.

I am about to illustrate some phases of a chronic malady with the narrative of cases of the kind last indicated—namely, cases which were not in a Hospital, and which, owing to their position in life, were under my observation for lengthened periods of time.

Case 1.—This case illustrates some peculiarities in the evacuation of urine and in the passage of a catheter, which resulted from an unusual condition of the prostate gland, with a corresponding change in the urethra and the urinary bladder.

Mr. M. first suffered retention of urine in consequence of overstaying the desire to evacuate in a journey by railway. He was at that time 58 years of age. It was ten years later that I first saw him. He applied to me to be relieved of an attack of retention. He was suffering extreme distress. From that period and up to his death, thirteen years afterwards, this gentleman visited me frequently for the same purpose. He sometimes applied to me at short intervals, but he was once, during my knowledge of him, as long as fifteen months without suffering inconvenience or needing assistance. The disability to pass urine always arose from the same cause—namely, overstaying the inclination to pass it, or overstaying the usual time of evacuation. The visits to me occurred, with very rare exceptions, during the night—most frequently about two or three o'clock in the morning, occasionally as late as six o'clock; very infrequently during the daytime. The common interval between the times of passing water was two hours or two hours and a half. When that time happened to be prolonged in any considerable degree the inability to evacuate occurred. The delay was easily avoided in the daytime—the waking hours; but at night the insensibility of sound sleep would now and then carry the patient over the proper margin of time. That was the common, if not the invariable, cause of the seizure.

Having, at his first visit to me, noticed a peculiarity in the position of the urinary canal, and perhaps having made a remark about it, I learnt that Mr. M. had previously sought the aid of other Surgeons. He said that he had suffered much pain and had lost blood whenever the instrument was passed. While the attack of disability to empty the bladder lasted the suffering of this gentleman was intense. That it was so was evident from his strong expression of pain, and from his extreme anxiety to obtain relief in the shortest time possible. From apprehension of recurrence of suffering, with the knowledge that it may recur any night, Mr. M., when quite well, was in the habit, during those many years, of making arrangements, often very ingenious, to secure access to relief in the

speediest way. Another measure of the pain endured on account of retention of urine, under different circumstances, may be given by reference to another person, a patient in the Hospital.

Case 2.—S. S. [Hospital Male Case-book, No. 21, p. 116], a man, aged 38, was brought into University College Hospital to be relieved of retention of urine resulting from organic stricture of the urethra. The House-Surgeon, unable to pass an instrument, gave full doses of opium, which, however, were not effectual either in enabling the patient to pass urine or in rendering the urethra passable to an instrument. I found it advisable to puncture the bladder through the rectum. The operation was attended with the immediate relief of pain which the evacuation of a distended bladder always affords. But pain having ceased, another difficulty arose. The patient had speedily the symptoms that result from an overdose of opium. It then required active recourse to the usual management of such a complication to prevent the patient being poisoned by the medicine, which during the continuance of his sufferings was innocuous. From the circumstances of this case we may judge, I think, that the pain Mr. M. seemed to endure was not the result of any mere apprehension as to results, or of excitability of temperament; we may judge that it was real pain, and intense. In the facts there is a sufficient explanation of the anxiety—even restlessness—of Mr. M. when quite free from any feelings of illness to insure means of obtaining speedy relief in the event of being surprised by recurrence of suffering. The facts also show the importance of any person in such circumstances being enabled to relieve himself.

When I first saw Mr. M. I wished him to use a catheter for himself; but he absolutely refused to make a trial, from fear that he must fail, and that he might do mischief on account of a degree of clumsiness of his fingers, which were partially stiffened by slight attacks of rheumatism. He had, besides, from former experience, a fear of any new trial, whether by himself or anyone else. At length, however, on an occasion that I proposed to be away from home—further away and for a longer time than usual—he made the attempt, and he succeeded with little more direction than is required in common cases. Thereafter I saw nothing of this gentleman until he had an attack of general illness. He had passed the eighty-

first year of his age in good health, when he had a severe attack of idiopathic erysipelas. After that illness had passed away, he sank from exhaustion, owing apparently to inability to take food of any kind.

The examination after death in so far as concerns our purpose gave the following results:—In the place of the urinary bladder at the fore part of the pelvis was a large mass, for the most part solid, which extended some way above the pubes (Fig. 1). This was, in fact, the urinary bladder, filled in great part with a firm tumour. The tumour itself was in part above the pubes—in the abdomen, therefore. A section of the whole having been made (Fig. 2), the tumour was found to be the prostate gland, enlarged, in an unusual position—above the urethra instead of below it, as is common. The upper end of the enlarged prostate is seen to be conical (Figs. 1 and 2)—so formed that urine would necessarily glide from it towards the urethra, unimpeded by the gland or any part of it. The lower part of the prostate (lateral lobes and the middle one) is represented by a thin layer of glandular substance mixed with muscular fibres. This is, as in the ordinary condition, continuous with the anterior part of the gland.

The urinary bladder was free to contain urine only in part. The bladder proper of the case was wholly in the abdomen or very nearly (Fig. 1). There was no dependent part (fundus) behind the opening into the urethra (Fig. 2), as is usual in the adult and is especially well marked in advanced age.

The urethra—in which a bougie has been placed by the dissector—continues from the back part of the bladder, instead of being at the fore part of that cavity. From this, the natural position, it was doubtless pressed away during the growth of the anterior tumour. The free course of the canal was not, it may be noticed, impeded by any obstruction, either by the prostate or any other structure.

The points of greatest interest in the foregoing case may be shortly stated as follows:—The power to evacuate urine remained entire except at intervals. All through the long series of years during which Mr. M. was liable to (and at intervals suffered from) retention, the inability to pass urine did not continue beyond the single seizure; insomuch that, after relief once given, the inability did not return except after a certain space of time—several days, or weeks, or even months.

On no more than two occasions during thirteen years was it necessary to resort to the use of the catheter a second time—not once a third time—on the same day; and even then the bladder had evacuated its contents spontaneously several times before the return of retention. Thus the recovery was complete each time after the single act of assistance; and so it was to the end.

Again, there was no indication, throughout the whole history of the case, that any urine remained after the spontaneous evacuation. Nor was there an indication that the kidneys or other part of the urinary organs were otherwise than healthy. The general health, too, was unimpaired except in so far as occasional slight rheumatism was concerned.

The question occurs, Whence arose the delay and difficulty which, according to Mr. M.'s statement, had at first been experienced in the use of the catheter? The answer must, I think, be this: The urethra was not in the usual position. Commonly in aged men suffering with retention of urine, that canal near its vesical end is raised above or in front of the place natural in previous life; for commonly—indeed, in my experience, almost invariably—the enlargement of the prostate which obstructs or interferes with the freedom of the flow of urine occurs in the part of the gland beneath or behind the urethra—between it and the rectum. Hence the Surgeon expects that the point of his instrument, when it approaches the bladder and is arrested in its course onwards, should be raised towards the pubes. Every tyro is familiar with the expedients, carefully described in elementary treatises, which help to overcome the impediment arising from the usual cause—viz., the tumour behind the urethra. But, in the case before us, the urethra was not raised or pushed forwards. On the contrary, it was behind its usual position—was pressed backwards, the enlargement of the prostate being before the canal. The difficulty, then, and delay, and loss of blood stated

FIG. 1.

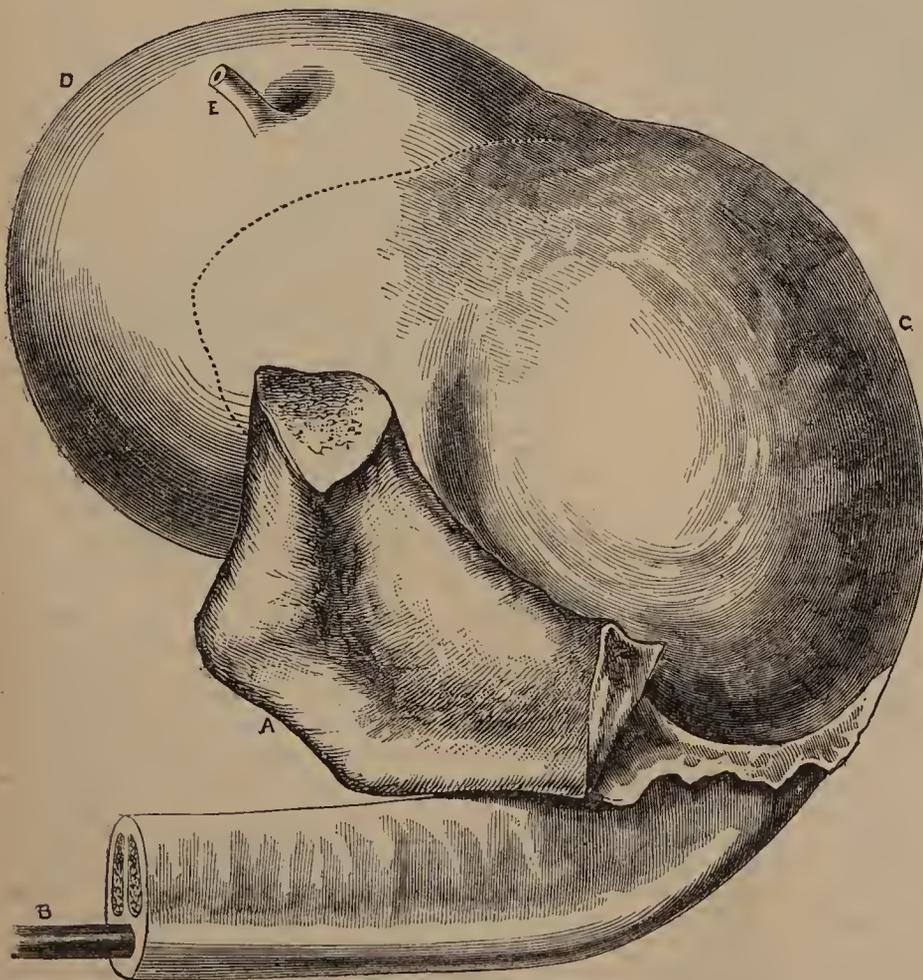

FIG. 1.—The pubic bones, with the urinary bladder, the prostate, and a portion of the penis, as seen from the left side. A, the symphysis of the pubes; B, bougie in the urethra; C, the back part of the enlarged prostate. None of the gland projects in the form of lateral or posterior lobes. The place of the upper end of the prostatic tumour is represented by a dotted curved line. D, the top of the bladder; E, the left ureter.

to have occurred in passing the catheter, arose, I apprehend, from the efforts to find the urethra in the accustomed place of aged persons affected with retention of urine.

It has been stated that Mr. M.'s distress had its beginning in a railway journey, and that the retention of urine recurred invariably from delaying the evacuation. Many aged persons begin to suffer in the same way—*i.e.*, in some form of travelling or in the too protracted delay of the evacuation under any circumstances. There are, however, points of clear difference between the case narrated and those ordinarily met with. In the latter the first distress does not usually pass away quickly as in the case of Mr. M. That case was, judging from my own experience, singular both in the frequent recurrence of retention and in its rapid cessation. But, instead of speaking in general terms as to results of other cases, I shall refer to one or two actual examples of the malady; noticing the facts, however, only so far as they bear upon the point now in question.

The wood engravings have been diminished one-third from the drawings made at my desire by Mr. Ford from the preparation No. 2499A in the Museum of the College of Surgeons, to which I presented it.

FIG. 2.

FIG. 2.—A vertical section in the middle of the parts represented in the preceding figure, the bones omitted. The letters as in Fig. 1. A part of one vesicula seminalis exists in the preparation opposite the lower end of the structure which covers the bougie.

Case 3.—A gentleman aged 64 years, while engaged in some scientific inquiries, drove with friends for several hours through one of our midland counties. In the evening, when he arrived at his journey's end, he was unable to pass water. After some ineffectual attempts to relieve him, he came to his home in London. The disability, and the difficulty experienced in passing a catheter, were found, as expected, to be connected with enlargement of the prostate gland. Sixteen days elapsed before there was any natural discharge of urine; and then only a little was passed without aid. It was twelve days later—four weeks from the attack of retention—that the patient became independent of assistance. Now, more than ten years from the

incident referred to, this gentleman appears to be, and I am assured is, in good health.

One other case will be enough for my present purpose—namely, the further illustration of the varied and often serious effects of delay of the evacuation of urine in aged persons.

Case 4.—A robust man, in excellent health, aged 66 years, in high official position, actively engaged for several hours day after day in the work of his office, was obliged by the illness of a member of his family to travel by railway a distance of about 150 miles from London. When he arrived he was unable to pass urine. In affording relief there was considerable delay; and much difficulty, occasioning severe distress, was said to have occurred. Returned after more than a week to London, this gentleman continued to suffer. He had pain about the pelvis and renal region, with a good deal of constitutional disturbance. The prostate was found, by examination through the rectum, to be much enlarged and prominent there. Urine passed involuntarily. There was no accumulation in the bladder.

At the end of four months the patient was much improved in health, and he went to his country home. But I learnt that in two months later, having been exposed to damp during some occupation out of doors, he was suddenly seized with a return of the worst symptoms in an aggravated form, accompanied with copious discharge of puriform matter from the urethra; and he sank rapidly.

In the three cases the alteration of structure which preceded the sudden seizure of pain and illness, affected the same organ—the prostate. But while in the first the upper part of the gland was enlarged, the lower and lateral part was so altered in the other two. This latter is the common condition.

The disability which the three suffered being the same, and the circumstances under which it arose in all being also the same, I would inquire what was its immediate cause? and why were the results of the cases different—using the first and most remarkable case for the elucidation of the others, which may be considered typical of large numbers?

Inasmuch as the only change of condition when the malady began was the unwonted accumulation of urine, it must be concluded that the inability to evacuate was owing to the over-distension of the bladder diminished in its capacity, and the enfeebling—in a measure paralysing—effect on the muscular fibres unduly stretched by the distension. As to the difference of the results: The expulsive power in Case 1, though impaired by the cause adverted to, was yet, the first difficulty being overcome, equal to the accomplishment of the natural function, because, in all likelihood, of the entire freedom of the urethra from encroachment or obstruction of any kind; while in the other cases the diminished muscular power was insufficient to overcome the impediment which the prostate afforded to the flow of urine. With the recovery of muscular tone the expulsive power was restored. So it is in most cases; but in some instances the paralysis is permanent.

Now, seeing that in consequence of the enlargement of a natural structure—not a disease—which frequently, but by no means invariably or even generally, accompanies advancing age, many men, while still in good health of body and in vigour of intellect, are liable to be struck down with painful illness of some duration [Cases 3 and 4]—nay, to be permanently damaged, in health, or even to have life cut short [Case 4]—seeing, moreover, that the evils are excited by what appears so small a cause—one clearly preventable—it will be conceded that those liable to

such evils should be carefully provided with the means of avoiding them. One obvious precaution is necessary. Though well known, it is too little resorted to. Why? Apparatus with various adjustments to hinder the necessity for delaying the evacuation are to be had; but unfortunately they are commonly said by those who have worn them to be so little convenient that risk is preferred to the discomfort of the protection against it. So it was in Case 4, and so I have known it in several others. There seems to be wanted the zeal of an intelligent maker or seller of such apparatus, to learn by observation on himself the defects of construction which interfere with comfort, and so to arrive at a satisfactory arrangement.

The following microscopical drawings, made from the preparation No. 2499A in the Museum of the College of Surgeons, with the statement respecting the structure of the prostatic tumour, relate to Case 2, and have been furnished to me, at my request, by Mr. James F. Godhart, Assistant-Conservator of the Museum.

FIG. 3.

FIG. 3 shows a fibrous stroma, bounding many spaces filled with cells. Of these many have escaped, leaving the spaces empty. *a a* fibrous stroma, *b b* empty spaces, *c c* spaces still containing cells, *d* space more highly magnified in Fig. 4.

FIG. 4.

FIG. 4.—A single space (gland acinus). The cells are arranged somewhat regularly alongside each other, and often in beaded strings radiating from centre to circumference. A very delicate hyaline substance connects them together.

Structure.—The tumour forms a solid mass, without apparent distinction into lobes, except at the lower and posterior parts, where a small lobe is separated from the rest by the urethra, through which the catheter is passed. Both this small posterior portion and the large mass have a common structure—adenoid in its nature. No normal prostate tissue exists apart from the glandular tumour, except at the most dependent part. Here below the urethra is some stretched and apparently wasted, but otherwise normal, prostate structure. This would probably correspond to a lower lobe.

(To be continued.)

APPLICATION IN INFANTILE ERYSIPELAS.—Professor Trousseau recommends the following solution to be applied by means of a small brush to all parts of the infant's body upon which erysipelas has made its appearance:—Ether sulphuric, 60; camphor, 30 parts.—*Union Méd.*, May 7.

THE PHYSIOLOGY AND CLINICAL USE OF THE SPHYGMOGRAPH.

By F. A. MAHOMED,

Student of Guy's Hospital.

No. VI.

On Mitral Stenosis—Cardiographic Proof of the Mode of Production of the Presystolic Murmur—Special Characters of the Apex-beat and Pulse—Effect on the Circulation generally—Notes of Cases.

(Vide Plate Published with Medical Times and Gazette, April 13.)

IN the present communication it is intended to draw attention to the effect produced upon the circulation and upon the heart by mitral stenosis, and while doing so certain facts will be brought forward which appear to the writer to throw much light on the pathology of this disease, and on the production of the auscultatory sounds accompanying it. Although it should be stated that a sphygmographic tracing in this disease does not necessarily possess any diagnostic characteristics, still it will be found that under certain conditions it may do so, and that if taken together with tracings obtained of the apex of the heart, very valuable information is afforded, and in many cases a diagnosis may be arrived at.

The mode of production of the bruits which accompany contraction of the mitral orifice is at present by far the most keenly debated point in cardiac pathology; and it is only with the greatest diffidence that the discussion of a question on which the most brilliant observers differ is entered upon—indeed it would not be, but that the results obtained appear too important to be passed over in silence.

On the physical signs which accompany contraction of the mitral orifice, I believe all are now agreed; it is upon the mode of production of these signs that so many differ. Any Physician who hears a harsh churning bruit, localised at the apex, and occurring during "*le grand silence*"—namely, after the second and before the first sound—followed or not by an ordinary systolic murmur, and accompanied by the "*frémissement cataire*," will assert that the mitral orifice is contracted. But whether the so-called presystolic murmur is *auricular-systolic* or *ventricular-systolic*, whether it is a *direct* or *regurgitant* murmur, is the question which still requires solution, and on this question the sphygmograph and cardiograph combined appear to give almost decisive evidence.

The characteristic murmur of mitral contraction, which is now generally described by the term "*presystolic*," is found to take place at various intervals before the first sound, sometimes occurring as a short murmur immediately before it, and at other times commencing immediately after the second sound and continuing up to the first, or again appearing to be only a reduplication of the second sound. Sometimes it is present, sometimes absent, and its character varies from day to day.

Now, it is well known that in the normal condition the contraction of the auricle is a rapid, short movement, immediately preceding the more sustained ventricular contraction. It is apparent in an apex tracing of the heart as a slight elevation preceding the commencement of the main upstroke. It can be seen in a well-marked degree, and of a longer duration than normal, in Fig. 10, Pl. iv. That this elevation is really caused by the auricular contraction has been proved beyond doubt—first by Marey, and since then by many other leading physiologists. One experiment that is almost conclusive of this fact is that in which three small bags, connected with polygraphic levers, are introduced—one into the auricle, another into the ventricle, and the third placed over the apex of the heart of an animal—the three levers writing simultaneously and immediately below one another, when it is found that the elevation corresponding to that seen in Fig. 10, immediately preceding the main upstroke produced by the systole of the ventricle, exactly corresponds to the movements of the lever connected with the interior of the auricle. Again, another fact in proof of this is that hypertrophy of the auricle may be diagnosed by the increased size of this elevation, as seen in Fig. 6, Pl. iii. This diagnosis was confirmed by an autopsy, as stated in the last paper. Accepting this point, then, a solution may be found to the irregularity in rhythm of the presystolic bruit. It may be asked, How can a bruit occurring immediately after the second sound be produced by the contraction of the auricle, which is said to be instantaneous? It is owing to the contraction of a hypertrophied auricle when resisted by a contracted mitral orifice, often occurring earlier and lasting longer than usual. That this actually takes place is shown by Fig. 12, Pl. iv.,

This case will be mentioned more fully below. It is only desired at present to call attention to this tracing of the apex of the heart. It will be noticed that the action is irregular, and previous to the first cardiac contraction recorded in the tracing there is a long intermission apparent. During almost the whole of this period the auricle was contracting. The short upstroke indicating its commencement is seen to take place very soon after the termination of the preceding ventricular systole, and it is succeeded by a gradually ascending line, terminated by the sudden vertical upstroke of the next contraction. In the succeeding contractions, which were more regular, the auricular systole is seen more or less well marked, but in each instance extending over a somewhat longer period than normal.

This peculiarity in rhythm I have frequently found in mitral stenosis. The physical conditions prompting its occurrence are evident: the left auricle, unable to thoroughly evacuate its contents, owing to the obstruction at the mitral orifice, remains more or less full, and is generally distended at the termination of the ventricular systole, during which time it has been receiving more blood. It is thus stimulated to contract, and this it does slowly and with effort. But this is not always the case. The ventricle often will not adapt itself to the altered rhythm of the auricle, but contracts immediately after the latter; and when this occurs earlier than usual, following immediately the termination of the previous contraction of the ventricle, as described above, it gives rise to another peculiarity in rhythm—namely, the occurrence of a secondary contraction of the ventricle, which is indicated both by cardiographic and sphygmographic tracings. This is seen in Figs. 3, 4, 14, and 16, Pl. iv. Whenever the pulse in mitral contraction is made slow by digitalis, this character may be brought out—indeed, it may be considered almost diagnostic of the disease; so especially may this peculiar form of irregularity when occurring in the pulse without being produced by artificial means. The secondary beat occurs after the closure of the aortic valves, or of the dicrotic wave in the tracings. The condition of the auricle described above also accounts for the pulse in cases where there is considerable mitral obstruction, being usually rapid.

It is very interesting to find that these results obtained by mechanical means coincide with the observations of some of the most careful auscultators who have paid special attention to this subject, but whose observations, lacking the indisputable proof of instrumental aid, might perhaps otherwise be open to doubt. Dr. Wilks, in his paper on "History of Valvular Disease of the Heart" (Guy's Hospital Reports, 1871), quotes a case of Laennec's, and makes the following remark:—"One point alluded to in the above case is of interest, as it has not yet been clearly elucidated, and that is his referring the bruit to the slower contraction of the auricle." Dr. Fagge also, in his paper "On the Murmurs attendant on Mitral Contraction," mentions several cases in which he considered that the "systole of the hypertrophied auricular appendix occurred so early that it seemed to follow a second sound rather than to precede the next first sound." Moreover, he discusses at length the double rhythm, occurring in the case of E. B., whose tracings appear in Plate iv., and remarks on its production by digitalis; he also quotes Duroziez, who states that in one case, while digitalis was being given, "the pulse generally became slower, and became double, each strong pulsation being followed by a feeble one." It appears, therefore, that if proof of the prolonged contraction of the auricle occurring during the ventricular diastole and time of rest could be given, the fact of the *presystolic* murmur being *auricular-systolic* must be admitted; and this proof is obtained by aid of the cardiograph and sphygmograph. Moreover, I can but think that these observations completely overthrow any theory of the production of this bruit by an early and gradual commencement of the ventricular systole, as suggested by Dr. Barclay in his papers on this subject, which appeared recently in the *Lancet*. As to the truth of these inferences I must appeal to the judgment of more mature minds than my own, and those more capable of deciding a question of such intricacy.

So far the general results obtained by aid of the sphygmograph have been discussed; the cases that appear in the Plate may now be referred to individually.

Fig. 1 was obtained from J. C., a man admitted under Dr. Wilks, April 8, 1871, with symptoms of heart disease. The bruit most usually heard was systolic, audible at the apex, in the axilla, and posteriorly, but occasionally a distinct presystolic bruit was audible, and at times no abnormal sound could be detected; a "purring tremor" was faintly perceptible over the cardiac region. When this tracing was obtained he

was in an apparently moribund condition, though he lingered for a week or two afterwards. The autopsy confirmed the diagnosis made during life, of a contracted mitral. This valve was constricted, and there were thick vegetations on its auricular surface. The left ventricle was normal in size, but the left auricle was dilated and greatly hypertrophied. The right side was also dilated. The tracing obtained differs very markedly from that which would be found in a case of mitral regurgitant disease where the patient was approaching dissolution. In such a case the pulse would be irregular, the upstrokes sloping and very short, and dicrotism absent. Here the upstroke is vertical, percussion not being interfered with; the mitral valve still offering a point of resistance for the ventricle to contract against. The pulse is quick, owing to the over-distended auricle being always ready to contract and relieve its distension; and it is also dicrotic. The obstruction being great, the venous circulation was engorged; and this acted in the same way as obstruction to the capillaries, causing a large part of the contraction of the heart to be expended in dilating the elastic aorta, and thus producing a well-marked dicrotic wave. This does not occur in simple regurgitant disease, though the venous engorgement may be as great; for, as previously noticed, less blood is driven into the aorta, and with less force: its elastic coat, therefore, is not distended.

Figs. 2, 3, and 4 were obtained at different times from the pulse of E. B., a patient under the care of Dr. Fagge. The case has been discussed by him very fully in his paper "On the Presystolic Murmur" referred to above. It will be unnecessary to enter into particulars of the case here, beyond stating that a presystolic bruit was distinctly audible, and that no doubt was entertained of the nature of the disease. In Fig. 2 there is no point of interest about the pulse, except the undulation in the respiratory line. This is of frequent occurrence in mitral obstruction. It is not very noticeable in the fragment of the tracing reproduced in the plate; but if a horizontal line be drawn from the base of the first upstroke to that of the last, the upstrokes between them will be seen not to reach the same level. In Fig. 3 the peculiar rhythm referred to above, and described at some length by Dr. Fagge, will be seen to be produced. This tracing was obtained after exercise. In Fig. 4 the same result was obtained as a more permanent condition by the use of digitalis. It will be seen that in both instances the secondary contraction of the ventricle occurs after the aortic notch—that is, after the closure of the semi-lunar valves.

Figs. 5, 6, and 7 were obtained from a patient who was admitted under the care of Mr. Cooper Forster for surgical treatment, but died in the Hospital from cardiac disease. Contraction of the mitral orifice was diagnosed during life by Dr. Goodhart, by whom a presystolic murmur was heard. When I examined him the action of the heart was too rapid to admit of the nature of the bruit being discovered. The autopsy revealed a dilated right side, an hypertrophied left auricle, and a mitral valve admitting only one finger. The tracings show great and increasing obstruction to the circulation. In Fig. 5 the pulse, though small, has a well-marked percussion-wave, and a large amount of dicrotism from the obstruction to the venous circulation. In Fig. 6, taken a few days later, the dicrotism is still more marked, the pulse now being hyperdicrotic; and Fig. 7, taken on the following day, which was two or three before death occurred, shows a failing heart—the pulse has become irregular, small, and feeble; the apices of the tracing are rounded; and after a few somewhat more efficient contractions come a series of very feeble inefficient attempts, sufficient to produce a slight impulse at the wrist, but insufficient to distend the aorta and produce a dicrotic wave.

The case of C. D., from whom Figs. 8, 9, 10, 11, and 12 were obtained, presents a considerable amount of interest. She was first admitted under the care of Dr. Moxon on May 17, 1871. She had never suffered from rheumatism, but there was a systolic mitral murmur audible at the apex, and faintly between the scapulae. Her case was complicated by purpura and hydroa; but these points require no further notice here. During her stay in the Hospital at this time the second sound occasionally appeared to be reduplicated. There was also a *frémissement* perceptible over the cardiac region, and the question of contracted mitral was raised, but not generally entertained. At this time I felt but little doubt of the nature of the case, for the reduplication of the second sound that was heard at the apex sometimes assumed a much more bruit-like character, and appeared to be a presystolic murmur. My diagnosis was still more sustained by finding that a tracing of the apex represented in Fig. 10 showed an hypertrophied and slowly contracting auricle. Fig. 7, obtained soon after her admission,

indicated an excited action of her heart, the percussion-wave being very well marked, while the tidal is comparatively small. Fig. 8 represents her pulse later, when the general condition had much improved. The tidal wave is now much larger, and bears a fair proportion to the percussion. She left the Hospital in July, but was again admitted, under Dr. Habershon, on account of increased cardiac symptoms in August. She now appears to have suffered from pulmonary apoplexy. The murmur is described as that of regurgitant mitral. No mention is made in the report of its presystolic character, but it is stated that just before leaving the Hospital the murmur entirely disappeared, and the sounds of the heart were normal. I did not see her during this period, but in January, 1872, she was once more admitted, this time under the care of Dr. Fagge. She had again suffered from pulmonary apoplexy, and the action of the heart was irregular. There was a well-marked thrill over it, and the predominant murmur was that probably produced by mitral regurgitation; but the presystolic murmur was now much more marked than formerly; it was especially distinct during the intervals of intermission. During these long periods of pause this harsh murmur was plainly heard ending before the systole, and separated by a short interval from the regurgitant murmur. Dr. Fagge was quite convinced of the character of the murmur, and it was now generally looked upon as a case of contracted mitral. The tracing obtained of the apex-beat (Fig. 12) has been already referred to. The early commencement and prolonged duration of the auricular contraction make it of the greatest interest. Fig. 11 represents her pulse a few days later, when her condition had much improved. It is perfectly normal in appearance, the circulation being apparently carried on efficiently. This probably is owing to two facts—first, that the disease of the valve is not very excessive; secondly, that the pulse being slow, and the auricle (as seen in the tracings of the apex) having learnt to contract slowly and to commence its contractions earlier than usual, is able to thoroughly empty itself, and accordingly makes the ventricular contraction more efficient. While she is kept at rest in the Hospital this state of things continues, and her condition improves; but on returning home and renewing her usual occupation the rapidity of the heart's action is increased, the left auricle is no longer able to completely empty itself, and the right side becomes distended. Her symptoms now increase, and she suffers from the ordinary troubles of cardiac disease.

The diagnosis in the last case in this plate is perhaps open to doubt, the evidence of constricted mitral being chiefly sphygmographic and cardiographic.

M. A. B. was admitted into the clinical ward, January 27, 1872, under the care of Dr. Wilks. She has had three previous attacks of rheumatism; the first attack, eleven years ago, being accompanied by palpitation and pain in the left side. On admission she was suffering from subacute rheumatism and heart disease. The following note was made by the Clinical Assistant:—"Loud bruit with the first sound; heard best at apex. It can be traced into the axilla, and round as far as the superior angle of the scapula. Apex-beat normal. Slight thrill over it." Several times when examining her heart I thought that there was a presystolic bruit, especially when its action was irregular. During a period of intermission I have heard a bruit, which commenced after the second sound, and ended before the first, and possessed a different tone from the blowing systolic bruit which was usually audible; but this observation was not generally agreed with. Her pulse was then 80, and it is not described as irregular. On February 12 the heart's action was very irregular. She was ordered—Tr. digitalis $\text{m}\times.$, ex aqua, three times a day. The following day the tracing represented in Fig. 13 was obtained. It may be noticed that it is extremely irregular, the irregularity bearing no relation to the respiratory movements, as that of mitral regurgitation usually does. In the first large wave in this tracing a slight secondary contraction is indicated by an irregularity in the downstroke after the aortic notch. Fig. 14 represents a cardiographic tracing taken two days subsequently. It may be noticed previous to the fifth contraction figured in the tracing that there is a well-marked and gradual auricular contraction. The next contraction that occurs is seen to be followed by a secondary contraction like that previously seen several times in the tracings of the pulse in this and other cases. By February 24 the digitalis had taken effect, and the pulse was almost perfectly regular. Pressing the drug a little further, on the 26th it assumed the characteristic irregularity of a secondary contraction. This is well seen in the last tracing in this plate.

So much for the indications afforded by these instrumental

means of contraction of the mitral orifice. To sum up the whole, it may be said—first, that light may be thrown on the mode of production of the bruit heard; and secondly, that though the sphygmograph may not in all cases enable us to diagnose the disease, still it may often afford strong indications to assist us, and at least will give negative evidence.

SATURDAY, MAY 18, 1872.

THE ROYAL MEDICAL BENEVOLENT COLLEGE.

THE Council of the Royal Medical Benevolent College were able to lay a good report for the past year before the annual meeting of governors and before the general public at the dinner at Willis's Rooms on Friday last. The institution has, indeed, progressed so rapidly that already there are signs that the vigorous portion is likely to break away from the less active, and maintain an independent existence; and that such should be the case we, for our part, cordially hope. As a school Epsom is most flourishing. Already there are in the ranks of our Profession a large number of very able men who are proud to look back upon being old Epsom boys, and that, too, notwithstanding the drag of the title; for it is not to be concealed that a large number of those who send their sons there, and a still larger number of those who are sent there, do strenuously object to the title. They pay their way and want nothing to do with benevolence. As a striking corroboration of this we might refer to what meets the eye of the visitor leaving Epsom and entering on the road which leads to the College. There in olden times was a sign-post pointing the way to the Royal Medical Benevolent College, but this has been so cunningly curtailed that only the word "College" is left—a word which, on the whole, fairly answers the original purpose.

It is matter for congratulation that the Profession has there a College where a first-rate education—everything included—can be obtained for £45. We are also glad that there are a certain number of foundation scholarships open to the Profession, whereby a good education can be obtained free of charge; but we are strongly opposed to increasing the number of these. Even now the difficulty of canvassing, and the expense it

entails, throw serious obstacles in the way of these doing unmixed good; much rather would we prefer the system recently introduced of giving exhibitions, whereby, let us say, the College education is defrayed, and only that of living has to be paid by the parents. This, where it is workable, is a system much more likely to foster independence than the other. It is, at the same time, rather honourable to the boy than otherwise—which, in the meantime, a foundation scholarship is not.

One great step has, however, been taken to raise the school. Erasmus Wilson has munificently undertaken to build a master's house with accommodation for thirty boys. These will of course be taken at advanced rates, but the advantages will be correspondingly great; and we may hope in no long time to see others of the masters provided for in like manner. We hold, then, that nothing is more likely to raise the whole tone of the school over its present high level than such plans.

It is befitting that in a school specially devoted to the sons of Medical men the teaching of science should take an appropriate place. Such teaching has been begun, and we understand that next term there will be a resident master, who will devote his attention solely to this. But it seems to us that there is a danger ahead to be strenuously guarded against—viz., the introduction of the vicious system of teaching science as an end, not as a means—as an end, that is to say, to the procuring of rewards and scholarships, and not as a means of training valuable in the highest degree.

There is yet one portion of our subject we touch upon with reluctance. It cannot be disguised that there is a kind of split in the camp of the supporters of this institution. Its object is twofold, and whereas some devote their attention and keenest sympathies to the school, others do the like to the asylum. We confess ourselves of those who would gladly see the two apart, in place at all events. The introduction of the two extremes of life into the same building was not happy; and whilst ardently wishing success to this portion of the institution, as to the other, we should be heartily glad to see the old people elsewhere comfortably housed. Let us hope the Council will find some way out of the difficulty.

"THE PRACTISING CHEMIST."

"The practising chemist"—by which designation we do not indicate merely those who, like Mr. Andrews, of recent notoriety, practise under cover of a questionable degree, but those who openly practise for and visit patients as Medical men, without even the semblance of diploma or licence—must certainly be dealt with in the next Medical Act, whenever it may please the Legislature to turn its attention to that important desideratum. Time was when any man could, by the common law, practise as a Medical man or open a shop for the sale of drugs, and even combine the two callings. But the common law, the law of primitive times, is still dear in theory to the hearts of Englishmen, and is generally tenderly dealt with by Acts of Parliament. Hence the Medical Act of 1858 inflicts no penalty upon the most audacious quack beyond that of disabling him from recovering charges for medicine and attendance, unless he goes the length of wilfully and falsely proclaiming himself an M.D., or affects some title implying that he is registered under the Act. If he stops short of this he may act the part of a Medical man with impunity, by simply taking the precaution and enjoying the advantage of demanding "cash on delivery." It is true he may still have the dread of the Apothecaries' Society, or even of the Royal College of Physicians, before his eyes; but if he be a duly registered pharmaceutical chemist, authorised to sell drugs and poisons, he knows the extreme difficulty of proving an infringement of the rights of the former, and looks upon the antiquated jurisdiction of the latter as a mere *brutum fulmen*. At all events, he can only be

proceeded against by those bodies themselves. He may have infringed their prerogatives, but with this the public have nothing to do. No officer of health, no sanitary commissioner, no private nor public prosecutor (if such latter functionary existed), could take the place of those august bodies, or even put them in motion. His name may be removed from the register of the Pharmaceutical Society if he is practising under the right of a Medical degree, foreign or domestic; but if he has avoided that pitfall he is safe. The Pharmaceutical Society has no power to sue for penalties for the infringement of the privileges of other bodies. The Licentiate of the Royal College of Physicians may suffer in his exercise of pharmacy—the general Practitioner may be likewise damaged—nay, even the Fellow of the Royal College of Surgeons, or the Fellow of the Royal College of Physicians may find himself supplanted by an ignorant bone-setter, or a prescribing drug-seller—but the remedy is *in nubibus*. The "practising chemist," authorised to dispense and compound the prescriptions of Medical men, may surely pay a visit to a customer and tender advice, sheltering himself from the objection of having prescribed the medicine supplied, in having compounded it from a Physician's prescription, duly copied in his prescription-book; but, conscious that he cannot recover charges for Medical attendance, he is content to include in the price of his medicine a sum sufficiently remunerative for his extra trouble. Now, what is the remedy for this state of things? A short enactment to the following effect:—"That if any chemist, etc., shall himself prescribe medicine for any other person, or shall compound medicine from the prescription of any Medical man, except at the request of such Medical Practitioner, or of the holder of the prescription, or shall give Medical or Surgical advice to, or perform any Surgical operation upon, or attend and visit any patient as a Medical Practitioner, he shall be liable upon conviction before two justices of the peace, for every such offence, to a penalty not exceeding £50." A right of appeal to the Court of Queen's Bench should be allowed. If some such stringent measure is not adopted, the "practising chemist" will before long be giving certificates of death and its cause, as even here the law in strictness only requires that *some person present at, or in attendance during, the last illness* of the deceased, or in case of the death or default of such person, the occupier of the house, or if the occupier be the person deceased, some inmate of the house, etc., in which the death took place, should supply the registrar with information upon being requested so to do, *according to the best of his (or her) ability*, of all particulars touching the death of such person. Thus, that which was intended to form an exception may become the rule—that which was intended to meet the unavoidable absence of Medical attendance during the last illness may be abused and distorted to confirm the intrusion of the "practising chemist," to the exclusion of the Medical man, at least among that large class of half-educated people who look upon all chemists' shops as "doctors'" shops, and fancy they discern in many coloured bottles labelled with hieroglyphics the cabalistic signs of the art divine.

BOWS AND ARROWS.

How many, or rather how few, Surgeons ever think that in these days the treatment of wounds by arrows can form a real and not unimportant part of military Surgery! or how few among us, civilians or soldiers, could, in these times of *armes à précision*, and breech-loading rifles that are deadly at such distances as to make useless the artillery of a few years back, hear without a "laugh of merry scorn" a suggestion that archers might be advantageously employed with regular troops, or that soldiers should, like our ironclads, wear defensive armour to protect them, not against bullets, but against arrows! Would not each and all be ready to quote Sir Dugald Dalgetty's expressions of contempt for bows and arrows? "Bows and arrows!" exclaimed Dalgetty, "Ha! ha! ha! have Robin Hood and Little

Jackback again? Bows and arrows! Why, the sight has not been seen in a civilised war for a hundred years. Bows and arrows! and why not weaver's beams, as in the days of Goliath? Ah! that Dugald Dalgetty, of Drumthwacket, should have lived to see men fight with bows and arrows! The immortal Gustavus would never have believed it, nor Wallenstein, nor Butler, nor old Tibby."

Of course, however, we all know that bows and arrows have been most formidable and effective weapons in the chase and in war, through numberless ages in the world's history, from the time when Ishmael "dwelt in the wilderness, and became an archer," down to nearly the end of the sixteenth century, when "Good Queen Bess" engaged by treaty to supply the King of France with 6000 men, partly armed with long-, partly with cross-bows; and later than that. "Every schoolboy" knows all about the archers of the Greek and Roman armies, about the mighty bow of Ulysses, and about those mounted archers the Parthians, unconquered and unconquerable until the Romans copied their mode of fighting; and of course every youth who thinks of trying to become, in these glorious days of competitive examination, even a tide-waiter at the Custom-house, or a Post-office *galopin*, knows how the English long-bow won the battles of Cressy, Poitiers, and Agincourt, and can tell how, in many a stubborn fight with the Scots, "the English shafts in volleys hail'd," and how, when there "fell England's arrow-flight like rain," steel-clad knights and men-at-arms were alike mown down, and melted away before the destructive horizontal and vertical fire. We suppose even that the Surgical student of the period must be well up in Homer's description of wounds by arrows, be able to cite Chiron and Machaon's patients, to describe how Hippocrates, Diocles, and Celsus extracted arrow-heads, and perhaps even be acquainted with what Paulus Ægineta and sensible old Ambrose Paré wrote on the treatment of arrow wounds. But one hardly expects to find injuries of this kind treated of in modern works on Surgery, and we must own that we were considerably surprised when, on taking up, the other day, a "Report on Surgical Cases in the Army," published by the Government of a country which is the nursery and home, if not the very cradle, of the rifle and the six-shooter, we lighted on a report on arrow wounds.

This report, which was issued by the "War Department, Surgeon-General's Office, Washington, 1871," is extremely interesting, and forces us to have a much higher respect for the bow as a weapon of war, even in the hands of Indians and against rifle-armed soldiers, than we could have entertained before reading it. Looking at the steel-headed arrows of our ancestors, it is easy to imagine that the long-bow, in the hands of the English archer, was a most effective weapon, especially before "villanous saltpetre was digg'd out of the bowels of the harmless earth"; but who would expect to find Indian bows and arrows avail aught against the soldiers of the United States? Yet we find Dr. Bill remarking on "the rapidity with which the American Indians discharge their arrows"; and of the first seven cases of arrow wounds mentioned in this report five were fatal. Dr. Bill states that "it is exceptional to meet with a single wound; if one arrow takes effect, it is immediately followed by two or more others"; and this is well shown by the cases in the report—thus, "Private C. 2, 13th Infantry, received, May 24, 1868, while on herding duty, about half a mile from Camp Reeve, seven arrow wounds. One arrow entered the cavity through the eighth dorsal vertebra, and one through the ninth; three passed through the forearm, one between the fifth and sixth ribs on the right side, and one through the palmar surface of the right hand. Death was apparently instantaneous." Again—"N. C. received nine arrow wounds—one in the post-gluteal region, one in the left lung, one in the abdomen, one penetrating the humerus," and so on. The arrow in the gluteal region had penetrated ten inches and a half. The man died a

few hours after admission to Hospital. Private C. D. S. received five arrow wounds, and was scalped. He died in a few hours from the wound inflicted by one of the arrows, which, piercing the cartilage at the junction of the first rib with the sternum, "had cut the edge of the right lung, and had inflicted a slight wound, one-eighth of an inch in length, in the descending vena cava," causing fatal hæmorrhage. And private J. S., a cavalry soldier, was wounded by three arrows, one of which, passing through the right lumbar region, "penetrated the abdominal cavity to a depth of about eight inches or more," and of this wound the man died the next day.

Then special reports are given of eight cases of arrow wounds of the head and neck; in five the cranial cavity was penetrated, and of these five patients four died. One case we will quote, to show the force with which the Indians can discharge their arrows. Private M. W., 4th Cavalry, was killed by Indians while on duty as one of a mail-stage guard. "The escort being attacked by a band of Comanches, this soldier was wounded by an iron-headed arrow, which entered the squamous portion of the left temporal bone, and penetrated the left cerebral hemisphere to a depth of an inch or more, causing intracranial bleeding, which was speedily fatal. The skull was punctured without fissuring. There was no splintering internally; the vitreous table was as cleanly divided as the outer table." It appears that some difference of opinion obtains as to the characters of the penetrating wounds of the skull by arrows. Dr. Bill believes that they are generally "characterised by a linear puncture of the outer table, corresponding to the size of the arrowhead, with a crack usually extending from either edge proportionate in length to the momentum of the arrow, while the inner table, struck by the arrow's point at a reduced velocity, is usually splintered and depressed." But it appears that the specimens in the Army Medical Museum "show both tables of the calvaria punctured, with little or no fissuring externally or internally. In all the specimens the arrowheads have been literally impacted, the vitreous table being penetrated as cleanly as the outer." Indeed, the reporter says that "the force with which arrows are projected by the Indians is so great that it has been estimated that the initial velocity of the missile nearly equals that of a musket-ball. At a short distance an arrow will perforate the larger bones without comminuting them, or causing a slight fissure only, resembling the effect of a pistol-ball fired through a pane of glass a few yards off." The report from which we quote gives seven special cases of arrow wounds of the chest, most of which were fatal; but there were "two remarkable instances of recovery after penetration of the pleural cavity by arrows." Wounds of the abdomen are, as might be expected, very fatal: of nine cases reported seven were mortal, "and in the two cases of recovery there was room for doubt whether the arrowhead penetrated the peritoneal sac." The Indians are well aware, it appears, of this great fatality of arrow wounds of the abdomen, and, according to Dr. Bill, they always aim at the umbilicus, so that "the Mexicans are accustomed, when fighting the Indians, to envelope the abdomen as the most vulnerable part in many folds of a blanket." One curious case is mentioned of a man who was accidentally wounded by an arrow, "which entered the back three inches to the right of the fifth lumbar vertebra, and emerged about two inches to the right of the ensiform cartilage," thus completely transfixing the body; but he recovered quickly and perfectly. In all, we are given reports of eighty-three cases of arrow wounds, of which "twenty-six, including nearly all in which the three great cavities or the larger bones or joints were involved, proved fatal;" but, the reporter remarks, "a greater fatality would be represented had more complete returns been made." And our Professional brethren are sometimes victims to the arrow as well as to the bullet, for the reporter adds—"for example, in some recent instances, the Surgeon's own name would be among those appearing in the

list of killed and wounded" had the returns been complete. Some of the engagements in which arrows were employed with deadly effect were by no means slight affairs, for, among several of the casualties of which the reporter could not find any return, one is mentioned in which a colonel of infantry and forty-nine soldiers were killed, "most of them by arrow wounds." It would appear that generally no particular difference exists between the war-arrow of the Indian and the arrow for the chase, except in one important point. We are told that, "in order to prevent the easy extraction of the arrowheads, those of the war-arrows are often only glued to the shaft, which glue, becoming softened from blood, etc., readily detaches the head from the shaft."

It is worth remarking that the reporter gives no support to the old and widespread belief in the poisoning of arrowheads. The Medical Museum contains many specimens of arrows which were believed by their collectors to be poisoned; but the reporter says, "repeated experiments that I have made, of inserting the points beneath the skin of small animals—as frogs, birds, and mice—have had negative results, the punctures healing readily, and the animals surviving. The Indians may dip their arrowheads in rattlesnake venom or the decayed livers of animals, as is commonly stated, but it is more than doubtful if the arrows thereby become poisonous."

It is to be observed that the report nowhere mentions the distance at which the arrows which proved so deadly were discharged; but, seeing how effective and fatal their fire can be, we can hardly wonder that Dr. Bill, who has seen so much of it, should "suggest the employment of archers with regular troops to pick off sentinels noiselessly," though we may agree in the observation that "he remains more strictly in his province as a Medical officer in advising a cuirass for soldiers employed in Indian hostilities."

Before quitting our subject we must add a word in admiration of the splendid way in which these reports of the American War Department are got up and issued. If this excellence is a result of Republicanism we are almost persuaded to become followers of Citizen Dilke.

THE WEEK.

TOPICS OF THE DAY.

A VERY large deputation of members of Parliament, accompanied by Mr. Curgenvin, attended at the Home Office on Saturday last, to present memorials to the Home Secretary, signed by 87 Surgeons and Physicians of eminence in London, 279 Physicians and Surgeons of the towns where the Contagious Diseases Acts are in operation, and 2143 other members of the Medical Profession. The memorialists prayed the Government to leave the present Contagious Diseases Acts, as far as their main principles are concerned, unaltered. The weight and influence of the gentlemen forming the deputation are enough, we should think, to discourage a stronger man than Mr. Bruce from attempting to interfere, at the instance of the classes who oppose these Acts, with measures which already are said to have reduced venereal diseases in the towns where the Acts are in operation one-half. In promising to lay the matter before his colleagues, Mr. Bruce did all that could be expected from him; but we shall be surprised if any part of the Contagious Diseases Acts of 1866 and 1869 be repealed in the present session.

The meeting which was held under the presidency of the Archbishop of Canterbury on Tuesday last for the purpose of raising funds to wipe off the debt on King's College will, we hope, give a successful impetus to that work. King's College is the largest educational establishment in London in which, in addition to ancient and modern learning and science, the principles of the National Church are taught. It educates 900 adult students (including the Medical) and 450 boys. "*Sancte et*

sapienter" is its motto, and we may hopefully believe that the inscription over its gate is not belied within its walls. On the whole it is perhaps the most successful attempt of modern times to unite dogmatic religious teaching with a free study of science and literature. But the history of its debt is a striking instance of the narrow insular prejudices of some of our religionists. The College was founded to oppose the "godless" University of London, now University College. This was at the time of the Roman Catholic Emancipation movement, and amongst the supporters of King's College were Sir Robert Peel and the Duke of Wellington, both of whom were in favour of Roman Catholic Emancipation. Party feeling ran very high on the matter, and amongst other results was a duel between the Iron Duke and the Earl of Winchelsea. Another result was that a portion of the Council and original supporters of King's College, who had promised large sums for its maintenance, on the plea that they had no confidence in the Duke and Sir Robert Peel broke their words, refused to pay their money, and left King's College £13,000 in debt. This specimen of Christian unity and fidelity was worthy the religious bigotry from which it emanated. We trust that the attempt to remove the debt will be successful. Not only is King's College one of the most useful and best managed of the London Medical Schools, but it is an admirable training-place for all kinds of work. Convinced as we are that society cannot exist without religious belief, we wish success to an institution which teaches the best system of morality, and the only historic faith (with the exception of the Jewish and the Mahomedan, the latter of which is a mongrel offshoot of Christianity) that the world possesses.

The case of Mr. Edmunds, the solicitor, of Newent, who was acquitted last week at the Central Criminal Court of a charge of manslaughter of his wife, is not a pleasant one in its Medical aspect. The main witnesses against Mr. Edmunds were a servant and his niece and Dr. Bass Smith, who had been called in at the time of Mrs. Edmunds's death, and had given a certificate to the effect that the death was due to natural causes. But we conceive that the circumstances brought out in the evidence are of a kind to demand investigation, inasmuch as Dr. Bass Smith is a Practitioner of Medicine registered under the Act of 1858.

We are glad to see that the Kensington Vestry have spontaneously raised the salary of their Medical Officer of Health, Dr. Dudfield, from £200 to £300 per annum. At the meeting at which this unusual piece of liberality was perpetrated, Mr. Bosanquet said that the difference between an efficient and a bad Medical Officer of Health was thousands of pounds in the ratepayers' pockets in favour of the former. We are glad to see that the schoolmaster is abroad, and we hope that the other metropolitan vestries will speedily follow the example set them by Kensington. We congratulate Dr. Dudfield on the appreciation shown of his services, and we still more congratulate the Vestry and inhabitants of Kensington on having secured them.

The *Times* Bengal correspondent, in his letter dated Calcutta, April 19, which appeared in the *Times* of Monday last, writes:

"Calcutta and the neighbourhood are suffering very severely from a disease only known previously to the older Medical Practitioners—the 'dengue fever,' or 'red,' or 'dandy fever.' It is not dangerous to life, but the pain in the joints is said to be dreadful, and a rash like that of scarlet fever appears. The pain is described as somewhat of the nature of an acute rheumatism. The fever appears to be well known in other tropical countries, but has not been remarked in India, save in a very few cases, since 1853. A large number of people have been attacked by it in Calcutta, and there is a general dread of it.

"A very severe form of cholera is reported to have broken out in the pretty French settlement at Chandernagore, about seventeen miles (I write from memory) from Calcutta. The troops, and especially coolies, returning from the Looshai expedition have suffered severely from cholera."

Dengue seems to be a fever which combines the characters of an exanthematous with those of a rheumatic fever—in fact, its nosological name is *scarlatina rheumatica*. It has been described by several Indian and American Physicians. It has prevailed in various parts of India, in the Southern States of America, and even in New York, and in the West Indies. The disease is characterised by a sudden attack of pain and swelling of the joints, succeeded by high temperature and intense pain in the head and eyeballs. Swellings of the lymphatic glands and testicles are common. There is then a distinct remission, which is afterwards followed by an eruption that appears on the fifth, sixth, or seventh day, and which sometimes resembles the rash of scarlatina, sometimes that of measles. The disease has never been observed in England, although a rheumatic form of scarlatina is not very uncommon here.

Mr. Moore, the Curator of the Gardens of the Apothecaries' Society at Chelsea, will deliver a course of lectures on botany this year, under the auspices of the Master and Wardens of the Society. The lectures, six in number, will be delivered on Wednesday and Saturday afternoons, commencing on Saturday, May 25. Medical Practitioners and registered Medical students can obtain cards of admission to the lectures on application at the Hall.

DR. BALLARD AT WALSALL.—THE DOUBLE HOSPITAL FUNCTIONARIES UNDER EXISTING SANITARY LAW.

WE learn from the *Midland Counties Express* that there were no deaths from small-pox last week in Wolverhampton, and that the vaccination of babies is being carried on with a most creditable vigour and success. For instance, out of 451 children born in Willenhall and Wednesfield during the last four months of 1871, 391 had been vaccinated, three were found insusceptible, seven had removed, forty-five died, and the remaining five were all in hand. If registered children are looked after thus, there will soon be no reason to complain of the general state of vaccination.

The small-pox is still very prevalent at Walsall, which has been, in consequence, visited by Dr. Ballard on behalf of the Local Government Board. The Walsall local authority had written to the Local Government Board to inquire whether they, as sewer authority (*i.e.*, local authority), being bound to provide Hospital accommodation during epidemics by the Sanitary Act of 1866, might enter into a contract for this purpose with the guardians, who have, of course, some Hospital attached to their workhouse. The answer is important:—

“You inquire whether they will sanction an arrangement proposed to be entered into by the Guardians of the Walsall Union with the Council of the Borough of Walsall, acting as sewer authority, by which the Guardians may be enabled to receive and treat in the temporary Small-pox Hospital at the workhouse as many non-pauper patients as could be accommodated, on payment of a weekly sum for their maintenance. I am directed to state that the Board are of opinion that the Guardians, even with the Board's sanction, cannot legally enter into such an arrangement as that proposed. The Board have, however, introduced a provision into the Public Health Bill, now before Parliament, for the purpose of enabling Guardians to receive pay patients into the infectious wards of the workhouse.

At a meeting of the Guardians, the following uncomplimentary picture is drawn by Mr. Palmer, one of the vaccinators:—

“What is the state of Walsall? Filthy accumulations prevail, often by the dwellings of the miserably poor. Their own uncleanness I fear will be a thing of permanence. Were the middens closely inspected much would in a short time be gained. Till the last week there were tenements in Navigation-street where they had no privies fit for use. For months they received excrements in the houses. All the ash-pits where I reside in Bridgeman-place are an existing nuisance, full to repletion. Where can be the service of small-pox return papers and appointment of additional vaccinators? Leave the Medical men their harvest of revaccinations. Let tumbrels and scavengers be actively employed and this malady and the advent of malignant fever will be prevented.”

Dr. Ballard then laid before the Guardians the following practical summary of their duties, which may be usefully applied elsewhere:—

“It would be advisable for the Board to issue a placard calling attention to the fact that small-pox was amongst them, stating the hours when the vaccinator would attend to special cases, and advising the population to be re-vaccinated. It became the duty of the Guardians—who were the nuisance authorities for such parts of the district as were not under the jurisdiction of Local Boards, to use measures for preventing the spread of the disease. In such districts it was their duty to exercise the power given to them under the Sanitary Act of 1866, more especially that contained in the 22nd, 29th, and 37th and 39th sections of that Act. It was the duty of the Guardians, in districts for which they were the nuisance authorities, to serve upon the owners or occupiers of houses notices to cleanse and disinfect within twenty-four hours; and in the event of the work not being done within that time the Board had power to do the work and charge the owner or occupier with the costs incurred. In such cases, where the owners or occupiers were too poor to do the work, the Board had power to pay the costs of performing the same. The Act also gave them power to erect a place where infected clothing might be disinfected. He thought that the Guardians did not require a building for that purpose, as the clothing might be disinfected in those houses where the inmates had suffered from small-pox. The 24th section gave them power to provide a vehicle for the conveyance of persons suffering from infectious diseases. He saw that the Guardians had provided a vehicle, but he was bound to tell them that it was not safe to convey small-pox cases in. It was possible that some day when they had a very bad case to remove they would find the patient dead before he reached his destination, for persons suffering from small-pox often died in transition. The vehicle ought to be so constructed that the occupant could lie down whilst being conveyed. The Guardians were further empowered to proceed against persons exposing themselves in the streets whilst suffering from the disease, and to prosecute persons for dealing with infected clothing.”

ANOMALIES IN THE VACCINATION ACT.

VACCINATION has sufficient difficulties to contend with in the ignorance and prejudice of many foolish and unreflecting persons. Nothing is more difficult to eradicate than such prejudices. Education is not always sufficient to effect this. We much regret, then, that any mere technical objections should be taken to the Vaccination Act. The following proceedings are undoubtedly strictly legal, but are they wise or equitable? What can the public think of them? Their effects must be inimical to the progress of vaccination, particularly in the rural districts. At the West Riding Court, last week, Thos. Colbeck, miner, Milnthorp, was charged with neglecting within three months of the birth of his child to take it to a properly qualified Practitioner to have it vaccinated. Mr. Roberts, the Vaccination Officer for the Wakefield Union, supported the summons. The case was a singular one. The child had been vaccinated by Mr. J. Newton, an unqualified assistant of Dr. Wade's, who resides in the district, and the certificate had been signed by him “*pro* W. S. Wade.” The legal adviser of the Local Government Board had refused to receive the certificates as valid, hence the present proceedings. Mr. Roberts said he had given notice to Mr. Newton to discontinue the practice, but he refused to do so. The Chairman said if Dr. Wade had signed it, it would have been right. Mr. Roberts remarked that if the certificate had been signed by Dr. Wade he would have had no objections. He had registered many signed by Dr. Wade. The Chairman asked if there was no power of delegation. Mr. Banks replied in the negative. If that were so a Medical Practitioner might scatter himself all over the country. Mr. Wainwright remarked that Mr. Newton was the joint agent of Dr. Wade. Mr. Banks replied that no person could certify that there had been successful vaccination unless he had been duly registered; no other person had a right to sign the certificate. The Chairman asked, As there are other cases would Mr. Roberts be satisfied with a

penalty in one case? Mr. Roberts had no objection to withdraw the other cases providing that the costs were paid. He only wanted the law to be carried out, and had no feeling in the matter. The Chairman said they would impose a penalty of 2s. 6d. in Colbeck's case, and 9s. costs. In the other cases there would be 9s. costs in each case to pay, amounting altogether to 38s. 6d. We do not hesitate to say that these proceedings will do much injury to the cause of vaccination.

ARMY MEDICAL DEPARTMENT.

WE are happy to hear that the sluggish stream in which the senior members of the Army Medical Service have for so long been jogging along to their own great apparent contentment, but to the fretting and fuming of the obstructed masses behind them, is likely soon to be stirred into unwonted activity and life by the sudden descent of the good angel "Retirement," bearing "Promotion" on her wings. Such visits have latterly been so few and far between that the approaching event well deserves the appellation of angelic. Inspectors-General Lawson, Paynter, and Dane are shortly about to retire; the last-named officer, we hear, is likely to get the good service pension of £100 per annum. Inspector-General Mouat is now on his homeward journey from Bombay, in delicate health, but his retirement is not expected to be immediately necessary in consequence. The promotions among the Deputy Inspectors-General will probably be strictly according to seniority, in which case Drs. J. Fraser, C.B., J. H. Ker Innes, C.B., and Professor Longmore, C.B., will be the first on the list. Deputy Inspectors-General O'Flaherty, C.B., and Balfour are also mentioned as being about to be promoted. It is expected that the promotions of Professor Longmore and of Dr. Balfour will be special, and that both these gentlemen will be retained in their present respective appointments. We should have been glad to have been able to include the name of Dr. C. A. Gordon, C.B., among the new Inspectors-General, and trust that before very long we may have the pleasure of recording his promotion as a recognition, late though it may be, of his eminent services in India, and lately as one of the Medical Commissioners sent by our Government into Paris during the siege. Inspector-General Muir, C.B., has arrived in London to assume his duties as head of the Sanitary Branch of the Army Medical Department.

UNIVERSITY OF LONDON.—PRESENTATION-DAY.

ON Wednesday afternoon, May 15, the annual meeting of the Senate and graduates and their friends took place, under the presidency of the Right Honourable Earl Granville, K.G., the Chancellor. The graduates who had passed in the several faculties during the preceding year, and the undergraduates who had obtained exhibitions, prizes, and medals, were presented to the Chancellor to receive their diplomas and distinctions. The Registrar, Dr. Carpenter, read a report of every examination held during the year. After congratulating the successful candidates, the Chancellor, in a brief speech, alluded in a graceful and feeling manner to the loss the University had sustained by the death of Mr. Grote, the late Vice-Chancellor. The Right Hon. Robert Lowe, the Member for the University, next addressed the meeting at some length, touching upon several points of importance to the University. He strongly advocated such a modification in the matriculation examination as would open a University career to students without requiring of them any knowledge of Greek. This proposition has been before the Annual Committee of Convocation for some time, although at present nothing definite is settled upon; but the arguments urged in its favour by Mr. Lowe express views held by a large number of the members of Convocation. In contrasting the inducements offered to students by the Universities of Oxford and Cambridge with those held out by the University of London, Mr. Lowe remarked that in the former the degrees were

not nearly so difficult to attain, and that throughout and after the course necessary for their attainment handsome prizes and fellowships were within the reach of diligent men; but that at London, where the degrees were more difficult to be gained, there was but scanty provision for remunerating or continuing hard intellectual work. Although Government could not do more to increase the number or value of the scholarships, Mr. Lowe threw out the hope that some of those rich men—of whom there are many in this metropolis—having money to give away, and wanting a good object upon which to bestow it, would see this want in the University as he saw it, and leave some of their wealth to provide for it. We thoroughly endorse this good wish.

DR. HILL AND THE ST. PANCRAS GUARDIANS.

How can the affairs of a large parish like St. Pancras be conducted properly when vestrymen are apparently totally ignorant of the law, and set at defiance the opinions of their own legal advisers? The course pursued by the guardians of St. Pancras with respect to Dr. Hill is really deplorable, exemplifying as it does a degree of ignorance and obstinacy which can scarcely be surpassed. It will be remembered that Dr. Hill had informed the Board that he should be contravening an Act of Parliament if he did not make post-mortem examinations on the order of the coroner. The guardians doubted this, and applied to their own solicitor for advice. The opinion of this gentleman was laid before the Board at their last meeting, and was to the following effect: that, according to the terms of 6 and 7 William IV., cap. 89, sec. 5 and 6, the Medical Officer was compelled to attend coroners' inquests, and it was his duty, should the coroner require him, to make a post-mortem examination in cases where he had been the last Medical Practitioner in attendance upon the deceased. The coroner had only the power to call in another Medical Practitioner when he suspected that the attending Medical Officer had not exercised proper Medical skill. We do not place implicit faith in this opinion, which in one respect is certainly erroneous. The coroner has the power to summon any Medical witness he pleases, provided the witness be properly qualified. But if the solicitor was in error, what are we to think of one of the guardians, who said that there was no law in the land that could compel a man to make a post-mortem examination unless he wished to do it? We refer the sapient guardian to the Medical Witnesses Act. Of course Mr. Watkins "condemned in strong terms the course hitherto pursued by the Medical Officer." This is the present condition of the "happy family."

SANITARY KNOWLEDGE OF MEDICAL PRACTITIONERS.

How far the Medical gentlemen of Worcester are open to the reflections of a member of their Town Council we cannot say, but strongly suspect Mr. Bozward thinks he "knows more than other people." Here is his dictum respecting the city of Worcester, its Medical citizens, and the hygienic condition of the city:—

"At the quarterly meeting of the Worcester Town Council last week, Mr. Bozward, a Councillor, speaking on the proposed appointment of a Government officer of health and sanitary inspectors, said he did not think that Medical gentlemen were the best judges on sanitary matters. He did not think that the present system of drainage of the city was calculated to promote the public health. He believed it had not been shown yet that even in that city the Medical Profession had been aware of the dangerous character of the present system of sewerage, the want of ventilation, and the excessive danger of sewer gases finding their way into people's houses and poisoning the inmates. Mr. Bozward added, that twenty years' experience of the drainage of that city and the opinions of the Medical gentlemen thereupon, showed that the Medical Profession were not sufficiently well up in sanitary matters as to justify that Council in spending the ratepayers' money in appointing a public Medical Officer of Health."

OXFORD SCHOOL OF NATURAL SCIENCE.

THE Board of Studies in Natural Science at Oxford have just issued a series of instructions as to the range of the subjects included in each examination. We are bound to say that if fairly acted up to, which we have not the slightest doubt will be the case, this examination will speedily attain to an eminence, which in the meantime is highly desirable, as a good ordinary science degree. Turning to biology as the subject with which we are most immediately concerned, we are tempted to make certain remarks, especially with regard to the books recommended. As to general anatomy and histology, we miss certainly the best book we know for the student—viz., Frey's "Histologie." This, as translated into French by Ranvier, is certainly a readily accessible and most useful work on the subject. So, too, for comparative histology, Leydig's is about the best book, and it is not mentioned. A book well worth referring to in comparative anatomy—Oscar Schmidt's—is not given. Hermann's "Handbuch der Biologie" is a book we do not know—if in existence. Hermann's "Grundriss der Physiologie" is well known, and deservedly so. Vierordt's "Physiology" is certainly better worth studying than some here mentioned. Though physiological chemistry is included in the list of subjects, there is no reference to the admirable works of Kühne or Hoppe-Seyler. On the whole the list wants revision.

SOCIETY FOR THE RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.

Is there any class of the community less provident than our brethren? We doubt it. There are, no doubt, many causes for the poverty in which many die. We are compelled to "keep up an appearance," occasionally to live at "a going point," and to leave those who are near and dear to us in poverty. We say "compelled," but it is not so; a little foresight, a little providence, would save at least the last and the worst of the miseries. There is a society in London, well known, rich, generous, and giving its bounty like the spring of Hoadly,

"That was scarcely heard or seen to flow."

And for two guineas a year—little enough as a premium for such an assurance—a man may obtain for his wife and children a yearly allowance after his death, which, if not sufficient "for all things," keeps them at least in comfort. The poorest amongst us can hardly say he cannot afford such a payment; and yet in this great metropolis and its suburbs, numbering some thousands of Practitioners, there are but 411 members, being a decrease of eighteen on the previous year. The report of the Society, as read at the annual meeting held last week, was as follows:—

"Receipts £2936; grants £2600; the expenses are £250—leaving a balance in favour of the Society of £83. During the year nine new members had been elected, seventeen members had died, ten had resigned or ceased to be members. Four widows and seven children had been added to the list of recipients of grants, four widows and fourteen children had died or become ineligible for relief. The numbers on the books at the present time are fifty-five widows and forty-three children."

We earnestly urge upon our brethren to join this excellent Society, and upon those who can afford it to contribute liberally to its funds. If the curtain could be drawn which shrouds the forms of many of the recipients of the Society's donations the surprise would be great, indeed, to see that some of them had once moved in the highest ranks of the Profession.

HEALTH OF LIVERPOOL.

A GREAT many cases of small-pox are being introduced into Liverpool by emigrants. Within five days of last week twelve patients suffering from it arrived in two vessels from New York, and on Thursday, the 9th inst., two German emigrants, ill of the same disease, were received into the parish Hospital. Dr. Trench, in announcing these facts, warned the inhabitants of the town against any relaxation in vaccination and disinfection.

"THE LONDON HOSPITAL SCANDAL."

WE insert elsewhere a few words on this matter from the pen of one of the fairest and most judicially minded members of our Profession. If a scandal exist which affects the character of any man acting in a public capacity, it is of no use to complain of one of the later steps, but the whole thing *ab initio* should be laid bare to the judgment of those whose place it is to form a judgment. Three questions at least are involved. One is the alleged occurrence of an accident during a Surgical operation; and in this case the boldest rule is the wisest, and Liston's example might be usefully followed when he brought his well-known aneurism case before the Medico-Chirurgical Society. A second question is the duty of colleagues to each other in case of difference as to practice; and a third is the general efficiency of a Hospital as a place for the relief of the sick poor, and the duty or otherwise of Hospital officers to represent to the Committee any circumstances which may interfere with its efficacy. Every case must be judged on its own merits; and for this purpose we want the facts.

DR. MOUAT ON THE ANDAMAN ISLANDS.

THE inhabitants of Dublin had the opportunity during the past week of hearing two most interesting and instructive lectures on the Andaman Islands delivered, on the 9th and 10th inst., by Dr. F. J. Mouat, late Inspector-General of Prisons in Lower Bengal, and of at the same time contributing to the funds of the City of Dublin Hospital, on which the present epidemic of small-pox has made sad inroads. We regret to observe that neither thirst for information, a desire to contribute towards such a laudable object, nor even the presence of the Lord-Lieutenant and his "faëry queen," was sufficient to induce the citizens of Dublin to attend in such large numbers as might have been expected. The lectures were so fully reported in the Dublin papers that the absentees have had ample means of estimating the value of the information given by Dr. Mouat, though they can never by simple perusal compensate themselves for the loss they sustained in not having heard the lectures delivered in the vivacious and brilliant style now well known to the frequenters of many of the London societies.

UNIVERSITY COLLEGE HOSPITAL DINNER.

THE annual dinner in aid of the funds of this Hospital was held at Willis's rooms on Thursday, May 9, his Royal Highness Prince Arthur in the chair. The royal president was well supported, and fulfilled his duties in an exceedingly pleasing manner. His bearing—modest, yet dignified—was such as we rarely see in one so young, and clearly betokened the care with which he has been trained for his high estate. It is no part of our business to extol the merits of University College Hospital, though we may admire the singular good fortune it has had in gathering such a staff as it possesses, and to make a small Hospital of 150 beds one of the leading schools in the metropolis—certainly the one to which last year there was the largest number of entries. Altogether the dinner was a success, not the least happy incident in its course being an admirable speech from Sir William Jenner. A liberal list of subscriptions was announced in the course of the evening.

MM. FANO AND FERREOGObI.

IN reference to the alleged deaths of these gentlemen, we have received a letter from our Paris correspondent, who says—

"Allow me to correct an error into which you have been led by the Paris journals, and which appeared in your editorial of the 11th inst., with respect to the deaths of MM. Fano and Ferreogobi, two well-known Surgeons, who had disappeared since the repression of the insurrection, and who are stated to have been among the victims who were summarily executed by the Versailles troops whilst they were endeavouring to protect a number of wounded insurgents near the Place St.

Sulpice, in the conflict of last year. Whether the above be true or not it is not for me to say, and we must only wait the result of the inquiry which you say has commenced into the matter; but what I can say, and vouch for, is that, whatever has become of M. Ferreogobi, M. Fano, the well-known Surgeon and *agrégé* of the Faculty, who is, besides, a distinguished oculist, is still alive, and there can be no doubt of the fact, for I saw him yesterday. It was a young Doctor of the name of Fanau who, it is said, was shot under the above painful circumstances, but as there were different versions of the affair published at the time, I shall not trouble you with them here."

SMALL-POX JOTTINGS.

ONLY one death during the past fortnight from small-pox was reported last week to the Mile-end Old Town Vestry; in Poplar it was on the increase.—In Kensington during the past month small-pox had been fatal to five persons, and the number of new cases was twenty-four.—In Lambeth the disease is still decreasing.—The Lords of the Admiralty have ordered that for the future all engineer students and shipwright's apprentices are to be revaccinated before they are entered upon the books of Chatham Dockyard.—The return from the Small-pox Hospital, Aberdeen, up to Monday shows—Total number of cases admitted since opening, 198; number of patients in Hospital, 21; total discharged recovered 144; total dead, 33.—The fatal cases of small-pox in London, which in the two previous weeks had been forty-one and sixty-two, declined last week to thirty-nine.—During the past fortnight there have been six deaths from small-pox in Chelsea. Dr. A. B. Barclay reports—"I have the best reason for believing that the case reported a fortnight ago as one of cerebro-spinal meningitis was one of undetected small-pox of the petechial kind. This is one of the most malignant forms in which the disease presents itself, and is almost invariably fatal before the small-pox vesicle shows itself. The immediate occurrence of another case of small-pox in the same house, and the detailed description of the case, leave no doubt in my mind as to its true character.—In the week ending Saturday, May 11, forty-seven deaths from small-pox were registered in Dublin. This is a decrease of ten on the number registered in the previous week.

PAROCHIAL MEDICAL OFFICERS IN SCOTLAND.

At a meeting last week of the Garioch and Northern Medical Association, it was unanimously resolved to petition Parliament in favour of that part of Mr. Craufurd's Bill relating to Medical relief—more especially Clauses 28 and 29—which would "assure to the Medical officers of parochial boards such a secure tenure of office as to render them more independent in their intelligent exertions for the good of the community, and place them in a position more consonant with the dignity and deserts of the Profession."

POOR-LAW MEDICAL OFFICERS' ASSOCIATION, IRELAND.

THE annual meeting of this important Association, which has already effected great good, will be held on Monday, June 3. We hope it will be numerously attended. The objects of the Association are known to our readers. We heartily commend them to our Irish brethren, who, if united and firm, can carry out, we believe, all that they contemplate doing.

FROM ABROAD.—CLINICAL INSTRUCTION AT VIENNA.

A LETTER from Dr. O'Connell in the *Boston Medical Journal* for April 4, describing the opportunities and circumstances of the Vienna Medical School, contains some observations of interest. First, as regards the patients. These, on account of the poverty of the lower classes, are enormous in number, supplying the clinical Professors with never-failing material; and the consequence is that they have to submit to what may be almost called a brutality of treatment that would not be tolerated here, and still less in the United States.

"They are compelled by necessity to avail themselves of Hospital treatment, and submit to what in America would be termed 'whatever indignities' the Professors choose to inflict upon them. Thus, in the lecture-room of Professor Hebra it is not an unusual occurrence for patients, stark naked, to be kept standing and shivering, on exhibition before the students, a half-hour at a time. Indeed, the length of time the patient is kept standing is not a matter of consideration at all; his feelings do not form any part of the case, and the Herr Professor lectures on until he is fully satisfied, however long it may take—the unresisting individual being required afterwards patiently to exhibit himself to the closer scrutiny of whoever may have the desire to examine him. At the lectures on syphilis the same freedom of exhibition is exercised on the patients, male and female. They are obliged to expose themselves in whatever attitude will show the disease to the best advantage, and none of them even suspect that they have the slightest right to object to the treatment—to the repeated inspection before students, or to being made continually the subjects of lectures. And so it is in every department of the Hospital. Even the pangs of labour are no protection to the poor female whose case can be made of any use for giving information to the student, or for illustrating any point of theory or practice referred to in former lectures. And this may, perhaps, indicate how little regard is likely to be paid to patients whose cases would naturally excite less sympathy."

After describing the almost unlimited facility which students have of visiting the Hospital when they will, by day or night, Dr. O'Connell refers to the special courses of lectures delivered in it, which render it so attractive to the foreign student and Practitioner.

"But the real value of Vienna to the American student, who, having graduated already, or having practised his Profession at home, comes here principally to refresh himself in studies already made, or to enable him to fill up deficiencies here and there, consists in the facilities which exist for taking *special courses* of lectures and instruction on any subject connected with Medicine. The regular Professors pass along in the even tenor of their way, lecturing day after day and semester after semester, in a routine manner, because this has become their regular business for life. Their duties are fixed; their salaries are, to a great extent, fixed too; retirement on a pension awaits the close of a life spent in teaching; and unless they are ambitious to acquire a reputation (which, by-the-by, they have generally achieved, or have irretrievably failed to achieve, before they became Professors), there is no special incentive for exertion. They do not give special courses. Besides the Professors, however, there are two other classes of instructors who are permitted to avail themselves of the advantages of the Hospital, and who, being unprovided with salaries, find it convenient to strive for emolument and reputation at the same time by giving the special instruction—in short courses of from four to eight weeks—which makes Vienna an attraction to the foreigner. These are the *Docentes*, who are practically aspirants for Professorships, and the *Assistants* to the Professors.

"Thus it will be seen that of the three classes of instructors, those who are most prominent before the Medical Profession at large—those who have acquired a world-wide reputation already, perhaps, and who might be supposed to be the real foundation of the popularity in the Vienna school—have practically little to do with it. Their lectures are fashioned for students who are learning the elements, and who are required to study for years before graduating here, rather than for the graduate who has learned the elements already, and who wishes to acquire special advanced information in relation to particular facts. In illustration of this point it may not perhaps be improper to refer to some of the names of which Vienna is justly proud, and which may make my meaning clear. Taking, for instance, the subject of pathological anatomy, for the study of which, in spite of its immense amount of material, Vienna presents no facilities whatever, the name of Professor Rokitansky looms up, a power in itself. His reputation as a pathologist requires no mention from me. He has a large class made up, by compulsion, of those students who must submit to his examination before they can graduate; but his delivery, his mouthing of his words, is such that even the Germans have the greatest difficulty in guessing what he wishes to express, and as a lecturer he is far from being a success. The other instruction obtainable in this branch consists of short courses of superficial lectures given by his assistants, who, in common with the older assistants and *Docentes*, mark the distinction between their listeners by

charging foreigners an increased price. Thus the famous Professor Rokitansky cannot instruct well, and his subject is too deep for the superficial touch of his assistants. To a person already well informed there is, of course, ample opportunity here to see specimens of rare interest every day; but to the beginner it is difficult to make any progress. Again, another name that is known to fame—Professor Hebra. His lectures are very amusing and very entertaining, and no one can question his ability and knowledge; but his teachings are rambling and unsystematic, and the eagerness with which the special courses delivered by Docentes are sought for, for the purpose of learning to diagnose, &c., indicates how his well-deserved reputation compares with his value as a teacher. And, not to multiply examples, I may say also, in reference to Professor Braun, that there is no method or system in his teaching of obstetrics. Of course there can be no question of his thorough acquaintance with his subject, but his lectures are rambling and wordy; and were it not that he uses the material at his command so freely, and is ready to grant the students any privileges of examination or observation they wish for, there would be little that he says worth transcribing. He is very popular, however, and his class is always large, because the students who wish to graduate are obliged to take his course; and for all others the taking a ticket for his lectures is a necessary preliminary to the free use of the parturient ward as 'Praktikant.'

"From this it will be seen that the special advantages of Vienna do not consist in its possession of instructors who are already known to fame—of men whose reputation is world-wide. Docentes (of whom, perhaps, nobody outside Vienna has ever heard) and Professors' Assistants (persons of no definite position as men of science) are the individuals who make it attractive, not so much from their ability as from the fact that they are permitted to use the patients and material of the Hospital for illustrating their special courses of lectures, and because they are permitted to deliver lectures on particular subjects with which they have made themselves familiar. Does this statement of facts suggest anything in relation to what might be done in Boston?"

In reply to this query, which is obviously of much more general application, Dr. O'Connell expresses his conviction that, while eschewing the abusive mode of dealing with patients practised in Vienna, a system analogous to that carried out there by the agency of Docentes and Professors' Assistants might be easily organised, and would prove highly serviceable.

PARLIAMENTARY—GOVERNMENT LICENSING BILL—CONTAGIOUS DISEASES ACTS—PUBLIC HEALTH BILL.

ON Friday, May 10, the Government Licensing Bill passed through Committee in the House of Lords.

ON Monday, in the House of Commons,

Sir J. Pakington said that, having had the honour of attending at the Home Office on Saturday, with a very large deputation of members of Parliament, to present memorials, numerous signed by Medical men in different parts of England, and praying that the principle of the Contagious Diseases Acts might be maintained, he wished to ask the Home Secretary whether he would lay on the table the memorials with names and other particulars.

Mr. Bruce said that perhaps his right hon. friend would move for their production.

Lord E. Cecil asked whether there was any chance of the Public Health Bill coming on that night, and, if not, for what object it appeared on the notice paper.

Mr. Stansfeld said there was no chance of its being brought on that night.

Lord E. Cecil: The right hon. gentleman has not answered my second question.

The House adjourned until Monday, the 27th inst.

PREDICTION OF THE ERUPTION OF VESUVIUS.—M. Silbermann addressed a letter to the President of the Académie des Sciences, which was dated Saturday evening, May 4, and forwarded by post. In this he announced that on Monday morning, May 6, an eruption of Vesuvius, more violent than those which had preceded it, would take place. In the letter he detailed the atmospheric conditions which induced him to predict the greater violence of the eruption than to take place.

"THE LONDON HOSPITAL SCANDAL."

(From a Correspondent.)

THE recent painful discussions epitomised under the title of "The London Hospital Scandal" raise several questions of a grave public, Professional, and personal character. It is very easy to leap to a hasty decision, as one of our contemporaries, following its natural instinct, has done; but it must be obvious to everyone who has paid ever so little attention to the discussion, that the most important part of the case has not yet been made known, and that it is at present impossible to pass a satisfactory judgment even upon a part of it. The case as it at present stands appears to be as follows:—Circumstances are alleged to have occurred at the Hospital affecting one of the Surgeons, which a colleague felt it to be his duty to communicate to the Chairman of the House Committee. We do not know what those circumstances are; that is, we know them only by vague report, not by precise evidence. Without knowing these circumstances, and therefore, of course, without knowing the nature and extent of the grounds which impelled his colleague to take so grave a step, he has been heartily abused on the somewhat rash assumption that no misconduct—nothing, in fact—can justify one member of a staff from making a representation on the subject to the lay authorities except upon formal consultation with his colleagues. It may be admitted, *in limine*, that such consultation is desirable as a general principle, and probably Mr. Maunder himself will admit that it would have been as well even in this case, with all its exceptional characters, to have adopted this course. But it would be quite an error to suppose that Mr. Maunder stood alone amongst his colleagues in the view which he took. He was the man who acted; but others, and not the least weighty of the staff, felt and feel that he was justified in what he did.

Whether Mr. Maunder be right or wrong on this point is, however, really beside the question. It is a false issue ingeniously raised to divert attention from the graver questions which the public and the Profession are concerned to settle. If the Medical Profession were to accept the proposition that under no circumstances is a member of a Hospital staff to make any representation affecting a colleague, without previous formal deliberation with the staff as a whole, to the governing body, the inevitable result would be that all confidence would be lost between the governing body and the staff; and this means that the present cordial relations between the Medical Profession and the public would sustain the rudest shock. The staff of a Hospital would come to be looked upon as members of a trades union, acting upon the narrowest rules of class interest—as setting themselves in antagonism with the rest of the community. To taboo a man who refuses to enter into a conspiracy of this kind is a thing that can never happen in the Medical Profession, whose just influence for good depends so much upon the unselfish relations it possesses with all classes of the community. The folly of condemning such conduct as unprofessional is only equalled by the absurdity of another proposition, emanating, as might be expected, from the same source—namely, that every individual member of a staff must hold his tongue if the senior Surgeon does not choose to speak.

We have adverted to these points in the discussion because they are those which have been most pertinaciously kept before the Profession. But it must be abundantly clear to everyone that the real question, that upon which the subsidiary ones have been grafted, has only been superficially touched. It must, we venture to think, be clear to Mr. Rivington and his friends that he does not do himself justice, even if he succeed in attaching odium to Mr. Maunder for bringing his conduct before the body under which they both hold office in an irregular manner. When things have gone so far they must go farther. Neither the public nor the Profession can be satisfied with matters as they now stand. The case must be investigated calmly and fairly before a competent tribunal. It is to the interest not less of Mr. Rivington than of Mr. Maunder, as it certainly is to the interest of the London Hospital, that a complete and authentic statement of facts should be substituted as early as possible for the vague, and therefore damaging, rumours, and the painful and useless recriminations now filling the air.

THE FIRST REPORT OF THE LOCAL GOVERNMENT BOARD.

THE Local Government Board was only constituted on August 19 last, but has managed to make of its proceedings during the short period which has since elapsed a blue-book of startling dimensions. This is, in fact, a "three-headed monster," and comprises, in addition to the usual report of the Poor-law Board, the reports of Mr. Tom Taylor on the working of the Local Government Act, etc., and of Mr. Simon on the Public Health. There are visible distinct signs of *imperium in imperio*, inseparable, it may be assumed, from a department in a transition state. No doubt the fusion will be more complete before the publication of the next report. To us, the subdivision is to a certain extent useful, as it renders it possible to deal the more readily with each branch of administration.

Turning first to the Poor-law branch, we find that even under administrators of opposite political views, Mr. Gathorne Hardy's plans for the amelioration of the condition of the sick poor have not been abandoned. "Continued progress," says the Report, "has been made during the past year in providing in the metropolis separate accommodation for the sick." Thus, at Bethnal-green a new wing to the workhouse brings the total indoor accommodation up to 1562; at Camberwell a separate Infirmary for 186 patients has been planned; at Chelsea a site has been secured; at Fulham new wings to the existing Infirmary are in course of erection; in St. George's, Hanover-square, the increase is less; in St. George's-in-the-East a separate Infirmary has been erected and is certified for 257 inmates.

The additional infirm wards at St. Luke's in the Holborn Union, on the same principle as those which have given so much satisfaction at St. Marylebone, were ready for occupation on June 1, 1871, and this workhouse, inclusive of these wards, is now fitted to receive 898 sick poor.

The Guardians of Islington, it appears, whose workhouse was given over to the Managers of the Metropolitan Asylum District for Convalescents from Small-pox from March 13 to October 14, 1871, now propose to utilise its site for a dispensary relief office and outdoor labour yard. For their sick, as we understand, though that is not stated in this Report, they have ample space in their new workhouse at Upper Holloway. At Kensington, Shoreditch, St. Saviour's, and Woolwich new infirmary wards are either completed or in course of construction; but the guardians of the Saint Olave's Union appear to have successfully resisted the efforts of the old and new Central Boards to bring them up to the mark of modern requirements. In speaking of the wants of this union the Report is almost plaintive. An infirmary is wanted, and should be built; or is not wanted, and should be allowed to pass out of mind, and out of the annual reports.

Since the last Report a sick asylum has been opened for 586 patients of the Poplar and Stepney Unions, the guardians of which are thus enabled to devote their workhouses, the former entirely to able-bodied poor, and the latter to the aged and infirm of both unions. The Poplar guardians, availing themselves of Section 50 of the Metropolitan Poor Act, 1867, are enabled to aid other unions and parishes in dealing with their able-bodied, and in carrying out the workhouse test—notably those of St. George's and St. Marylebone, who "have already availed themselves of the opportunity thus afforded them of separating some of the most troublesome of that class from the other inmates of their workhouses. The result has been that very few have accepted the offer of relief on those terms, and those who have done so have almost immediately taken their discharge."

The Report adverts to the results of an interesting experiment which was one of the results of the Metropolitan Poor Act—the placing of pauper boys in a ship instead of in a district school on shore. The ship used for this purpose has been lent by the Lords of the Admiralty, and is moored off Grays, in Essex. The Report says—"We have recently assented to a proposal on the part of the managers to receive into the ship boys from unions and parishes not situated within the metropolis. We have also assented to the purchase by the managers of a small sailing tender at a cost not exceeding 500*l.*, which will convey all stores and water required for the training ship, hitherto the cause of very considerable expenditure for lighterage, and which will, it is anticipated, have a most beneficial effect upon the boys in accustoming them to the sea and in developing habits of practical seamanship."

The progress of Dispensaries in the metropolis must form the subject of our next examination of the Report.

REVIEWS.

Clinical Lectures on the Diseases of Women. By Sir JAMES Y. SIMPSON, Bart. Edited by ALEXANDER R. SIMPSON, M.D. Edinburgh: A. and C. Black. 1872.

[SECOND NOTICE.]

THE larger portion of these Lectures having first appeared in our columns, it will be unnecessary for us to do more than emphatically declare our sense of their great merit, and to remind our readers of the large field of practice over which their teachings extend. The first lecture in the book, however, is reprinted from the volume of Simpson's "Obstetric Memoirs and Contributions," edited by Drs. Priestley and Storer. It is on the subject of the Diagnosis of the Diseases of Women. As it has been long in the hands of the Profession, it may be enough to observe that we know of no better introduction to the study of the diseases of the female reproductive organs than this lecture. The young Practitioner will find in it an account, and a rational one, of that long list of maladies which accompany and mark uterine disease, and which an older generation of teachers was content to ignore, which afforded the quacks their richest harvest, and were given up in despair or prescribed for, but rarely cured, by the legitimate Physician. The lectures which follow are on Vesico-Vaginal Fistula, and on Pelvic Cellulitis. The latter subject was one of Simpson's own. We do not mean by this that he was the first to describe the disease. In modern times it was first noticed by Marchal de Calvi, and amongst ourselves by Professors Doherty, of Galway, and Churchill, of Dublin; but Simpson's teaching and writings were amongst the first which directed Professional attention earnestly to the subject, and his clear instructions as to the Surgical treatment to be pursued render these lectures of the greatest practical value. Pelvic Peritonitis, Peri-uterine or Pelvic Hæmatocele, follow, and bear the same original stamp. In fact, the whole character of these lectures is sustained by the foundation they have in the personal observation and clinical work of the author. It is clear at every page that Sir James Simpson neither borrows from the work of others nor from his own imagination. The latter faculty, indeed, was not wanting; but it was never employed to invent, but only to illustrate.

Passing over four lectures on Cancer of the Uterus and Carcinoma of the Uterus and Mamma, we light on one on "Coccygodynia, and the Diseases and Deformities of the Coccyx." "Coccygodynia" was the term applied by Simpson to a painful affection of the coccyx, which he believed was caused by the action of the muscles attached to it—the glutei, levator ani, and sphincter. He proposed and performed an operation for the relief of this affection, which was the complete separation, by subcutaneous section with a tenotomy-knife, from the coccyx of the muscular and tendinous fibres that are in connexion with it. That this proceeding answered in some instances we have evidence in the cases related by Simpson. In others he acknowledged it failed, and in some of these he had recourse to the removal of a portion of the bone itself. We are not aware that these proceedings have been frequently repeated by others, but cases of severe pain referred to the coccyx are not very uncommon, and where other treatment has not succeeded, Simpson's operation might, we think, be tried. As to the manner in which the separation of the bone from the surrounding muscular and fibrous tissue relieves pain, we are not certain that Simpson's opinion is a correct one—in fact, he himself has suggested another explanation. He writes—"I would only add, in connexion with this point, that there is a leash of nerves lying all round the coccyx, and I once imagined that the relief obtained by isolation of the bone was due to section of these nervous cords." He goes on to say, however, that he thinks the explanation of pain from muscular action is the more probable, and that after the operation no more pain is experienced, simply because the parts are placed in a condition of absolute rest.

Passing over the lectures on Dysmenorrhœa, Closures and Contractions of the Vagina, Caruncles of the Urethra, Diseases of the Vulva, Surgical Fever, Phlegmasia Dolens—all of which contain a vast deal of original and thoughtful teaching—we come to two lectures on Spurious Pregnancy or Pseudocyesis. These lectures form a good specimen of Simpson's manner of treating a subject. He brings together all that he can find on it in ancient and modern authors, recounts cases of his own and such as have occurred within his knowledge, gives full, clear, and precise directions for making a diagnosis, and then,

recognising—in a condition which had been passed over as hysteria or delusion by nearly all modern scientific writers, and had no place in literature except as having furnished a butt for the ridicule of the coarse humourists of the last century—a substantive disease, proceeds to discuss its special pathology. In many of these cases the uterus and ovaries are affected by some form of ordinary disease, but more frequently there is no trace of uterine affection; these local affections, therefore, are to be regarded rather as coincidences than of the intimate nature of the malady. He then notices that spurious pregnancy has been observed in the lower animals. On this point he quotes Harvey, who pointed out, in his work on "Animal Generation," that "overfed bitches, which admit the dog without fecundation following, are nevertheless observed to be sluggish about the time they should have whelped, and to bark as they do when their time is at hand; also to filch away the whelps from another bitch, to tend and lick them, and also to fight fiercely for them. Others have milk—or colostrum, as it is called—in their teats, and are, moreover, subject to the diseases of those which have whelped," etc. Some modern observations confirming the occurrence of these symptoms in the lower animals are added. The clue obtained Simpson thus follows:—"When observed in the lower animals, spurious pregnancy has been remarked to occur within a certain period after the time of heat, and to be distinctly connected with that condition; so that in them it is most probably dependent on the physiological change or changes which are at that time set up in the uterus and ovaries. Menstruation in the human female, as you know, corresponds to the phenomenon of heat in the lower animals—in as far, at least, as the process of ovulation and the ripening of a Graafian vesicle is concerned; and I believe that the aggregate of symptoms which we class under the designation of spurious pregnancy in women is, in some way or other, dependent upon the changes which occur in the ovaries and in the uterus at the period of menstruation. When the irritation associated with the normal or physiological changes in these organs is somewhat excessive either in degree or in duration, and is repeated from month to month, the sympathetic phenomena excited at one period have not had time, in some instances, to subside before a new stimulus is supplied for their continuation by the recurrence of the menstrual molimen. True pregnancy occurs when the ovulum which escapes from the Graafian vesicle duly meets within the mother's body with male spermatozoa, and, as a consequence, a long nine months of local and constitutional phenomena immediately begins to be set up. But the same series of constitutional phenomena, at least, is set up in cases of pseudocyesis when an ovulum escapes, or a reproductive nisus occurs, without any male spermatozoa being present, these phenomena occasionally ending, as we have seen, at the usual extreme term of utero-gestation, in a simulated parturition, or in a kind of *Lucina sine fœtu*, just as in some cases, as among the unmarried, they commence by a kind of *Lucina sine cubitu*, to borrow the language of the old physiologists."

We cannot leave Sir James Simpson on this subject without reproducing from the fund of capital stories with which he used to spice his lectures the very good one of Dupuytren which occurs at page 381. He was consulted by a lady, who asked what was to be done in her case, as she had now been in the family-way for fourteen years. The great Parisian Surgeon gave it as his opinion that, as the boy must be tolerably well grown by that time, the best thing that the lady could do was to swallow a tutor immediately, that his education might not be neglected.

The lectures on Fibroid Tumours, Polypi, Leucorrhœa, Chronic Metritis, Prolapsus Uteri, and Retroversion of the Uterus are amongst those that did not appear in our columns. Simpson was quite alive to the latest advances in the pathology of the diseases on which he treated. He recognised in fibroid tumour of the uterus an example of the myomata or muscle tumours; and on this he founded his treatment. He says—"The fibres, then, are simply those of ordinary connective tissue, and the nucleated fibre-cells are nothing more than the elements of involuntary muscle. But how does this alter our notions as to their curability? Why, knowing as we do that the great mass of muscular matter developed in the uterus during pregnancy gets almost entirely absorbed within six or seven weeks after delivery, we are led, from the very nature of the fibroid tumour, to entertain a hope of the possibility of its disappearing by absorption too." He believes that the spontaneous disappearance by absorption of these tumours is by no means uncommon, and gives instances of it; and he thinks that in bromide of potassium, continued

for a long time, we have an agent of the greatest value in retarding the development and reducing the bulk of these growths. With regard to Surgical measures, gastrotomy and excision of the tumour through the abdominal walls is not recommended by him, although in one case he performed the operation. Enucleation and removal through the vagina he thinks may be tried in some of the cases of submucous tumour when the symptoms are urgent and demand interference. But in the case of large-sized tumours, the operation he affirms to be "attended with the utmost risk, from the great danger that there is of inflammation being set up in the large ragged excavation out of which the morbid mass has been dragged, and also from the likelihood of injury to the peritoneal surface if the tumour have involved much of the thickness of the walls. So that," he adds, "although I have seen one or two successful cases of the enucleation of fibroid tumours of considerable size, I regard it as an unjustifiable operation where the tumour is not already distinctly in process of descent, and I have become more and more inclined to restrict the operation to cases of tumours of small dimensions, when it may certainly be had recourse to with the most hopeful prospects." Removal of portions of the tumour is an operation he thinks of scarcely less risk from the chance of fatal inflammation.

We might continue our gleanings from these admirable volumes to a much greater extent, but we wish only to give our readers a sufficient knowledge of their contents to induce them to peruse them for themselves. We know of few sets of writings in modern Medicine of greater originality or interest, and whether we agree or disagree with the author on points of practice or observation, we cannot refuse the homage to his memory which his genius and industry combined demand.

NEW BOOKS, WITH SHORT CRITIQUES.

History of Medicine from the Earliest Ages to the commencement of the Nineteenth Century. By ROBLEY DUNGLISON, M.D., LL.D., late Professor of the Institutes of Medicine, etc. Arranged and edited by RICHARD J. DUNGLISON, M.D. Philadelphia: Lindsay and Blakiston. 1872. Pp. 287.

** Amongst the duties which devolved on the late Dr. Dunglison, as Professor of the Institutes of Medicine in the University of Virginia, was that of teaching "the history of the progress and theories of Medicine." Few branches of Medical knowledge, in our opinion, are more salutary, and few deserve better to be systematically and carefully taught. The students who attended Dr. Dunglison's lectures had advantages which their successors in the present day do not enjoy, and which this publication is intended to give them. In a short space it enables them to gather a pretty correct view of the state of Medicine amongst the ancient nations, and its progress to the present day. It does what a book of its size can do, and may serve as a useful index to the student who desires to push his researches further into the history and development of any particular point. We must add that Dr. Richard J. Dunglison would have raised a monument more worthy of his distinguished father if he could have found time for a more thorough revision and emendation of the text, and verification of quotations and references. We should like him to verify "the axiom" of Hippocrates, said to be "contained in the sixth book of the Epidemics"—"*Nature is the first of Physicians.*" We should like a reference, too, to the original passage of Galen on which Dr. Dunglison founds the statement—"It is presumable that his practice at Rome was not very extensive, as he mentions having gone twice a day into the country to visit one of his servants, who was labouring under ophthalmia." As it is, there is scarcely a single reference throughout the book; doubtless they did not form part of the original plan, but Dr. Richard Dunglison, in erecting this literary monument to his father, would have done well to make it complete. The account of Hippocrates shows how difficult it is to discriminate which are the genuine works of the Father of Physic; but the author writes in the true Hippocratic spirit, and winds up with practical remarks on the necessity of observation and the distrust of all sects and systems.

Introduction to the Study of Biology. By H. ALLEYNE NICHOLSON, M.D., D.Sc., etc., etc., Professor of Natural History and Botany in University College, Toronto. Edinburgh and London: Blackwood. 1872. Pp. 162.

** A work based upon the introduction to the author's "Manual of Zoology," and intended as an elementary work for the student of Biology. It begins with the differences between

dead and living bodies, the general phenomena of life, and conditions necessary for its manifestation; next the differences between animals and plants; then the differences between various organisms, the doctrine of form, and the doctrine of function, with a chapter on the mixed questions of analogy, homology, homogeny, homoplasia, and homomorphism—a chapter which there is no need to advise the student to skip for the present, and to indulge largely in the knowledge of what things are, before attempting metaphysical conceptions of how they come to be. Then we have a chapter on the principles of classification, followed by chapters on the elementary chemistry and physiology of living beings, which lead to concluding chapters on the "origin of species," and the relations of living beings to time and space. It will thus be seen that Dr. Nicholson's work covers a large ground of fact and speculation. The desideratum in such a work for beginners is that the language shall be clear, and the sentences short. The author, whilst admitting that the term "vital force" has been largely abused, still holds, with Beale, that the term is a necessity of science, to express the cause of changes which chemistry and physics cannot solve.

Address delivered at the Anniversary Meeting of the Geological Society of London on February 16, 1872. By JOSEPH PRESTWICH, F.R.S., etc., President of the Society. London: Taylor and Francis. 1872. Pp. 66.

* * * We have already quoted largely from this excellent address, in reference to the contamination of water-bearing strata by sewage; but we should be doing the author an injustice were we to omit to say that whether for literary skill, for good taste, or for the amount of solid information conveyed, this discourse takes the highest rank amongst compositions of its class. We may refer to the obituary notices of Murchison, Lonsdale, Yates, Herschel, Grote, Robert Chambers, Harcourt, Tate, Mushet, Meeson, and Lortet, and amongst them Rose, of Swaffham, an old and much-honoured member of our own Profession. The passages on the water-bearing strata of London, on well contamination, and on the extent of the English coal-beds ought to receive due attention from politicians and sanitarians.

FOREIGN AND COLONIAL CORRESPONDENCE.

FRANCE.

PARIS, May 7, 1872.

THE "FATHER" OF FRENCH MEDICAL LITERATURE—PROFESSOR BROCA ON THE BRAIN—NEW ANTISEPTIC—M. ROGER ON BRONCHIECTASIS AND DIPHTHERIA—"SURGICAL CONSTITUTION" OF HOSPITAL AIR—DOCTRESSES—CASTIAUX'S ASPIRATOR.

DR. CAFFE, the principal editor of the *Journal des Connaissances Médicales*, who from his age is styled the Father of the Medical Press in Paris, has just recovered from a severe attack of illness, and resumed his weekly *soirées*. They are more of a literary and scientific than of a strictly social character, and are the general rendezvous of the representatives of the different professions.

On Wednesday last the first of a series of monthly meetings, recently organised by the medical press of Paris, took place at Dr. Caffé's, the object of which is to establish a proper understanding between its members and to guard the interest of the Profession at large. After a long discussion as to the best manner of carrying out these desirable ends, the following resolution was unanimously adopted:—"That a committee of three members of the medical press, with Dr. Caffé as President, be appointed to organise a 'Conseil de Famille,' composed of principal editors of the medical journals." These *réunions* will take place alternately on the first of each month, at the editors' private residences, and are confined to the editors and their staff, who, however, have the privilege of inviting even occasional contributors.

Professor Broca has begun a course of lectures on Craniology, which is open to the public as well as to the members of the Profession. Craniology, he said, was the most important branch of anthropology, as it not only treated of the structure and uses of the cranium, but of the brain, by which man is distinguished from the brute creation and even from the monkey, his nearest congener. It was not only by the weight of the brain that man was distinguishable from the other animals, but by the number and form of its convolutions, which were greater in number and much more developed in man.

The lowest weight ever known of the human brain was found in a male adult to be a little over 1000 grammes, or about 33 ounces, and 860 grammes in a female savage—both however being considerably greater than the weight of the brain in the adult male gorilla, which amounts to only 560 grammes. These characters, he said, not only distinguished man from the other animals, but they distinguished the different races; and in this respect the negro would stand the lowest in the scale of mankind.

At a meeting of the Anthropological Society which took place last week, M. Broca exhibited three mummified brains which were forwarded from Bucharest, and which belonged respectively to a Jew, a Roumanian, and a Greek. These were presented, not to explain any differences of race, but to show the remarkable state of preservation they were in, which was effected by a process recommended by M. Broca, of which the following is the formula:—Strong nitric acid 333 grammes water to two litres, or in the proportion of nitric acid one part, water six parts—the quantity of the entire solution amounting to two litres for each brain (the latter being divested of its membranes), which is allowed to stand for two days, at the end of which 666 grammes are added to the above, and the whole to stand for two days longer, after which the liquid is drawn off, and the brain is then exposed to a dry atmosphere. In a short time the brain becomes of the consistence of paste-board, and will remain in a state of preservation for any length of time. In this state, however, the brain is not suited for any other study than that of the convolutions, which can be done here even better than in the fresh subject. M. Broca told me that this preparation could not be applied to any of the other tissues of the body.

M. Roger, Physician to the Hôpital des Enfants Malades, has just begun his clinical lectures; but before entering upon the subject matter of the day's lesson, he exhibited the lungs of a child who died from bronchiectasis, or dilatation of the bronchial tubes, which he said was extremely rare in children. In the present case, the dilatations, amounting to four or five, which occupied the upper and middle lobes, were saccular, and were during life supposed to be tubercular cavities. Fortunately, however, the treatment generally adopted in both cases being about the same, the error of diagnosis could not here have done any very great harm.

Struck by the number of cases admitted into the Hospital, and the number of deaths exhibited in the mortuary returns from croup and "*angine couenneuse*" (diphtheria)—those from the former amounting for the week ending April 26 to fifteen, and those from diphtheria to eight—the lecturer observed that before the war and the disasters which followed this would perhaps not be considered an enormous proportion; but, as the population of Paris, which in the middle of 1870 amounted to nearly 3,000,000, is reduced to just about half that number, it is evident that under present circumstances the proportion of deaths must be looked upon as alarming, and he at least would consider these diseases as reigning epidemically in Paris. The public, he said, shared in the alarm, as the mortuary returns are published in the daily papers—which, he said was objectionable, as people were generally apt to misinterpret figures; and he could not see of what use it would be to the non-Professional world to be informed of the number of deaths that take place from disease. But surely, if kept in the dark, people would suspect the existence of epidemics where there were none, and thus be kept constantly in a state of terror; whereas, when these actually take place and are made known, the public would be induced to resort to such measures as would secure them against an attack.

By last week's return I find that the mortality in Paris has been considerably increased; but this is not confined to the two diseases referred to above. Erysipelas and puerperal affections are also on the increase; and it is to the same common cause, the "Medical constitution" (the bugbear of French Surgeons), that is attributed the great fatality of Surgical affections. I do not deny that atmospheric influences play a great rôle in the dissemination of disease; but the most potent causes are to be found in the Hospitals themselves, which in Paris are proverbially insanitary from overcrowding, and where the patients are miserably treated. About a fortnight ago I witnessed two operations by M. Richet on two female patients in the Hôtel-Dieu—one for a vesico-uterine fistula and the other for hæmorrhoids. The former was done after the manner of Marion Sims, and the latter consisted of a mixed method of the extemporaneous ligature (*ligature extemporanée*) and the actual cautery, to which I shall revert more fully on a future occasion. On Saturday M. Richet announced the death of both these patients from peritonitis, the cause of which affec-

tion, in the present examples, he could not explain in any other way than the one above referred to, as there were simultaneously in his wards a case of traumatic erysipelas and two cases of puerperal fever.

To return to M. Roger, the worthy Professor observed that diphtheria and croup were one and the same disease, but separated only by clinical tradition. He gave us nothing new as to the pathology of these dreadful affections, and not much more of their therapeutics; but he bade us never to forget that they were both eminently contagious and inoculable, and whenever any one member of a family be affected he should at once be removed. Neither disease, he said, was peculiar to children or adults; and as they are both of them sporadic, epidemic, and endemic, these conditions, as in all other cases, respect neither age nor sex. Diphtheria, he said, may remain latent for a considerable time, and he related a very remarkable example of this in a case that occurred in his private practice. He was summoned about a year ago to Boulogne to see a youth suffering from this affection, and on his arrival he directed that the other children (two girls) should be immediately removed. The boy died in forty-eight hours after the visit, and the two sisters who were sent to Paris fell victims to the disease a fortnight after, although on leaving Boulogne they were apparently quite well.

It is curious to observe the difference of treatment in the same Hospital of the same disease. For instance, in the "Hôpital des Enfants," M. Bouchut prefers tartar emetic as a vomitive in croup; whereas M. Roger employs ipecacuanha, as he says that tartar emetic is a dangerous remedy, and that ipecacuanha was sufficient for all purposes of vomiting, and the consequent ejection of the false membranes, without producing that great depression so inseparable from tartar emetic. The syrup of ipecacuanha, however, of the French Pharmacopœia—the *vomitif par excellence* for children—is not sufficiently energetic; in these cases he would therefore add from ten to twenty grains of the powder to each ounce of the syrup, according to the age of the patient, or, if necessary, have recourse to sulphate of copper in preference to tartar emetic. Tracheotomy, continued M. Roger, was his *dernière ressource* in croup, but which should not be put off too long; for, if practised when the asphyxia is far advanced, the patient often dies from the effects of the operation.

At M. Roger's clinique I noticed the presence of two young ladies, one English and the other an American, who it appears are *aspirantes* for the unenviable position of Doctoresses. If they confine their studies to the Hôpital des Enfants, or to the Maternité, nothing can be said against them; but directly they wander to other regions they are clearly out of their sphere, and even Æsculapius himself would probably disown them, as he never calculated upon having female disciples. I cannot do better than direct their attention to "A Woman-Doctor's Thoughts on Women-Doctors," which appeared in your last issue, for their edification; and this reminds me that, besides other weak points, women are in one particular respect eminently disqualified for the Medical Profession, and that is—the impossibility of their keeping a secret. This is so notorious that in Russia, where the telegraph-offices were chiefly filled by women, the Government lately had to dismiss them all, as their confidential correspondence became as publicly known as the most commonplace events of the day; but directly the female clerks were got rid of, matters returned to their normal condition.

On Wednesday, M. Bécлар, the newly appointed Professor of Physiology, began his course of lectures at the School of Medicine under the most favourable auspices, if one can judge from the audience present. The amphitheatre was full to the ceiling, and many Professors and Practitioners honoured the lecturer with their presence. The worthy Professor, after having defined physiology as being the science of living beings, or organic bodies only, said that this term was used in contradistinction to biology, which was the science of nature in its entirety, including everything, animate or inanimate; or, more correctly speaking, organic and inorganic; and whilst the latter were known by certain fixed characters, the former possessed certain properties expressed by the terms "nutrivity," "reproductibility," and "excitability." He then passed in review the most important discoveries in physiology, foremost of which he placed those of Harvey and Charles Bell, and dwelt upon the advantages of vivisection, without which such discoveries could not have been made.

On Tuesday last M. Béhier described the aspirator of M. Castiaux, an *interne* of the Hôtel-Dieu, of which you will have seen a description in the Paris medical journals. In the first place, there is nothing new in its mechanism, it being

simply a modification of Maisonneuve's and Dieulafoy's aspirators, but is more complicated, and consequently more expensive than either. Castiaux's apparatus, however, may be employed for other purposes besides those assigned to the other instruments. Its force is so great that it may be readily converted into a spray-producer, or used for piercing the skin, an operation frequently resorted to where an immediate cautery or issue is required and is called "aqua-puncture."

Those who have resided in Paris will remember the "Trink-halles," or drinking-booths, that are established in various parts of the city for the use of the public in summer. These have already been opened for the season, and are welcome, as the weather has already become sufficiently warm to excite thirst; and at these miniature "châlets" you can get a tumbler of delicious soda-water, called "eau de Seltz" by the French, flavoured with any kind of syrup, for two sous (one penny), and, what adds to the charm, these drinks are served out by girls who are in general good-looking. In winter these fair damsels are replaced by members of the rougher sex, in every sense of the word—being generally Auvergnats—who serve out broiled chestnuts, a small measure of which you can get for a halfpenny. These may be looked upon as "weather signs," as they return every year with remarkable regularity; and to them may be added the public swimming-baths, which are already being established in their usual places on the Seine. The public baths in Paris are most luxurious establishments; and I must say that our Gallic friends, in this respect at least, are far ahead of the Anglo-Saxons, for the first-rate swimming-baths in London are far inferior to the worst ones in Paris.

Among the "weather signs" in Paris may be included the swallows which have come back, besides the "cafés chantants" and open-air concerts, which are also open during the fine weather in the evening, and form the great attraction for visitors as well as for the Parisians. These are situated in the Champs Elysées, where for a franc or two you can have your cup of coffee or any other drink, and listen to the best music and operettas in the world. What can be more soothing or refreshing after a hard day's work, whether of mind or body?

AUSTRIA.

VIENNA, May 1.

THE RESULTS OF PROFESSOR STRICKER'S INVESTIGATIONS ON THE NATURE OF DR. LOSTORFER'S CORPUSCLES—(continued).

HAVING given still more detailed advice on and explanation of the method of investigation, Professor Stricker shows that under such circumstances it can easily be understood how it was possible for him to continually observe many preparations during several days. Standing on such ground, he is able to declare that the corpuscles, which he looked upon as products of coagulation or as pieces of protoplasm, disappear, as a rule, after twenty-four hours' germination. For the present purpose it is of no consequence whether or not the explanation of these bodies be right or wrong. The importance rests in their identity with the corpuscles of Lostorfer, and in the question whether the latter are products of the former. In both instances they would evidence that Lostorfer's bodies may be found in fresh blood of healthy as well as of diseased individuals. This, however, is not the case. Professor Stricker has registered all alterations occurring in plasma-islets of recent preparations, and has been convinced that new granules, which had not been seen in the field before, sprang up immediately around the bodies of fresh blood, although the contours of the latter had already been indistinct and faded away, and that these new granules under continual observation were seen to become larger and larger until they had assumed the shape of Lostorfer's corpuscles. In what manner the bodies of fresh blood perish cannot be said, nor does the phenomenon touch the question under consideration.

The preliminary question—viz., whether or not Lostorfer's corpuscles may be found in fresh blood—has now partly been answered; but the following observation replies to it in a still more positive manner:—There was, in the month of March, in Professor Zeissl's wards, a syphilitic patient whose blood was particularly suitable for Professor Stricker's experiments. He was about 22 years of age, ill-nourished, and had acquired syphilis four months before, consisting originally of a chancre, which was, however, followed by an exanthem and by iritis. From the hands of this patient a few drops of blood were taken, and objects prepared from them, when it was found,

after twenty-four hours, that the edges of the covering-glass were literally covered with the corpuscles in question. A second series of objects exhibited the same appearance. In a third series, however, the same result was not obtained after thirty-six hours, the corpuscles becoming visible only after forty-eight hours.

At about the time of examination of the last series, fires had been discontinued in the laboratory, notwithstanding the still low temperature of the atmosphere. On consideration of the circumstances which might have been productive of the ill-success just mentioned, Professor Stricker's attention was drawn to the difference of temperature, and on the next day the laboratory was heated again to 22° Centigrade. About three hours afterwards the corpuscles made again their appearance in large numbers. Some of them were of such a large size as imperatively to produce the suspicion in the observer's mind either of their having already existed in the fresh blood and escaped observation, or of their having had a rapid growth in this instance—a growth which must be capable of direct observation. On the next day, therefore, a new object was taken, the laboratory heated as the day before, and a certain point of the object's edges put under No. 10 of Hartnack's immersion-lenses and observed. About thirteen minutes might have elapsed since the blood had been taken from the patient, when Stricker thought he perceived some granules within the plasma-islet, which hitherto had been perfectly transparent. Ten minutes later the granules had attained such a definite character as to permit the observer to distinctly notice their position, while at the same time numerous new granules seemed to spring into existence in the same islet. After the lapse of half an hour the first observed granules were of such a size as to be decidedly recognised as those looked for, and after about one hour and a half they were as large as a small pus-corpuscle, whilst the whole plasma-islet was swarming with similar but smaller bodies. Stricker had now no doubt whatever of having Losterfer's corpuscles before him, which he had seen growing within a plasma-islet under his very eyes. On the following day the experiment was repeated in the same manner, with the exception that, instead of heating the room, the object-bearer of the microscope was heated to 25° Centigrade. The result was exactly the same.

Having thus obtained a positive reply to the preliminary question, Professor Stricker now proceeded to answer the principal question—namely, What is the nature of the corpuscles: are they organic or inorganic? The facts hitherto arrived at do not warrant a reply to either of the two possibilities. It is true we have seen the bodies growing, but mere growth is not sufficiently characteristic to give a decision. Losterfer announced that the corpuscles produced projections. This is true, but Stricker has positively observed some of these buds not to be the result of growth, but of opposition. In their quite recent state most of the corpuscles are spheroid, appearing homogeneous if viewed by No. 10 or even by No. 15 of Hartnack's immersion-lenses. Stricker now succeeded in directly observing a small corpuscle, lying sometimes near a bigger one, approaching to the latter, ultimately adhering to it, giving the impression of a small head with a mark of strangulation between it and the bigger body. After some time this line became altered in shape, the bodies assuming the appearance of clubs and lastly of globes. Stricker, of course, could not say whether all budded corpuscles originated in the same manner; but the observation was sufficient to enable him to pronounce that such buds are of no significance whatever as to the life of these formations. Thus, from the fact of their growing we can form no conclusion as to the nature of the corpuscles. The only conclusion warranted is their being formations hitherto unknown in blood.

In the meantime another experiment was made, which led nearer towards the explanation of the nature of the corpuscles. Professor Stricker noticed that the bodies are differently acted upon by chemicals immediately after having grown on the heated object-bearer, and differently when preserved several days as granules in the germinating apparatus. In the last instance they resist strongly the influence of acids as well as of alkalines, shrivelling a little, but not being destroyed. But, having been developed, they are destroyed by the chemicals mentioned, and even by water. For this reason it is important that no water should be admixed with the object at the commencement of germination.

REPORTS OF SOCIETIES.

THE PATHOLOGICAL SOCIETY.

TUESDAY, MAY 7.

Mr. HILTON in the Chair.

AFTER several reports from the Morbid Growth Committee had been read, Dr. Sanderson, as had been arranged, introduced the subject of Pyæmia.

Dr. SANDERSON began his address by relating his first experiments as to the effect of inoculating the lower animals with pyæmic liquids. In the autumn of 1867 he had injected the purulent liquid contained in the ankle-joint of a patient who had died a few hours before with metastatic abscesses, general suppurative arthritis, and intense septicæmia, under the skin in three animals, a dog and two guineapigs. The two guineapigs died within short periods (fifteen and twenty days), and exhibited symptoms of great intensity. Both had metastatic abscesses, but in one of them the lungs were already beset with minute nodules resembling miliary tubercles. The dog lived seven weeks. In this case there were no secondary abscesses, but miliary tubercles of the liver and spleen. From one of the guineapigs two others were inoculated, of which one died of pyæmic, subcutaneous abscesses without visceral disease; the other, which lived longer, had no abscesses, but tuberculous disease of the lungs. During the same winter other experiments of the same kind were made, all of which seemed to show that by the inoculation of pyæmic products two sets of lesions might be produced—as an immediate result, metastatic abscesses accompanied by a general typhoid state, which was often fatal; as an ulterior result, either disseminated nodules, at first hard but afterwards becoming caseous at their centres, or interstitial induration—both forms of lesion having their seat chiefly in the lungs, spleen, and liver, but also occurring in other viscera.

Having stated these facts, which he said had even in 1868 led him to regard it as probable that the two forms of infective lesions—the tuberculous and the pyæmic—were connected together etiologically and genetically, he referred to another fact which resulted from experiments made in 1871, as to the existence of bacteria in animal liquids and the circumstances which determine their occurrence. These experiments had shown, that whereas bacteria could not be shown to be present either actually or in germ in the healthy liquids or tissues, or in the products of healthy inflammation, they were present potentially in pyæmic liquids—that is to say, that whereas ordinary pus could be kept for days or even weeks free from bacteria, provided the precautions against “spontaneous generation” were observed, pyæmic pus cannot be so kept, and moreover possesses the property of at once determining the development of bacteria in any suitable liquid to which it is added. At that time he had concluded from insufficient observation, as he now knows, that pyæmic pus did not itself contain visible bacteria.

A short account was next given of certain researches made during last summer in association with Dr. Klein as to the channels by which infective poisons are distributed from their centres of origin. Referring to the last occasion on which he had brought the subject of the intimate pathology of tubercle before the Society, and to the doctrine he had then advocated that tuberculosis is an irritative overgrowth of a pre-existing tissue, he said it had then been shown that the process, whether in its disseminated or interstitial form, has its seat in a certain tissue, and this tissue had been termed adenoid or lymphatic, both words implying its intimate and special relation with the lymphatic system; but the precise anatomical nature of this relation had been imperfectly made out. No further progress was made till last May, when Dr. Klein came to England with the distinct object before him of co-operating in the investigation of this very question. The field taken up was the peritoneum—the reason of the choice being that that membrane, and especially the omentum and diaphragm, had already been the subject of investigation as favourite seats of tuberculis. Those researches have not merely served to elucidate one or two anatomical facts of very great importance to the pathologist—*e.g.*, the existence of a lymphatic system in the omentum, and its distribution, and the mode in which the peritoneum communicates with the lymphatic system—but have rendered it possible to give an account which, so far as the peritoneum is concerned, is tolerably exact and complete, both of the normal process of absorption and of the changes which the absorbing tissues undergo when they are entered by infective agents.

A CONVALESCENT HOME for the children of poor parents was opened last week at Rhyl.

In the course of these experiments it was found that not only as regards the property of any given peritonitis to assume the infective character, but as regards the intensity of the infective results and their duration, there were endless varieties. In one set of cases the secondary lesions were suppurative, the constitutional disturbance intense, and the fatal result rapid; in another the lesions were vascular new growths, firm at first, afterwards becoming caseous, the progress slow and the functional disturbance imperceptible. And then it appeared that in all those instances in which the pyæmia—that is, the acute character—manifested itself bacteria were present not merely in the purulent liquids but in the blood. Under these circumstances attention was directed from the effects to the poison itself. Soon after the opening of the Brown Institution, it was found that the practice of the hospital for animals was likely to afford the required material—in short, that pyæmia occurred in dogs under circumstances very similar to those which determine it in human beings, and exhibited similar symtomatological and pathological aspects. A series of experiments were therefore commenced in January last, having for their object to acquire a knowledge of the morbid poison, and particularly to discover by what conditions the variations of its intensity were governed. With reference to these experiments Dr. Sanderson would not anticipate the complete account of them in the report of the Medical Officer of the Privy Council, but would confine himself to giving an account of one series, and exhibiting the action of the pyæmic poison during life, and the post-mortem appearances. But before doing so he would state shortly what he understood to be the signification of the term “pyæmia.” He then proceeded to say: “The word pyæmia is apt to be used in somewhat different senses, according as the person using it has before him the Medical or Surgical aspect of the disease. To define it completely we must, I think take into account its mode of origin, its symptoms, and the anatomical changes which it produces, not confining our attention to either of these to the exclusion of the rest. With this consideration in view I would comprehend in my definition the following propositions:—

“1. Pyæmia originates by the introduction into the living tissues, and eventually into the blood, of a poison, which is itself a product of inflammation. 2. The action of the poison manifests itself in an alteration of the blood, and in disorder of the vital functions. The former of these is characterised by the presence of bacteria, and by change in the optical characters of the blood, which often becomes obviously more transparent and darker by reflected light than it is naturally. Of the latter—viz., the general disorders of the vital functions—the most prominent phenomenon is fever, which in the more intense forms of the affection is followed by collapse, which culminates in death. 3. More remotely the disease manifests itself in secondary suppurations—*i.e.*, in the formation of metastatic abscesses—which may occur either in the internal organs or underneath the skin. The special characters of these metastatic (as I am in the habit of calling them) infective abscesses, are those which are well known, both to Surgeons and Physicians. They have the additional less-known character, that the pus they contain is full of bacteria. 4. Pyæmia differs from tuberculosis in the rapidity of its progress, and in the obvious character of the anatomical changes of which it consists. Whereas by tuberculosis we are understood to mean anatomically the overgrowth of cells in certain tissues which we designate lymphatic on account of their proved anatomical relation to the lymphatic system, the secondary inflammations of pyæmia result in the formation of infective abscesses. 5. Pyæmia resembles tuberculosis in its mode of origin. Both spring from inflammations, and, so far as relates to the anatomical characters of the lesions, both are inflammations. To both, therefore, the term secondary or infective inflammation is applicable.”

“So much for the disease itself. Let me now,” said Dr. Sanderson, “draw your attention to the nature of the poison. I wish to show, first, that every pyæmic abscess contains a poison, which, when introduced either into the circulation or into a serous cavity, produces the symptoms of pyæmia; and secondly, that we have this poison so entirely in our possession, and so far under control, that, beginning with an agent so mild in its action that it produces no marked symptoms we can convert it into an agent of such intensity that it kills in two or three hours with the formidable symptoms seen in the case we have now before us. This intensification is effected by a process which may be called cultivation. Dr. Klein made the important discovery, that if a pyæmic liquid was transferred to the peritoneum of a guineapig, and allowed to remain there for a couple of days, although it did not at first produce any

intense symptoms in the animal itself, its toxic intensity increased in such a degree that when the transudation liquid produced in this way was injected to another animal it had acquired the most deadly activity; and that all such extremely active liquids were crowded with bacteria of a particular character, the increased number of which seemed to be in proportion to their toxic properties.”

Dr. Sanderson then proceeded to exhibit a dog into the abdominal cavity of which six drops of a pyæmic transudation liquid had been injected three hours before. The animal was in a state of profound collapse, accompanied with vomiting, purging, and cramps of the extremities. Shortly afterwards the animal was killed and the abdominal cavity opened. The peritoneum contained liquid slightly stained with blood, which on microscopical examination was found to be crowded with bacteria. The intestines were distended with a frothy liquid which possessed none of the characters of the natural contents which had been found in other cases to be charged with shed epithelium. The internal surface of the whole of the alimentary canal, from the stomach downwards, was intensely injected, and presented appearances which (as had been found by more careful investigation in previous cases) were due to the separation of the epithelium from the surface of the mucosa, and the infiltration of that tissue with liquid.

The material which produced these results was obtained as follows:—Pus from a pyæmic abscess of spontaneous (*i.e.*, accidental) origin was introduced into the peritoneal cavity of a guineapig, and allowed to remain there for two days. It was then withdrawn from the guineapig, and some of it at once injected into the peritoneum of a dog. The dog was affected in exactly the same way as the animal exhibited to the Society. The remainder of the liquid was kept for five weeks in hermetically sealed tubes, after which six drops were injected into the peritoneum of a guineapig, which showed its action to have become relatively feeble. After two days the transudation liquid produced was (the day before) tested with a third guineapig, and found to be extremely active. This afternoon it was injected into the peritoneum of the dog exhibited. Dr. Sanderson then concluded by saying, “Such are the facts. The all-important question remains, Do these experiments concern us as Physicians and Surgeons, or not? I think they do. But what I want is to prove it; for I am well aware that unless clinical observation comes in aid of pathological experiment, the results of the latter do not tell practically. Let me state what are the lines of inquiry I desire to see taken up. The first question is—Do the characters which we have shown to be present in the products of acute secondary inflammation in the lower animals also exist in similar products in man? The second is more important still—Can it be shown that human pyæmic products when tested by inoculation possess exactly the same morbid properties as those which are possessed by the liquids to which our experiments relate? It is for these inquiries that I earnestly ask the assistance of Hospital Surgeons.

“Finally, I would say a word as to the limits of the question now before us. With regard particularly to the question of bacteria, I desire to keep to the bare facts of disease, and not to diverge into discussions as to their origin. It is a matter to me of comparative indifference how they originate. Our observations lead us to conclude—first, that they afford a characteristic by which we may distinguish the products of infective inflammations from those which are not infective, and that their number affords an indication of the degree of infectiveness; and, secondly, that their presence in the blood is an indication of that constitutional disturbance which accompanies infective inflammation, not merely when that disturbance assumes the degree of intensity of which we have an example before us, but in the slighter form of irritative fever. If these facts prove to be true, not only in the lower animals, but in man, their importance is quite unaffected by any theory we may entertain as to the origin of bacteria.”

The PRESIDENT said Dr. Sanderson had entered on the study of the subject in a very thorough manner; his experiments were most striking.

Dr. CRISP did not believe pyæmia and tubercle had anything in common. Besides, tubercle in man and in the lower animals by no means meant the same thing. In monkeys, for instance, there was no bleeding from the tuberculous lung, and the spleen was generally affected. Pyæmia in the lower animals was rare.

Dr. BASTIAN said there was no case on record where bacteria were found in the blood of man during life. Do they occur in the blood of animals as bacteria or as the germs of these? That was a material question. If so, what was the relation of

these to the disease; were they its causes or its consequences? If causes of the disease, what was the difference between the disease thus caused and other animal diseases produced in like manner? Bacteria were constantly in communication with an animal during life, whether well or wounded. Fluids containing bacteria had been injected into animals, and no result followed. The question of the origin of these bacteria was really one of importance. They are invariably found in the vessels of individuals dying of high temperature, though none are discoverable during life. How, then, were they produced?

Mr. HULKE asked Dr. Sanderson to clear away certain obscurities. Did he use the term septicæmia and pyæmia as synonymous? Pyæmia he took to mean the introduction of pus into the vessels in some form or other; septicæmia he looked upon as produced by the introduction of some putrescent matter. Thus, in Dr. Sanderson's earliest experiments the dog seemed to be the subject of septicæmia. In an experiment he made, pus was filtered and the filtrate injected into the veins of a dog. Then followed rise of temperature and loss of appetite promptly, but these subsided and the dog got well. But if pus was injected unfiltered, especially if it had stood, then follow not only these symptoms, but also multiple abscesses. Putrid fluids, whether animal or vegetable, gave rise to symptoms such as those first mentioned.

Mr. SPENCER WELLS questioned if the physiological poison was always the cause. Sometimes, he thought, the poison was a chemical one. He recalled to mind a case where, after an operation on the abdomen, fluid collected in that cavity. He withdrew it, and an extract of it killed rabbits in very small quantity.

Dr. C. J. B. WILLIAMS could not come to any definite conclusion as to bacteria—whether they were a consequence or a cause of disease. In all probability a good many poisonous matters were developed in disease. Some of the processes were allied to suppuration or a similar condition.

Dr. MURCHISON referred to the possibility of idiopathic pyæmia. He had several times seen patients die of it in typhus where there was no ulceration of any kind. In great epidemics it was often common, especially if more than one case was in the house at a time.

Mr. HENRY LEE considered inflammation produced by a putrid substance more fatal than if of spontaneous origin. Putrid fluids, too, were more deadly at one time than at another. Thus, chronic pus was less active than that the product of acute inflammation.

Dr. ANSTIE had seen several cases of pyæmia where there was no recognisable wound or putrid fluid. In one set of cases there was nothing to begin with except a catarrh or cold; in another only foul smells, as drains.

Dr. CAYLEY had not quite followed Dr. Sanderson's experiments. What happened to the animal in which the pus remained forty-eight hours? The fluid removed from its abdomen could not be the same as that introduced.

Mr. HULKE said a kind of alkaloid sepsin had been separated from putrid pus abroad.

Dr. SANDERSON replied shortly that, as regards bacteria in general, he was well aware from his own experiments that the ordinary bacteria of putrefaction possess no toxic action, and that liquids containing them could be injected into the circulation of living animals without result. As regards the bacteria of pyæmic products, he had carefully guarded against the inference that they are the efficient cause of pyæmia. He regarded them only as characteristic inhabitants of infective liquids, and therefore very probably carriers of infection. As regards the word "septicæmia," he understood it to mean a state of the blood which is only present in the most intense forms of pyæmia; and he entirely agreed with Mr. Hulke in regarding metastatic abscesses as an accident rather than as an essential of pyæmic infection. The theory that the pyæmic poison is dependent on an alkaloid would be disproved in case it should appear that it is incapable of diffusion. On this question further inquiries were necessary.

TESTIMONIAL.—Mr. Alfred Fleischmann, having resigned his practice at Cheltenham, has been presented with a testimonial by his *clientèle*. The testimonial consisted of a valuable watch and chain, a Roman intaglio ring, a diamond pin, a despatch-case, and an inlaid revolver. Mr. Fleischmann is about to take up his residence in the Isle of Capri, in the Bay of Naples. The island is one of the most beautiful and healthy in the Mediterranean, and has now the advantage of a resident English Medical Practitioner.

NEW INVENTIONS.

THE PORTE KNAPSACK.

THIS is the invention of a wanderer amongst the High Alps—Mr. William White, F.S.A. It is a simple contrivance for carrying the knapsack so as to give freedom from strain on the front of the arm, and from pressure on the back, the weight being carried directly on the top of the shoulder by webs kept in tension by a light cane frame. Thus the usual fastening straps hang loose instead of carrying the weight, and ventilation is afforded to the back.

MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen having undergone the necessary examinations for the diploma, were admitted Members of the College at a meeting of the Court of Examiners on the 14th inst., viz.:—

Berry, Dennis, Barnard Castle, student of the Newcastle School.
Bowman, George, M.B. Edin., Manchester, of the Edinburgh School.
Bralley, William Arthur, M.A. and M.B. Cantab., Cambridge, of Guy's Hospital.
Clarke, John Teasdale, Newcastle-on-Tyne, of the Newcastle School.
Cooke, John, Hoxton-street, of the London Hospital.
Deakin, Charles Washington Shirley, Hereford, of University College.
Ellis, Hyacinth D'Arcy, Tipton, Staffordshire, of the Birmingham School.
Evans, Lawford David, L.R.C.P. Edin., Ruthin, Denbighshire, of St. Bartholomew's Hospital.
Green, James, Bolton, Lancashire, of the Manchester School.
Grogono, Walter Atkins, L.S.A., Stratford, Essex, of the London Hospital.
James, Cyrus, L.S.A., Highworth, Wilts, of the London Hospital.
Kelly, William, Liverpool, of the Liverpool School.
McOscar, John, M.D. St. Andrews, Argyll-street, Regent-street, of the Middlesex Hospital.
Morris, John Henry, Burslem, Staffordshire, of the Manchester School.
Orwin, Arthur Wigelsworth, Granville-terrace, W., of the Charing-cross Hospital.
Paterson, Robert Haldane, L.R.C.P. Edin., Brigg, Lincolnshire, of Guy's Hospital.
Perkins, Whitfield, L.S.A., Camberwell, of Guy's Hospital.
Roose, Edward Charles Robson, L.R.C.P. and S. Edin., and L.S.A., Brighton, of Guy's Hospital.
Steele, Sidney Thomas, L.R.C.P. Edin., Bath, of St. Bartholomew's Hospital.
Tatum, Herbert Thomas, Twickenham, of St. George's Hospital.
Williams, Leonard, M.A. Cantab., Victoria-square, S.W., of St. Thomas's Hospital.

The following gentlemen passed on the 15th inst., viz.:—

Bishop, Sydney Olive, Sandhurst, Berks, student of St. Bartholomew's Hospital.
Cole, George Martin, Westbourne-villas, of St. Mary's Hospital.
Dawes, Richard S. Mark, Mornington-road, of University College.
Graham, George William, L.R.C.P. Edin. and L.S.A., Winchester, of Guy's Hospital.
Harries, Thomas David, L.R.C.P. Lond. and L.S.A., Llancaust, Pembroke-shire, of Guy's Hospital.
Jones, Owen Thomas, Bangor, North Wales, of St. Bartholomew's Hospital.
Miller, John Alexander, Great Percy-street, of St. Bartholomew's Hospital.
Odling, Tom Francis, Buslingthorpe, Lincolnshire, of St. Bartholomew's Hospital.
Price, Edwin, Dudley, Worcestershire, of the Birmingham School.

Five gentlemen passed their examinations in Surgery, and when qualified in Medicine will be admitted Members of the College; and seventeen candidates having failed to acquit themselves to the satisfaction of the Court of Examiners, were referred to their Hospital studies for six months. The half-yearly examination of candidates for the Fellowship of the College commences this day (Friday), for which sixty gentlemen have entered their names.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received Certificates to practise, on Thursday, May 9:—

Aubrey, Richard, Weston-super-Mare.
Lewis, Frederick William, Llandoverly, Carmarthen.
Pritchard, Robert Clement, Puckeridge, Herts.
Saer, David Protheroe, Pembroke Dock.
Walker, William Newman, Tollington-park, N.

As an Assistant in Compounding and Dispensing Medicines:
Dismorr, Henry, Gravesend, Kent.

The following gentlemen also on the same day passed their Primary Professional Examination:—

Willcocks, Alexander John, Guy's Hospital.
Young, George William, London Hospital.

APOTHECARIES' HALL, DUBLIN.—At examinations held in the first and third weeks of April, the following gentlemen,

having passed their Professional examination, obtained the Licence to practise Medicine :—

Fitzgerald, Francis J.	Raverty, James.
Kennedy, Nicholas J.	Simpson, Boyle V.

Certificates in Arts, entitling the holders to commence their Medical studies, were granted to the following :—

Brennan, James.	Lyons, John.
Carr, William.	McQuade, Patrick Carolan.
Denning, Arthur Francis.	Oldham, Edward.
Healey, Thomas.	Sharpe, James.
Keene, Patrick.	Sproule, Simon Davenport.

The prize of five guineas annually given by the Council was awarded to Herbert Alexander Auchinleck at an examination held on May 6 and 7.

APPOINTMENTS.

* * * The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

- BOYLE, A. A., L.R.C.P.E., L.R.C.S.E.—Medical Officer for the Hutton District, Stokesley Union, *vice* E. J. Wilson, L.S.A., deceased.
- CAMPBELL, WILLIAM, M.B., C.M.—Joint House-Surgeon to the Royal Infirmary, Dundee, *vice* D. S. Moon, L.R.C.P. Edin., L.R.C.S., resigned.
- CARTER, ALBERT EDWARD, L.R.C.P. Edin., L.M., L.R.C.S.I.—Medical Officer of the South Division of the Liverpool Police, *vice* T. R. Bickerton, F.R.C.S. Edin., L.S.A. Lond., deceased.
- CHAMBERS, PEARSON, A.P.S.—Assistant Dispenser to the Eastern Dispensary, Liverpool.
- COURTENAY, EDWARD MAZIERE, M.B., C.M.—Assistant Medical Officer to the Derby County Asylum, Mickleover.
- EAGER, THOMAS CAWLEY, M.R.C.S. Eng., L.S.A.—Medical Officer for the Woking District, Guildford Union, Surrey.
- FORSYTH, THURSTAN, L.R.C.P. Edin., L.S.A. Lond.—Medical Officer for the Smalley District of the Belper Union, Derbyshire.
- GREEN, CHARLES, M.R.C.S. Eng., L.S.A.—House-Surgeon to the District Hospital, West Bromwich.
- JEFFERISS, WALTER R. S., M.B., L.R.C.P. Edin., L.R.C.S. Edin.—Medical Officer for Evie, Orkney.
- KEMPSTER, WILLIAM HENRY, L.R.C.P. Edin., M.R.C.S. Eng., L.S.A.—Medical Officer for the Eastern District of the Parish of Battersea.
- LLOYD, W., M.B.—House-Surgeon to the Carmarthenshire Infirmary, Carmarthen.
- LONG, MARK, M.D., L.R.C.S.I., L.S.A. Lond.—Medical Officer for the 7th District, Hackney Union.
- MCINNES, JAMES, L.F.P.S. Glasg.—Medical Officer for No. 3 District of Barony Parish, Glasgow, *vice* George Burn, M.D. Edin.
- MILSOME, JOHN RUDDELL, M.D., L.R.C.P.L., M.R.C.S. Eng.—Medical Officer for the Workhouse, Chertsey, Surrey.
- MOSS, HUGH, M.D., St. And., M.R.C.S. Eng., L.S.A.—Medical Officer for the Congleton District, Congleton Union, Cheshire.
- PERCIVAL, GEORGE HENRY, M.R.C.S. Eng., L.S.A.—Assistant Medical Officer to the Salop and Montgomery Lunatic Asylum, Shrewsbury.
- PRITCHARD, URBAN, M.D. Edin., M.B., L.R.C.P. Lond., L.S.A.—Demonstrator of Practical Physiology at King's College.
- PROVIS, WILTON, L.R.C.P., M.R.C.S.—Medical Officer for No. 2 District, Mere, Wiltshire.
- ROWLANDS, JAMES D., M.R.C.S. Eng., L.S.A.—Visiting-Surgeon to the Carmarthenshire Infirmary, Carmarthen.
- WATKINS, D. R., M.R.C.S. Eng., L.M., L.S.A.—Visiting-Surgeon to the Carmarthenshire Infirmary, Carmarthen.
- WHITE, WILLIAM, A.B.T.C.D., L.R.C.S.I., L.K.Q.C.P., L.M.—Medical Officer for the Dispensary District, Celbridge, co. Kildare.
- WILSON, WILLIAM, M.D., L.K.Q.C.P. Irel.—Medical Officer for the Burt District, Londonderry Union.

NAVAL APPOINTMENTS.

ADMIRALTY, May 7.—Francis Yeates Toms has this day been promoted to the rank of Staff Surgeon in her Majesty's Fleet, with seniority of April 25, 1872.

BIRTHS.

- BRAID.—On May 9, at The Grove, Burgess Hill, Sussex, the wife of James Braid, M.D., of a daughter.
- BROOKES.—On May 12, at 94, Kennington-road, S.E., the wife of Robert Charles Brookes, M.R.C.S., of Westminster-bridge-road, of a daughter.
- CARVER.—On May 11, at 58, Corpus-buildings, Cambridge, the wife of Edmund Carver, M.B., of a son.
- CLARK.—On April 27, the wife of T. Clark, L.R.C.P. Edin., L.R.C.S., Dunster, Somerset, of a daughter.
- KINGSFORD.—On May 11, at Upper Clapton, the wife of C. D. Kingsford, M.D., M.R.C.S. Eng., L.S.A., of a son.
- LEAKE.—On May 13, at Sunnyside, St. Margaret's, Twickenham, the wife of Dr. Jonas R. Leake, half-pay, 80th Regiment, of a daughter.
- MILLAR.—On May 12, at 2, Belsize-park-gardens, the wife of L. S. Millar, M.D., of a daughter.
- WALLIS.—On May 7, at Weymouth, the wife of Staff Surgeon W. B. Wallis, late 74th Highlanders, of a daughter.
- WIGMORE.—On May 12, at 31, Inverness-road, Hyde-park West, the wife of William Wigmore, M.R.C.S. Eng., of a daughter.
- WORKMAN.—On May 8, at Castle-street, Reading, the wife of F. Workman, M.R.C.S. Eng., L.S.A., of a daughter.

MARRIAGES.

- FULLER—LANG.—On May 11, at St. Michael's, Sittingbourne, James Mortimer Fuller, M.R.C.S.E., L.S.A., second son of Hugh Pittor Fuller, M.R.C.S. Eng., L.S.A., St. John's-wood, to Ella, second surviving daughter of the late William Robert Lang, Esq., H.M. Dockyards, and Captain Royal D. Y. Brigade of Artillery.
- HENSER—FRANCIS.—On May 8, at St. Peter's Church, Rochester, Dan Henser, to Emily Cornelia, eldest daughter of Dr. C. R. Francis, Deputy Inspector-General of Hospitals, Dinapore.
- MOXON—BENNETT.—On May 8, at Linton, Cambridgeshire, John Holt Moxon, of Rugeley, Staffordshire, to Harriette Georgiana, elder daughter of Frederick Bennett, M.R.C.S.E., of Linton, Cambridgeshire.
- WILSON—HOPGOOD.—On May 9, at St. Saviour's, Paddington, the Rev. Augustus Charles Hodgson Wilson, son of the Rev. W. Wilson, vicar of Desborough, to Honor Hutchings, eldest daughter of Joseph Hopgood, M.R.C.S., of 130, Portsdown-road, Maida-vale.

DEATHS.

- ARNOLD, FRANCES, widow of the late J. C. Arnold, M.R.C.S. Eng., L.S.A., of Blackburn, and eldest daughter of the late W. M. Epton, of Langton, at Langton-by-Wragby, on May 6, aged 33.
- CARRUTHERS, JAMES, M.R.C.S. Eng., L.S.A., at Finchley, on May 10, aged 50 years.
- COBBE, CHARLES, M.R.C.S. Eng., at his residence, 2, Nottingham-terrace, York-gate, on May 13, aged 53 years.
- DUKES, SELINA, the beloved wife of William Profit Dukes, L.R.C.P. Edin., M.R.C.S. Eng., at Spitalfields, on May 10, aged 33.
- FOX, EDWARD LLOYD HARRIES, M.D., M.B., M.S., M.R.C.S. Eng., L.S.A., son of L. Owen Fox, M.D., L.R.C.P., F.R.C.S., L.S.A., at Broughton, Hants, on May 11, aged 30.
- GRAHAM, ELIZABETH BELSCHES, relict of the late Robert Graham, M.D., Professor of Botany in the University of Edinburgh, at Coldoch, Perthshire, on May 13, in her 76th year.
- HENDE, WILLIAM WENTWORTH, M.D., at his residence, Southfields, Leicester, on May 11, in his 52nd year.
- JOTHAM, GEORGE WILLIAM, M.R.C.S., L.S.A., at Elderfield, Kidderminster, on May 7, aged 67.
- MUMFORD, MAUD VIOLET, the infant daughter of William Lugar Mumford, M.D., on May 9, aged 12 days.
- ROBERTS, PRISCILLA, relict of William Roberts, late Surgeon of the Royals, at Sydenham, on May 10, aged 84.

VACANCIES.

- In the following list the nature of the office vacant, the qualifications required in the Candidate, the person to whom application should be made, and the day of election (as far as known) are stated in succession.
- BRADFORD INFIRMARY.—Senior House-Surgeon. Diplomas and testimonials to be sent to Mr. C. Woodcock, at the Infirmary, on or before May 22.
- GLOUCESTER DISPENSARY.—Dispenser, registered under the Pharmacy Act, and otherwise duly qualified. Apply to George Whitcombe, Esq., Gloucester, from whom further particulars may be obtained.
- INFIRMARY FOR CONSUMPTION AND DISEASES OF THE CHEST, 26, MARGARET-STREET, CAVENDISH-SQUARE.—Visiting Physician. Candidates must be Members of the Royal College of Physicians, London. Testimonials to be sent to Francis Baily, Secretary.
- NORTH RIDING INFIRMARY, MIDDLESBOROUGH-ON-TEES.—House-Surgeon. Candidates must be Fellows or Members of one of the Royal Colleges of Surgeons of the United Kingdom. Applications and testimonials to be sent to the Secretary, on or before June 12.
- UNIVERSITY COLLEGE HOSPITAL.—Resident Medical Officer. Applications and testimonials to be sent to John Robson, B.A., Secretary to the Council, on or before May 18.

UNION AND PAROCHIAL MEDICAL SERVICE.

* * * The area of each district is stated in acres. The population is computed according to the census of 1861.

RESIGNATION.

Bideford Union.—The Buckland Brewer District is vacant; area 12,929; population 2500; salary £45 per annum. The Abbotsham District is vacant; area 1758; population 365; salary £4 10s. per annum.

APPOINTMENTS.

- Congleton Union.*—Hugh Moss, M.D. St. And., M.R.C.S. Eng., L.S.A., to the Congleton District.
- Hackney Union.*—Mark Long, L.R.C.S. Ire., M.D.Q.U. Ire., L.S.A., to the Seventh District.
- Tamworth Union.*—Wm. R. Brunton, M.R.C.S. Eng., L.S.A., to the Tamworth District and the Workhouse.
- Westminster Union.*—George E. C. Jackson, M.R.C.S.E., L.R.C.P. Edin., to the Western District.

PROFESSOR STROMEYER is at present in England.

HIS ROYAL HIGHNESS PRINCE ARTHUR will open the Liverpool New Southern Hospital on Whit Tuesday.

MR. WHITMORE has been elected Medical Officer of Health for the Kensington New Infirmary.

THE Medical Officer of Health for Kensington, Dr. Dudfield, has had his salary raised from £200 to £300 a year.

THE RECENT CONCOURS AT THE PARIS FACULTY OF MEDICINE.—The *concours* for the election of seven *Agrégés* or Assistant-Professors has just terminated in the choice of MM. Hayem, Damaschino, Fernet, Lancereaux, Bergeron, Duguet, and Rigal. There were thirteen competitors, and some of the judges have been heard to say that this is the most remarkable *concours* which has taken place for a long time, so great and so equal was the merit of the candidates.

THE LEVÉE.—At the *levée* held on Monday, at St. James's Palace, by his Royal Highness the Duke of Edinburgh, on behalf of her Majesty, the following presentations were made:—Dr. George Paddock Bate, Queen's Own Light Infantry Militia, by Major Ardwick Burgess; Surgeon R. W. Jackson, 100th Regiment, by the Adjutant-General; Deputy-Inspector-General Ivey, on appointment as Medical Officer to the Tower, by General Lord de Ros; Staff-Surgeon C. M. M. Miller, M.D., by the Adjutant-General; Dr. G. Oppert, by the Earl of Cork; Gopaul Chunder Roy, M.D., F.R.C.S., by the Secretary of State; Drs. Cape, Francis Hawkins, Morell-Mackenzie, George Owen Rees, W. Sedgwick Saunders.

THE Pharmaceutical Society gave a *conversazione* at the South Kensington Museum on Wednesday evening, which was largely attended by members of the Medical Profession and of other scientific bodies. There was some good singing and instrumental music, and the whole affair went off brilliantly.

CHOLERA, which had subsided in Jounpore, is reported on the 15th ult. to have broken out again seriously, and is spreading over the district. The average number of deaths is said to exceed 300 a day.

SELBY UNION.—Mr. John Fothergill, late Medical Officer for the Selby District and the Workhouse, has been granted a superannuation allowance of £30 per annum. He had been in office since the year 1838.

THE INFIRMARY FOR EPILEPSY AND PARALYSIS.—The Committee of this institution have secured a noble house, with grounds, in Portland-terrace, Regent's-park, and expect to get the alterations completed and the new premises opened by June 1.

THE MITCHAM SCHOOLS.—Ophthalmia and other diseases, which have long been greatly prevalent amongst the children of the Mitcham establishment, will, it is hoped, be obviated, the Holborn Guardians having unanimously decided to improve the drainage.

GAROTTING IN DUBLIN.—We understand that about a fortnight since, Dr. F. Kirkpatrick, Vice-President of the Royal College of Surgeons, Ireland, while proceeding to visit a patient at ten o'clock at night, was garotted in one of the most fashionable streets of Dublin, and deprived of his watch and chain. One of a gang of three men quickly rendered Dr. Kirkpatrick insensible by pressing firmly on the carotid arteries on both sides.

PRESENTATION.—Mr. James Mill, of Thurso, has been publicly presented with a handsome brougham, a silver tea-service, and a timepiece, the latter bearing the following inscription:—"Presented to James Mill, Esq., J.P., Surgeon, Thurso, by a number of his friends in the county of Caithness, as a mark of their appreciation of his valuable services as a Medical Practitioner for forty-five years, and as a magistrate."

ASSOCIATION OF MEDICAL OFFICERS OF HEALTH.—The next meeting of this Association (being the last of the present session), will be held on Saturday, May 18, at the Scottish Corporation Hall, Crane-court, Fleet-street, at half-past seven; Robert Drutt, M.R.C.P., Lond., F.R.C.S., in the chair. Dr. Wyatt Crane, Medical Officer of Health, Leicester, will be balloted for as an extra-metropolitan member. Dr. Henry Letheby will read a paper entitled "The Facts elicited by the present Epidemic of Small-pox, in reference to the Rise and Progress of the Disease, its Average Mortality, its Epidemic Periodicity, and the Prophylactic Influence of Primary and Secondary Vaccination."

THE ROYAL POLYTECHNIC INSTITUTION.—The directors of this Institution have determined to reorganise the scientific department of the Polytechnic: as a commencement they have completely refitted the laboratory, and made arrangements by which pupils can be received, and all scientific pursuits conducted with the greatest regard to perfection and economy. They have elected Professor E. V. Gardner, F.C.S., F.S.A. etc., a gentleman well known for many years past as an experienced chemist, to be their Professor of Chemistry, and have placed the arrangements under his care. Professor Gardner it may be remembered was Professor of Chemistry to the original Royal Polytechnic, and then directed the scientific department with great success, not only as regards the pupils themselves, but also as a financial undertaking. Particular attention has been paid to the subject of investigations connected with patents and inventions, that they may be conducted privately. Patentees will be able to derive the benefits to be obtained from the experience of the Professor aided by the extensive school of models and apparatus in the Institution.

EXAMINATION QUESTIONS.—The following were the questions on Surgical Anatomy and the Principles and Practice of Surgery and Medicine submitted to the candidates for the diploma of Membership of the College of Surgeons on the 10th and 11th instant, viz.:—1. Enumerate the various dislocations of the head of the thigh-bone, and describe the position of the limb in each kind. 2. What are the symptoms of chronic rheumatic arthritis? Describe the appearances which are observable in joints that have been affected with this disease, and mention the joints most liable to it. 3. Mention the parts successively divided in making a dorsal flap in Chopart's operation, commencing the incision on the outer side of the foot. 4. What are the pathological changes which lead to the occurrence of senile gangrene? Describe the symptoms of the disease, including the premonitory, its usual progress, and the treatment. 5. Name in order the structures that must be divided in the lateral operation of lithotomy, and the parts liable to be wounded. 6. Describe the various kinds of opacity of the cornea, their causes, the prognosis, and treatment.—1. Describe the symptoms which are produced by the passage of a gall-stone and of a calculus from the kidney, and mention the treatment you would adopt for their relief. 2. You are called to a patient who has been suddenly taken ill shortly before, and you find her much prostrated, complaining of pain in the abdomen, and lying with her lower limbs drawn up. What are the different causes upon which her state may depend? and what would you do for her relief? 3. Write a prescription in Latin, in full, and the directions in English, for a diuretic draught, and a mixture to allay nausea and vomiting. What are the preparations of the following substances contained in the British Pharmacopœia: lead, arsenic, silver; and for what purposes, and in what doses, would you use them?

EXHIBITION OF ARTS, INDUSTRIES, AND MANUFACTURES, DUBLIN.—Owing to the liberality of Sir Arthur Guinness, Bart., and Mr. E. Cecil Guinness, the Exhibition Palace, Earlsfort-terrace, Dublin, has been placed at the disposal of a very influential committee of noblemen and gentlemen for the purpose of establishing an Exhibition of Fine Arts, Industries, and Manufactures. Suitable space has been allotted to the various sections of (1) Natural Products; (2) Works of Art and Industries, and Manufactures. The first section will be of special interest to the Medical Profession, including as it does minerals, vegetable and animal products, chemical products, food, raw materials, and the immediate product of their manufacture. The second section will include a national portrait gallery of eminent persons connected with Ireland by birth or services. In the loan museum will be found a probably unexampled collection of ceramic ware, and to this her Majesty the Queen has largely contributed. The arrangement of the sections is rapidly approaching completion, and the Exhibition is to be opened by H.R.H. the Duke of Edinburgh, Knight of St. Patrick, on the 5th proximo. We wish the undertaking all the success it so well deserves from the public and national spirit displayed by its more immediate promoters.

THE MERCANTILE MARINE AND EPIDEMICAL DISEASE.—On April 28 last Dr. Charles Frederick Moore, the Medical Inspector of Seamen for Dublin, brought under the consideration of the Local Marine Board in that city the great importance of preventive measures in respect of the present frequent carriage of disease by means of coasting and other shipping. He alluded to a previous recommendation, endorsed by the Local Marine Board at Dublin early in 1871, that vaccination and revaccination should be encouraged among the crews of all vessels trading to or from infected ports, which, unfortunately, was never carried out; and to the great advantage obtainable by the systematic supervision and inspection by the Medical Inspectors of all ships and crews, especially during the present general diffusion of epidemical disease. He endeavoured to show how each locality, subsequently to receiving infected persons or effects, becomes itself in turn the means of diffusing disease to other ports. The great value of considering such matters, and of sparing no reasonable expense to prevent our ships and ports becoming infected, at the present moment forces itself upon us, inasmuch as Continental powers have commenced to place quarantine upon our shipping. Dr. Moore also alluded to the value of the Contagious Diseases Prevention Act, as seen in some of the English ports, where it has been enforced with the best effects. He, moreover, pointed out that prevention of disease was truly an imperial and a national question, and consequently deserved the best consideration of the authorities.

LARGE HYDROCELE.—Dr. Meachem (*New York Medical Journal*, April, 1872) relates an instance of a hydrocele which reached to within four inches of the knee-joint and measured twenty-three inches in circumference. On its being tapped, five quarts of a very dark, almost black, serum (the hydrocele originated in a severe blow received fifteen years before) was discharged. Within three years paracentesis has been repeated six times, never less than three pints being discharged—the fluid being much lighter in colour on these latter occasions. The patient refused to consent to other than palliative treatment.

SUBCUTANEOUS INJECTION OF STRYCHNIA IN AMBLYOPIA.—Dr. Cohn, of Breslau, states that he draws the following general conclusion from the trials which he has made in fifty cases of Nagel's plan of injecting into the temporal region strychnia in doses of two milligrammes—no other means being contemporaneously employed:—In all cases in which the ophthalmoscope explains nothing, a trial of the strychnia is decidedly indicated, and the prognosis, especially in hyperopia with amblyopia, is very favourable. Its utility is very doubtful in the first traces of commencing degeneration of the optic nerve, and it is absolutely useless in decided atrophy. He has never seen any mischief result from the use of the strychnia in this dose.—*Wiener Med. Woch.*, No. 13.

A PROFITABLE PATIENT.—M. Latour, referring to the death of M. Cherest while still young, mentions a singular patient who contributed to his income 14,600 francs per annum, and in leap-years 14,640. This patient, a well-known person in the mercantile world, had a terrible fear of dying, and besought Cherest to pay him a visit while in bed every morning at nine o'clock, his fee being forty francs per visit. Cherest consented, and for several years paid his daily visits, always receiving his forty-franc piece. During the last years of his life this patient, a very old man, became really ill, and exacted first two visits a day, then three, and then four, always paying his forty francs for each.—*Union Méd.*, May 4.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon.*

Hospital Sunday.—We have received a communication from Mr. F. W. Lowndes, of Liverpool, well and favourably known by his energy in the correction of abuses, and for his large-hearted charity. Our correspondent suggests that there should be a "Hospital Sunday" in London, and refers with pride and satisfaction to the munificent collections made in the churches of the various denominations in Liverpool and Birmingham. He thinks that a like result might be obtained in the metropolis, and strongly urges a trial of the plan. We cannot agree with Mr. Lowndes that the plan could be easily carried out in London, but the time will no doubt come when some effort will be made in that quarter.

Dublin.—"The Daily Express" of the 7th instant contains the following with reference to the establishment of a Convalescent Hospital:—

"The Public Health Committee of the Corporation have failed in obtaining a building suitable for a Convalescent Hospital, and ask the citizens to believe that they have done their utmost to carry out their wishes, expressed at the meeting held a month ago at the Mansion-house. They take credit to themselves for having met a dozen times, with an average attendance of sixteen members. We do not, however, believe that public credulity is so great as to suppose that if the Committee had really desired to procure a Hospital, they could not have found some building which might be converted to such a purpose. We believe that Mr. Byrne gave a more accurate view of their deliberations in saying that they spent a month in trying not to do it, and have succeeded in their object. A resolution has been adopted by the Council which seems to indicate an honest desire to provide the required building, and we may hope that it will stimulate the Committee to more active exertions. A doubt exists as to the source from which funds for the existence and maintenance of a Convalescent Home can be obtained, and the amount available for the purpose, but Mr. Byrne and Mr. Maclean suggested means of obviating this difficulty, which we believe it will be ultimately found is more imaginary than real. It is satisfactory to know that in the meantime sufficient accommodation can be procured in some of the leading Hospitals which have set apart a portion of their buildings for the care and treatment of convalescent patients."

DOCTORS AND CHEMISTS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Your correspondent, "Fifty-five No. 2," has very reasonably complained of the injustice done to duly qualified Medical Practitioners by those who are merely chemists presuming to prescribe for patients over the counter and to visit them at their own houses.

I have always been of opinion that prescribing by a chemist, or by any one who has not been properly educated in the diagnosis and treatment of disease, is dangerous folly; but I regret that this evil has its origin from Medical Practitioners themselves, who have encroached upon the province of chemists by selling drugs, not only in what are known by a grandiloquent misnomer as "open surgeries," but also in what are much more objectionable—open shops, in which, besides drugs, such miscellaneous articles as soap,

corn-flour, and brushes are sold. A Surgeon or Physician should know and maintain the dignity of his Profession, and not degrade it by becoming a tradesman; for such he certainly is, as long as he traffics in any kind of goods for profit.

According to the Continental system, Medical men are forbidden by law to dispense their own medicines, which must be compounded by the recognised *pharmaciens*. It is greatly to be desired that this restriction should be established in England; but even without it I am persuaded that chemists would at once cease to prescribe and visit, if members of the Medical Profession would cease to dispense and to keep drug stores. "*Ne sutor ultra crepidam*" should be the maxim both of Doctors and chemists.

I am, &c., D. CARROLL, LL.B.,
25, Gt. Coram-street, W.C., May 13. Registered Chemist (exam.).

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—The complaints of your correspondent about the abuses of practising chemists are decidedly too well founded; but whoever has visited foreign countries will tell you that the greater number of chemists—or, at least, a good majority of that worthy corporation—do the same everywhere, only varying their way of proceeding according to the customs and laws of the countries. Wherever laws stepped in for protection the measures taken turned out to be a failure. In parts of Germany, for instance, the District Medical Officer was bound to watch quacks and to prosecute them whenever cases of this kind came under his notice. Now, charlatanism and quackery have never been less flourishing and in favour there than here or anywhere else. Restrictions and punishments did not add martyrdom and glory to their impure practices, thus raising their value much higher in the eyes of public opinion, and so much to the detriment and disgust of the Medical Profession, that from different quarters voices are calling for the abolition of these antiquated restrictions. There will be no remedy found out for the injuries inflicted upon the honest by the dishonest, except in the higher education of the people. I enclose my card.

London, May 10. I am, &c., W.

HOW TO UTILISE CRIMINALS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Opposed to the loss of life by murder, there is the saving of life by the Medico-chirurgical art. It becomes a question whether we cannot render those who take away human life capable of ministering to the saving and prolonging of life, by means of the method which is about to be suggested. Taking the capital punishment as a simple act, it is the destruction of a life without direct compensation. In a political economy view it is simply a case to the debtor side, with no creditor page at all to compensate. Now, if we could render these forfeited lives subservient to the saving of life, we should have a debtor as well as a creditor account, and perhaps a satisfactory balance. There are many questions of communicability of disease which are still disputed; there is the action of drugs and medicines, which, for want of the *corpus vile*, on which *experimentum fiat*, have to be decided by the risk of such valuable lives as those of our best physiologists themselves. This is indeed a waste for any State to make, and the more so when they have at disposal so many forfeited lives on which these very experiments might be performed without any loss to the community, even should the result prove fatal. But in the greater majority of cases, the fatal result need not be anticipated, and yet the information obtained might be most valuable. Thus, we do not know whether the diseases known as scarlatina, measles, small-pox, etc., are conveyed by food, air, or contact of skin with skin. Now, the forfeited lives might, with perfect justice, be made use of for the purpose of deciding such points as well as others of the character of more purely physiological investigations. Surely it is not more cruel to endanger these forfeited lives than to take them away altogether. It may be argued that in the one case the suffering is short and decisive, whilst in the other it is prolonged and often dangerous. But he who takes the life of another should be subjected to a terror of a deterrent character; and it would seem that to be condemned to be the subject of physiological investigation might have more of terror in it than even death itself.

I will not prejudice the case by signing my name to this letter, though I enclose my card, which is my guarantee that I feel this is a question worthy of thought. I am, &c., CALUMET.

PERIODICALS AND NEWSPAPERS RECEIVED—

Nature—Melbourne Argus, March 28—Dublin Journal of Medical Science—Madras Monthly Medical Journal—Medical Press.

COMMUNICATIONS have been received from—

Mr. T. PIPER; Dr. BEIGEL; Dr. CRACE CALVERT; Dr. D. W. ROBERTS; Dr. W. WILSON; Mr. FLEISCHMANN; Dr. W. H. PEARSE; Dr. R. LAWSON; Dr. DUFIELD; Mr. R. QUAIN; Mr. J. CHATTO; Professor FLOWER; Mr. D. CARROLL; Dr. PHILLIPS; Mr. F. H. HEMMING; Dr. VINEN; Dr. STEVENSON; Dr. H. HARRIS; Dr. SHEEN; Mr. NETTLESHIP; Mr. CHAPMAN; Mr. WHITMORE; Mr. CHARLES HILL; Dr. SEDGWICK; Mr. J. HUTCHINSON.

BOOKS RECEIVED—

A Manual of Chemical Physiology, by J. L. W. Thudichum, M.D.—Handbook of Law and Lunacy, by J. T. Sabben, M.D., and J. H. Balfour Browne, Barrister-at-Law—The Chronic Diseases of Women, by Louis Michels, M.D.—The New Patent relating to the Sewage of Towns, by Mr. J. Brough Pow—Bromide of Potassium, etc., by E. H. Clarke, M.D., and R. Amory, M.D.—The Tendency of Disease to Cause Disease, by W. H. Spencer, M.A., M.B.—Forty-sixth Annual Report of the Massachusetts Eye and Ear Infirmary—No Case against the United Kingdom Alliance and the Permissive Bill: a reprint and review of a pamphlet entitled "The Case against the United Kingdom Alliance and the Permissive Bill"—Injuries of Nerves and their Consequences, by S. Weir Mitchell, M.D.—Man in the Past, Present, and Future (from the German of Dr. L. Büchner), by W. S. Dallas, F.L.S.

APPOINTMENTS FOR THE WEEK.

May 18. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; King's, 2 p.m.; Charing-cross, 2 p.m.; Royal Free, 2 p.m.; Hospital for Women, 9½ a.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. Thomas's, 9½ a.m.

ASSOCIATION OF MEDICAL OFFICERS OF HEALTH, 7½ p.m. Dr. Letheby, "The Facts elicited by the present Epidemic of Small-pox, in reference to the Rise and Progress of the Disease, its Average Mortality, its Epidemic Periodicity, and the Prophylactic Influence of Primary and Secondary Vaccination."

ROYAL INSTITUTION, 3 p.m. Prof. Roscoe, "On the Chemical Action of Light."

20. Monday.

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; St. Peter's Hospital for Stone, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

ANTHROPOLOGICAL INSTITUTE, 8 p.m. Meeting.

21. Tuesday.

Operations at Guy's, 1½ p.m.; Westminster, 2 p.m.; National Orthopædic, Great Portland-street, 2 p.m.; Royal Free, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; West London, 3 p.m.

PATHOLOGICAL SOCIETY, 8 p.m. Dr. Burdon-Sanderson, "Microscopical Specimens in illustration of his recent Demonstration on Pyæmia." Dr. Crisp, "Recent Specimens of Tubercle in a Fowl;" "Disease of the Cerebellum; Intussusception in an Infant." Mr. Wood, "Pelvis and Genital Organs of an Adult Hermaphrodite." Mr. Holmes, "Tumours of the Scalp; Melanosis of the Penis." Dr. Moxon, "Lymphoid Cancer of the Small Intestine." Mr. Hulke, "The Parts after Operation for Cancer of the Penis." Mr. Gay, "A Cyst; Sequestrum from the Tibia." Dr. Wiltshire, "Enlargement of Clitoris and Labia Minora." Mr. Arnott, "Multiple Exostosis." Mr. Sutton Townsend, "Ossified Aneurism of the Left Ventricle of the Heart." Dr. Bristowe, "Cardiac Disease, with Embolism of the Middle Cerebral Artery." Dr. M. Mackenzie, "Cancer of the Larynx, with Enlargement of the Thyroid Body." Mr. Sebastian Wilkinson, "Malignant Disease of the Eyeball, Brain, and Cranium." Mr. W. Adams, "Exostosis removed from the Head of the Tibia; the Two Legs of a Club-footed Child, showing good Union of the Posterior Tibial Tendons." Dr. Hawkes, "An Intracranial Tumour." Mr. Morris, "Hydatid Cyst between Diaphragm and Liver; Myxoma of Breast."

ROYAL INSTITUTION, 3 p.m. Mr. E. B. Tylor, "On the Development of Belief and Custom amongst the Lower Races of Mankind."

22. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1¼ p.m.; Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.; St. Thomas's, 1½ p.m.; Samaritan, 2.30 p.m.; King's College Hospital (by Mr. Wood), 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. George's (ophthalmic operations), 1¼ p.m.

SOCIETY OF ARTS, 8 p.m. Meeting.

23. Thursday.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Royal Orthopædic, 2 p.m.; University College Hospital, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

ROYAL INSTITUTION, 3 p.m. Prof. Tyndall, "On Heat and Light."

24. Friday.

Operations at Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.

CLINICAL SOCIETY, 8½ p.m. Dr. Broadbent, "Left Hemiplegia, with Convulsions and Coma." Dr. Andrew, "On a Case of unusual Daily Range of Temperature associated with Vegetations on Mitral Valve and Infarctus of Spleen." Mr. Cooper Forster, "Case of Irritable Bladder in a Child." Mr. T. Smith, "Case of Gastrotomy." Mr. MacCormac, "Case of Gastrotomy."

QUEKETT MICROSCOPICAL CLUB, 8 p.m. Meeting. ROYAL INSTITUTION, 9 p.m. Prof. Clifford, "Babbage's Calculating Machines."

VITAL STATISTICS OF LONDON.

Week ending Saturday, May 11, 1872.

BIRTHS.

Births of Boys, 1117; Girls, 1006; Total, 2123. Average of 10 corresponding weeks, 1862-71, 2079 0.

At the Royal Observatory, Greenwich, the mean reading of the barometer in the week was 29.56 in. The highest was 30.07 in. on Friday evening, and the lowest 29.22 in. on Tuesday afternoon.

* The figures in this column, excepting those for London and Dublin, are the unrevised numbers enumerated in April, 1871, raised to the middle of 1872 by the addition of a year and a quarter's increase, calculated on the rate which prevailed between 1861 and 1871. The London population is now based upon the number enumerated in April, 1871, as revised at the Census Office; this revision added 2456 (principally shipping population) to the unrevised number published in the preliminary Census Report. The population of Dublin is taken as stationary.

ORIGINAL LECTURES.

LECTURES ON THE
PRINCIPLES OF THE TREATMENT OF
FEVER.

By Dr. LIONEL S. BEALE, F.R.S.,

Fellow of the Royal College of Physicians; Physician to King's College Hospital.

LECTURE IV.

OF THE ACTION OF STIMULANTS IN SEVERE CASES OF FEBRILE AND INFLAMMATORY DISEASES, AND OF THE PRINCIPLES UPON WHICH THEIR ADMINISTRATION IS BASED.

ALTHOUGH probably every Practitioner will admit that some cases of febrile disease will make a good recovery without being subjected to any Medical treatment whatever, few will be disposed to deny that, even in the mildest attack, judicious Medical care is of advantage to the patient. And while it is of the utmost importance for the proper management of the case that we should learn as soon as possible whether it is likely to become severe, it is clear that only the well-informed Practitioner, who has watched the patient from day to day, will be able to form a correct judgment concerning so important a matter. In slight cases of fever it is not necessary to prescribe any form of alcohol, but, as has been already intimated, in severe cases it is sometimes desirable to give a considerable quantity of stimulant, and there is good reason for the conclusion that in some instances life has been saved by the administration of very large quantities of brandy or whisky. It has been found that persons suffering from fever will bear alcohol without any narcotic intoxicating effect whatever being induced. It has been demonstrated that a large amount (upwards of twenty ounces of French brandy in twenty-four hours) does not cause delirium in fever patients, does not produce inflammation of the brain, nor increase bronchitis or pneumonia if present. Neither does the alcohol augment dyspnoea even when very urgent. On the other hand, it is a fact that patients suffering from fever complicated with severe and extensive inflammation of internal organs—lungs, pleura, pericardium—have progressed favourably towards convalescence while taking brandy at the rate of more than twenty ounces in the twenty-four hours.

Nevertheless there still continues much difference of opinion concerning the propriety of prescribing, the utility, and mode of action of this important agent, in severe forms of disease; and although there are few Hospital Physicians who would treat desperate cases of fever absolutely without alcohol, there are many who give only a few glasses of wine to patients for whom some of us would not hesitate to prescribe much larger quantities of stronger stimulants, because we have learnt that by this means the period of convalescence is shortened, and the patient makes a better recovery.

Considering the grave importance of this practical question, it seems to me desirable that it should be fully discussed; and at the risk of being considered tedious, I propose to pass in review some of the facts and observations which, as I pointed out long ago, justify the administration of alcohol, and enable us to form some notion concerning the precise manner in which this substance acts advantageously in some cases of fever. In this way I hope to be able to support and explain the favourable results of clinical experience. Of the scientific arguments many are based upon minute observations of my own extending over many years, and which were carried out without reference to the question at issue, and indeed without the thought that they might at some future time assist in elucidating it.

Objections to the Administration of Alcohol in Inflammation.—It is interesting, if in some respects painful and depressing, to study the wonderful alterations which have taken place in our views concerning the nature and treatment of important general pathological changes. The process called *inflammation* lies at the root of many of the disorders—acute and chronic—from which civilised man and the higher animals suffer. Inflammatory action is, as it were, the point round which Medical theories revolve, and differences regarding the nature of the phenomena comprised under inflammation have led to divisions upon the most important questions of practice, and have caused the greatest differences of opinion regarding the proper treatment of disease. Inflammation is a subject which always excites intense interest, and even now the nature of the changes taking place cannot be discussed without much feeling. The

calm necessary for the steady prosecution of scientific discovery is not unfrequently disturbed by the vehemence and warmth of debate as to the proper interpretation of observed facts.

The term "inflammation" involves increased action; and in all inflammations it is true that there is increased action. In order to combat this undue action and reduce the burning activity of the inflammation, we used to be taught to give remedies which depressed the heart's action and reduced the patient's strength. But it has long been observed that many forms of inflammation are only seen in systems already reduced and exhausted by disease, misery, or privation. There are many cases in which frequency of pulse, violent delirium, extreme prostration, and all those symptoms known to accompany extensive inflammatory action, are associated with a general state of the system which can hardly be made lower than it is without great risk to life. Nevertheless, with such confidence was the truth of the old combustion theory of inflammation believed in and taught, that the efforts to quench the fire or to moderate its intensity so absorbed the attention of the Physician, that there was danger of losing the patient ere efforts employed to check the disease could prove successful.

Oftentimes in Medicine and in science have facts been explained by theories which had never been deduced from the results of experiment; and when new facts opposed to a theory had been demonstrated, men have sometimes said the facts could not be true, and have persisted in acting upon the theory; at the same time appealing to the dogmas upon which the theory was based to confirm them in the action which, it is to be feared, they had already determined to take. In days long gone by, stimulants had from time to time been given by intelligent Doctors, in low conditions of the system accompanied by local inflammations; and in many cases when the patient felt better after taking wine, Practitioners in olden time have even allowed a repetition of the practice, although they felt conscious it was against what was regarded by them as sound principles of treatment which they dared not doubt. The favourable action was ingeniously explained by the discovery of some idiosyncrasy or peculiarity in the constitution of the individual patient, instead of being attributed to changes consequent upon the action of the stimulant upon the phenomena of a particular abnormal state.

Change in Practice.—By degrees, however, it came to be observed that stimulants seemed to act favourably in very many cases in which their administration was quite opposed to theory, and was in direct antagonism with the doctrines then taught; and at last it was admitted that experience was to be trusted, and that the doctrines formerly taught could not be true in all cases. Still more recently scientific observation and experiment have demonstrated that facts which had been appealed to had been misinterpreted and misunderstood, and that a plan of treatment at variance with the one formerly popular, and in harmony with that now followed out, was really indicated. No one who knows what changes are taking place in fever or inflammation would say that he objects to the exhibition of stimulants *because* some kind of inflammation or local fever is present. In fevers, which are in reality but general inflammations, the pulse has been observed by hundreds of Practitioners to diminish in frequency, delirium to give place to calm consciousness, and the feverish state cease while the patient is taking stimulants. Forty years ago such conditions would have been treated by bleeding, calomel, antimony, and lowering remedies.

Dr. Graves, of Dublin, who, like Todd, had been a teacher of physiology, advocated, as long ago as 1833, support in the treatment of fever; and a stimulating system had been carried into practice by Dr. Blakiston during the epidemic of influenza at Birmingham, about the year 1837.^(a) But it was reserved for Dr. Graves' pupil, Todd, to carry out this stimulating plan of treatment to its fullest extent, and to apply it more generally. During many of the earlier years of his life, Dr. Todd treated cases of acute disease like most Practitioners of that day; and in his oldest case-books are records of cases of acute pericarditis which were bled and treated by mercury to salivation; cases of pneumonia which were treated by bleeding and tartar emetic; cases of fever in which a supporting plan was very hesitatingly and very imperfectly carried out. Slowly and gradually his treatment was much modified; and at length he became a strong opponent of the doctrines upon which the so-called *proper treatment* of inflammatory action was supposed to be based. Pericarditis and peritonitis were treated with opium without the mercury; stimulants were given, and the lancet was completely laid aside. Pneumonia was combated by counter-

(a) "Clinical Observations on Diseases of the Heart," etc., p. 13.

irritation and soothing poultices, and the skin and kidneys were made to act freely. The strength was supported; nourishing food was given; and if the powers of the patient flagged, brandy was administered, at first in small doses, but in many bad cases it was increased to considerable quantities. Desperate cases of low fever and extensive internal inflammation were treated by very large quantities of stimulants, the amount being varied from time to time according to the symptoms present and the progress of the case; but the proportion was not limited by any inflexible or arbitrary rule.

It is, however, only during the last twenty-five years that we have actually demonstrated that alcohol administered in small and oft-repeated doses does not excite or increase the inflammatory process, and that inflammation may cease while a patient is taking considerable quantities of alcohol; but even to this day there remain not a few who are not convinced of the truth of these remarks. Some have fallen into the error of supposing that Practitioners who advocate the use of stimulants in fever, order large quantities in every case. Practitioners have been accused of giving brandy in a routine manner, inconsiderately and indiscriminately. But this is a very grave charge to make, and ought to be supported, by those who prefer it, by reference to special cases. Mild cases of fever and inflammation were treated by Dr. Todd without stimulants altogether, or with very moderate quantities; but as this Physician was naturally desirous of treating as many desperate cases of febrile disease as possible, a very large number of the worst forms of acute disease admitted into the Hospital were placed under his care. The curious argument was adopted by some, that because very large quantities of alcohol were administered in some exceptional cases, equally large doses were given by him in all cases.

Unfortunately the question of stimulation is one which has not always been considered upon its merits only. The zealous opposition to a particular practice upon religious, political, or moral grounds may, without due care upon his part, quite unfit a man for the investigation of the effects of that practice upon the tissues of the living body under the varying circumstances of health, disease, climate, age, rest, anxiety, labour, etc. Such opposition ought to be discouraged.

Objections on account of the large quantity of Stimulants given.—Many objections have been offered to the "enormous amount" of stimulants given; but these objections do not rest upon actual evidence, and the arguments adduced against the system pursued have been satisfactorily answered. It seems never to have occurred to some, who have not hesitated to state the exact quantity of alcohol which in their opinion should never be exceeded, that an amount which might be excessive if given to a person weighing six stone, would be but a moderate dose, and perhaps insufficient, in the case of one weighing three times as much. In this matter it is wonderful that people who pride themselves upon the practical tendencies of their minds, instead of allowing themselves to be influenced by facts and reason, should act as if every individual were exactly alike and had been cast in the same mould. Some persons are better treated without alcohol, while others, suffering from the very same disorder, require a good allowance of stimulant. The difficulties of explaining this and many familiar facts are great indeed—perhaps insurmountable in the present state of our knowledge. Many of us have remarked how readily some persons when exposed to contagion contract the disease, while others altogether escape, or if attacked, progress favourably in spite of circumstances the most adverse. Original hereditary defects affecting the organs of circulation and the nervous system, particularly weak heart, will doubtless account for some of the cases we have observed. There is reason to think that many children who die early might have reached old age if they could have been preserved up to the period of early youth; while there is no doubt that in other instances adolescence, or a still later period of life, constitutes the critical period when exposure to the influence of contagious poison might be more disastrous than at any other time of life. Such considerations must always influence our judgment in determining the proper treatment, especially as regards the quantity of alcohol. In the regulation of the amount of food for prisoners, the inmates of workhouses, Hospitals, and charitable institutions, there is too great a desire on the part of the authorities to adopt uniformity; as if every individual required precisely the same quantity. The consequence is that a diet which is low for some is more than sufficient for others. Some will be half-starved while others will be well fed—perhaps over-fed. Some of our Hospital authorities are painfully inflexible in these matters, and are continually trying to discover a diet that shall equally suit patients of all ages and every kind of disease.

The diet-tables are changed every few years, and the Physicians and Surgeons continually blamed for ordering extras. (b) Under the uniformity system it is clear that to the little people and the light weights is accorded a not perfectly fair advantage in the struggle for existence. It is of some importance for the Physician, among other particulars, to take carefully into his consideration, when prescribing and regulating the proportion of food and stimulant, the weight and vigour of the individual patient. For although it is true that in proportion to their weight small animals require much more food than large ones, a heavy man should, as a general rule, have a more liberal diet than a light one; and in apportioning the quantity of stimulant to the sick, this fact must not be neglected. But it must at the same time be borne in mind that by habit and other circumstances some persons have been led to take, and hence require, a larger proportion of food and stimulants than others of the same weight.

In low diseases the quantity of stimulants required during a short period may be very large; indeed, the patient's life seems sometimes to depend alone on the frequent doses of alcohol (occasionally as much as an ounce or even two ounces an hour) which are poured into the stomach and taken up by the blood; and it is remarkable that as long as the case does well the stimulant seems to be absorbed almost as fast as it is introduced into the stomach: a little escapes in the urine, in the breath, and perspiration, but by far the larger portion is used up in the system, and in two or three different ways helps to keep the patient alive at a time when the disease places him in the greatest jeopardy.

It was pointed out more than twenty years ago, that in some cases the period of convalescence was much shortened; in cases necessarily fatal, life was prolonged; and it is believed that many desperate cases of low fever, pneumonia, acute rheumatism, etc., have been saved by the administration of large quantities of stimulants. If a collection could be made of some of the most serious instances of febrile diseases that have recovered under alcohol from the practice of a considerable number of Medical Practitioners, I feel sure that so strong a case would be made out in favour of this mode of treatment that it would be generally adopted. Moreover, there are cases which have injudiciously been "given up" by the Doctor that have recovered under the administration of stimulants, and it has occasionally happened that the delirious state has been relieved by an act performed by the patient in his delirium. Dr. Winn sends me the following interesting remarks in connexion with an instance of this:—"As regards the use of alcohol in disease, I learnt a lesson when a student which I have never forgotten. I was attending the Fever Hospital at Glasgow, a city which was then quite a hotbed of fever, and I went there with my mind fully imbued with the antiphlogistic theories. Imagine my surprise on finding that the chief remedy employed, and successfully too, at that Hospital, in the worst cases of typhus, was whisky in frequent and large doses. I can now recall one case in particular—that of a patient in a state of acute delirium, whose head became quite clear after imbibing a bottle of whisky in about twenty-four hours!"

It may then be regarded as certain, that in a number of cases advantage has resulted from giving very large quantities of stimulants. Several remarkable instances will be found reported in Dr. Todd's "Clinical Lectures"; (c) but among the most striking are the two cases already alluded to, which have been recently recorded by Dr. Wilson Fox. Alcohol is the most powerful remedy we possess, and probably the only one by which we are enabled to save life in desperate cases of fever.

EFFECT OF THE IMPERIAL MEASURE.—It is said that since the imperial gill has been substituted for the old local smaller measure in the sale of spirits, the number of cases of drunkenness in Glasgow has increased. Though so much larger, "a gill's a gill for a' that" is the popular sentiment.

(b) Surely the time has come when the Medical staff of our great public charities should be permitted to exercise a little more influence in the management of the institutions in which they are the chief workers than heretofore. In some of our London hospitals any single member of the committee, or the secretary, who may be completely unacquainted with disease, and quite unable to judge of the requirements of the sick, exercises more control in the management of the institution than the entire Medical staff. In some cases, the Medical officers are far too much in the position of servants, who are expected to execute the orders given by the authorities under whom and for whom they are supposed to work. It is, however, very doubtful if such relationship between those who manage the institution and those who are responsible for the treatment of the sick is the most advantageous that is possible.

(c) "Clinical Lectures" By R. B. Todd, M.D., F.R.S. Edited by Lionel S. Beale.

ORIGINAL COMMUNICATIONS.

CONSIDERATIONS RESPECTING
THE PRODUCTION OF HEAD SYMPTOMS.By C. HANDFIELD JONES, M.B., F.R.S.,
Physician to St. Mary's Hospital.

THE encephalon is, we know, an aggregate of nervous centres having different functions. The hemispheres are the organs of the intellectual functions; the corpora striata, with some associated masses of grey matter, minister to voluntary muscular action; the tubercula quadrigemina to vision; the cerebellum is probably concerned in co-ordinating muscular movements; and the several nuclei at the origins of the nerves constitute the centres appropriated to their respective functions. This being admitted, it is of course quite possible that a local damage may have a purely local effect—that no other function may be interfered with than that of the part injured. That this actually occurs we know by the familiar event of hemiplegia from disease limited to the corpora striata, unattended with loss of consciousness. Hæmorrhage in the crus cerebri has the same effect, and so it would seem has extravasation into the thalamus opticus (*vide* Andral, p. 103, and Callender, "Anatomy of Brain Shocks," Nos. 71, 72). Extensive disease of the cortical substance of the hemispheres produces deterioration of the mental faculties. Destruction of the quadrigeminal tubercles causes blindness. Now, in these and like instances the functional disorder is the necessary consequence of the organic lesion. It would be as unreasonable to expect a man to walk with a smashed femur as with a broken-up corpus striatum. It must, however, be postulated that the damage to the nervous centre shall not be very limited, for then its effect may be imperceptible, or nearly so. This absence of symptoms is mostly observed in instances where the lesion has been slowly produced; but Mr. Callender relates the case of a man, aged 27, who died from acute rheumatism without any cerebral symptoms. Yet his left corpus striatum was soft and red (inflamed), and in its anterior ventricular part was an abscess about the size of a small marble, containing ordinary pus. (No. 46.) This hardly reads like a description of a chronic abscess.

What I have said thus far is chiefly by way of preamble. The next point I submit is one which tends to limit and modify the applicability of the preceding to individual cases. It is, I believe, generally admitted; but is often, I think, tacitly ignored; and its full importance has scarcely been recognised by any writers except Andral and Brown-Séguard. The latter has admirably expounded and enforced it in his lectures (*vide Lancet*, 1861). (a) The view I allude to is that of the interdependence of the encephalic nervous centres—the liability of an injury in one to occasion disorder in others. Anatomically regarded, the nervous centres are quite as remarkable for their commissural connexions as for their separation, perhaps more so. Though it is not exactly true that if one suffer all the others suffer with it, yet it is very usual that one or more are thus secondarily or sympathetically affected. And it is very noteworthy that the signs of disordered function in the sympathising centre may be more prominent and demonstrative than those resulting from the original injury. These secondary derangements are, however, less permanent than the primary, and often have only a brief duration. They prove, however, not unfrequently the immediate cause of death, by arresting the action of the lungs or heart. There is great variety in the occurrence of these secondary disturbances in different individuals in whom the same primary lesion occurs: one centre may be attacked in one person, and a different one in another. To explain this inconsistency in the disturbances evoked by similar primary lesions is as impossible as it is to say why dyspepsia will cause a headache in one person, asthma in a second, and palpitation in a third. We can only suppose that the centre which succumbs to the irritation is probably the one whose nutrition is feeblest and most unstable. The proneness of the nervous tissue to take on secondary disorder will be much increased by any cause of general deterioration—as alcoholism, uræmia, foul air, and the like.

What has been said of the influence of one centre on another

(a) He says, p. 1, vol. ii., "In this introductory lecture I will try to show that the symptoms of disease of the brain, and also of neuroses symptomatic of brain disease—*i.e.*, hemiplegia, loss of speech, anæsthesia, alterations of the various senses, convulsive affections, insanity, etc.—are almost always caused in a manner completely different from that which is universally admitted."

seems also to apply to different parts of the same centre. For it is well known that persons may recover from the paralysis or other loss of power caused by a lesion, and live on some considerable time, though all the while, as shown by a later autopsy, the gap made in the centre by the lesion has never been replaced by normal tissue, perhaps remains as an evident cavity. It seems, therefore, that it is not the mere loss alone of a certain quantity of tissue—say of corpus striatum—which does the mischief, but this *plus* some morbid influence exerted on the rest of the centre by the diseased focus. The former is nearly constant, the latter varying. The above statement seems to be borne out by cases where the morbid change takes place so gradually that the part of the centre remaining sound gets, as it were, accustomed to the lesion, and continues to function in its usual manner. Thus a large abscess may form in one cerebral hemisphere and no symptoms appear, while a hæmorrhage of less than half the extent would inevitably cause most serious disturbance.

It may be well now to enter more into detail, and to refer to some particular instances. Let us take first the cerebellum. In Andral's work four cases are given, and three quoted of hæmorrhage into one of the lateral lobes causing hemiplegia of the opposite side. But there is plenty of evidence that such lesion may occur without any hemiplegia. The same authority gives three cases of softening of one lateral lobe of the cerebellum, in two of which there was opposite hemiplegia, while in the third there was no paralysis, but convulsive agitation of the limbs on both sides. Tumours and abscesses produced most constantly pain at posterior part of head, and vomiting. Other occasional symptoms are convulsions, amaurosis, unconsciousness, vertigo, tinnitus aurium, sensory disorder of one side, paralysis of sixth pair. The only conclusion that clinical experience at present warrants is that cerebellar lesion does not produce constantly any special symptom, but may give rise to very various, such as often imply disorder of remote centres.

Hæmorrhage into the pons Varolii usually gives rise to unconsciousness more or less complete—*i.e.*, to paralysis of both hemispheres, coupled with hemiplegia, and irritation or paralysis of the third, facial, vagi, and hypoglossal nerves. The clot need not be very large—one half the size of a walnut will produce complete unconsciousness for sixty-six hours, terminating in death. No other lesion was found at the autopsy (*vide* Pathological Transactions, vol. xi., p. 11). But we should not be inclined to expect, as physiologists, that disease of the pons would cause any loss of consciousness, and Dr. Wilks tells us that in disease of this locality there is not necessarily any loss of consciousness. The pupils are often minutely contracted, which must imply a sort of stimulation of the roots of the third pair. But they may be dilated or natural (*vide* St. Bartholomew's Hospital Reports, vol. v., p. 197). Loss of speech and difficulty of swallowing, when present, indicate affection of the glosso-pharyngeal vagi, and hypoglossal nerves, whose nuclei lie in the medulla oblongata. I think it can hardly be questioned that all the nerves I have mentioned have had their function deranged in cases where the lesion did not extend to the medulla oblongata, and so could not have involved the nuclei. In a case related by Dr. Wilks the loss of speech seems to have been rather owing to aphasia than to aphonia, which would imply, according to current views, paralysis of a still more remote centre. In a case recorded in the Pathological Transactions, vol. xii., p. 16, besides temporary motor and permanent sensory disorder of the right limbs, indistinct speech, and difficult deglutition, there was material impairment of vision, which persisted during the seven or eight days that the patient survived. The intelligence in this case was perfect, but there was great drowsiness for five or six days, succeeded by coma. After death a clot the size of a pea was found in the posterior left part of the pons, nearly at mid-level, in the line of the tract of fibres leading from the lateral columns of the medulla to the brain. Here the tubercula quadrigemina and the cerebral hemispheres seem to have suffered a secondary paresis.

If the above statements are accepted, it must be concluded that besides the derangements of motion and sensation, which a lesion of small extent and limited to this part may be expected to produce, others also occur which indicate the operation of an influence extending far beyond the seat of primary mischief.

Hæmorrhage into the corpora striata or optic thalami often produces unconsciousness, lasting a few hours, sometimes longer. In Mr. Callender's seventy-first case it lasted four days, ceasing after depletion. Dr. Wilks gives a case at page 179, where the patient remained very stuporous—half-conscious—for eleven

days after he was attacked, and died three days later comatose from softening of the right corpus striatum. There was left hemiplegia. The anterior lobes were adherent to the ethmoid bone, which was diseased. Dr. Hughlings-Jackson relates a case of right hemiplegia, with impairment of intellect continuing several days from softening of the left corpus striatum.

In the downward direction we find, besides motor hemiplegia and more or less sensory, loss of speech (aphonia), facial and lingual paralysis. The aphonia is often very marked, and of considerable duration; the other affections are mostly slighter and more transient.

Now, supposing the lesion limited to one of these ganglia, it is difficult to see how the unconsciousness is to be accounted for, except on the hypothesis of an influence exerted on the connected hemispheres by the focus of disease; and the same explanation must apply, I think, to the paralysis of lower centres, for plenty of channels would still remain open for transmission of volitional impulses from above. The transient duration and incompleteness of these paralyzes seem to me very indicative of their dependence on shock and not on organic lesion.

The cerebral hemispheres are the highest and most extensive of all the nervous centres, and it cannot but be of much interest to inquire what effects are produced by lesions confined to them. It seems to be pretty well established that injury of the surface of one of them may produce opposite hemiplegia, consciousness persisting. Mr. J. Hutchinson's statements on this point are of great importance. From observation of a considerable number of cases, he finds that when laceration involves the middle of one hemisphere, there often exists more or less hemiplegia on the opposite side. When the anterior lobes are lacerated, hemiplegia does not result; the posterior are very seldom injured. Hemiplegia from laceration is characterised by loss of sensibility, which suffers but little in the ordinary form. Two cases occurring in Hutchinson's experience are, he says, well-nigh conclusive as to the influence of laceration of the middle lobe in causing hemiplegia. In each of them a man was admitted with a severe compound fracture of one parietal bone, retaining his consciousness, but hemiplegic on the opposite side. In each the skull was trephined, and large portions of bone removed and the dura mater left exposed, so that there was no longer any possibility of local compression. In each case the hemiplegia persisted, and in each the post-mortem showed that the damage consisted in extensive laceration of the brain surface (*vide Medical Times and Gazette*, Feb. 3, 1868). Dr. Wilks (p. 187) records the following highly important case, though, with his wonted candour, he seems to desiderate some further assurance of its absolute accuracy:—The patient was a woman, aged 36, who died with nearly the whole of the right hemisphere in a peculiar state of disease. The whole cineritious substance appeared to be undergoing disintegration. The left hemisphere was healthy. The symptoms were left hemiplegia without conscious loss of power, and some slowness of mental action.

Mr. Hutchinson and Dr. Wilks are agreed as to the possibility of arachnitis of the surface of one hemisphere causing hemiplegia on the opposite side. The latter states that he has seen many cases of unilateral arachnitis without paralysis, as well as some with. In most of those associated with paralysis there existed also injury of the brain, and Dr. Wilks was at first disposed to explain the presence of paralysis by an extension of disease to the centres. He now regards, however, the connexion of hemiplegia with arachnitis as a fact, his own experience being corroborated by Mr. Hutchinson's. In the fourth volume of the London Hospital Reports, p. 53, this excellent Surgeon speaks of hemiplegia as being the usual symptom of arachnitis produced by injury to the head. Dr. Wilks mentions two cases of injury to the head with unilateral arachnitis and hemiplegia. In one, besides purulent lymph beneath the arachnoid, the grey matter was infiltrated with inflammatory products; in the other the brain was reduced to a pulp beneath a fracture, the arachnitis was on the other side, and the hemiplegia opposite.

Sir T. Watson records in his "Lectures," vol. i., p. 333, two cases which afford, I think, additional evidence. They were instances of Pott's puffy tumour after injury of the scalp. In the first there was right hemiplegia succeeding to convulsions of right side, and stupor from which he could easily be roused. The second had incomplete hemiplegia, but no other head symptom until fatal coma supervened. Both were trephined, and the dura mater slit open, but without advantage. Only three drachms of pus escaped from the wound in the first case, where the arachnoid had a thick coating of purulent lymph. In the second the inflammatory exudation seems to have been

in less amount. Besides the arachnitis the dissection detected in neither any morbid change in the brain. Sir T. Watson ascribes the symptoms in these cases to pressure from the effused pus and lymph. But I venture to differ from my old master, as I can hardly think that after removing a piece of the cranial wall and opening the dura mater any material pressure could have existed. Moreover, Mr. Hutchinson's observations—especially one related in London Hospital Reports, vol. iv., p. 14—incline me very much to think that too much has been made of this cause, and that symptoms which are supposed to result from compression may often really be due to laceration or concussion. In the case alluded to the upper surface of the hemispheres was hollowed into a cavity capable of holding an adult fist, and filled with pus, yet until forty-eight hours before death he had no paralysis or unconsciousness, but intense headache. Dr. Gibson also relates the case of a man, aged 36, who died twelve days after a fall on his head, having been insensible all the time, with right hemiplegia and spasmodic movements of the left limbs. The autopsy disclosed no disease whatever in the brain except two symmetrical filbert-sized clots in the anterior lobes. He remarks that compression of the brain had no share whatever, or only the very smallest, in causing the symptoms, which were mainly due to concussion (*vide Edinburgh Medical Journal*, 1870, p. 197).

While touching on this matter of injury to the superficial part of the brain, I cannot help alluding to Mr. Cline's case, cited also by Sir T. Watson. Here a man, who had received an injury of the head causing fracture, with depression of one of the parietal bones, was apparently insensible, and lay with flexed fingers and upturned corneæ, dead to the outer world for more than twelve months. As soon as the pressing bone was removed, the eyes and fingers were restored to their natural position, and though at first stupid and incoherent, he soon became rational and well. Alluding to such cases, Mr. Hutchinson says—"The portion of bone depressed must be very large indeed which could cause symptoms of compression. In ordinary cases the extent to which the cranial cavity is diminished by a depressed fracture is very trivial. . . . In all the cases of extensive depression which I have seen, the so-called symptoms of compression were wholly absent" (London Hospital Reports, vol. iv., p. 13). Now this case of Mr. Cline's, it seems to me, may be very fitly compared with others where the symptoms were not stupor or paralysis, but hyper-excitability and convulsions, and which in some instances have been relieved in the same way—viz., by trephining. Dr. Skae (*Edinburgh Medical Journal*, 1866, p. 684) relates a case of epilepsy complicated with mania, where the maniacal paroxysms lessened in severity, and have for three years ceased, since the performance of trephining, though previously they occurred regularly every month. Mr. Bryant gives (*vide Pathological Transactions*, vol. xii., p. 12) another good instance of the same kind. The bones of the skull were diseased, carious, and necrosed, and a distinct nodule of new bone existed on the piece removed by the trephine. The man had epileptic fits and severe and constant pains in the head at the seat of disease, and partial hemiplegia. The operation was attended with immediate relief—the fits ceased directly; all headache and paralysis disappeared. After two months, however, the bad symptoms returned, and death took place. Syphilitic deposits were found in the liver and spleen, arachnitis of the hemisphere corresponding to the external lesion, and diseased bone. A case very similar is given by Andral (p. 1, Spillar's translation). A man, aged 61, died with a fibrous vegetation, of the size of a large nut, on the inner surface of the dura mater. It sank deep into the cerebral substance, which of course it must have irritated. The symptoms were—at first headache, at times insupportable; as this ceased right hemiplegia supervened, both of motion and sensation, and paralysis of the sphincter vesicæ.

In all the above instances, including Mr. Cline's, I submit the idea of *irritation*—of which more presently—is that which most correctly expresses the nature of the morbid action. In Cline's case, in fact, as well as in the first of Sir T. Watson's, the spasmodic or convulsive symptoms decidedly point in this direction. In cases of arachnitis attended with hemiplegia, I think the paralysis may be ranked with convulsions, contraction of one of the limbs, delirium, head pain not corresponding to the seat of the lesion, dilatation of pupils, coma, and, like them, may be ascribed to an irritation proceeding from the diseased part and acting injuriously on connected centres. There can be no doubt that morbid action does exist, and that it does injuriously affect other regions besides its own locality. Very limited mischief may have an extensive *retentissement*. I have

seen a patch of pus on the arachnoid at the left margin of the cerebellum cause severe convulsions and coma, speedily proving fatal. Abercrombie's twelfth case, page 55, is also a good example.

Nothing advanced above is, of course, intended to question the established doctrine that pressure, when considerable, is an efficient cause of coma and general paralysis. I only express the opinion that many cases to which this view has been applied are better explained on that of irritation. A large mass of blood between the bone and dura mater may be taken as a type of a pressure-producing cause, roughened and spiculous bone as a type of an irritating. Tumours may belong in different instances to one or other class.

It is a remarkable thing that in some cases of ruptured meningeal artery, with effusion of blood between the bone and dura mater, there may be partial hemiplegia without loss of consciousness. As Dr. Wilks says, if these cases are to be explained on the view of pressure, the persistence of consciousness must be attributed to the function of the other hemisphere remaining intact. This might be favoured by direction of the pressure, lateral being stated by Mayo to be without effect, though vertical produces stupor. Mr. Hutehinson, however, says that "pressure on any part of either hemisphere of the cerebrum will certainly, after a while, influence the other also." Local pressure for a short time, however, may have local effect, as in a case recorded by this Surgeon, where there was manifest left hemiplegia six hours after the injury, but next day it had completely passed off, and he died in asthenia on the eighth day. At the post-mortem three ounces of blood were found effused into the right sphenoidal fossa. In any case of injury the gradual supervention and increase of stupor and paralysis points strongly to their dependence on effusion of blood.

The following case may be related here as illustrating the remote effects of hæmorrhage into one hemisphere:—A lady of middle age got headache, and the following night left her bed, seemed mazed and lost, and soon became semi-comatose and speechless. She survived five days, and died comatose with relaxed limbs. A considerable effusion of blood was found in the cortical substance of posterior part of left hemisphere, breaking up its tissue in a longitudinal tract running from behind forwards close by the longitudinal fissure. In its immediate vicinity there were numerous spots of capillary apoplexy. All the rest of the cerebrum, including the basal ganglia, appeared healthy. A nut-sized patch of pale red softening was found in posterior part of cerebellum. It seems to me impossible to account for the stupor increasing up to fatal coma, as well as the speechlessness, by reference solely to the local lesions, without having regard to the influence they exerted on the sound hemisphere and the medulla oblongata, or the third left frontal gyrus.

(To be continued.)

ON THE USE OF THE TRACHEAL TAMPON.

By F. JUNKER, M.D.,

Late Physician to the Samaritan Free Hospital, London.

(Concluded from page 511.)

THE method of plugging the trachea is accomplished in the following manner:—The patient having been brought under the influence of the anæsthetic, tracheotomy is performed either above or below the thyroid gland, according to the nature of the case. The incision must be large enough to admit the tube with the collapsed tampon; the division of the cricoid cartilage may therefore become requisite in the supra-thyroid operation. The edges of the tracheal wound must be secured by silk threads, by means of which the trachea will be drawn forward and the wound kept patent whilst the tube with the collapsed plug is introduced. This having been achieved, the threads are slightly loosened, and the point of the indiarubber balloon fixed to the inflating tube of the tampon, which is then expanded by gentle compression of the balloon. A certain resistance shows that the plug is sufficiently filled and in close apposition to the walls of the trachea, in which case the tube will become less movable, and will, when slightly drawn forward, recoil. The inflating tube, after having been closed with a small metal clamp, should then be secured to the tape which fixes the canula round the neck.

If the plugging of the trachea has been resorted to as a preliminary act to another operation, the administration of the anæsthetic is continued through the tracheal wound. This may be accomplished in various ways. Dr. Trendelenburg uses

a funnel-shaped instrument of japanned tin. Its outlet is furnished with an indiarubber tube stiffened by a spiral wire of about two or three feet in length, which, by means of a cone-shaped nozzle, fits into the external aperture of the tracheotomy canula. About one centimetre above the rim of the inlet of the funnel a raised wire frame covered with dimity is fixed, on which the anæsthetic fluid is dropped. A circle of small holes drilled around the edge of the funnel assists the admission of fresh air. (The complete apparatus may be obtained of Messrs. Krohne and Sesemann, 8, Duke-street, Manchester-square, W.) The narcosis may also be kept up by holding Esmarch-Skinner's well-known mask to the aperture. With great advantage also the apparatus may be applied which I had devised several years ago for the administration of bichloride of methylene, and which is described in No. 920 (vol. i. for 1868) of the *Medical Times and Gazette*, and had been exhibited at the meeting of the St. Andrews University Association in 1867, and fully described in its *Transactions*.

This apparatus serves both for the administration of chloroform and of bichloride of methylene. It has since been adopted in the Samaritan Free and other Hospitals, and by Mr. Spencer Wells in all his operations, and has also been introduced abroad. By connecting the tube which conducts the air saturated with the anæsthetic vapour to the aperture of the canula instead of to the usual mask, all the advantages of this method of administering anæsthetics may be obtained in tracheal narcotisation.

In all cases of plugging the trachea preliminary to facial or pharyngeal operations accompanied with profuse hæmorrhage, Dr. Trendelenburg's tracheal narcotisation is of twofold advantage: the movements of the operator will not be encumbered by the apparatus, and, what is of the highest importance, the aperture of the canula will be completely protected against the entry of blood flowing down the neck. It will be, therefore, desirable to leave the care of the tampon, after its inflation, entirely to the assistant who is in charge of the anæsthetic. No fears need be entertained of the slipping of the plug or tracheotomy canula. The tampon, when sufficiently inflated, will safely be lodged within the trachea, and nevertheless, from its elasticity, permit a certain degree of movability of the tube in every direction, which is necessary lest rapid movements of the patient's head should interfere with its safe adjustment. A simple experiment will show this. If the instrument is introduced into a glass tube of the diameter of the trachea, and its plug sufficiently expanded, and water put into the glass tube above the plug, the tracheotomy canula with the internal wall of the tampon may be seen making considerable movements upwards and downwards, without the external wall of the tampon being displaced from the wall of the glass tube or a drop of water passing between them.

Before the removal of the plug after the operation, the larynx—viz., the portion of the trachea above the tampon—has to be carefully irrigated with warm water by introducing into the trachea a delicate curved nozzle of the irrigator-tube through the superior angle of the tracheal incision. A portion of the blood accumulated in the larynx will be discharged through the glottis. Larger clots, which cannot pass the rima glottidis, will become loosened by the jet of water, and may be removed through the incision by means of a dressing-forceps after the withdrawal of the plug. Smaller clots may remain without danger in the larynx. They will be easily expelled by coughing, as sometimes occurs with large masses of mucus in acute laryngitis. Besides, the presence of clots of coagulated blood in the air-passages is not so much to be feared; it is only the fluid blood when passing into the smaller bronchi and into the alveoli, and coagulating there, that is fraught with danger. The plug before its removal must be emptied of its contained air by opening the clamp, after which it may be easily pulled out with the canula.

After cleaning the larynx thoroughly of all the blood-clots, a common tracheotomy tube is introduced, and the silk threads are withdrawn from the wound. The canula ought to be worn until all danger of hæmorrhage has passed away and the internal dressing of wound removed. After this the tracheal wound may be allowed to heal up in the usual way.

Dr. Trendelenburg gives the following indications for the use of the tracheal tampon as a preliminary operation:—

1. In all larger operations within or at the larynx: *a*, In laryngotomy after Desault; *b*, in the removal of large polypi from the larynx through the mouth; *c*, in subhyoid laryngotomy after Malgaigne, when the tumour has to be removed through the incision.
2. In all operations in the buccal and pharyngeal cavities in

which sudden and profuse hæmorrhage is to be apprehended : *d*, In resection of the superior maxillary bone; *e*, in resections of large portions, especially of the body of the inferior maxillary bone; *f*, in extirpation of larger naso-pharyngeal polypi.

Here I may suggest that, in the operation of complete or partial removal of the tongue, in which the patient, having half rallied from the influence of the anæsthetic, struggles and renders the arrest of the generally very profuse hæmorrhage still more difficult, and where the dangers from inspiration of blood are eminent, the use of the tracheal tampon and the administration of anæsthetics through the tracheotomy canula would certainly prove a great boon both to the operator and the patient, and may likely become a legitimate practice.

In other operations in the buccal cavity in which hæmorrhage is not so sudden as to bring on asphyxia from inspiration of blood, nor so profuse as to require a speedy termination of the operation on account of the dangers arising from the loss of blood, and in which the blood can either be mopped out with sponges or expectorated, as in uranoplastic, the plugging of the trachea is only indicated when the administration of anæsthetics is to be continued during the whole time of the operation.

The tracheal tampon may perhaps also be of use in the operation for cleft palate in infants, which can only be performed with comparative ease under chloroform. This operation should be performed at the earliest age possible, so that the proper development and growth of the affected parts should not be too long arrested, and the restoration of the normal voice and formation of speech not hindered.

Also, in other difficult operations in the larynx, which are not attended with much hæmorrhage, and which are performed with the aid of the laryngoscope, the tracheal plug may be of great assistance in order to enable the Surgeon to operate under chloroform, and to dispense with the long and tedious practising with the laryngoscope necessary in order to accustom the patient to the use of the instrument.

Besides the temporary use of the tracheal plug-canula during the above-named operations as an auxiliary, there are cases in which this instrument will be found more extensively applicable. Thus, the plugging of the trachea for a lengthened period may become desirable during the after-treatment of all operations and injuries (as in suicides) in which deglutition is impeded, and danger is apprehended from the entry of blood, saliva, pus, or food into the bronchi. Pneumonia, as already mentioned, is frequently the sequel of such cases. A fistulous opening made below the hyoid bone would assist the drainage of accumulated secretions from the pharyngeal cavity. The continued plugging of the trachea, however, affords a far more complete and safer protection to the lungs against the entry of extraneous substances.

Besides the entry of pus and saliva, the intrusion of food into the trachea after resection of the inferior maxillary bone can hardly be prevented, even when the œsophagus bougie is used for feeding. The most careful introduction of the œsophagus bougie may easily produce anti-peristaltic movements, and cause a regurgitation of the contents of the stomach, of which a portion may find its way into the trachea. The following accident, which occurred to one of my former fellow-students, at that time clinical assistant to Professor Skoda at Vienna, will serve to show that this danger is a real one, and may happen under any circumstances. Dr. R—, who, as Resident Physician, occupied a set of rooms above the clinical wards of the Professor, was found one morning dead in bed, with his head hanging over the edge of the mattress. At the post-mortem examination the mouth, trachea, and the bronchi to their minutest ramifications were found filled with the contents of the stomach. It was proved that he had returned about midnight from a supper-party, having been in perfect health, and that when in bed he had been seized with sickness, and that in relieving his stomach its contents had passed into the trachea, and caused death from asphyxia. Similar cases are on record in which drunken persons taken to a police-station have been found dead in their cells the following morning, and in which the cause of death has been due to the entry of vomited matter into the air-passages while in a helpless condition.

In cases of suicide and other injuries such as already mentioned, the following operation may be performed:—The trachea is opened below the thyroid gland by a somewhat larger incision than is usually made in tracheotomy. Through the wound two tampon-canulas are introduced, the point of the one being directed upwards, that of the other downwards, of which every twenty-four hours alternately the superior or

inferior plug is inflated. In order not to require too large an incision for the introduction of both tampon-canulas, the superior canula, which drains the fluid from the larynx, and which may be somewhat less thick than the superior tube, should be bent either towards the right or the left side at its greatest curvature. These canulas need not be furnished with a shield, as the inflated tampons will keep them sufficiently firm *in situ*.

The tampon-canula has also been used in the local treatment of diphtheria. Guided by several successful inoculations of diphtheria into the tracheal mucous membrane in animals, Dr. Trendelenburg agrees with those who maintain that diphtheria is a merely local complaint, and he has consequently treated all fresh cases of this disease with local cauterisation. In nine cases which had come under his treatment up to the time at which he read his paper on this subject before the Medical Society of Berlin in 1870, he succeeded in arresting the local progress of the disease after painting the larynx two or three times with a strong solution of muriatic acid (1 to 2). The fact that this very old and apparently correct method of local cauterisation or of the disinfection of the focus of the disease is still so little in favour with a great number of Practitioners may thus be accounted for—that the caustics hitherto used (*viz.*, chlorine-water) have not been strong enough and not applied with sufficient energy. Besides, the infection frequently spreads at a very early period to the posterior surface of the velum and into the posterior nares, where it can only with difficulty be reached with the caustics. When the infection, however, has already extended to the larynx, every method until now employed of local disinfection of all the diseased parts will be of no avail. The local affection of the tonsils is in some cases so very slight that it is often overlooked, and aid is called in only at the last stage of the disease.

In such cases Dr. Trendelenburg's method of thoroughly washing out the buccal, nasal, and pharyngeal cavities, as well as the larynx, with a sufficiently strong disinfecting or caustic solution, after previously plugging the trachea and the œsophagus, might be of advantage. A short report of one of his cases successfully treated in this way will best illustrate this method.

In a child 3 years old, a thick whitish coating was visible on the tonsils and the velum. The right nostril was perfectly plugged by muco-purulent masses, and showed a vividly red seam at the border of the mucous membrane; whilst the left nostril was free. The voice was hoarse, and during the inspiration the characteristic whistling sound could be heard at some distance. Towards evening the dyspnoea, which had been very slight in the morning, increased, and became considerable, although not alarming towards 4 a.m. At 9 a.m., however, the symptoms were so threatening that tracheotomy became urgent, which was performed above the thyroid gland, and the tampon-canula introduced through the wound after some muco-purulent matter had been expelled by coughing. Distinct diphtheritic pseudo-membranes could not be seen. The plug had been moistened previously with carbolised oil (1 to 6), in order to disinfect the trachea as much as possible. After inflation of the tampon, a Heister's speculum was introduced into the mouth, the œsophagus plugged with pieces of sponge secured by thread, and the complete occlusion of both trachea and œsophagus tested by pouring water into the buccal cavity. The little patient continued to be kept under the influence of chloroform, and in a recumbent position, and had his eyes protected by pieces of folded linen, whilst the buccal and nasal cavities were filled to overflowing with a solution of sulpho-carbolate of zinc (1 per cent. of strength). The nozzle of an irrigator filled with the same solution was then introduced alternately into the mouth and both nostrils. The currents thus produced removed large quantities of membranous shreds and muco-purulent matter from the fauces, and especially from the right nostril. After having in this manner continued irrigation for about five minutes, and the fluid then running off perfectly clear, the solution of zinc was drained off by raising and bending forward the patient's head. The cavities were then freely irrigated with clean water in a similar manner for a few minutes longer, and both the plugs removed from the trachea and œsophagus. During the following few hours the child was rather restless—tossing about on the bed, probably from pain in the mouth and from increased secretion of saliva. There was very little coughing, however, and the respiration and deglutition were perfectly easy and unembarrassed. On careful examination of the fauces the following morning, large deeply excavated ulcers with small greyish patches in the centre were still found on both tonsils. These were painted with a weak solution of muriatic acid. Except a strong

capillary injection and a few minute denuded spots on the velum, nothing abnormal was noticed. Thenceforth the patient's condition continued to improve rapidly. It was possible to remove the tracheotomy canula on the sixth day. The wound, which at this early period already showed healthy granulation and perfect absence of diphtheritic membranes, was completely united on the fourteenth day. Absorption of carbolic acid could not be traced in the urine. In this case nasal diphtheria—one of the most dangerous forms of the disease—had already commenced. The favourable result will show that this method of treatment is both practicable and safe. Of course tracheotomy ought not to be delayed until the disease has already spread into the bronchi, and must be performed at an early period, as soon as the commencement of dyspnoea, stridor, and aphonia indicates that the process has involved the glottis, especially in older children, in whom alarming dyspnoea sets in much later.

In another case, in which, after tracheotomy, a membranous cast of several inches in length was expelled from the trachea during the act of coughing, and which was treated in the same manner, the air-passage was already affected, and death occurred on the third day after the operation from extension of the disease.

Here it may be observed that in children in advanced stages of the disease with great dyspnoea and cyanosis, and where the extremities are cold, tracheotomy may be performed without anaesthesia, the little patients being already under the narcotic influence of the hypercarbonised blood. They will lie quietly, and bear the incision without indicating any sensation of pain.

It will be found advantageous to place a thin indiarubber tube above the tampon-canula, in order to irrigate the larynx from below. After tracheotomy, even when the dyspnoea resulting from occlusion of the glottis has been relieved, the *rima glottidis* may remain spasmodically closed by reflex action, owing to contact with the fluid from above, in cases in which the anaesthesia is not very profound. In such cases the larynx would not be completely disinfected unless direct irrigation from below were had recourse to. Even strong disinfecting fluids may be used without danger, provided copious irrigation with clean water be afterwards applied.

Instead of using sponges for plugging the oesophagus, an indiarubber tube of ten centimetres in length, and closed at its apex, may be introduced by means of a blunt-pointed bougie, and inflated afterwards. Attempts to plug the trachea in the local treatment of diphtheria without previous tracheotomy, in imitation of the old French method of catheterisation of the larynx, by furnishing the larynx-catheter with a plug, have failed owing to the great inconvenience in applying it and the imperfect occlusion produced.

Bearing on the treatment of diphtheria and croup, I may mention a new mode of treatment—viz., by inhalations of bromine—lately practised abroad with considerable success. It was suggested by the discovery that diphtheritic membranes are more readily dissolved by bromide of potassium than by lime-water or any other agent usually applied for this purpose.

The administration of this remedy is easy and simple: a sponge, saturated in a solution of bromine and bromide of potassium (one grain of each to the ounce of distilled water), is placed within a funnel-shaped piece of cardboard, which is held in a similar manner as in the administration of chloroform, close to the mouth and nose during five to ten minutes every hour or half-hour, according to the urgency of the case. These vapours are well borne by the patient, even by infants under one year old.

London.

COMPLICATIONS OF PREGNANCY.

By FRANCIS R. HOGG, M.D., R.H.A.,

Fellow of the Royal Medical and Chirurgical and Obstetrical Societies.

Out of 750 recent personal inquiries, seventeen women who gave birth to sixty-six children, of whom forty-one so far survive, stated that they suffered from hæmoptysis in the early months of pregnancy. Several were the youngest of large families; three had phthisical and eight asthmatical histories; nearly all married early. In three instances the labours were associated with hæmorrhage, in four the placenta adherent, in three the presentation footling. Several had variola when young—in three instances a second attack. Others had ague, pneumonia, bronchitis, or rheumatic fever before marriage. One phthisical woman, inclined to hæmoptysis during pregnancy, bore five healthy children, then aborted twins at three

days' interval. In a former pregnancy she applied croton oil to her chest, and the child showed the characteristic eruption. Coincident often with the straining of morning sickness, most of the women state that hæmoptysis ceased at quickening, but in three instances this complication only occurred between the seventh and ninth month. One woman, aged 40, commenced to menstruate at 19, married at 20, spent fourteen years in India, was there affected with dysentery, and, as a rule, during the early months of six pregnancies suffered from ague as well as hæmoptysis, and invariably after delivery had Peshawur fever in addition to mammary abscesses. Out of six children three survive.

Hæmorrhage.—Endeavouring to separate instances of menstruation, out of 700 inquiries seven women confessed to attacks of uterine hæmorrhage, each succeeded by milk fever. One generally had mal-presentation, such as hand or foot; another three face presentations; a third hand presentations, each labour hæmorrhagic.

Epistaxis.—One, occurring frequently; the labour rapid, placenta adherent, child alive. Menstruates during lactation. Before marriage had typhus.

Jaundice.—Two. One in seventh month, child alive; inclined to abort; children all weakly; had typhus before marriage. The other, a dyspeptic dressmaker, inclined to neuralgia and ophthalmia, her sisters epileptic; states that jaundice, running on from sixth to ninth month, subsided after delivery; the child stillborn.

Mammary Abscess.—One, fourteen days before delivery; attributed to cold.

Ague.—Out of 700 inquiries, eight Irishwomen, inclined also to hepatitis, contracted in India; only one aborted. The condition subsided after delivery, but the children invariably inclined to convulsions. My impression is that foetal monstrosities have something in connexion with ague—that infantile ailments of the spleen are contracted in utero, and that ague is lost by transfer from mother to child.

Dysentery.—Three. One in India; the children born prematurely; inclined to eczema. Another in New Zealand, contracting disease at quickening, the labour lingering; hand presentation; stillborn child. The third at the Cape, aborted.

Variola.—One at Christmas in India; the nearest case three miles off; no other person affected. Recovered fourteen days before a natural labour; child healthy.

Scarlet Fever.—Two. One at six months, recovered before labour; the other at seven months, contracted from her own child, only ill fourteen days. In both, children unaffected.

Measles.—One in eighth month of sixth pregnancy at Peshawur; recovered before labour; child unaffected.

Typhus.—One in seventh month; slight attack.

Remittent Fever.—Two. One at the Cape in the eighth month; labour hæmorrhagic; milk fever; child alive. The other in England at the fourth month; labour lingering; child dead; pleurisy supervened.

Simple Fever.—Three. Continued in one after delivery.

Pneumonia.—Five instances. One in New Zealand at fifth month; severe attack; labour hæmorrhagic; child alive; puerperal mania, five months deluded with the idea of being dead. As a rule the others had tedious labours; adherent placenta.

Convulsions.—Seven instances, all of whom had scarlet fever severely. Four were genuine epileptics; one had two attacks weekly, each lasting two hours, the patient, forewarned, retiring to bed; the labour attended with hæmorrhage; the child alive. Another had one convulsion at quickening, repeated convulsions in a three days' labour; no bad result. A third at quickening, occasionally after, and during a two days' labour; the child dead; milk fever; mammary abscesses; has lost three out of five children from convulsions. A fourth had one attack at quickening, but no more. The fifth had one attack a week before delivery; no bad result. The sixth attacked two months before delivery; child stillborn. The seventh, attributing epilepsy originally to fright of insects, states that she menstruated up to quickening, then had occasional convulsions after; labour tedious; child dead; has lost two out of three children through convulsions.

Hooping-cough.—One, a nervous inflammatory subject, who underwent every complaint (this included) during infancy. Married at 15; had Maltese and Indian fevers. When three months pregnant with fourth child went into quarters at Shoe-buryness lately vacated by a family suffering from hooping-cough, which she contracted. The attack all through pregnancy occurred every hour daily, lasting ten minutes, and associated with epistaxis, vomiting, diarrhoea, hernia, loss of power over the bladder. Easy labour; cough subsided; child unaffected.

An unhappy woman, now pregnant, affords the following history:—Aged 32; is the only surviving child of five. Her mother phthisical. Commenced to menstruate at 18; married at 22. Soon fell pregnant; labour natural. Second labour, foot presentation; alive. Third at eight months; shoulder presentation; alive. Fourth natural. After twelve months' nursing, contracted scarlet fever, followed by dropsy, her infant escaping. Fifth labour at seven months; child footling, dead. Sixth labour at seven months; child lived three months. Seventh pregnancy, in sixth month attended with pneumonia; labour at seven; placenta prævia; hand presentation; child dead. Suffers from bronchitis during pregnancy, as a rule.

In a former series of notes, instances of erysipelas, sunstroke, rheumatic and yellow fevers, moon-blindness, and obstinate sneezing were recorded as occurring during pregnancy.

ON TWO RECENT CASES OF POISONING AT MANCHESTER.

By F. CRACE CALVERT, Ph.D., F.R.S.

THE late Mr. Harris, Assistant-Surgeon at the New Bridge-street Workhouse, Manchester, having been poisoned by atropine, the stomach, urine, and some of the blood were sent to me for examination. As there have been only few cases reported of death by this alkaloid in a free state, I thought it might be interesting to some of your readers to give an outline of the process adopted for its separation and the tests employed for its detection.

The different substances were respectively heated with a little hydrochloric acid, and then about two ounces of alcohol added, and the solution left thirty-six hours to dialyse. The liquors were then evaporated almost to dryness, a strong solution of potash added, and then shaken up with chloroform. The chloroform solution was evaporated to dryness, and a drop of dilute hydrochloric acid and some distilled water added, and it was again evaporated to dryness. Distilled water was added a second time, and the liquor was ready for testing. The reagents I found the most sensitive were an aqueous solution of iodine, which gives a precipitate with one part of atropine in 20,000 of water; a solution of iodide of mercury in iodide of potassium, which is almost equally delicate; tincture of gall-nuts, also very delicate; and bichloride of platinum and picric acid. These two latter, however, require some time before the precipitate appears, and then it takes the form in both cases of yellow crystalline plates. In solutions much more concentrated than the above I failed to obtain precipitates with either chloride of gold or bromine dissolved in bromide of potassium. The most distinctive test, however, was the dilatation of the pupil of the eye of a dog. All these tests can be tried where very little atropine is present; for in this case not more than two and one-third grains could have been put into the milk of which Mr. Harris partook. He only took part, and it was tasted by two servants who were also made ill and vomited, and a portion was thrown away. I obtained all the reactions in the residues obtained from the blood, two samples of urine, and the contents of the stomach, and also in those obtained from the vomits of the two servants. The dilatation of the pupils of the dog's eyes could in every case be seen, even after twenty-four hours, and, in the case of the urine and contents of the stomach, after seventy-two hours.

In a case of poisoning by strychnine, which occurred a fortnight ago at Hyde, I adopted with very good results the following process:—

I boiled the contents of the stomach with a small quantity of hydrochloric and sulphuric acids, concentrated and agitated with an equal volume of chloroform. The chloroform on separating contained almost the whole of the strychnine. It was then evaporated, and a little hydrochloric acid added to the residue, which was diluted with water and dialysed. The dialysed liquor was evaporated nearly to dryness, and mixed with a solution of potash. This was again shaken with chloroform, which on evaporation left the strychnine in a state of purity. The modification of the bichromate of potash test proposed by Otto gave far better results than the tests as ordinarily employed. His process consists in adding to the strychnine solution a cold saturated solution of bichromate of potash, when a yellow crystalline precipitate is produced. The excess of bichromate is then carefully washed away, and concentrated sulphuric acid added to the chromate of strychnine, when a most intense purple colour is produced, which has a far greater permanence than that obtained in the usual method.

REPORTS OF HOSPITAL PRACTICE

IN

MEDICINE AND SURGERY.

KING'S COLLEGE HOSPITAL.

TUMOUR OF ANTRUM—REMOVAL OF GREATER PORTION OF THE SUPERIOR MAXILLA.

(Under the care of Sir WILLIAM FERGUSSON.)

IN January we had the opportunity of seeing Sir W. Fergusson remove a portion of the superior maxilla of a woman for a tumour of the antrum. The operation was performed in the manner recommended by Sir William in his writings and practice. For the following we are indebted to the Registrar, Mr. Roche:—

H. H., aged 57, between eight and nine years ago first noticed a small lump in her left cheek about the size of a hazelnut. Increased very slowly, and caused little or no pain for some years. About twelve months ago a sanguineous discharge came from the tumour, which had increased so as to be about the size of an egg. This discharge came from a portion which had protruded itself between the lip and the gum in the canine fossa. The tumour since then has increased so as to protrude the cheek, and on admission (December 2, 1871) it was found projecting on the left side of the palate, which it involved, together with the whole alveolar ridge on that side. All the teeth on the left side and behind were gone. It presented also in the canine fossa. There was no crackling on pressing it at any part. The left eye was not displaced. There was a small opening in the posterior projection in the mouth, giving exit to a purulent fluid. This the House-Surgeon enlarged, and pus and gritty particles escaped. He also subsequently made an opening in the canine projection, and gave exit to one or two ounces of pus. After these openings the tumour decreased considerably, and the general health of the woman having improved, Sir W. Fergusson decided upon removing the growth with a portion of the maxilla.

After removal the parts were taken to the museum of the College of Surgeons, and we have obtained the following description from Dr. Goodheart, who examined them there:—

"The tumour measures $2\frac{1}{2}$ by $2\frac{1}{2}$ inches, and except at its posterior part, which had pushed into the pterygo-maxillary fossa, it was covered externally by a very thin layer of bone (wall of antrum). This layer was not attacked by the tumour, neither was a part of the ascending process of the superior maxilla, which was removed with the growth. The hard palate was completely gone on this side, excepting only a very thin external plate; the remainder was replaced by a soft growth, such as constituted the whole mass. On section of the tumour, a large cavity was exposed in its centre, containing a calcareous mass about an inch in diameter. The surfaces of the tumour next to this were sloughy-looking and grey. The soft parts of the growth cut with a smooth section, somewhat like raw potato, and no juice was obtained by scraping. Histologically it is composed of young fibrous tissue with hyaline-like and large spindle-shaped nuclear bodies in places. Some parts of the tumour have a regular pseudo-laminated fibrous disposition of tissue, as if it would eventually become formed fibrous tissue. In other places it is less regularly arranged, with very small hyaline nuclei scattered about. Throughout the tumour are many small calcareous nodules of various shapes, mostly of dark outline and crescentic border, and without any distinct connexion with the tissues amidst which they lie. The calcareous nodule in the centre was made up of acicular crystals of mineral matter, and entangled in its pores a number of shrivelled corpuscles, nucleated and pus-like. Pathologically the growth appears to have been a fibrous tumour growing into the antrum and invading the bone. This subsequently underwent calcareous degeneration to a greater extent in the centre than externally, and then necrosis took place, leaving a sequestrum in the centre of the tumour, with only partially calcified wall around it."

MIDDLESEX HOSPITAL.

EXCISION OF THE SHOULDER-JOINT.

(Under the care of Mr. HULKE.)

A TALL, thin woman, aged 35, a housekeeper in a country village, was admitted into Bird ward on March 7, 1871, with sinuses in the posterior fold of the armpit, and scars of others in the anterior fold. The slightest movement of the humerus

on the scapula was very painful, and grating was felt in the joint. The muscles about the shoulder were wasted.

The patient said that the joint first began to be painful about seven years before. For a long time the pain was neither severe nor constant. After three years she went to a bone-setter, Mr. Hutton, who told her the shoulder was out, and handled it very roughly for the purpose of putting it in. After this the pain grew more severe, and soon an abscess burst through the front of the armpit. At this time she entered a Hospital, where the shoulder was galvanised. After seven weeks the abscess closed, and she returned to work.

In February, 1871, the pain again became severe, and another abscess broke in the place of the present sinus.

All the signs pointed to a carious state of the joint, but it was hoped that by giving it complete rest and securing a free exit for the discharge a cure might take place without excision, which she positively declined.

The sinuses were laid open—they were traced to the neck of the scapula; but no sequestrum was discovered here, nor was any opening found in the capsular ligament. Drainage-tubes were inserted, and the arm was fixed.

These measures were followed by improvement, but some weeks later the discharge again increased, and the shoulder became more painful and more swollen. At this time the actual cautery was used with remarkable benefit, and she soon after left the Hospital by her own request, with the joint much less swollen and free from pain. One of the sinuses remained open.

August 28.—She was readmitted with fresh abscesses, and great swelling over the front of the joint. The slightest movement caused excruciating pain. The abscesses were laid open, and the inflammatory swelling subsided considerably.

September 1.—The head of the humerus was excised through a single longitudinal incision over the bicipital groove. The periosteum with the muscular insertions was stripped off before dividing the bone. The caput humeri was thoroughly carious. This was at once followed by relief, and although her recovery was retarded by an attack of bronchitis, she gained a very useful arm. The form of the shoulder resembled closely that of the left one, and there was much less deformity than is usually noticed in cases where the periosteum with the muscular insertion into the humeral tuberosities are sacrificed with the head of the bone. The insufficiency of the deltoid was referable rather to wasting consequent on long disease of the muscle than to injury in the excision.

DRUNKARDS AT LIVERPOOL.—Since the publication of their names in the local press every Monday fewer have gone "the whole voyage." On Monday last the number was only eighty-six, while before Mr. Gladstone's scheme came into operation 200 was about the average number of culprits.

FORTHCOMING CONGRESSES.—Besides the Lyons Medical Congress, to commence on September 18 next, there are several others of interest forthcoming. The International Congress for Ethnology and Prehistoric Archæology, which held its fifth meeting at Bologna last year, is to be held at Brussels from August 22 to August 30. It will be chiefly engaged in examining into ethnological and prehistoric questions relating to Belgium. On October 5 is also to be opened the eleventh Italian Congress of Science and Letters at Rome. The first of these was held at Pisa in 1839. In 1862 the tenth was held at Sienna, when it was decided that no other should be held until the eleventh had been held in Rome—a very improbable event at that time. In 1873 an International Medical Congress is to be held at Vienna.

THE CORRESPONDING MEMBERS OF THE ACADEMIE DE MÉDECINE.—M. Barth, the President, and his officials have made a most urgent call on these honourable persons to manifest their existence, in order that the list of the Academy may be verified and amended, and the number of vacancies ascertained. It seems they are seventy-five in number, and only thirty-six of them have been polite enough to reply to a circular that has been addressed to them. The Academy is very desirous of knowing whether the silence of the thirty-nine others is to be attributed to negligence, want of politeness, or that painful but very excusable reason, death. Another circular has therefore been addressed to them in peremptory terms, and those who do not reply will be regarded as either resigned or dead, and their places will be filled up from the list of numerous candidates awaiting the honour. The President observed, appropriately enough, that these Corresponding Members ill justify their title by not even replying to the missives of the Academy.

BÜCHNERISM AND SCIENCE.

In another page will be found a notice of half a dozen books relating to that kind of border-land where science and religion seem to meet, and which, like other border-lands, is often the battle-field between opposing clans. Foremost amongst these books is one by the well-known philosopher, Büchner, of Darmstadt, which has been translated by an eminent man of letters, and which, from the nature of its contents, is likely to be pretty widely read, even by those who may find it a little shocking. Büchner's views are, as might have been expected, of what is called the extreme school; he repudiates religion and authority, disbelieves a future state with its rewards and punishments, would loosen the tie of matrimony, confiscate a good deal of property, and put a modified egotism as the spring of conduct, where we now put love of God and love of one's neighbour. Well, there is nothing very new in this, and we need scarcely take the trouble to refute it; what we simply desire to state is, that Büchner and those who agree with him have no right to call these views *scientific*, or to pretend that they flow by any sane process of reasoning from any mass of ascertained fact. It is sometimes alleged that Tory parsons, and women who have outlived their loveliness, are wont to regard "science" as an invention of the devil. "See, sir," they may say, pointing to Büchner's book, "how your modern science, Darwinism, and evolution, and parthenogenesis, and all such audacious theories, lead to atheism and revolution."

To comfort such as entertain these fears, we venture to assert that "science" leads to no such results; and that Büchner's book, so far as it pretends to do so, is just as scientific, and no more so, than the romances of "Frankenstein," or "Monte Christo," or "Gulliver's Travels." He gives a very interesting quantity of scientific data, it is true; but between these and the conclusions which he ventures upon in his speculations on the "future of man" there is absolutely no connexion.

A hundred years ago, philosophers who wished to attack religion, government, and property, were wont to rail at the vices inherent in civilisation, and vaunted the virtues of savagery. The noble, wild, untutored Indian—*l'Ingénu*—

was then the type of perfection. The lower classes, too, were represented in the cant of the French Revolutionary writers as simple and austere in their habits, frugal, earning by their toil what sufficed for their simple wants,^(a) etc., according to the clap-trap of the time. And if the bottom of society was really better than the top, there was some excuse for turning society upside down.

But what are the scientific data of Büchner? Do they show that rude, untutored man is endowed with heroic virtue? On the contrary, he represents the great mass of the whole human race as but just one shade higher than the monkey; he represents "natural man" as having no shame, no virtue, no natural affection; in fact, almost *totidem verbis*, he gives them the moral and physical qualities that Swift gave to *Yahoos*. He represents them as inherently stationary, or improving by the slowest degrees, unless they are roused and guided by some catastrophe, or by a highly endowed individual who becomes their king or prophet! He gives the most dismal pictures of the earliest members of the human race, as having no organised community, no marriage, no relation between parent and child; no provision for the future, no accumulated capital. He rebukes the lower classes of his own country for their absurd railings against "capital," and for the crude and unworkable communism which they aim at. Such a man, if consistent, would advocate a monarchical or aristocratic government. To advocate universal suffrage would be to give the reins entirely into the most monkeyish hands. He speaks largely of the "State"—says that it ought to distribute property, and help those who need help; he also evidently implies that it is the duty of a minority to attempt a revolution, if they believe it to be for the general welfare. This is Whiggery, which is but one form of aristocracy. When he talks of "law" and "necessity" he introduces metaphysical notions incompatible with the existence of nothing but matter and its forces. Moreover, when he says "that nothing higher or more perfect than man has been produced by Nature, and that it is not only the right but the duty of man to regard himself as the ruler over all existences accessible to him, and to guide and change them as much as possible for his own necessity and purposes," he shows himself a thorough anthropocentric, and quotes the Bible without knowing it.

As for Büchner's speculations on the eternal existence of force and matter, the impossibility of creation, and the non-existence of a Deity and a future state—they are no part of science. Real science flows from what we can see, and feel, and measure, and weigh, and not from speculations on the incomprehensible and transcendental. Every scholar knows these things by heart who has read Cicero "De Natura Deorum." There are well known passages in Cicero "De Senectute" which supply as good answers as can be desired to those who disbelieve in a future state. All these are old vagaries of the human mind, and the notion of tacking them on to modern science is preposterous. We might as well say that the Pyramids were built under Queen Victoria. A man may be an atheist, but he does not get his atheism out of the doctrine of cell development or of the conservation of force.

IRREGULAR PRACTICE.

In a case lately tried in the Home Circuit, irregular practice developed itself in a somewhat remarkable manner. We all know that what are called "practising chemists" do a large trade over the counter, and, when the knife is not to be used, undertake to treat any kind of disease. So long as life does not appear to be in jeopardy, the "Doctor" administers medicines and takes his fee. But when he becomes alarmed, or a fatal result is anticipated, he directs his patient to go to a regular Doctor, who is competent to give a certificate of the death

(if death occur), and who thus, as it were, becomes the dupe and the shielder of the quack or chemist. These cases constantly occur, and yet what steps have we taken to prevent illegal practice and protect the health and life of the public? Literally nothing.

The new phase of irregular practice to which we allude developed itself in a trial for breach of promise. The plaintiff was a young woman of respectability, and gave her evidence with great propriety and clearness. The defendant declared he broke off the match in consequence of the unchasteness of the plaintiff, and called in support of his case Mr. Richard Thomas, "a chemist at Dover." This witness swore that he had a considerable practice in treating a certain class of diseases. The plaintiff had been examined by his wife in the latter part of 1870, and he gave her medicine on his wife's report. He told defendant of the occurrence. On cross-examination, he admitted he had told a friend that morning that defendant should settle the case for £200. He also "contradicted himself," as the judge said, "over and over again on material points, and the defendant's case rests upon his evidence." Yet the defendant's counsel, in spite of the hint given from the bench, persisted in going on with the case, and actually called Mrs. Thomas into the box to prove that she had examined the plaintiff. The jury did not think it necessary to trouble his Lordship to go into the evidence. Here is the satisfactory conclusion of the trial as reported in the newspapers:—

"His Lordship (Mr. Justice Quain) observed that it was monstrous to suppose that any young woman's character could be taken away by such infamous evidence as they had heard, and coming from such a source. Although they had very properly altogether acquitted the plaintiff on the foul charge that had been brought against her, yet the fact that it had been made and persisted in to the last was calculated to prejudice her in her future life—not only in getting a husband, but also in obtaining a respectable situation in a drapery or millinery establishment. She was entitled to substantial, but not of course to excessive or vindictive damages.

"The jury found for the plaintiff—damages £300. They added an unanimous expression of opinion that Miss White left the Court without the slightest stain upon her character.

"His Lordship: In that opinion, gentlemen, I entirely concur."

Really there is something appalling in the circumstances of this trial. An ignorant woman, and a man as ignorant, positively swore in a court of justice that a chaste and, as it was proved, respectable woman was labouring under a loathsome disease. Now, we know in some of the discharges of women it is sometimes very difficult to decide, without corroborative evidence, whether they arise from what may be called natural causes or are the result of impure connexion. Men of the profoundest knowledge and of the largest experience would hesitate in some cases from a mere examination to pronounce positively upon what cause such discharge arose. But we have this wife of a "chemist," who after all is probably a mere "drug seller," speaking with unqualified authority on the matter. Surely there should be some "remedy," as the lawyers say, for such a "wrong." But we question whether such a remedy exists.

It is remarkable that the judge did not refer in more specific terms to the evidence of the "chemist" and his wife. Surely it was a fitting occasion for a man, closely connected with two eminent members of our Profession, to make some remarks on the state of the law which permitted evidence like that he characterised as "infamous" to be received at all. But being received, and doing all the mischief that it could, might he not have suggested with propriety an alteration in the law, which enabled perfectly unqualified and ignorant persons to give evidence on a question of science—that evidence having a tendency to ruin the character and blast the reputation of a respectable woman? The jury used a wise discretion in expressing their opinion, "that Miss White left the court

(a) By-the-bye, if any of our readers want a good novel, thoroughly unobjectionable, and giving a capital picture of these times and of this cant, let him get "Mademoiselle de Malepière," from Hachette's, for a shilling.

without the slightest stain upon her character." But as the judge observed, the charge having been made and persisted in must more or less damage her. Now, can we point to another country in Europe where witnesses like Thomas and his wife would be let "scot free" after such evidence as they gave? It must be recollected that this "chemist" swore that he had a large practice in a certain class of diseases, and yet he had no qualification whatever. This is "free trade" in physic.

THE WEEK.

TOPICS OF THE DAY.

WE hear that the Bill which is intended to give to the Society of Apothecaries the necessary powers to join in forming a Conjoint Examination Board for England and Wales is to be introduced into the House of Lords shortly after this Whitsuntide recess, and it is expected that it will be passed in the present session.

A sensational article, entitled "Transportation by Order of Medicine," containing a most unjust attack on the Profession, has recently appeared in the *Pall-mall Gazette*, and was copied into the *Times* of Monday last. The article, one would suppose, must have originated in some personal pique against some one of our leading Physicians. It delineates in a highly coloured description the case of a young couple, of whom the consumptive wife has been ordered to the South of France by some Physician, and paints the miseries and expense which accrue to both of them in consequence. Now, all we have to say is, that under no circumstances can Medical men or men of any other profession be expected to be infallible—all we can do is to advise to the best of our judgment and ability; and that, in truth, there is no Profession which has so much consideration for the means and circumstances of those who consult them as the Medical. If a patient will be honest and tell his Physician that he cannot afford a certain plan of treatment, the Doctor will always be ready to suggest an alternative. With regard to the enormous expense of getting to and living at health resorts, and the wretched accommodation obtained at them, the writer draws on his imagination. The expense of getting to the Riviera is from five to eight pounds, and a patient can live there well in an excellent hotel for ten francs a day. Of course the change may not do all the good that is expected from it; but change to a sunny climate and to a bright scene is often the only thing that offers the smallest hope. All plans of treatment are more or less expensive, and none are infallible cures. This is our answer to the elegiacs of the *Pall-mall Gazette*.

We hear that the Middlesex Hospital is to be closed during the month of August for the purpose of introducing a new system of thorough drainage.

Dr. John Murray has been appointed joint Lecturer on Pathology with Dr. Cayley in the Middlesex Hospital School, and it is intended to appoint in the same School a Lecturer on Psychological Medicine.

Professor Corfield's lectures on Hygiene, at University College, will commence on Tuesday, the 28th inst., at twelve o'clock.

NONE TOO SOON.

It will be remembered that some time since thirty-four Medical students were prosecuted and convicted at Havana on very questionable evidence for "desecrating the graves of Castanon." They were condemned to imprisonment and disgrace. The verdict and the sentence were condemned as unjust and arbitrary, and the authorities were soundly rated. Now the Spanish Government appears at last to be ashamed of its conduct. At all events, the last number of the *Madrid Gazette* contains an amnesty for the culprits, who have been in prison for upwards of six months.

ROYAL COLLEGE OF SURGEONS.

THE following is an abstract of the unconfirmed minutes of the ordinary meeting of the Council on the 13th inst. :—

The Secretary reported that he had not had time to complete the report of candidates passed and rejected in the Professional examinations for the Membership in pursuance of the resolution of the Council at its last meeting, but that such report would be ready for presentation at the meeting of the Council in June.

The permission of the Senate of the University of London to hold the Preliminary Examinations of the College in June and December next in the rooms of the University was reported.

The Council adopted the usual resolutions with respect to the meeting of Fellows to be held on July 4 next for the election of Members of the Council (on which occasion Messrs. Hancock and Curling, the Vice-Presidents of the College, will offer themselves for re-election, and the vacancy caused by the death of Mr. Solly will be filled).

The Council accepted with thanks a copy of Rembrandt's picture of "Nicholas Tulp the Anatomist, and his Pupils," and two drawings of diseased bones by J. Koenig, the property of the late Mr. Abernethy, presented by Mr. Henry Spencer Smith.

Moved by Mr. South, and seconded by Mr. Erichsen, and resolved *nem. con.*—"That the anatomical teachers of London and the provinces be requested to inform the Council of the number of bodies received for dissection by the pupils of each school, exclusive of the bodies received for the anatomical lectures and demonstrations, from the commencement of last winter session to the present date.

Mr. Erichsen gave notice of the following motion at the next meeting of the Council, viz. :—"That the Court of Examiners of the College be requested to take steps to ascertain the manner in which 'Practical Surgery' and 'Practical Physiology' have been taught in the different schools in the metropolis and the provinces, and that they report to the Council the result of such inquiry."

THE SANITARY STAFF AT GLASGOW.

THE present sanitary staff of the city of Glasgow is, according to the unanimous testimony of the members of the Police Board, both competent, zealous, and efficient. The Medical part of it was reorganised in the year 1869, when to the distinguished Professor, Dr. Gairdner, at the head of it was allotted a salary of £300, to an assistant £200, and to the district Surgeons various sums which raised the whole sum spent in Medical salaries to £740. The service performed during the last two years had been "large and faithful," to quote from the speech of Mr. Ure, one of the members of the Board. The Lord Provost said that Dr. Gairdner had been of immense service to the city; he had not sought them—they had sought him; and only two years ago the staff had been reorganised. All the world out of Glasgow would deeply regret any change that should deprive the Glaswegians of Dr. Gairdner's services. Between the two plans of retaining a first-class man like Dr. Gairdner as responsible superintendent and organiser, under whom the existing curative Medical officers should attend to the sanitary state of their respective districts, and of employing one Physician at £600 a year who should devote his whole time, there is no doubt in our mind that the former is to be preferred. "Sanitary science" is in a very infant state; and in order that it may not get into wrong grooves, it is well that some of those who practise it should keep up their alliance with general pathology and physic.

NEW COTTAGE HOSPITAL.

ON Wednesday a Cottage Hospital, erected on the Marquis of Ailesbury's estate at Savernake, near Marlborough, was opened. The Bishop of Salisbury took part in the ceremony, and a distinguished party from Savernake House were present.

DR. STROMEYER'S SPEECH AT ST. THOMAS'S HOSPITAL.

OUR readers will agree with us in thanking Mr. MacCormac for procuring us the pleasure of hearing and reading the remarkable speech by Dr. Stromeyer, which we print in this week's *Medical Times and Gazette*. It is not merely the intrinsic gratification afforded us by the veteran orator, whose lifelong devotion to the civil practice of his Profession, varied by service in many a campaign, bespeaks him a master in every branch, but that which arises from the truth, breadth, and candour of his criticisms on our own greatest Surgeons. What keenness of observation and thorough knowledge of human nature mark his sketches of Astley Cooper, Abernethy, and Guthrie! Stromeyer is conservative in two senses—he repudiates interference, though sanctioned by the “schools,” when his own experience tells him that it is unnecessary and injurious. Witness, for example, his remarks on trephining, on the treatment of fractures, on the operation for cataract. He is conservative in another sense—in retaining old methods of treatment, spite of a temporary lack of fashion. His remarks on bleeding were warmly applauded, though—so rusty has the lancet and the use of it become—some of his younger auditors seemed as if they knew not the meaning of the old joke about practising bleeding on a cabbage-leaf. But the tide is turning, and the lancet may yet have to be kept sharp. The remarks on starched bandages, and on venous thrombosis as a cause of gangrene and of symptoms like pyæmia, will all be appreciated. But we need not pick out the plums for our readers, who will devour the whole. The oration gives us all the pleasure we should get from a grand picture by Sir Joshua of the life and times of our fathers. We will only add, what English Surgeon is there who could at Hanover or Paris deliver such a piece of word-painting in fluent German or French?

PARIS NEWS.

UNABLE to give the whole of our Paris correspondent's letter this week, we may call attention to the following extracts:—

“Paris, May 21.

“In my letter which appeared in the *Medical Times and Gazette* of the 4th instant, I noticed the ‘*concours* for the aggregation,’ and gave you a list of the candidates with the subjects of examination affixed to their names. This examination was for the appointment of Sub-professors in Medicine, and the names of the successful candidates will be found in your last week's issue, page 587. I have now to announce the opening of the *concours* for the Surgical and Obstetrical Department, for which there are five vacancies, three for the former and two for the latter, and the following have presented themselves as candidates in Surgery:—MM. Nicaise, Terrier, Delens, Horteloup, Lucas-Championnière, Auger, and Henri Bergeron. For the section of Accouchement, MM. Chantreuil, Charpentier, and De Soyre. The examining board is composed of M. Gosselin, president; MM. Broca, Pajot, Dolbeau, Tillaux, Duplay, and Larrey, members. The Surgical candidates go through the same ordeal as the Medical, and those under notice are now at the ‘*Epreuves préparatoires*,’ the subject being: ‘*La Vessie au point de vue Anatomique et Physiologique.*’”

PROPOSED FACULTY OF MEDICINE AT BORDEAUX.

IT is reported that M. Jules Simon, the Minister of Public Instruction, has accepted in principle the creation of a Faculty of Medicine at Bordeaux to replace that of Strasburg, and that a commission has been appointed to report upon the project in question. It is also in contemplation to establish a School of Medicine and a School of Pharmacy at Lyons.

PROFESSOR VERNEUIL.

DR. VERNEUIL, a well-known Surgeon and academician, and Professor of Surgical Pathology at the School of Medicine, has been appointed Professor of Clinical Surgery in the room of Professor Langier, deceased. The latter appointment is considered a promotion, as the Clinical Professorship of Medicine or Surgery is the highest attainable by the Faculty in Paris. Up till now these appointments have been obtained according

to seniority; but it is in contemplation to abolish the system, and to give them to the most qualified, as it has been objected that the best lecturers are not always the best clinicians.

MURDER OF A PHARMACIEN BY THE PARIS COMMUNISTS.

OUR correspondent writing from Paris, says—“The anniversary of the entry of the Versailles troops into Paris painfully reminded me of the dreadful scenes I had witnessed and the unheard-of atrocities committed during the furious struggle between the insurgents and the regular army. Among the melancholy events that then took place I may mention that related of a Pharmacien in the Rue de Richelieu by the name of Koeh, who was brutally murdered by the Communist soldiers simply because he refused to help them in raising a barricade in his neighbourhood. Not only did he refuse his aid, but he attempted to lecture them on their conduct, whereupon two of the men attacked him in his own shop. The Pharmacien, however, true to his drugs, kept them at bay with a bottle of sulphuric acid in his hand, which he threatened to bespatter them with if they dared to touch him. The men, finding a dangerous weapon before them, beat their retreat, but soon returned with a reinforcement. The poor Pharmacien, considering it would be useless to resist, was carried out of his shop, and, after a sham ‘drumhead’ court-martial, was ruthlessly shot in the presence of his wife and children, who implored the ruffians for mercy.”

CONDITIONS ON WHICH ENGLISH PHYSICIANS MAY PRACTISE IN FRANCE.

OUR Paris correspondent tells us—“With respect to your inquiry as to whether an English Physician residing permanently or temporarily in France can practise among his own countrymen, I was informed, at the Secretary's Office at the School of Medicine, that a person so practising may not be interfered with by the authorities, but he would always run the risk of being persecuted or even prosecuted by others, as it is illegal to practise on French territory without the degree of one of its Universities or special authority from the Government. This latter, the secretary thought, would not, under the circumstances you mention, be refused. Application should be made to the Minister of Public Instruction; and I have to add that, when such permission is obtained, one can practise indiscriminately among the natives as well, and that the same fee (about £51) will have to be paid for the permission as for the degree of M.D.”

THE BIENNIAL FESTIVAL OF THE HOSPITAL FOR DISEASES OF THE THROAT.

THIS biennial festival was held on Wednesday, the 22nd inst., at Willis's Rooms, the Earl of Clarendon in the chair. A large company of ladies and gentlemen sat down to dinner, and a pleasant evening was passed under the Earl's able presidency. Contributions to the amount of £1500 were announced in the course of the evening. The most important announcement was, however, to the effect that the Committee are in search of a more central and convenient site for the Hospital. The present premises in Golden-square are convenient enough, but they are not easily got at. Now, when the Hospital has attained to the rank it has among special institutions, it is much sought after by foreign Doctors who come to see London practice, and it is hardly possible to direct them so as to enable them to reach the Hospital without inconvenience.

SMALL-POX JOTTINGS.

ONLY two cases of small-pox during the past fortnight are reported in Newington.—There were no deaths last week from small-pox in the Mile-end Old Town district.—Small-pox was on the increase amongst the inmates of the St. Mary-lebone Workhouse, eight having had to be transferred to the

Small-pox Hospital, as against six the week before.—Four new cases of the disease, all vaccinated persons, were last week reported to the St. James's (Westminster) Vestry.—A Parliamentary return of the number of summary convictions under the Vaccination Act of 1867, for neglecting or refusing vaccination to a child, shows that in the three years 1868-70 they were 1516 in England, only 2 in Scotland, and no fewer than 2872 in Ireland.—In the Aberdeen Small-pox Hospital the return for the week ending Saturday last shows—Total number of cases admitted since opening, 201; number of patients in Hospital, 18; total discharged recovered, 149; total dead, 34.—The deaths from small-pox in the Whitechapel district for the quarter ending March 30 last were eleven.—The fatal cases of small-pox in the metropolis, which in the two previous weeks had been sixty-two and thirty-nine, rose again last week to fifty-four.—Dr. Aldis, of St. George's, Hanover-square, reports for the week ending the 18th instant three cases of small-pox, two of which were removed to the Hospital.—Eight cases, including three deaths, have occurred at a house in Rutland-street. At different times a notice was served, when it was partly cleansed, etc.; but the owner having discontinued to carry out the order, the Committee recommended proceedings to be taken.

TEA DRUNKENNESS.

DR. ARLIDGE, of Stoke-upon-Trent, has directed the attention of the public and the Government to an important evil now very prevalent in the neighbourhood of the Potteries, and, we may add, very generally throughout the kingdom. We allude to the excessive use of tea as a beverage. Amongst workwomen this drink is resorted to many times a day, in large and strong doses, often without sugar and milk, and generally accompanied by food of anything but a nutritious character. The results are a derangement of the stomach in connexion with uterine derangements. He says—"I will take this opportunity of remarking upon the lamentable amount of sickness consequent upon the abuse of tea by women of the working classes. Instead of using tea as an occasional beverage they make it a principal article of diet, and drink it usually without milk or sugar several times a day. At most meals bread and butter is the only solid accompaniment. In many cases, doubtless, poverty imposes on them a meagre diet, but even in such the one alluded to might be advantageously replaced by other kinds of food not more expensive." And Dr. Arlidge adds—"Bitter and strong is the agitation at the present period against beer and other intoxicating liquors as the root of all evils, but in my opinion there is room for agitation against tea-drinking as carried on in the way spoken of, for I am convinced that a deterioration of health among the working classes, and a lower vitality in the rising generation, are consequences of the abuse of the beverage in question." Every Medical Practitioner at all acquainted with the habits of the working classes can confirm the accuracy of Dr. Arlidge's remarks. Alcoholic-drinking to excess, like all abuses, is fraught with much mischief, dangers, and miseries of the worst description; but we feel convinced that a moderate and careful use of some pure wine—such as, for instance, claret—is far more conducive to health, and to morality, too, than "teetotalism" such as Dr. Arlidge describes.

OPIUM-EATING IN AMERICA.

It is stated by the *Philadelphia Ledger* that opium-eating has become very general in the United States, and particularly in the west. The Legislature of Kentucky, with a view of checking the practice, has just passed an Act by which, on the affidavit of two respectable citizens, any person who, through the excessive use of opium, arsenic, hasheesh, or of any drug, has become incompetent to manage himself or his estate, may be confined in an asylum and placed under guardianship, as in

the case of habitual drunkards and lunatics. It is very doubtful, however, if legislation will effect much good in such a case.

FROM ABROAD.—THE ACADEMIE DE MÉDECINE DE PARIS.—TRACHEOTOMY BY MEANS OF GALVANO-CAUSTIC—EXPULSION OF A HONORARY MEMBER FROM THE BRUSSELS MEDICAL SOCIETY.

At a recent meeting of the Académie de Médecine, M. Larrey alluded to the utterly inadequate provision made by the State for the purposes of the Academy, which is a State institution. It seems that it only receives the trifling annual sum of 45,000 fr., out of which, besides providing for all its other necessities, it has to pay 5000 fr. to another State institution—the Administration of Public Assistance—for the portion of the Charité Hospital which it is allowed to occupy, having no abode of its own provided. Of course this penurious treatment comes out all the more strongly when contrasted with the large sums lavished by the German Government for the purpose of founding the new University at Strasburg, or as some suppose for galvanising it into a premature display of teaching power. Here of course the political object has to be borne in mind; but for a long time past—long before the late untimely war—the minds of Frenchmen have been painfully excited by contrasting the liberal and even lavish expenditure devoted to scientific institutions, even by the poorer German states, with the paltry sums expended by so wealthy a country as France, so reckless in the disposal of large sums in other directions. It may not be generally known that even from her Faculties of Medicine, after paying the Professors, much more is handed into the national exchequer than would suffice to place the Academy on a satisfactory basis. The immediate cause of Baron Larrey's calling the attention of the Academy again to the subject is the unfortunate condition of its library. This, as regards both its printed and manuscript contents, is a valuable one, and has been enriched ever since the foundation of the Academy by a continued stream of donations by almost every Medical author of repute, while its collection of periodical publications is large. For want of a proper library these various works are obliged to be stowed away in garrets, cellars, and wherever, in fact, space can be found, and the consequence is that some of them are undergoing a rapid process of deterioration by damp and mildew. The President, M. Barth, stated that the present as well as the preceding Governments have been repeatedly addressed concerning the necessities of the Academy. Promises have been made, but nothing has been done, and an appeal to the liberality of the National Assembly seemed the only resource.

M. Cloquet truly observed that the Academy is a national foundation recognised by the State, and frequently consulted by the Government on important questions, and that it surely ought—like the other academics—to be honourably lodged, in place of having to pay a rent for a locality utterly unworthy of it. Professor Chauffard observed that the evil of which the Academy was complaining was one that extended all over France. On every side, in the schools as well as the great scientific establishments, everything was arrested by like miseries from this question of money. Other nations were prodigal in their contributions for the purpose of favouring the progress of science, while here millions were expended on enterprises which he would not stay to characterise, parsimony being the order of the day only when the great interests of science came into question. This is disgraceful, and he could not help loudly expressing his indignation.

Certainly for the last year or so the French have been taking the first steps for remedying evils by the most free acknowledgement of their existence, both by speech and pamphlet; and the formation of a large "French Association for the Advancement of Science" entirely by voluntary subscriptions supplied on a liberal scale, and unconnected with Government aid, is a good sign. At present it is obvious that it is only by volunteer efforts of this kind that any great

reforms can be accomplished, for the Government, in the present warlike temper of the country, will be compelled—as in the days of Pitt amongst ourselves—to regard everything as subordinate to the production of gunpowder.

At another meeting of the Académie, M. Verneuil described a new mode of performing tracheotomy. Wishing to avoid the danger of hæmorrhage which so frequently occurs in adults, he determined, in an enfeebled patient, 38 years of age, suffering from phthisis with urgent laryngeal complications, to operate by means of galvano-caustic. The galvanic knife, heated to a dull red, divided the different tissues with ease, the ordinary knife not having been used during the operation. This, although performed with great deliberation, did not occupy more than five minutes. Only a few drops of blood were lost, and none of the usual cough was excited on first opening the trachea. The pain of the operation was not severe, and the canula was removed on the tenth day. All present were struck with the ease with which the operation was executed, but this was to some extent due to the emaciated condition of the patient. Still, the galvano-cautery will always be found a simple and useful means of dividing the pre-tracheal soft parts. There is of course the objection that a somewhat cumbersome apparatus has to be employed, and that tracheotomy is often too urgent an operation to admit of any delay. This objection is only partially true; and the fact that the operation performed in this manner is less alarming and dangerous, may induce resort to it in many cases where tracheotomy would otherwise be neglected.

M. Chassaignac observed that, as hæmorrhage constitutes the great danger in tracheotomy, M. Verneuil's operation calls for attention, although he believes that in less skilful hands it will not prove so successful. The great difficulty is the proper heating of the knife. If this is carried to a white heat it divides the tissues like a bistoury, and hæmorrhage occurs. M. Chassaignac finds the *écraseur* a more simple means of preventing hæmorrhage. Raising up the skin and other soft parts in front of the trachea, and passing in the curved needle with a chain of the *écraseur*, the trachea is laid bare without any flow of blood. M. Guérin maintained that *subcutaneous tracheotomy*, which he introduced thirty years ago, is a more satisfactory procedure than either of the above; for, the wound in the skin being at several centimetres distance from that in the trachea (favoured in this respect by the elasticity of the skin in this region), the blood flows externally, and is prevented entering the trachea, its doing this being the source of danger rather than the amount of hæmorrhage.

A short time since we copied from the *Presse Médicale Belge* an astounding table of fees circulated by post, together with his titles, by a consulting Practitioner, who was a Commander of the Order of Leopold and an Officer of the Legion of Honour. The price of the consultation fees varied from 3 fr. to 10 fr., according to the hours (between nine and three) at which advice was sought. If, however, a special hour was fixed or a consultation was held at the patient's house, then the fee mounted up to 20 fr. Vaccinations and revaccinations were performed for 10 fr.; and to those who were even too poor to pay the half-crown fee the Doctor gave gratuitous advice every Monday. From a later number of the same journal (May 12) we learn that this elastic Doctor is Dr. Merchie, who ought at least, from his position, to have had a somewhat higher notion of Professional dignity. He had been formerly an Inspector-General of the Army, and is now in receipt of his pension. Fortunately he had at one time been considered a person of sufficient note to be elected as a honorary member of the most important Belgian Medical Society—the Société Royale des Sciences Médicales de Bruxelles; for this has furnished a means of visiting him with a very creditable expression of Professional opinion. A letter was addressed to

Dr. Merchie from the Society informing him that the circumstances above alluded to furnished, in the Society's unanimous opinion, good ground for putting into force the statute which regulated expulsion from that body, but that it was willing to hear what he had to say in his defence. And the curious part of the matter is that the accused does not treat the affair with defiance, but really seems to think he has a defence. To be sure it is but a lame one, as might be expected. He says that he is quite in an exceptional position as compared with any of his *confrères*. He has been a Doctor in Medicine and Surgery for forty years, and has always honourably performed his duties in the army. He is entirely ignorant of the usages of civil practice, and when he retired from the army he thought that he should be doing rightly in turning to advantage the experience he had gained in the Hospitals by setting up as a consulting Practitioner. He therefore opened his *cabinet*, where persons of all classes, even including the indigent, might avail themselves of his advice. He never sees patients at their own houses except in consultation, and therefore cannot clash with the interests of the general Practitioners; and to the patients he sees at his own place he merely gives his advice, and is done with them. What there is in this contrary to "Professional dignity" he cannot for the life of him see; and as to the tariff of fees which he had adopted for his "own private use," what can there be reprehensible in that? His only object in framing it was to make a difference between those who were in easy circumstances and those to whom fortune had not been favourable. "It is a practice generally admitted, and which, in my opinion, has the advantage of placing my patients at their ease and sparing my own delicacy." Is it the very limited publicity which he gave to his scheme that is complained of? But whenever a new tariff of fees is adopted surely it must be made known to the public, "and I cannot see how, in a country like ours, in which liberty and independence constitute the principal prerogatives of a citizen, such an innovation can be regarded as an attack on the Medical Profession."

Such obtuseness as this could only be met in one way, and the Society, after considering this extraordinary letter, and declaring the justification insufficient, unanimously resolved that the name of its writer should be erased from the list of members of the Society.

AN ADDRESS ON
ENGLISH RECOLLECTIONS OF A GERMAN
SURGEON.

BEING A SPEECH DELIVERED AT ST. THOMAS'S HOSPITAL,
MAY 23, 1872.

By Dr. STROMEYER, of Hanover.

GENTLEMEN,—I suppose I may leave it to the kind care of my youngest English friend, Mr. William MacCormac, to account for the liberty I take in addressing you. Let me ask your indulgence for spoiling the Queen's English, which is not my native language. This is the first time that I speak to an English audience. As a Surgeon, I dare say, I am not quite a foreigner, having got a sprinkling of English Surgery even by inheritance. My father, who was a member of the Royal Medico-Chirurgical Society in London, and well known in his time, by having introduced vaccination in Germany, was a regular pupil of St. Thomas's Hospital, from 1792 to 1793, under Mr. Cline, at a time when Sir Astley Cooper was a demonstrator of anatomy there. He had a very high opinion of English Surgery, and used to say that the best Surgeons in the universe were to be found in London; that during a twelve-months' presence there he witnessed only a very few cases in which his opinion was different about the propriety of the operations which he daily saw performed. He was able to judge for himself, being already 30 years old when in London,

and having been a pupil and assistant of Professor Richter in Göttingen. I followed my father's example, and have been a pupil myself at St. Thomas's Hospital in 1827 and 1828. Mr. Henry Green introduced me there, and made me acquainted with the splendid circle of Surgeons then living in London—Benjamin Travers and John Tyrrell, of St. Thomas's Hospital; Bransby Cooper, Aston Key, and Mr. Morgan, of Guy's Hospital; William Lawrence and Henry Erle, of St. Bartholomew's Hospital; Sir Benjamin Brodie and Mr. Rose, of St. George's Hospital; Sir Charles Bell, of Middlesex Hospital; Mr. Guthrie, of Westminster Hospital; Mr. Wardrop, of Westminster Eye Infirmary. Sir Astley Cooper had already retired to the country. I have only seen him on an occasional visit to St. Thomas's Hospital, where he used to come from time to time when he was tired, as he said, of looking after the ewes. It was highly gratifying to see how his presence used to be hailed. The same scene took place when old John Abernethy appeared in St. Bartholomew's Hospital. The students flocked around him, and he generally gave them a speech, in parting, in the open court of the Hospital, ending by quoting Shakespeare. Being very partial myself to the great poet, I liked these quotations, which reminded me of Sydenham recommending to read "Don Quixote." For a Surgeon, nothing is so injurious as dullness; he must always be in good spirits when his services are required. Sir Astley Cooper used to say that a Surgeon ought not to read too much; but this, I suppose, meant dull authors, not Shakespeare or Cervantes, who are both of them very accurate observers of human nature, like Dickens, Sterne, and Fielding, whose "Tom Jones," I daresay, you may happen to know.

I could speak for hours if I were to say what influence the Surgeons in London whom I have named have had on my mental development. First of all, I admire the truly noble character of the Profession, the good feeling of its masters to each other, their candour, their humanity in the treatment of severe cases. I can only repeat what my father said fifty years ago—the operations which I saw were, all of them, necessary, well planned, and, in most cases, executed with great dexterity. Manual dexterity was considered as a quality which scarcely deserved to be mentioned; it was only spoken of where it shone by its absence in a bungling operator. Every operation was executed with the sole view to save the patient's life or to diminish his sufferings, not to show the dexterity of a *virtuoso*. Circular amputation was preferred to the more showy flap amputation. This I had not forgotten when I had some influence in recommending the circular amputation in times of war, where it is of greater importance still than in chronic cases of civil practice. In 1827 I examined the invalids in Greenwich Hospital, on whom amputation had been performed by the flap method, and found that the fleshy cushion had disappeared entirely. Besides this, I admired English Surgery for the simplicity of its application. The great conformity of principles resulting from simplicity struck me as highly valuable, because it makes a deep impression on the mind of a younger member. This conformity gives English Surgery a national character. It is not the same in other countries, where only your very particular friends admit that you are right in saying that two and two make four, or that a severe gunshot fracture of the knee-joint requires amputation.

I was well satisfied with the great caution of English Surgeons in adopting innovations. I saw no resections then, and there was no trace of lithotripsy yet. It is better to begin slowly, and then to go on steadily. This is otherwise in Germany and in France, where Surgeons are fond of novelties. At present you may witness the effect of greater caution. Sir Henry Thompson has eclipsed the inventor of lithotripsy, Civiale himself, whose instruments, indeed, were not worth trying till Heurteloup had found the right ones for him. Sir William Fergusson, by his articular resections, has surpassed most Continental Surgeons. Mr. Spencer Wells, in ovariectomy, all living Surgeons.

From what I had observed in London, I came to the conclusion that the beneficial influence of Surgery and the high standing of the Profession depend chiefly—(1) on the good feeling of its members towards their patients and towards each other, not excluding those of a former time; (2) on simplicity; (3) on a total abnegation of selfishness in planning and executing Surgical operations.

You may ask me, gentlemen, why I could not have learned that just as well in Germany. There is no place there which can boast of such a number of great Surgeons at the same time. Our greatest capitals have but a few Surgeons of eminence

in comparison. Whatever may be their merit, their example is not so striking as that of a whole body acting the same principles. In Paris the number of Surgeons is greater than in our German universities of Berlin or Vienna, but not to be compared to London, which I consider is a central point of Surgery for the whole globe. This, gentlemen, you may consider as the sincere opinion of a man who has watched the progress of Surgery during half a century. I wish it may remain so for centuries.

After having been in London, I happened to be in Paris at a time when Lisfranc was thundering against Dupuytren, whom he used to call "le barbare de la Seine," as a sample of good feeling amongst the Profession there. It is one of the great advantages of travelling, and of seeing eminent men of other countries, that, by observing them in their activity, one may acquire a better notion of their character. Their writings excite greater interest, because we are inclined to give them greater credit. I always admired the simplicity of style in English authors in general, and of Surgical writers in particular. Sterne ridicules the pompous style by mentioning the expression of his French barber about the solidity of a new wig, "You may immerse it into the ocean." An Englishman, says Sterne, would have preferred a pail of water. To avoid the barber's style, I took precious good care never to say ocean when I meant a pail of water.

After sketching these general impressions, permit me, gentlemen, to give a few particulars of the manner in which some of my English teachers have influenced me. Having so lately seen one of the greatest battle-fields of modern history—that of Sedan, where I met Mr. William MacCormac, who, from over-exertion, did not look quite so well as to-day—and the siege of Paris afterwards, let me speak of Mr. Guthrie first. I cannot say that I liked him personally quite so well as many of the others; but I admired his energy in maintaining the great principles acquired in the Peninsular War—the necessity of early primary operations, of tying a wounded artery, if possible, on the wounded spot itself. I have done all in my power to keep his doctrines, those of the admirable Hennen, and of old Baron Larrey, in fresh memory since 1848, when the time seemed to approach that Germany must go to war for its own development. For a man of sense, there can be no doubt about the necessity of early primary operations; but in military practice there are difficulties in which it is the duty of every Medical man to maintain the sacred cause of humanity. This sentiment was appreciated even by a conqueror like Napoleon I., who said of Larrey that he was the most virtuous man he had ever known. It was one of Mr. Guthrie's best qualities that he always gave very positive reasons for what he did; so another person could easily find out whether his own views must be in accordance with Mr. Guthrie's opinions. There was no fickleness about him. I differed from him in one essential point—that of his preferring amputation for gunshot-fractured thigh to conservative treatment. Guthrie puts too much stress upon the imperfections of conservative treatment, the result of which is often a very disabled limb, whose possession does not make the patient very comfortable. But these imperfections admit of improvement, while a high amputation gives no prospect of better chances: it will always remain a very dangerous operation. Our first object is to save a man's life, and the second to make him comfortable, but not in his grave. My results of conservative treatment in gunshot-fractured thigh, during the first three campaigns of 1849, 1850, and 1866, did not go beyond 50 per cent. healed. I saw the reasons of our failures, tried to avoid them, and went on with conservative treatment. In the two campaigns of Schleswig-Holstein (1849 and 1850) the patients had to be carried to considerable distances. After the battle of Langensalza, in 1866, I was unable to prevent many cases from being spoiled by an injudicious use of plaster bandages. It was in Floing, near Sedan, where we succeeded in saving 77 per cent., twenty-seven amongst thirty-five patients, who had been carried to no great distance, and were treated without putting much restraint on their shattered limbs.

From my own father I had learned the advantages of Percival Pott's position, which may be employed during the first period in most cases; in others or later the double inclined plane, or a straight wire basket, will suffice. According to my opinion, the great principles to be followed in compound fractures in general are—(1) dressing the wounds without lifting the limb; (2) avoiding constriction; and (3) not irritating the muscles in straining them by mechanical contrivances. A gunshot-fractured thigh permits a weight to be suspended to it, keeping the limb a little at rest, like the hand of an assistant, but not an extension by weight or other contrivance, that

gives the limb its proper length, except in very few cases, as mentioned by Mr. MacCormac in his "Notes and Recollections," which healed without difficulties and without any perceptible shortening. The most common case is, that for some time after the accident the muscles retain a tendency to retract, which is increased by opposition, and ceases by-and-by in a favourable position of the broken limb. The idea of subduing muscular action by constant extension, even in compound fractures, is not new; but it had not been tried before by contrivances so dangerous as a plaster of Paris bandage. This is applied under chloroform, which relaxes the muscles; the limb is made straight, and as long as its fellow. When the action of chloroform has ceased, the muscles recover their activity, and are kept in extension in spite of their violent efforts to contract, which often break the plaster bandage. The tension, which is kept up by mechanical means, makes the sensibility rise to a high pitch, and severe inflammation follows. If the plaster bandage be loosely applied, by putting wadding and a flannel roller between, it is often well borne, but the limb is as short afterwards as if no bandage had been employed. While I was writing this in Hanover, on May 1, a young captain came to me, from whose gait no one would have thought that he had had a gunshot-fractured thigh in 1870. A plaster bandage had been applied on the third day: he could not bear it. The Surgeon who took it off next day told him that the fragments had taken a bad position under the bandage. From this time he was treated without restraint, and cured in six weeks, his limb lying in a wire basket. The shortening was one inch of his left lower extremity. His brother met with the same accident at the same time, but was healed with a shortening of five inches. Large splinters came away by suppuration, some of them being three inches long. The captain came to consult me about his brother. He is in service again long ago.

The danger of early plaster bandages on other parts of the skeleton is less than in the thigh; but it exists and is very great in the humerus, where pressure is very liable to stop the venous current, or to drive a splinter of bone into the brachial artery. I treat these fractures by letting the arm lean on a soft cushion, which is tied to the thorax, the forearm being suspended in a sling. In Schleswig-Holstein I had twenty-four successful cases amongst twenty-nine. One of the German Surgeons who took part in the late war—Dr. Rapprecht, of Munich—prefers the plaster bandage; but amongst the three cases which he had to treat there was one which proved fatal on the seventeenth day by hæmorrhage, a splinter of bone having opened the brachial artery.

I differ from Mr. Guthrie besides in his appreciation of trephining the skull, which I have tried to exclude entirely from military practice, as useless in some and unnecessary in other cases. I consider a state of coma from depressed skull no more as an indication for applying the trepan than a comatose state in typhus as an indication to rouse the patient from it by any other means but those which are in accordance with his general state—cold, for instance, but not stimulants. As soon as the fragments of skull become detached by suppuration, the comatose state ceases by itself.

The great difficulty in settling this skull question consists in this—that some patients survive the use of the trepan, or of an early extraction of splinters, and that some recover their senses very soon after the operation. This seems to be a conclusive proof of the legitimacy of active interference. But there is no depending upon it; the patient may die just as well after having recovered his senses completely, and, as experience has shown, more easily than if you let him continue comatose by not disturbing the splinters. This might have been expected, from very solid physiological reasons. By taking away the splinters at an early period in cases where the dura mater is wounded, you open the arachnoid cavity; air and acrid matter can enter it. Brain-substance, when bruised, thus becomes putrid, while it might have been eliminated by reabsorption without access of air. Subcutaneous operations practised in modern times have done a great deal to put more stress on excluding air; but even before their time, Dease and Sir Benjamin Brodie came to a conclusion that access of air was to be avoided in cases of fractured skull, and that no interference ought to take place for depression unless it was warranted by cerebral symptoms. John Hunter was not yet arrived at this degree of caution when he said in his Lectures (Palmer's edition, vol. i., p. 493)—"All fractures of the skull may be called compound; for if not so naturally, they are made so by the removal of the scalp."

In the retrograde tendency of Surgical interference with a broken skull it was an important step not to remove the scalp; but other steps were to be argued. An open scalp wound over

a broken skull does not produce a great change in the danger of the case. Spreading inflammation of the membranes of the brain or deep-seated suppuration does not necessarily follow from it; but these are very likely to take place if you open the arachnoid cavity by removing the splinters which have kept it closed. When the splinters come away by a very limited suppuration at a later period, the arachnoid cavity is closed by adhesions of dura mater to the brain. It is often impossible to say beforehand whether the dura mater has been opened or not. If it is open, the danger is rendered much greater by removing the splinters. The *Medical Times and Gazette* of 1860 contains a list of eighty-three cases in which the trepan had been used, fifty-one of whom died, and thirty-two recovered. Amongst those who did well the dura mater had been wounded; but in three cases the others as well were such that, according to my experience, they might have recovered without using the trepan or early extraction of splinters. Gunshot fractures of the skull are always compound; their successful treatment without active interference deprives this of one of its strongholds—the presence of an open wound, which formerly seemed to permit further violence. During the two Schleswig-Holstein campaigns of 1849 and 1850, I had to treat forty cases of gunshot-fractured skull, thirty-three of whom recovered, and seven died. We had one case of trephining with happy result, but it was of that description that it might have done well without interference. The others were subjected to an antiphlogistic treatment by ice, bleeding, purgative medicines, and low diet. The splinters were not removed before being quite loose. I have been blamed by Mr. Pirogoff and others for totally excluding active local interference in gunshot skull fractures; many others have followed my example. You will admit, gentlemen, that there is no knowing of what use a thing may be before having tried it. My object was to know how far we might get without active interference. The result was not unsatisfactory. It was the same thing with treating typhus patients without stimulants. By trying it, on physiological principles derived from morbid anatomy, I found it very successful. What has pleased me most, from a Medical point of view, during the late war, was to find two Hospitals in Rheims and one in Versailles where the number of deaths from typhus was not above 8 per cent. Weak broth and some ounces of very sour wine were all the stimulants employed till the fever was over. The wine which I tasted was so sour that it must have contained more acid than common vinegar does, as I know from comparative experiments with potash. So it probably did the same service as phosphoric acid, which I prefer, with a well-boiled water-gruel for diet during the febrile stage. The two Hospitals in Rheims were close to each other; in one, the patients were cooled by immersion—in the other, by active ventilation in tents, while the results were quite the same in both. In other Hospitals, the mortality from typhus amounted to 25, even to 50, per cent. Nothing shows the great value of the Medical art and science better than such striking differences in the results of treatment under the same circumstances in regard to constitution, causes, and symptoms.

During great part of my presence in London I used to see the Surgical patients at St. Bartholomew's Hospital under the care of that clever and highly accomplished Surgeon, Mr. W. Lawrence, whose kindness and very instructive conversation I shall never forget. I saw a great number of patients under him with phlegmonous inflammation, who were treated by incisions at an early stage before suppuration had set in. This bold practice was at that time little known in Germany, where it was spread afterwards, and is generally employed up to this day. Cases of this description do not permit hesitation, and show the use of the treatment very evidently. The effect of an antiphlogistic treatment is not so striking in many other cases. It is only by a longer experience that a Surgeon is enabled to say whether a case of fractured skull, or a compound fracture of a limb, has been greatly benefited by a venesection, which has been made, not in a late period when suppuration is forming, but early, when reaction is taking place, when the face becomes flushed, and the pulse full and hard. Amongst the many wise things which Sir Astley Cooper has said, was the advice to visit a patient with a broken skull three times a day, in order to find the proper time for bleeding him. This does not produce a similar effect like an incision in phlegmonous inflammation; it does not restore the patient's consciousness, but it keeps him alive. That this really takes place can only be judged from other cases in which bleeding at a proper time has been omitted. But bleeding is out of fashion now in Germany as well as elsewhere. The discovery that pneumonia can be cured without bleeding has been the first.

cause of this antipathy. I have treated pneumonia myself without bleeding, and had very good results. I lost but five patients out of 558 during ten years in the general military Hospital of Hanover, from 1853 to 1864. Our patients were cupped once, and took phosphoric acid. I never allowed this to be a proof that venesection was equally unnecessary in Surgical cases, which have no typical course like pneumonia. It was a mistake of former times that pneumonia might be subdued by repeated bleeding—it runs its course in spite of that. I have tried in vain to maintain its use in Surgical practice: there is no swimming right across a mighty stream; one must wait for the proper time of low water to cross it. It must be some years ago that Mr. Syme said bleeding-lancets were to be found in Great Britain no more. This, I suspect, has been the acme of antipathy to bleeding. From that moment it was no more a distinction not to bleed. Bleeding ventures to show its head again in the *Medical Times and Gazette* now rather timidly—recording cases which would have been fatal without venesection. Lancets can be easily supplied again, and a few cabbage-leaves, as Dickens says, will be sufficient to give a little practice before opening a vein in man. Perhaps I am mistaken in my expectation that bleeding will soon have its turn again. Perhaps I shall be damned in a future time for having been the last of the Mohicans recommending venesection. At all events, I would in that case meet very good company—all my old friends in London.

On July 6, 1827, I witnessed the first case of hæmorrhage from thrombosed vein, in St. Thomas's Hospital, under Mr. Tyrrell's care. A shoemaker had been stabbed by his own wife with an awl in the right upper-arm. The wound appeared trifling to him—he did not notice it for some days: then an immense swelling of the upper-arm took place; the forearm became gangrenous. Mr. Tyrrell amputated close to the axilla. In examining the separated limb, it was found that the brachial vein had been freely opened by the instrument; that a large hole, filled with coagulated blood, had formed near the vessels. The brachial vein was thrombosed to a considerable extent above the puncture. It struck me that the internal bleeding must have taken place after the obstruction of the brachial vein, and that gangrene had been produced by stagnation. I remembered this case many years later, when I found, in military practice, that secondary hæmorrhages in open wounds take place from similar causes. I described them under the name of phlebotatic hæmorrhages. Others prefer to call them pyæmic, putting little stress upon the venous obstruction. But pyæmia does not always exist in these cases, and the influence of venous obstruction on hæmorrhage is evident. You will see this, if you should happen to bleed again, which must be done by stopping the venous current above the place where you open the vein. Every open wound would bleed under a similar contrivance. Let me observe here, what I have forgotten to mention elsewhere, that capillary thrombosis of some extent below an injured vessel must have the same effect as thrombosis of the main vein, because it increases the degree of pressure which the column of blood exerts in entering the limb. The quality of the blood in it must become altered by impediments of either kind, and healthy nutrition cannot be kept up.

These observations are of great interest in military Surgery: they teach us to be very cautious in treating wounds which may have affected vessels of considerable size, whose bleeding has been arrested by bruising or by coagula. The injured vessels may heal without hæmorrhage, if the reflux of venous blood remain free; but if there be any obstruction, either by capillary or venous thrombosis, secondary hæmorrhage can occur. Before this takes place, the wound often changes its aspect from altered nutrition. Mr. Guthrie's plan of tying a wounded artery on the spot often does very well in minor vessels, but it often fails in the femoral artery. The large vein accompanying it has often been torn or bruised by the same ball. After tying the artery on the spot, the vein often becomes totally impermeable, and then hæmorrhage recurs, or the limb becomes gangrenous. It may be proper in some cases to gain time by putting a ligature above the wounded spot; before new hæmorrhage occurs, the vein may have undergone a favourable change. In other cases, it is better to amputate at once.

I cannot dismiss Mr. Tyrrell's name here without mentioning how I used to admire his cataract operations. He did them generally by a superior corneal incision, of the greatest regularity. I adopted his method of sitting behind the patient's head in operating on the right eye. I had seen Graefe the elder in Berlin, Jaeger the elder in Vienna, and Roux in Paris, perform extraction, as well with the left as with the right hand,

but I preferred the more cautious English way. I often thought of Tyrrell's beautiful operations and their results when the time came that iridectomy seemed necessary for the great majority of cataracts before extracting them. I have hailed Dr. Liebreich's innovation as a candid acknowledgment that modern oculists had gone too far in this respect, and that the iris ought to be spared if possible or reasonable.

To Sir Benjamin Brodie I feel very thankful to this day for what I have seen of him in treating diseases of the urinary organs, but chiefly for his skill in diseased joints. He was the first Surgeon who enjoined the doctrine of keeping diseased joints at rest by putting them on a splint. The leather splints, which he recommended, had been partly superseded by starch or plaster bandages, but I use the leather splints constantly in many chronic cases, when the patient is to go out to bathe, or to use other local applications. Sir Benjamin Brodie's influence on the treatment of articular diseases has been great in Germany. His work on the subject has been translated, in 1821, by Dr. Holscher of Hanover. It had to fight its way in Germany against Rost's authority, who had introduced the red-hot iron as a general remedy for most chronic cases. It is used no more now. The great principle which Mr. Hilton has so ably advocated, of keeping diseased parts at rest, either by mechanical or by physiological means, has done away with the red-hot iron. It was Sir Benjamin Brodie's farther merit to point out cases where articular disease is spurious, and where rest proves hurtful. I consider Brodie's work on local nervous affections, published in 1837, as one of the greatest value on account of the number of persons who may be benefited by his doctrines. I had given a short extract of it in my "Manual of Surgery," but this had no effect in rousing the public attention. My German countrymen imagined that local nervous affections were a particular gift of nature to English young ladies. Not a month passes but I see a striking case in Hanover. My son-in-law, Professor Esmarch, who travels a great deal during his vacations, has been able to pick out a number of cases in different parts of Germany, and to extricate them from the spider's web of injudicious treatment. Perhaps I ought to have written myself about this subject more at large, but I despaired of doing it better than Sir Benjamin Brodie. Professor Esmarch published a small volume last year on "Articular Neurosis," which, I hope, will go far in spreading Sir Benjamin Brodie's doctrines, whose German translation has failed to produce the desired effect. This subject is intimately connected with the exertions of that great genius, whose discovery of the different roots of motor and sensitive nerves has spread a lustre on our century.

Perhaps no man has given so much to think to his contemporaries as Sir Charles Bell. He did not live long enough to witness the wide expanse of studies derived from so simple a source as that of the different roots. Bell's researches on paralysis of the facial nerve alone were sufficient to create a number of similar ones. The connexion of this illness with rheumatism; the liability which persons have for it who are subject to abdominal affections; to impediments in the circulation of the abdominal viscera, pointed to other diseases with diminished nervous energy—in the organs of sight and of hearing, for instance.

In following the hints given by Charles Bell, I found that every local affection originating from violence, or spontaneous inflammation, was influenced in its course by an enlarged liver or spleen, and that, for a cure, it is necessary to reduce their size. This accounts for the very general, but more empirical, use of blue pill and bark, and advises us to examine the size of the liver and spleen, by percussion, especially in chronic cases which show very little tendency to heal—in secondary or tertiary syphilis, for instance.

Marshall Hall's discovery of the reflex function gave a new stimulus to think on the great importance of Bell's discovery, from which it had taken its origin. This doctrine of the reflex action of the nervous system can only be compared to the discovery of the blood circulation. It gave an idea of the manner in which the nervous action is kept on day and night, and reflex action following the other. Trying to understand this action, I was led to assume a second principle, which is ultimately blended with reflex action. I found that immoderate reflex action in muscles, or muscular organs, was generally combined with painful feelings, sometimes in the neighbourhood, sometimes remote from the seat of spasm. As a similar train of combined sensations must take place during healthy action of muscles or muscular organs, I guessed that the action of the muscular system was necessary to maintain the nervous energy.

Sir Benjamin Brodie, in his work on local nervous affections, opposes the popular use of the name of spasm for painful

feelings. This is the case in Germany. People make no difference between *Krampfe*, spasm, croup, and *Schmerz*, pain. There is some reason for it; where there is spasm, there used to be pain, but often in remote parts. Instead of pain, spasm is often combined with altered sensibility, partial or general. The German name for hysteria is *Mutterkrampfe*, mother cramps. The uterus being a muscular organ, it may well be that hysteria partially consists of habitual spasm of the uterus, as a reflex action from the ovaries, or from other parts of the system. This idea was well known in England in former times. You can find it in Shakespeare's *King Lear*, who is made to say, "How this mother swells up towards my heart."

One of the most striking examples of pain originating in spasm, is that of the glans penis, from contractions of the bladder around a stone in it. Another well-known example is pain in the knee, arising from reflex spasm of the flexor muscles of the hip-joint, from inflammation of its bones, sometimes from other causes.

In a particular case, where there was no inflamed hip-joint, I succeeded in doing away with the knee-pain by dividing the rectus and rectinæus muscles. I have pointed out sensations, combined with muscular action, in all the organs of sense and in many cases of disease. I have written on my theory of combined motor and sensitive nervous energy, first, in Hanover, 1837, in the *Göttinger Gelehrten Anzeigen*, an article which I reproduced in Latin, after having become Professor of Surgery in Erlangen. I have followed up this subject no farther, because it would have cost me the exertion of a whole life to carry it to a degree of perfection equivalent to a clear demonstration by physical evidence. But the fact that every pain, which evidently does not depend upon local alteration of texture, depends on spasmodic action of some muscular organ, has been of great use to me in practice, and I can advise you to put this question to yourself in every case of that description, Where is the seat of spasm? Remember that it is as well in the voluntary muscles as in the involuntary ones that spasms can take place. Perhaps you little suspect that the liver is an organ whose muscular energy is of great importance. But if you had felt the pain in passing a biliary calculus, you would think otherwise. I have felt it myself, and took six grains of opium in one night for it.

Pains in remote parts of the body are very frequent in liver complaints, in the shoulder, in the head, or in other parts. I could tell a great number of cases in which local nervous affection of an extremity proceeded from the liver, others from the accumulation of hard fæces in the large intestines, keeping up spastic action for their expulsion. It is very easy to cure them, after having found the real cause, without any toxic application whatever to the affected limb.

After having spoken of such a variety of things and for such a length of time already, let me bid you farewell now, gentlemen, and thank you heartily for the kind attention with which you have been listening to me. I wish you may remember your studies in London with the same feelings of gratitude and satisfaction as I do after forty-four years of practical life.

A CHAPTER IN THE HISTORY OF CHOLERA.

Communicated by Dr. CHARLES ROGERS,
Historiographer to the Historical Society (Earl Russell, President).

ON Friday evening, the 26th ult., Mr. B. G. Jenkins, of the Inner Temple, read before the Historical Society a remarkable paper on Cholera, founded on a communication to the Russian Imperial Academy of Sciences, and now in the hands of the Medical Council of the Minister of the Interior.

Mr. Jenkins maintained that no true advance could be made in any science founded on experience and looking to facts for its development, until the facts of that science, so far as they extended, had been recorded and correctly interpreted, and that it is because we have been looking at the facts, which have been accumulating for half a century, as facts, without attempting to show—or rather, without succeeding in showing—in what relation they stand to each other, that we are really no wiser than we were forty years ago. He held that, instead of one "home" of cholera in the delta of the Ganges, there were seven, all situated on or near the tropic of Cancer, equally distant from each other, of which the most important is that at the mouth of the Ganges; that the others are to the east of China, to the north of Mecca, on the West Coast of Africa, to the north of the West India Islands, to the west of Lower

California, and among the Sandwich Islands; and that a reference to the map would show that the recorded appearances of cholera over the globe may be satisfactorily explained by supposing seven atmospheric streams, each 1400 miles in breadth, to proceed in a north-west direction; and that at some periods, as in 1833, 1850, and 1866, nearly all the streams were in activity.

Having pointed out the course of these streams on a map especially prepared, and shown how the disease moved within the limits of each, in both the north-west course and its south-east extension across the equator, Mr. Jenkins, in tracing in detail the course of the cholera in India during 1817 and 1818, called attention to a remarkable law which manifested itself—a law which he held to be applicable generally wherever cholera appears. Although the course of cholera during 1817 was not very clear, still it was, he believed, evident that it was north-west and south-west. The lull in virulence and advance which occurred in December, 1817, continued till March, 1818, when cholera broke out again just where it had ceased the previous December. He drew attention to a very recent similar instance: the cholera last year halted on the western border of Russia, and about a fortnight ago broke out in Poland, which augurs ill for the north of England this year. The remarkable law which manifested itself was that in 1818 the cholera advanced simultaneously in two directions—north-west and south-west—in such a manner that all places attacked at any given time by its north-west advance were situated at right angles to all the places attacked at the same time by its south-west advance. The mode of double advance was made evident by cutting a piece of paper square, placing a corner upon the map at Calcutta, and moving it across India in a direct line to Surat. In 1819 the cholera crossed the Arabian Sea to Muscat, and passed simultaneously through Persia, and up to 1823 advanced as far as Asia Minor and the Caspian, and then died out. In 1823 a fresh outbreak occurred in India; this steadily proceeded to the north-west, and halted in the west provinces of Russia in 1830, and the next year broke out in full force in the same locality—thus presenting a parallel to 1871-72—and went as far as Britain. By referring to the map, he said it would be seen that all places attacked by this stream of cholera lie within the boundaries represented by two lines—one drawn from the southern point of India to the north of England, and the other from the Ganges through Orenburg to Archangel. Mr. Jenkins having described with great minuteness the rise and progress of the other six streams, bringing the subject down to the present year, stated that Europe was liable to attack from two great sources—India and Arabia—Russia and Northern (and partly Central) Europe coming under the influence of the Indian stream, Southern and Western (and partly Central) Europe under the influence of the Arabian, and that the Continent would certainly be attacked by both this year. He called attention to a fact worthy of mention, that all the places recorded by Dr. Gavin Milroy as hitherto unaffected by cholera lie outside these streams, or in their possible, but not actual, extension.

Having stated that he was prepared to give in another paper on the origin of the disease a full explanation of some well-known points about cholera, such as its partial connexion with the east wind, its following the course of large rivers, its greater prevalence on tertiary strata, alluvial tracts, and the deltas of rivers, and its comparative rarity on secondary and primary strata, Mr. Jenkins proceeded as follows:—

"It was not my intention at the present time to enter into the question of the origin of the disease, but having read a few days ago that Dr. Buchanan in this very hall congratulated the meeting on being able to number among the things of the past the time when the propagation of cholera was supposed to be due to all manner of cosmic influences, and on having reached 'a solid basis of fact and knowledge upon which further observation might be built with security,' I am tempted to observe that I, for one, maintain that this despised theory, which Dr. Buchanan fancies is buried and put out of sight, is the correct one. I maintain that cosmic influence lies at the origin of cholera—that cholera is intimately connected with auroral displays and with solar disturbances. I believe that I am able to show that a remarkable connexion exists between the maxima and minima of cholera epidemics and of solar spots; and in directing your attention to this map, on which I have represented graphically the amount of cholera and the number of sun-spots for the last fifty years, I wish to show that there is here also 'a solid basis of fact and knowledge upon which further observation might be built with security.' You are all probably aware that the great astronomer Schwabe discovered that the sun-spots have what is called a ten-year period—that is, there is a

minimum of spots every ten years. It was also discovered that the diurnal variation in the amount of the declination of the magnetic needle has a ten-year period. The same was proved in regard to earth-currents, and also auroral. The maxima and minima of the four were found to be contemporaneous. This was a great result; but Professor Wolf, on tabulating all the sun-spots from the year 1611, discovered that the period was not ten years but 11.11 years. This period is now the accepted one for sun-spots, and it has been established for the magnetic declination, and by Wolf for auroral. Now, it is a curious fact that the last year of every century—as 1800—has a minimum of sun-spots; so that the minima are 1800, 1811.11, 1822.22, 1833.33, etc. The maxima do not lie midway between the minima, but anticipate it, by falling on the year 4.77 after a minimum—for example, 1800 was a minimum year, then 1804.77 was a maximum year.

“Now, cholera epidemics have, I believe, a period equal to a period and a half of sun-spots. Reckoning, then, from 1800, we get as a period and a half the date 1816.66, which was shortly before the great Indian outbreak; also, 1833.33, 1849.99, 1866.66—years having a maximum of cholera; and 1883.33 as the next year in which there will be a cholera maximum. It follows from what has been already said that 1783.33 would be a year in which cholera would be at a maximum. Now, it is a fact that in April, 1783, there was a great outbreak of cholera at Hurdwar.

“I would call attention to the parallelism of increase and decrease of these curves. I am not prepared to say that sun-spots originate cholera, for they may both be the effects of some other cause, which may, indeed, be the action of the other planets upon the earth and upon the sun. If that be the case—and I see no reason why it should not—we may then have an explanation of the minor periods, and of the large period of fifty-six years, which Wolf believes he has detected, and also of the minor periods observed in cholera epidemics.

“My own opinion, derived from an investigation of the subject, is that each planet in coming to and going from perihelion—more especially about the time of the equinoxes—produces a violent action upon the sun, and has a violent sympathetic action produced within itself; internally manifested by earthquakes, externally by auroral displays and volcanic eruptions, such as that of Vesuvius at the present moment—in fact, just such an action as develops the tail of a comet when it is coming to or going from perihelion. And when two or more planets happen to be coming to or going from perihelion at the same time, and are in or nearly in the same line with the sun—being, of course, nearly in the same plane—the combined violent action produces a maximum of sun-spots, and in connexion with it a maximum of cholera on the earth. The number of deaths from cholera in any year—for example, the deaths from cholera in Calcutta during the six years 1865-70—increased as the sun passed from perihelion, especially after March 21; came to a maximum when it was in aphelion; and increased again when the earth passed to perihelion, and notably after equinoctial day—thus acting as a fair test of my theory.”

Man in the Past, Present, and Future. A Popular Account of the Results of recent Scientific Research as regards the Origin, Position, and Prospects of the Human Race. From the German of Dr. L. BÜCHNER, author of “Force and Matter,” etc. By W. S. DALLAS, F.L.S. London: Asher and Co. 1872. Pp. 362.

THE list of books before us bears witness to the insatiable curiosity of mankind as to their origin and their future destiny. When we consider that these books contain between three and four thousand pages, by writers of the most diverse schools of

thought, on the most intricate of subjects and the most awful, and that language itself often fails to express clearly what the writers mean, we shrink from attempting to construct an essay on their subject as a whole. We can but undertake the humbler task of describing each book by itself.

In choosing which book to begin with, we naturally take the simplest, which, without doubt, is Büchner's. This author's views have all the force and lucidity which flow from entire consistency and simplicity. His well-known book, “Kraft und Stoff,” contained his creed—short, dogmatic, and unmistakable. There exist “force and matter,” nothing else. Force is a property of matter, and cannot exist without matter. Matter, therefore, is immortal and eternal, and could not have been created, because to suppose a (creative) force existing before matter and independent of matter is impossible. Matter is infinite. It has laws which are immutable, eternal, and universal. There is no such thing as a “supernatural.” Life comes spontaneously, according to law, and is no work of a Creator. There is no design in nature; this is a fiction of the human mind, which admires what itself has fancied. There is no God, no soul, no free will, no life after death. Are these sentiments immoral and contrary to public policy? We can't help that, says Büchner, if they are true.^(a)

Such is the writer whose work on “Man” is presented to us in an English dress by Mr. W. S. Dallas, with a slightly apologetic intimation that he does not participate in his extreme views, and thoroughly differs from some of his conclusions upon moral and social questions. We can assure Mr. Dallas that there is not the least need of apology. We want to know things as they are; and the history of opinion is a part, and as essential a part, of the history of our times, as is the history of meteors, pestilences, sun-spots, chemical discoveries, mechanical inventions, and political revolutions.

Dr. Büchner in his introduction states his problem, which is to determine man's place in nature, and in so doing to demolish one of the cardinal errors bequeathed from less enlightened times. One error which prevailed down to the sixteenth century was the *geocentric*—the notion that the earth was the centre of the universe, and that sun, moon, and stars were made to dance attendance on it. The other is the *anthropocentric*, “which even still governs the great majority of mankind,” and “regards man as the centre and sole object of the whole organic creation—as the image of God or the ruler and centre of the terrestrial world, the whole mechanism of which has been organised, and exists solely, for his use and with reference to his special needs.” This prejudice has been dissipated by modern science, of which Dr. Büchner professes to give the processes and results.

He proceeds in his first part to discuss “Our origin.” But this title is scarcely exact; it should have been “Our original condition,” for the whole scope of this part is to show, by a laborious, yet interesting *résumé* of all the observations on the subject—from Frere's discovery of flint chips at Hoxne in the last century to the latest observations of Lyall and Lartet—that man has existed for thousands, perhaps hundreds of thousands of ages on the earth, and that all evidence shows him to have been at first a mere barbarian. Here comes a point which Büchner evidently feels to be a difficulty. Savages are virtually stationary for terms of almost “infinite duration.” Thousands of years pass without any improvement, as is evident in the case of the Australian hordes at the present day; or, if there be a fit of improvement, it may cease and become stereotyped, as in the case of the Chinese. So that, even after the “large and powerful animals” and the “mighty geological catastrophes” of the diluvian period had run their course, “impulses of some particular kind would be required to rouse the primeval savage from that sluggish, inactive, and unintellectual state in which one generation after another had sunk into the grave, like the beasts surrounding them, and to force upon him, as it were, the necessity of advancing in civilisation. Amongst impulses of this kind,” continues Büchner, “I reckon prominent natural phenomena, geographical or climatic changes, the immigration or eruption of foreign races, wars, famines, expulsions from old dwelling-places, migrations, the commencement of relations of traffic and commerce, the gradual improvement of language, etc., and especially the rise of certain highly endowed individuals who possessed themselves of a political or spiritual sovereignty.” Without such impulses, says Büchner, we might to-day have been as savage as our savagest ancestors. There is positively, he affirms, no such thing as an “innate and necessary instinct of progress in human nature.” This is

(a) “Force and Matter: Empirico-Philosophical Studies.” Edited by Collingwood. London: Trübner. 1864.

proved by the fact that nations may not only be stationary, but may, like the ancient great empires, decay and vanish.

We cannot help noticing in passing, how thoroughly accordant in main points these admissions of Büchner are with the sentiments of the upholders of what he calls the "Judæo-Christian fables." Whether "God sends a prophet" or whether a "highly endowed individual" arises, the fact seems the same; for the "Judæo-Christian" fabulist may ask on the principle of *è nihilo nihil fit*, and "no force can be self-generated," whence these "highly endowed individuals" rose from, and who or what gave them their "endowments."

In his second part, entitled "What are we?" Büchner gives what properly is the answer to his first question. He enters into the history of development in general, and the development of man in particular, and comes to the now familiar conclusion that we are the climax of an extinct family of catarrhine apes. Whether the development took place gradually by natural selection in accordance with the Darwinian theory, or *per saltum* on Owen's theory—whether it occurred at one place and time, or many—in fact, whether we are descended from one or many human ancestors—does not matter. Man only differs from his cousins in the degree, not in the kind of his endowments.

The third part of Büchner's book is entitled "Where are we going?" and is the most important; because, having settled "What we are," he believes he can satisfactorily predict what we are likely to be. But this question is much more simple than as it is usually stated by theologians. They would perplex us about an imaginary future life, which Büchner assures us is not to be. Some persons also perplex themselves with the question *why* we exist; some going so far as to affirm that we are in a state of preparation for a better state of existence, or even *ad majorem Dei gloriam*. *Nugæ!* We are here *because we are here*, and if wise will make ourselves as comfortable as we can. We are here, not by our own choice, nor yet by the act of a Creator, but by evolution according to natural law. "Man has no one to thank for his existence, and must seek the purpose of his existence only in himself and his own welfare and that of his race." Society needs to be improved and organised, so that the struggle for means of existence may be lessened; and that individuals, instead of merely striving that themselves may live, may devote their energy to the welfare of their race in general. Thus earth will become in the end the Paradise such as theologians feign it to have been at first.

The details of the author's scheme of the reconstitution of society are given under different sections. *Government* must be republican. *Nationalities* must be constituted in some undescribed way, so as to eradicate the national hatred and jealousy which have been created by "misguided sovereigns with enormous armies." Disputes will easily be settled by a national Areopagus(?). *Society* must be organised on the principle that "all men at their birth bring with them into the world an equal right to all the (material or intellectual) possessions of mankind existing at that moment." Every man may earn what he can, and enjoy it, but at his death it becomes common property. The author's views as to land are of the *philosophical*, J. S. Mill, communistic sort. *Capital* he does not rail at *per se*, like an ignorant trades unionist, much as he objects to its accumulation in single hands. Respecting *labour*, he rebukes working men for having yielded to the delusions of *crude communism*. The *family* he regards as too powerful, and that the State ought to provide *education* and dictate its kind. He might have fortified this part of his argument by quoting Lemuel Gulliver's account of the education of the Lilliputians. *Women* he desires to raise and emancipate. But would he give women political power, or the franchise? He is not such a fool. "The still prevalent intellectual immaturity and want of discretion in the female sex, and especially its weakness in respect of *religion*, make its complete political emancipation appear impossible." *Marriage* should be free—both to form and to dissolve. *Morals* are founded on reciprocity and mutual advantage. A criminal is a person "who places his own *I* higher than the interests and laws of the common weal." *Religion* will vanish as knowledge increases. So will *philosophy*, so far as it seeks to know things as they are, apart from things as they seem. Such are Büchner's doctrines, and his disciples at their death may enjoy the consciousness of having served the progress of humanity, whilst themselves lose their individual existence just as drops of rain are lost in the sea.

The next book to notice is "Mankind," by an "M.A. of Balliol College." He intimates that the origin and destiny of man may be explained by Revelation or by Science. He begins with the former, and devotes the first 736 pages of his work to the annihilation of all religious systems and traditions,

beginning with the Mosaic. He begins with the history of the discovery of the book of the law by Hilkiah the priest in the temple at Jerusalem, in the reign of King Josiah. He intimates that a large portion of the alleged Mosaic writings were then forged by Hilkiah, and based upon the allegories of the Egyptian priests, under which were conveyed lessons in natural history, astronomy, and morality. A large portion of the M.A.'s book consists of an explication of the Egyptian philosophy which lies hidden under the narrative in Genesis. He then subjects the New Testament to the most severe criticism—in fact, seems to compile most things which can be raised against the integrity of the text and the authority of the writers. He shows the astronomical problems contained under the religious myths of Jews, Babylonians, Hindoos, Persians, etc. When we come to the end of the book we find the statement that Nature Worship is "the primary and universal religion of mankind," and that it lies hid under all myths and allegories, Pagan, Jewish, or Christian. Nature is the Eternal Universal Mother. "From her we sprang, and to her we must return; but the very fact that, finite beings as we are, we can aspire to the Infinite is a proof that we are immortal. We are sure that glorious and ennobling hope cannot have been implanted in us in vain, whatever may be the way in which it is to be realised."

The next work we shall notice is Mr. Ponton's on the "Beginning." Believing that too much stress has been laid on mere geology as a means of exploring the beginning of things as they are, he discusses "the possible antiquity of nature, its earliest condition, the constitution of the luminiferous ether, the probable manner in which matter may have become distributed into definite masses constituting suns and planets." The relation of solar energy to life, the phenomena of organisation, and the origin of genera and species are then discussed. In the second part he attempts the task of reconciling the Mosaic cosmogony to modern science. The writer is evidently a man of good scientific acquirements, and gives us a large amount of information, whilst we must not omit to say that the book winds up with about twenty exquisite engravings of the forms of pollen, and of polycystina and diatoms, as revealed by the microscope, as evidences of the beauty with which the Omnipotent has deigned to clothe the humblest of His works, and of the mathematical laws which He has established.

The chief interest in Mr. Ponton's book, however, consists in its vitalistic doctrine. He repudiates the notion that life is a ferm or conversion of ordinary force. "The solar undulations cannot of themselves either generate life or become converted into life. . . . To effect the conversion there is required the intervention of that third somewhat which we call a living being. This is the real agent in changing mechanical force into vital energy, and *vice versa*. . . . Whilst the force displayed by living organisms is only a portion of the energy of the sunbeams in another form, we must, on the other hand, recognise a special power in the living beings themselves—that, namely, of converting one species of force into another. But there seems little reason to doubt that they are capable of exerting other powers peculiar to themselves, the results of which cannot be regarded as the equivalents of any purely mechanical forces already existing in matter." Without food a man cannot think; but the food is not the cause of the thought, nor thought the representative of the food. A spark will blow up a powder-magazine; so acts food in relation to thought. Lord Orford crossed his greyhound with a bulldog. In six or seven generations the offspring lost all traces of the outward bulldog form, but retained its courage and perseverance. Are courage and perseverance, asks our author, inherent in material atoms, and transmissible, like a contagious disease?

Mr. Ponton's views of the nature and operation of the vital force seem to us original. He intimates that the Creator was pleased at some remote period to create an infinite variety and number of what Mr. Ponton calls "organisers." These are immaterial substances, endowed with the life which the Creator gives them, and answering to what most people understand by the term "soul." These organisers organise organisms. These immaterial essences, souls, or organisers are of various grades, some having little more than power of organising—say an amœba—whilst the highest "are endowed with volition, emotion, instinct, imagination, memory, reason, consciousness," and are, in fact, human souls. These "organisers," sent upon the earth, and finding the necessary pabulum, are the efficient cause of the production of living beings out of the material substances which they collect, and the forces that they control. Mr. Ponton rejects alike the doctrine of evolution and that of

instantaneous creation, as held popularly. He believes the first human being was possibly developed out of some temporary "nurse form," just as the Medusa is. He claims for his immaterial organisers the properties of extension, infinite divisibility and extensibility, power of coalescence, and penetrability. The development of Eve out of Adam's side is an example of germination.

Now we must approach Dr. Martyn Paine's "Physiology of the Soul and of Instinct," a work written with great learning and cogency of reasoning, to dissipate all modern views of materialism, evolution, theoretical geology, and physical origin of life, and to establish the independent existence of the soul and of instinct, and the literal truth of the Mosaic narrative of the Creation and the Flood. He begins with a demonstration, deduced from a most complete exposition of the structure and functions of the nervous system, of the *substantive existence and self-acting nature* of the soul, the essence of which seems to be this:—Bodily changes, such as muscular movement, laughter, flushing, etc., etc., may be produced by extraneous substances acting directly or reflectedly on the nervous centres. But the mind can do the same.—(P. 67.) Therefore the mind is something apart from the brain: seated in it, governing it; but not derived from it. Dr. Martyn Paine must forgive us if we say that this reminds us of the syllogism—A is B, and C is B, therefore C is A. He also gives a laborious definition and demonstration of "instinct," which, he says, is an immaterial principle inherent in animals, but perishing at their death. He repudiates the doctrine of conservation of force so far as applied to the origin of vital force. He equally repudiates all the doctrine of evolution, and asserts that every species of animal was created perfect in its adult form.

In the "Institutes of Medicine," of which a ninth edition is before us, the author now having laboured at Medicine for fifty-four years, and taught as Professor for twenty-seven, gives us his latest views on the principal doctrines of disease and treatment. The same thorough conservatism and resistance to modern forms of thought mark this work also. "Solidism and vitalism," he says, "will form the basis of these Institutes." All humoral pathology, therefore, is derided, not merely as insufficient *per se*, or as partial truth, but as absurd, and contrary to the truth. Absorption in the ordinary sense is denied. Medicines cannot act on the blood. Chemical pathology is ridiculed. Blood is healthy when the solids are healthy. Animal heat is a nervous phenomenon. Medicines act on the nervous system. Inflammation is the work of the bloodvessels, as explained by John Hunter. If we desired to characterise this able, closely-argued, pugnacious, voluminous work, we should describe it as upholding the doctrines of the date of 1820—of the time of Travers, Armstrong, and Abernethy. Bloodletting is largely recommended, because of its action on the vessels through the nervous system. All ideas of the quantity or composition of the blood are ignored.

We have thus brought before our readers a great variety of opinions, all professing to be derived from or related to the science of biology. They vary from the most audacious atheism to the most pitiful Bibliolatry. As regards their influence on religion, we may say that the open enemy is better than the injudicious friend.

PROVINCIAL CORRESPONDENCE.

LIVERPOOL.

May 21.

OPENING OF THE ROYAL SOUTHERN HOSPITAL.

THE new Southern Hospital, henceforward by her Majesty's permission to be called the Royal Southern Hospital, was opened to-day by his Royal Highness Prince Arthur. About 1200 ladies and gentlemen were admitted by ticket to view the ceremony. The Prince was received by the Committee and Honorary Staff, and after receiving and replying to an address, passed through and inspected a number of the wards, and formally declared the building opened.

Concurrently with the opening of the Hospital took place that of the magnificent Sefton-park, purchased by the Corporation of Liverpool from Earl Sefton, and laid out as a place of public recreation. In this park there is being held, during the week of Whitsuntide, a bazaar and flower show for the benefit of the Hospital; and from the immense number who visited it on the opening day, and who will doubtless continue to do so during the week, a very large and much-needed increase will accrue to the Hospital funds.

The Hospital, including two airing yards, occupies an area whose length is 300 feet and breadth 180 feet. Its front faces the west, and there is a considerable ascent from it eastward in the direction of the length of the building. It has been constructed on the pavilion system, the materials used being grey bricks, with stone sills, etc., intersected with horizontal bands of blue bricks. The frontage is occupied by the administrative department, which is most commodious and spacious, and is only two storeys high in the centre and three at the ends, so as to cause as little obstruction as possible to a free current of air between the ward blocks, which run nearly due east and west, one on either side, and have a clear breadth of 100 feet between them. Each block contains two large and three small wards, the large ones being 113 feet long by twenty-seven feet wide and sixteen feet high, and intended to accommodate twenty-six beds in each, allowing thus 1877 cubic feet for each patient; while the smaller ones, designed to accommodate twelve beds in each, are fifty-four feet in length by twenty-seven in breadth and sixteen in height, with a cubic space therefore for each patient of 1944 feet. Attached to each ward adjoining the staircase are nurses' sitting-room and sculleries, and small wards for special cases, while at the ends of each are water-closets, lavatories, and baths, which occupy four towers, one at either angle of the parallelogram, and are so arranged that their ventilation is quite distinct and cut off from the wards. Food lifts are provided from and to each scullery, and foul linen shoots on each landing to a receptacle below on the ground-floor. These are ventilated on to roof. Between the ward blocks, but on the ground-floor, and therefore quite removed from proximity to the wards themselves, are a post-mortem room, dispensary, laboratory, and dead-house, the access to and exits from the first and last being so arranged as to be quite private. On the first-floor, one on either side of the centre of a corridor which joins the two blocks, are the chapel and operating theatre, while the roof of this corridor is asphalted and open to the sky, and forms a most agreeable mode of communication between the second-floors of the blocks. The wards are exceedingly well lighted by large windows on each side, and a still larger one at that extremity which is open to the outside. The ventilation is effected by two upright flues in each ward carried up above the eaves of the roof, and close to the ceiling of either side are "Sheringham" ventilators, one being placed between every two successive windows. The fireplaces were designed expressly for the building; they are open, and each stove has two fireplace openings placed back to back. They are placed in the centre of the wards, and one wrought-iron flue-pipe for each tier of stoves is carried up through floors of wards to the roof. This flue has an outer casting of iron, between which and the flue itself is a space of two inches. The sides of the stove are formed into an air-chamber, and to this is brought between the girders of floors the external fresh air, which, after being warmed, escapes into the ward through the open-work grating in the sides of the stove. The artificial lighting is effected by Benham's ventilating gas globe lights, thus preventing the use or vitiation of the air of the ward. The ceilings are formed of the Dennett arching, and the sides of the walls are plastered, excepting to a height of seven feet, where they are lined by Parian cement. There is a hydraulic lift, for patients, from the ground-floor to each floor of wards. The ward bedsteads are similar to those used in the new St. Thomas's Hospital, London. All the windows are provided with blue check linen blinds, which soften the light, and prevent any bright glare dazzling the patients' eyes.

The large accident-ward is situated very conveniently for access, and of course on the ground-floor; and on the same side of the building, though separated from it by a very wide interval, is a large out-patients' waiting-room, forty-three feet by twenty-five, and twenty feet high, having open-framed timbered roof. In the block of buildings forming the administrative department are several small private wards.

The building is of a simple Gothic style of architecture, and its general aspect is very bold and effective. It can be well seen, and forms a very prominent object when viewed from the river, over which, with its docks, etc., and the adjoining Cheshire shore, is a magnificent view from the large window at the western extremity of the higher wards. It is designed to accommodate about 200 patients.

ADULTERATION OF BEER.—The conductors of the Royal Polytechnic Institution have instituted a series of popular lectures on "Wine, Beer, and Spirits, with special reference to Adulteration."

GENERAL CORRESPONDENCE.

THE WORCESTER INFIRMARY.

LETTER FROM DR. STRANGE AND MR. BUDD.

[To the Editor of the Medical Times and Gazette.]

SIR,—In the *Lancet* of the 4th inst. appeared an article reflecting upon the Worcester Infirmary and its honorary Medical staff. That letter contained many errors as to facts. Upon the discourteous and entirely unfounded insinuations contained in that article we studiously avoided making any comment, confining ourselves to a correction of errors of statement which were calculated to mislead our Professional brethren. To our very temperate letter in reply, the *Lancet*, in its issue of the 18th inst., appended such extraordinary personal remarks that it is impossible for us, having regard to our own self-respect, to hold further communication with that journal on the subject, even to correct its own misstatements. We have, therefore, to ask you, Sir, to grant us a small space in which to put before the Profession the simple undistorted facts of the case. In fact, the articles in question remind us of nothing so much as the celebrated brief for a defendant, which was endorsed with the words "No case; abuse the plaintiff's attorney."

There are two principal misstatements in the *Lancet's* first article, and reiterated in the second, which we are desirous should not go uncorrected. In order to prove its insinuations of exclusiveness and cliquism, that journal started with "supposing" that "there are, or may be, two Physicians in Worcester who are eligible to be Physicians to the Infirmary, but who are not so appointed." We replied, that of the only two graduates practising here, one had declined to offer himself for the recent vacancy, and the application of the other was not entertained by the committee. Upon this point the *Lancet* ventures to contradict us flatly. Quoting from the Medical Directory, it now says, "There are *three* Physicians, and not two only, who might be eligible for the office." Upon this point we adhere strictly to our former statement. We had further stated that, out of thirteen Medical men practising in this city, unconnected with the Infirmary, *all*, with the exception of two, had been frequently present, by invitation, at the operations. The proper inference from these words we take to be that the thirteen are *all* the Medical men practising in this city who are unconnected with the Infirmary. Yet the *Lancet* has the hardihood to ask, "Why thirteen, when there are twenty-seven in the Directory?" Thus clearly wishing its readers to understand that there are actually the latter number, and that only thirteen of them had been invited to witness the operations.

Here, again, we have to reassert the truth of the figures as given by us, both as regards the number of the Physicians and of other Practitioners in Worcester. How the discrepancy between us and the *Lancet* arises may be easily explained. Everyone must know that it is almost impossible for the "local list" of the Medical Directory, with all the care of its editors, to be strictly accurate in the case of any considerable town. For instance, the Directory of 1871 contains the names of nine persons as living in this city, of whom some are dead, others removed, and the rest never resident here at all. As to the other misstatement of the *Lancet*, whilst we repeat that most of the Practitioners in the city have been frequently invited to witness interesting operations, we affirm that the rule of the Infirmary—which that journal calls preposterous—affords every reasonable facility for their doing so without invitation, there being a fixed and well-known day and hour for operating, at which it has always given us pleasure to see our brethren present. Can the *Lancet* point to more liberal customs than these at any other Hospital?

To sum up the whole matter in this dispute, Sir, which would never have arisen had the *Lancet* observed the same wholesome rule as ourselves, viz., to take no notice of anonymous newspaper articles, we say—1st. That no Hospital in the kingdom has a larger proportional staff to patients than that at Worcester; very few so large. We say, 2nd. That its doors are open to our brethren, come from whence they may, at all reasonable hours, and that this fact may easily be known by anyone interested in the matter.

One word more, Sir, and, so far as we are concerned, this unpleasant correspondence is closed. The *Lancet*, after making this entirely unprovoked and unjust attack upon us, with no better foundation than that of an anonymous letter, and in a style which we leave to be judged of by its own readers, takes a parting fling at provincial Hospitals in general, and, without

producing one particle of evidence of any mismanagement on the part of their Medical officers, proceeds to insult them by an implied threat that the same battle which that journal fought with the London Hospitals, some forty years ago, will be fought against the "rampant evils" of provincial towns. We will express a hope that when this catastrophe shall happen, and the shafts of the Medical thunderer are ready to be hurled at the heads of these foredoomed institutions, the editor of that journal will kindly call to mind the saying which he may have heard in his youth—viz., "Ingenuas dedicisse fideliter artes, emollit mores, nec sinit esse ferus."

We are, &c.,

WILLIAM STRANGE, M.D.

HERBERT W. BUDD, F.R.C.S.

(On behalf of the Medical Staff of the Worcester Infirmary).
Worcester, May 22.

REPORTS OF SOCIETIES.

CLINICAL SOCIETY OF LONDON.

FRIDAY, APRIL 26.

OWEN REES, M.D., in the Chair.

DR. GREENHOW related the history of a case of Diphtheria which was followed by Paralysis. The patient, a brass finisher, aged 32, was admitted into the Middlesex Hospital on May 27, 1871, with all the well-marked symptoms of diphtheria. Under treatment he so far recovered that, at his own desire, he left the Hospital on June 27. His voice had still a nasal twang, and he had difficulty in swallowing solids. The left side of the soft palate acted imperfectly, and he had some asthenopia, so that he was only able to read for a few minutes at a time. On August 9 he was readmitted into the Hospital with symptoms of paralysis rapidly coming on. He had the sensation of pins and needles up the legs as high as the knees, and in the hands and arms up to the elbows. For a time the loss of sensation and power increased until he could scarcely grasp with his hands or walk without assistance. The two symptoms, however, which gave special interest to this case were, the slowness of pulse, which only set in as the throat symptoms began to subside, the pulse falling as low as 56; and a remarkable tenderness on pressure of the large nerves of the extremities. Firm pressure on the ulnar, radial, and crural nerves produced great pain, sufficient to make the man call out and to cause his face to flinch. The patient ultimately recovered, and was discharged from the Hospital in the following October.

DR. BROADBENT thought diphtheritic paralysis affected a nerve-trunk rather than either of its extremities. One idea of its origin was that neuritis communicated from the throat affected the medulla. This was inconsistent with fact. Really it was due to a neuritis of the trunk, but he had had no means of investigating this notion.

MR. HOLMES exhibited a patient from whom he had excised the whole of the second metatarsal bone, and afterwards the whole row of the tarso-metatarsal joints, the latter operation being undertaken as a substitute for Lisfranc's amputation. The original disease in the second metatarsal bone depended on a traumatic cause; and the affection of the tarso-metatarsal joints was due probably to violence done in removing the head of that bone from the box in which it is embedded between the cuneiform bones. The man recovered, and the foot, though hardly yet quite sound, promises to be perfectly useful. The case was exhibited partly as an interesting example of a probably unique operation, but chiefly to show the success with which excision may be substituted for amputation in affections of the bones of the foot due to traumatic causes.

DR. DUCKWORTH described four cases of Molluscum Contagiosum (three of the patients being exhibited) which occurred in one family, and which appeared to favour the theory held by many observers that this affection was truly contagious. The disease began in the first child of a woman soon after its birth more than three years ago. The mother became affected upon the face nine months ago. The first child was then treated, and had the tumours removed. The second baby next presented mollusca about the face, and lastly, the grandmother, who slept with one of the children, became affected. As showing how the different theories of this disease were still *sub judice*, Dr. Duckworth referred to other cases which had occurred in his own practice and in that of others, where the disease arose and

pursued its course in a manner which seemed to favour the view held by some observers that molluscum was sometimes an epidemic affection.

Dr. TILBURY FOX mentioned a case where the mother got it from her child. Last year a family of seven came under his notice, all affected with this disease at the same time. These did not seem to have communicated the disease from one to another.

Dr. TILBURY FOX exhibited a patient the subject of Leprosy; and Dr. ANSTIE narrated the case of a gentleman who was infected with the disease in India.

Dr. OWEN REES said that, with regard to leprosy, they had at the College of Physicians come to the conclusion that the nomenclature was imperfect, as there were anæsthetic spots in the tuberculated form. They therefore recommended the terms tuberculata and non-tuberculata. He was not certain if there were any cases without anæsthesia.

Mr. BRUDENELL CARTER saw a good many cases in Norway. There was muscular wasting in all, and Bidentkap apparently looked for it in all, especially of the thenar and hypothenar eminences. Sometimes it extended to the arm. Query: Did these spots explain the witch-marks of old times? Leprosy was more likely to prevail then than now.

Dr. ANSTIE said there certainly was a good deal of the disease formerly prevalent in this country.

Dr. BUZZARD confirmed Dr. Anstie's statements as to his case. The patient was drowned accidentally, apparently in an epileptic fit. On examination they found both the median and ulnar nerves enlarged, especially near the palm of the hand. Dr. Bakewell confirmed his idea as to the nature of the case. He thought they should have no hard-and-fast line as to what is leprosy and what not.

Dr. TILBURY FOX said there was no doubt about Dr. Anstie's case, and its improvement under treatment. He had never seen tubercular leprosy without some anæsthesia somewhere. In his case there was very little, but there was some. He believed there were certain forms of what might be called abortive leprosy.

The CHAIRMAN referred to a case in his practice which also occurred in a patient who had never been abroad.

OBITUARY.

ALEXANDER BROWNE, M.D.

DR. BROWNE was descended from an ancient, and at one time a very powerful family—the Brownes of Carslinth (a younger brother being the last abbot of New Abbey). Dr. Browne was born at Langlands, in the parish of Twynholm, in 1800. He attended the parish school for some time, then the Academy of Kirkcudbright, from which, at the age of 13, he went to the University of Edinburgh. There he remained until he took his degree of M.D., after which he went to Paris, and studied for some time in some of the best schools in France. Upon his return to England in 1825 he entered the army. He was first appointed Hospital Assistant to the forces; soon after he was gazetted Assistant-Surgeon, under Sir James McGregor (who showed him great kindness, and fully appreciated his worth), to the 23rd Royal Welsh Fusiliers. He accompanied his regiment in an expedition to Portugal in 1826, and returned with it in 1827 to Gibraltar. He was selected by Sir George Don, the governor of that fortress, to proceed on a Medical mission to the Emperor of Morocco, who had applied to the British Government for a Medical officer to be sent to him. Dr. Browne was either selected or volunteered, and it has been said that none of the staff were very willing to go, for fear, if the Emperor died, the poor Doctor, though he had done his best, might lose his head. But Dr. Browne went, regardless of the issue. He was accompanied by the Hon. Captain Beauclerc and other officers, and protected by a large escort of Moorish military. He cured the Emperor of ague, from which he had long suffered, and his son of a scrofulous disease, and he *Professionally* visited the Emperor's harem, accompanied always by the head eunuch with a drawn sword.

In this expedition he acquitted himself admirably, and to the entire satisfaction of the Emperor, who used all means to induce him to remain as *his own Physician*, to the exclusion of all the native Physicians he had—even offering him a special harem for himself. But the offer failed to attract him, and feeling the Emperor wished to retain him for life, and that there would be a difficulty in getting away so as to retain the Emperor's good graces, and part in peace, it so happened that he was seized with dysentery. For this he blamed

the climate, and no doubt with perfect truth. He, however, was so ill that even his death was reported. Having no European Professional brother with him, he was compelled to prescribe for and even to bleed himself. He suffered from the effects of this attack for a long time, but to it he seems to have been indebted for getting happily away from the Emperor. At parting an event occurred which well deserves to be recorded. Being unable to speak the Arabic language, he was, while in Morocco, constantly accompanied by an interpreter, who was one of the Jewish race—so despised and oppressed by the Moors at that time that they would not allow them to pass a mosque without taking off their slippers, the infringement of this law being severely punished by the bastinado, which was often inflicted to the horror of many Europeans who witnessed it. When Dr. Browne was taking leave of his Majesty he was asked what special mark of favour or what present he would wish to be conferred on him; and here the nobleness of his spirit was most conspicuous, and astonished the monarch and all around him, when he replied that he wanted nothing for himself, but that he wished to ask one favour for his poor despised Jewish interpreter, which was that he might be allowed by a permission from the Emperor to pass the mosque with slippers on his feet; “for I have heard,” said the Doctor, “though you call us, who are Christians, ‘infidel dogs,’ we are allowed to pass; and the poor Jew is no worse than ourselves.” The Emperor was amazed at such a request, which was instantly granted, and he declared that he had never seen such an instance of generous, unselfish, disinterested conduct before; and he gave him a hundred sheep and liberty to export a couple of Arabic horses. Dr. Browne kept notes of this expedition, but they were never printed. Captain Beauclerc published a short account of it after their return, and Dr. Browne came to England on short sick leave soon after, and was at Chatham in 1828.

The fearful epidemic of yellow fever which broke out in Gibraltar in the autumn of that year, in which fifteen Medical gentlemen died, caused the Government at home to send out a brig of war with a party of Medical gentlemen, among whom was Dr. Browne. Shortly after they reached Gibraltar, Dr. Browne had a severe attack of the fever. After his recovery he took a prominent part in the discussions on the contagious or non-contagious nature of the disease. He adopted the latter opinion, and his views were highly esteemed by Monsieur Chevon and the two other members of the Medical committee sent out by the French Government to inquire into the nature of the fever, especially in regard to its asserted importation from the Havana, or its local origin from malaria in Gibraltar itself. Dr. Browne remained with the 23rd Regiment till 1840, when he accompanied it to Nova Scotia. Then he was promoted to the rank of full Surgeon to the 37th Regiment. The regiment returned to Europe in 1842, and was stationed in Ireland. Afterwards Dr. Browne went with the 37th to Ceylon. It has been stated that he was appointed Governor of the Hospital in Ceylon, but it is not clear that he held any particular charge there excepting the duties devolving upon him as the Surgeon of his own regiment, in which there was a very great amount of sickness, and he himself was among the sufferers. After his recovery, as the period of his service for full pay was completed, he went to Malta, in the hope of recruiting his strength, but finding that the Director-General was promoting others—his juniors and inferiors—over his head, he resolved to retire from the service, and did so in 1849 or in the beginning of 1850.

Dr. Browne's annual reports were admirable productions, thoroughly investigating the subjects on which he treated, and it was universally felt that the service had, by his retirement, sustained a severe loss; for had he been promoted, as in justice he ought to have been, he would have been an ornament to the department in its highest grades.

During the years of Dr. Browne's retirement till a few weeks before his death, which took place on April 15 last—though he appeared very little in public, and, indeed, was rather a recluse, and saw or visited none except his most intimate friends, whom he was always glad to receive at his own house—he took the deepest interest in everything affecting the welfare of his country, and a large portion of his time was employed in studying its social, political, moral, and religious phases from the earliest period down to the present time. His great desire was to increase the knowledge and promote the happiness of his species. His charities were most liberal, though given in the most unostentatious manner. His intellectual powers were naturally above the common order, and they were greatly improved by a life of constant and rigid study. He was an

admirable classical scholar, and deeply learned in all historical subjects. He was a great antiquarian, and he has left a great amount of MSS.

About the end of January last his health, which for some years had been precarious, grew gradually worse, and weeks before he was confined to bed he was fully conscious that his end was approaching. British cholera, and violent retching, which soon followed, and which occasioned the rupture of a bloodvessel near the heart or of a valve of the heart itself, and the impossibility of getting any food to remain on the stomach, hastened the crisis. All was done that the warmest affection and the best Medical skill could devise to restore him and prolong his life, but in vain. He retained the use of all his faculties to the very last.

It is unnecessary, after what has been stated, to give at length an estimate of Dr. Browne's character as a philanthropist, a scholar, a Physician, and a gentleman.

JAMES LUNDIN BROWN, M.D.

DR. JAMES LUNDIN BROWN, who died at Malvern on May 2 last, was a graduate of the University of Edinburgh. After leaving college he carried on his Medical education at the Edinburgh Infirmary, St. Bartholomew's Hospital, and the Hospitals of Paris and Dublin. He entered the army in 1854, on the outbreak of the Russian war, and, as Assistant-Surgeon in the Rifle Brigade, 2nd battalion, went through the Crimean campaign. To the practical experience gained in that war he doubtless owed much of his Surgical knowledge and skill, while the hardships he underwent would largely aid in imparting to him that knowledge of men and that genial sympathy with them which formed a feature in his Professional life. After the Crimea, not liking the inactivity of Aldershot, he left the army, and took a country practice at Rickmansworth, Herts, where he remained five years. He then spent two years in travel and study, visiting Florence and Rome, and devoting himself mainly to art, the classics, and Dante. After this, he settled down to a practice at Malvern Wells, where he married in 1871; but before the close of the year he had the great misfortune to lose both his wife in childbirth and his child. After this sad event he never applied himself again to the duties of his Profession, and died, as has been said, early in May. It is to be regretted that Dr. Lundin Brown never published anything, as, from the stores of knowledge he had accumulated, his unusual powers of thought and expression, and the fragments he has left, he could undoubtedly have contributed usefully to general literature; while, from his devotion to his Profession, especially in certain branches, such as gunshot wounds and diseases of the eye, he was possibly in a position to make valuable additions to Medical science. He was a great student of theology, a science of which he was particularly fond. He was also a master of many tongues, being well versed in classics, and able to converse in the modern languages. Above all, he was eminently a good man, and, like so many Physicians, was as a friend and father to his patients, many of whom (especially those of the poorer class) share with his relatives the sorrow of his loss.

EDWARD LLOYD HARRIES FOX.

It is with sincere regret that we have to announce the decease of this young and promising member of the Profession, which took place at Broughton, Hants, on May 11, after a painful illness of many weeks' duration. He was 30 years of age, and the fifth of a family of nine sons, of whom Tilbury Fox, well known to the Profession, is the eldest surviving. His father, L. Owen Fox, M.D., F.R.C.S., is now practising at Broughton. Deceased received his preliminary education at Queenwood College (where Tyndall, Frankland, and Debus taught natural science), and from thence matriculated at the University of London in the first division. He entered at University College, where his father, two brothers, and six pupils of his father had received their Medical education. The first class he attended was Practical Chemistry, and at its conclusion he carried off the gold medal. His Hospital studies were followed under Jenner, whose assistant Fox became, and for whose mode of teaching and profound Medical knowledge he entertained the highest veneration, and was always delighted to acknowledge that his successful career was due to the excellent training which he received under this distinguished teacher. On taking his degree of M.B. he took a second place in Medicine, the scholarship and gold medal in Midwifery, and the scholarship and medal in Forensic Medicine. At this time he became a candidate for

the House-Surgeoncy at the Winchester County Hospital, but was unsuccessful because of some religious difficulties not worth recalling. Deceased was offered the post of Resident Medical Officer at University College Hospital, but, being fond of country life, he elected to join his father at Broughton. Having taken the M.D. degree (Lond.), he went in for the degree of Master in Surgery. There were only three candidates—Beck (Demonstrator of Anatomy at University College), Howse (Demonstrator at Guy's), and deceased. The result was that all were starred equal for gold medal. On a second trial Beck was the victor. Fox was now elected Fellow of University College. During his Hospital career deceased caught scarlatina, followed by dropsy and hæmaturia. After a residence in the country these symptoms subsided, but were never entirely absent, but accompanied by increased impulse of the heart. Albuminuria recently appeared, and, much to his vexation, Fox was compelled to give up work. Œdema of the lungs, cardiac dyspnoea, and dropsy of the extremities eventually set in, and brought his life to a close. His death has caused a universal feeling of regret. His gentle bearing, amiable disposition, patience, and conscientiousness had endeared him to all, and especially to the poor, who have lost a kind friend. His remains were interred on Thursday, in the churchyard of his native village, attended by a large concourse of old friends from the surrounding villages. It is intended to erect, by public subscription, some tribute to his memory, and this will probably be an organ for the church in the choir of which he used to sing. A village committee was formed after the funeral, and £62 subscribed in a few minutes. On Monday evening the subscriptions had reached to upwards of £100.

DR. JOHN H. PATTERSON.

WE have received the following additional particulars respecting this meritorious officer, whose death we recorded in our obituary last week:—

Dr. John H. Patterson, Deputy Inspector-General of Hospitals and Fleets, died at Bournemouth on May 1. He was appointed Assistant-Surgeon, July, 1838; Surgeon, November, 1845; Staff Surgeon, December, 1861; Deputy Inspector-General, October, 1868. Served in the Crimea during the whole of the late Russian war, and was Senior Medical Officer on the Sea of Azof for the entire period operations were carried on there. After the battle of the Alma, when several hundred wounded Russians were left on the field, as Senior Surgeon present he was unremittingly employed for two days in superintending the removal of the wounded there from the field of battle to the hospital transport, and also in the performance of Surgical operations previously to their being transferred to the Hospital at Odessa. He afterwards served as Staff Surgeon of Deptford Dockyard; but his health having completely broken down from disease contracted in the service, he was compelled to be invalided. In addition to the above-mentioned services, he served during the civil war on the north coast of Spain from 1838 to 1840; and during the expected Chartist riots in London in 1848 he received the thanks of the Lords of the Admiralty, through the Medical Director-General, for attendance at Somerset House on that occasion.

MEDICAL NEWS.

KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.—At the monthly examinations held on May 13, 15, and 16, the licence to practise Medicine was granted to the following successful candidates:—

Crosbie, Leslie.	Nugent, Edward Joseph.
Fitzgerald, Michael.	Turner, Charles Palmerston.
M'Swiny, Myles O'Connell.	Woods, William.
Middleton, William Henry.	

The Midwifery diploma was granted to the following:—

Fitzgerald, Michael.	M'Swiny, Myles O'Connell.
Middleton, William Henry.	Turner, Charles Palmerston.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following Members of the College, having undergone the necessary examinations, were admitted Licentiates in Midwifery at a meeting of the Board on the 22nd inst. :—

Bland, George, L.R.C.P. Lond. and L.S.A., Macclesfield, diploma of Membership dated January 26, 1872, of St. Bartholomew's Hospital.
Parkes, William Edmund, L.S.A., Birmingham, April 30, 1872, of Queen's College, Birmingham.

Two candidates were referred to a written examination, and three candidates were rejected.

Fellowship Examinations.—The half-yearly examination of candidates for the diploma of Fellow of the Royal College of Surgeons was commenced on Saturday last, when fifty-eight gentlemen entered for the *Primary*—viz., thirteen Members of the College of from three to twenty-five years' membership, thirty-nine who had passed the *Primary Membership*, and six who had not undergone any previous examination. Of the fifty-eight candidates, twenty-three were rejected, and the following passed, viz. :—

Adams, James, student of St. Bartholomew's Hospital.
Anderson, Richard John, of the Belfast School.
Ashby, Henry, of Guy's Hospital.
Browne, George Buckstone, of University College.
Chaffers, Edward, M.R.C.S. and L.S.A., of St. Thomas's Hospital.
Colgate, Henry, of University College.
Gibbins, Ashley, of King's College.
Greensill, Edward Samuel, of St. Bartholomew's Hospital.
Haig, Percy de Haga, of St. Bartholomew's Hospital.
Harrison, Charles Edward, of St. Bartholomew's Hospital.
Hetley, Henry, of Guy's Hospital.
Houghton, Walter Benoni, of University College.
Hott, Herbert James, of St. Bartholomew's Hospital.
Jacobson, Walter Hamilton Acland, of Guy's Hospital.
Jameson, Hampden Gurney, of University College.
McKay, Henry Kellock, of Guy's Hospital.
Nicholls, Henry Alfred Alford, of St. Bartholomew's Hospital.
Odell, William, of St. Bartholomew's Hospital.
Owen, Charles William, of St. Thomas's Hospital.
Owen, Edmund Blackett, M.R.C.S., of St. Mary's Hospital.
Palmer, Frederick John Morton, of Guy's Hospital.
Paul, Frank Thomas, of Guy's Hospital.
Sawtell, Tom Henry, of St. Bartholomew's Hospital.
Schlesinger, Barthold Maurice, of St. Mary's Hospital.
Snell, George, of Guy's Hospital.
Steticker, William, of Guy's Hospital.
Simpson, Thomas, M.R.C.S. Eng., L.R.C.P. Edin., of St. Bartholomew's Hospital.
Thomas, Andrew Appleby, M.R.C.S. Eng., of Guy's Hospital.
Tootell, Edward, of St. Bartholomew's Hospital.
Vincent, Henry Bird, of St. Bartholomew's Hospital.
Vines, Sidney Howard, of Guy's Hospital.
Webber, William Littleton, of St. Bartholomew's Hospital.
Wherry, George Edward, of St. Thomas's Hospital.
White, Ernest William, of King's College.
Whittle, Edward George, of University College.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received Certificates to practise, on Thursday, May 16 :—

Davies, John Hopkyn, Lampeter, S. Wales.
Maberly, Frederick Herbert, Birmingham.
Murphy, Robert William, Hobart Town, Tasmania.
Murrell, Clement Frederick Fenn, Great Yarmouth.

As Assistants in Compounding and Dispensing Medicines:—

Barnes, Edward, Hilsea, Portsmouth.
Cowley, Henry William, Nottingham.
Russell, Matthew, Whitehaven.
Tansley, Arthur James, Stow, Staffordshire.
Turner, Joseph Kitchin, Whitehaven.

APPOINTMENTS.

* * * The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

BARRETT, JAMES MATTHIAS, L.R.C.S.I., L.M.—Medical Officer for the Kilkullen Dispensary District, Naas, co. Kildare.
BETTS, JOHN, L.R.C.P. Lond., M.R.C.S.—Medical Officer and Public Vaccinator for the Fourth District of the Malmesbury Union, *vice* L. Smith, M.R.C.S. Eng., L.S.A., deceased.
CLARKE, SAMUEL, L.R.C.S.I., L.K. & Q.C.P.I., L.M.—Medical Officer for the Drum Dispensary District, Cootehill, co. Cavan.
GIBSON, J. BURNS, M.D.—Medical Officer to the Bideford Dispensary, *vice* Dr. Hoyle, deceased.
HAINES, ALFRED HENRY, M.R.C.S. Eng., L.S.A.—Medical Officer for the Long Sutton District, Holbeach Union, Lincolnshire.
JACKMAN, RICHARD HAYES, L.R.C.S.I., L.A.H., L.M.—Medical Officer for the Holycross Dispensary District, Thurles, county Tipperary.
KIDD, GEORGE H., M.D., F.R.C.S.I.—Medical Officer to the Masonic Female Orphan School, Dublin, *vice* Dr. T. E. Beatty, deceased.
LOW, DAVID, M.B., C.M.—Assistant-Physician to the Perth County Asylum.
MCLAY, WILLIAM—Assistant-Apothecary to the Dispensary, Parliamentary-road, Glasgow.
O'BRIEN, P. C., M.D., M.S.—Medical Officer for the Askaton Dispensary District, Rathkeale, co. Limerick.
RAWSON, EDWARD ALBERT, L.R.C.S.I., L.M., L.S.—Medical Officer to the Carlow Fever Hospital.
REID, JOHN, L.F.P.S. Glas.—Parochial Medical Officer for the Troon District of the Parish of Dundonald, Ayrshire.
RITCHIE, A. RAMSAY, M.D., L.R.C.P., and L.R.C.S. Edin.—Parochial Medical Officer for Monifeth, Forfarshire.
SHEPPARD, WALTER, M.D., M.R.C.S., L.M.—Medical Officer for the Third District of the Alton Union.

BIRTHS.

BANKART.—On May 19, at 19, Southernhay, Exeter, the wife of James Bankart, M.B., of a daughter.
BARNES.—On May 18, at Dorset House, Ewell, Surrey, the wife of G. R. Barnes, M.D., of a daughter.
CHARLTON.—On May 17, at Fareham, Hants, the wife of Egbert Charlton, M.D., of a daughter.
ELLERY.—On May 16, at Ridgway, Plympton, Devon, the wife of R. Ellery, L.R.C.P., M.R.C.S., L.S.A., of a daughter.
THOROWGOOD.—On May 19, at 61, Welbeck-street, Cavendish-square, the wife of John C. Thorowgood, M.D., of a son.
WILBE.—On May 19, at York Lodge, Finchley-road, N.W., the wife of R. Haydock Wilbe, M.D., of a son.

MARRIAGES.

DE MORGAN—WRIGHT.—On March 13, at Graham's Town, South Africa, Edward Lindsey De Morgan, M.R.C.S., son of the late Augustus De Morgan, to Ada Margaret Wright.
HAYES—WEBB.—On May 7, at St. Michael's Church, Basingstoke, Hawkesley Roche Hayes, L.R.C.P. Lond., M.R.C.S. Eng., L.M., son of the late Francis Hayes, A.M., M.D., of Bandon, Cork, to Cassandra Charlotte, elder daughter of Charles Webb, M.R.C.S. Eng., L.S.A., J.P., Basingstoke, granddaughter of the late Tobias Frere, Esq., of Stamford Brook, Chiswick.
MABERLEY—DENING.—On May 8, at Trinity Church, Great Malvern, Frederick Herbert Maberley, L.R.C.P. Edin., M.R.C.S., L.S.A., 10, Crescent, Birmingham, to Elizabeth Salter, third daughter of the late John Dening, Esq., Pitt, Ottery St. Mary's, Devon.
MOORE—SMITH.—On May 21, at Plymouth, Milner Montgomery Moore, M.R.C.S., L.R.C.P. Lond., third son of the late Edward Duke Moore, Esq., of Arlington-street, Piccadilly, to Marie Caroline, eldest daughter of Robert Henry Smith, Esq., Army Control Staff.
OLIVER—GALT.—On April 16, at St. James's Cathedral, Toronto, Canada, William Silver Oliver, M.D., Staff Surgeon, to Elizabeth Alice, eldest daughter of the Hon. Mr. Justice Galt, of Toronto.
THOMSON—FINLAY.—On May 16, at Lochleven Lodge, Trinity, Edinburgh, John W. Thomson, M.D., Brechin, to Jessie Bannatyne, daughter of William Finlay, M.D., Trinity.
WORMALD—HOOD.—On May 16, at St. Matthew's, Croydon, Edward, second son of John Wormald, Esq., to Annette, elder daughter of the late Sir W. Charles Hood, M.D.
WRIGHT—SHAW.—On May 18, at St. Stephen's Church, Dublin, Edward Perceval Wright, M.A., M.D., F.R.C.S.I., Professor of Botany in the University of Dublin, to Emily Charlotte (Amy), second daughter of Lieutenant-Colonel Ponsonby Shaw, late of her Majesty's Madras Army.

DEATHS.

BRUCE, GEORGIANA HALDANE, widow of the late Walter Bruce, M.D., at 20, Lansdowne-crescent, Edinburgh, on May 3.
COOKESLEY, Lieutenant J. F., Royal Artillery, youngest son of the late J. M. Cookesley, M.D., of Boulogne-sur-Mer, at Cherra Poonjee, India, of liver complaint, brought on by exposure and privation during the Looshai campaign, on April 4, aged 31.
CORMACK, WILLIAM HINE, Purser in the Royal Mail Packet Company's Service, eldest son of Sir John Rose Cormack, M.D., of Paris, at Nova Friburgo, Brazil, after a long and painful illness, on April 8, aged 28.
HURLOCK, ELIZABETH MARY, wife of the Rev. Joseph Hurlock, M.A., M.D., at Brighton, aged 64.
JACKSON, PETER NEVILL, Surgeon Scots Greys, second son of H. W. Jackson, Esq., Riston Grange, Beverley, at Portobello, Edinburgh, on May 14, aged 43.
JAMIESON, JEMIMA BROWN, wife of Robert Jamieson, M.A., M.D., L.R.C.S., Physician to the Royal Lunatic Asylum of Aberdeen, at Elmhill, Aberdeen, on May 17.
MONTGOMERY, AMELIA, wife of James Montgomery, M.D., and youngest daughter of the late Rev. Robert Dillon, M.A., vicar of Gulval, Cornwall, on May 11, at Penzance, in the 72nd year of her age.

VACANCIES.

In the following list the nature of the office vacant, the qualifications required in the Candidate, the person to whom application should be made, and the day of election (as far as known) are stated in succession.
AMERSHAM UNION.—Medical Officer for the Workhouse, and Medical Officer for the Amersham District. Candidates must possess the qualifications required by the Consolidated Orders of the Local Government Board. Applications and testimonials to be sent to Mr. Henry Bedford, Clerk to the Guardians, on or before June 11.
BROMPTON HOSPITAL FOR CONSUMPTION.—Resident Clinical Assistant. Applications, with testimonials, to be sent in on or before June 3. Further particulars may be obtained at the Hospital.
CANCER HOSPITAL.—Surgeon. Candidates must be registered Members of the Royal College of Surgeons of England, practising only as consulting Surgeons. Applications, with testimonials, to be addressed to the Chairman of the Weekly Board, at 167, Piccadilly, and to be sent in on or before June 4.
GLOUCESTER DISPENSARY.—Dispenser, registered under the Pharmacy Act, and otherwise duly qualified. Apply to George Whitcombe, Esq., Gloucester, from whom further particulars may be obtained.
INFIRMARY FOR CONSUMPTION AND DISEASES OF THE CHEST, 26, MARGARET-STREET, CAVENDISH-SQUARE.—Visiting Physician. Candidates must be Members of the Royal College of Physicians, London. Testimonials to be sent to Francis Baily, Secretary.
LEOMINSTER UNION.—Medical Officer for the Workhouse and No. 1 District. Applications, with testimonials, to be sent in on or before June 7, to Mr. Edwin Gregg, Clerk to the Guardians, Leominster.
LONOTOWN UNION.—Medical Officer. Candidates must be duly qualified in accordance with the regulations of the Local Government Board. Applications to be sent on or before June 1, to Mr. C. B. Hodgson, Clerk to the Guardians, Carlisle.

MIDDLESEX HOSPITAL.—Lectureship on Psychological Medicine. Applications must be sent to the Dean of the Hospital not later than June 18.

NORTH RIDING INFIRMARY, MIDDLESBOROUGH-ON-TEES.—House-Surgeon. Candidates must be Fellows or Members of one of the Royal Colleges of Surgeons of the United Kingdom. Applications and testimonials to be sent to the Secretary, on or before June 12.

STRAND UNION.—District Medical Officer. Applications and testimonials and qualifications to be sent to the Guardians of the Strand Union, 6, Bow-street, W.C., on or before May 25.

UNION AND PAROCHIAL MEDICAL SERVICE.

** The area of each district is stated in acres. The population is computed according to the census of 1861.

RESIGNATIONS.

Newbury Union.—Mr. Hawkins has resigned the Second District; area 20,633; population 6899; salary £140 per annum.

Strand Union.—The St. Martin's-in-the-Fields District is vacant; salary £150 per annum.

APPOINTMENTS.

Chertsey Union.—John R. Milsome, M.D., L.R.C.P. Lond., M.R.C.S. Eng., to the Chertsey District and the Workhouse.

Chorlton Union.—Robert E. Hammond, M.R.C.S. Eng., L.R.C.P. Lond., to the Gorton District. George R. Brebner, B.M. and M.C. Univ. Edin., to the Openshaw District.

Huddersfield Union.—Frederick C. G. Ellerton, M.R.C.S. Eng., L.S.A., to the Lindley District.

Newcastle-upon-Tyne Union.—Jonathan Dalglish, M.R.C.S. Eng., L.S.A., to the Sixth District.

New Forest Union.—Henry Viant, L.R.C.P. Edin., M.R.C.S. Eng., L.S.A., to the Eling District.

Stafford Union.—Charles H. Greaves, M.R.C.S. Eng., L.S.A., to the Stafford District and the Workhouse.

Tamworth Union.—Spencer Edmonds, M.R.C.S. Eng., L.S.A., to the Clifton District.

West Ward Union.—A. Lindsay, B.M. Univ. Glasg., L.R.C.S. Edin., for the Shap District.

Weymouth Union.—Wm. T. Boreham, L.R.C.P. Edin., M.R.C.S. Eng., L.S.A., to the Abbotsbury District.

THE PRINCESS ALICE.—Dr. Hoffmeister left Cowes on Saturday for the New Palace, Darmstadt, to be present at the confinement of H.R.H. the Princess Louis of Hesse, which is expected shortly.

THE Royal Medical and Chirurgical Society have issued cards for a *conversazione* at 53, Berners-street, on Friday, June 7, at 9 p.m.

DENGUE FEVER is very prevalent at Calcutta.

A COTTAGE HOSPITAL is to be erected at Chippenham.

We learn from Monte Video that a disease resembling yellow fever appeared in the squares on April 27, and a military cordon was established around the affected districts. Buildings were closed, and the inhabitants forcibly conveyed in two Government steamers to Flores Island to perform quarantine.

A CAUTION.—Mr. David Davies, Surgeon, of Leominster, has been fined £1 and costs for having twice kissed a lady who came to consult him as to the beating of her heart, and which he declared beat "naturally enough."

THE body of the late Mr. Peter Nevill Jackson, Surgeon Scots Greys, was removed from Portobello to the Waverley Railway, Edinburgh, for conveyance to Beverley, on Saturday last, followed by the officers and men of the Scots Greys, the 93rd Highlanders, the Royal Artillery stationed at Leith Fort, and H.M.S. *Favourite*, in the presence of between 40,000 and 50,000 spectators. The bands of the Scots Greys and the 93rd played during the route.

It is stated, says the *Homeward Mail*, that in the Tanjore district no fewer than nineteen persons in every 100,000 die annually from snake-bite. Taking the population according to the census this would give nearly 330 deaths per annum in that district alone, and assuming the rate of mortality over the whole Presidency of Madras to be only half that which prevails in the Tanjore district, and the population to be 30,000,000, we get the startling total of close on 3000 people annually dying from snake-bites.

POOR-LAW MEDICAL OFFICERS' ASSOCIATION.—A meeting of the Council of this Association and of the committee appointed last March to watch the progress of the Public Health Bill through the House, will be held at the Medical Club, 9, Spring-gardens, on Tuesday, May 28, at 7.30 p.m., for the purpose of considering the amendments of the clauses relating to Poor-law Medical relief, and of taking such further action as may appear desirable.

THE LYONS CONGRESS.—The following gentlemen have sent in their adhesion to the Congress:—Mr. Henry Lee, Dr. Herbert Davies, Mr. Critchett, Mr. T. Bryant, Dr. Brewer, M.P., Deputy Inspector-General Gordon, C.B., M.D., Surgeon Wagner, U.S. Army, Dr. Thorowgood, Dr. Corfield, Dr. De Styrup, Dr. C. R. Drysdale, Dr. A. H. Jacob, Dr. Henry Harris, and Dr. G. Bolster. Mr. Victor de Méric had previously sent his adhesion direct to Lyons.

COLLEGIATE PRIZES.—The following are the subjects for the prizes for the present and ensuing year at the Royal College of Surgeons, viz.:—The Collegial Triennial Prize, consisting of the John Hunter Medal, executed in gold, to the value of fifty guineas, or, at the option of the successful author of the dissertation, of the said medal executed in bronze, with an honorarium of £50. The subject of this Prize is—"The Structure and Functions of the Medulla Oblongata, including the Connexions of the Central Nerve-roots." The dissertation may be illustrated by preparations and drawings. Jacksonian Prize: The amount of the dividend, between £10 and £11, received from the trust. The subject for the prize for the present year (1872)—is "The Diseases of the Nose, including those of the Sinuses connected with it, and their Treatment." The dissertation may be illustrated by drawings, preparations, etc. The subject for the prize for the ensuing year (1873) is—"Ununited Fractures." The dissertation may be illustrated by drawings, preparations, etc.

PRESENTATIONS.—Dr. Robert Cocks, of Dundee, and Mrs. Cocks have been presented with a French clock and silver salver and other plate of the value of £600. The clock bears the following inscription:—"Presented to Robert Cocks, Esq., M.D., Dundee, by his patients on the occasion of his retiring from general practice, as expressive of their high esteem and high appreciation of his Professional character and talents. May, 1872." The salver bears the following inscription:—"Presented to Mrs. Cocks, in connexion with a gift to Dr. Cocks from his patients on the occasion of his retiring from the general practice of his Profession. Dundee, May, 1872." The presentation was made in the Albert Institute Hall, in the presence of a large assemblage of the principal residents—Provost Yeaman presiding.—Mr. John Binns has been presented, in the Public Hall, Haslingden, with a silver salver, tea and coffee service, and a timepiece, of the value of £145, by 190 subscribers.

UNIVERSITY OF GLASGOW.—List of Degrees conferred during Session 1871-72.—*Doctors of Medicine and Masters in Surgery*: James Caithness, Scotland; John P. MacIntyre, West Indies. *Doctors of Medicine*: John H. Arbuckle, M.B., Scotland; Hugh Arthur, M.B., Scotland; Samuel Biggart, M.B., Ireland; John Booth, M.B., England; John E. Brodie, M.B., Scotland; Murdoch Cameron, M.B., Scotland; Neil Carmichael, M.B., Scotland; William Crawford, M.B., Scotland; Girdharlal Ratanlal Daphtary, India; William Dougan, M.B., Scotland; Frederick B. Fisher, M.B., England; Robert Forsyth, M.B., Scotland; William W. Fulton, M.B., Ireland; James Galloway, M.B., Scotland; John Gardner, M.B., Scotland; James St. Clair Gray, M.B., Scotland; Robert Hamilton, M.B., Scotland; James P. Heeney, Ireland; John Percival Hunt, England; W. Goodfellow Laidlaw, M.B., Scotland; John Lonie, M.B., Scotland; Thomas Lyle, M.B., Ireland; James M'Connochie, Ireland; Alex. William M'Farlane, M.B., England; William M'Lachlan, M.B., Scotland; Robert Ayre Smith, M.B., England; Peter Stewart, M.B., Scotland; Robert D. Taylor, Scotland; Archibald Templeton, M.B., Scotland; William Wyllie, M.B., Scotland. *Bachelors of Medicine and Masters in Surgery*: John Adams, Scotland; William S. Anderson, Scotland; Thomas Arthur, Scotland; John Banks, Scotland; George Calderwood, Scotland; Edward E. Campbell, Scotland; John Caskie, Scotland; James Cathcart, Ireland; William Clark, Scotland; William Clements, Ireland; John Craig, Scotland; James Diamond, Scotland; Henry H. Dunbar, Scotland; Samson Gemmell, Scotland; William Haldane, Scotland; John W. Herd, Scotland; John Josiah Jones, Wales; James Kennedy, Ireland; David N. Knox, M.A., Scotland; Thomas M'C. Lees, Scotland; William Leith, Scotland; John C. Maddever, Scotland; John Miller, Scotland; Andrew Black Morrison, Scotland; Robert Murdoch, Scotland; Charles McBride, Scotland; John D. Macdonald, Scotland; Thomas Scotland, Scotland; Peter Stewart, Scotland; John Strang, Scotland; Robert Turner, Scotland; David Young, Scotland. *Bachelors of Medicine*: Zalnoor Allee Ahmed, Assam; William B. Allin, England; James C. Burnett, England; William L. Cunningham, Scotland; William J. Fleming, Scotland; David G. Kennedy, Ireland; George Ronald, Scotland; Christopher Strang, Scotland. *Masters in Surgery*: William Gardiner, M.D., England; William Marshall, M.D., Scotland; Peter H. M. M'Kellar, M.B., Scotland; John Harris Ross, M.D., England. The following gentlemen were named as entitled to Honours, to High Commendation, and to Commendation, on account of distinguished merit at the various Examinations for the Degrees of M.B. and C.M.:—I. *Honours*: John D. Macdonald, M.B., C.M.; Samson Gemmell, M.B.,

C.M. II. *High Commendation*: William S. Anderson, M.B., C.M.; Thomas Scotland, M.B., C.M. III. *Commendation*: George Ronald, M.B.; William B. Allin, M.B.

NOTES, QUERIES, AND REPLIES.

What questioneth much shall learn much.—Bacon.

Dr. A. S.—So far as we can promise anything, the paper on "Hay Fever" shall be inserted. "Seasons roll on," etc.

Dr. Newbould, Gisborne, Australia.—Post-office order received, with thanks.

S. D. C.—The "Dublin Manual," or Meadows.

Quis Custodiet ipsos Custodes?—Our malicious "devil" involved us last week in as pretty a clerical error as could be wished. Referring to the Oxford Natural Science Examinations, we questioned the exactness of the title of Hermann's work, which should have been "Grundriss," not Grunedins.

MONSIEUR HENRY DUNANT.

Some friends of M. Dunant, founder of the international work in favour of the wounded in war, now make an appeal to the public in his favour.

This important charitable work, in which M. Dunant took the initiative eleven years ago, has exhausted all his resources; and while so many victims of war have benefited by his labours, he himself has, in promoting this work, been reduced to a state of pecuniary difficulty.

The work of M. Dunant, published soon after the Italian war, and entitled "Un Souvenir de Solferino," pointed out the insufficiency of the means existing after that great battle to meet the requirements of the wounded and the urgent necessity there was of instituting a system of volunteer help for similar occasions; that work, translated into almost every European language, may be considered as having given the great stimulus to the various societies since organised under the Red Cross of Geneva.

Besides this, M. Dunant is the promoter of the Convention of Geneva. It is to his personal activity and to his perseverance and incessant efforts, to his travels throughout Europe during several years, that can be attributed this first diplomatic treaty in favour of humanity—in fact, it is owing to his own labours and initiative that the societies of the Red Cross have been founded in the divers countries of the Continent, in Berlin as well as in Paris, according to the plan he traced in his works.

Since then misfortune has overtaken M. Dunant, who possesses now actually nothing, having sacrificed his own private fortune, and having devoted himself entirely to this work of charity and mercy. A few of his friends have formed themselves into a committee in Paris for the purpose of drawing attention to his circumstances, and, if possible, obtaining the means of relieving his misfortune.

Deputy Inspector-General Dr. Gordon, C.B., Dover, has kindly undertaken to receive and forward contributions; and it is accordingly requested

that such friends in England as desire to assist will be pleased to communicate with him. Subscriptions addressed to the undersigned will also be thankfully received by M. Baron Dutille de la Tuque, 2, Rue Mœnner, Place de l'Europe, Paris.

(Signed)

COMTE DE FLAVIGNY, President of the French Red Cross Society in favour of Wounded in War.

ELIE DE BEAUMONT, Member of the Institute of France, President of the Universal Alliance of Order and Civilisation.

F. MARBEAU, President of Société des Criches.

THE MARQUIS OF FORBIN JANSON SARCIN DE TASSY, Member of the Institute of France.

COMTE DE HONDETOT, Member of the Institute of France.

F. G. EICHHOFF, Member of the Institute of France.

L. DE CAZENOVE, Colonel STAAFF, Military Attaché of the Legation of Norway and Sweden.

FULTON CUTTING, of New York.

THE BARON DUTILLE DE LA TUQUE.

N.B.—Her Majesty the Empress Augusta of Germany was the first who gave M. Dunant a token of her munificence.

A QUERY IN PHYSICS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—In a recent discussion the following question was presented to my mind, a solution to which I have as yet failed to glean from any elementary works on Natural Philosophy. I trust you will aid me by giving me your opinion in the Correspondent's column of the *Medical Times and Gazette*. Regarding cohesion as a distinct force, is it supposed that this force is convertible into other natural forces, such as heat, electricity, etc., etc.? To illustrate the objects of my question—Is the fluid condition of water due to the conversion of cohesive force into a larger amount of heat (specific) by the peculiar molecular constitution of water, just as the more viscid condition of oils, albumen, etc., might be due to a smaller amount of heat derived from cohesion; the amount of heat, etc., generated depending wholly upon the nature or molecular condition of the material considered? Perhaps you may consider this an unreasonable question, but as I cannot see my way out of the maze, I trust you will kindly lend me a light upon the subject. I enclose my card.

I am, &c.,
A. L.

Bury Port, May 18.

HOW TO UTILISE CRIMINALS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—It may be interesting to your correspondent "Calumet," to know that the above subject formerly occupied considerable public attention in non-professional journals, and was put to a practical test on several occasions. He will find in the first volume of the *Gentleman's Magazine*, that on "Saturday January 2, 1731, there was great talk of an experiment to be made on Charles Ray in Newgate, a malefactor, reprieved on that occasion. It was said to be in order to discover whether deafness is not to be cured by purging. The tympanum was to be cut by an instrument in order to demonstrate whether the hearing proceeds from the tympanum or the nerves that lie between that and the conceptor of the ear, it being the opinion of some that deafness is principally occasioned by obstructions in the said nerves." Again, *The Daily Post-Boy* of December 29, 1731, published some proposals for castrating criminals, extracted from a pamphlet published in Ireland, showing that if this plan were adopted, and 500 examples made, it would have such an influence upon the wicked that our judges and juries would have much less business on their hands.

"That castration would cool the heat of those guilty of rape and nameless offences," and (adds the *Gentleman's Magazine*) "that as theft and rapine often run in the blood, such a law would disable a set of vile people from leaving their pernicious breed behind them."

Hector Botius affirms that the ancient Scots gelded such as laboured under madness, or infectious distempers, which they thought might be communicated to their offspring.

Perhaps "Calumet" has forgotten that only a few years ago the bodies of all murderers executed at the Old Bailey were given to the College of Surgeons, and by the Council of that institution distributed to the anatomical schools in this metropolis. This has since been repealed, to the loss of the schools. When George Foster was executed for murder on January 18, 1803, Professor Adini, on a visit to this country, subjected the body to the galvanic process, under the inspection of Mr. Thomas Keate, Mr. (afterwards Sir) Wm. Blizard, that veteran anatomist Mr. J. C. Carpc, and several other gentlemen. Some curious and horrible courtions took place: the eyes opened, legs kicked out, the right hand was clenched and raised, and Mr. P. William Paas (the beadle to the Surgeons' Company), who was officially present, received such a violent blow, and was so alarmed, that he was at once taken home, and died soon after, never having recovered from the shock. The late Sir William Blizard, of the London Hospital, always took a great interest in the experiments on the bodies of these criminals, many of which I witnessed "when George III. was King." Mr. Clift, the Conservator of the Hunterian Museum (who, with his son, was always present), kept a record, which I believe is now in the possession of his successor, Professor Flower, F.R.S. Mr. W. Home Clift was very successful in the portraits he took of all these criminals, both male and female.

I am, &c.,

T. M. S.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Allow me to express my entire concurrence in the proposal of your correspondent "Calumet," in your issue of May 18, to make use of convicts under sentence of death for murder, for the purpose of elucidating by experiment important questions in the etiology and treatment of disease. The proposal is not open to any objection on moral grounds. Those who wilfully destroy human life may fairly be required to contribute to the knowledge of the means of preserving it, and in no way could they more effectually do so than by becoming the subjects of experiment. There can be no doubt that the slow progress of Medicine is due to the fact of its having hitherto had so few facilities of resorting to experiment, that great interest of discovery so freely employed by the other sciences, and without which they could not advance as they do. Physiology, aided by experiment, is making rapid strides, while the treatment of disease, guided as it is by the unsteady light of observation, improves very slowly. It is idle to expect that the public will seriously consider the question of sanitary reform and submit to the pecuniary burdens which such reform involves, while the most conflicting opinions exist in the Profession as to the mode in which the different zymotic diseases are propagated. How can Medical

men be competent to advise regarding the prevention of these diseases while such radical differences of opinion exist among themselves regarding the fundamental question of the manner in which the diseases are propagated? is a question constantly asked, and one to which it is not easy to give a satisfactory answer.

In the time of George II., convicts under sentence of death were employed for the purpose of determining experimentally the safety and value of inoculation as a preventive of small-pox, and with decisive results. That the same method of investigation has not been applied in other questions is due entirely to the fact that the public has not realised the incalculable benefits to mankind that would flow from experiment being associated with observation in the discovery of the laws that regulate the propagation of zymotic disease.

Dr. Burdon-Sanderson and others are endeavouring to obtain this knowledge by experiments on the lower animals. The results Dr. Sanderson has already obtained are of the greatest value; but the constitution of the lower animals differs so much from that of man, that the inferences warranted by such experiments cannot be extended to man without much reserve.

The *Medical Times and Gazette* of December 10, 1870, No. 1067, urged the expediency of utilising convicts in the manner now suggested by your correspondent, and I hope it will again and again press the subject upon public attention. The ultimate adoption of the proposal is certain. Medical knowledge is of too vast importance to mankind for its extension to be left much longer dependent upon observation, when by the association of experiment with observation it would make more progress in a year than it has hitherto done in a century. I am, &c., SCRUTATOR.

APPOINTMENTS FOR THE WEEK.

May 25. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; King's, 2 p.m.; Charing-cross, 2 p.m.; Royal Free, 2 p.m.; Hospital for Women, 9½ a.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. Thomas's, 9½ a.m.

ROYAL INSTITUTION, 3 p.m. Prof. Roscoe, "On the Chemical Action of Light."

27. Monday.

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; St. Peter's Hospital for Stone, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

28. Tuesday.

Operations at Guy's, 1½ p.m.; Westminster, 2 p.m.; National Orthopædic, Great Portland-street, 2 p.m.; Royal Free, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; West London, 3 p.m.

ROYAL INSTITUTION, 3 p.m. Mr. E. B. Tylor, "On the Development of Belief and Custom amongst the Lower Races of Mankind."

ROYAL MEDICAL AND CHIRURGICAL SOCIETY, 8½ p.m. Sir W. Gull, Bart., M.D., and Dr. Sutton, "On the Pathology of the Morbid State commonly called Chronic Bright's Disease, with Contracted Kidney."

29. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1½ p.m.; Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.; St. Thomas's, 1½ p.m.; Samaritan, 2.30 p.m.; King's College Hospital (by Mr. Wood), 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. George's (ophthalmic operations), 1½ p.m.

SOCIETY OF ARTS, 8 p.m. Meeting.

30. Thursday.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Royal Orthopædic, 2 p.m.; University College Hospital, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m. GRESHAM COLLEGE, 7 p.m. Dr. E. Symes Thompson, "On Prescriptions." LONDON INSTITUTION, 7½ p.m. Walter Noel Hartley, F.C.S., "Experimental Evidence against the Spontaneous Generation of Living Things." ROYAL INSTITUTION, 3 p.m. Prof. Tyndall, "On Heat and Light."

31. Friday.

Operations at Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.

GRESHAM COLLEGE, 7 p.m. Dr. E. Symes Thompson, "On Mineral and Vegetable Tonics."

ROYAL INSTITUTION, 9 p.m. Mr. E. J. Poynter, "On Old and New Art."

At the Royal Observatory, Greenwich, the mean reading of the barometer in the week was 29.59 in. The highest was 29.83 in. at the beginning of the week, and the lowest 29.39 in. on Saturday morning.

* The figures in this column, excepting those for London and Dublin, are the unrevised numbers enumerated in April, 1871, raised to the middle of 1872 by the addition of a year and a quarter's increase, calculated on the rate which prevailed between 1861 and 1871. The London population is now based upon the number enumerated in April, 1871, as revised at the Census Office; this revision added 2456 (principally shipping population) to the unrevised number published in the preliminary Census Report. The population of Dublin is taken as stationary.

ORIGINAL LECTURES.

LECTURES ON
EXCISION OF THE HIP-JOINT.By HENRY HANCOCK, V.P.R.C.S.E.,
Senior Surgeon to Charing-cross Hospital.

(Continued from page 483.)

The following cases are of great interest:—

C. L., aged 9, admitted into Charing-cross Hospital July 5, 1870, was a thin, scrofulous child. She had had a severe fall about three years previously, and had been attended at home for about a year, during which time she limped about the house. Afterwards she became an in-patient at King's College Hospital, where she remained for three months. When admitted into Charing-cross she was quite unable to walk. Iodide of iron and cod-liver oil, with good food, and extension by means of the sand-bag, were employed; but three months after her admission an abscess formed on the outside of the thigh, burst, and continued to discharge more or less for about six months. She now became so weak and emaciated that it was necessary to remove the head of the femur and part of the great trochanter. During the operation, in attempting to rotate the limb so as to evert the head of the bone, the femur broke in two places—at the junction of the middle and upper, and middle and lower thirds. When the head of the bone was removed, the shaft was found to be reduced to a mere thin shell of bone, so that doubts arose whether the limb should not be at once removed at the hip-joint; but the patient was too feeble to admit of this proceeding. Accordingly, the limb was placed on an interrupted splint. She gradually rallied after the operation, and in the course of two months the bone was found to have thoroughly united, the patient having gained flesh and strength. At the present time (January 10, 1872) there is still a slight discharge from a small opening on the outer side of the thigh.

W. M., aged 7, admitted to Charing-cross Hospital November 15, 1870, with symptoms of inflammation of hip-joint. Extension by means of sand-bag, tonics, and good food were of no avail. After some weeks an abscess formed on the outer side of the thigh, and was allowed to burst. It continued to discharge until March 8, 1871, when I excised the hip-joint, taking away the head and part of the great trochanter, also removing a little dead bone from the acetabulum. An interrupted thigh-splint was applied, and the ease went on well for about six weeks, when the child became very restless, and the almost continuous movement of the head of the bone in the soft parts caused profuse suppuration both on the inside and outside of the thigh, and the child began to lose ground—the belly became swollen, the skin dry and scaly, and the countenance pale and waxy. In August the child was fastened in a wire cradle (designed by Mr. Slack, the House-Surgeon), which fixed the pelvis and both legs so firmly that the child could be turned on his side or lifted out of bed without the slightest movement in the joints of the lower extremities. From that time the child has slowly and steadily improved. The sinuses are now obliterated, and the patient is fast progressing towards recovery.

There are few operations to which the terms "bloody and formidable" can be applied with less propriety than to excision of the hip-joint. Considering the extent of the wound, there is scarcely an operation in the whole range of Surgery attended with a smaller loss of blood. Of the whole number of cases recorded, although many are described as "attended with very trifling bleeding," "not a single vessel required to be tied," etc. In three cases only—viz., one operated upon by Mr. Caesar Hawkins, another by the late Mr. Ure, and one by myself—has the employment of ligatures been alluded to.

Among 139 cases, I find three recorded as having died from hæmorrhage, but in two of these even those most opposed to the operation would hardly be inclined to attribute death to that cause. In one the hæmorrhage resulted from ulceration of the profunda vein, and death occurred the night of the operation. Mr. Haynes Walton thus describes the case:—

"When I next saw him (a boy aged 12) he was reduced almost to a skeleton. Abscess and fever had done their worst. Soon after another abscess was opened by me on the inside of the thigh. From this escaped much fetid pus and blood. Thus reduced there remained but one chance for life—namely, an operation—and to this I accordingly resorted. At 8 o'clock

the same evening there came on a serious hæmorrhage, and before I could reach him he was dead. A post-mortem examination showed that the abscess had extended deep amongst the adductor muscles of the thigh, isolating the great arteries and veins. Where the profunda vein joined the femoral was a small ulcerated opening, and from this had arisen the fatal hæmorrhage."

In the other case, operated upon by Mr. Caesar Hawkins, we are told—

"A little hæmorrhage took place after the child's removal into the ward, but this was easily arrested, and the progress was pretty favourable for two days. Still it would appear that the little patient's strength had been so materially diminished by the long-continued diseased state of the hip that she could not withstand the shock of the operation, as she died on the third day after it."

Nor is the operation by any means of the formidable nature which has been implied. It must be remembered that the patients operated upon are always more or less attenuated. True that in some instances the parts in the neighbourhood of the joint are thickened by the preceding inflammation and suppuration, but in all these the greater trochanter may be felt as a girdle for the incision, and it is, after all, a mere matter of dissection, and that of a very easy and rough character, to enable us to reach the joint or the displaced head. In the latter case some Surgeons, with Mr. Caesar Hawkins, prefer a longitudinal incision over the great trochanter; others, with Sir William Fergusson, employ a crucial incision. Mr. Anthony White made a longitudinal incision beginning above the head of the femur and carried downwards in the course of the femur, with a second at right angles backwards towards the nates. Others, again, make a semilunar incision, the concavity directed forwards towards the groin. For myself I infinitely prefer the crucial system. It gives room for manipulation; it is attended with less tension from post-operative swelling and inflammation; and its posterior limb, as the patient lies in bed, affords a ready and depending outlet for any discharge which may occur, and thus diminishes the risk of collections of matter in the neighbourhood of the adductor muscles, which sometimes occur in the progress of cure.

In concluding this subject, I would again urge the value of time in the performance of this operation. I have now performed it some seven times, and can safely affirm that the earlier the operation is performed after constitutional treatment has failed, the better is the ultimate result, and more favourable are the symptoms intervening between the procedure and convalescence. When the head of the bone within the acetabulum is carious, where there is abscess at the same time, if, in spite of the constitutional treatment, rest, and extension of the limb, the pain continues and the patient's health fails, the operation, in my opinion, should be performed without further delay, even though there may not be any grating sensation present when the joint-surfaces are pressed together. The preparation upon the table, taken from one of my most successful cases, was removed exactly under these circumstances. There were caries, suppuration, rapid depreciation of health, but no grating sensation—in fact, the acetabulum was sound—and the patient did remarkably well. When to these symptoms the grating be added, that is an additional reason against further delay, as then in all probability the acetabulum is implicated in the mischief; though this is not always the case, as it has been found that this grating has arisen from the friction against a detached neck of the femur or a necrosed portion of bone lying loose within the acetabulum, the latter being sound. This was the case in the instance of the little boy, whose head of the thigh-bone was broken into pieces by being thrown down and kicked. In that case, also, the acetabulum was free from disease.

Mr. Holmes, who acknowledges that he began with a strong prejudice against the operation, frankly admits having met with several cases in which it certainly appeared to him to have saved life. He has well pointed out how rarely spontaneous recovery occurs in cases of hip-joint disease attended by suppuration, whilst the head of the femur remains *in situ*, and the ulcerated surfaces are still in apposition. I willingly admit that when spontaneous dislocation does occur, it may be regarded as a process of natural cure; but how few, comparatively, of patients suffering from hip-joint disease ever live to reach this stage. The operation is comparatively new, and the cases have been recorded in sufficient numbers to compare its success with our other operative procedures; and from the results it may at first sight appear to have been less successful than some others. It has been attempted to compare its results with those of amputation of the thigh; but this is a very

fanciful proceeding, and those who trouble themselves to do so should remember that in these cases the selection is not as to this or that method—it lies between this operation and death. And when we regard the results of the operation, we should also remember what were the results of hip-joint disease when left to itself uncombated by operative procedure. Had these cases been tabulated, as those submitted to operation have been, we might then have drawn a legitimate comparison between the two, and I have very little doubt that the results would have supported the operation. Unfortunately, we have not the materials for this test, but we have all the opportunity of judging of the amount of suffering—nay, anguish—which this operation is destined to alleviate.

Look at a patient wasted to a shadow, confined to his bed, not for months only, but for five years, in constant pain and in the last stage of exhaustion from long-continued discharge; with his leg flexed on his thigh, that thigh drawn across its fellow, or with the knee forcibly fixed and pressed against the opposite thigh; constantly lying on one side, his spine becoming distorted, his chest thrown forward, and his hands employed night and day incessantly maintaining a fixed position of the limb and endeavouring to prevent the intense agony which occurs on the slightest movement, his sufferings still further increased by the bedsores resulting from the constant pressure on the one hip. Often must we all have witnessed this sad scene. Often have I seen the poor hip-joint patient, when all others have slept, still wakeful and anxiously engrossed with the one and monotonous task of steadying the knee and preventing movement. Look again at this patient when the operation is performed; his position now is no longer one of constraint and torture, it is one of comparative comfort and rest. He no longer suffers the extreme pain, he no longer exists in dread of the slightest movement or jar, his countenance loses its drawn and anxious appearance, the hectic subsides, and whatever may be the ultimate result, we at all events have the satisfaction of feeling that by the operation we have alleviated a very vast amount of suffering, almost beyond the power of endurance. Few indeed can there be amongst us who have had any experience of the operation without having observed the great and almost instantaneous relief following its performance. And who will not agree with me in feeling that this fact alone is a very strong argument in favour of its adoption?

But, it is argued, carious hip-joint disease is so essentially of scrofulous origin that those suffering from it are predisposed to consumption, and are consequently unable to bear the shock of so severe an operation.

I do not think the existence of incipient phthisis or lung mischief an insuperable barrier to its performance. We have all seen, with the late Mr. Solly, how frequently lung mischief subsides after the removal of local drain or irritation. In determining the propriety of performing this operation in cases where there is much cough and expectoration, I am guided chiefly by the same rules which govern me in operating for fistula in ano. When the fistula in ano supervenes on cough and expectoration, I leave the patient alone; but when the fistula is the original disease, I regard the violence of the cough and the amount of expectoration only as so much evidence of the extent of constitutional derangement from local irritation, and I lose as little time as possible in performing the operation, and in thus relieving the constitution from the cause of disturbance. I have here collected the particulars of 136 cases of resection of the hip-joint—of these sixty-eight, or exactly one-half, are reported to have terminated successfully; forty-eight, or a fraction above one-third, died; and the result of twenty-two, or a fraction below one-sixth, was doubtful.

In arriving at these numbers I have reckoned as doubtful all those reported as “doing well” and those in progress of treatment, so that the sixty-eight successful cases may be taken as completed.

With regard to the forty-eight cases reported to have terminated fatally; few operations have been subjected to a more rigidly impartial scrutiny than has this, an impartiality which in some instances appears to me to simulate injustice. For instance, of these forty-eight, ten are stated to have died of phthisis and lung disease; of these ten, three died some months after the operation; in one the patient was cured, was able to walk well, so much so that he was employed to deliver circulars about from house to house. Several months afterwards he was attacked by lung disease, and died, nineteen months after the operation, of consumption. In another, the patient died of consumption three years after he had entirely recovered from the operation. And again, in the case of a child, aged 4½ years, it was operated upon in May, 1862, and was doing well; in July it

was attacked by measles; in September it had so far recovered that it was able to move about and go to Brighton, where it caught cold, ending in pneumonia, in which condition it was returned in December to the Children's Hospital, where the disease merged into chronic consolidation of the lungs, terminating in general œdema and death.

One patient cured of the operation died two months afterwards of dysentery; in another, again, the caries is said to have returned; at the end of the year the limb was amputated at the joint, and the patient died the same evening. Again, a patient died the evening of the operation of hæmorrhage; the profunda vein was found ulcerated. One died of bed-sores; one of cerebral disease, eighteen months after the operation; one of caries of the vertebræ; one of Bright's disease, eleven weeks after the operation; one of psoas abscess; one of uræmic convulsions; one of diphtheria; four of pyæmia—or 8 per cent. of the fatal cases; in this respect contrasting very favourably with excision of the knee-joint, wherein the proportion of deaths from this cause is given as high as 28 per cent., or seventeen as against sixty.

Setting aside those cases in which death cannot fairly be connected with the operation, I find that the period between that proceeding and the death of the patient varied from three days to ten months, or upon an average fifty days. The earliest period of life at which the operation has been performed is 3 years, the latest 61 years of age.

The ages at which the operation has been performed and the number of times at each year of life are as follows, arranged according to frequency:—

Age.	No. of operations.	Successes.	Deaths.	Age.	No. of operations.	Successes.	Deaths.
8	13	10	3	17	2	2	0
10	11	7	4	21	2	2	0
6	6	4	2	32	2	2	0
7	6	5	1	3	2	1	1
11	5	3	2	23	2	1	1
14	5	4	1	2	2	0	2
9	4	3	1	54	2	0	2
13	4	2	2	49	1	1	0
4	3	2	1	15	1	0	1
5	3	2	1	24	1	0	1
12	3	1	2	27	1	0	1
18	3	2	1	30	1	0	1
20	3	0	3	32	1	0	1
26	3	2	1	41	1	0	1
16	2	2	0	61	1	0	1

So that at the respective ages of 16, 17, 21, 32, and 49, all the operations were successful.

At the age of 7 the rate of success against deaths is 5 to 1; at 14, 4 to 1; at 8, rather more than 3 to 1; at 9, 3 to 1; at 4, 5, 6, 18, and 26, 2 to 1; at ten, rather less than 2 to 1; at 11, 3 to 2; at 3, 13, and 23, equal; at 12, 1 to 2; and at the ages of 15, 20, 22, 24, 27, 30, 33, 41, 54, and 61, all died.

Whilst the number of operations performed has been infinitely greater during the first ten years of life, its success has been equally great as compared with any succeeding period of ten years. Thus, up to 10 years of age we find the number of operations performed 48; of these, 34 succeeded, 14 (or 29 per cent.) died. From 11 to 20, both included, the number of completed cases was 27; of these, 15 recovered, 12 (or 44 per cent.) died. From 21 to 30, both inclusive, the number of completed cases were 12; of these, 5 only recovered, 7 (or 58 per cent.) died. From 31 to 40 were 3 cases; of these, 2 recovered, 1 (or 33 per cent.) died. From 41 to 50 were 2 cases; of these, 1 succeeded, 1 (or 50 per cent.) died. From 51 to 60 were 2 cases; both died; and above 60 was one case, which died also.

Since writing the above I am indebted to Mr. Carr Jackson for the following unique case, wherein excision of the head of the femur having failed, he amputated the limb at the hip-joint with the most perfect success:—

R. J., aged 19, was admitted into the Great Northern Hospital in March, 1871. He had always enjoyed good health up to the commencement of this disease of the hip-joint. He had no recollection of any injury beyond what might have occurred after exhaustive runs after the hounds. Mr. Jackson first saw him in February, 1865. He had then been confined to his bed for three weeks, but had suffered great pain from hip to knee for twelve months previously, with gradually increasing lameness. There was neither suppuration nor sinus, but the head of the femur rested on the body of the pubis, the limb being shortened and everted. Mr. Jackson reduced the dislocation (the bone returning to the socket with a snap), and applied a splint. In the following August and

abscess formed behind the great trochanter, and subsequently others in various parts of the thigh. He became emaciated suffering from hectic and night-sweats, so that in 1871 it was decided to excise the head and great trochanter of the femur. When this was done the softened condition of the shaft induced Mr. Jackson to remove a slice, in the hope of arriving at healthy bone, but without success. The acetabulum was not much implicated. The operation, however, was followed by great improvement in his general health. The wound made in the operation and several of the sinuses healed, and he left London for the country able to bear some weight on the limb. Unhappily, the improvement was only temporary: one by one the sinuses reopened, and his health became so much impaired that Mr. Jackson, with the concurrence of his colleagues Messrs. Gay and W. Adams, amputated the thigh at the hip-joint, cutting through a very strong fibrous investment which united the end of the femur to the pelvis. The examination of the bone after amputation showed that two actions were going on—the one reparative, by which a number of osteo-plastic growths projected from the upper portion of the bone; the other destructive, reducing the bone to a soft spongy consistence having the character of expended cancellous tissue with numerous foramina and suppuration within. The patient completely recovered.

LECTURES ON THE COMPARATIVE ANATOMY OF THE ORGANS OF DIGESTION OF THE MAMMALIA.

DELIVERED AT THE ROYAL COLLEGE OF SURGEONS OF ENGLAND IN
FEBRUARY AND MARCH, 1872,

By WILLIAM HENRY FLOWER, F.R.S.,
Hunterian Professor.

LECTURE VI.

THE order CARNIVORA consists of a large number of species which in the main are flesh-eaters, existing by the direct destruction of other vertebrated animals, and having their general organisation adapted to the requirements of such a mode of subsistence. As, however, is usually the case, we find within the limits of the order, as defined by structural characters, considerable modifications of habits and diet, some of the minor groups conforming strictly to the usual characteristics of the order, while others afford instances of great elasticity in this respect, even in a state of nature adapting themselves readily to modifications of external circumstances. Thus, among the bears the species which inhabit the arctic regions are exclusively carnivorous, feeding on seals and fish, while those of the plains and jungles of India are mostly vegetable feeders. The same circumstance is observed in the genus *Canis*, and in both cases without any important modification of the organs concerned in obtaining or assimilating their food.

The terrestrial carnivora (sub-order *Fissipedia*) are divided primarily into three groups, having respectively the dog, the cat, and the bear, for types. As the first-named animal is one of the best known, as well as the most generalised form of the order, its structure may be conveniently taken as a representative of the whole. The dentition of the dog presents the well-known characteristics of the order. The incisors are small, so as not to interfere with the penetrating action of the great sharp-pointed canines, which, by their distance apart, have great power in seizing and holding the struggling prey; the anterior teeth of the molar series are pointed or scissor-like, to tear and cut the flesh from the bones, while the posterior ones alone retain the crushing form from which their name is derived. In the more specialised carnivorous animals, as the cats, the incisors are still smaller, the canines more powerful and wider apart in proportion to the length of the jaws, and the crushing is quite subordinate to the cutting part of the molars. On the other hand, in the omnivorous forms the reverse conditions prevail.

The lips are well-developed and lax, and the mucous membrane of their edges, especially in the lower lip, developed into sensitive fringe-like processes, but the lining of the cheeks is smooth. The edge of the lower lip is firmly bound to the gum in the interval between the canine and the first premolar tooth.

The hard palate is raised into a number of curved transverse

ridges, notched at the edge. The posterior margin of the soft palate is thin, rather produced in the middle, but scarcely so much as to constitute an uvula. The tonsils consist of large horizontally-placed crescentic depressions, the concavity of the crescent turned downwards, with a thin overhanging upper margin, and a thickened projecting lower lip, which folds back or upwards into the depression. Numerous openings of follicles are scattered over the floor of the depression.

The tongue is long and lax, narrow at the base, then widening and keeping much the same width to near the apex, which is rounded. The upper surface is flat, with a median linear depression in the anterior half, and the edges are thin, especially in front. The conical papillæ are small and closely set in regular oblique lines, forming a sort of Mosaic pavement all over the dorsal surface. They are conical in form, with the apex directed backwards, with one principal and several accessory points, and covered with a hard epithelium. At the tip and edges of the tongue they are longer and softer, and at the base they become very large, single-pointed, and quite soft. Among these are scattered, especially near the sides and anterior part of the organ, numerous round-tipped fungiform papillæ, which are, however, not very conspicuous, being scarcely larger than the others. There are but two circumvallate papillæ of moderate size. The free part of the under surface of the tongue is quite smooth. There is no sublingua like that of the lemurs; but on the lower part of the frænum is a bifid leaf-like salivary papilla, on the under surface of which the submaxillary ducts open. Extending backwards on each side of the frænum is a conspicuous fold of lax mucous membrane, not enclosing any glandular structures.

In the median line of the anterior part of the tongue, near its lower surface, is the organ known as the *lytta*, or "worm," about which the popular superstition of the ancients still exists in many parts of this country. (a) It is a cylindrical, or rather fusiform, body, about one-fourth of the whole length of the tongue, and of the thickness in the middle of a crowquill, loosely embedded in the areolar tissue of the septum, from which it is very easily detached. In front it is firmly connected with the mucous membrane forming the tip of the tongue; behind it gradually tapers off, and ends in a fine filament, which is lost in the areolar tissue of the septum. No muscular fibres are inserted into it. Its structure has been erroneously described as fibro-cartilaginous; but it consists of fibrous tissue, fat, and striped muscular fibres. The latter are mostly disposed transversely in a layer which forms the upper or dorsal part of the body, the inferior part being chiefly made up of fat cells enclosed within a strong fibrous sheath. The use of this peculiar body is not clearly understood, but it is supposed to give support by its rigidity to the long extensible tongue while lapping water. No marked difference in this function has, however, been observed in dogs in which the *lytta* has been extirpated.

The parotid gland is moderately developed in the form of a crescent embracing the lower side of the cartilaginous external auditory meatus. It consists of pale, loose lobules. The duct leaves the lower and anterior part, running directly forwards across the masseter muscle, and opens in the cheek opposite the middle of the great upper sectorial tooth, or fourth premolar. The submaxillary gland is rather larger than the parotid, and more solid and rounded. It is situated behind the angle of the jaw, coming in contact with the parotid above. Its duct runs forward in the usual course, to open, as before mentioned, on the under surface of the sublingual salivary plate. There is no sublingual gland in the situation in which it is found in the Primates, but an elongated lobular glandular mass lying in contact with the posterior half of Wharton's duct and with the submaxillary gland itself, and having a duct which accompanies Wharton's duct in the course, lying to its inner side and opening close to it, has been considered the sublingual by some anatomists, as Bernard, (b) while others, as Meckel, look upon it as an accessory submaxillary gland. The buccal glands are greatly developed, forming a conspicuous linear series, opening by distinct orifices in the smooth mucous membrane of the mouth opposite the lower teeth from the first premolar backwards, and ascending posteriorly to the angle of the mouth. The zygomatic gland appears to belong to the same system. It is a distinct oval lobular mass, about the size of a hazel-nut, situated beneath the anterior root of the zygoma in the floor of

(a) *λύσσα* (*Attic, λύττα*), madness. "A small worm under the tongue of dogs, which being extracted is supposed to prevent their becoming mad" (Dunbar's Greek Lexicon). For the anatomical structure and supposed functions of this organ see Virchow's "Archiv," vol. vii. (1854), p. 170 and p. 571.

(b) Cf. Bernard, "Leçons de Physiologie Experimentale" (1856), p. 90.

the orbit. Its duct is very short, and opens with the mouth close to the hinder edge of the posterior molar tooth. (c)

The stomach of the dog consists of a sub-globular cardiac portion and a narrower pyloric portion, separated by a well-marked constriction. The mucous coat is soft and smooth, and in the greater part thrown into small irregular folds when the organ is contracted, but which are quite effaced when it is distended. In the pyloric compartment there are permanent folds of the lining membrane, producing strongly marked ridges, irregularly reticulating, except near the pylorus, where they become more longitudinal. The great omentum depends from the great curvature, and returns behind the stomach to the root of the mesocolon, with which its posterior layer becomes continuous, without any direct connexion with any part of the intestine. The small intestine is about six or seven times, and the large intestine about the same length as the body, but these proportions vary somewhat in different individuals. The duodenum forms a wide fold loosely suspended by mesentery, passing down nearly to the right iliac region before it crosses

FIG. 22.

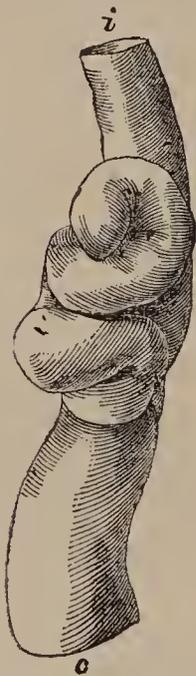

FIG. 22.—Caecum of an Arctic fox (*Canis lagopus*): *i* ileum, *c* colon. In the natural position the colon is uppermost. In the domestic dog the caecum is usually somewhat shorter and less convoluted.

of tolerable regularity are found almost throughout its length. The lining membrane of the colon is smooth, with numerous lenticular solitary glands in its lower half.

The liver lies across the diaphragmatic end of the abdomen, extending as much to the left as to the right side. The suspensory ligament is in the middle line, and very little developed. The umbilical fissure, Fig. 23, *u*, is very deep, reaching three-fourths of the distance from the free to the attached border, and divides the whole organ into segments of nearly equal magnitude. The lateral fissures extend quite to the attached margin of the liver. The left central lobe, *lc*, is small and simple. The left lateral, *ll*, is by far the largest of the lobes, with a semicircular free margin, usually presenting many irregular notches. The right central, *rc*, is larger than the left central, and is divided into two parts by a deep cystic fissure, within which the gall-bladder, *g*, lies, usually visible on the upper surfaces of the organ. The right lateral lobe, *rl*, is of moderate size, and subtriangular in form; its free border is usually notched. The caudate lobe, *c*, is nearly as large as the last named, and very distinctly divided from it. It is connected with the Spigelian lobe by a very narrow neck, on which the vena cava lies; beyond this it expands greatly; the right border has a very deep renal fossa. The Spigelian lobe, *s*, is prominent, tongue-like, divided by a notch into a larger (left) and a smaller (right) lobule. The common bile-duct enters the duodenum four to five inches from the pylorus.

(c) For the structure and function of the zygomatic gland of the dog, see Kehrer, "Über den Bau und die Verrichtung der Augenhöhendrüse," in Henle and Pfeufer's *Zeitschrift*, vol. xxix., p. 88. 1867.

The pancreas consists of rather loose lobules, and is elongated and narrow. One part (corresponding to the "body" of the

FIG. 23.

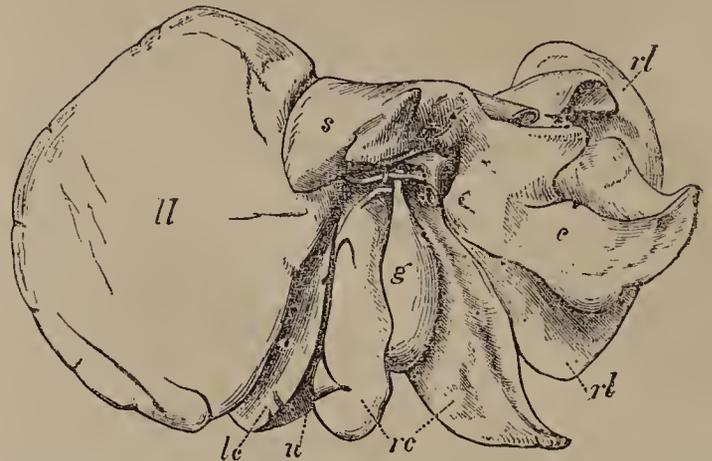

FIG. 23.—Under surface of the liver of a dog: *u* umbilical fissure, *ll* left lateral lobe, *lc* left central lobe, *rc* right central lobe, *rl* right lateral lobe, *c* caudate lobe, *s* Spigelian lobe, *g* gall-bladder.

human pancreas) lies between the layers of the posterior fold of the great omentum, below and behind the lower border of the stomach, reaching on the left to the spleen, near which it increases in thickness; on the right the "head" is prolonged between the layers of the meso-duodenum, descending on the concavity of the curve of that part of the intestine for about half its length, and sending off a prolongation upwards and to the right from its termination. It has two ducts, one of which joins the common bile-duct before entering the intestine, and the other enters separately several inches lower down.

All the members of the genus *Canis*, including the various species of wild dogs, wolves, jackals, and foxes, as well as the closely allied genera *Lycan* (Cape hunting-dog) and *Octocyon* (long-eared African fox), appear to agree in all essentials with the common dog in the structure of their digestive organs, especially in the characteristic form of the caecum.

(To be continued.)

ORIGINAL COMMUNICATIONS.

CLINICAL OBSERVATIONS ON SOME FORMS OF ENLARGEMENT OF THE PROSTATE GLAND

IN CONNEXION WITH DISEASES OF THE URINARY ORGANS.

By RICHARD QUAIN, F.R.S.,

Emeritus Professor of Clinical Surgery in University College.

(Continued from page 569.)

THE facts of the case first narrated in these observations may be made further available for elucidating others by comparison or contrast with an example of disease arising from a different form of alteration of the same organ—the prostate gland. The case I select for this purpose—one of a class not unfrequently met with in practice—was under my observation at the same time, it so happened, with that first case, when it was approaching its close.

Case 5.—Continued Suffering and Extensive Disease of the Urinary Organs, resulting from Difficult and Imperfect Evacuation of Urine.

Mr. R., aged 70 years, whom I saw with Mr. Jakins, told the story of his malady in a written statement which he prepared for me. A few extracts may be usefully made: "Nearly four years ago, at Scarborough, I drank three or four tumblers a day of the water of the well there, and sometimes kept it too long. A difficulty in passing water came on, and I could not refrain from passing it more than two hours at a time. I underwent (elsewhere) in the same year a course of Medical treatment, taking many medicines—the last steel. From this, as well as from the other medicines, I derived no benefit. Then I had hip-baths at 80°. After that time a catheter was passed (once), and a full pint of urine was drawn off. Three years later I went to a hydropathic establishment," the patient continues; "there the steam-bath, packing, and mustard plasters were used; and I had more than anything tepid baths, which were

occasionally run down to cold. . . . But after three months persevering I was no better."

When I first saw him, Mr. R. stated that for nearly four years he had to get out of bed not less than five times every night in order to pass water; and that in the daytime the intervals between the periods of evacuation have been one hour—sometimes two hours. He complains that "he is slow to begin, and has to make efforts, when, at times, a stream will come."

He expresses himself much weakened and depressed by his long-continued illness and suffering. He appears so, and upon examination he proves to be so. About a pint and a half of urine is passed daily by voluntary effort; "but a good deal (patient believes) remains behind each time."

A considerable quantity being found with a catheter to remain after the natural evacuation, it was determined to empty the bladder at short intervals. The patient, after having made a trial or two, in which some blood appeared, declined to pass the instrument again for himself; but he came morning and evening some distance to attain what he had found to be a great relief and comfort. The urine was at first pale and opaque—not offensive—but it afforded evidence of deep organic change of the kidney in the form of abundant casts of tubes. Soon after pus was also found. Under an acute attack—pyelitis—the patient sank, four years after a urinary complaint was first recognised by himself.

The condition of the urinary organs was ascertained to be as follows:—Both the kidneys much diminished in size, shrunk, were leather-like to the feel. The pelves of both and their divisions were largely dilated and thickened, and smeared with pus. The ureters likewise were dilated and thickened. The bladder, unnaturally capacious, was in the recent state partly divided into two nearly equal portions—upper and lower—by a transverse constriction. This appearance is effaced in the preparation. A dependent part behind drops from the fundus deeply below the level of the orifice of the urethra; and that dependent part is further deepened by a projection from the prostate. The muscular fibres, much hypertrophied, project in bundles prominently inwards. A sac of considerable size has been formed behind, its orifice being near that of the right ureter. The bladder is thus, as stated in the catalogue, "fasciculated and sacculated." (See Fig. 5.)

The prostate is generally enlarged, but not immoderately so, with the exception of the middle lobe. From it a semi-circular outgrowth projects into the bladder at the vesical orifice of the urethra, which it surrounds (Fig. 5, c and e).

FIG. 5.

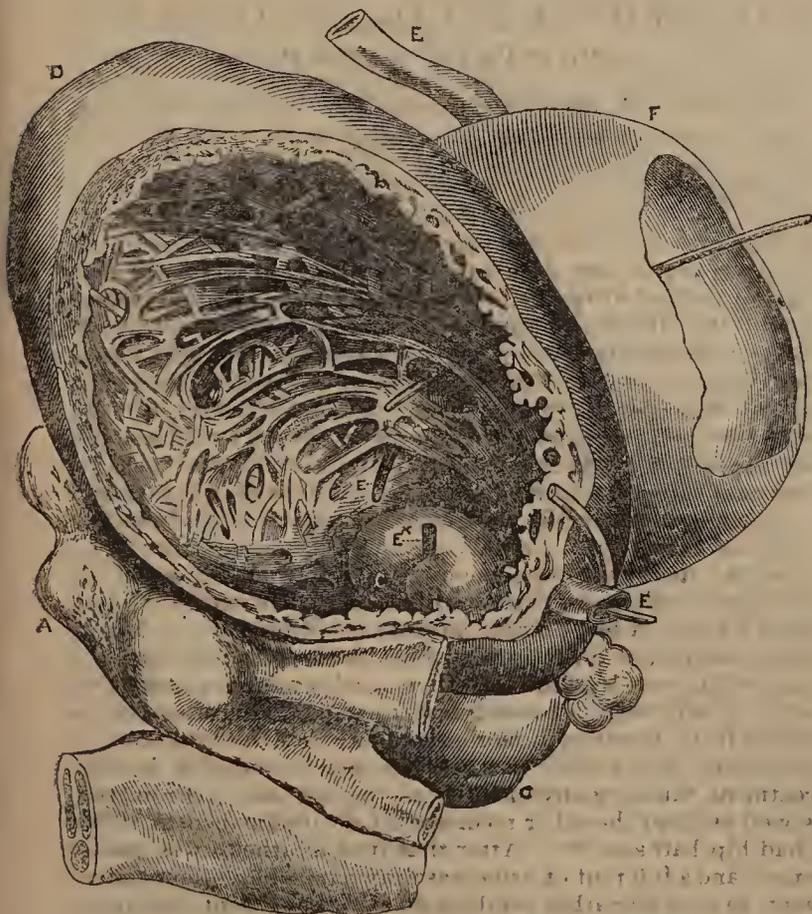

FIG. 5.—A, pubic bones; C, prostate, without and within the bladder; D, urinary bladder; E, ureters; F, sac.

The crescentic outgrowth of the middle lobe was found, by the microscopical observation of Mr. Goodhart, to be "made up of fibrous tissue, condensed connective tissue, and gland structure apparently healthy, but in small quantity." Mr. Goodhart adds—"I think, also, muscular fibre-cells are present, but the parts are so shrivelled that one cannot be certain."

The figure 5 was drawn by Mr. Ford, from the preparation 1982A in the Museum of the College of Surgeons, to which I presented it soon after removal. The bladder is opened on the left side; the pubic bones are below it, with part of the penis; the sac behind. This is laid open. The enlarged and prominent muscular structure of the bladder is represented. The prostate is shown behind the pubes, with a vesicula seminalis at its back part. The crescentic outgrowth of the middle lobe is seen to encircle a black point, e*, which reaches into the orifice of the urethra. Four points of probes or of whalebone indicate the positions respectively of the ureters, the urethra, and the sac.

In order to arrive at the indications of the treatment of such a case as the foregoing it is necessary to trace the sequence of events in the series of morbid changes which has been set forth. As regards the urinary bladder: after the continued formation of an increased quantity of urine—the result of largo daily draughts of a mineral water—there occurred frequent need for the evacuation, together with difficulty in attaining the object; and, in consequence, forcing efforts to overcome the difficulty supervened. The discharge of urine being effected as far as was possible, there still remained the feeling "that a good deal remained behind." The obstacle to the free passage of urine was obviously the valvular effect of the outgrowth from the middle lobe of the prostate; and that outgrowth, as it has been already stated, besides obstructing the flow of urine, had another evil effect—it contributed to the detention of urine in the bladder, by deepening its fundus. To the forced action of the bladder the thickened and prominent condition (hypertrophy) of the muscular structure was owing.

The formation of the sac is to be thus accounted for:—The bladder exercises strong pressure on the fluid within it (a pressure increasing in force in all likelihood with the increasing size of the muscular structure), and the natural outlet for the escape of the fluid being interrupted, the membranes yielded at some weaker point—as at an interspace of the muscular fibres. Yielding, the fibro-cellular and mucous membranes were gradually protruded, and constituted the sac. In some cases several are formed. The size such formations attain is often considerable. The increase of the size—often rapid increase—is attributable to the fact that, whatever the size the sac may have attained, the force of the fluid pressure conveyed to every part of its circumference of like extent with the orifice is the same as the force communicated to the fluid at the orifice itself. From this it will be judged how large the pressure over the whole sac is, and how much cause there is for speedy increase of its size.

In the ureters and the kidneys the origin and progress of morbid change was, I apprehend, as follows:—During the forced contraction of the bladder upon the fluid within it (the natural escape being stopped or impeded) the descent through each ureter was arrested, and urine became accumulated in the canal, the pelvis of the kidney included. At the orifice of the ureter pressure was exercised as upon the whole interior of the bladder, and that pressure on the fluid in the vesical end of the little column of fluid in the ureter was communicated with the same force to every part of like extent of the ureter itself and of the pelvis of the kidney. Nay, the pressure must be held to have gone still further. It was conveyed into the substance of the kidney through fluid in the urine-bearing tubules of the organ. So the pressure affected the whole kidney, tubules, and doubtless the bloodvessels connected with them. If the ureter be supposed to have been empty or imperfectly filled with urine proceeding from the kidney when the straining pressure of the bladder begins, the fluid from the bladder is forced backwards into it through its orifice—naturally a minute orifice, but by the progress of morbid action enlarged, thickened, and patulous; and the pressure upwards is the same. It is that strong pressure of the bladder upon the fluid within it and through it on the fluid higher up—whether arrested in its descent or forced upwards, or both—which caused the dilatation and thickening of the excretory apparatus above the bladder, and which caused also the atrophy and disorganisation of the kidney. All the destructive processes originated in the impediment to the discharge of urine by the urethra. When that impediment is occasioned by another cause—as by neglected stricture of the urethra—the history of

the case is for the most part the same, and the story of morbid change the same.

It may here be mentioned that the force of fluid pressure referred to as accounting for the growth and size of a vesical sac, and for the morbid condition of the kidney and ureter, in the preceding case, is an illustration of that property of fluid pressure named in physics "the hydrostatic paradox." An important application of the principle or fact has been made in the construction of the "hydraulic press."

The constant detention of part of the urine was in this case an additional source of discomfort, and probably of evil. This might be inferred from the fact of relief being given by its removal. But inasmuch as, in that instance, it was in association with extensive disease of the urinary organs, it will be well to look at the condition—the persistence of "residual" urine—in a case in which the morbid change of structure did not extend beyond its actual seat—the bladder.

Case 6.—Detention of a portion of the Urine in the Bladder.

In 1851 I saw a gentleman, Mr. H. T., aged about 35, in consultation with Dr. (now Sir William) Jenner. The patient had been ailing for some time, though not suffering from any acute or obvious disease. He felt, as he himself said, "all over unwell." I learnt from Dr. Jenner that there was not—there had not been—an increase of the temperature of the body, or pain, or any apparent organic disease. The urine was voided freely, and in full quantity. There was no indication of an accumulation in the bladder, which was not in any degree above the pubes. The reaction was acid. But it (the urine) was found to contain pus; and this was the only evidence of a morbid condition anywhere. There was no renal disease. Albumen present in the urine was sufficiently accounted for by the pus it contained. In order that the condition of the only organ as to which there was evidence of a morbid state should be ascertained more fully, a catheter was used after the patient had voided urine, and a considerable additional quantity followed by the instrument. Afterwards the bladder was emptied twice daily. All the unpleasant symptoms—the feeling of illness—soon passed away. Mr. H. T. learnt to relieve himself with the catheter. He regained his usual health, and needed no Professional assistance—still, however, using his catheter.

Something of the further history: I have lately seen this gentleman for a local ailment unconnected with the urinary organs. His condition since 1851 may be briefly stated from his own account of it. First, however, it may be well to mention that he is in affluent circumstances, and engages only in such occupation as he desires for his health or amusement. A few years after the illness of which an account has been given, Mr. H. T. became a member of a volunteer corps, and for several years performed the duties of that position. During the whole of the time since his illness (twenty-one years) he has used the catheter without intermission twice daily, morning and evening. He passes urine before the instrument is used, and several times during the day as well. The quantity voided naturally is about half as much as that removed with the instrument, and that proportion remains about as it was at the beginning. It is, however, liable to fluctuation. "Sometimes," writes Mr. H. T., "I have passed water more freely for perhaps a week, and this has been followed by a period of inactivity. Occasionally, though rarely, the bladder all but empties itself. I can in no way account for the change." The general health is good. No inconvenience has been in all those years at any time felt in the urinary organs, nor has any local damage whatever been once occasioned by the use of the catheter.

It was manifest that the whole of the illness this patient felt in 1851 was due to the fact that some urine remained constantly in the bladder.

As to the cause of the inability to effect complete evacuation of urine in this case, the direct evidence was not altogether satisfactory. There was no defect as regards the general nervous system—the nerve-centre or the nerves elsewhere. No muscular paralysis existed, except that of the bladder, to which the malady seemed to be wholly confined. The patient, when closely questioned by his Physician, recalled the circumstance that on one occasion of some engagement in society, while travelling abroad, he deferred the evacuation for an unusual length of time, and he remembered that once afterwards the urine smelt badly. But as he had not felt actual pain, and had not been put to inconvenience requiring special attention, the incident made but little impression on his mind. It is probable that the bladder was unduly distended on that or some other occasion, and that the paralysis was the result. In such circumstances the muscular fibres, being overstretched, lose power, as stated in Cases 3 and 4 respectively. The nerves,

it may be presumed, are similarly affected. With such alteration of these structures, the mucous membrane and its blood-vessels do not retain their natural or healthful condition, and pus is formed. The local paralysis—if we may not in the case before us ascribe it with any certainty to forced distension of the organ—must still own a morbid change analogous to that indicated. If, however, that be the true interpretation of the cause of the disability that existed—it is certainly the most probable—the case adds other evidence to that already given by cases of prostatic enlargement as to the mischief that is liable to arise from undue delay of the urinary evacuation. It commonly happens that the paralysis ceases, the muscular fibres regaining their natural power (Case 3).

A sufficient summary of the facts of the case for my purpose here may be as follows:—Continuous detention of a portion of urine after the natural evacuation caused actual illness, and, if not checked, would, it can scarcely be doubted, have caused disease also. The removal of "residual" urine had the effect of restoring the health so impaired. By the same means the beneficial results thus attained have been continued during a long series of years, and without inflicting local or other injury.

With a view to practical conclusions respecting the case of Mr. R. (Case 5), I would now compare or contrast it with that of Mr. M. (Case 1). While the source of all the suffering that existed in both was caused by hypertrophy of the same structure, analysis of the leading facts shows, as regards the first case, that there was an absence of suffering except at intervals; that the general health was not impaired; that the duration of life was not abridged; and that all this was so because the prostate, notwithstanding its large size, did not interfere with the functions of any part of the urinary organs, and, specially as applying to our present subject, did not interfere with the facility (except at intervals) and completeness of the urinary evacuation. While, on the contrary, in Case 5, though the part primarily affected was less augmented in size than in the case just noticed, suffering soon came to be almost constant; the general health was rapidly impaired; death occurred in four years from the first manifestation of local inconvenience, and was the direct result of disease of the urinary organs; the whole train of evils having been caused by unceasing difficulty in effecting the evacuation of urine and the continued incompleteness of the evacuation occasioned by the hypertrophied gland.

Now, and lastly, comes the question which is the sole object of all investigation of the nature of disease, and of tracing the similitudes and differences of examples of any form of disease; namely, the question as to the cure or the method of treatment. The question in the matter before us is—What means might have been used in Case 5 to place it, as far as art could accomplish, in the same favourable circumstances as Case 1; or rather—for the case is the type of a good number, and hence its chief importance to us—what means should be used in other persons with indications of coming disease believed to be similar, in order to hinder or to arrest near the onset the train of the organic changes which grew rapidly to their fatal height in that case? The object to be attained is to hinder or to arrest at the earliest period "the long delay" of which Mr. R. complained, and the forcing efforts to empty the bladder which we have traced working their disastrous effects (Case 5); and at the same time to prevent the detention of residual urine. There is no likelihood that in the senile form of prostatic enlargement or outgrowth now under consideration, any treatment by drugs or other agencies affecting the system generally, whether intended to diminish the presumed cause of the obstruction or to augment the expulsive power, would accomplish the object. The impediment is mechanical, and must be counteracted by mechanical means. The use of the catheter is the resource; but the instrument must be used from the beginning as nearly as possible—from the time the difficulty in evacuating the urine is recognised. Moreover, in order to prevent the straining efforts which worked so much mischief (Case 5), the instrument is to be used as often as evacuation is needed; and therein the patient must minister to himself.

It should be understood that much of the success of management depends on the proper adaptation of the instrument to the case. In Case 1 a long silver catheter of the kind known as prostatic, with a wide curve, was easily passed. The instrument made for that gentleman's own use was designedly constructed with a wider curve than is usual. The rigid material was in that instance not objectionable, being but infrequently used, the whole canal being at the same time free from obstruction to the course of the instrument. In Case 6 an ordinary gum-elastic catheter has been in every way suitable. It has been unchanged in kind or size during the whole period that

an instrument has been used; but in that case there was no prostatic enlargement. I know of several persons, however, who with that enlargement have been passing such instruments for long periods of time—eight to twelve years and upwards; some who pass urine only in that way.

Yet cases are met with in which, while difficulty occurs as to the passage of some instruments, facility is secured by others of a different kind. For many years I have derived much advantage from gum-elastic catheters which I got from Paris. The instruments I refer to differ much from those which have long been in use here; they are more flexible, in a degree limp; they taper towards the end, where they terminate with or without a small grain-like bulb. Another useful form has been added from the same source—one bent near the end (*condé, elbowed*). Such catheters were long a desideratum at our instrument makers. One had to be supplied from France—a great inconvenience to patients. Recently instruments of the kind I refer to have become procurable in some places here, and of good construction.

Whatever be the form of the catheter or the material of which it is constructed, it is essential that it shall be introduced and withdrawn with ease, and that there shall be no evidence in its use of wound or abrasion, such as is afforded by an appearance of blood.

CASE OF FUSIFORM ANEURISM OF THE FEMORAL ARTERY CURED BY COMPRESSION.

By JAMES SPENCE, F.R.C.S.,

Professor of Surgery, University of Edinburgh.

R. J., SEAMAN, aged 32, admitted into Hospital, January 12, 1871, suffering from a fusiform aneurism of the left femoral artery at its lower part.

On examination, a pulsating tumour is felt in the lower part of Hunter's canal, a little above the point where the anastomotica magna comes off from the superficial femoral. A little fullness, but no projecting swelling is seen externally. The aneurism when defined is about two inches long by one and a half broad, and spindle-shaped.

History.—The patient first felt pain ten days before admission. He is a seaman on board the *Pharos*, and having to walk daily from North Leith to his ship, he noticed that his leg became painful, making him walk lame before reaching the ship. He thought at first that the pain was rheumatic; but as it continued he applied to Dr. M. Bain, R.N., who sent him into the Infirmary.

Patient says that firm pressure over the tumour causes the pain to cease, but when this is removed the pain at once returns and remains, unless pressure again be made.

January 15.—On examination, Mr. Spence decided on treating the aneurism by compression. Patient ordered to take the following medicines:—℞. Potass. bromid. ʒjv., aquæ ad ʒvj.—a tablespoonful every evening; and ℞. Potass. iod. ʒij., aquæ ad ʒvj.—a tablespoonful thrice daily.

16th.—Dr. Watson's "pressure apparatus" was applied to-day over the common femoral (the skin being previously dusted with fine fullers' earth), the weight being so directed as to press upon the common femoral just as it comes out of the pelvis in the upper part of Scarpa's triangle. The weight caused great pain; but the patient was able to bear it, and the circulation through the artery was completely arrested. During the night and day the weight was taken off at intervals. The pulsation became less and less, and ceased in the evening.

18th.—Weight taken off at twelve o'clock to-day, and no pulsation felt.

19th.—To-night, at twelve o'clock, the weight was replaced, as Mr. Spence thought he felt slight pulsation; and it was kept on continuously till the hour of the visit at noon the next day.

20th.—No pulsation. The limb is flexed, a pillow being placed under the knee, which is turned out. Patient told to compress the artery with his thumb, so as to weaken the flow of blood to the thigh. Not only is the knee bent, but the femur is likewise flexed on the pelvis, thus weakening the force of the blood by making a curve in the artery. Ice to be applied over the seat of the aneurism.

27th.—Slight pulsation felt at intervals, and ice kept on constantly.

February 2.—Ice taken off. Patient said that about five o'clock in the morning, when he awoke, there was great itching

and irritation over the aneurism; but now (12 noon) all pain had disappeared.

(On January 26 a lighter form of compression—Hoey's compressor—was put on, and a piece of sponge was placed between the pad and the skin to ease the pain.)

February 3.—The light-pressure apparatus was again put on for a short time.

9th.—The patient allowed ale or porter, but any change of pulse to be carefully watched. No thrill felt to-day. The ice has been discontinued since February 2.

March 2.—The patient left to-day cured.

May, 1872.—He has been back once or twice complaining of slight pain; but there is no return of the aneurism. He was advised not to take much exertion, and to avoid straining the limb in any way. I have seen the patient recently, and there is no return of the aneurism.

Remarks on the case of R. J.—The points of interest in this case are—1st. The nature of the aneurism; 2nd. The special conditions of the portion of the femoral artery affected; and, 3rd. The success obtained by the method of treatment adopted. As to the nature of the aneurism: Fusiform aneurisms, formed by dilatation of all the arterial tunics, are admittedly less favourable for the process of cure than lateral sacculated aneurisms, because of the less tendency to the formation of coagulum within the dilatation. The internal coat for some time retains its smooth character, and the current of blood through the vessel sweeps with equal force in all directions, and thus prevents or delays the process of obstruction at the diseased part; hence this variety of aneurism is not favourable for treatment either by ligature or compression. The chances of firm obstruction by a consolidated clot being small, the risk is that the retrograde circulation may gradually re-establish the aneurism after ligature, whilst, if compression be resorted to, the dilated part of the vessel may again become distended by the direct current after the compression is removed. The only condition favourable to coagulation in such an aneurism is that which Sir Charles Bell long ago pointed out—viz., that whenever the coats of an artery, owing to irritation or disease, lose their power of reacting on the blood current, that fluid tends to coagulate, as it would in an inorganic tube, and thus the diseased part will ultimately become obstructed unless the disturbing force of the direct current of blood prevents this taking place. Fusiform aneurism is not common in the lower extremity. I have only met with one instance of it in the popliteal artery, and in that case graduated compression fairly persisted in for upwards of six months failed to effect a cure. I then tied the femoral with complete success. (The case is recorded in my "Lectures on Surgery," p. 622.) Having the result of that case before me, it may be asked what decided me on treating this case by compression in preference to ligature. My decision resulted from a consideration of the peculiar conditions of the part of the femoral in which the disease was situated. The oblong aneurism was in that part of the femoral immediately above the origin of the great anastomotica artery, and as the contents of the dilated portion were quite fluid, such a direct retrograde feeder would have speedily refilled the vessel, and acted as a disturbing element in preventing the formation of a coagulum. Indeed, I determined that, if compression failed, I would cut down upon the vessel in Hunter's canal, place ligatures above and below the dilated part, and tie the anastomotica at the same time, as I considered that ligature by the Hunterian method would not effect a cure under such circumstances. The successful result in this case I believe to be due to the method of compression used. From what I have observed of gradual and graduated compression in my own practice or that of others, I have not been favourably impressed by it. Indeed, I have stated elsewhere as my opinion—"I believe that our success will depend on how far we are able to arrest completely the circulation through the femoral." The compression apparatus of my colleague, Dr. Watson, seemed to me well suited to obstruct thoroughly the circulation through the artery; whilst, from its form and mode of action, the patient would be able to bear the pressure for a sufficient length of time to allow permanent changes to take place in the aneurism. In this case the compression required to be reapplied, in consequence of some doubtful symptoms of returning pulsation, and the compression was assisted by dry cold applied over the aneurism. But these precautionary measures, and also the prolonged rest, were used from a consideration of the character of the fusiform aneurism, to guard against tendency to recurrence of the circulation through the dilated part of the vessel, and to allow time for its obliteration. The result fully justified the opinion I had formed as to the method of treatment.

THE
INCUBATION OF SMALL-POX IN UTERO.

By THOMAS SUTTON TOWNSEND,
Resident Medical Officer at the Stanhope-street Dispensary.

THE subject of variolous contagion reaching the foetus has always been a subject of much interest, particularly so when associated with the fact that the parent, although doubtless transmitting the disease, may herself be so proof against its poison as to allow it to pass through her system without apparently producing any disturbance or symptoms whatever, and yet her offspring, at birth or shortly afterwards, may be found affected with a disease which it has contracted whilst in utero. The following remarkable case will, I think, illustrate this fact, and add another strong proof to those we now happily have of the immense value of vaccination:—

A male infant, 18 days old, was brought to the Stanhope-street Dispensary by its mother in December last. She gave the following history of it:—At its birth it was in an apparently healthy condition, but from the first it had been very fretful and restless. When 5 days old it became feverish, and in a day or two an eruption appeared on its face, and afterwards its hands, which the mother thought was what she was pleased to term "gum rash." To use her own words, "Ten days before coming to me white blisters had taken the places of the red points, and these had increased to their present size, and had turned yellow four or five days ago." Having no one to do anything for her, she had postponed getting Medical advice until she could come to the Dispensary. When I first saw the baby, its face, head, neck, and hands were much swollen, and covered with a copious eruption of semi-confluent small-pox. Its eyes were completely closed, and saliva was running freely from its mouth. The contents of the vesicles were purulent, and, as nearly as one could judge from the history of the case and its appearances, it was the ninth or tenth day of the eruption, or the eleventh or twelfth of the disease—the fatal days—of a severe attack of semi-confluent variola. In a few days the vesicles began to rupture, and desiccation set in. The child did well.

Now, supposing this to be a case of small-pox—and a more typical one could not have presented itself—and taking for granted the fact, which is, I believe, an established one, that the period of incubation of non-inoculated pocks is from ten to fourteen days—at any rate, more than four days—this infant must have contracted the disease while in utero. The mother, aged 24, a strong healthy woman, was at her usual employment until the evening before she was confined. She had not had a symptom or ailment of any kind during the time she was carrying the child or since. Her right arm presented two well-marked vaccination scars, and her face showed here and there a "pit," from a very slight attack of small-pox when a child. "We all had it," she said; and her mother confirmed this statement. About the time of her confinement there was a good deal of small-pox in the neighbourhood; she had been about very much, and had several times passed a house when the clothes and bedding of small-pox patients were being carried out to be disinfected, and on one occasion, shortly before her confinement, she had been much shocked at hearing that a friend had lost three of her children from this disease.

In a paper(a) read before the Medical and Chirurgical Society in 1809, Dr. Jenner gave an account of two cases of small-pox infection communicated to the foetus in utero under peculiar circumstances. He says it is only under particular circumstances that any proof of the presence of small-pox can be adduced in those cases in which it passes through the frame without producing eruptions or in any perceptible degree disturbing the animal functions. Such proof, however, is afforded by the obvious infection of the foetus before birth, communicated through the mother, she being already secure from any visible occurrence of the disorder.

He gives two cases illustrating this, one of them exactly analogous to that which I have described—a lady who, a few days previous to her confinement, had met a very disgusting object whose face was covered with the small-pox. The smell and appearance of the poor creature affected her much at the time; and though she mentioned the circumstance on her return home, she had no idea her infant could become infected, having had the small-pox herself when a child. During a few days after its birth the little one seemed quite well; but on the fifth day it became indisposed, and on the seventh

small-pox appeared. The pustules were very few in number, and matured completely. Some matter taken from one of them was used for inoculation, and produced the disease correctly. The mother was not sensible of any indisposition herself from this exposure, nor had she any appearance of small-pox.

The second case is that of small-pox in the foetus, the result of inoculation in the mother five weeks before her confinement. In this case, as in the last, small-pox was produced by inoculating from the pustules.

Dr. George Pearson(b) has described the effects of variolous infection on pregnant women. Dr. Mortimer(c) describes the case of a lady who, when within a fortnight or three weeks of her confinement, had held a conversation at the distance of thirty or forty yards with a person with small-pox in a state of maturation, and gave it her infant.

It was a saying, I believe, of Dr. Jenner, that patients whose faces are swollen a good deal for four days, and who have pretty free salivation, nearly always do well. These two points were very noticeable in the case which has been the subject of this article.

REPORTS OF HOSPITAL PRACTICE

IN
MEDICINE AND SURGERY.

MIDDLESEX HOSPITAL.

FOR notes of the following cases we are indebted to Mr. Pitts, Junior House-Surgeon:—

Case 1.—*Laceration of Anterior Tibial Artery—Amputation through the Knee-joint—Torsion of Vessels.*

(Under the care of Mr. DE MORGAN.)

Walter P., aged 22, admitted March 26, with a lacerated wound of the left leg, caused a short time before admission by falling through a skylight. On the outer side of the left leg, about six inches below the patella, was an oblique cut two inches long, and extending deeply. Blood was flowing freely, and it was evident some large artery was divided, but no vessel could be seen, although the wound was enlarged. From it a piece of glass was removed, and it was then plugged with lint dipped in carbolic lotion.

March 28.—The finger could be passed between the bones to the other side of the limb, and a pulsating artery felt at the bottom. Pulse 108; temperature 100.8°. The dressing was then removed, and the foot found to be quite cold. No pulsation could be detected in the anterior or posterior tibial arteries. A considerable quantity of air was found in the cellular tissue, and the leg was beginning to become gangrenous. 4 p.m.: The leg was amputated at the knee by a short anterior and a long posterior flap; the patella was left *in situ*, and the condyles were not sawn off. The popliteal artery and one or two small vessels were controlled by torsion.

On the following day the stump looked well, the patient had passed a good night, and up to the present time he has been progressing favourably.

Examination of the Wound after removal of the Limb.—Over the inner side of the dorsum of the foot was an irregularly quadrangular outline of dull pinkish-blue discoloration, limiting a dull white central area of skin. The colour of the skin over the centre and the sides of the leg was mottled white and purplish. The arteries of the foot were not felt to pulsate. The soft parts of the foot and leg were emphysematous. At the junction of the upper with the middle third of the leg on the fore and outer aspect was a semilunar-shaped opening in the skin, two inches and a half long, the axis being obliquely downwards and inwards; through this opening was seen torn muscular tissue, along which the finger could be passed to the lower extremity of the popliteal space, and in front of the vessels in that situation—the finger traversing in this course between the upper extremities of the tibia and fibula above the interosseous ligament. Blood and air were effused between the muscles on the front and outer side of the leg and the deep fascia. One inch from its origin, along its front border, some of the superficial fibres of the peroneus longus were seen lacerated. On separating the upper extremities of the peronei, extensor longus digitorum, and tibialis anticus muscles, there was found a space, having the tibia deprived of its periosteum on its inner

(a) *Med. Chir. Trans.*, vol. i., p. 269.

(b) Duncan's "Medical Commentaries," Decade 2, vol. ix., pp. 213.

(c) *Philosophical Transactions*, vol. xlvi., pp. 232.

boundary, and the fibula deprived of its periosteum on its outer boundary, with softened, lacerated muscle around and extending from the front to the posterior aspect of the limb. Where the anterior tibial artery was passing from the posterior to the anterior surface of the limb, it was laid completely open along its inner aspect for nearly an inch in extent. The vein lying to the inner side of the artery was completely divided; there was also complete division of a large branch of artery spreading into the peroneus longus. The vein accompanying this artery was also divided. Upon the front aspect of the anterior tibial artery was a circular opening on a level with the upper end of the part of the divided vein. The upper end of the divided vein was retracted upwards beneath the tibialis anticus; but when this was seized and brought down to the corresponding lower fragment, the branch of artery which passes into the substance of the peroneus longus muscle was brought down, and was found to correspond with the circular opening in the front wall of the anterior tibial artery. There was a slight laceration of the vein on the outer side of the anterior tibial artery. The tibialis anticus was divided three inches below its upper extremity by an oblique incision passing through nearly the whole substance of the muscle, taking the same direction as the incision in the skin. The posterior vessels were uninjured.

Case 2.—Avulsion of the Right Arm of a woman by falling upon iron railings.

(Under the care of Mr. NUNN.)

Hannah W., aged 62, servant, residing at Broad-street, Golden-square, admitted April 2, 1872. A short time before admission she got on to the roof of the house to see after some work that had been done, and, as it was supposed, she lost her footing, and fell over the parapet. In falling, her arm was caught by the iron railings in front of the house, and transfixed one of them rather above the junction of the upper with middle thirds. It was completely severed, so that for the few minutes before she was taken down she hung only by the sleeve of her dress.

On admission, at 1.30 p.m., she was in a state of severe collapse; her clothes on the right side of her body were saturated with blood, and, on examination, the right arm was found to be completely torn off below the shoulder; the head of the humerus and one inch of the shaft only remained, and the portion of the shaft was very much splintered and driven up into the head. The biceps muscle was torn transversely across at the junction of the tendinous with the muscular portion, and the other muscles, especially the triceps, were very much lacerated. The laceration of the skin was somewhat irregular, and extended around the arm to the same level everywhere, except on the outer surface, where a triangular piece was left about two inches longer than the rest. The rupture through the skin corresponded in position and in outline with the laceration through the muscles. The torn end of the musculo-spiral nerve was three or four inches in length, and the axillary artery was divided about where it becomes brachial; but the other nerves and vessels were torn off very short. The artery had by this time contracted, so that very little bleeding was going on, but it could be seen pulsating. Three or four ribs on the right side were broken about their middle, and the base of the scapula was fractured. She was unable to give any account as to how the accident happened. The splintered pieces of shaft and head of the humerus were removed; the wound was well sponged out with carbolic lotion, and covered in by the skin which remained. The pulse was very weak, compressible, and irregular. The patient was in a state of profound collapse, and so remained until her death the following morning.

On examining the severed arm three hours after the accident, the muscular fibre to the naked eye presented a polished, oily appearance, both in the course of the fibres and at their lacerated surfaces; the muscles were very soft, and the bundles of fasciculi were easily torn from each other. Small fragments of muscular tissue could be drawn out by the forceps into long gelatinous-like strings, as fine or finer than the threads of a spider's web. In microscopic examination there was seen a considerable quantity of minute bright granules, of more or less circular form, and of various sizes, situated in the substance of the muscular fibre, arranged for the most part in a direction parallel with the longitudinal fibrils, but not uniformly so; these were scattered throughout the whole thickness of the fibre, but were most numerous, and in some cases aggregated into masses, a little way from the margin; in some places these rounded granules were of much larger size, as many as five or six times larger than the majority. The

muscles of the forearm presented the same features as those of the lacerated parts; these appearances left no doubt of the advanced fatty degeneration of the tissues. The circumference of the humerus was two inches and a half; the thickness of the cortical portion of the bone was less than one-eighth of an inch; the direction of the fracture obliquely downwards and forwards. The medulla of the bone was a mere blood-stained pulp.

Post-mortem Examination of the Body.—Much blood was found effused into the tissues around the shoulder. A comminuted fracture extended across the base of the scapula of the same side. The second, third, fourth, and fifth ribs were broken about their middle. There was a large increase of the normal deposit of fat on the surface of the heart, and on microscopic examination the muscular structure of the heart, as well as that of most of the muscles of the body which were examined, were found in a very advanced state of fatty degeneration.

Case 3.—Compound Comminuted Fracture of the Right Hand—Amputation of Forearm—Torsion of Vessels.

(Under the care of Mr. HENRY MORRIS.)

Wm. Albert M., a lad 15 years of age, engaged as a music-smith, was admitted into Clayton ward, under Mr. Morris, on January 12, 1872. Shortly before admission, while at his usual occupation, his right hand was caught in some portion of the machinery, and so much injury was done to the soft parts of the hand and lower end of the forearm that amputation of the forearm was considered necessary. This was performed below the insertion of the pronator radii teres, by cutting a flap on the extensor side from without inwards and then transfixing. The radial and ulnar arteries were controlled by torsion, the flaps kept together by four carbolised sutures, and the stump covered with Lister's carbolic gauze and oil-silk. On February 20 he was discharged; the wound quite healed, and there was good power of pronation and supination. On examination of the parts after removal, the following conditions were seen:—The integuments of the palm were so lacerated as to expose the tendons, muscles, and nerves, which were all more or less injured; the ulnar artery was torn across. The soft tissues of the radial half of the ball of the thumb were uninjured, as was the thumb itself. The laceration extended for about one inch above the wrist-joint along the forearm. On the dorsal surface the skin was torn transversely in three places. The two distal phalanges of the index finger and all the phalanges and metacarpal bones of the middle and two ulnar fingers were fractured and comminuted; some of the detached fragments of bone, having been turned out from their positions, were lying on the surfaces of the extensor and flexor tendons.

EDINBURGH ROYAL INFIRMARY.

CASE OF LACERATION OF THE PERINEUM—OPERATION—CURE.

(Under the care of Dr. MATTHEWS DUNCAN.)

[Reported by Dr. J. R. HARDIE.]

D. S., AGED 25, admitted to ward 16, November 7, 1871, is married, and has had one child. She complains of inability to retain her fæces. When her bowels are in a natural condition the motions come away without her having the least power to control them, although making the strongest efforts to restrain herself; when troubled with diarrhoea she has no knowledge of their passage, the matters voided coming away by the front. Patient was confined on February 18 last; the labour was precipitate, lasting for about an hour. A midwife attended her. Her present illness followed this confinement. The monthly periods are regular, and she has no other discharge.

On a physical examination being made, the perineum is observed to be lacerated from the fourchette in front backward to the orifice of the anus and through its sphincter, extending up the recto-vaginal septum for fully an inch. On inserting the finger into the gut, there is no tightness at its lower orifice. There is no irritation about the parts.

November 13.—The perineum was restored in the usual manner; nine stitches were put in. Patient ordered one grain of opium night and morning, and to have her urine drawn off by catheter.

18th.—Some discharge from the wound.

20th.—Three sutures removed.

23rd.—One suture removed.

25th.—The remaining sutures were taken out to-day. Some difficulty was experienced with those above the sphincter ani. The perineum is healed up well posteriorly, but anteriorly for about half an inch no union has taken place.

Most unfortunately the discussion took one groove, and stuck in it for the most part, so that the very many important questions connected with chronic Bright's disease were eclipsed by a matter of detail. Of course, statements such as those advanced by Sir W. Gull and Dr. Sutton would be sure to draw a reply from Dr. George Johnson, though his rightful place as leader in the debate was usurped by Dr. Broadbent, who came elaborately prepared to support the view of muscular hypertrophy as the cause of the increase in the thickness of the vessels' walls. The question was not, therefore, discussed on its broad merits, but was rather an affair of outposts, muscular hypertrophy being contended for on one side, hyaline fibroid thickening on the other. It is a pity a great and most important subject should be thus handled; for if we are to be practical we must devote our attention to something very different from such, comparatively speaking, petty details.

The authors of the paper certainly laid themselves open to the criticism that they proposed to deal with the whole subject of chronic Bright's disease with contracted kidney, whereas in reality they only dealt with one variety of it; for if they meant their description to apply to *all* forms of contracted kidney, the description they give of the origin of the contracting material was inaccurate. They themselves described unwittingly histological conditions very various in their character, and to be found in very various stages of the disease; for assuredly the structure of a contracting kidney is not the same in all stages.

We in this country take as our type of contracting kidney what has also been called the gouty kidney, though it may have nothing to do with gout. The contraction in it is due to proliferation of the intertubular connective tissue, so that at one time the tissue seems filled with elements similar to leucocytes, these subsequently giving way to connective tissue of the ordinary type, with its ordinary tendency to contraction and its results.

But abroad an illustrious school of clinical observers have very different views. Of these the latest exponent is Rosenstein—no mean authority on the subject. They divide the nephritis, which ends in contracted kidney, into three stages—the stage of hyperæmia, the stage of exudation, and the stage of atrophy.

In the earliest of these stages the kidney is about normal in size, dark red in colour, and rich in blood. The tubular epithelium is somewhat enlarged, as are the Malpighian bodies. The vessels are slightly thickened, and show many nuclei with acetic acid.

In the next stage the epithelium swells more and more, so as to occlude the tubules, and press upon and obstruct the intertubular vessels. The bulk of the kidney is thus increased. The walls of the vessels are thickened, and the intertubular connective tissue proliferates, corpuscles and fibres appearing abundantly. On this follows atrophy. The epithelial cells in the tubules break down, and are carried away; the canals collapse; and so atrophy is produced. This, it is distinctly stated, may occur quite independently of any change in interstitial tissue; but as a rule both the tubular and intertubular structures take part in the process. Such, briefly, is the description given by certain authors of the mode in which the contracted kidney originates. And no doubt some forms of contracted kidney do so; but in a certain number, especially as seen in this country, the interstitial change seems to precede the epithelial one. All contracted kidneys do not pass through the same stages; and we are by no means prepared to say that some do not originate in the fashion described by Sir W. Gull and Dr. Sutton. What we do say is this: All most certainly do not so originate.

But it is to the clinical phenomena of the disease characterised by a contracted kidney that attention is most deservedly due; and as the pathological condition is only of interest to

us as giving rise to these symptoms, it was unfortunate they were not kept more steadily in view in discussing the subject.

The kidney has a double function to perform—the one, however, subsidiary to the other. These are the elimination of nitrogenous refuse and the evolution of water, the former, however, being more important than the latter. If urea, let us say (though that is certainly not everything), is retained in the system, we have uræmia, as it is called; if water is retained, we have dropsy. Ordinarily the two things go together, but it is just in chronic Bright's disease with contracted kidney that they least frequently do so. It is true that there is another factor in the disease—what is commonly looked upon as the chief one—viz., albuminuria. The loss of albumen may give rise to great bodily weakness, just as in prolonged suppuration; and albuminuria is more dangerous than prolonged suppuration on account of its other accompaniments; but as far as mere bodily loss is concerned the two may be compared.

But now, if we inquire into the characteristics of urine in chronic Bright's disease with contracted kidney, we find it very abundant, of low specific gravity, and containing little albumen. It is very abundant, for it frequently exceeds 100 oz. daily; and of low specific gravity—1006 or less—this being mainly due to the absence of urea. With such a flow of urine dropsy is not to be greatly dreaded; it may lightly come and go, but it is not a threatening danger promising a speedy end to life. The albumen is in small quantity—its loss is not to be greatly dreaded, and yet the condition, as a whole, is fraught with danger, and very frequently—we might almost say invariably—ends in death. What is the reason of this? The reason is, though much urine is passed it contains little urinary matter—even the sum total is far too small—and so the patient lives in constant risk of uræmia.

We nowadays commonly accept gout as being the product of imperfect metamorphosis of nitrogenous matters and their retention in the system, and we well know that gout is accompanied in many instances by typical examples of contracted kidney, which have not run through the stages mentioned by Traube and Rosenstein. So, too, we do not think it necessary that a man should have a well-marked gouty paroxysm to make it plain to us that he is suffering from the effects of the gouty poison, be that what it may. It is manifested to us in a thousand other ways—disturbed digestion, cough, general pains, perverted secretions, and such-like.

If, now, we reflect on the conditions of contracted kidney apart from gout, need we be surprised to find that there are constitutional signs of the contracted kidney before it manifests itself by albuminuria? Albuminuria is never a marked feature in the disease; need we be surprised that it does not show itself as early as some of the other symptoms? Retention of urinary matters constitutes the most important feature of the disease, and that, as far as the urine is concerned, which most frequently causes death. Need we wonder that some signs of this retention manifest themselves before the albuminuria?

Chronic Bright's disease with contracted kidneys is essentially a chronic disease; it must have lasted a long time for the kidney to become small. Moreover, to enable the individual to live, a certain amount of nitrogenous refuse must be eliminated; and as, apparently, the conditions imply the necessity of eliminating along with it a large amount of water, that compensatory action which always arises in a self-adjusting machine like our body appears under such conditions, we have the hydraulic apparatus of the body adapted for exerting increased pressure on the kidney, which of course means increased secretion of fluid. The passage of fluid through the kidneys is obstructed, and so it is, on both Dr. George Johnson's and Sir William Gull's theories, in the arterioles of the body; as a consequence, the left ventricle is greatly hypertrophied, its power is increased, and the tension of the blood within the arteries is increased also. In this way an imperfect balance between the formation of urica and its elimination is kept up. But

the balance tends to incline to the side of retention, and it may suddenly, from various causes, incline to that side somewhat more. From the slighter indications of blood-poisoning we may pass to the more severe and fatal, convulsions in the result. But this hypertrophied heart is not the product of any irritant; if so, the hypertrophy would be symmetrical, and it would not take the form of muscular fibre, but of imperfect connective tissue.

We look upon Sir W. Gull and Dr. Sutton's paper as one of exceeding great value, all the more that it directs early attention to the essential phenomenon of the disease which is not albuminuria; but we do regret that the discussion on it should in great measure have degenerated into a squabble between supporters of local theories of vascular hypertrophy, instead of dealing with the great broad features of one of the most important diseases we have to deal with.

DR. GAIRDNER ON PREVENTIVE *VERSUS* CURATIVE MEDICINE.

THE old proverb "Prevention is better than cure" does not lose its significance when applied to the Medical art. It really seems contrary to common sense that large sums should be annually spent in treating diseases which are a result, whilst nothing, or almost nothing, is done to get rid of the filth and overcrowding which are the main causes. Let us take, by way of example, the Bolton town and district as described by Dr. Ballard. Children are swept off by scarlet fever and diarrhoea. What is the common course suggested? Establish Dispensaries, give drugs, and pay the parish Surgeons liberally to attend the sick. So say we; but along with this, we say, pay the Surgeons liberally for reporting their fever and diarrhoea cases, and for reporting on the nuisances which give rise to them. Not one drop of physic nor one farthing of Poor-law relief ought to go into courts and alleys where the air is poisoned by privies. To give relief and medicine, and leave the nuisance, is a waste in itself, and a robbery of the ratepayers.

That the curative Medical Officers—in other words the Poor-law Medical Officers—must combine preventive with their curative functions, is a thing which the common sense of the public must demand, and which these gentlemen see will give them claims to higher remuneration and public credit. To notice whether the poor dwellings which they enter are crowded or unventilated, or dirty, or poisoned with the stench of middens, and the ground around unswept and unpaved, will involve no great mental exhaustion, and after all it is on the petty details of daily life like these that health mainly depends. There are other functions, such as chemical analysis, statistical reports, manufacturing nuisances, which will of necessity require the occasional aid of an expert; and there are plenty of functions which will require the men who undertake them to give their whole time to them, without the embarrassment of private practice.

But for all this it will be a great calamity if the separation of curative from preventive Medicine be carried too far, and if the rule be established that Medical Officers of Health universally must be out of practice. On this point we take leave to quote from a letter from Professor Gairdner which was read before the Social Science Association at a late meeting:—

"As a Health Officer of a certain amount of experience, who has also held other offices and Professional positions, I should like to submit some—to my mind, very cogent—arguments against what I suppose to be the drift of much that has been said and written lately on this subject. It seems to me that whatever may be the occasional disadvantages of the combination of sanitary duties with private practice, or with other Medical offices, they are as nothing compared with the evil of splitting up, deliberately and by a preconcerted plan, the Medical Profession and the art of healing into *two separate halves*—a preventive and a curative portion—which would be the inevitable result of a logical adherence to the formula of 'separation' of duties. The Medical Profession generally

requires sanitary knowledge—*i.e.*, knowledge of the causes and prevention of disease—to complete the cycle of its means towards cure of disease; and the sanitary officer *requires* equally, in my opinion, to be kept in close relations of acquaintance with the facts and generalisations of Medical practice, otherwise he is sure to become a man of red tape and officialism—a *doctrinaire*, in short. . . . It has been to me a great source of strength all along, and also a source of intellectual satisfaction, to think that I was not a mere official person; and on the other hand one, not the least powerful, among the reasons that induced me to accept a sanitary office, was the belief that I could bring the teachings of preventive science to bear on the actual practice, and still more on the teaching, of Medicine as a healing art."

These are weighty words, and deserve full consideration. That large numbers of Medical men should be divorced from practice and from the necessity of keeping alive their pathological knowledge, and therefore thoroughly official and dependent upon Government, is a condition of things of which we have as yet no experience. It may lead to a stereotyped Chinese system, or may not; but we hold it better that Medical men, as a rule, should keep fast the tie that connects them with pathology and preserves the independence of practice.

DR. BALLARD AT BOLTON.

WE have before us a report of the results of Dr. Ballard's official visitation of the town and neighbourhood of Bolton, in Lancashire, which presents some remarkable features. The visitation was made in consequence of the high death-rate in general, but especially among infants. These preliminary facts are verified by some very striking statistical returns, drawn up for the purpose by the Registrar-General. These returns show that illegitimate births are above the average in Bolton, that the general mortality per 1000 of the Boltonians between 1861-70 was 25.8, and of infants 20 per 1000 living—averages far too high, although lower than they were in the ten years preceding; moreover, that the death-rate of babies in Bolton town was as nearly as possible double what it was in the surrounding villages within the same registration district. Well, figures are not amusing, and we must refer the statistician to Dr. Ballard's report; but we may give some details of the most appalling picture which he draws of dirt, drink, indecency, waste, disease, and degeneration in one of the centres of England's manufacturing industry.

The population of Bolton and its surrounding villages—both male and female—is engaged in cotton-mills, in the iron manufacture, or coal mining. These occupations unavoidably involve a great disposition to phthisis. Intemperance is very prevalent. Of Bolton itself many parts are as crowded with houses as they possibly can be. Many houses are built back to back and in courts, so as to render ventilation difficult. Paving and scavenging are neglected. The sewers are said to be ample, but there is no provision against the entry of sewer gas into the houses. Faecal matters are mixed with the ashes in middens, which are unspeakably and abominably neglected. The water supply is good and sufficient. The women and children are largely employed in the factories. The younger women are unchaste, and the old ones drunken. The children are stunted and degenerate, owing to the bad health and intemperance of the parents, and bad feeding. The houses are unventilated and indecently overcrowded. Diarrhoea and scarlatina are very fatal. The infant mortality is very high, and there is no certainty—such as may be afforded by a Medical certificate—that some are not due to neglect or criminal carelessness. Amongst the causes of infant mortality may be reckoned the above-named crowded state of dwellings, the impurity of the air within and without, and the imperfect light, due to the overhanging canopy of smoke. The mothers are ignorant how to bring children up, and follow the vicious customs which they witnessed during their own childhood. But above all these Dr. Ballard places the neglect of their homes and children by the women who work at the factories.

"In some cases women have been known to return as early as a fortnight after their infant has been born, and very commonly they return to their factory labour within the month. If the woman should chance to have a relative or female friend at home, or a girl sufficiently old to carry the baby, with whom she can leave it, this is the plan usually adopted; but if not, when she leaves for the mill at half-past five o'clock in the morning, she takes the baby out of a warm bed and carries it to some person (generally an elderly female), with whom she leaves it for the day. In preference she will carry it to some one residing near the factory at which she works, and this may be half a mile or a mile from her house. The season of the year makes no difference. If the distance be not too great, the mother will return at breakfast- or dinner-time, or both, to suckle her infant, otherwise she will not see it again until she leaves work in the evening. In the meantime the infant must be fed. Very young babies are fed usually with milk (such as it is!) out of a bottle. Some of these bottles which I saw in use were uncleansed, sour, and encrusted with curdled milk; and the Medical men informed me that this quite coincides with their own repeated observations. In other cases the youngest infants are fed, as those a few months old are, with bread sopped in warm water in a cup, which is left for hours upon the hob to keep warm and become sour. When about to be used, the bread is broken down with the spoon, and a little milk is added. I saw one cup of sopped bread thus prepared for use. It was said to have been boiled, but it contained tough pieces which boiling had not even softened. A halfpenny-worth or a penny-worth of milk (quarter of a pint to a pint, according to quality) per diem is considered a liberal allowance. The mothers pay, I understand, from 2s. 6d. to 3s. 6d. per week to the persons who take charge of their babies; this to include the food. These persons having their own household business to attend to, and moreover a certain and considerable amount of neighbourly visiting and gossiping to perform, commonly depute some little girl to hold the baby in their absence; and such children may be seen any day and at any hour, and almost anywhere in the town, sitting on the doorstep of the house, exposing the infant to the cooling influence of the draught between the door and the fire. It is no matter for surprise that this system of management results in all the evils of mal-nutrition, in attacks of diarrhoea in the summer and of pulmonary inflammation in the winter, and very often in the death of the infants. One of the district registrars informed me that he had often occasion to reprove mothers coming to him for the necessary certificate to present to the burial clubs in which their infants had been entered, on account of the jaunty air with which they made the application. In the course of my experience as a Medical Officer of Health (continues Dr. Ballard), I have seen a great deal of the families of the poor in London, but I can safely say that during the few days I was engaged in visiting the habitations of the operatives in Bolton, I saw a larger number of miserably emaciated infants undergoing the process of gradual starvation upon the system there in vogue than I had ever seen before in as many months.

"In a dirty unventilated house in Glazebrook-lane there was a very emaciated infant in the arms of a woman far advanced in pregnancy, whose husband was in prison, and who, for a time, was residing with her mother. The infant, I found on inquiry, was the illegitimate child of a 'factory lass,' and was nearly 9 months old, although, from its size, it did not appear more than 5 months old. It was being attended by a Doctor, who was giving it medicine, as it had been suffering from diarrhoea. The woman had had the care of this baby ever since it was born, the mother bringing it at six o'clock in the morning and taking it away at six in the evening. She paid 3s. 6d. per week to the old woman who kept the house. She said she gave it 'milk, and arrowroot, and such-like,' and showed me some sopped bread with plenty of lumps in it, which she said had been boiled. 'Yes, she gave it milk—a penny-worth a day.' I saw the milk; it was very poor indeed; and, although it had been standing for five hours, presented scarcely a trace of cream upon the top."

It will be learned with something like pleasure that the sufferings of these poor little creatures are abridged by the administration of "cordials," "infant preservatives," and other narcotics.

Dr. Ballard gives the Bolton authorities due credit for the efforts they have made to improve their town; but he shows how utterly inadequate these efforts have yet been, and how little they comprehend the powers and duties thrown upon them by the Sanitary Act, 1866. But he is not satisfied with

sensational denunciations—he gives them the most precise recommendations as to the steps they should pursue; and we hope that it will be his privilege in a future report to testify to the execution of his behests. A strong but courteous central authority is evidently needed to instruct these local authorities in matters so new to them as the keeping their population in health.

THE WEEK.

TOPICS OF THE DAY.

THE efforts that are being made by the English and Irish Associations of Poor-law Medical Officers to obtain for Irish Dispensary Medical Officers and Registrars of Births and Deaths the benefits of the Union Officers' (Ireland) Superannuation Amendment Bill now before Parliament, deserve to be seconded by the whole political influence of the Medical Profession throughout the three kingdoms. Of all the officers connected with poor relief in Ireland the Medical Officers are those who—owing to their status and education, the dangers they undergo in the performance of their duties, and their scanty remuneration—most deserve and require a liberal superannuation in old age. Mr. Gladstone's Government is not in a position to turn a deaf ear to the representations of so powerful a body as the Profession of Medicine, and we hope that the influence of Medical Practitioners through their representatives in the House of Commons will be used to prevent the exclusion of Irish Dispensary Medical Officers and Registrars of Births and Deaths from the advantages to be secured by the Bill.

From what Mr. Lowe said on the occasion of the admission to degrees at the University of London, it seems pretty certain that the Government will offer no opposition to a measure which shall enable the University of London tentatively to co-operate in a Conjoint Board of Examinations. We hear also that they will support the Apothecaries' Society in obtaining powers to enter into the same league. The Bill of the latter Society for the purpose is, we hear, drafted, and has received the approval of the Privy Council. We may therefore renew our hope that a perfect Conjoint Board for England may yet be constructed. But the prospect in Scotland and Ireland is by no means so clear. The feeling of the Profession in the northern kingdom is not warmly in favour of a uniform admission to the Profession; nay, as is well known, it is in many influential quarters decidedly opposed to it. Of course, before the final step is taken, it is well that the Profession should look at the matter on all sides. In favour of Conjoint Boards there are the following very cogent arguments:—First, that it is only by a uniform examination that the public can be protected from the competition downwards of hungry Examining and Licensing Bodies. Secondly, that it is desirable that the minimum of knowledge possessed by every Medical Practitioner should be a fixed, and not a variable quantity. Thirdly, that the Profession will be a more united and more compact body when its members shall all be admitted by the same portal into its ranks. These arguments are, to our mind, of great weight, and fully justify the attempt which is now being made. But, on the other side, there are arguments which at least require examination. The first of these is, that if the Conjoint Board fixes its standard high, it will simply play into the hands of practising druggists and quacks of all kinds. If, on the other hand, it fixes low, it will, instead of raising the Profession, simply produce a uniform dead level of inferior qualifications. As it is, in consequence of some of the leading Examining Boards demanding a high standard of qualification, the numbers entering the Medical Profession are said to be diminishing, and a large part of town practice is falling into the hands of the pharmaceutical chemist. On the contrary, if all competition between the Examining Bodies upwards as well as downwards

be abolished, we shall have the rank and file of the Profession certainly reduced to a level below that to which the Act of 1815, and the exertions of the Medical Council, have at present raised them. The financial question has also to be considered. The Conjoint Board cannot work cheaply. The majority of Medical Practitioners must get their living by attending the majority of the population, and these constitute the lower middle and poor classes. These persons cannot pay large fees, they cannot pay for both Medicine and attendance, and therefore the incomes of their Medical advisers will never average more than the earnings of an ordinary clerk after a fair period of service in a City house. It is useless to suppose that fathers who have sons to place out in life will be willing to spend a very large sum of money, and to subject their sons to a long, expensive career of education and a difficult examination, to enable them to earn an income which would not satisfy an ordinary tradesman. The supply of Medical men for Poor-law appointments and for poor districts will fall short, and the result is not difficult to foresee. The State will step in, and we shall have an examination of an inferior and cheaper kind to meet the want thus created. We do not say that these undesirable conditions may not be avoided by forethought and consideration on the part of the Licensing Bodies who combine; but they are real dangers, nevertheless, and they must be looked fairly in the face, and be provided for before we destroy the existing state of things.

At the annual meeting of the Royal Geographical Society on Monday, the President, Sir H. C. Rawlinson, gave some good reasons for his belief in the safety of Dr. Livingstone. He stated that the Mr. Stanley whom the telegrams reported to have been with Livingstone is an American gentleman sent out by the *New York Herald* entirely for journalistic purposes, with a *carte blanche* as to expense, his instructions being to proceed into Central Africa and "interview" Livingstone—an example of newspaper enterprise, we should suppose, unrivalled in the history of the world. There appears, however, to be a report that Livingstone, although alive, is in some way crippled. Mr. Stanley saw two natives, each of whom asserted that Livingstone had been badly injured in an encounter with a wild buffalo.

Letters from Calcutta report that the dengue fever is still raging in the city and neighbourhood. The *Times* correspondent, who dates on May 3, asserts that there is scarcely a house into which the fever has not entered, and that it usually goes through the entire inmates.

SHALL INFECTIOUS DISEASES BE TAKEN INTO COTTAGE HOSPITALS?

THE fourth report of the Committee of Management of the Petworth Cottage Hospital, which we have just received, although necessarily brief, suggests to us one or two points of importance, which we have long expected would force themselves on the notice of the managing bodies of these Hospitals. We find that the number of patients has greatly fallen off, and as the receipts for the year were £126 2s. 7d., the patients themselves, or those who send them, paying considerably more than one-fourth of the whole of the current expenses, the Hospital has a balance for the year of £39 11s. 7d., which, added to the sum in hand at the commencement of the year, makes a total balance of £121 17s. 5d. These facts show that although the Committee possesses a flourishing exchequer, it is nevertheless not doing all the good in its power with the means at its disposal. The cause of the paucity of patients, and the consequent large balance, is due to the admission of infectious diseases into the building. Now, we are fully alive to the importance—we might say necessity—of every town having some commodious refuge for persons labouring under infectious complaints who cannot safely or conveniently be treated in their own homes; but it does not therefore follow that a cottage Hospital should be used for this purpose. If

it is so appropriated, then let the local public be made fully aware of its use, and let the building have some more distinctive title, such as the "Cottage Fever Hospital." On no account should patients suffering from non-infectious ailments be treated under the same roof with small-pox, scarlatina, and typhus cases, nor ought the former when once admitted to run the risk of having to be removed shortly after admission because a servant of an annual subscriber is suspected to be suffering from small-pox. Yet such a *contretemps* we remember hearing of; and the exposure to such a risk, as well as the natural objection which people have of going into a building for a long time after the actual presence in it of infection, are highly discouraging to those who would otherwise be only too glad to take advantage of the benefits of such institutions. It would materially widen the field of usefulness of a cottage Hospital, and thereby conduce to the good of the town and neighbourhood in which it stands, if no infectious cases were ever admitted. The Committee of the Petworth Hospital have by their experience been taught to take this view too, for they raise the question—"How far it is expedient to continue to use the cottage Hospital for infectious cases . . . or whether the results of the past year can be looked upon as satisfactory." To this latter part of their question we answer emphatically—No! It may be gratifying to the treasurer to have accumulated in four years a balance of over £120, but the best use he could make of it would be to expend it in providing fitting accommodation, *detached from the cottage Hospital*, for fever and small-pox cases, and thereby to keep the Hospital itself for the more numerous class of general injuries and diseases. These Hospitals are rapidly on the increase, and only last week we chronicled the erection of two new ones. It would be wise, therefore, if in every case these questions should be answered—"Do we intend this building to be an Infirmary or Hospital for general cases, or are we going to use it as a pest-house?" If the affirmative is given to the latter, then let the building be named accordingly; if the reply be that it is for both purposes, then the undertaking will be irrational, and the result unsatisfactory. There is another point upon which we will add a word or two, and which we are surprised to find has been made so much of. It is the jealousy which exists against the cottage Hospitals by those connected with some provincial Hospitals and Infirmaries. It is frequently supposed that the former will injure the latter by depriving them of many of their best cases. In one case we know of the feeling has been carried very high, but we are convinced this is quite unreasonable. Having seen much of the working of these cottage Hospitals, and of the kind of cases treated in them, we see no reason to suppose that the practice of the large provincial and metropolitan Hospitals will be altered or diminished by them. Severe cases of compound fractures, scalds and burns, rheumatic fever, and pneumonia are not the cases which are sent twenty or thirty miles to a large Hospital, but are precisely the ones which are benefited and received into cottage Hospitals. The cases of this sort which reach the larger Hospitals are those which happen in the neighbourhood of these larger institutions; and as these neighbourhoods are generally very large, the presence of cottage Hospitals in the outlying towns will have no effect upon the practice or the usefulness of county Hospitals.

HOSPITALS FOR EPIDEMIC DISEASES.

IT is time something definite was done respecting the general establishment of Hospitals for epidemic diseases. As a rule, we believe the objections which have been hitherto raised have been chiefly against the localities of such Hospitals, rather than against the principle of their establishment. The matter, however, would seem to be debatable, for at a meeting of the Aberdeen, Banff, and Kincardine Branch of the British Medical Association last week, at which seventeen Medical Practitioners were present, the following resolution was unanimously agreed

to:—"That the Aberdeen, Banff, and Kincardine Branch of the British Medical Association, while condemning the present proposed site of the Epidemic Hospital at Mounthooly, would be willing to appoint a committee to confer with the local authority on the subject of epidemic Hospitals generally, and that this resolution be sent to the local authority."

ST. THOMAS'S BIENNIAL FESTIVAL.

As had been anticipated, a large number of old students of St. Thomas's Hospital assembled at the Cannon-street Hotel on Tuesday last, being the day fixed for the first biennial dinner since the opening of the new Hospital. The grand hall was well filled. Dr. Risdon Bennett was in the chair; he was supported on the right by Sir Francis Hicks, and on the left by Mr. Le Gros Clark. The toasts were limited to six, and the speakers were earnestly entreated to observe brevity. With one or two exceptions the speeches were brief and to the point. Professor Stromeyer replied for the visitors. At such a gathering of past *alumni* of St. Thomas's, it could hardly be expected but that some allusion should be made to the subject which excited so much surprise and ill-feeling about this time last year. We allude to the filling up of the six vacancies on the staff by the appointment of six outsiders. It seems a pity, however, that this unpleasant subject should have been revived, and that some explanation seemed necessary at a social gathering of gentlemen where the theme of the speeches was the glory of St. Thomas's. The Dean—perhaps, in his official capacity, avoiding the main issue—expressed his conviction that in constructing the staff the governing body had been solely actuated by a desire to obtain the best men. No one ever objected to the introduction of outsiders; but we believe the Profession generally, including the staff, were of opinion that some of the six vacancies should have been given to St. Thomas's men. A silence which might be felt pervaded the company when any allusion was made to this subject; everyone seemed anxious at such a *réunion* of old friends to pass on to a more cheerful topic. There seemed to be a general impression, however, especially when the devilled whitebait was being handed round, that there are just as good fish to be found on the Surrey side of the Thames as ever came out of it, although some have tried the small pools on the other side of the water with the expectation of catching salmon. Mr. MacCormac did not seem to appreciate the "thin silver streak" bisecting the metropolis; he thought that Father Thames might prove a troublesome neighbour. He was struck with the number of fire-engines at the New Hospital; as some of the new introductions might succeed in setting the Thames on fire, it was also necessary to take precautions lest the "great lights" should burn too brightly. The band of the Coldstreams discoursed sweet music at intervals during the evening, and the company separated shortly after ten o'clock much pleased with the evening's entertainment.

THE SMALL-POX EPIDEMIC IN THE WEST INDIES.

OUR correspondent in Trinidad writes us word that the epidemic is now over in the Port of Spain and the neighbourhood, but is still severe in some of the country districts. It is getting into the sugar estates, among the coolie labourers, and will probably linger there for some months. It is also spreading in Jamaica. The other West Indian islands rigorously quarantine Trinidad, and have refused to receive bills of health for Port of Spain alone. Their sanitary authorities declare that they will not grant free *pratique* to vessels from Trinidad until small-pox has entirely disappeared from that island. It is now, and has been for the last six months, almost impossible to go from Trinidad to the other islands without first going to the United States or to Europe. Dr. Gavin Milroy had to go into quarantine at Dominica on his way home. Remarkable success in the treatment of the disease has been obtained by the

use of the wet sheet and cold affusion. We hope to be able to give further particulars by next mail.

CHOLERA ON THE MARCH.

HOWEVER ignorant we may be as to the origin of cholera, there are some facts connected with the disease clear and patent. That it is spread largely and widely by the caravans of the East has been proved on more than one occasion. Another instance in proof of this is recorded in a late number of the *Journal de Genève*, which states: "The caravan from this city left Mecca on February 25 with an effective of 4000 pilgrims, and arrived on March 10 at the tomb of the prophet at Medina. During the fortnight 400 persons died of cholera. There were at that moment at Medina 7000 strangers, among whom the scourge was raging with terrible severity. Before the arrival of the Damascus caravan it appeared to have abated, but it immediately broke out again with violence."

STATISTICS OF PAUPER SICKNESS.

DR. E. SMITH, Poor-law Inspector, in his statistics just published of pauper sickness, says that in "all England and Wales there were 840,388 outdoor paupers at the end of Lady-day quarter, 1870, of whom 106,323, or 12·7 per cent., were on the Medical officers' books through sickness, accident, old age, or infirmity." One of the inferences drawn by Dr. Smith is that the excessive number on the Medical officers' books in certain English counties arises from the fact of the labouring population of those districts being underfed. The proportion varied widely in different parts of the kingdom. In Cardiganshire and Pembrokeshire it was under 5 per cent., and in Berkshire it was 25 per cent. These were the extremes.

OPHTHALMIA AND ILLNESS IN THE MITCHAM SCHOOLS.

SOME time since we noticed that ophthalmia was very prevalent in the schools at Mitcham. Under proper regulations, better drainage, ventilation, and attention to the diet of the children, the disease has diminished in a very remarkable manner. Last week only seven boys and eleven girls were suffering from the disease. The health of the children, too, had generally improved, and contrasts favourably with the corresponding period of last year. There were last week only thirty children in the Infirmary suffering from illness; this time last year the number was forty-nine.

POISONOUS ICES.

Now that the season for ice-eating is near at hand, it may be as well to state, as a matter of precaution, that the German Medical journals are calling attention to the circumstance that several cases of poisoning by vanilla ices have of late years occurred in Paris, Altona, Munich, Vienna, and other places.

DR. BUCHANAN ON COTTON SIZING.

WE have received copies of reports from the Local Government Office, which indicate a wholesome activity in the Central Sanitary Administration. Amongst them is one by Dr. Buchanan on the "Sizing Processes used in the Cotton Manufacture at Todmorden," which is remarkable not only for the conscientious care it shows in investigating facts, but for its demonstration of the wide-spreading and little-dreamed-of consequences of remote effects. Phthisis is rampant at Todmorden, because of the Russian and American wars. And this is an abridged version of Dr. Buchanan's story:—

"Up to twenty years ago, 'sizing' of cotton consisted in the use of some fermented flour and tallow, in order to give tenacity to the warp and to lessen friction in the weaving process. The amount of such size required for this purpose was about 20 per cent. of the weight of the warps. About twenty years ago it was observed by some sizers that the brownish colour given to cotton cloths by size made from inferior kinds of flour could be reduced by the addition of a small quantity

of China clay to the size; and further, that this material so far reduced the glutinous quality of the flour that the sized warps would weave easily with a less amount of tallow in the size. . . . In 1854, at the time of the Russian war, the increased price of the usual sizing materials led to further substitution of China clay. In 1862 the American war produced the English cotton famine. Cotton then very rapidly rose in price, and the better sorts were almost unattainable. . . . Warps of shorter-fibred cotton are difficult to weave, unless the needful tenacity of the twist be given by a larger amount of size than would be wanted for better sorts. Of size, made of flour and tallow, warps from the worse kinds of cotton are stated to require even more than 20 per cent. of their weight. But the lack of cotton in 1862 introduced another practice. With the scarcity of raw material came the practice of giving a fictitious weight to cloths containing less cotton, in order to make it appear that they contained more. It became a matter of rivalry with sizers, which of them could 'put on' most foreign matter upon the cotton warps. . . . For the last three years every yard of cotton cloth made at Todmorden has been weighted with quantities of size, not required for any manufacturing purpose, but used as an adulteration. The 'size' may still consist, in the main, of flour and tallow, some sort of salt being added either for the purpose of lessening the glutinous quality of the flour, or else for the further purpose of retaining moisture, and thus of increasing weight. Epsom salts and chloride of magnesium (with sulphate and chloride of zinc, not yet in common use at Todmorden) have been the principal salts used for one or both of these purposes. . . . In weaving warps of inferior cotton, weighted with China clay and flour mixed with deliquescent salts, there is especial occasion to keep the weaving-sheds damp, as in this way the brittle compound of cotton, flour, and clay is less liable to break, the clay comes off less, and the resulting cloth is also heavier by the weight of the retained moisture. In these weaving-sheds the excess of damp in the air, desired for facility of weaving, especially for weaving the over-sized warps, is obtained from the moisture retained in the size, and (incidentally, yet probably in most part) from the persons of the workers, while there is careful avoidance of any draught that could dry the tender warp. Windows and so-called 'ventilators' are habitually kept closed. In all the sheds there was more or less dust. The stranger-visitor experienced in all the more dusty sheds, and roughly in proportion to the amount of visible dust, very great irritation in the nose, and in a less degree to the eyes and throat. To this irritating effect of the dust a frequent visitor, and still more a weaver, gets speedily accustomed. . . . All the Medical men in Todmorden agree that lung diseases are greatly prevalent there, and that the circumstances of employment in the cotton manufacture conduce to such diseases. There is a general agreement, too, that cotton-workers, with a family tendency to consumption, have that tendency developed; and that those who, without such tendency, continue to work in mills up to 40 or 50 years of age very commonly break down with lung disease. It is also agreed that they suffer much, and more than other people, from dyspepsia. A very intelligent overlooker, who accompanied me through one of the most important establishments of the town, expressed his own belief that weaving was not so healthy a branch of the cotton manufacture as before heavy sizing was in vogue, and that fewer weavers now pass middle age without getting something the matter with their lungs."

Dust, as Dr. Buchanan remarks, kills slowly, so that its victims may lead crippled lives for some years before they go to swell the lung-disease column of the Registrar-General. The investigation was made at the request of the workmen employed in the factories, and we hope will lead to a reform.

SMALL-POX JOTTINGS.

THE deaths from small-pox in St. Pancras in the past month fell from eight to six.—The Medical Officer reported last week that Clerkenwell was entirely free from the disease.—Small-pox is very prevalent in Leicester. Both the temporary Hospitals are full, and upwards of 500 cases are requiring admission. The deaths average over twelve a week, and so virulent is the disease that many of those attacked succumb after a few days' illness.—Five deaths from small-pox occurred in the Poplar Union in the past fortnight, and twenty-five new cases were brought under notice. In the same period eighty-three persons were vaccinated at the public

stations.—There were on the 18th ult. eleven small-pox patients under treatment in the North-street Infirmary.—Eleven deaths are reported from small-pox in the Hackney district during the past fortnight.—The deaths from small-pox in Ireland in the last quarter of 1871 alone were 441.—The last week's return of small-pox cases in the Aberdeen Small-pox Hospital shows—Total number of cases admitted since opening, 210; new cases admitted on Monday last, 3; number of patients now in Hospital, 18; total discharged recovered, 158; total dead, 34.—Fifty-four deaths from small-pox occurred in the metropolis last week.—Dr. Aldis, St. George's, Hanover-square, reported last week two cases of small-pox; both were sent to the Hospital.

FROM ABROAD.—GEH. MED.-RATH MÜLLER ON MILITARY REVACCINATION—M. DEMARQUAY ON ASPIRATION IN THE REDUCTION OF HERNIA.

WE have frequently noticed in this journal the communications of Geh. Med.-Rath E. Müller, Director of the Berlin Vaccination Institution, upon glycerined vaccine lymph; and we return to the subject because we believe that the great difficulty, which during the late epidemic of small-pox was so often experienced both in this country and in France in procuring a supply of reliable lymph, would never have occurred had Dr. Müller's recommendations been attended to. His latest communication on the subject appears in the *Berlin Klin. Woch.* for April 29, and is entitled "Military Revaccination." In this he adverts to the large scale on which revaccination had to be carried on during the late war, where so many troops had to be protected against the small-pox prevailing in the enemy's country, while vast numbers of French troops were "interned" in Germany. Before the introduction of this new plan the military Surgeons had often very great difficulty in obtaining the requisite lymph. They obtained as much as they could from the establishments, and then revaccinated from the finest revaccination pustules that presented themselves. Some danger was incurred thus of also transmitting disease, while the lymph derived from revaccination is supposed to possess less protective power.

Military Surgeons are saved all trouble now on this score by the employment of glycerined lymph. Six years have now elapsed since the discovery of its advantages, and Dr. Müller, during this period, has been untiringly endeavouring to make these known more widely. The late war, occurring amidst the prevalence of small-pox, has amply demonstrated its value; for it was found that, on the outbreak of the disease, the only provision in Germany of lymph capable of meeting the emergency existed at the Berlin Institution, and supplies had to be obtained from it for revaccination in Baden, and for revaccinating the Saxon and Württemberg armies. Without the aid of glycerine the immense supplies for both civil and military Practitioners, at home and abroad, never could have been sent; and the army Surgeons can best judge what influence the withholding of such revaccination might have had on the course of the campaign. Still, in general, only enough lymph could be sent to set the revaccination process going, the revaccinating from arm to arm still continuing to be practised. In fact, but few military Surgeons prepare the glycerined lymph themselves, although this can be so easily done. If during the summer each were to vaccinate a few healthy children, he might lay by a stock of glycerined lymph (which keeps for months or years) that would enable him to revaccinate whole batches of recruits on the same day.

"It is, indeed," says Dr. Müller, "a most surprising fact how long a discovery, the advantages of which are so obvious, and can be put in force with so little trouble, is in making its way. Most of those who apply at the establishment ask expressly for the glycerined lymph, being convinced of its excellence and of its preferableness to pure lymph; but yet very few prepare it for themselves. Were such preparation general among vaccinators, the institution would have become

well-nigh superfluous; whereas, on the contrary, our expeditions of lymph are ever on the increase. The recent report on vaccination in Würtemberg bears witness to the utility of the glycerined lymph; yet had it been properly utilised there would not have been the want of lymph there was for the purpose of revaccinating the army."

At the meeting of the Académie de Médecine on May 21, M. Demarquay presented a man, 21 years of age, in whom he had reduced a strangulated congenital inguinal hernia by the aid of aspiration. On May 5 a tumour appeared in the left groin, accompanied by severe pains and vomiting, which persisted next day. At the end of twenty-four hours he was taken to the Paris Maison de Santé, where the taxis was employed without success. Ice was applied during the next twelve hours, when M. Demarquay saw the patient. His features had undergone great change, and fever was set up. A congenital, elongated, voluminous inguinal hernia was found to exist, and M. Demarquay paid the more attention to other measures inasmuch as he had never succeeded in curing this description of hernia by operation. He applied carefully the taxis, while the patient was put into a deep sleep, with no effect, and he determined to try the effect of removing the intestinal liquids and gases by means of aspiration. A fine trocar was passed into the centre of the tumour, and, by means of Potain's aspirator, about 120 grammes of intestinal liquid were drawn into the recipient. The tumour subsided completely, and, the trocar having been removed, some minutes were allowed to elapse without touching the tumour, in order to observe whether new liquids or gases would enter the strangulated intestine. No renewal of the tumefaction took place, and very slight pressure upwards sufficed to procure the return of the intestine into the cavity of the abdomen. The patient was kept quiet, and on low diet, fractional doses of opium being administered. No ill consequence followed. The case M. Demarquay regards as striking, and he proposes to apply this new mode of treatment—1. In all congenital hernias and to recent hernias which become strangulated at the time of their formation. 2. To old hernias which were quite reducible a few days prior to strangulation, and in large umbilical hernias that have been recently strangulated. 3. Aspiration, which has for its object facilitating the employment of the taxis, should only be employed at an early period, when one can be well-nigh certain of returning into the abdomen the intestine in an unaltered state, and capable of resuming its functions.

PARLIAMENTARY.—THE CONTAGIOUS DISEASES ACT—NAVAL MEDICAL SERVICE.

On Monday, May 27, in the House of Commons, Mr. W. Fowler gave a notice that he would, on June 11, move for leave to bring in a Bill to repeal the Contagious Diseases Acts.

In the debate on the naval estimates, on the vote for £59,926 for Medical establishments at home and abroad,

Sir J. Hay wished to ask the First Lord of the Admiralty how it was that when eleven of the crew of the *Rinaldo* were wounded in an attack upon a piratical community on the coast of Sumatra there was no Medical man on board to attend to them. It was of the first importance that when ships were ordered on such expeditions they should carry Surgeons.

Mr. Goschen explained that on the occasion in question the chief Surgeon belonging to the *Rinaldo* had been directed by the Commander-in-Chief in China to attend to the Hospital at Hong-Kong, and that at the same time the Assistant-Surgeon was laid up by illness at Singapore.

In reply to Dr. Brewer,

Mr. Shaw Lefevre said the subject of Dental Surgery as practised in the navy had not been specially brought under the notice of the Admiralty.

The vote was agreed to, as was also a vote of £18,728 for Marine Divisions.

The Government of St. Petersburg has been informed by the Russian Embassy at Teheran that fever and cholera have entirely disappeared from Persia.

ON THE FACTS ELICITED BY
THE PRESENT EPIDEMIC OF SMALL-POX
IN REFERENCE TO THE
RISE AND PROGRESS OF THE DISEASE, ITS AVERAGE MORTALITY,
ITS EPIDEMIC PERIODICITY, AND THE PROPHYLACTIC INFLUENCE
OF PRIMARY AND SECONDARY VACCINATION.(a)

By HENRY LETHEBY, M.B. Lond., etc.

DR. LETHEBY alluded to the fact that the present epidemic of small-pox is one of the severest on record, there having been nothing like it since the practice of compulsory vaccination. It resembled, indeed, the state of things in the days of Jenner, when, according to Sir Gilbert Blane, the average annual mortality from the disease was about 30 per 10,000 of the population. As regards the onset and progress of the present epidemic, it would seem, from the returns of the Small-pox Hospital at Upper Holloway, that it began to show unusual severity as far back as the month of November, 1869, and that it steadily advanced month by month throughout the whole of the following year (1870)—the largest number of admissions being in the month of December, 1870. According to the Registrar-General's returns of deaths in London it appears that the first indication of the epidemic was in the first week of October, 1870, when the mortality from the disease rose from an average of about 12 in the week to 27. After that, with slight variations, it slowly and steadily increased, the number of deaths at the close of the year being over 100 a week. For the next four months it grew in proportions until it reached to 288 in the week. This was in the first week of May, 1871, and it is the largest weekly mortality for the year, for from that time it slowly declined. In the City of London the period of greatest intensity was from November, 1870, to June of last year.

The mortality from the disease has been unusually large, for it has amounted to 19 per cent. of the admissions into the Small-pox Hospital at Upper Holloway, to 18.2 per cent. in the Hospital of the Metropolitan Asylum District at Stockwell, to 19.2 per cent. in the Hospital at Hampstead, and to 19.8 per cent. in that at Homerton—the average for the whole of the cases (10,991) treated in the four Hospitals being 19.1 per cent. This is an excessively high proportion; for, according to the statistics of the Small-pox Hospital, the death-rate ordinarily ranges from 12.9 per cent. (1864) to 17 per cent. (1863)—the average for many years being only 14.3 per cent.

The force of the epidemic may also be estimated by the death-rate per 10,000 of the population. In all England during the last twenty years the average annual mortality from small-pox has been only 2 per 10,000 of the people, and in London during the last ten years it has been 2.7 per 10,000, and in the City 1.6; whereas, in 1870, during the present epidemic, it was 24.2 per 10,000 of the population of London, and 11.5 per 10,000 of the City. The City occupies an intermediate position between the eastern districts of London (where the disease has been most severe) and the western, and no doubt it represents the mean force of the epidemic.

Dr. Letheby exhibited tables of the death-rates of the disease in England, in London, and in the City, for each year since 1851, and they showed a remarkable periodicity of the disease. In the City, for example, the intervals of calm and of great severity were as nearly as possible two years. In London it is generally about three years, and in other places from four to five years—the period being no doubt determined by the density of the population, the habits of the people, and the efficiency of vaccination.

Dr. Letheby entered very fully into the subject of the prophylactic power of vaccination, and he showed that although a very large proportion of the cases had been vaccinated—amounting in the City to 73.9 per cent. of those attacked by disease, at the Small-pox Hospital to 79.3 per cent., and at the three Hospitals of the Asylum District Board to 74.8 per cent.—yet it was manifest that the operation had been either imperfectly performed, or had been weakened by the afflux of time. But even with these disadvantages the mortality among those who had been vaccinated was remarkably small in comparison with the unvaccinated; for while the general mortality was at the rate of 19.1 per cent. of all who were attacked with the disease, it was only 10.7 per cent. among the vaccinated, and as high as 45.9 per cent. among the unvaccinated. In the City

(a) Abstract of paper read before the Association of Medical Officers of Health.

of London the proportions were 7.5 per cent. among the vaccinated, and 36.8 per cent. among the unvaccinated. These numbers are not very different from the proportion which Mr. Marson has found to be the average at the Small-pox Hospital, the mortality of the unvaccinated being about five times as great as that of the vaccinated. As regards the ages at death, Dr. Letheby stated that in the City during the last thirteen years he found that of every 100 deaths from small-pox 43.1 were less than 5 years of age, 16.2 at from 5 to 15 years of age, and 40.7 at 15 and upwards. In the whole of the metropolis the proportions at different ages were—55 per cent. under 5 years of age, 15 per cent. at from 5 to 15 years of age, 22 per cent. at from 15 to 35, 7 per cent. at from 35 to 55, and only 1 per cent. above that age. In all England the proportions are a little different, 56 per cent. being under 5 years of age, 16 per cent. at from 5 to 15, 20 per cent. at from 15 to 35, 6 per cent. at from 35 to 55, and 2 per cent. above that age. It is also remarkable that the mortality is somewhat different with the two sexes—up to 15 years of age the females die in largest proportion, and after that age the males.

The conclusion from the inquiry was, that vaccination in infancy, when properly performed, was protective during the growth of the body, and that revaccination was necessary at the age of 15, or thereabout, to protect the system during the remainder of life. Abundant illustration of this was given from both English and Foreign statistics. In discussing the pathological relations of the disease, and the remarkable correlative quantivalence of zymotic maladies, Dr. Letheby referred to the various theories which have been advanced to account for them, as the influence of molecular motion, the action of specific principles, and the operation of living germs; and he concluded by saying "that although the entire phenomena of zymotic diseases, and especially the reproductive powers of them, are hardly consonant with what we know of the physical manifestations of molecular motion, yet there is much about them—as, for example, their modes of attack, their periodicity, the regularity of their progress, the order of their decline, and, above all, the quantitative or complementary relations of them—which points to a probable correlation of some kind. But whether the relation is in the quality of the contagion, or in the nature of the material upon which it acts, or in the force which governs its manifestations, is a problem for searching inquiry; for at present no man can safely dogmatise on this obscure subject by saying that these diseases are caused by matter in a peculiar state of motion, or by living germs with their faculty of reproduction, or by the so-called 'zymotic principles' of the Registrar-General. All that we can certainly say of these maladies is, that, be their origin what it may, or their correlation as close as can be, they are governed by laws which are quite within the reach of human investigation; and that although perhaps we shall never be able to banish such diseases from the community, yet we have always power to mitigate their force, to regulate their actions, and to bring them under the control of hygienic influences. This, in fact, is the practical aim of sanitary science, however much it may be disturbed by the fanciful theories of dreamy physicists or by the sensational rhapsodies of popular writers."

POOR-LAW MEDICAL OFFICERS' ASSOCIATION.

At a meeting of the Poor-law Medical Officers' Association held at the Medical Club on Tuesday, May 28, certain amendments to the Public Health Bill were read and discussed. A resolution was then proposed by Mr. Wickham Barnes, and seconded by Dr. Montague Thomas, honorary secretaries to the Association—"That this meeting thoroughly approves of, and will endeavour to support, the 13th clause of the Public Health Bill, appointing Poor-law Medical Officers Health Officers, seeing in that clause an earnest endeavour on the part of the Local Government Board to improve the status, as well as the remuneration, of the Poor-law Medical Officers." Considerable discussion followed, the opinion of the meeting being that the clause had not been properly understood by its opponents, it having been viewed by them in too narrow and suspicious a light. On the resolution being put to the meeting, it was carried. Mr. Barnes then proposed that a memorial be addressed to Mr. Stansfeld, praying that a superannuation clause be added to the Bill; but though the meeting were unanimous in the objects of the resolution, it was considered

advisable to wait for another opportunity. A communication having been read by the President from Dr. Maunsell, of Dublin, relative to a Bill to amend the Act providing for superannuation allowances to officers, it was proposed by Mr. Barnes, and seconded by Dr. Vance, and carried—"That it is desirable, in the opinion of this Association, that a clause should be introduced into the Bill, so that Union Officers shall include Medical Officers of the Dispensaries of such Unions, and that the words 'superintendent registrars' shall be followed by the words 'and registrars,' so that the Dispensary Physicians of Ireland may be able to compute the fees from registration in estimating their salary for the purpose of superannuation; and this Association pledges itself to exert its Parliamentary influence in aid of the above amendment."

MORE NOTES ON WINE.

SWEET AUSTRALIAN WINES.—VERDEILHO; PEWSEY VALE WINES; DENYER'S RHEINGAU CHAMPAGNE; SAN LUCAR SHERRY.

WE are reproached by an Australian friend for not doing justice to some of the Australian wine of which samples have been sent to this country. In the first place we are desired to notice the exquisite sweet wines. Now, sweet wine is a special article—it is not destined to be used with food as an *appetiser*, like Bordeaux or Ofner; nor yet after food as a *cordial*, like old dry sherry; but as a nutrient by itself, or with some light article of food in the intervals of more serious meals. Such a wine is the Lunel, the Rivas Altes, the Constantia, and, above all, the Tokay. Now, there were in the Exhibition of 1851 samples of sweet wine, of deep amber colour, fragrant without sickliness, and satisfying but not cloying. Of this wine some samples are before us from the cellars of Mr. Denman—some marvellously preserved, but some, alas! fairly decayed; all vinous strength dissipated, but a faint flavour of its former self. But what there was preserved is paralleled by some samples with which we have been favoured by Mr. P. B. Burgoyne, of *Verdeilho*, a light-coloured fragrant sweet wine, from Gilbert's vineyard at Pewsey Vale, near Adelaide. This wine is not to be had here at present, but we are requested to notice it amongst the potentialities of Australian produce. Any Physician who has a patient that requires eight meals a-day may be grateful for the opportunity of using such saccharine stimulant. But there are other Pewsey Vale wines to be had, both red and white. The "Pewsey Vale White, vintage 1864," is an example of the power of these wines, both in alcoholic strength and vinous flavour. The strength of this wine is equal to 25 per cent. of proof spirit, without evidence or suspicion of fortification; the vinous flavour intense, and the taste has qualities which approximate to those of a fine dry sherry—in saying which we pay a high compliment to dry sherry, for much of the liquid sold under that name tastes more of Glauber's salts than of wine. The "Pewsey Vale Red," also 1864, is a fine mature wine, grapy and potent, alcoholic strength 24°, fit to rank with Hermitage. The Tintara, we are glad to learn, is used in at least one Hospital, instead of the *banañ* "Tarragona," or "Hospital port."

Amongst new samples of wine that have been brought under our notice we may mention the "Sparkling Rheingau Champagne," a wine said to be made from champagne grapes grown in the Rheingau. We have often spoken of the importance, to sick people of all classes, of being able to procure sparkling wine, and of the absurdity of supposing that nothing will do save the very expensive wines of Rheims and Verzenay. We therefore welcomed the Vouvray, and the sparkling wines of Ackerman Laurance of Saumur, the champagne of Mr. Patrick Auld, the Styrian Champagne, and others, as well-directed efforts to supply an acknowledged want. Now we have another string to our bow, in a wine of the champagne character imported by Mr. Denyer, of 95, Regent-street, and sold at a moderate price. It has the first characteristic—viz., that it tastes of wine: it is perhaps a trifle too sweet, but it is perfectly wholesome, and the best wish we could form for many a poor creature would be that they might get enough of it. The introduction of such good useful varieties of wine is a public benefit.

We have also received two samples of Manzanilla imported from San Lucar by the same firm. It is thoroughly dry and clean, has the peculiar bitterish taste which is a well-known characteristic of the Manzanilla, moderate alcoholic strength,

nothing hot and fiery, and a softness which will greatly improve by keeping. The manner in which the samples are packed indicates great care and ingenuity.

WHITBREAD'S BOTTLED BEER.

THE consumption of bottled beer has of late years very greatly increased; and if restrictions on the hours of sale in public houses are enforced, as seems likely to be the case, the quantity so consumed is very likely to increase still more. In Scotland up to a few years ago there was little or no consumption of beer, but the taste for it has spread as the use of whisky has diminished, but from various causes the consumption has taken the shape of bottled beer instead of draught beer, so that the bottling trade is now one of very great importance in that country.

Very frequently it is the duty of a Medical man to prescribe stimulants. Very frequently, too, the patients so prescribed for are not in a position to obtain that best of all stimulants, good old and well-matured wine. The use of spirits among the class of patients who are likely to derive most advantage from properly selected stimulants—viz., women—is certainly not a thing to be encouraged, and so we are compelled to fall back on homely beer. And there can be no doubt but that in appropriate cases beer is quite as good a stimulant as wine; but then it must be good—and here we are at the mercy of the publican. There are a very large number of people—in point of fact, the majority of those who drink beer—who never think of going to the brewer himself; their wine, spirit, and beer merchant is the publican. Now, it is rather a hard thing to say, but we fear if the quality of the beer were tried all round the public-houses in London we should find it bad in a majority.

It is easy to say to such people, "Go direct to the brewer"; but the best quality of ale and stout—let us say, for the sake of example, Allsopp's and Reid's (we do not say they are better than all others)—can only be obtained in quantities of eighteen gallons, and that means a very considerable investment of money to poor people. It is quite true good beer can be got on different terms; but we are expressly speaking of the best qualities brewed. For many people, therefore, it would be a matter of great importance to be able to procure beer of the best quality at a cheap price in such a form that it can be used at any time they choose without getting in eighteen gallons at a time or sending to the public-house for it. Bottled beer offers the necessary facility; but hitherto the bottling trade has been worked in such a way as to repel rather than to attract customers. Many and grievous have been the complaints against bottled beer, and, we fear, with only too just a foundation; for this is the rule in dealing with bottled beer—you must rely on the reputation, not of the brewer, but of the bottler. The great brewers, like Bass and Allsopp, send out good beer, and they issue along with each barrel a certain number of labels; but the bottler need not put a drop of these beers in his labelled bottles—he may put in trash of the vilest description, and label it as he will. And this is done. We could mention bottling firms whose beer only the most parching thirst could induce us to touch, whilst we could mention others from whom you never by any chance get a bottle of bad beer.

At one time there was a kind of safety for us, because bottlers could only put in bottles a beer that had body enough to make it keep for a time. If it turned off, it was of course useless. But the indefatigable chemist, who plays such an important part in the concoction of modern wines and beers, made a discovery—he took advantage of the property of sulphites to arrest fermentation and absorb oxygen. Sulphite of soda was tried, but the taste would not do—it was too nauseous; the lime salt succeeded better, and now you may bottle anything you like, only you must not too particularly inquire into the character of the sediment at the bottom, nor the origin of the smell—not exactly that of hops or malt—which comes from the bottle when the cork is drawn.

To get a good sound beer in bottle we want two things—*absolute cleanliness* and good material—to begin with. We lay especial stress on the former, for it is that, simple though it be, which is too often neglected. And if you put ever so good beer in dirty bottles, the result will be the reverse of satisfactory.

We have been induced to make these observations *apropos* of certain specimens of bottled beer submitted to us. The beer

is Whitbread's and it is bottled by Mr. Robert Baker, of 277, Gray's-inn-road, W.C. We have since visited the bottling premises, and can say this, that there cleanliness rule and reign. And the product is good; the beer fairly tested is excellent. Six kinds of beer altogether are bottled. Two of these—the extra stout and old ale—are very fine; but it is of the former we mainly desire to speak. It has often been our desire to prescribe stout for a patient who could digest it, and we had only Guinness's to fall back upon. Now, without derogating for a moment from the admirable qualities of the Dublin product, we can obtain here in London a beer—if you know where to go for it—which, in the estimation of many, is far superior. Such a beer we have frequently desired to obtain in bottle, but never could until we came across this, which is Whitbread's best, duly matured in wood and bottled with all proper precautions when fully ripe. This beer we can fully commend to our readers, though even the inferior quality—ordinary stout—is very much better than that usually obtainable. The price, too, is most moderate: the ordinary stout is sold retail at the rate of threepence per pint; the extra stout costs a halfpenny more. It is, moreover, to be noted that the bottles are all imperial pints, no "reputed" measures being used. We should say, "Give it a trial."

REVIEWS.

Disease Germs: their Nature and Origin. By LIONEL S. BEALE, M.B., F.R.S. Second edition. Twenty-eight plates, containing many coloured illustrations. London: J. and A. Churchill. 1872. Pp. 472.

THIS book contains a good deal more than the title would lead us to expect, and deals with a good many disputed points. There will be found in it much information as to Dr. Charlton Bastian's latest researches on the spontaneous development or generation of organic beings, in which Dr. Beale takes the negative side very strongly. Anyone who is acquainted with his works will also be prepared to meet with an exposition of his views as to the nature of life, which he maintains not to be a mere result of physical forces—a "kind of motion"—but of some superior force, by which the ordinary physical forces are controlled. Beale consequently believes that the organisms which are developed (to use the common phrase) "spontaneously" in dead and decaying animal and vegetable matter are not of new origin, but are the offspring of germs conveyed by the atmosphere.

This leads us to some reflections on the atmosphere, and on its power of upholding and conveying bodies in a state of minute division. That the air in certain conditions is loaded with such particles is evident from the inspection of a sunbeam pouring into any darkened chamber. The nature of this atmospheric dust has often been the subject of examination—for instance, years ago by Raspail, by Mr. Alfred Smeé, Dr. R. D. Thomson, Mr. Samuelson, and many others; and it was thoroughly well-known that starch granules, particles of hair and wool, filaments of cotton and silk, fragments of insects—as, for instance, the scales of the common clothes moth—pollen granules, vegetable germs, and other organic substances, are mixed with the finely powdered clay or silica, ashes, soot, oxide of iron, and the like, that constitute ordinary dust. The dust of a drawing-room after a carpet dance, and that of a pauper school lavatory after the children's heads have been combed, of Piccadilly during March, and of a hayfield in July, must each contain its peculiar constituents, of which a considerable portion has been long known to be organic. Dr. Buchanan, for example, finds *fat* amongst the dust of the Rochdale cotton factories, along with the clay and flour that are used with it to dress the cotton-cloth.

Here Dr. Beale records the somewhat retrograde step made by our great physicist, Dr. Tyndall, when he brought the subject of dust in a somewhat sensational manner before the Royal Institution two years ago. Beale, like an accomplished pugilist, gets Tyndall's "nob into chancery," if we may borrow the language of the "ring," and administers punishment with great gusto. He pokes fun at Tyndall for bringing the electric light, and all the other tremendous resources of physical science at the Royal Institution, to show (1st) that dust doth float in the air, which the common world would not deny, seeing that they had seen it daily in the sunbeams; (2nd) that dusty air, when left at rest, will clear by subsidence—a fact of great interest; inasmuch as Beale sarcastically observes it showeth that ponderable matter really hath weight and is subject to the attraction of gravitation; (3rd) that dust is really com-

combustible—a conclusion which must have been highly comforting to the physiological and pathological teachers, who had been long instructing their pupils how not to mistake for morbid products the particles of fir-wood, chips of cedar-wood pencils, starch, dust, and cotton occasionally found in urine, into which they might be floated by the air. To teach teachers who knew that such things are found in dust that they will burn—nay, that they will smoke if burnt—is, *certainly*, giving them something to think about. It was felt at the time that Dr. Tyndall had taken a wrong step, and we may enjoy, as lookers-on, the punishment which Beale lays on so vigorously; but we need not forget Tyndall's practical recommendation of a cotton-wool respirator for firemen and others, who not only breathe dust, but red-hot dust.

Dust, then, is partly organic in its nature, and doubtless contains abundance of germs of lowly organised vegetable life; but Beale does not believe that vegetable organisms, fungi and the like, are a *cause* of disease. That they largely flourish in diseased, decaying, and defunct organisms is not to be doubted; but this only shows that their germs are present everywhere and at all times, interpenetrating all our tissues, yet only capable of germinating and growing when the superior powers of the inhabited organism are quenched by disease or death.

As an instance of the amount of interference which Beale believes vegetable germs to be capable of effecting, we may quote his observations on the bacteria:—"The higher life is, as I think, everywhere interpenetrated by the lowest life. Probably there is not a tissue in which these germs do not exist, nor is the blood of man free from them. . . . Millions are always present on the dorsum of the tongue and in the alimentary canal, but remain in a germ or embryonic state." The normal secretions of the alimentary canal prevent their growth, and the nourishment comes to us instead of being appropriated by them. But what happens if some of these fluids be suppressed or changed in quality? The bacteria grow and multiply, and the nourishment is no longer absorbed into our bodies. If a child be poorly it ceases to digest its milk; this becomes the prey of hordes of bacteria. Fresh milk administered becomes similarly tainted, diarrhoea ensues, and the best way of cutting this short is the old-fashioned plan of sweeping the bowels clean out by a gentle aperient. He condemns Simon's adoption of Hallier's fungus theory of cholera, and Sanderson's leucubrations on the same points. Taking the animal creation as a whole, we think he hardly does justice to the disease-producing powers of vegetable parasites.

Thus Beale comforts us with regard to the dangers of vegetable germs—and, by-the-by, indulges in one or two knock-down blows at the sensational statements sometimes heard, that the dust in the atmosphere is "all germs," perhaps self-generated. But his tale is quite different when he comes to germs of an animal nature. Here, beginning with his now well-known views of the nature of "living" matter, he builds up an elaborate demonstration of the causation, propagation, and mechanism of the diseases which are ranked as "zymotic" or "contagious," and attempts to show that the treatment of these diseases which is generally successful or beneficial is in entire harmony with his views of the nature and properties of "living" matter.

Beale, as is well known (and we cannot point to a handier exposition of his views than was contained in the reports of his original lectures at the College of Physicians in 1861, published in our columns), takes as his starting-point the original "germinal matter" or "bioplasm" of the ovum, which is also known to physiologists by the name of "protoplasm." This structureless marvellous substance has the power of growing, and also of developing by its inherent powers and under due conditions all the structures of living beings, in health and in disease. Its most familiar forms in the adult animal are the "nuclei" of tissues and the white corpuscles of the blood. During certain diseases the white corpuscles or the bioplasm of tissue, whilst it loses its power of assisting in the development of higher tissue, yet acquires the power of almost indefinite self-multiplication. Examples of this are afforded by the bioplasm—say of the cuticular cells—after a blister, which, instead of forming a horny covering to the cutis, multiply prodigiously in the embryonic form, and constitute what is called pus. The same with an inflamed mucous membrane, or any part if injured: there is in the vessels, in their interstices and on the surface, a most rapid growth and multiplication (not mere *accumulation*) of the particles of bioplasm constituting exudation, suppuration, etc. In many instances (pyæmia, variola, vaccinia) the degraded bioplasm possesses extraordinary vitality, may preserve this vitality for long periods, is

capable of transplantation, and when transplanted into another organism may increase and multiply, and reproduce a series of all the changes of which itself was the result. *Pus* is degraded bioplasm in its fullest development—possibly dead and effete; but the liquids of diseased organisms (such as vaccine lymph) contain active living particles, thousands of degrees smaller than pus, and (as was proved in the cattle plague) capable of being given off from the mucous membranes, and floating in the air. Beale descants more or less at length on the various kinds of disease germs which may be the issue of the degraded but actively growing bioplasm of a diseased animal, specifying the lymph—as of puerperal peritonitis—capable of poisoning wounds, the pus of gonorrhoea and ophthalmia, the germs in vaccine and small-pox virus, in various kinds of fever, syphilis, tubercle, and cancer.

He next shows that disease germs may *float* in the air (not that they are *volatile*, as ammonia is), may be carried by water, and so may get access to the lungs or stomach, or, lastly, some may enter through the skin. He points to the conjunctiva, and especially to wounds, and to the uterus after delivery, as furnishing surfaces peculiarly liable to afford entrance to disease germs, and thus explains the well-known liability of wounded and parturient patients to Hospital diseases, which are types of germ-produced diseases. Badly filled capillaries, and moist relaxed membranes, with low general *tone*, favour their admission. Certain states of the blood are favourable to their multiplication and activity; and more especially the presence of half-oxidised material not yet converted into urea or other products fit for elimination. Such matter constitutes an *extractive* soluble in hot water; and the presence of this extractive in the blood in excess has been proved in the cattle plague. The phenomena attending the entrance and rapid multiplication of diseased bioplasm are fully discussed, and amongst them a few words are said about feverish rise of temperature, which Beale does not attribute to increased oxidation, but to the multiplication of bioplasm. Here we think Liebig's explanation of the potential oxidation and heat production during the conversion of starch into fat might have been appealed to with advantage. The effects of the multiplication of bioplasm are shown to be obstruction of the capillary circulation in skin and mucous membranes and elsewhere, as evidenced by *rashes*, and even destruction of tissues, as in severe variola and carbuncle. The life period of most disease germs in any individual organism seems limited; they cease after a definite period to grow, and become oxidised and eliminated in the ordinary course.

But with regard to the ordinary sense in which the word "elimination" is used—with respect to the poison of cholera or scarlet fever, for example—Beale looks upon it as a thorough mistake, and his opinions on this point deserve full consideration, inasmuch as they are subjects of microscopic research in which he has few rivals. Looking upon the "poisons" of scarlet fever and cholera, for example, as something in the blood, of a living nature in active growth, he denies such matter can be eliminated as such by gland cells. He believes that the "destruction" of gland cells in the act of secretion is exaggerated; he refers the desquamation of cuticle after scarlet fever, not to the cuticle being the recipient or eliminator of a poison, but to its nutrition being stopped by the deranged circulation in the height of the fever. The idea that the absorbent villi of the small intestines eliminate a poison he looks on as preposterous. On the abstruse subject of the protection afforded by one attack of zymotic disease, Beale intimates that the cause is probably not the exhaustion of a pabulum once for all, but the persistence of some remains of the original morbid bioplasm.

We have no space left for an analysis of the remainder of this work, every page of which bears the impress of its author's great ingenuity in applying his physiological views to the treatment of disease and the explanation of the action of remedies. He gives a full account of treatment, preventive and curative, and in the former order includes an analysis of Lister's antiseptic method. He believes that the carbolic vapour acts, not in protecting wounds from aerial germs, but in solidifying the bioplasm on the wounded surface, and rendering it less susceptible of that morbid growth known as suppuration. His views on *pabulum* are peculiar; he believes that in some blood diseased bioplasm cannot live, and under this head he gives a good deal of sensible matter on the circumstances which render people liable or not to take fevers. The remarks on support, on irritation, on treatment generally, on the action of alcohol locally and generally, have all the marks of originality and thoughtfulness, and deserve a fuller criticism than we can give them. Anyone who reads the

present book will find his ideas on pathology stretched in many unexpected directions, and new interpretations suggested of familiar phenomena. The illustrations, printed in colours, are unique and beautiful.

FOREIGN AND COLONIAL CORRESPONDENCE.

FRANCE.

PARIS, May 28.

FRENCH MINERAL WATERS—OPHTHALMIC SPECIALTIES—M. DE WECKER—NEW OPERATION FOR CATARACT—THE BEST STREET PAVEMENT—FRENCH TEMPERANCE SOCIETIES.

ONE of the results of the late war has been the discovery that France was the only country of Europe that was endowed with all that was necessary to render man happy and comfortable, even with respect to its mineral waters, which are second to none in the world; that its inhabitants had no occasion whatever to have recourse to the empire of Germany, as was formerly the vogue, for any of these; and that even the waters of Carlsbad might be dispensed with, as it is found that those of Montmirail-Vaqueyras (Vaucluse) are alterative and aperient. These waters have been analysed by M. Ossian Henry, Chemical Analyst to the Academy of Medicine, and are found to be eminently saline, the following being the principal ingredients of which they are composed:—Anhydric sulphates of magnesia, soda, and lime; chlorides of magnesium, sodium, and calcium; iodine, phosphates, silica, and alum; sesquioxide of iron, traces of arsenic, and an appreciable quantity of organic matter. This subject is so much at heart with the French just now, that it is to constitute the entire course of lectures by Professor Gubler at the School of Medicine for this session, and thus punish the Germans. Poor revenge!

Dr. De Wecker, one of the most distinguished oculists of Paris, has resumed at his clinique a course of lectures on Ophthalmological Medicine and Surgery, with practical lessons on the use of the ophthalmoscope. Specialism is not much countenanced in France, yet I have seen specialists consulted by some of the most eminent Physicians and Surgeons in difficult cases, who, when they have to do with such a delicate organ as the eye, hand the case over to an oculist. The specialists in Paris having no Hospitals, these are replaced by cliniques at their own expense, where advice is given gratuitously to those who wish to avail themselves of it. This is taken advantage of by the same class that resort to Hospitals and Dispensaries, where the applicants are treated as out-patients. Dr. De Wecker, however, has founded a Hospital of his own (or rather Maison de Santé, as the French do not like the word Hospital), where applicants of all classes are treated, either as in- or out-patients, the former paying for their boarding and lodging. Here one can have first-rate advice and treatment for diseases of the eye gratis, and the institution seems greatly appreciated, as it is generally full. These gentlemen (the specialists) are generally very obliging, as they not only admit other Practitioners to their consultations, but they deliver gratuitous lectures for their benefit. I have paid frequent visits to Dr. De Wecker's Hospital, and found nothing wanting for the treatment of this special class of diseases. Dr. De Wecker, who is a pupil of the illustrious De Graefe, is a most cautious yet brilliant operator, and is, above all, a practical Physician. Through the kindness of Dr. Georges Martin, his Chef de Clinique, I am enabled to present you with an abstract of the statistical report of Dr. De Wecker's clinique, as it may prove interesting to your ophthalmological readers. The report gives an account of the operations which were performed during the last half of the year 1871, which are as follows:—1. Cataracts, 95. 2. Iridectomy, 61. 3. Strabotomy, 43. The operations for cataract are divided as follows:—Eighty-six for spontaneous cataract; five for traumatic ditto; four congenital ditto.

The eighty-six spontaneous and the five traumatic cases were all operated on after M. De Graefe's method of extraction, modified, however, as regards the division of the sclerotic on the one hand and the opening of the anterior portion of the capsule of the crystalline lens on the other. An incision is made in the sclerotic itself one "millimètre" (a) outside the edge of the cornea in a horizontal line, passing two millimètres

below the superior border of the latter, and thus bringing the instrument out at a level of the superior border of this membrane.

By this method a small flap is formed, of which the apex corresponds exactly with the superior edge of the cornea, and the base situated two millimètres lower down corresponds with the entire breadth of the membrane at this level, extending two millimètres (one on each side) into the sclerotic. Thus in a cornea of twelve millimètres of horizontal diameter a section of from eleven to eleven and a half millimètres wide is obtained; whereas the maximum of De Graefe's measures only from ten to ten and a half millimètres.

The other modification introduced by Dr. De Wecker was effected in the third time of the operation, the classical method of which consisted in making a simple incision in the anterior aspect of the lenticular capsule, whereas Dr. De Wecker removed a quadrangular portion of the capsule before proceeding to the extraction of the lens, and the instrument employed for the operation is a modification of the iridectomy forceps, to which he has given the name of "pince eystitome." The after treatment adopted in these cases is also deserving of notice; this consists in applying over each eye two circular pieces of fine linen, over which is placed some cotton-wool, and the whole maintained by a binocular flannel bandage. In the evening of the operation a draught containing chloral hydrate (three grammes) is given to the patient so as to insure a good night's rest, and the following morning, when the dressing is removed, and if the pupil is clear and sufficiently dilated, the instillation of atropine is withheld, the solution being employed only when the aqueous humour is a little cloudy, or when freed from cortical masses floating in it, or when the iris is threatened with inflammation; otherwise atropine, even a neutral solution of it, would add to the irritability of the eye. In general Dr. De Wecker does not wait until the cataract is mature, but operates at once in the event of both eyes becoming affected at the same time, and that the patient is no longer able to read or write or follow his usual occupation. With respect to the operation itself, he dwells upon the advantage of a large section of the sclerotic, by which means the crystalline lens slips out more easily, preceded and followed by a certain quantity of transparent masses of cortical substance. The failure and the dangers attending the operation for cataract, he adds, often depend, not on an opening too large, but insufficient, and which, in 1786, Wenzel had already pointed out in his treatise on Cataract.

Of the sixty-one cases of *iridectomy* twenty-eight were "optical" and twenty-three "antiphlogistic," and Dr. De Wecker draws attention to the fact that the operation, to be useful in glaucoma and other analogous affections, must be performed *early*, as it is scarcely ever attended with danger. As regards *sclerotomy*, which Professor Quaglino proposes to substitute for iridectomy, Dr. De Wecker observes that whatever may be its utility in other affections, he cannot recommend it as a substitute for iridectomy in glaucoma, as the latter has been proved by experience to be eminently superior to sclerotomy in its entire innocuity, and what enhances the value of the former operation is the incision in the sclerotic, and not the excision of a portion of the iris. Sclerotomy was performed seven times at the Clinique for confirmed glaucoma, but only to relieve the pain and other inflammatory symptoms. The result was the same as that by iridectomy.

Dr. De Wecker, in conjunction with Dr. De Jaeger, has written an excellent treatise on the diseases of the eye, containing an Atlas of Ophthalmoscopy, eighty-nine woodcuts in the text, and twenty-nine chromo-lithographic plates. The work is compendious and complete in its way, and will be found useful not only to the student of ophthalmoscopy, but to the more advanced Practitioner.

In a former letter I mentioned that owing to the increasing difficulties of free circulation in the streets it was proposed to have subterranean boulevards in the most commercial quarters. It is now in contemplation to intersect Paris by tramways and underground railways; the establishment of the former has just been decided upon, and they are to communicate with the suburban towns immediately outside the fortifications. The importance of this measure is incalculable in a sanitary as well as a commercial point of view, and we can only wish it every success. Of course every precaution is to be taken for the lighting and proper ventilation of the underground railways.

The municipal authorities of Paris are puzzled as to the material to be adopted for the streets. It is found that macadamised roads, though comfortable for those who ride in carriages, are detestable for foot-passengers during the rains, when they become slushy; besides which, they are fatiguing to

(a) 2.1166 millimètres are equal to an English line.

the horses, as the draught is greater; and the keeping them in repair costs at least one-third more than the ordinary pavements. Bituminised roads, besides having the latter drawback, are dangerous for horses, as they are very slippery in all weathers. Stone pavements are noisy, so they are now trying wooden ones in some of the streets; but I am afraid they will not answer, as, notwithstanding that the wood is hard and the bricks are coated over with tar, they are not completely waterproof, and the drainage would in consequence be defective. Another objection against them is that they damp the rattling of the carriages, and thus many accidents have occurred of people being thrown down or run over in the streets. There is nothing, in my opinion, equal to granite for paving the streets, as being cleaner, healthier, and more economical in every respect than the other systems.

The French Temperance Association held its first meeting on Sunday, the 12th inst., under the Presidentship *pro tempore* of M. Barth. The object of the meeting was simply to organise a committee of management and a council, which, as you will find by the list published in the Paris journals, are composed of laymen as well as of members of the Medical Profession, of which M. Hippolyte Passy, Member of the Institute, has been elected president. The subscription for founders of the association is twenty francs, and for all others ten francs per annum. These will be entitled to receive the publications of the society and to take part in the elections for the council and committee, but the founders alone will be eligible as members for either. After a while other subscribers of a trifling sum will be admitted, whose privileges, of course, will be more limited.

AUSTRIA.

VIENNA, May 27.

RESULTS OF PROFESSOR STRICKER'S INVESTIGATIONS ON THE NATURE OF DR. LOSTORFER'S CORPUSCLES—(concluded).

At this stage Professor Stricker was about concluding his experiments, and registering merely the indefinite results. However, before doing so, he was anxious to know whether or not more useful experience might be gained by exposing the objects to a higher temperature. This had already been done previously, and the corpuscles were seen perishing under the formation of vacuoles, and it has just been the intention of the experimentalist to study the origin of the vacuoles. Heating, however, a preparation slowly to 38° C. (made of the blood of the above-mentioned patient), a most remarkable aspect was revealed to the eyes of the observer. A plasma-islet, hitherto perfectly transparent, after fifteen minutes became so perfectly filled with granules as to give the impression of the disappearance of transparency by some precipitate. These granules were growing fast, and it was curious to observe a large number of them exhibiting knob-like projections. When observing such a corpuscle continually, as long as the eye would tolerate it, the two little bodies—viz., the corpuscles and the knob—were seen to retreat and to approach each other. Further observation showed them to be connected by means of a fine elastic thread, allowing the movements just described. The number of corpuscles seemed still on the increase, although their size did not assume the extent of the bodies when being slowly heated to from 22° to 25° C.

Having repeated the experiments on the next day with preparations of the blood taken from the same patient, and having obtained the same results, Professor Stricker considered the principal question solved. According to the present state of our knowledge we can only explain the phenomena of the corpuscles separating and approaching by the assumption of the elasticity of the joining thread of the bodies, themselves being organisms.

Now the phenomena of growth had assumed a more precise significance. It has been said that the projections may also be the result of apposition, but this was only said in order to show how attempts have been made to explain the mode of growth before the results just described had been obtained. A similar mode of cell-division has frequently been observed by Stricker in excised pieces of tissues of the frog, the two halves of a dividing cell being connected by a thread, the latter frequently changing its optic properties and becoming invisible, and the whole process seeming finished, the two halves nevertheless approaching each other and becoming confluent. It is a fact well known to all histo-pathologists that pus-corpuscles under certain circumstances of division do not assume a considerable size, but increase rapidly, and form tissue as soon as the conditions become unfavourable to partition. These observations are in accord with the experiment made on

the corpuscles in question, assuming a larger size under a temperature of from 22 to 25° C., but growing larger in number under 38° C.

Concerning the origin of the organisms there is only one alternative of their coming either from the atmosphere or from the blood, the germs in the latter case having already existed in the circulating blood, or being later admixed by heterogenesis. The latter alternative is not likely to gain adherents, and Stricker himself would not like to be considered as such; the *generatio æquivoca*, however, cannot be denied to be one of the possibilities in this instance to be taken into consideration.

The second question to be solved is whether or not the organisms in question are peculiar to syphilitic blood. To this question Stricker at once replied in the negative. He has used for his experiments thirteen patients suffering from general syphilis. Nine of them exhibited large numbers of the organisms; in two cases they decidedly did not exist at all; and in two there were very few, so that it was advisable to consider these cases likewise as negative—making up altogether nine positive and four negative cases. The first case of lupus at Stricker's disposal also exhibited large numbers of the organisms, and there were likewise nine cases, in one of which the corpuscles were discovered, though not in large masses, making two positive cases in nine cases of lupus.

The results thus obtained seemed to support to a certain degree Dr. Losterfer's teaching. In thirty-seven non-syphilitic cases Professor Stricker found the organisms in but two, and even in these two cases the supposition was admissible that a thorough difference between lupus and syphilis was not beyond all doubt.

In the meantime an occurrence took place which drew Professor Stricker's attention towards another direction. The patient whose blood had served for the preparation of the objects for the investigation was attacked with hæmoptysis, and as the results had been obtained in no other person in such a pregnant manner, the idea was not to be dismissed from consideration that ill-nutrition or a combination of syphilis with some other general disease might be the cause of the numerous development of corpuscles in this patient. This induced Stricker to experiment with blood from individuals suffering from grave chronic illnesses. The experiments were made with few patients only, but suffice, however, to arrive at certain conclusions for the present. Large numbers of the organisms were found in a case of cancer of the stomach, and in two cases of tuberculosis. Having further been discovered in a very advanced case of altered nutrition—namely, in Bright's disease combined with heart disease—and in another case of anæmia after small-pox, Professor Stricker considered his investigations advanced far enough to arrive at conclusions sufficient to pronounce the organisms in question not to be *exclusively* characteristic to blood of syphilitic patients. Considering, however, that they have not been discovered in a considerable number of healthy persons, and of patients suffering from acute diseases, the discovery of Losterfer must be admitted to be of some importance for pathology in general and for syphilis in particular. Of course, we are not warranted in denying altogether the existence of the alleged elements in healthy persons and in sufferers from acute disease. For that purpose the number of experiments is insufficient; but Professor Stricker thinks his experiments sufficient to show the prevalence of the newly discovered bodies in the blood of individuals subject to long-lasting chronic disease, and particularly to syphilis.

GENERAL CORRESPONDENCE.

IRISH UNION OFFICERS' SUPERANNUATION.

LETTER FROM DR. J. ROGERS.

[To the Editor of the Medical Times and Gazette.]

SIR,—I beg to forward you a copy of a Bill, which has been sent me by Dr. Maunsell, of Dublin, with a request that I would ask you to insert it in your this week's issue. The Bill as brought in by Lord Hartington and the Irish Attorney-General excludes Dispensary Medical Officers and Registrars of Births and Deaths from its advantages, and is as printed in Roman type. Dr. Maunsell desires me to get the amendments (printed in italics) added thereto. Will you, therefore, call attention to them editorially. Our Association met last night, and resolved to co-operate with the Irish Association in urging that these amendments should be conceded. I am, &c.,
33, Dean-street, Soho, May 24. Jos. ROGERS.

Union and Dispensary Officers' (Ireland) Superannuation (35 Viet.).

A Bill to Amend the Acts providing Superannuation Allowances to Officers of Unions and of Dispensary Districts of such Unions in Ireland.

Whereas it is expedient that the Acts of the twenty-eighth year of the reign of her present Majesty, chapter twenty-six, and of the thirty-second and thirty-third years of the reign of her present Majesty, chapter fifty, providing Superannuation for Officers of Unions in Ireland and for Medical Officers of Poor-law Unions and of Dispensary Districts of such Unions in Ireland, should be amended. Be it therefore enacted by the Queen's most excellent Majesty, by and with the advice and consent of the Lords Spiritual and Temporal, and Commons, in this present Parliament assembled, and by the authority of the same, as follows:—

1. This Act and the recited Acts may be cited together for all purposes as "The Union and Dispensary Officers' (Ireland) Superannuation Acts, 1866, 1869, and 1872."

2. The Superintendent Registrar and the Registrars of Births, Deaths, and Marriages appointed in any Union in Ireland shall be deemed Officers within the operation of the recited Acts; and in computing the salary of any Officer of a Union or Dispensary district of such Union under the recited Acts and this Act, the amount of the emoluments of his office on the average of the three years concluded in the last preceding quarter may be taken into calculation by the guardians, and charged upon the rates of the Union at large.

A DISESTABLISHED PROFESSION.

[To the Editor of the Medical Times and Gazette.]

SIR,—Wise men keep their eyes open to matters of fact, and are conscious that there is no security for any established system or school of thought if popular prejudice, ignorance, supposed convenience, or economy run counter to it. Medicine has been heretofore, in a certain degree, established or protected by the State. The Apothecaries' Act gives power to recover penalties from unqualified persons for visiting and sending medicine. But these laws depend upon public opinion for their force, and if all classes—magistrates, county-court judges, jurymen, and tradesmen—choose to go to a chemist for Medical attendance and medicine, who shall hinder them? It is of no use to rail against the Pharmaceutical Society or the chemists. There is a demand for the system of ready advice over the counter, and the dose off-hand, with a charge (nominally) for the medicine alone; and so long as that demand continues, it will be impossible by any system of penalties to prevent men from supplying it. Here is a crucial point. Suppose a message comes to a chemist that a woman is bleeding to death in the next street—it may be from wound, or from hæmoptysis, or from parturition—is that chemist to go? Would that incarnation of popular sentiment, the "British Jury," sanction his not going? But if he go in a case of emergency, is he to be subject to a penalty if he attends in other cases? How is a chemist to know whether a case he is sent to is one of urgency or not?

It is really too late in the day to attempt to fence in Medical practice by any form of protection. In order that Medicine may flourish, and its general Practitioners be well remunerated, two things are requisite—one, that the public shall believe in their skill; the other, that they shall have easy access, and be able to obtain medicine at one charge. If these two conditions be fulfilled, the general Practitioner will keep all that the chemist is now supplanting him in.

All that a Government can do is to put disabilities in the way of irregular Practitioners, and to employ none for any official purpose who have not gone through a regular education; but there is no security against any absurdities or heresies within our own body—homœopathy, for example. I believe that some men have been elected parish Doctors who practise on this (so-called) "principle."

The sum of the matter is, Mr. Editor, that we must trust in ourselves and keep our powder dry. Government may disestablish us, gives us no privileges, and put quacks on an equal footing; but they cannot disendow us so long as the public choose to pay us. Show me a Medical man of good sense and experience, who sticks to his business, and is qualified to get on in the world, and you will find that he holds his own, and does not complain if his patients get a black dose at the chemist's. If any men do complain of the chemists, let them come down from their stilts and compete with them fairly.

I am, &c., SEXAGENARIUS.

THE NEW FRENCH MEDICAL FACULTIES.—According to the journal *La France*, the Minister of Public Instruction has in preparation a Bill for the complete reorganisation of Medical education. He will propose maintaining the present Medical Faculties at Montpellier and Paris, giving some extension to the latter, and creating new Faculties at Bordeaux, Lyons, Nantes, Lille, and Nancy.—*Gaz. Méd.*, May 25.

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, MAY 14.

GEO. CRITCHETT, F.R.C.S., Vice-President, in the Chair.

THE following papers by Mr. M'CARTHY, Assistant-Surgeon to the London Hospital, were communicated by Mr. Curling, the President of the Society:—(1) "A Description of some Renal Calculi of unusual shape found in the Kidney of a Patient who died of Cancer of the Uterus," etc. (2) "An Account of a Case of Intestinal Obstruction in which an Artificial Anus was established successfully in the Small Intestine; recovery and subsequent death from Cancer and Fatty Degeneration of the Heart."

With regard to the second paper,

The CHAIRMAN applied to Mr. MAUNDER, who remarked that he was led to advise operative procedure, inasmuch as there was evident contraction and gradual filling up of the canal. He considered that much of the success that attended the operation was due to the skill and "elegance" with which it was performed.

Mr. TIMOTHY HOLMES commented upon the great interest of the case, but wished to know why the small rather than the large intestine was opened, and, as the obstruction depended upon cancer, why not have ascertained how far the ascending colon was free. He believed that it was extremely difficult in all these cases to arrive at an exact diagnosis, and suggested that the amount of fluid injected per rectum was a far better indication of the seat of obstruction than the O'Beirne tube, the usefulness of which latter was, according to his knowledge and belief, much overrated. In concluding, he expressed grave doubts as to the propriety of an early operation, and thought that in such cases it was often well if the patient was saved from the Surgeon altogether.

Mr. THOMAS SMITH dwelt emphatically on the difficulties that occurred in returning the intestine when it escaped from the opening in the abdominal cavity, and quoted several cases in illustration thereof.

Mr. JOHN WOOD had seen this kind of operation performed, had performed it twice himself, and had not found insuperable difficulty in returning the intestine; but if such difficulty existed he should not hesitate to puncture with a trocar and canula, because whether air or fluid be present some amount of benefit must follow. He doubted, however, the wisdom of the operation, as all patients died.

Mr. HULKE took some sort of exception to the particulars of the operation, asserting that the operator could not know what part of the small bowel was caught up.

Mr. M'CARTHY, in reply, said that he had not used injections; that he did not operate as suggested by Mr. Holmes, because the right colon might have been diseased as well as the left; and that his knowledge of regional anatomy enabled him to state a belief that the lower part of the ileum was usually situated at the place where in this case he had found it.

Mr. ROBERT HAMILTON read a paper, "On the Synovial Membranes in Pyæmia." After a brief account of the views at present held by the majority of writers on pyæmia as to the way in which the morbid changes found in this disease are brought about, the author dwells upon the fact of the synovial membranes being so generally attacked in pyæmia—a circumstance that has not hitherto attracted sufficient attention, though it makes it extremely probable that the first step in those forms of surgical pyæmia most commonly met with in Hospital practice is to be found there. All the cases occurring at the Southern Hospital for the last thirteen years, of which particulars have been kept, had some joint affection. In some the pathological changes in the joint were slight, in others most extensive. That the disease observable in the joints begins in the synovial membrane is rendered probable from the character of the pain, and from the appearances found after death. The poison of pyæmia, as observed in Hospital practice, is *sui generis*. Whether generated in the system from a combination of constitutional and surrounding conditions, or entering as a specific germ through a wound, it is a poison having a special affinity for certain structures, and to these it passes at once. The structures are here assumed to be the synovial membranes. In what this affinity or attractiveness consists we are as yet ignorant, and can but illustrate it by

what takes place in other diseases, such as the cholera poison, and the scarlatinal poison, or the producer of tetanus; whether it is a something evolved within the system, or introduced from without, it goes at once to certain nerve-tissues, and in them creates changes which set up other morbid action. Many drugs illustrate the same fact. Strychnia when swallowed, or when subcutaneously injected, has but one form of action, like the poison of tetanus—it affects nerve-tissue only. The strong analogy between pyæmia at the commencement, and acute rheumatism, has often been observed. In both there are the rigors, the fever, the rapid pulse, the profuse sweating; but above all there is the pain and swelling of one or more joints. It seems probable that in both an entity has entered the system whose habitat is the joints. We cannot tell in what consists the difference of the two poisons, so that the one as a rule eventuates in recovery, and the other in a train of pathological changes whose termination is death. In both cases the tissue first affected is the synovial membrane. The abnormal action induced in it leads to an increased secretion of synovia, probably unaltered in its character and constituents in rheumatism, but of an abnormal kind in pyæmia. In the case of the synovial fluids there is in most joints a limit to its quantity; so tightly is the synovial sac compressed by surrounding tissues which are not yielding that an amount of tension quickly ensues, which leads to a forced absorption of some of the effused fluid, and then ensues in acute rheumatism, and probably as a necessary sequence, an extension of the disease to other synovial sacs, and often to the pericardium, a serous membrane, but closely allied in its nature to a synovial membrane. This augmented synovial fluid is in rheumatism a bland and innocuous fluid—a mere increase of the natural secretion; but in pyæmia it is in a decomposing state, developing rapidly germs of a lower organisation; and when such a fluid has been absorbed, and in its course reaches the minute capillaries of the lungs, some of its morbid cells coagulate the fibrine of the blood there, and become arrested, and thus are formed the nuclei with which the lungs are studded, around which more fibrine is deposited, and the pathological changes follow described by Virchow and others. In conclusion, the author states that in limiting the paper to a consideration of the fact of the synovial membranes being the tissues first affected in many forms of pyæmia, he had not lost sight of the probability of many other phases of pyæmia having their beginnings in one or other of the serous membranes, these two membranes being so closely allied in their microscopic characters.

Mr. HULKE failed to understand the theory of the author as to the re-entrance of fluid into the joints, and hoped to have heard some suggestion explanatory of the source of pus found in the joints, and how perichyphites, etc., originate under such circumstances. He also averred his belief that many cases of pyæmia occur without any affections of joints.

Mr. WOOD failed to understand how joints can, as it were, manufacture a poison without some predisposition on the part of the fluids of the body, and then only the joints should be affected rather than any other part.

Mr. HAMILTON, in reply, regretted that he had not been sufficiently understood. He believed that the fluid spread from one joint to another, on account of the pressure exercised on the synovial membrane, which forced the fluid into the circulation. His observations as to the presence of living organisms in the fluid were made irrespective of the results recorded by Dr. Burdon-Sanderson. He had never any case of pyæmia without some stiffness, if not positively acute affection, of the joints.

A paper by Dr. W. MURRAY, "On Some Further Attempts to Cure Large Internal Aneurisms," was communicated by Dr. SYMES THOMPSON. This is an account of some attempts to cure internal aneurisms by the insertion of foreign bodies with a view to the formation of clots in the interior of the sac. Some of these bodies were introduced and again withdrawn (needles), and their introduction was repeated at intervals with manifest thickening of the aneurismal walls on each occasion; others were of a material the presence of which would be as harmless as possible (carbolised catgut), and they were used because of the hope that their absorption might take place after the work of coagulation was completed. Lastly, wire was tried, as in Mr. Moor's case, and with more favourable results as regards the preservation of the patient's life, he having laid more than three weeks with twenty-four feet of wire in him. Although none of these efforts were actually successful in curing the patient, they mark out a line of practice which may some day be perfectly safe and successful.

Mr. TIMOTHY HOLMES thought Dr. Murray's paper useful as tending to show the harmlessness of such operations, and to

indicate that Surgeons might meddle with aneurisms to a much greater extent than was generally imagined. After remarking that the introduction of carbolised catgut was manifestly useless (because it would soften rapidly) he said that Mr. Moore's case (the preparation is now in the Middlesex Hospital) showed markedly the dangers of the operation, and it was evident that wire or any other material of sufficient hardness to help coagulation when introduced into the sac, must, by rubbing against the walls of the latter, tend to set up a dangerous degree of inflammation.

Dr. ANDREW demurred to the wisdom of Surgical interference, inasmuch as external ruptures of the sac are extremely rare, and any modes of procedure such as those described would tend to produce a clot around the strongest instead of the weakest portion of the sac.

CLINICAL SOCIETY OF LONDON.

FRIDAY, MAY 10.

SIR WILLIAM GULL, Bart., M.D., F.R.S., in the Chair.

Dr. BURNLEY YEO read a paper "On a Case of Paralysis of the senses of Taste and Smell following Concussion of the Brain." The patient, a man, aged 50, came to King's College Hospital on January 11, having four months before been thrown out of a cart. He was admitted into St. Thomas's Hospital in a semi-conscious state, under the care of Mr. Croft. A slight contusion was discovered on the back of the head, but there was no fractured bone. He vomited, was delirious and insensible during the night, and in the morning complained of much pain in the head, which was relieved by aperients. He soon recovered, and, feeling well, discharged himself after he had been in the Hospital about a week. He found, however, that he could neither taste nor smell. This condition had persisted ever since the accident. He had suffered also a good deal from giddiness, and from severe pains on the right side of the head. He had been a perfectly healthy man, and quite free from any syphilitic taint. The patient's statements were thoroughly tested. Salt, sugar, solution of quinine, dilute acids, tincture of assafoetida, were applied to the tip, the centre, and back part of the tongue, to the under as well as the upper surface, but were not recognised in any degree. The tongue, however, was sensitive to the slightest touch, and its movements were perfect. The sense of smell, similarly tested, was found to be absent. The patient was ordered five grains of iodide of potassium three times a day. The first two doses produced such violent symptoms of iodism that it could not be continued. The dose was therefore reduced to two grains; and as this also acted in the same way, only one grain three times a day was given. This dose, at first, produced iodism, and afterwards purged him; he, however, continued to take it. In a few days the sense of taste began to return. On January 25 he could taste solution of quinine as bitter, and tincture of assafoetida as bitter; but he could detect no odour in the latter. He could distinguish salt from sugar, but not tea from coffee. The sense of taste continued to return rapidly. On February 11, he was able to taste the flavour of meat for the first time for twenty weeks. He could also now perceive strong odours; but smell came back less rapidly and less perfectly than taste. In connexion with the return of smell, he complained of a curious subjective affection of this sense; a foul smell comes into his nose like that of a stale tobacco pipe, and it seems to come down from the head! By March 20 the patient was quite well. Dr. Yeo thought this case offered many points of clinical and physiological interest. He thought it a somewhat rare circumstance to find the senses of taste and smell clearly absent together without any other affection of the nervous system. The absence of taste could not, in this case, be simply the consequence of loss of smell, as solution of quinine and tincture of assafoetida were, at first, not distinguishable from water; and when the latter was first recognised, it was as a bitter substance, and its peculiar flavour was not perceived: moreover, the sense of smell returned much later than the sense of taste. It was difficult to say what could be the lesion which would produce paralysis of these two special nerves and of no others. This difficulty was increased rather than diminished by the very remarkable manner in which the administration of iodide of potassium had been followed by the recovery of both senses.

Dr. LOCKHART CLARKE believed the condition to depend on shock. He had seen several similar cases originating in this cause. He did not think there was any lesion, and was of opinion that, probably, the stimulation of the nasal mucous

membrane produced the cure. He related the case of a child who, by standing on its head, brought on symptoms of concussion and hyperæsthesia of the leg, with the exception of the parts about the knee. The child had previously suffered from chorea, and indeed still presented slight symptoms of that affection. The child had, previously to being seen by Dr. Clarke, been confined to bed for four months. By local treatment the limb got well in six weeks.

Dr. HUGHLINGS-JACKSON thought the case a very interesting and yet a very puzzling one. He had not seen complete loss of smell and complete loss of taste together. Not very unfrequently a patient would say he had lost of taste when examination showed clearly that he had lost smell alone. The subjective sensations complained of by Dr. Yeo's patient were very important. Such subjective sensations occurred as a so-called aura in some epileptiform seizures, and especially in those cases in which consciousness was lost without convulsions; in some cases there were convulsions. Dr. Hughlings-Jackson believed that in these cases there was disease in the region of the anterior cerebral artery, and that the subjective sensations were of particularly evil omen as to mental failure.

Dr. BROADBENT said that he had seen two cases in which incomplete loss of smell and taste had become permanent. He doubted whether there was total loss of taste in Dr. Yeo's patient, and related the details of an interesting case, showing the possibility of Dr. Yeo's patient having meant that he could not distinguish all the features of the various substances.

Dr. BUZZARD, referring to a case related to the Society by Dr. Anstie, in which severe neuralgia of the fifth nerve was accompanied by loss of smell and taste, suggested the possibility that, in Dr. Yeo's case, a lesion of the trigeminus had caused the loss of the same two special senses, the integrity of this nerve being apparently as necessary for the proper action of the olfactory lobes as for the perfection of the sense of taste.

Mr. CHRISTOPHER HEATH had seen more than one case in which taste and smell were gone, and alluded to the case of a lady who, after an accident, lost both taste and smell. This lady had, strange to say, found several among her Indian friends who had also lost both senses.

The PRESIDENT thought that the cases were not very rare. It was very difficult to separate taste, touch, and smell. In the present case, quinine was not felt in any degree by touch or smell, but touch was not gone. He thought there may have been shock to the sympathetic centres in the neck, and through this channel to the nerves of taste and smell.

Dr. L. CLARKE referred to a case of locomotor ataxy he had already published, in which both taste and smell were lost.

The PRESIDENT observed that Dr. Clarke's case exemplified what he had just said about the sympathetic.

Dr. YEO then made a few remarks in reply.

Dr. BAÜMLER communicated a case of Enteritis, illustrating the dangerous effect which in cases of this kind may follow the use of the mildest purgative even after all acute symptoms have subsided. The patient, a young man aged 22, was taken ill, after some irregularity of diet, with symptoms threatening peritonitis. There was great pain in, and extreme tenderness of, the abdomen, with some distension, besides high pyrexia. With rest and opium, these symptoms subsided in a few days; and on the sixth day of illness a furred state of the tongue, slight tenderness in the cæcal region, and constipation were the only abnormal symptoms remaining; pulse and temperature being quite normal, and the appetite returning. On the following day, the bowels not having acted for five days, and the descending colon being filled with solid fæces, half an ounce of castor-oil was given. No sooner had this commenced acting, than all the previous symptoms returned; the temperature again exceeding 102° Fahr., and the patient for some days being in a somewhat critical state. Gradually, however, the symptoms subsided. On the seventh day of this relapse the pyrexia declined, and the bowels, which had not been open since the action of the castor-oil, moved spontaneously. From that day the recovery was uninterrupted.

The PRESIDENT observed that the question raised by the paper amounted to this—Was the medicine put into the intestine less irritating than the contents? It did not appear to have been so in the present case.

It has been resolved by the St. Pancras Vestry to petition Parliament against the Steam Boilers Bill, which proposes to give power to coroners to hold inquiries in all cases of explosions at the cost of the county rates.

OBITUARY.

J. C. WEEDEN COOKE, M.R.C.S., ETC.

THIS well-known Surgeon died a few days ago at the age of 56. He was educated at the Middlesex Hospital, and for many years was Surgeon to the Royal Free and Cancer Hospitals. He belonged to several of the Medical Societies, but attended chiefly the Medical Society of London, at the meetings of which he was a frequent speaker and contributor of papers and cases. Author of "Cancer, its Allies and Counterfeits," 1865; "On Hydrocephalus," 1850; "Nature and Art in the Cure of Syphilis," 1861; "Prospects and Retrospects in Physic and Surgery," 1863; "On the Unity of Disease," 1866; "Urethral Diseases," 1867. Contributed various papers "On Cancer," *Lancet*, 1853, 1857, 1858, 1867; "New Instrument for the Gradual Reduction of Dislocation of the Os Femoris," *Ibid.*, 1855; "Surgical Diseases of the Tongue," *Medical Times and Gazette*, 1861; and other papers to Medical journals. Mr. Cooke was a painstaking and laborious Practitioner; but he was not a man above the average, so far as powers of observation and the treatment of disease are concerned. He was rather heavy than brilliant—rather "slow" than decided. He was an amiable man, and much esteemed by those who knew him.

ROBERT WIGHT, M.D., F.R.S.,

DIED on the 26th inst., at Grazeley Lodge, Reading. Dr. Wight was born at Ormiston, Haddingtonshire, in 1796, and graduated at Edinburgh in 1816. After making one or two voyages as Surgeon to a ship, he went out to the Madras Presidency, India, in 1819. He was Assistant-Surgeon, and afterwards Surgeon, to the 33rd Native Light Infantry. It is, however, as a botanist of untiring energy and extraordinary sagacity and tact that Dr. Wight is best known. His publications are very numerous and of great value and importance. They were compiled under circumstances which would have appalled a less energetic man. As it is they form an enduring memento of his industry. His appreciation of structure and affinities was not less remarkable than his industry. Dr. Wight contributed several papers to various scientific journals on subjects connected with *Materia Medica*, as also on matters connected with the cultivation of cotton and other products in India. He became a Fellow of the Royal Society in 1854 on his final retirement from India.

GEORGE WILLIAM JOTHAM, M.R.C.S. ENG., L.S.A.

WE regret to record the death of Mr. George William Jotham, of Kidderminster, who, after a long life spent in the active duties of his Profession, died on May 7. Mr. Jotham, who had been the leading general Practitioner in Kidderminster and surrounding district, was born at Bradford, Wiltshire, in 1804, and studied at St. Bartholomew's Hospital, having been a pupil of the great Abernethy. In the year 1828 he came to Kidderminster, and in 1831 was appointed an Hon. Surgeon to the Infirmary, which post he held with much credit to himself and for the welfare of the institution until within a month or two of his death. When he found his health failing, and that he could no longer conscientiously perform the active duties of his office, he tendered his resignation, which was accepted by the Committee of Management with great regret, who at the same time passed a resolution—"That, while greatly regretting the resignation of the Senior Hon. Surgeon, who has been for forty-one years connected with this institution, they cannot refrain from showing their sense of esteem for his services in past years, and acknowledging the very warm interest he has always taken in all connected with the Infirmary." At the same meeting he was unanimously elected Consulting Surgeon. His loss will be acutely felt in the district through which his practice extended, for he was not only prized for his skill and sound knowledge as a Surgeon, but also for his thorough and uniform kindness and benevolence of heart.

WILLIAM STEWARD, SURGEON.

WE regret to record the melancholy death by drowning of the above gentleman. Mr. Steward resided at Camphill, Lumphanan, and was 70 years of age. On Wednesday week he was found lying dead in the side ditch of the road, opposite a croft at Camphill, in about seven inches of muddy water. The body was found by a woman passing, who got it removed to the residence of the deceased. Mr. Steward had been away from home in the morning, but had returned, and again left about midday to see a patient. It is supposed he had stumbled

into the ditch on his way home from this visit, and being rather infirm had been unable to extricate himself. Dr. Smith saw the body immediately after it was found, but could render no assistance.

HENRY HARRIS, M.R.C.S.,

DIED at a very advanced age at Brighton the week before last. He was for many years in general practice in Fenchurch-street in the City. He was one of the most successful "general Practitioners" of the day, and was one of the hardest worked. He suffered from illness for some time before his death. We believe he made no contribution to the literature of the Profession.

PETER NEVILL JACKSON, M.R.C.S., L.S.A.,

SURGEON of the 2nd Dragoons, died at Edinburgh on the 14th ult., aged 43. He entered the service April, 1854, and became Surgeon June, 1865. He served in the Eastern campaign of 1854-55, including the battles of Balaklava and Inkermann, and the siege of Sebastopol—medal with three clasps, and Turkish medal. Served in the Indian campaign, and was present in the action at Bootwab—medal.

NEW INVENTIONS.

THE APOLLINARIS WATER.

WE have long been familiar with the Apollinaris, and have frequently partaken of it at the tables of gastronomic *cognoscenti*; but we never paid any serious attention to the subject till stimulated by the receipt of a sample from Messrs. Blanchard, of 169, Regent-street. It is a natural effervescing alkaline water of great delicacy of taste, well adapted for table use, and calculated to displace the Nassau seltzers. It is brisker and not so soft as the latter, and consequently more appetising. It is not so alkaline and heavy as Vichy. All these waters have their special uses; and the Physician who has to recommend something slightly diuretic, refreshing, and antacid to a gouty patient, will find plenty of cases in which the Apollinaris water may be of great service, whether quaffed at dinner or at bedtime. It is economical in its use, as it does not speedily become flat on exposure to the air.

WESTERTON'S PATENT ZYMOTIC DISINFECTING FLUID.

"THIS is a new candidate for favour as a disinfectant. It differs from fluids of this description generally, in being highly *volatile*, and is intended to "disseminate disinfecting matter in the atmosphere." We have used the fluid somewhat extensively, and are fully satisfied that it is a valuable addition to our list of disinfecting agents.

MEDICAL NEWS.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received Certificates to practise, on Thursday, May 23:—

Bennett, William Edward, Stoke, Devonport.
Lyell, Robert Wishart, Upper Norwood.
O'Connor, Watkin Roberts, Berners-street, W.

As an Assistant in Compounding and Dispensing Medicines—
Poyser, Robert, Wirksworth, Derbyshire.

The following gentleman also on the same day passed his Primary Professional Examination:—

Dobson, Joseph, Leeds Hospital.

APPOINTMENTS.

* * * The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

CARTRIGHT, HAMILTON SAMUEL, M.R.C.S., L.D.S.—Assistant-Surgeon to the Dental Hospital, Soho-square, *vice* John Scully, M.R.C.S., L.D.S., resigned.

COLEMAN, JAMES JOSEPH, L.R.C.S.—Medical Officer for Division No. 1 of the Cloonbur District, Oughterard Union, county Galway, *vice* Edward McGuire, L.K.Q.C.P.I., resigned.

COLLINS, THOMAS, M.R.C.S. Eng., L.A.H.—Deputy Governor of the Apothecaries' Hall, Dublin.

DEAKIN, C. W. SHIRLEY, M.R.C.S.—House-Surgeon to the Male Lock Hospital, Dean-street, Soho-square, *vice* A. Appleby Thomas, L.R.C.P., M.R.C.S., resigned.

ELLIOTT, THOMAS, A.B., M.B., L.R.C.S.I.—Resident Medical Officer to the General Hospital and Dispensary, Douglas, Isle of Man, *vice* S. Laird, M.D., M.R.C.S.L.

HILL, JOHN D., F.R.C.S., L.S.A.—Surgeon to the Royal Orthopædic Hospital, Oxford-street.

MCDOWELL, CHARLES W., M.B., L.R.C.S.I., L.A.H.—Medical Officer for the Dispensary District of Carlow Union, Ireland.

O'DWYER, JOHN, L.R.C.P. Edin., L.R.C.S.I.—Medical Officer and Public Vaccinator for the Scrooby District of East Retford Union.

PURCELL, JAMES GEORGE, L.R.C.P. Edin., M.R.C.S. Eng., L.M.—Medical Officer to the Workhouse, Knutsford, Cheshire.

RAYNER, HENRY, M.D., M.R.C.S., L.S.A., M.S.—Medical Superintendent of the Male Department of Middlesex County Asylum, Hanwell.

ROBERTSON, G. J. E.—House-Surgeon to the District Infirmary, Ashton-under-Lyne.

ROGERS, JOSEPH, M.D., M.R.C.S. Eng., L.S.A.—Medical Officer to the Westminster Workhouse, Poland-street.

SHEPPARD, H. H., M.R.C.S. Eng.—Surgeon to the Norwich Friendly Societies Medical Institute.

BIRTHS.

BOURNE.—On May 20, at Mountfield, Musbury, near Axminster, the wife of Walter Bourne, M.D., of a son.

KIRKMAN.—On May 19, at Barming-heath, Maidstone, the wife of W. P. Kirkman, M.D., M.R.C.S., L.S.A., of a son.

MAFFEY.—On May 23, at St. John's, Wakefield, the wife of John Maffey, L.R.C.P., of a daughter.

MOORE.—On May 26, the wife of Walter Moore, M.R.C.S. Eng., L.S.A., Stourport, Worcestershire, of a daughter.

PROPERT.—On May 28, at 100, Gloucester-place, Portman-square, the wife of J. Lumsden Propert, M.B., M.R.C.S., L.S.A., of a son.

WARD.—On May 23, at the Royal Arsenal, Woolwich, the wife of William Pearson Ward, Surgeon-Major Royal Artillery, of a son.

WESTON.—On May 21, at Stafford, the wife of E. F. Weston, M.R.C.S. Eng., L.S.A., of a daughter.

MARRIAGES.

ROWELL—FITZPATRICK.—On May 16, at St. Mary-of-the-Angels, Bayswater, W. Patrick Irvine, second son of the late Joseph Rowell, Esq., of Aberdeen, to Henrietta Clothilda, youngest daughter of the late Percy Fitzpatrick, M.D., M.R.C.S.L. (formerly of H.M.'s 51st Regiment), magistrate of Mauritius, and granddaughter of the late Hon. Andrew Maure, member of the Legislative Council, Mauritius.

EDWARDES—GAIR.—On May 22, at St. Paul's, York, Edgecumbe Ferguson, of the Inner Temple, London, and Windlesham Hall, Surrey, barrister-at-law, son of the late Edgecumbe Windeatt Edwardes, Physician-General Bombay Army, to Emily Gair, daughter of the late Joseph Dobson, Esq., of Selby.

HAMILTON—REYNER.—On May 23, at the Albion Chapel, Alexander Hamilton, L.R.C.P. Edin., L.R.C.S., to Heleu, third daughter of Frederick Reyner, Esq., of Thornfield Hall, Ashton-under-Lyne.

HAYWARD—WALKER.—On May 23, at St. Saviour's, Paddington, John Hayward, Esq., second son of Frederick Hayward, Esq., both of Needham Market, Suffolk, to Alice, second daughter of John B. Walker, M.R.C.S. Eng., L.S.A., of 17, Clifton-gardens, Maida-vale.

DEATHS.

BARNETT, SAMUEL BOYD, M.D., fourth and youngest son of the late Hon. Samuel Whitehouse Barnett, at 2, Clarendon-gardens, Maida-vale, on May 22.

CORNWALL, JAMES, M.D., F.R.C.S.E., suddenly, at Edinburgh, on May 18.

HARRIS, CHARLES, M.R.C.S. Eng., at his residence, 67, Lansdowne-place, Brighton, late of 13, Fenchurch-street, and 76, Guildford-street, Russell-square, London, on May 23, in the 82nd year of his age.

HUTCHISON, GEORGE S., M.R.C.S. Eng., L.S.A., second son of Charles Hutchison, M.D., of Norwich, on May 24, in his 40th year.

MARTIN, JANET, the beloved wife of Curtiss Martiu, M.R.C.S. Eng., H.M.'s 41st Regiment, at Umballa, Punjab, on her way to England, on April 28, aged 28.

POPE, SARAH ELIZA, widow of Jonas Hall Pope, Esq., Surgeon, formerly of Manchester-square, on May 24, aged 64.

VACANCIES.

In the following list the nature of the office vacant, the qualifications required in the Candidate, the person to whom application should be made, and the day of election (as far as known) are stated in succession.

AMERSHAM UNION.—Medical Officer for the Workhouse, and Medical Officer for the Amersham District. Candidates must possess the qualifications required by the Consolidated Orders of the Local Government Board. Applications and testimonials to be sent to Mr. Henry Bedford, Clerk to the Guardians, on or before June 11.

BROMPTON HOSPITAL FOR CONSUMPTION.—Resident Clinical Assistant. Applications, with testimonials, to be sent in on or before June 3. Further particulars may be obtained at the Hospital.

CANCER HOSPITAL.—Surgeon. Candidates must be registered Members of the Royal College of Surgeons of England, practising only as consulting Surgeons. Applications, with testimonials, addressed to the Chairman of the Weekly Board, at 167, Piccadilly, to be sent in on or before June 4.

EAST LONDON HOSPITAL FOR CHILDREN AND DISPENSARY FOR WOMEN, RATCLIFFE-CROSS.—Visiting Physician. Candidates must be Fellows or Members of the Royal College of Physicians of London, or F.R.C.P. Edinburgh or Dublin, or Graduates in Medicine of a British University, or of the Universities of Paris, Vienna, Berliu, or other universities approved by the General Medical Council, and be legally qualified to practise Medicine in England. Applications to be sent to the Secretary, at the Hospital, before June 17.

ESSEX LUNATIC ASYLUM, BRENTWOOD.—Second Assistant Medical Officer and Dispenser. Candidates must be Licentiates of the Apothecaries'

Company and possess a Surgical qualification. Applications, stating former occupation, to Dr. Campbell, Medical Superintendent, County Asylum, Brentwood.

EVELINA HOSPITAL FOR SICK CHILDREN, SOUTHWARK-BRIDGE-ROAD, S.E.—Registrar. Candidates must possess one qualification. Applications with testimonials to be sent to the Managing Committee, at the Hospital, on or before June 3.

GLOUCESTER DISPENSARY.—Dispenser, registered under the Pharmacy Act, and otherwise duly qualified. Apply to George Whitcombe, Esq., Gloucester, from whom further particulars may be obtained.

INFIRMARY FOR CONSUMPTION AND DISEASES OF THE CHEST, 26, MARGARET-STREET, CAVENDISH-SQUARE.—Visiting Physician. Candidates must be Members of the Royal College of Physicians, London. Testimonials to be sent to Francis Baily, Secretary.

LEEDS UNION.—Medical Officer for the Workhouse and Industrial School. Candidates must possess the qualifications laid down by the Local Government Board. Applications with testimonials to be sent on or before June 12.

LEOMINSTER UNION.—Medical Officer for the Workhouse and No. 1 District. Applications, with testimonials, to be sent on or before June 7, to Mr. Edwin Gregg, Clerk to the Guardians, Leominster.

LIVERPOOL NORTHERN HOSPITAL.—House-Surgeon. Candidates must possess a Medical and a Surgical qualification from one or more British Colleges or Institutions recognised under the Medical Act. Applications and testimonials to the Chairman of the Committee not later than June 15.

LONDON FEVER HOSPITAL, LIVERPOOL-ROAD, ISLINGTON.—Resident Medical Officer. Applications with testimonials to be sent to the Secretary, on or before June 11.

LONGTOWN UNION.—Medical Officer. Candidates must be duly qualified in accordance with the regulations of the Local Government Board. Applications to be sent on or before June 1, to Mr. C. B. Hodgson, Clerk to the Guardians, Carlisle.

MIDDLESEX HOSPITAL.—Lectureship on Psychological Medicine. Applications must be sent to the Dean of the Hospital not later than June 18.

NORTH RIDING INFIRMARY, MIDDLESBOROUGH-ON-TEES.—House-Surgeon. Candidates must be Fellows or Members of one of the Royal Colleges of Surgeons of the United Kingdom. Applications and testimonials to be sent to the Secretary, on or before June 12.

ONGAR UNION, ESSEX.—Medical Officer. Candidates must be duly qualified. Applications with testimonials to be sent to Charles Mott, Clerk to the Guardians, Chipping Ongar, on or before eleven o'clock on June 4.

UNION AND PAROCHIAL MEDICAL SERVICE.

* * The area of each district is stated in acres. The population is computed according to the census of 1861.

RESIGNATIONS.

Bury St. Edmunds Incorporation.—The Fourth District is vacant; salary £30 per annum. The Fifth District is vacant; salary £30 per annum. The Workhouse is vacant; salary £30 per annum.

Ongar Union.—Mr. Wm. Gilmour has resigned the First District; area 13,730; population 3003; salary £105 per annum.

Thingoe Union.—The Second District is vacant; area 14,780; population 3552; salary £84 per annum.

West Ham Union.—Mr. James C. Foley has resigned the Second District; population about 1100; salary £80 per annum.

APPOINTMENTS.

Amphill Union.—Alfred R. Lee, L.R.C.P. Edin., M.R.C.S. Eng., L.S.A., to the Silsoe District.

Aysgarth Union.—Alfred Baker, M.R.C.S. Eng., L.R.C.P. Edin.; to the Workhouse. Joseph Thompson, M.R.C.S. Eng., L.R.C.P. Edin., to the Hawes District.

East Retford Union.—John O'Dwyer, L.R.C.S. Ire., L.R.C.P. Edin., to the Scrooby District.

Guildford Union.—Thos. C. Eager, M.R.C.S. Eng., L.R.C.P. Edin., L.S.A., to the Woking District.

Manchester Township.—George A. Kenyon, B.M. Univ. Lond., L.R.C.P. Lond., M.R.C.S. Eng., as Assistant Medical Officer at the Crumpsall Workhouse.

Skirlaugh Union.—Wm. H. Browne, L.R.C.P. Edin., L.R.C.S. Edin., to the Aldborough District.

MESSRS. COLE AND NEIGHBOUR, the Vaccination Inspectors to the Holborn Union, have respectively had their salaries raised from £60 to £70 per annum.

The appointment of Mr. John Browne as Vaccination Officer for Islington at a salary of £120 per annum has been approved by the Local Government Board.

Two of the local (Dublin) papers—the *Freeman's Journal* (of Friday) and the *Irish Times* (of Saturday)—have it that Dr. Stokes is to be made a baronet.

The mortality returns for the City are still below the average for the corresponding period of the last ten years, and indicate a satisfactory state of the public health.

The Council of the French Society of Succour to the Sick and Wounded in the late war have presented Mr. J. Robert Walker, of Clifton-gardens, Maida-vale, with a diploma and bronze cross for his services at Beaumont, Saarbrück, Metz, etc.

The Halifax Infirmary is to be enlarged at a cost of £3300, and when completed will give room for twenty-eight additional beds.

The Board of Guardians of the Kilmallock Union, co. Limerick, have raised the salary of Mr. Daniel Riordan, Medical Officer for the Hospital Dispensary District, from £100 to £120 per annum.

The will of Dr. Thomas Barnes, of Bunker's-hill, Carlisle, has been proved under £90,000.

THE MILITARY MEDICAL SCHOOL AT VAL-DE-GRÂCE.—Professor Laveran has been appointed Director of Val-de-Grâce, in the place of the late Professor Michel Lévy.

SMALL-POX IN DUBLIN.—Since the second week in March, 1871, when the first fatal case of the present epidemic of small-pox occurred in Dublin, 1168 deaths from the disease have been registered in that city up to May 18, 1872. Of this number 1080 have been registered since November 18 last, within a period of exactly six months.

ROYAL DUBLIN SOCIETY.—One of the afternoon scientific lectures was delivered in the lecture-room of the Society on Saturday last, by Mr. C. R. C. Tichborne, Fellow of the Chemical Society of London, whose researches in chemistry are so widely known and appreciated. The subject of the lecture was "Decomposition and Dissociation." Chemical affinity was explained as being subject to the influence of the forces of electricity, heat, and gravity. A "decomposition" was the result of the action of one or more such forces on a compound molecule, and by this action a new substance was formed. A series of experiments, wherein typical decompositions were effected, illustrated this part of the lecture. The term "dissociation" was applied to processes which were in reality only stages of decomposition. The little that was known of the dissociation of molecules in solution was due to the lecturer's own investigations, while gaseous dissociation had attracted more attention on the Continent.

HOSPITAL SUNDAY.—The vicar and churchwardens of St. Matthew's, City-road, have decided to establish a Hospital Sunday. The offertories on the Second Sunday after Trinity will this year be given to the Royal Hospital for Diseases of the Chest, City-road, and the North-Eastern Hospital for Children—institutions which confer much benefit on the poor of the parish and neighbourhood.

THE IRISH MEDICAL ASSOCIATION.—The annual meeting and dinner are announced to take place in the Albert Hall of the Royal College of Surgeons, Dublin, on Monday next, June 3. Several matters of deep interest to the Profession generally, and to Poor-law Medical Officers in particular, are to be brought under consideration. Among these may be mentioned the question of improved sanitary legislation and the suggested formation of a Conjoint Examining Board.

PROFESSOR HOLMES.—The following is the programme of the Professor's first three "Lectures on the Surgical Treatment of Aneurism in its various forms," to be delivered at the Royal College of Surgeons on Monday, Wednesday, and Friday, at 4 p.m., commencing on Monday, June 3, 1872, viz.:—Lecture I. (June 3), *Thoracic Aneurisms*.—Introduction. Propositions intended to be established in these lectures. Thoracic aneurisms are legitimate subjects for Medical and Surgical treatment. The Medical or internal treatment of aneurism. This plan should be first tried in all cases of thoracic and abdominal aneurism. Brasdor's operation. Theoretical reasoning by which its adoption has been recommended. Pathological facts showing the effects of spontaneous distal obliteration of arteries in innominate aneurism. Instance of spontaneous cure from distal impaction of clot in the carotid. Its exact analogy with a case of distal ligature of the carotid, by Dr. Wright, of Montreal. Mr. S. Lane's and Sir W. Ferguson's cases of distal ligature of the common carotid. Effects of spontaneous distal obliteration of the subclavian artery in innominate aneurism. In such cases the distal ligature of the carotid may be trusted to produce complete obliteration of the sac. Lecture II. (June 5), *Thoracic Aneurisms* (continued).—Pathological facts showing the effect of distal obliteration of arteries in aortic aneurism. Mr. Guthrie's objections to the distal operation examined. Review of cases of distal operation in thoracic aneurism:—1. Four cases of successive distal ligature of carotid and subclavian. Cure in Fearn's case. 2. Simultaneous double distal ligature. Two cases in which the operation was carried out strictly on Brasdor's method. Six cases in which Wardrop's plan was adopted. Hobart's case, where union is said to have taken place in the first part of the subclavian after ligature. Heath's case of temporary recovery. Case in which the arteries were tied with carbolic catgut. 3. Cases of distal ligature of the carotid only. *a.* Eleven cases in which the aneurism was innominate. Wright's case, where cure was almost complete. *b.* Seven cases of mixed innominate aneurism. Cure in Evans's and Morrison's cases. *c.* Four cases of ligature of the right carotid in aortic aneurism mistaken for innominate. *d.* Seven cases of ligature of the left carotid in aneurism of the aorta. Beneficial effect in many

of these latter. Case under the care of Dr. Cockle and Mr. Heath. 4. Two cases of distal ligature of the third part of the right subclavian in innominate aneurism. Lecture III. (June 7), *Thoracic Aneurisms* (continued).—Conclusions justified by present experience as to the applicability of Brasdor's operation in innominate aneurism. Can Brasdor's method be applied in its integrity, by the ligature of the first part of the subclavian, along with or after that of the carotid? This depends on the possibility of securing an artery so as to obliterate without dividing it. This has been attempted by temporary ligature, the *presse-artère* or acupuncture, and by silver ligature. None of these, except the *presse-artère*, has as yet afforded definite proof of success, and this only exceptionally. Carbolised catgut ligature. History of the use of catgut for this purpose. Reasons of its general failure in the hands of Astley Cooper, Porta, etc. General success of the carbolised catgut ligature in securing rapid union of the deep parts of the wound. Preparation showing ligature of the carotid and subclavian arteries with this substance successfully, and with no division of the continuity of either vessel. If this result can be uniformly secured, the subclavian might be tied in its first part. Conclusions as to the applicability of the distal operation in the treatment of aortic aneurism. Probable reasons of its beneficial effect in this form of aneurism. *Galvano-puncture in Thoracic Aneurism*.—General considerations on the admissibility of this method of treatment for aneurism in general.

ROYAL COLLEGE OF SURGEONS.—At the pass examinations of members for the Fellowship of the College, which were brought to a close on Saturday last, ten candidates were successful and six were referred to their Professional studies for twelve months. One candidate, who passed in Surgery, will be admitted a Fellow when qualified in Medicine; the others had either passed in Medicine for the Membership of the College or had Medical degrees from other institutions. The following were the questions on Anatomy and Physiology submitted at the primary "written":—1. Describe the operation of excision of the upper jaw, and state for what disease this operation may be required. 2. Describe the formation, spontaneous evacuation, and healing of a scrofulous abscess, giving an explanation of the pathological phenomena attending each stage of its progress. 3. Give the symptoms, causes, and treatment of acute and chronic glaucoma, including the appearances usually presented under the ophthalmoscope. 4. In a case of compound dislocation of the ankle, state the local and general or constitutional conditions of the patient and the external circumstances that would guide you in determining upon the propriety of amputation, and as to the site at which it should be performed. The following were the questions on Pathology, Therapeutics, and Surgery at the "pass," viz.:—1. Describe the course and relations of the nerves which supply the following muscles, tracing them from their origin to the part of the muscle at which they enter: Subclavius, serratus magnus, obturator internus, pectineus, popliteus, and aconeus. 2. Describe the exact relations and structure of each bronchus, of its subdivisions, and of the air-cells. State what nerves accompany the bronchi in their distribution, and their several functions. 3. Describe the development of the mammalian heart, and give an account of its construction in the different classes of vertebrata. 4. Describe the form and dimensions, in its different parts, of the vertebral canal; enumerate its contents; and give a description of the structure and uses of the membranes of the spinal cord.

HEALTH OF SCOTLAND.—The Registrar-General's report for the quarter ending March 31 last states:—Of the zymotic class of diseases, small-pox was the most fatal, the deaths therefrom numbering 461 in January, 319 in February, and 244 in March. During former epidemics of this disease the highest mortality has generally occurred in either January or February, depending on which was the coldest month. It is satisfactory to find that the mortality of this loathsome disease has been steadily on the decline since January, having attained its maximum mortality during that month. In October the deaths therefrom were 80, in November 157, and in December 354. Fever, in like manner, has been diminished with the advent of milder weather, seeing the deaths numbered 119 in January, 94 in February, and 81 in March. The deaths from measles diminished from 50 in January to 15 in March. Those from scarlatina were 94 in January, 80 in February, and 72 in March. Diphtheria has diminished in greater proportion than scarlatina, for the deaths, which were 45 in January, were only 27 in February, and 26 in March. The deaths from hooping-cough, like those from consumption, had, however, rather increased with the advance of the season, seeing that the 160 deaths in

January increased to 191 in March; but the increase of bronchitic complications, caused by the biting easterly and northerly winds, probably accounts for the increase. The deaths from erysipelas notably diminished with the advance of the season, 17 deaths having occurred in January, 10 in February, and 7 in March. Year after year it is observed that the deaths from consumption are not highest in the coldest months, but in those during which the northerly and easterly winds are the prevalent aerial currents. Correcting for difference in length of days, this was distinctly noticed during the past quarter, seeing that 300 deaths therefrom occurred in January, 319 in February, and 323 in March. Diseases of the brain were most fatal during the coldest month, seeing that they caused 241 deaths in January, 222 deaths in February, and 193 in March. Diseases of the heart caused 109 deaths in January, 108 in February, and 118 in March. Diseases of the digestive organs were most fatal in February, having caused 165 deaths in January, 176 in February, and 135 in March. Debility from premature birth caused 126 deaths in January, 109 in February, and 107 in March. Old age, without specific disease, caused 112 deaths in January, 99 in February, and 101 in March. Deaths from violence numbered 117 in January, 75 in February, and 89 in March.

THE SEASIDE.—Among the loungers at the sea-side there is a broad distinction to be drawn between those who are taking whole holidays and those who are only taking half-holidays. Those who mix up pleasure with their work have to mix up work with their pleasure. If business, books, and papers are not absent from their minds, they only catch fearful because fugitive joys. To many, what sensations of delight and unalloyed pleasure are recalled by the words—"at Ilfracombe." There still remains the reinvigorated constitution, and many happy memories of freshening breezes, dashing seas, and a rock-bound coast. In the great palace by the shore there one meets with what is so much wanted at the seaside—cheerful society. You hear all that is going on, the various places to pic-nic, boat, ride, drive, or walk along the picturesque shore. There is a reading-room for the politically inclined, billiards for those whose legs are not tired after the day's excursion, a noble *salle-à-manger* in which appetites may be appeased, and a delightful drawing-room, with the charms of conversation and music, varied with an occasional dance. In fine, a visitor to the Ilfracombe Hotel will have many a *souvenir* on which to dwell with grateful and pleasing remembrance.—*Post*, May 29.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon*.

Dr. Williams's Lecture is unfortunately delayed this week. Mr. Bryant's Lecture is in type.

Mr. Maccabe's performances at the Charing-cross Theatre, in King William-street, are well calculated to stimulate the digestive organs, dispel melancholy, and set the diaphragm and respiratory muscles in a state of agreeable titillation.

Mr. Samuel Welch, Stanstead.—We have carefully perused the account of the inquest held at Stanstead railway-station, and really cannot find any fault either with the mode in which the inquest was conducted, or the verdict arrived at by the jury. The evidence of Mr. Haynes we consider to have been fair and unobjectionable. If Mr. Welch could have given any valuable information to the court and jury, it was his duty to have presented himself for examination. The coroner, we believe, would not have objected to it. If Mr. Welch has just cause to complain, we should be glad to know on what ground. As the sworn evidence presents itself to us we can discover no such ground.

PROTECTION FOR MEDICINE.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I have read with much interest your article on "Irregular Practice" in your issue of May 25. It is surely time for the Profession, as a body, to agitate for protection, as well for the public as for itself, against the irregular practice that now prevails so largely. A better time than the present could not well occur, for it is likely that before long a general election will take place, and pressure might be brought to bear upon candidates for seats in Parliament to support a Bill containing the requisite provisions.

It is very unjust that qualified Medical men should be left entirely without legal remedy against such a state of matters as at present exists. No man is allowed to practise as a barrister or as a solicitor in the courts of law without due licence. No man is allowed even to sell drugs without being duly qualified. If he does, he can be proceeded against, convicted on proof, and prevented from repeating the offence. In these cases the State carries out the bargain which it has made with the parties; but though it has virtually made the same bargain with those who, at large expense of time and money, purchased its permission to practise Medicine, it allows

any Jack, Tom, or Harry who pleases to play with the health and character of the subject; and when such an one comes before a court of law, as in the case of Thomas, he leaves the court free as ever, to continue and increase, if he is able, the "considerable practice" which he avowed himself to have.

A most painful case of the same kind occurred in my own experience. An elderly gentleman foolishly consulted a druggist at the commencement of a cancerous affection, of which he eventually died. The druggist pronounced it venereal, and treated him most vigorously with mercury for syphilis. His relatives somehow heard of the judgment that had been pronounced, and a most painful family estrangement, lasting for many months, was the result, of which, when after long concealment I became aware, I was able, to the intense relief of all, to set at once and completely at rest. A first year's student could not have mistaken the case.

If the law does not soon come to the aid of the Profession, qualified Medical men will ere long be rare, for those now in practice will not only not enter any of their own sons to the study of Medicine, but will also warn their friends against the folly of doing so. I am, &c.,
May 27. AN OLD M.D.

CORRIGENDUM.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Be good enough to correct an error in the abstract of my paper on "A Chapter in the History of Cholera." Line 4 from the end, read "minimum" for "maximum," in the sentence "came to a maximum when it was in aphelion." I am, &c.,
May 29. B. G. JENKINS.

COMMUNICATIONS have been received from—

Dr. BOGGS; Dr. JOHN DUNCAN; Mr. J. CHATTO; Dr. J. R. HARDIE; Dr. EUSTACE SMITH; Mr. T. M. STONE; Mr. RICHARD QUAIN; Professor FLOWER; Mr. PLAXTON; Dr. LOEWENBERG; Mr. F. T. PROCTER; AN OLD M.D.; Dr. GOODMAN; Dr. BAKWELL; Dr. PORTER SMITH; Dr. HUTCHISON; Dr. ROGERS; Dr. MASTERS; Dr. R. C. R. JORDAN; Dr. SANSON.

BOOKS RECEIVED—

Our Lord's Miracles of Healing, by the Rev. T. W. Belcher, M.D., M.A.—The Influence of Vaccination, Age, Sex, and Occupation on the Mortality in Small-pox, by Robert Grieve, M.D.—As Regards Protoplasm, by James Hutchinson Stirling, F.R.C.S., LL.D.—First Annual Report of the Committee of Stockwell Fever Hospital—An Exposition of Fallacies in the Hypothesis of Mr. Darwin, by C. R. Bree, M.D., F.Z.S.—Report on the Small-pox Epidemic as observed in the Hardwicke Hospital from April 1, 1871, to March 31, 1872, by R. D. Lyons, M.B., T.C.D., M.R.I.A.—Annual Report of the Village Hospital, Hambrook—Annual Report of the Broadmoor Criminal Lunatic Asylum—Annual Report of the Royal Edinburgh Asylum for the Insane—Introduction to Palaeontological Botany, by Dr. J. Hutton Balfour—Guide to Trefriy and the Vale of Conway Spa, by John W. Hayward, M.D., second edition—On the Treatment of Carbuncle, by J. Murray, M.A., M.D.

PERIODICALS AND NEWSPAPERS RECEIVED—

Nature—Journal of the Scottish Meteorological Society—Medical Archives, No. 3—Medical Press.

APPOINTMENTS FOR THE WEEK.

June 1. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; King's, 2 p.m.; Charing-cross, 2 p.m.; Royal Free, 2 p.m.; Hospital for Women, 9½ a.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. Thomas's, 9½ a.m.
ROYAL INSTITUTION, 3 p.m. Prof. Roscoe, "On the Chemical Action of Light."

3. Monday.

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; St. Peter's Hospital for Stone, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

ANTHROPOLOGICAL INSTITUTE, 8 p.m. Meeting.
ROYAL INSTITUTION, 2 p.m. General Monthly Meeting.

4. Tuesday.

Operations at Guy's, 1½ p.m.; Westminster, 2 p.m.; National Orthopædic, Great Portland-street, 2 p.m.; Royal Free, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; West London, 3 p.m.

ROYAL INSTITUTION, 3 p.m. Mr. E. B. Tylor, "On the Development of Belief and Custom amongst the Lower Races of Mankind."

5. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1¼ p.m.; Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.; St. Thomas's, 1½ p.m.; Samaritan, 2.30 p.m.; King's College Hospital (by Mr. Wood), 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. George's (ophthalmic operations), 1¼ p.m.

OBSTETRICAL SOCIETY, 8 p.m. Dr. Matthews Duncan, "On Long Delay of Labour after Discharge of Liquor Amnii." Dr. Aveling, "On Post-mortem Delivery." And other Papers.

ROYAL MICROSCOPICAL SOCIETY, 8 p.m. Mr. Chas. Cubitt, "Remarks on the Homological Position of the Members constituting the Theated Section of the Rotatoria." Mr. Isaac Roberts, "On a Micro-pantograph."

6. Thursday.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Royal Orthopædic, 2 p.m.; University College Hospital, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.
ROYAL INSTITUTION, 3 p.m. Dr. Tyndall, "On Heat and Light."

7. Friday.

Operations at Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.
ROYAL INSTITUTION, 9 p.m. Dr. Odling, "History of Ozone."

VITAL STATISTICS OF LONDON.

Week ending Saturday, May 25, 1872.

BIRTHS.

Births of Boys, 1162; Girls, 1096; Total, 2258.
Average of 10 corresponding weeks, 1862-71, 1979.5.

DEATHS.

At the Royal Observatory, Greenwich, the mean reading of the barometer in the week was 29.76 in. The highest was 30.11 in. at the end, and the lowest 29.50 in. at the beginning of the week.

* The figures in this column, excepting those for London and Dublin, are the unrevised numbers enumerated in April, 1871, raised to the middle of 1872 by the addition of a year and a quarter's increase, calculated on the rate which prevailed between 1861 and 1871. The London population is now based upon the number enumerated in April, 1871, as revised at the Census Office; this revision added 2456 (principally shipping population) to the unrevised number published in the preliminary Census Report. The population of Dublin is taken as stationary.

PART IX.

SPASMODIC ASTHMA.

Character and Pathology. Experiments proving the Irritability of the Bronchi. Functions of the Bronchial Muscles. Effects of Drugs. Causes and Consequences of Bronchial Spasm. Asthmatic Bronchitis. Bronchial Glandular, and Membranous Induration. Frightful Symptoms of Asthma—Why not Dangerous. Treatment very Successful in Simple Spasmodic Asthma. Treatment of Complications. Change of Air.

I HAVE now to call your attention to a group of affections which go under the title of *asthma*. This word is commonly used as synonymous with dyspnoea, or difficult breathing; but it is more convenient and practical, as well as correct, to restrict it to those kinds of difficult breathing which are accompanied by audible *whczzing*. Here is at once a great practical distinction from the dyspnoea of pleurisy, of pneumonia, of diseases of the heart, and of diseases of the blood (anæmia and toxæmia)—these are all *panting*, or *gasping*, with breath short and frequent, but with little or no wheeze. The dyspnoea of *asthma*, on the other hand, is essentially *wheezy* and *prolonged*, affecting the inspiration, or the expiration, or both. This is most distinctly witnessed in spasmodic asthma and pulmonary emphysema; but it applies more or less to severe bronchitis and bronchial catarrh, which carry with them more or less of the asthmatic wheeze.

The simplest, as well as the most characteristic variety of these, is the purely spasmodic asthma. A person subject to this may be attacked suddenly on entering a close or dusty room, on inhaling the fumes from a stable, the odour of ippecacuanha, or other smells in peculiar cases; or, more commonly, he awakes in the middle of the night with a feeling of oppression approaching to suffocation—referred by some to the throat, by others to the sternum, by others to the epigastrium—obliging the patient to sit up in bed or in a chair, with the elbows rested on the knees, the shoulders elevated, and the head bowed forward, but all labouring to the utmost in strong prolonged efforts of inspiration and expiration. This painful struggle for breath may last from a few minutes to several days, according to the severity of the paroxysm; and frightful as it seems to witness, and distressing to the patient, yet it is not dangerous; sooner or later the tight breath is relaxed, cough and expectoration sometimes accompanying its relaxation.

Seeing how violently all the muscles of inspiration and expiration partake in the struggle of a severe paroxysm of spasmodic asthma, we cannot much wonder at the notions of older writers on the subject (Bree and others), that the disease depended on an excessive and convulsive action of all these muscles. Laennec first pointed out the true pathology of asthma in tracing it to a spasmodic contraction of the bronchial tubes, which so much impedes the ingress and egress of air in respiration as to call for excessive and violent action of the respiratory forces to effect it. In this temporary constriction of the bronchial tubes we see the immediate cause of the difficult breathing; and this, too, is the cause of its most characteristic sign—the loud wheezing, whistling, piping, and cooing sounds which attend the paroxysm.

The correctness of Laennec's view of spasmodic asthma had, however, been called in question by several writers, who opposed to it the very daring assertion that the bronchial tubes do not really possess muscularity. The supposed muscular fibres, which had been demonstrated by Reisseissen, were declared not to be muscular at all, but merely elastic, and therefore could not be the seat of spasmodic contraction. To settle this question, about twenty years ago I made a series of experiments on animals, and they proved beyond doubt not only the muscularity of the bronchial fibres, but also the kind and degree of irritability which they possess. Under the influence of a galvanic, mechanical, or chemical stimulus the circular fibres of the bronchi contract readily but slowly, and

gradually relax when the stimulus is withdrawn. The contraction is more tardy than that of the œsophagus, but more prompt than that of the arteries, and relaxation does not follow for some minutes after. Like other muscular contractility, it becomes exhausted after continued stimulation, and it is recovered by a period of rest.

Although it has been generally admitted that my experiments have clearly proved the muscular contractility of the bronchial tubes, yet from the remarks of recent writers on the subject it appears to me that the physiological offices of this property have not been generally understood. Thus it has been supposed that the bronchial muscles contribute to the rhythmical process of expiration; but if they do so at all it can only be to a slight extent, as their movement is much slower than that of ordinary respiration, besides which it appears to be limited to the larger and middle-sized tubes, and does not extend to those of smallest size. A galvanic current caused little or no contraction when passed through a lobe within an inch or two of its margin; but the contraction was marked when the current was passed along any of the tubes of the size of a small crowquill upwards. I cannot, therefore, concur in the notion propounded by Dr. Gairdner in one of his able papers, that the finest bronchi have a peristaltic or vermicular motion like that of the intestines, and that this is the chief means by which fluids are expelled from these tubes. It is probable that ciliary motion contributes to this end, but the expulsion of mucus and other fluids from the bronchial tree is mainly effected in the manner which I pointed out more than twenty years ago—by the rapidly increasing velocity with which the air in expiration passes from the pulmonary cells to the narrower converging bronchi, and carries with it any loose liquid in its way. The air in entering the lungs passes with decreasing velocity and force as it spreads into the minute tubes and cells, the combined area of which vastly exceeds that of the large branches and trunk of the bronchial tree. On its return in expiration this is reversed; the motion is more rapid and forcible as it converges towards the trachea and glottis, where the process is brought to its consummation in special efforts of expectoration and coughing. This draining operation of the expiratory act is promoted on the one hand by increasing the force of the act by muscular effort; and, on the other, by a moderate contraction of the tubes, which augments the velocity and sweeping power of the air in passing through them. This contraction is effected by the bronchial muscles, which thus assist in the process of clearing the tubes. But if these muscles act in excess, they render the passage too narrow both for free expiration and for expectoration; and this is just what occurs in the asthmatic spasm, which renders these processes slow and difficult. This is the view of the function of the bronchial muscles which my experiments led me to entertain, and which I published and taught in my lectures more than twenty years since. Dr. Hyde Salter, in his late able and elaborate work on asthma,^(a) proposes a like opinion, and suggests that the bronchial muscles may also be useful in impeding the entrance of irritating matters into the lungs.

But the most interesting fact discovered by my experiments, with regard to this bronchial contractility, was, that it is influenced differently from that of other muscles by various poisonous or medicinal agents.^(b) Thus, hydrocyanic acid did not impair it at all, opium and morphia very little, conium and aconite a little more, but belladonna and stramonium almost destroyed it; so that in animals poisoned by these drugs the bronchi showed scarcely any signs of contractility when stimulated. In animals poisoned with strychnia the bronchi seemed permanently contracted, so that a stimulus had no further effect. This is another proof of the antagonistic action of strychnia and belladonna. Now, it is well worthy of remark that the action of these several drugs on the bronchial tubes is quite different from what it is on the œsophagus and intestinal canal. Thus, in animals poisoned with belladonna the œsophagus was as irritable as ever; in those poisoned with opium, on the other hand, the contractility of the alimentary canal is much impaired. This fact has led me to give belladonna in preference to opium in cases of intestinal colic with constipation, and with a far more satisfactory result. I think this mode of investigation worthy of attention as a means of extending pathological and therapeutical knowledge. We want a more elementary study of the operation of medicines, an examination of the effect of simple drugs on the functions of elementary tissues, and on the constituents of the blood; for

(a) Dr. Hyde Salter on "Asthma," 1860, p. 55.

(b) *Transactions of the British Association for the Advancement of Science*, 1840. Read at the meeting at Glasgow.

without this we cannot hope to understand the operation of complex medicines on the whole frame.

To return to the pathology of spasmodic asthma: there is, then, no reason to doubt that a continued contraction or tonic spasm of the muscular fibres of the bronchi—constriction of these tubes—is the essential characteristic of this disease. No doubt the contraction of the bronchial, as of other muscles, is controlled by nervous influence; and many of the phenomena of spasmodic asthma exemplify the reflex action of the nervous system in exciting the spasm—for example, mental agitation or irritation of the stomach by indigestible matter will often bring on a fit of asthma—but the nervous element is often not obvious in the clinical observation of the disease. Thus, spasmodic asthma often affects persons, not otherwise nervous, when they inhale peculiar smells or when they catch cold; and in my experiments I found that irritating the eighth nerves had little effect on the contraction of the bronchial muscles, which, on the contrary, readily answered to direct irritation. But it is open to further inquiry whether, like the heart and arteries, these contractile fibres are not more influenced through the sympathetic than through the spinal nerves.

However induced, this constriction of the tubes renders the ingress and egress of air to and from the lungs difficult and noisy, so that the process of breathing becomes very laborious and prolonged; all the muscles of inspiration, ordinary and supplementary, are called into violent action, and so the struggle goes on until the spasm is relaxed. If this takes place soon the attack ceases, and there is no remaining disorder; but if the spasm lasts long other disorder ensues in the bronchial membrane and other parts concerned. They become congested from the imperfect and laborious breathing, and this congestion causes increased and disordered secretion; hence cough and expectoration of a catarrhal character commonly accompany or follow a prolonged fit of asthma. So, likewise, if these asthmatic attacks recur frequently, they tend to produce more permanent congestion and thickening of the air-passages, which continue in the intervals between the attacks, and thus the disease passes from the paroxysmal or intermittent asthma into a more habitual or constant asthma, with which is associated more or less of the general dilatation of the air-cells, called by Laennec emphysema of the lungs. I will allude to this again afterwards.

Spasmodic asthma, or bronchial spasm, may originate like a common cold or bronchial catarrh, or from exposure to the effluvia of a hayfield, of a stable, of a close room, of ipsecacuanha, or of other dust; or it may arise from some unknown impurity or peculiarity in the air of certain places; or it may be induced by indigestion, by gouty or other irritating matters in the blood, or by mental emotion. The kind known under the term of "hay-asthma" is very common, and I have no doubt is excited by pollen-germs, or some effluvia from flowering grass and other vegetables. It is more distinctly catarrhal in nature, being often preceded or accompanied by sneezing, coryza, and other symptoms of membranous irritation. But in whatever way asthma may have its origin, when it has once occurred it is very apt to return again, and may be re-excited by any of the causes just mentioned; and, generally speaking, the more frequently it recurs, the longer and more severe are the attacks, and the more likely to leave the breathing embarrassed in the intervals.

But you may well ask, further, "What is the peculiarity that makes persons asthmatic?"—that is to say, that makes the causes above mentioned excite in them contraction of the bronchial muscles, instead of causing the more common effects resulting from the operation of these causes on persons in general. We may reply, "A peculiar irritability of these muscles or of the nerves exciting them." But this is only an expression of the fact, and does not explain why these muscles should be more irritable in asthmatic persons than in others. This subject requires more investigation. I do not feel that I can answer it fully, so as to include all instances; but I think that I have traced in several cases signs of a slight structural peculiarity which may give to the bronchial muscles an unusual liability to spasm. This may be designated under the general term of a *slight induration or thickening at or near the root of the lungs*. In a considerable number of those subject to attacks of asthma, even at an early period, when they are few and far between, I have found, in the absence of the paroxysms, more or less of whiffing or tubular sound in one or both inter-scapular spaces, generally most in expiration. This may be from enlarged bronchial glands, which are of common occurrence in children, often accompanying enlarged tonsils; or it may be from interstitial deposit under the mucous membrane at or below the bifurcation of the trachea; or it may be

from slight partial induration of the pulmonary texture, such as that resulting from an old tuberculous lesion, whether in the form of dwindled and contracted tubercle or calcified induration, but of very limited extent. (c) Either of these lesions, trifling as they may be in extent, may increase the irritability of the bronchial tubes, not only by mechanical irritation, but by partially obstructing the circulation underneath the tubes, and thus throwing more blood to the muscular fibres and mucous membrane. It is in favour of this view of the pathological cause of the asthmatic spasm that such changes to an increased extent certainly do occur after often-repeated and severe attacks, and operate as the causes of their continuance and aggravation. In cases of confirmed and habitual asthma we have abundant evidence, both during life and after death, of the increased vascularity and thickening of the mucous membrane and subjacent tissues, which changes we shall afterwards find to be concerned in producing the general emphysema of the lungs which usually supervenes.

Spasmodic asthma is of common occurrence in childhood, and is then frequently complicated with eczematous and other eruptions on the skin. So, likewise, in adult life it often occurs in connexion with gout and with psoriasis, all being dependent on a morbid material in the blood; and this point should be kept in view in the treatment.

Few complaints vary in their tractability more than asthma. Some (even severe cases) yield to treatment so promptly and permanently that their cures may be ranked among the great successes of Medicine. I could cite from my notes scores of such, in which the disease has been either entirely cured, or the attacks have been rendered so few and so tractable as very little to interfere with the health of the subject. In most of these cases the disease had been comparatively recent, the attacks dating back only a few weeks or months, with clear intervals between them; but in a few instances asthmatics of several years' duration have been cured. But most of the inveterate cases admit only of alleviation and mitigation to an extent also very variable—sometimes considerable and enduring; at others, imperfect and impaired by frequent relapses. The causes of these great differences in the tractability of asthma are to be found in the structural changes which may precede, accompany, or follow the spasm. Bronchial spasm itself is a simple pathological element, and may be readily relieved by appropriate remedies; but if it is excited by a constant cause of irritation in the bronchial glands, at the root of the lungs, or elsewhere, it is liable to recur again so soon as the influence of the remedy is withdrawn. Or, if the spasm have existed long enough to greatly derange the circulation in the lungs and bronchial tubes, and to cause congestion and swelling of the mucous membrane, with excessive and disordered secretion, then the relaxation of the spasm alone will not be enough to effect a cure. Further, the treatment becomes still more complicated and difficult, when, from repeated recurrence of the attacks, the nutrition of the affected parts has partaken of the disorder, and the narrowing and thickening of the bronchial tubes, and the mechanical distension of the air-cells, become more permanent and convert the case from *spasmodic* or *paroxysmal* into one of *habitual* asthma.

I have before stated that, frightful as the difficulty of breathing is in a severe fit of asthma, appearing to threaten suffocation, yet it is very rarely fatal, unless when complicated with disease of the heart, kidney, or other important organ. The mere spasm of the bronchi, although it seems to bring a patient to the verge of asphyxia, is not sufficient to destroy life. Why is this, when it encroaches on the vital function of respiration more than even some fatal disorders? I think that the solution of this question lies in the fact that a certain degree of deterioration in the air or of the blood in the lungs tends to relax the spasm. In other words, when the air and blood become loaded with accumulating carbonic acid to a certain extent, this diminishes the muscular contractility, and the spasm is so far relaxed as to ease the breathing and prevent suffocation. In corroboration of this notion I shall adduce two facts. One is that observed by Laennec, that during the asthmatic attack very little natural breath-sound can be heard in the lungs, but that if the patient be desired to hold his breath for a few seconds, or to count numbers aloud as long as he can without taking breath, then the next breath is much more full and deep, as if the spasm had yielded for the moment.

(c) I have known several cases in which individuals have been threatened with pulmonary tubercle in early life, have escaped that danger, but in subsequent years have become asthmatic; and I have met with many instances of asthmatic parents having consumptive children. Yet asthma in its confirmed forms, whether spasmodic or emphysematous, prevents the deposition of tubercle in the lungs. See our work on "Pulmonary Consumption."

Laennec used to say "that the spasm was thus overcome by surprise"; but the more rational explanation is that the holding the breath accelerated the deterioration of the air to the degree in which it acts as a sedative on the bronchial fibres, which being thereby relaxed, the next breath is taken with more freedom.

The second fact bearing on the same point is that ascertained by my friend Professor Simpson, of Edinburgh, that the spasm of asthma may sometimes be relieved by breathing air containing an increased quantity of carbonic acid gas. I have tried this agent, and am convinced that it has some power, but as a remedy it is far less effectual than others to be mentioned presently. But this power of carbonic acid to relax the spasm affords a probable explanation of the limitation to the suffocative influence of asthma.

From what has been said, it may be inferred that the treatment of asthma must vary much in its simplicity and success according to the unity or complication of the disease. Against the bronchial spasm we have remedies which are pretty effectual in most cases. Belladonna and stramonium rarely fail to relieve the bronchial spasm; and in transient cases, where this is the only element, they may suffice to cure the disease. The extracts are the most reliable preparations, and may be given in doses of from a quarter of a grain to half a grain every three, four, or six hours whilst the tendency to spasm lasts. The dryness of the throat which both these drugs often cause may be counteracted by frequently sipping linseed-tea or barley-water. Sometimes, however, this dryness is useful in moderating the catarrhal flux which may follow the spasm.

But in most cases there exists something more than the mere spasm; and therefore we commonly have to give these anti-spasmodics in combination with other remedies. Thus, often there is an inflammatory cold, calling for the addition of salines and counter-irritation; and this may amount to bronchitis, requiring the aid of small doses of tartarised antimony. In chronic cases, when the attacks have recurred frequently or lasted long, there is no combination more beneficial than that of iodide of potassium, in two- or three-grain doses, and ten or fifteen grains of bicarbonate of potash, with the stramonium or belladonna. I believe that I speak within bounds when I say that, with a combination of this kind, I have cured or greatly relieved hundreds of cases of asthma. The efficacy of the alkaline iodide probably depends on its eliminative and deobstruent action, increasing the secretion of the kidneys and of the bronchial membrane, and promoting the absorption or dispersion of the thickenings and deposits in the tubes, bronchial glands, and at the root of the lungs, which I have mentioned as being often concerned in exciting or perpetuating the attacks of asthma. The diuretic or eliminative action of these medicines may be advantageously increased in some cases by the addition of squill, colchicum, or tincture of cantharides, particularly where there are indications of gout or of disease of the skin. On a similar principle, in chronic cases certain mineral waters are sometimes useful, particularly those of Eauxbonnes and Cauterets in the Pyrenees, Vichy, and Ems.

There are several other remedies for asthma in common use—generally much inferior in efficacy to the preceding, but occasionally useful as subsidiary aids, and sometimes they are our chief resources where those disagree. Such is the ethereal tincture of lobelia, which in doses of from twenty to sixty drops I have known in a few instances quite successful; more frequently it has failed, and sometimes caused much nausea and discomfort. Indian hemp, in doses of a grain of the extract, gave signal relief in two instances, where the usual remedies had disagreed; but in other cases it has quite failed, and has sometimes caused distressing disturbance of the brain and heart. Smoking cigarettes of stramonium, or of the *datura tatula*, inhaling chloroform (which for safety should be mixed with sulphuric ether and alcohol), and breathing the fumes of burning nitre-paper, are expedients which often give relief in individual cases; and although this relief is less complete and permanent than that following the use of the remedies first recommended, yet they may be useful where these fail, and, being prompt in operation, may be employed to ward off slight attacks where stronger agents are not required, or before the latter can be brought into effective operation.

Rarely we meet with cases of asthma so severe and obstinate as to resist all medicinal remedies; or it may be that the patient becomes tired of taking medicines, and renounces them in disgust—nay, sometimes I have known the symptoms aggravated by those which are commonly the most successful. In some of these change of air has succeeded wonderfully, and this not always when the change has been of the most

salubrious character. In fact, the caprices of asthma with regard to air are very curious, and can hardly be accounted for. In most instances, however, a dry atmosphere agrees better than a damp one, and the air of a large town better than that of the country, especially if this be low and damp. Of places in which I have known asthmatics most free from attacks I would mention London (several parts of the West-end), Tunbridge Wells, Clifton, Brighton, and Margate (in summer); abroad, Paris, Pau, and Hyères. But asthmatic subjects should try for themselves, and remain as much as possible in the locality that they find by experience to best suit them. In the case of hay-asthma, the avoidance of the country during the hay-making season is necessary with many individuals, and the change found commonly to answer best is either to London or the seaside.

LECTURE ON FISSURE OF THE ANUS.

DELIVERED AT THE FACULTY OF MEDICINE OF PARIS,
ON MAY 1, 1872,(a)

By Dr. DOLBEAU,

Professor of Surgery at the Faculty of Medicine of Paris.

GENTLEMEN,—I feel rather embarrassed to give you a definition of fissure of the anus. Certain classical authors speak of it as "*the fissures of the anus*"; others, amongst whom is Boyer, as a disease quite apart, and term it "*the anal fissure*." I shall endeavour to prove to you that this disagreement only exists in appearance.

The fissure of the anus described for the first time by Boyer is a Surgical complaint, for it is generally cured by an operation. It exists generally between the ages of 18 and 30, and is most prevalent from the age of 20 to 25. Some authors have considered young infants as liable to be attacked by this complaint, which is a complete delusion. *Women* are more subject to it than men; and this is a point not to be lost sight of, in consequence of the important rôle played by the nervous element in the symptomatic evolution of this malady. The fissure appears without any appreciable cause, and is characterised by a series of phenomena of increasing activity, which can be divided into several periods.

In the first period the patient, in going to the water-closet, feels for the first time a burning sensation, with sharp cutting pain, which becomes worse for some moments after defecation, lasts for one or several hours, and then ceases completely. Very often the patient complains of a vague *malaise*, and of prostration, producing definitely feelings of nausea. These symptoms become quickly worse, and, in addition to the sharp pain which accompanies and follows an evacuation, there succeeds a dreadful anguish at the moment that the sphincter gives passage to the stercoral cylinder. The patients are generally subject to constipation. This sensation has been compared to the pain produced by a red-hot iron, or tearing away a tissue with a pair of forceps, or to a violent rent of the fundus; and in all the comparisons made by the patients there invariably occurs the remembrance of a horrible burning sensation.

Often "the stools" are followed by the expulsion of a few drops of blood, which has no sort of relation to the hæmorrhoidal flux, and which is always greatly exaggerated by the patients. After defecation the pain gets stronger and stronger, until it becomes horrible, and if once witnessed can never be forgotten.

This state of suffering lasts three, four, five, or six hours after the expulsion of the fæces; it has been known to exist an entire day. Every stool is followed by the same crisis, and interrupts most suddenly the state of absolute calm in which the patient was previous to visiting the water-closet.

During the *accès* (the fit of pain) every movement is impossible. Coughing, sneezing, laughing, even the effort of talking aggravates the pain, and the patient keeps himself in a state of immobility, bent double, the forehead covered with sweat, so great is the pain.

This group of violent symptoms constitutes fissure of the anus.

Upon examining the anus you will at first perceive nothing. The margin is normal, and the only thing you will be able to find in a very few cases will be some hæmorrhoids, but so slightly prominent as to prevent you at once from attributing to them the cause of the dreadful pain you observe. On

(a) Reported by Osborne C. Powell, M.D.

examining most minutely the anus, fold by fold (*plicatura*), you may perceive a little fissure, situated generally in the posterior part of the anus, on the median line, sometimes on the sides or in front of the anus. This little narrow fissure sort of crack is similar to what is seen on the lips in cold weather when they are chapped. The slightest pressure exercised upon this little fissure with the point of a probe or with the finger provokes this horrid burning pain. Chloroform is here of great utility in enabling you to complete the inspection of this region by the introduction of a speculum ani, by which you perceive that this little lineal crack grows larger as it ascends, but in every case observed never goes beyond the superior sphincter; but it often happens that, in spite of the most attentive examination, not the smallest trace of a crack can be found, even in the case of patients attacked with the symptoms in their most violent form, which will lead you at once to the conclusion that the existence of this fissure is not necessary, and in no way constitutes the basis of the complaint.

Blondin, who has carefully studied this complaint, proposed a classification purely anatomical of the fissure of the anus. He described a cutaneous fissure identical with what syphilographers call "the rhagas," and he named it "sub-sphincterian fissure." Next to this he recognised one which he named "intra-sphincterian," and lastly a "super-sphincterian fissure." These different lesions do exist, but they constitute no necessary analogy with the group of symptoms previously described, and which alone forms the subject of this lecture.

Dr. Gosselin (*Hôpital la Charité*) divides fissures of the anus into—fissures where the pain is supportable, and fissures where the pain is unbearable—according as the anatomical lesion may be accompanied with slight or great pain.

For my part, I think it highly inconvenient to consider the anatomical lesion as sufficient to characterise the malady which we are at present studying, because, on the one hand, severe fissural symptoms have been known to exist without one's having been able to discover the slightest fissure; and, on the other hand, fissures of considerable extent have been known to give rise only to most moderate symptoms.

In cases of persons suffering from hæmorrhoids, and where they assume the form of atonic ulceration, you have seen fissural phenomena (and you know what I mean by this expression) to exist, and in other cases you have seen them fail to appear, although in both cases the anatomical conditions were precisely identical, and very grave. How can one account for these moderate sufferings in the case of some patients, and those atrocious sufferings in the case of others, in presence of an anatomical lesion precisely identical in both cases? The explanation is this: those patients who suffer most are under the influence of a new element—viz., anal neuralgia; for a neuralgia, wherever its seat may be, can be allied with very many anatomical causes, but it can also depend upon that peculiar state of general predisposition that Dr. Bouchut calls by the name of "neurosis." The neuralgia of the anus is not an exception to this rule. It is produced either by a fissure or by a neurosis, but it is not necessarily accompanied by an anatomical lesion.

After the manner of other descriptions of neuralgia—such as the facial neuralgia, for example, which is sometimes accompanied by *tic douloureux*, and even by tonic convulsions, sometimes producing contraction—the neuralgia of the anus provokes a contraction of the sphincter, the rigidity of which would at times astonish you. It is in cases of this kind where men whose sagacity is beyond all doubt—such as Velpeau and Nélaton, our masters—have been unable to find the least trace of a fissure; consequently, we are here necessarily led to believe in the essential nature of this neuralgia. We are, therefore, now in a position to give a definition of this malady. Consequently, I define "fissure of the anus as being a spasmodic neuralgia of the anus, with or without a fissure."

The irritation of the anus by the incessant contact of irritant liquids, which in certain cases run from the vagina, may be the occasion of painful symptoms; but never will these phenomena reach the degree of activity described in the important pathological group we have just been taking into consideration. The age, the sex, conditions of local irritation are accidental causes of anal fissure, and a very important one is constipation.

Diagnosis.—The diagnosis is not difficult to make. It is entirely contained in the description of the symptoms that the patient gives to the Medical man he consults. But if you interrogate your patient in a superficial manner—if you do not take into consideration the tendency that the patients all display to exaggerate their sufferings—you might be easily led to imagine that an anal fissure existed in cases where

patients were suffering from hæmorrhoids, with hard stools, or in cases of persons not sufficiently clean in their person, and where the anus was irritated by "runnings" from a neighbouring organ. It is in cases of this kind that baths and calming pomades produce marvellous cures. But remember once for all, the complaint that you have cured in this manner is never a fissure of the anus.

Your diagnosis will only be a true one when you have made a complete examination of the anal region; you well know that the necessity for touching is an absolute rule, and in all cases where you have not performed it your conclusions are necessarily uncertain. Endeavour to examine a patient with an anal fissure by the finger—it is almost an impossibility; you will provoke an awful attack of pain, and if your finger has been able to enter, the manner in which it is compressed by the sphincter proves that the dynamometric degree of contraction exercised much surpasses the normal contraction of this muscle which exists in an adult person; you will also be able to determine by it that the muscle has become as hard as wood. The existence of a fissure is very probable, and if you pass your finger in a posterior direction you will very likely bring on a neuralgic attack, exactly in the same way as touching a decayed tooth will produce "*tic douloureux*" in facial neuralgia. An examination conducted in this manner, and due attention paid to the few drops of blood passed by the patient, will enable you to make an unerring diagnosis; for, with regard to this last symptom, you will only have to consider the colour of the blood, which is pale rose, and the small quantity of it, to feel quite assured that it is not produced by a hæmorrhoidal flux.

The prognosis of the fissure of the anus is favourable, for it is a complaint which is curable; but if one mistake the nature of the malady, if the fear of pain prevent the patient from letting himself be properly examined, the repetition of these attacks depresses the *morale*, and throws the patient into a very grave state of physiological misery; many patients refuse to eat, in order to avoid going to the water-closet. Velpeau used to relate how a single operation had restored to health and life patients who had become living skeletons, incapable of standing on their limbs.

I think that Medical science embraces some cases of death where patients have been reduced to this extreme state of weakness. While admitting that this fatal termination seldom takes place, it must be borne in mind that anal fissure abandoned to itself gravely compromises the general health.

Treatment.—With regard to the treatment great disagreement exists amongst different Surgeons. Those who believe in essential ulceration of the anus prescribe tonics and astringent pomades. After this fashion Bretonneau treated the anal spasm by the extract of rhatany. With cleanliness, fomentations, and cylinders of charpie impregnated with rhatany, many fissures where the pain is supportable may be cured; but you will never cure the real fissure, so well described by Boyer, in this way. The first thing to do is to abolish the muscular element. Récamier, whose name is inseparable from the history of this malady, well comprehended that the fissural lesion is an element without importance, and he cured several patients by what he termed "cadenced massage." Chloroform was then unknown. He had the patient held by some strong assistants, and he introduced first one finger, then another, and so on until he had passed his whole hand into the rectum; he then bent his fingers, shut up his hand, and drew out his closed fist from the intestine. This was certainly a most rational operation, and the employment of chloroform in the present day permits us to practise it in a much less barbarous manner. Thus, the patient being put under the influence of chloroform, the Surgeon introduces his two thumbs into the rectum and endeavours to bring them into contact with the two ischias; at that moment one hears a strong cracking noise, and the operation is finished. The first stool after the operation is painful; but this pain is simply the result of the region being contused, and does not in the least resemble the pain which characterised the spasmodic attacks. The succeeding stools are without any pain, and the cure is assured.

The anatomical result of this forced dilatation is but little known. In 1856 I operated in this manner at the *Charité Hospital*, in the service of Dr. Brequet (where I was the *House-Surgeon*), on a young hysterical girl of 20 years of age. The operation was performed in the regular way, and the assistants heard, as well as myself, the cracking noise of which I have just spoken. The same evening a sharp attack of cholera carried off my patient. I seized this, the first opportunity I had had, of inspecting the state of the sphincter. I was then one of the prosectors of the Faculty, so I was well versed in

dissection. I found the sphincter intact, the cracking that we heard, and that I felt, was caused by the tearing of the mucous membrane, and the rent extended very far. The cure is thus complete after the operation; but it is not a lasting one, relapses often occurring. And this is another argument in favour of the neuralgic nature of this complaint. Forced dilatation is, however, by far the best sort of treatment, but it is not the most ancient.

Boyer was not afraid to incise the whole thickness of the sphincter with a strong bistoury. Blondin proposed and executed the subcutaneous section of this muscle. Gosselin proposed a mixed procedure, which consisted of incising in a direct manner the fissure in endeavouring only to cut the most superficial part of the muscle. Dr. Jobert (de Lamballe) used to excise the fissure. He met with some successes; but there is no record of what he did when the fissure did not exist.

Some Surgeons pretend to cure all these fissures by cauterisation with the nitrate of silver. They deceive themselves, for they only cure cases where the fissures are supportable. Thus, as a general rule, you will give the preference to forced dilatation, the patient being under chloroform.

Gentlemen, in terminating my lecture I must mention a particular complaint but little known, and the description of which finds a natural place at the side of the history of anal fissure. Certain persons, and particularly women affected with a fissural complaint, are subject simultaneously to spasmodic phenomena (very painful) in neighbouring organs—such as painful cramp of the bladder during micturition—which co-exist with the atrocious symptoms of the fissure of the anus.

During the period that I replaced Jobert at the Hôtel-Dieu, Dr. Vigla called me to see a young girl in his service who presented these three painful manifestations with predominance of anal neuralgia. Dr. Vigla informed me that forced dilatation had been performed twice without success, and begged of me to perform (which I did without any hopes of success) the subcutaneous section of the sphincter ani in this case. Complete success followed my operation. Dr. Vigla informed me that Jobert had cured, by the same operation, a young nun affected with what he called the neuralgia of the three sphincters—viz., anus, bladder, and vagina. You must therefore bear in mind that in certain exceptional cases some women may present signs of a triple neuralgia, and that this complex malady can be cured (I cannot explain by what mechanism) by the section of the sphincter ani.

Independently of the interest that I attach to this triperineal neuralgia, analagous to the trifacial neuralgia, we find in this fact a new confirmation of the opinion of Boyer as to the spasmodic nature of fissure of the anus.

ORIGINAL COMMUNICATIONS.

CONSIDERATIONS RESPECTING THE PRODUCTION OF HEAD SYMPTOMS.

By C. HANDFIELD JONES, M.B., F.R.S.,
Physician to St. Mary's Hospital.

(Continued from page 595.)

Dr. Todd makes the very important observation that blood effused between the dura mater and bone may very often cause not only paralysis but a rigidity of the paralysed muscles. He speaks of the hemisphere opposite the paralysed limbs being in a state of "irritant compression," which may result from depressed bone, or hæmorrhage outside or inside the dura mater. He cites a case which came under his own observation, where the muscles on the side opposite an hæmorrhage from the middle meningeal artery were quite rigid (*vide* p. 222).

In commenting upon a case of arachnitis with copious effusion of pus, which had compressed and formed a cavity on the surface of the left hemisphere, and where after some days of illness right hemiplegia ensued, attended with almost tetanic rigidity of the paralysed muscles, he says that this kind of hemiplegia is due to a cause which exercises at once a paralyzing and irritating influence on the brain; and that this influence is propagated to the spinal cord, and through the nerves implanted in that portion of the nervous centre to the muscles of the paralysed limbs, in which it excites contraction. (P. 224, "Clinical Lectures on Paralysis," etc.) These quotations show clearly that the idea of paralysis being caused by an influence—not only by local lesion—was familiar to Dr. Todd, and that he counted tonic spasm as quite compatible with

actual paralysis. The affinity between spasm and paralysis is affirmed by many other examples; and the above interesting observations seem to establish that both may be produced by a morbid cause operating on a centre whose function is rather intellectual than directly motor.

The next kind of evidence we have to consider is that afforded by tumours, abscesses, hydatids, etc., in the brain. These may from one point of view be grouped together as foreign bodies; and an important point in regard to their presence seems to be that for a considerable time they are often latent, and then—sometimes suddenly—give rise to severe symptoms. Dr. Hughlings-Jackson says—"It is beyond question certain that a person may have extensive disease of one cerebral hemisphere without any obvious symptoms. It is frequently so with abscess of the cerebral hemispheres." He thinks that "the general study of the doings of foreign bodies in the brain leads to the conclusion that changes do come of a material nature about the tumour, and that it is the spreading of these towards the motor tract and to the optic nervous system, etc., which gives rise to hemiplegia, convulsions, and amaurosis. As a matter of fact, hemiplegia and amaurosis do occur with gross disease of the surface of one hemisphere, and sometimes they do not. It seems clear, then, that the local disease is not the cause of these symptoms, but that they depend on changes which the local disease permits or gives rise to." (London Hospital Reports, vol. iv. p. 386.) Irritation, as applied to the effects of these foreign bodies, he holds to be often nothing more than a metaphysical explanation—*i.e.*, I suppose, none at all. There can be no doubt that the point here raised deserves very careful consideration. Tumours in other situations may excite changes in the surrounding tissues, and so they may in the delicate cerebral. If a "neuritis migrans" may occur in the nerves of the limbs, some analogous change may be conceived to be propagated from the focus of palpable disease to the centre whose function is impaired. Yet it is to be remarked that changes occurring around slow-growing tumours are generally very limited in extent, and little disposed to extend in one direction. With hydatid tumours this is especially the case. Such tumours occurring in the brain, and slowly enlarging, could hardly act otherwise than by pressure on adjacent tissues. This would cause wasting and absorption in its vicinity, and at a distance would be diffused throughout the cerebral mass, displacing the subarachnoid fluid, and compressing its bloodvessels more or less completely. I propose now to examine briefly various recorded cases, for the purpose of ascertaining how far their testimony supports Dr. Hughlings-Jackson's view, or the reverse. No selection of the cases has been made, save by excluding those where the lesion was too complex to admit of any conclusion.

1. In the *Pathological Transactions*, vol. vi., p. 17, Dr. Brinton relates the case of a fine healthy-looking man, aged 26, who had a series of epileptic fits, commencing October 1; on the 12th an attack of hemiplegia of right arm and leg—not after a fit—increasing drowsiness and stupor, deepening into coma, which proved fatal on the 31st. The hemiplegia was complete and permanent. The urine was normal. At the upper and inner part of the left hemisphere, rather anterior to its middle, there was a deposit of tubercloid material and tubercles occupying rather more than three square inches. The deposit was embedded in the grey matter of the convolutions, which was much congested. The arachnoid cavity contained about six ounces of bloody serum; the lateral ventricles a little. Almost all the hemisphere above the left lateral ventricle was firmer than healthy tissue, while the rest of the brain was notably softer. Dr. Brinton leaves it doubtful whether the hemiplegia was owing to the damaged state of the cortical grey substance, or to interstitial exudation between the white fibres beneath. I have little doubt myself that the first of these two causes is the real one, for the induration could hardly have produced such a sudden effect; and when more marked than it seems to have been in this case, it tends, according to Dr. R. Reynolds, to produce intellectual decay rather than paralysis. (*Vide* vol. ii., p. 483.) Still, the case should be noted as one which favours to some extent the view that the symptoms are dependent on material change. The coma may have been produced by the fluid in the arachnoid cavity, though I doubt very much whether this was so. Nothing is said of the convolutions being flattened.

2. In a case recorded by Dr. Markham (*Pathological Transactions*, vol. v., p. 15), the symptoms were—numbness in left hand and leg; loss of motor power in same, with rigidity of leg; ptosis of left eyelid; stupor deepening into coma. There was a cancerous tumour in the posterior lobe of right cerebral hemisphere, adherent to the dura mater and to the roughened

cranial bone, surrounded everywhere except below by cerebral matter, in appearance perfectly healthy, and well-defined in outline; for though the cerebral matter adhered at some parts, in none did it seem to pass into the tumour—it did not reach to or manifestly affect the ventricles or other parts of the brain. Here the evidence is pretty strong against the existence of any material change which would account for the hemiplegia, the ptosis, or the coma. The impairment of sensation is to be noted according with Mr. Hutchinson's observations respecting laceration of the hemisphere.

3. In a case, contributed by Dr. Monckton (*Pathological Transactions*, vol. vi., p. 4), of fibrous tumour of the dura mater corresponding to the right frontal eminence, the bone was slightly excavated by the outward pressure, a deeper excavation was found in the substance of the right anterior cerebral lobe, and the brain-tissue around this was much softened. The man suffered for years from intense pains in the forehead and temples more or less constantly, and from fits of epilepsy. No palsy. Here there was change around the tumour, but no paralysis and no stupor—only some mental disturbance occurred near the close.

4. In the same publication, vol. ix., p. 20, Dr. J. W. Ogle describes a case in which there were two carcinomatous tumours—one at the anterior extremity of the left hemisphere, the other at the posterior and superior part of the same. Both tumours, of bantam's-egg size, lay quite superficial, adherent to dura mater and arachnoid, and were easily enucleable from surrounding brain-tissue, which was somewhat softened immediately around them; but the softening did not extend to adjacent parts, and, excepting a slightly increased amount of ventricular fluid, the brain and its investments were otherwise healthy. There was paralysis of motion and sensation on the whole right side, as well as of vaso-motor influence; the temperature of the right arm was considerably higher than that of the left; double ptosis and partial facial paralysis; sickness, and slow, hesitating speech, with fits of agonising pain in the head, during which "he almost lost his reason." Death occurred by apnoea; perhaps from obstructed trachea. The extensive range of disorder in this case accords with the existence of two foci of diseased action, but it certainly seems counter to the evidence to believe that any material change had occurred except in the immediate vicinity of the tumours. The absence of unconsciousness in this case deserves to be specially noted in contrast to Cases 1 and 2; also the existence of sensory paralysis concurring with disease of the hemisphere, as in Case 2.

5. Dr. Murchison (*Pathological Transactions*, vol. xiii., p. 3) records a case where there were no symptoms at all of cerebral lesion, though a tumour the size of a potato-plum was embedded in the upper surface of the right hemisphere of the brain, at the junction of the middle with the posterior third—one inch and a half from the longitudinal fissure. The surrounding brain-substance was not at all softened, and contained no oily matter nor compound granular corpuscles. The patient died of advanced phthisis. This case is rather in favour of Dr. Hughlings-Jackson's views, as it shows an absence of change in the surrounding tissue coinciding with an absence of symptoms. I note, however, that it is this very circumferential tissue-change which conditionates "irritation." The extra-cranial disease probably was one cause of the tumour remaining quiet.

6. In the case of a girl, aged 13, recorded by Dr. R. Bennett (*Pathological Transactions*, vol. xiii., p. 7), there were two hydatid cysts in the middle and posterior lobes of the right cerebral hemisphere; the larger contained six ounces of fluid. The left optic tract was smaller than the right. The rest of the substance of both hemispheres, the cerebellum and mesocephale, and the medulla oblongata were apparently perfectly healthy, rather anæmic than otherwise. The posterior fontanelle was open. Little or no fluid in the lateral ventricles. The symptoms were severe headache, fits, impairment of vision, dilatation and fixedness of pupils, retinal anæmia, loss of control over the movements of legs so that she could not stand, palsy of sphincters. There was no stupor; the child was very intelligent. Death occurred in a prolonged convulsion. Considerable pressure must have been produced by the cysts in this case, but its effect would be lessened by the fontanelle remaining open. The retention of intelligence in this case and the absence of hemiplegia are very remarkable. So is the loss of vision; for the tubercula quadrigemina seem to have been healthy, and the left optic tract could hardly have been compressed by cysts in the right hemisphere. It is most probable that the loss of power over the lower limbs and sphincters depended on the intracranial mischief, yet one would like to have known certainly the state of the cord. The convulsions, which affected

both sides of the body equally, could not have depended on cerebral anæmia, for this, if chronic, has no such effect. Both they and the severe head pain can, I suppose, only be referred to "irritation," possibly acting on vaso-motor nerves; and I can see no other explanation to offer of the iris and sphincter palsy and the loss of control over the lower limbs. The centres presiding over these muscles must have been injuriously affected by the impressions conveyed to them. Had the arms not retained their power and had stupor existed pressure might have been reckoned an adequate cause of the phenomena; but as the case stands I cannot recognise this or altered structure as *veræ causæ*.

7. Dr. Goodfellow (*Pathological Transactions*, vol. xiii., p. 17) relates the case of a male, aged 52, who died with a considerable induration of the left middle lobe of the brain. The substance of the hemisphere at this part was indurated, forming a well-defined mass of a globular form, two inches and a quarter by one and three-quarters. It was closely adherent to the posterior two-thirds of the middle fossa of the skull. Around this circumscribed tumour the brain substance to the extent of half an inch to three-quarters was soft and diffuent and puriform, while all beyond was perfectly healthy. The bone was red and rough below the indurated part. The symptoms of decided illness extended over about six months. He had first an attack of giddiness and loss of consciousness, then severe pain in left side and back of head, vertigo, and some attacks of shivering, great impairment of memory, and occasional unconsciousness, great irritability and weakness. He was comatose for the last six hours of life. The day before death his mind was tolerably clear and active. Premonitory symptoms had been violent; fits of sneezing, pain in the left side of head, and deafness. The focus of disease in this instance was tolerably large, and not remote from the basal ganglia; there was a good deal of softening round it, probably inflammatory. This was a condition in which hemiplegia might well be expected, but except slight temporary numbness of the left leg there was no trace of it. His hemispheres, except occasional interruptions of unconsciousness, functioned tolerably well until quite the last. The only faculty which failed very much was that of memory, and it is certainly curious to find this defect so marked while so much of the organ which subserves its production was in a healthy state. The severe head pain must be referred to disease of the bone or dura mater. The case may be noted especially on account of the absence of hemiplegia and stupor considering the amount of change that had taken place around the primary lesion.

8. In *Pathological Transactions*, vol. iii., p. 246, Dr. Langmore reports the case of a male, aged 52, in whose right posterior cerebral lobe was found a soft tumour of the size of a pullet's egg. It was embedded in the substance of the hemisphere, and approached within a few lines of the surface. Four months before death he had frequent headache, with numbness down right arm. After a time the pain came on in paroxysms four or five times daily, each lasting twenty to thirty minutes, and so intense as to cause profuse perspiration. During the last two days of life delirium came on in the attacks, but he was perfectly conscious in the intervals. The attacks were preceded by pain and numbness in the right hand and arm. There was no paralysis. He died in convulsions. Here the symptoms were only pain on the side of the lesion, disturbance of the hemispheres occasioned by the pain, and vaso-motor palsy (inducing sweating) caused in the same way. The case contrasts strongly with Cases 2 and 4. It was not one of latent tumour. Why was there no hemiplegia? It would be, I am afraid, metaphysical to say that the irritation took a different direction; yet it is a fact that irritation from diseased teeth takes different directions in different cases.

9. Mr. Hutchinson records a case (*Pathological Transactions*, vol. xvi., p. 15) where there was an isolated mass of crude tubercle the size of a horse-bean in the extremity of the posterior horn of right lateral ventricle, with some adjacent softening. In left fissure of Sylvius, around the vessels, there were several ill-defined masses of tuberculoid matter with exudation matting all the parts together. The adjacent cortical substance was softened, especially in the anterior and upper part of the sphenoidal lobe and island of Reil. No other disease in head. The symptoms were aphasia for a week, then a series of epileptiform attacks and loss of power over sphincters. During the last few days he was insensible. The aphasia is explained by the seat of the lesion, and the convulsions by the diseased state of the membranes; but how are we to account for the sphincter paralysis, except we admit the existence of inhibitory irritation proceeding from one of the foci in the brain, and telling in-

juriously on the lower part of the cord? Dr. Todd recognises sphincter paralysis as by no means a rare accompaniment of diseased brain; and we may be pretty sure that if there was substantive disease of the cord, some paraplegic affection would have been noticed. The absence of hemiplegia is rather remarkable, as there was much softening close upon the left corpus striatum.

(To be continued.)

REMARKABLE CASE OF EXTRA-UTERINE FŒTATION.

By METCALFE JOHNSON, M.R.C.S.E., L.S.A.

In the following case the remarkable features are the length of time which has elapsed between the conception and the escape of the fœtus, the preservation of good average health during the whole period of forty-four years, and the perfect restoration of the catamenial discharge up to the age of 45:—

In January, 1870, I was passing the door of her house, when A. B., an old woman, 68 years of age, called me in to see her. Having told me a story of extra-uterine fœtation on a previous occasion, to which I had given little heed, I was somewhat surprised when she told me she had an extreme pain in her anus, and on examination found a hard substance impacted there, surrounded with fecal matter. This I removed without difficulty, and she expressed herself much relieved. Being still sceptical as to the extra-uterine fœtation, I thought this body might turn out to be an oyster-shell, as it had somewhat that form. She was at the time following her usual occupation of washing, and, accordingly, proceeded to wash the substance in the suds before her, when, to my no small surprise, I found it to be a perfect parietal bone. She then went upstairs, and fetched me two other bones, a small vertebra, and a compact wedge-shaped bone, which has the appearance of an ethmoid bone much compressed. These, she stated, had been passed by the bowel about three months since. On the following day she passed the frontal bone, and on the next a small vertebra. These had a strong fecal odour when given to me. Her manner and her anxiety to keep the matter a secret from her neighbours, showed me that the case was genuine, independent of my own personal removal of the parietal bone. Her statement is as follows:—

About forty-two or forty-three years ago, being then 26 years of age, and being, as she believed, at the full period of pregnancy, she felt labour pains coming on, and sent for the Doctor. After the lapse of three days a consultation was held, and a diagnosis of extra-uterine fœtation was pronounced. A memorandum in the books of the only Medical man of the three who attended her now living fixes the date in 1827. She then became very ill, and was confined to bed for three months. After this she was removed to the seaside, but shortly returned home (as she and they also expected) to die. Recovery, however, slowly took place, and in twelve months' time she was able to resume her employment as a washerwoman. For three or four months the catamenial flow was absent; but the flow of milk was excessive, and continued for a considerable time. The catamenia, however, returned in about four months, and continued to return at the proper intervals until the age of 45, when she ceased to menstruate entirely, and without any severe disturbance. The period, which consisted of four days, of sanguineous discharge remained after the event much the same as it had been before. Her estimate of the nine months' maturity of the child was founded on the last catamenial period, which was nine months before her labour pains (or what she supposed were such) came on. Her figure was large in front of the abdomen, but the greatest protuberance was to the left side. This enlargement, though slowly subsiding, never entirely left her. Thirty years ago she passed some small bones by the anus, which a midwife (since dead) told her were the fingers.

She is now a strong, healthy old woman, and follows her occupation of washing at home for her more wealthy neighbours. Until within the last three months she has been in the habit of going from home to wash.

At the present moment her figure is not perceptibly altered from that of any other old woman. There is still a slight enlargement in the left iliac region. Her pulse is regular; tongue clean; sleeps well, and beyond a slight leucorrhœa she suffers comparatively little.

In proof of her age, and the veracity of her statements, I have seen the copy of her baptismal register in 1802.

I made an analysis of the parietal bone, which weighed

thirty grains, and obtained the following results:—After sawing it into two pieces, one-half weighed thirteen grains; the residue, after burning in platinum crucible, was seven grains. The other remainder, after digestion in hydrochloric acid, gave five grains, from which I assume, allowing for loss, the percentage of earthy and animal matter to be as follows:—

Earthy matter	61·55
Animal matter	38·45

Total 100·00

Comparing this with the earthy matter in adult bones (66 per cent.), we find this bone to be as 61 to 66 of earthy matter, or, as I should assume, a very high percentage of earthy matter for bones in the fœtal condition.

The following, by Thomas Percival, M.D., F.R.S., and S.A., in the "Medical Commentaries," may be of interest to compare with my own case:—

In July, 1751, Mrs. T., aged 24, received a sudden shock of fright in the sixth month of her pregnancy, which occasioned some pain in the loins. The abdomen afterwards became much distended, but in half a year after subsided. Soon after her menses appeared at stated periods in sufficient quantity, always attended with violent pains. Milk flowed from the breasts for several years.

In 1757 she was afflicted with great flatulence, and often with hysterical fits. Her uterine discharges had become very putrid. Her health and strength seemed to be gradually impairing.

On May 13, 1772, she discharged by anus two bones of a child's head.

On the 14th she voided in the same way another bone of the head.

On the 17th she discharged the trunk of the body, wanting some of the viscera, of a female fœtus.

In about two months after this event she suddenly relapsed, and died in a few days.

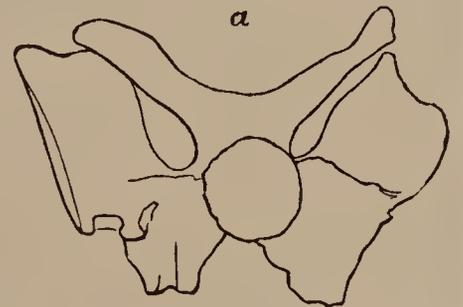

In the *London Medical Journal*, 1787, Michael Underwood, M.D., describes a case in which, in 1738, a woman, aged 30 years, after thirteen years passed some bones of a fœtus per anum, and finally ended a life of pain and suffering at the age of 70 years.

Other cases of bones passed per anum after many years are recorded by various authorities, but I have failed to find any history of a person able to discharge the active duties of a laborious life to the age of 70 years, but who, beyond a comparatively small amount of inconvenience, was but a slight sufferer, though the cavity of the abdomen was the seat of almost the entire bones of a full-grown fœtus.

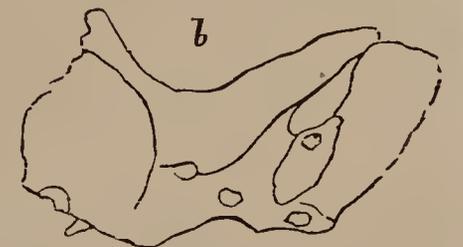

It is now more than two years since the first record of this case was made, but her health remains unimpaired, save a constant sort of leucorrhœa, which seems as though an effort of nature was being set up to restore matters to a healthy equilibrium.

I enclose with this a rough sketch of the two bones, which I am unable to recognise. One presents the appearance of an undeveloped sphenoid, while the other, as before remarked, has the aspect of a compressed ethmoid.

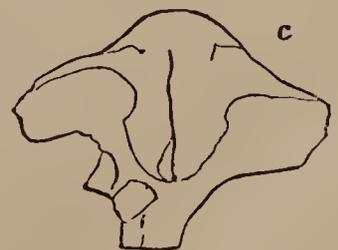

The bearing of these cases of unusual occurrence upon our daily practice is less evident than that of more frequently recurring diseases; nevertheless, there is an interest in the consideration of a rare case which seems to excite the attention more easily than other things. I trust, therefore, that this case may be acceptable to some of your readers.

Posterior aspect.

ON LIENTERIC DIARRHŒA IN CHILDREN.

By EUSTACE SMITH, M.D.,

Physician to H.M. the King of the Belgians; Assistant-Physician to the City of London Hospital for Diseases of the Chest, Victoria-park, etc.

A VARIETY of diarrhœa is not uncommon in children, the peculiarity of which consists in the fact that the motions contain little faecal matter, but are composed almost entirely of undigested food mixed with mucus so as to present a slimy appearance. These motions are passed very shortly after or even during a meal; the food taken appears to pass with extraordinary rapidity along the alimentary canal, and to be voided in almost the same state in which it was swallowed.

The condition which gives rise to this looseness of the bowels is no doubt an unnatural briskness of peristaltic action; the intestines are in a state of great irritability, so that food taken into the stomach is at once forced along the digestive tract with a rapidity which allows little digestion to take place during its passage.

This form of diarrhœa is found in children of from 3 or 4 to 9 or 10 years of age, and gives rise to much emaciation, pallor, languor, and to all the other signs of defective nutrition. At the same time the other consequences of irritable bowels are usually to be noted, and in bad cases night-terrors, nocturnal incontinence of urine, sudden faintness, unusual fretfulness and causeless crying are commonly sources of great anxiety to parents, who attribute them at once to that great bugbear of mothers, "irritation of the brain."

The bowels act three, four, or more times in the course of the day. There is almost always an evacuation in the morning on first rising from bed, and afterwards in the course of the day each meal is at once followed by a like movement of the bowels, the child having often to leave the table hurriedly, and frequently before the repast is actually concluded. Each motion is preceded by griping pains in the belly, and is characterised by excessive urgency, the patient having great difficulty in restraining his desire during the time necessary to enable him to reach the closet. These griping pains are not always followed by a stool, but may come on and go off at irregular times in the course of the day without any result. Sometimes, however, they are accompanied by a desire to go to stool, although no motion is actually passed. The tongue may be a little furred, but is usually clean, and is red at the tip and edges; the redness being due to small crimson papillæ, which are sometimes slightly elevated.

This variety of diarrhœa is not to be controlled by the ordinary astringents, and is very much increased by aperients as castor oil. Opium will, however, often check it temporarily; but for its permanent cure the best remedies are arsenic and tincture of nux vomica in small doses. The abnormal activity of peristaltic action to which the derangement is owing appears to be due to impressions of cold; and therefore, that the cure may be permanent, it is advisable to protect the belly by a broad flannel belt, so that the body may not be exposed to sudden chills.

The following short cases will serve as illustrations of this form of diarrhœa, and of the treatment to which it is most readily amenable:—

Master R., aged 5 years, was brought up to me from the country. "For the last twelve months he has been subject to prolonged attacks of diarrhœa, during which the bowels will act four or six times in the day. The motions usually follow a meal, and sometimes so urgently that he is obliged to leave the table before the repast is concluded. The motions are said 'to run from him,' and to contain much slimy matter. There is no straining, but the stools are preceded by some griping pains in the belly. He is fretful and rather thirsty, but sleeps well at night. He is losing flesh rapidly, although his appetite is large." The child was ordered to take three drops of tincture of nux vomica in a draught of citrate of potash three times a day before meals. A few days afterwards he returned very much better. The bowels were acting three times a day, not after meals. His appetite was more easily satisfied, and he had ceased to waste. A change was then made in his medicine to one drop of liq. arsenici chlor. in a nitric-acid mixture before each meal, and he was not seen again.

Elizabeth W., aged 4 years, had suffered for a long time from repeated attacks of diarrhœa, each of which lasted for many weeks together. The motions were said to follow immediately upon taking food, and to occur sometimes in the intervals between the meals, so that the bowels were frequently acted upon five or six times in the day. The stools were slimy, and were passed without straining or apparent

discomfort. The child was irritable in temper, and was very restless at night. Her appetite was capricious, and she was very fanciful in her eating. Her skin was exceedingly rough and dry. The tongue was clean, and over the surface were scattered light-red elevated papillæ. She was first seen on January 7, and was ordered to take one drop of liq. arsenicalis in a mixture containing citrate of iron and ammonia, with bicarbonate of soda, three times a day. A warm bath was recommended every night, for the purpose of softening the skin and removing the dry epithelium scales.

On January 14 the girl seemed better in herself, although the bowels were in the same condition as before. She had taken the medicine regularly, but each meal was still followed by the accustomed stool, and the child was still losing flesh. A mixture was then ordered containing laudanum and tincture of nux vomica—two drops of each to be taken before each meal. Considerable improvement followed the change of medicine—the appetite became very good, and the bowels, although still relaxed after each meal, yet did not act in the intervals, so that the daily number of evacuations was much reduced. The skin, owing to the nightly warm bath, had become soft and supple. One drop of liq. arsenici chlor. was then given three times a day in a nitric acid mixture, and the cure was soon complete.

In the following case the lienteric diarrhœa was associated with incontinence of urine:—Emma L., a girl of 8 years old, who had suffered from rickets during infancy, was brought for advice for an almost constant looseness of the bowels. The stools occurred directly after meals. She also complained of an inability to hold her water for long together, either in the day or night. She was ordered three drops of liq. strychniæ and ten drops of tincture of belladonna three times a day before meals. A few days afterwards she could hold her water very much better, but the bowels were still relaxed after meals, and were as loose as ever. One drop of liq. arsenici chlor. was then given with dilute nitric acid three times a day before meals, and in the course of a week greatly improved the character of the stools, which were more solid and healthy-looking, and were less commonly found to follow a meal, although they were still too frequently passed. The girl was said to be very nervous, and to complain of slight pains in the belly. The mixture was then changed to—℞. Tinct. nucis vomicæ ℥v., liq. arsenicalis ℥j., mist. pot. citrat. ℥ss. three times a day; and the motions soon became perfectly natural both in number and quality.

REPORTS OF HOSPITAL PRACTICE

IN

MEDICINE AND SURGERY.

ST. PETER'S HOSPITAL.

STONE IN THE BLADDER—LITHOTRITY—CURE.

(Under the care of Mr. TEEVAN.)

J. T., aged 25, cooper, was admitted into the Hospital June 5, 1867.

Past History.—Comes from Stourbridge, Worcestershire, where he was born. For some years past has noticed red gravel in his urine. Eighteen months ago passed two small stones. Has been troubled with pain in the perineum for a long time, but suffers none at the end of the penis. Blood is often seen in the urine.

Present Condition.—Is a very powerfully-built man, of symmetrical proportions, but of very pale aspect, and apparently greatly depressed in spirits. States that stream of urine is very small, but he has never suffered from retention. Generally he has to make water every half-hour, but on some days he can hold it for a longer period. The act of micturition is usually accompanied with that of defecation. Constantly passes some blood in urine. Much pus and albumen in water.

On May 27 the patient was examined by Mr. Teevan, who found a stone of considerable size, and as the urethra proved to be extremely sensitive, he was put on henbane and potash.

June 2.—The patient being under chloroform, Mr. Teevan passed a lithotrite to measure stone; but the bladder contracted firmly, expelling the urine, and preventing the instrument from being sufficiently open to grasp the calculus.

4th.—Mr. Teevan crushed the stone, which was one inch and three-quarters in diameter and phosphatic.

6th.—Operation repeated.

7th.—Many pieces of stone have come away to-day. Patient suffered much pain.

9th.—Yesterday a large fragment lodged in the perineum, causing much suffering, and to-day it came away.

10th.—Patient more comfortable. Was only called out of bed twice last night.

12th.—Is in a good deal of pain. Some blood has passed.

15th.—Lithotripsy performed. Much stone passed after this crushing.

20th.—Lithotripsy; but little *débris* came away.

24th.—To-day five large fragments were broken up, and much *débris* passed the next day.

28th.—Is feverish, and passing much blood. Ordered effervescing saline.

July 4.—Patient well enough to undergo another crushing.

11th.—The operation was repeated.

14th.—Health good. Urine getting clear.

Lithotripsy was performed on the 18th and 27th, and on August 9. A great deal of *débris* passed after each operation.

August 17.—Patient thinks he is nearly rid of the stone, as he experiences but little annoyance. A few small fragments were crushed to-day, and but little passed afterwards.

23rd.—The lithotrite was introduced to-day, but scarcely any stone was found.

September 1.—Is quite free from any pain in the bladder, which was examined with the lithotrite, and found free from any fragments. Patient holds his water comfortably for three hours.

July 1, 1868.—To-day the patient called at the Hospital to say that he had remained perfectly well since the operation, now nearly a year ago.

Mr. Teevan remarked that there were several points of interest in this case. In the first place, the stone was the largest he had crushed, the *débris* alone filling an ounce bottle; and although phosphatic, was tougher than such a stone usually is. Now, such a calculus was not to be attacked with a lithotrite unless there were strong reasons in support of such a course, which certainly in this case existed. The patient was a very powerful young man, and there was no reason to suppose that there was much amiss with his kidneys. One great point in favour of lithotripsy in this particular instance was that the urethra was unusually capacious, and thus enabled the bladder to rapidly get rid of the fragments after each operation; but, on the other hand, the canal was excessively sensitive. This, however, was not apparently such a drawback as at first sight it might appear; for it would usually be found that in vigorous young men, whose parts were well nourished and in a state of active life, the urethra was naturally more sensitive than the callous canal of old age. Although so many crushings were required to get rid of the stone, and the patient was consequently subjected to much pain and irritation, yet the result was all that could be desired; for when seen a year after the operation he still remained perfectly well, having been absolutely free from any annoyance all that period. Now, it cannot be said that lithotomy would have been as safe in this case as lithotripsy, for the former operation in a subject like this patient was by no means devoid of serious risk to life. A feeble old man would often make an excellent recovery after lithotomy; whilst a strong young man would occasionally die after being cut, with every chance apparently in his favour. In the former case it would seem as if the patient became, as it were, habituated to his state, and the operation did not cause the shock it produced in the latter.

SEAMEN'S HOSPITAL, GREENWICH.

TEN CASES OF SCURVY.

(Under the care of Dr. STEPHEN H. WARD and Dr. REGINALD THOMPSON.)

[Reported by Mr. ADAM YOUNG, House-Physician.]

J. H., aged 56, D. T., aged 30, and J. O., aged 21, were admitted into the Seamen's Hospital on April 4, all suffering severely from scurvy. Spongy gums, sallow pasty aspect, pearly conjunctive, and considerable emaciation were symptoms common to all. Two were the subjects of hard effusions about the muscles of the calf and tendons of the knee-joint, which latter were also the seat of extensive bruise-like discolorations. The third exhibited spots about the legs and thighs more akin to purpura, but one of his ankles was "brawny" to some extent. J. H. has now had four attacks of scurvy, the first having occurred fifteen years ago, and prior to this last illness

he had lived exclusively on ghee, rice, bread, and curry for five months, and on salt rations for four months more—so that he had, in fact, tasted little or no antiscorbutic food for at least nine months. J. O. signed articles and went out in the ship to Calcutta after a stay on shore of forty-eight hours only, having just returned from a voyage of five months' duration. The vessel in which these men returned home occupied 140 days on the passage, and touched nowhere. The provisions are reported to have been of middling quality, and the lime-juice was given and taken regularly. Six men were more or less affected with scurvy out of a crew of twenty-eight hands, but the men specially noted above were far more severely attacked than the rest.

E. S., aged 22, and T. G., aged 47, were sent to the *Dreadnought* Hospital on April 11 from the ship *Blanche*. Their legs were semi-flexed and greatly discoloured, their gums were swollen, and they were so excessively weak as to be hardly able to crawl upstairs. No other special symptoms existed. They had been landed after a long passage from the north-west coast of South America, but made no complaint as to the quality of provisions.

J. F. O., aged 34, J. C., aged 20, C. J. W., aged 20, F. L., aged 21, and C. A. R., aged 29—four Swedes and one Irishman—were admitted from the Swedish barque *Rosalie* on April 12, which vessel occupied more than four months in the passage from Batavia to Portland. These men were sent from the latter port to Greenwich by railway; one was carried and all were assisted into Hospital. The former exhibited all the usual symptoms of scurvy in a very marked degree, the gums almost concealed the teeth, and some of the latter had dropped out; there was also a tendency to syncope. Another of these cases exhibited some amount of scorbutic dysentery.

All these patients convalesced rapidly. Ten-grain doses of chlorate of potash, with decoction of bark, were given to four, and iron to one of them, whereas the rest were treated with a placebo mixture, and all were rationed on full meat diet (beef and mutton alternately), potatoes, greens, milk, lime-juice, and porter. The average stay in Hospital was ten days, and the cripple who was carried in was walking about his ward a week after admission.

Mr. Harry Leach thinks the following deductions worthy of record in connexion with these cases:—1. That no amount of lime-juice, however good its quality may be, and however regularly it may be taken, will of itself keep men free from scurvy beyond a certain time, if they are continuously fed on what may fairly be termed a poisonous diet. 2. That the five cases of scurvy received from the Swedish barque are readily accounted for, because the crews of Norwegian and Swedish vessels are not regularly supplied with lime-juice or any other special antiscorbutics, and it is a well-known fact that in consequence most of their vessels that go to ports beyond either the Cape of Good Hope or Cape Horn bring home scurvy-stricken crews. 3. That a man who has had scurvy once is, under analogous circumstances, more liable than others to a recurrence of the disease. 4. That though a great diminution of scurvy in the British mercantile marine has followed as a consequence of the operation of the Duke of Richmond's Act, it is highly desirable that shipowners should unite with the Marine Department of the Board of Trade and institute such alterations in the scales of diet now in use on long-voyage ships as shall render the "lime-juice" clauses of the Merchant Shipping Act (1867) unnecessary.

ROYAL INSTITUTION OF GREAT BRITAIN.—At the general monthly meeting, on Monday, June 3, the Earl of Rosse, B.A., D.C.L., F.R.S., Vice-President, in the chair, Charles Edward Beever, Esq., Frederick John Blake, Esq., Maurice Barnard Byles, Esq., C. F. Hancock, Esq., B.A., George Augustus Huddart, Esq., Joshua G. Kershaw, Esq., Henry Samuel King, Esq., Athol Maudslay, Esq., and Mrs. Ciccopiere St. Clair, were elected Members of the Royal Institution. The Managers reported that they had appointed William Rutherford, M.D., F.R.S.E., Fullerian Professor of Physiology.

THE REGULATIONS FOR A CONSTANT WATER-SUPPLY.—The Paddington Vestry has adopted a resolution recommending that the regulations for a constant water-supply, proposed by the water companies and amended by the Metropolitan Board of Works, be submitted to some independent Medical authority, such as the Association of the Medical Officers of Health, in order to obtain an opinion from a sanitary point of view generally, and in particular as to the expediency of using lead pipes.

SATURDAY, JUNE 8, 1872.

CO-OPERATIVE TEACHING.

AN article in last week's *Saturday Review*, entitled "Recent Changes at Oxford," chronicles very important alterations which can scarcely fail to prove reforms in the system of teaching at that University. These changes, which are probably as real and as important as the admission of non-collegiate students to university privileges and the abolition of tests, have been brought about very noiselessly, and have attracted far less of public attention than the last University Boat-race or Commemoration. They may be summed up under two heads—first, the co-operation of the tutors of several colleges for the purpose of teaching on a larger, broader, and more complete scale; and the second, the revival of the professoriate, and a consequent step towards the extinction of the coach system. There are nineteen colleges at Oxford, and the system which prevailed until recently there had its foundation in the theory that each college was bound to provide its students with special and complete education in all subjects necessary for the degree examinations. Each college, therefore, kept a staff of tutors or lecturers who year by year travelled over the same round with classes of a few men—perhaps from four to sixteen. It is easy to see that such a system was open to many objections. In the first place, it was a great waste of teaching power. In the second, as all the lecturers or tutors at the nineteen colleges were going all the year through the same routine of work, there was no impulse or opportunity given for any of them to strike out a line of his own by directing his energies to any particular section of the department of learning which he was obliged to treat as a whole. Thus all incentive to original scholarship was lost. Lastly, the system presupposed a much larger amount of teaching talent than experience shows we have a right to expect amongst a limited number of men, however well educated. To remedy these evils, three or four years ago, the simple plan of a combination of colleges for organising college lectures was adopted, and it is working well. Two unions, or federations, of colleges have been formed for the purposes of the classical school, one consisting of six

colleges, the other of three. At the end of each term the lecturers or tutors of the federate colleges meet together and arrange a joint scheme of lectures, each teacher undertaking the book or subject on which he feels himself most competent to teach. The joint course of lectures is open to the students of all the combining colleges without any extra charge, and they still have the opportunity of going to their respective college tutors for private instruction. Students of other colleges are admitted to the lectures on the payment of a small fee. In like manner five colleges have combined to organise a course of mathematical lectures, and the tutors and lecturers on modern history of fourteen colleges have entered into a similar union, to give a full course of teaching on this very wide subject. It is very safe to prophesy that, unless thoroughly mismanaged, this system of co-operative teaching must be of enormous benefit to the Oxford students.

The other reform is the revivification of the Oxford professoriate. Most of us remember Hogarth's caricature of the Oxford lecture. The marvellous representation of various shades of stupidity, silliness, vacuity, and fatigue in the bewigged and trencher-capped audience, and the personification of self-satisfaction, pomposity, and determination-to-read-through-his-manuscript, regardless of his hearers, portrayed in the lecturer—who, as tradition goes, was one Mr. Fisher, of Jesus College—who was wag or fool enough to sit to Hogarth for the portrait. But the state of things ridiculed by the genius (whom an Oxford don, irate at the satire, stigmatised as "an uneducated painter") was certainly a better one than that which prevailed ten or fifteen years ago, when professorships had become mere sinecures, many of the holders giving no lectures at all, and others reading a few *pro forma* which nobody attended. The result of this abuse, as may be supposed, was that the University, as a university, was practically what that arch-traitor to thorough education, Mr. Lowe, wishes all universities to become—a mere examining board, and not a teaching body. The real education at Oxford was in the hands of the college tutors and the coaches. But of late years a great change has come over the professoriate. A few distinguished men who were elected to professorships set the example of turning the University lectures into real practical courses of teaching. The heaven has worked, and now, as the writer of the article in the *Saturday Review* states, out of the whole number of forty-two professors thirty are delivering regular courses of lectures to a class, while of the rest nearly all have announced one, two, or more occasional public lectures, or else are giving private instruction. Not merely the University and its students, but the outside world of science and literature has already reaped the benefit of this regeneration.

We have dwelt thus long on these changes and reforms at Oxford because we think they have their lesson for our Medical colleges, schools, and teachers. Here in London we have not nineteen colleges, it is true, but we have ten Medical schools, besides the two Royal Colleges, where there are endowed professorships and lectureships; and the Chelsea Garden, where the Master and Wardens of the Apothecaries' Society have instituted a course of botanical lectures. Surely amongst all these Medical teaching bodies there must be an immense waste of teaching power and a commensurate necessity for co-operation. It is no exaggeration to say that ten courses of lectures on physiology, botany, chemistry, and other Medical subjects, all going over the same routine, and all addressed to the comparatively small class of Medical students in this metropolis, are at least seven too many. They are too many, because, out of so large a number as ten, some courses must be very inferior to others, and this would be the case if the size of the classes were equal; but how much more likely is it to be so when, as at some schools, the numbers attending the classes are so small as to be absolutely unremunerative. Teaching power is not the attribute of every man. Men may be excellent practical

Physicians and Surgeons—nay, excellent anatomists, physiologists, chemists, or botanists—and yet be utterly unable to impart to others a knowledge of what they know themselves. But our present system of Medical education presupposes that every man who is able to take a Hospital appointment is fit to teach. Never was a greater fallacy; but an equally great one is, that every Hospital must have a full Medical school attached to it in which all its honorary officers are to find chairs, which will indirectly remunerate them for their services. These two fallacies are at the root of the low standard of Medical education in the present day. The large number of rejections at the examining boards has lately been severely commented on in various quarters. We believe that the fault is neither with the examiners nor with the examinations, but with the faulty Medical education given in London and the provinces. One great reform would be a co-operation amongst the Hospitals of London similar to that which has been organised between the Colleges of Oxford. Let three or more Hospitals combine to institute full courses of lectures, each course not necessarily to be delivered entirely by one man, but special knowledge and aptitude for teaching to be secured for each subject, whether forming a course or part of a course, in succession. Let thus incentives for the cultivation of special branches of knowledge and of teaching power be afforded, and let the student be certain that he will receive from his lecturer not a mere dry *réchauffé* of the bones of worn-out text-books, but the muscle and marrow of his own study, observation, and experience, and we may be sure that a new and bright era of Medical discovery and research on the one hand, and of the diffusion of advanced Medical science on the other, will be inaugurated.

CHEMICAL CLIMATOLOGY.

OUR knowledge of the composition and properties of the atmosphere seems to be going on at an increasing rate. It is not quite a century since we learned the existence of oxygen. Within the memory of living people there were instruments known as *eudiometers*, to measure the quantity of oxygen, upon which it was supposed that the purity of the air depended. But, on the other hand, the results of imperfect experiments led to the supposition that chemistry was unable to detect any difference, so far as quantity is concerned, between the air of the highest mountain-top and that of the crowded city. Still, beginnings of a more exact knowledge were made here and there. The presence of carbonic acid was estimated by De Saussure at the end of the last century; but so far as we know, it was first measured for practical purposes by Dr. Bence Jones about twenty years ago, during some observations on the ventilation of St. Pancras Workhouse. Liebig estimated the ammonia, in that splendid work in which he showed that the bulk of the growth of vegetables comes not from the soil but from the air. But so rapidly have matters now advanced, that we have before us a pretty volume on "Chemical Climatology," by Dr. Angus Smith, whose active chemical insight and powers of observation have induced him to draw the greatest possible results from the researches which it is his duty to make as "Inspector of Alkali Works"—an office which makes him the protector of all living things from poisons diffused through the atmosphere. (a)

But, courteous reader, mark the word *chemical*—for there is a *physical* climatology or meteorology which has heretofore usurped all the attention of Mr. Glaisher and the weekly reports of the Registrar-General. This includes an account of the weight of the air, of its movement, of the quantity of moisture, of its rainfall, temperature, electrical state, and opacity with clouds, the only chemical item for which a column is reserved being ozone.

But, now that *chemical* climatology is set on its legs, future tables, in perhaps no long time, will tell us—first, of the *gases* always present in the air (the oxygen, nitrogen, and carbonic acid); secondly, of the *vapours* which may be found there, including everything vaporisable (sulphurous, muriatic, nitric, arsenious, and every other species of acid); thirdly, of the *solid inorganic* substances, comprising portions of the surface of the earth, of chalk in chalky districts, of sea-salt near the sea, of sulphate of soda formed by the mutual reactions of sea-salt and sulphuric acid, of carbon, of salts of ammonia, oxide of iron in manufacturing districts, and of ashes; fourthly, of the *solid organic* impurities, such as hairs, scales, and vegetable and animal *débris*, and the like; and fifthly, of the *solid organic living* bodies, amongst which must be included not merely the lofty eagle, or the voracious hawk, nor yet the swallows, nor the flies which are found in places reeking with organic vapours, coursing their prey, just as the swallows chase themselves, and which, as Dr. Angus Smith believes, may "feed on the substances that affect our sense of smell." Below these possibly are germs, whether organised like the sporules of fungi, or merely portions of diseased bioplasm as Dr. Beale suggests, and which possibly derive nourishment from floating particles of organic matter.

It will thus be seen that chemical climatology is a pretty extensive art and science. It includes methods for measuring volumes of air (by-and-by it will attain to weights), and subjecting these to washing or other processes for separating impurities, solid or soluble. The matters so separated may be submitted to the microscope, by which the form of organic substances and crystals may be determined; chemical tests (including the most delicate refinements of Wanklyn for detecting ammonia, free or in the form of albuminous substances) may be applied to the matters dissolved, and the gases be estimated by the ordinary processes. The rain must also be examined as Nature's own result of washing the atmosphere; and it will be found that rain-water, though it may be a model of purity away from man and his habitations, yet in and near towns presents every kind of contamination—so that drinking rain-water would be like drinking the water employed in washing persons or clothes.

Amidst the mighty mass of matter accumulated by Dr. Angus Smith's industry we can but call attention to one or two samples. Let us take the quantity of oxygen, the earliest point endeavoured to be estimated by eudiometry. Dr. Angus Smith gives a series of analyses, which make it clear that mountains and great plains have a different atmosphere from cities; but, still more, he shows the amount of difference. Thus, on the north-east seashore and open heaths in Scotland, he finds 20.9990 oxygen in 100 volumes of air. In open places of London in the summer, 20.9500. In the Court of Queen's Bench one day, 20.6500.

So it may be said that all the atmosphere in *open* places (of course a crowded court of justice does not come under this category) has a *similar* amount of oxygen, and that the differences are shown in the second decimal place.

Some people, says Dr. Smith, may ask what importance can be possibly attached to such minute quantities as require a second or third decimal place to express them. In the first place, then, although a little oxygen more or less might not affect us, it is certain that the missing volume of oxygen, when deficient, is replaced by carbonic acid or some other noxious substance. "Subtracting 0.980 from 0.999, we have a difference of 190 in a million. In a gallon of water there are 70,000 grains; let us put into it an impurity at the rate of 190 in a million; it amounts to 13.3 grains per gallon. This amount would be considered enormous if it consisted of putrefying matter, or any organic matter usually found in waters. But we drink only a comparatively small quantity of water, and the whole thirteen grains would not be swallowed in a day, whereas we take into our lungs from 1000 to 2000 gallons of air daily."

(a) "Disinfectants and Disinfection." By Robert Angus Smith, F.R.S., etc. Edinburgh: Edmonstone and Douglas. 1869.

"Air and Rain: the Beginnings of a Chemical Climatology." By Robert Angus Smith, Ph.D., F.R.S. London: Longmans. 1872.

Moreover, air enters the blood directly through the lungs; it is not filtered or digested, as matters are in the stomach.

We must say in praise of Dr. Angus Smith, that his zeal for his own special branch of study does not blind him to the fact that there are other things required besides mere purity of air. Whilst the mere sanitarian puts people into shivering draughts, Dr. Smith affirms that the first demand of nature is—not pure air, but warm air. Without warmth there can be no civilisation and no morals. When men are cold they cannot sit still and indulge in study. Rough physical exercise and drink become irresistibly tempting. We have seldom seen a subject treated of more comprehensively and temperately than Dr. Angus Smith treats of chemical climatology.

TOPICS OF THE DAY.

PROFESSORS H. E. ROSCOE AND B. STEWART, of Owen's College, Manchester, have, we are glad to see, ventured to attack the Chancellor of the Exchequer for one of the sweeping things he said at the presentation for degrees at the University of London. Mr. Lowe is reported "to have pointed out how the endowment of Professorships naturally tended to make teaching inefficient (seeing that the revenues come in independently of the results of teaching), suggesting that those who had any money to spare for the advancement of education should rather make it available in the forms of scholarships and exhibitions." To this shallow sophism the Manchester Professors reply by recounting the effects of the endowments in Owen's College, and in the Scottish and German Universities, on the cost of education, and on the efficiency of teachers; and they point out that the evils to be apprehended by an excessive endowment of scholarships are those of a "hot-bed regimen," by which young men are induced to enter professions in which there is no subsequent career open to them. They wind up with the home-thrust—"In conclusion, sir, we cannot understand why endowment naturally tends to make teaching inefficient in the case of a professor of science or arts more than it does in that of a minister of religion or a statesman." Mr. Lowe's reply is in effect that his speech, which occupied three-quarters of an hour in delivery, was reported in a few lines; but he defends his position that it is better to give money to young men than to pay persons to teach them, on the ground that in the latter case the inducement to the teacher to work is diminished, and that the student with money in his hand will be sure to find the best teacher for himself—to both which statements facts are absolutely opposed. Nobody has ever dared to say that the endowed Professors in German and Scottish Universities have not taught well, and some of the worst types of education to be obtained in England and Wales are only open to students with money in their own or their fathers' pockets. The fact is that Mr. Lowe cannot forget that he was once an Oxford coach, and that he is now Member for the University, which, not being a teaching body, but only an Examining Board, is running the risk of pushing its functions to excess, and is open to the accusation of being the great fosterer of the grinding system throughout the kingdom, and the embodiment of the Chinese as opposed to a real system of education.

An inquest was held last week on the body of a sailor who died shortly after swallowing a black draught, bought at a shop or open surgery in Limehouse. Another sailor was made very ill for several days by swallowing a black draught from the same source. The post-mortem examination revealed a natural condition of the organs, with the exception of congestion of the brain, and effusion into the chest and pericardium. The contents of the stomach were analysed by Dr. Meymott Tidy, of the London Hospital, who detected oxalic acid, and drew the inference that probably oxalic acid had been substituted for sulphate of magnesia in the black draught. The patient had

fallen down insensible after swallowing the draught, and had died soon afterwards. The owner of the shop where the draughts were purchased—a Medical man—said that they were part of a stock he bought in November from a former owner of the business. The account of the case contained in the *Times* newspaper omitted all special mention of the condition of the stomach—an important point in a supposed death from oxalic acid. But at any rate the case should furnish a warning to Medical men who keep open surgeries and chemists, not to send out medicines for the composition of which they cannot personally answer.

Dr. Poore, of Charing-cross Hospital, who accompanied the Prince of Wales on his recent tour, has had the good fortune to attend and successfully conduct through an attack of typhoid fever the Princess Thyra of Denmark. For this service he has received from the King of Denmark the Commandership of the Order of the Danebrog. Her Majesty has been graciously pleased to permit Dr. Poore to wear the decoration.

Dr. Rayner, late Assistant-Superintendent at Bedlam, has been appointed Superintendent of Hanwell Lunatic Asylum.

We have received a list of portraits of persons who have held honorary appointments in the Norfolk and Norwich Hospital from its foundation in 1771 to 1871. The portraits have been collected and placed in the Board-room by Mr. Charles Williams, Assistant-Surgeon to the Hospital. The list contains many distinguished names—amongst others those of Alderson, Rigby, Yelloly, Ranking, Gooch, Dalrymple, and Crosse. Not many provincial Hospitals could show so goodly a roll of worthies.

UNQUALIFIED PRACTITIONERS.

HAVE we any legal machinery by which we may "stamp out" the herd of advertising quacks and people practising without any qualification? The law is by no means stringent enough to meet all cases, but surely many of the flagrant instances might be dealt with by the statutes at present in force. We are glad to notice that on Saturday last Mr. Shirley Deakin, House-Surgeon of the Male Lock Hospital, Dean-street, Soho, waited upon Mr. Knox, at the request of the board of directors, to state that a number of letters had been received by the board asking whether certain advertising and bill-distributing unqualified practitioners were members of, or connected with the Hospital, and that it was the wish of the board to make it known as widely as possible that the persons in question had no authority to refer to the Lock Hospital, or to use its name in any way. One person, who used the name of Dr. Watson, and described himself as governor of the Lock Hospital, had no connexion whatever with the Hospital, and was, in fact, unknown to the board. He held in his hand a list of persons improperly practising in certain complaints in London. These were the principal offenders, and were thirty in number. He had also a list of others in Manchester, Liverpool, Birmingham, and other large provincial towns, and he would be much obliged by the magistrate informing him of the best way of proceeding against these parties, and of protecting the public, who were not only entrapped by the aid of advertisements, but by the distribution of bills in the public streets. Mr. Knox said he would most readily afford all the assistance in his power to diminish, if he could not entirely eradicate, what he conceived to be one of the greatest scandals of the metropolis. There were two ways of proceeding: one under the Act which dealt with unqualified and unlicensed Practitioners—a conviction having some time ago been obtained at that court; and the other by bringing to that court all persons found distributing offensive bills—and if brought before him he would most certainly send them to the Middlesex Sessions for the purpose of ascertaining whether the Middlesex magistrates would be inclined to second his efforts to abate an increasing nuisance. Mr. Deakin thanked the magistrate, and promised to communi-

cate the result of the interview to the board. Surely the evil might in some cases be met by the publication of the names of the offenders in the newspapers, or by summoning them before a magistrate for falsely assuming titles.

BRITISH MEDICAL ASSOCIATION.

WE understand that at the meeting of the British Medical Association, to be held at Birmingham in August this year, a feature of special interest is to be given to the annual museum, in the form of a collection of specimens, photographs, drawings, and diagrams illustrating diseases of the organs of circulation, and the instruments used in their detection and treatment. As a spacious room is to be set apart for the museum, the Committee hope to be able to display all specimens to advantage; and they further purpose to issue a printed catalogue of the contributions, which is to contain a brief description of each. The secretaries, to whom preparations are to be sent, are Mr. Bracey and Dr. Jolly, of Birmingham.

THE OBSTETRICAL SOCIETY AT BIRMINGHAM.

AT a meeting of the Medical Profession of Birmingham and the district, convened by circular, and held on Friday, May 31, at 3 p.m., in the theatre of the Midland Institute (James Johnston, Esq., M.B., Physician to the Queen's and Sick Children's Hospital, in the chair), the following resolutions were unanimously carried:—

"1. That this meeting is of opinion that as the Obstetrical Society has no charter or other legal status in the country, its action in the establishment of a board for the examination of and granting 'diplomas' to midwives is not advisable.

"2. That the establishment of a local board of the resident Fellows of the Obstetrical Society in Birmingham is unneeded and most undesirable.

"3. That copies of these resolutions be forwarded to the President and Council of the Obstetrical Society of London, and to the editors of the three London weekly Medical journals."

Is it desirable to employ midwives? If so, should they be educated and examined? If so, by whom? The Obstetrical Society is a purely voluntary association; so were the College of Physicians and Surgeons, the Institute of British Architects, of Civil Engineers, etc., before they had established their claims to a charter; and if the examination of midwives be politic, the Obstetrical Society may as well do it, till some other voluntary body steps into their place. But then comes the question, Is it desirable to extend the system of employing *howdies*, as they are called in the North? Would it not be safer if every labour were superintended by a qualified Practitioner?

RINGING THE DOCTOR'S BELL.

SOME time since we published the case of a boy whose tooth had been extracted by a Surgeon, who had been annoyed by the young scapegrace pulling his bell as "a lark." An action was brought against the Surgeon, and he had to pay damages. We have now to record a case somewhat similar, and in which the Doctor was again made defendant in an action. At Burnley, last week, Dr. Dean, a member of the Town Council, and in large practice, was charged with unlawfully, maliciously, and feloniously applying a certain corrosive to the forehead of Louis Calverley, with intent to disfigure, etc. It appeared, in evidence, that about a fortnight since the boy went to the Doctor's house to examine the bell-handle, which is in the shape of a closed fist. The bell rang, and the defendant came out. He took the boy into the surgery, and wrote the word "Bell" on the boy's forehead with caustic. The legal advisers on either side had a long consultation, the result of which was the withdrawal of the summons on defendant making an apology and paying costs. Undoubtedly, in the two cases, the defendants went far beyond the mark in the punishment they inflicted; but we believe no magistrate would convict a Surgeon of an offence if

he gave the runaway ringer a good horse-whipping. However, all things considered, we advise our brethren on no occasion to take the law into their own hands. Magistrates deal sharply with the silly and offensive people who ring Doctors' bells for amusement. Only last week, Mr. May, an undergraduate of Trinity College, Cambridge, was charged at the police-court with ringing Dr. Ransome's bell in Jesus-lane, and notwithstanding an offer to apologise, and a good character from his college tutor, he was fined 40s. and costs.

SMALL-POX IN DUBLIN.—ISOLATION OF PATIENTS.

DR. ROBERT D. LYONS, in his report of the epidemic in the Hardwicke Small-pox Hospital, Dublin, for the year ending March 31 last, says of the small-pox cases:—The admissions during that period were 612, and the deaths 121. Of the former 542 were found to have been vaccinated, 66 bore no marks of vaccination whatever, 4 were doubtful, and at least 3 had been revaccinated. Of the mortality of the non-vaccinated, only 12 out of 66 recovered; while of those protected by vaccination, 478 out of 542 recovered. Dr. Lyons adds that the mortality in different wards of the institution varied a good deal at different periods of the epidemic. But of all the wards in the institution, those which had been, as it were, extemporised presented (singular to say) a markedly favourable contrast when compared with the better organised wards in regard to mortality. These extemporised wards received in all 103 patients, amongst whom there were but fourteen deaths. He had on other occasions, when abroad, experienced very successful results in the treatment of epidemic disease in huts, tents, and marquees of the simplest construction. He was not so sure that palatial erections will be found the best for the treatment of any form of disease when tested by statistical results as to cures and deaths.

SMALL-POX JOTTINGS.

THERE were three deaths from small-pox during the past fortnight in Newington.—In the same period five deaths from the disease occurred in Chelsea.—There were fifty-four fatal cases of small-pox in the metropolis last week.—The return for the past week of the Aberdeen Small-pox Hospital shows:—Total number of cases admitted since opening, 214; new cases admitted on Saturday, 2; number of patients now in Hospital, 17; total discharged recovered, 162; total dead, 35.—The small-pox epidemic which has infected Edinburgh since the beginning of the winter is now considered to be virtually at an end.—In the Whitechapel district one new case of small-pox was reported last week.—In the same period one death from small-pox was reported to the Bermondsey Vestry.—Small-pox showed a decline last week in the metropolis, thirty-seven deaths only having occurred. In the two previous weeks the numbers were fifty-four each week.—Dr. Aldis, St. George's, Hanover-square, reported three cases of small-pox last week, two of which were sent to Hospital.

DISAPPEARANCE OF SMALL-POX IN PARIS.

THE Paris correspondent of the *Daily News*, writing on the 2nd inst., says:—"The small-pox, after gradually declining in Paris for the last two years, has now utterly disappeared from the bills of mortality. There is not a single case in the last death returns; and yet in this country there is no compulsory vaccination, and during the war and the Commune revaccination, in favour of which there was a feeble movement at the beginning of 1870, almost entirely went out of fashion. The reward of half-a-crown which the mayors are prepared to give to any poor woman who brings her child to be vaccinated, finds few takers among the classes which entertain a prejudice against the Jennerian specific. It is very perverse of unvaccinated Paris to be free from small-pox, while the disease rages in vaccinated London; but there are the hard facts, which I leave Doctors to reconcile with their absolute theories."

TESTIMONIAL TO AN ENGLISH PRACTITIONER AT PAU.

WE are always glad to hear of instances like the following in which a member of our Profession receives a valuable token of the esteem of those amongst whom he has lived and laboured. It having become known that Dr. Ottley, of Pau, was about to retire from practice, a number of his patients, friends, and Professional brethren determined on presenting him with a testimonial of their regard on his leaving France. On Tuesday, May 28, an elegant purse, bearing a suitable inscription, and containing a cheque for £328, was presented to Dr. Ottley in the name of the contributors by the Hon. Col. Spencer, the Rev. W. Tait, and the Rev. G. Brown, who added many kind expressions of regret at the departure of himself and family from Pau, where they had resided more than twenty years.

SMALL-POX AND VACCINATION IN PHILADELPHIA.

OUR American correspondent writes:—

"I have several times alluded in my letters to the prevalence of small-pox in Philadelphia. It is fast dying out here, and does not seem to be increasing in New York or elsewhere; and the results are already being systematically recorded for present use and future reference. Dr. William M. Welch, Physician in charge of the Small-pox Hospital of this city, has recently published his annual report for 1871, including statistics of 1227 cases of this disease treated there. A very large number of cases have been sent there for treatment since January 1, 1872, but these will, of course, be comprised in the report of the current year. It is a well-known fact that Philadelphia has never before been visited by an epidemic of equal magnitude or malignancy; and whatever statistics may be published hereafter, embracing a history of this recent invasion in its entirety, I will send you. Of the 1227 cases admitted, 361 died, or 29·42 per cent.; the rate of mortality among the variola cases being 52·14 per cent., while among those of varioloid it was only 1·45 per cent. The distinction between variola and varioloid, however, is not exactly the one universally adopted, and might not, therefore, correspond with statistics of other Hospitals, where the line is somewhat differently drawn. Dr. Welch classifies all diseases as varioloid which have been vaccinated, and in which the rash reaches its height on or before the sixth or seventh day from its appearance; and as variola all unvaccinated cases, and all others in which the rash has not arrived at maturity prior to a period varying from the seventh to the tenth day. During the same period, in the city at large, the Health Officer reported 8114 cases of small-pox, of which 1879 died, the rate of mortality being 23·15 per cent., which is, doubtless, the largest death-rate ever known in our city from this disease. The following table, derived from Dr. Welch's report, explains itself:—

	Admitted.	Died.	Per cent. of deaths.
Not vaccinated	390	254	65·12
Vaccinated in infancy—			
Good cicatrix	332	33	9·93
Fair „	166	27	16·26
Poor „	301	68	22·59
Total number vaccinated	799	128	16·00

"All the figures given lead to the indisputable confirmation of the importance of vaccination, and especially to the necessity of legislative enactments for the protection of every new-born babe by making vaccination absolutely compulsory."

A WELL-EARNED PENSION.

THE Middlesex magistrates have just granted a superannuation of £466 to Dr. William Chapman Begley, the Medical Superintendent of the male department of the Hanwell Lunatic Asylum. Dr. Begley richly deserves the annuity. He held the appointment for a period of thirty-four years, and fulfilled the important duties entrusted to him with an ability, energy, and humanity worthy of all praise. He was the efficient coadjutor of Conolly in carrying out the system of non-restraint. The magistrates, in granting the annuity to Dr. Begley, passed a warm eulogium on his conduct, and expressed a hope that "he might live many years to enjoy the pension so well deserved."

ISLINGTON MEDICAL SOCIETY.—DECLARATION ON ALCOHOL.

AT a meeting of the members of this Society, held on May 28, the following resolutions were adopted:—

"That this Society does not admit that there is any ground for the belief that alcohol is carelessly prescribed by the general body of Medical men. The Society therefore protests against the recent Declaration as uncalled for, unjustly laying a large body of Professional men under a stigma, and implying a confession in which the members of the Society decline to participate.

"That this Society protests against a scientific question, such as the therapeutic use of alcohol, being made the subject of a general declaration like that lately signed by many Physicians and Surgeons. This Society, while desirous also that the Medical Profession should use its influence in favour of temperance, and of legislation favouring temperance, thinks the Profession should act quite independently of any association holding extreme views.

"That the above resolutions be published in the weekly Medical journals."

ARMY MEDICAL DEPARTMENT.

IT is now stated, in well-informed circles, that the issue of the warrant so long looked for, and which is to do so much in this department and the Military Hospital Service, is stopped—it is said by the Treasury—some hitch having occurred.

FROM ABROAD.—THE LIÉGE TABLE OF FEES—THE MEDICAL PROFESSION AND THE FRENCH NATIONAL ASSEMBLY.

THE frequent attempts that have been made by Practitioners of different localities to bind themselves down to tables of fees which they have agreed upon, have hitherto not proved very successful. The greater *esprit de corps* that prevails among our brethren of the Continent gives them, perhaps, a better chance of succeeding, and, as their payments are generally wretchedly low, they have more reason to renew the attempts. At all events, those of Liège have resolved to try their hands, and a report addressed to them by Dr. Hieguet contains some passages worthy of attention. He begins with a comparison of the payments made to the lawyer and the Doctor, maintaining that the notable differences which exist in favour of the former are not justified either by the nature or the importance of the services rendered. In the nature of things, the Doctor, to whom the preservation or restoration of the most precious of possessions is confided, should be paid as well, if not better. One point he lays stress upon, too, is that there is less urgency in the appeal made to the lawyer, who may consider his cases at his leisure and fortify himself with his authorities; whereas the Doctor, whether by day or night, tired, or aroused from sleep, must at once, without delay, and often without any aid, come to a decision which may be of the last importance, entailing the most serious responsibility, and perhaps even marring his prospects for life. The lawyer encounters none of the risks to life that beset the Doctor throughout his career, whether as student or Practitioner, and to which so many fall victims. While he, too, has his assured leisure and his vacations, during which he may dismiss anxieties which are ever cankering the unfortunate Doctor, who cannot even feel assured of an undisturbed night or an uninterrupted meal. If, says the reporter, the public does not remunerate us in proportion to the services we render, this is entirely our own fault, and especially is it the fault of our seniors, who, solely engaged in attracting practice and fortune by display of their titles, have done little or nothing to raise the general prestige of the Profession—when, indeed, they have not competed for practice with young Practitioners and by aid of reduced fees. However, the remedy is in our own hands, for no law or regulation has fixed the charges between Practitioner and patient.

"How, then, ought the Doctor regulate his charges? As a general rule he should follow the example of the advocate. The man of law, taking into account the importance and issue of the cause, the labour of the investigations it has rendered needful, and the position of his client, charges a lump (*globale*)

sum. And so should the Doctor demand a round sum as his remuneration. Is not what happens nowadays absurdly unjust and ridiculous? You treat a wealthy person for some serious epidemic disease—say the cholera—which will either be cured or carry him off in some hours; and if you take as a basis the valuation of your charges by the number of visits, you will perhaps make a demand of twenty or thirty francs. But if the same person had become the subject of an affection unattended with danger, and not of a contagious character, and liable to relapses—as in neuralgia, for example—then your bill may relatively amount to a considerable sum. Is this just or reasonable?

“When in the same house there are several patients belonging to the same family, some of our *confrères* ask only half the price of a visit for the second or third patient, etc. We cannot give our approval to this mode of proceeding—in fact, it is not the journey to the house which constitutes the service rendered by the Doctor, and which has to be remunerated, but the attention which he has to pay to the patient; and the same attention to his case is required for every patient, however near they may be to each other. By such a rule we should act unjustly in charging a patient who lived next door the same fees as one who lived in a more or less distant street. I have yet to learn that a lawyer does not claim his entire fee when he defends the interests of a client in two different trials, or of two clients who are relatives residing under the same roof. Therefore the Doctor ought, as far as possible, make his charges *in globo*. But as there are many circumstances under which this is not possible, as in slight affections, calling for few and separated visits, we must also have a charge based upon the number of these. For persons who are able to pay a Medical man, we would fix three francs as a minimum charge for a single visit. When the patient moves in a higher circle we should charge more, and even double this sum.”

The following is the tariff adopted by the Medical Practitioners of Liège:—A simple visit or advice given by the Doctor at his own house, 3 fr.; a first visit, an urgent visit, one repeated at request in the evening or at a fixed hour, 6 fr. (the charges for visits paid to patients suffering from contagious diseases “should be left to the appreciation of the Practitioners”); a consultation during the day, 15 fr., and in the night 25 fr.; for every hour passed with the patient during the day 15 fr., and during the night 20 fr.; night visits (from 10 p.m. to 7 a.m.), 15 fr.; certificates, according to their nature, from 5 fr. to 20 fr.; a written opinion, 5 fr.; visits beyond the town to be charged at 20 fr. the league, the expenses of the journey being also paid by the patient. In minor Surgery the following charges are to be made:—(1) Venesection, extraction of a tooth, cauterisation, or dressing, 5 fr.; (2) application of a speculum, opening an abscess, catheterism, application of a bandage, seton, or issue, and vaccination, from 10 fr. to 15 fr.; (3) reduction of a hernia, tapping a hydrocele or an ascites, 25 fr.; (4) reduction of a dislocation or fracture, and paracentesis in empyema, independently of ulterior treatment, 50 fr.; a simple accouchement, 75 fr.

Notwithstanding the presence of above thirty Doctors of Medicine in the French National Assembly, the prospects of Medicine do not put on a very promising aspect in that supreme body. Many, indeed, regret the haste with which an appeal to it has been made for a reorganisation of the practice and teaching of Medicine and various other matters appertaining to our art. It would probably have been far better to have waited until the Assembly had acquired more deliberative power than it now seems to possess, or even to have deferred these subjects for the consideration of its successor—to be elected, it is to be hoped, in less exciting times. There would then have been time to have submitted the matters intended to be brought under its cognisance to a preliminary consideration by the Profession itself, which would have much aided the future deliberations of the Legislature. In the absence of this, there is danger of the Assembly passing some crude measures without any knowledge of their probable operation; and as its decisions are controlled or corroborated by no second Chamber, the Profession may unexpectedly find itself involved in some dilemma, the fruit of hasty, ignorant, or prejudiced legislation.

That all is not going on very well there may be concluded from a recent debate on the Bill for the “Composition and Organisation of the Administrative Commission of Provincial Hospitals and Hospices.” These are bodies upon which devolves the entire management of Hospitals, and, therefore, in their composition the Profession naturally desires to be represented. Consequently, after the members of the Commission had been selected from the municipalities, the council-generals, the prefecture, the courts of justice, chambers of commerce, and the pastors of the different religious persuasions, and it was found that there was no mention made of any Medical element, Dr. Chevandier, one of the Doctor-deputies, made a motion that the Doctors of the canton or the Council of Hygiene of the arrondissement should also nominate a member of the Commission. He supported it by various arguments, familiar enough to our readers, as demonstrating the utility, or rather the necessity, of a Medical member for the due consideration of questions of Hospital construction and management. He was listened to but impatiently, being frequently interrupted by the ominous “Divide!” However, Professor Bouisson, Dean of the Faculty of Montpellier, followed, and having the ear of the Chamber, and being an eloquent speaker, was listened to attentively, he having had the tact to commence his discourse with complimentary generalities as to the great value he attached to the non-Medical elements of the Commission. Afterwards he went on to dwell upon the importance of there being also a Medical member, for among other reasons, the interests of clinical instruction, which mere administrative commissions too often unduly restrict. Here he struck upon a sunken rock, as he soon found out to his dismay. After expatiating upon the many sacrifices which Medical men make in the service of the poor, and upon the readiness with which they at all times aid the cause of progress by the light of science (a sentiment responded to by cheers), he proposed a modification of M. Chevandier’s motion—viz., “That when there is in the chief town of a department a Faculty of Medicine or a preparatory School of Medicine, a member of the Commission shall be elected by such body.” This seems a modest proposition enough, but the Reporter of the Committee on the Bill was not of that opinion, and, after complimenting Professor Bouisson as one of the most illustrious representatives of the glorious Medical science of France, he declared that he could have nothing to do with his motion, which would create a new electoral body. When the Commission wanted Medical advice it would know where to look for it. And then he added, amidst loud cheers, that M. Bouisson’s argument in favour of clinical teaching was a powerful reason for rejecting his motion; for did it not go to place science before charity?

“When I heard the eminent man who has just addressed you,” concluded the Reporter, “speak thus of the interests of science and the needs of the clinic, and perceived under these words the necessity of having subjects for study and experiment, and when he spoke of the possible discussions on questions of this kind, I felt that we were even more right than we supposed ourselves in opposing the motion.”

The amendments were both lost. If this is a specimen of what the Profession has to expect at the hands of the Assembly, we can only wish it a happy deliverance from such friends.

PARLIAMENTARY.—SURGEON-MAJOR LOGIE—PUBLIC HEALTH (SCOTLAND)—INFANT LIFE PROTECTION—PUBLIC HEALTH BILL—SUPPLY—MILITIA SURGEONS.

In the House of Commons, on Thursday, May 30,

Lord Garlies, amid repeated manifestations of impatience, more especially from the Ministerial side of the House, put a long question to the Secretary of State for War on the subject of a reprimand which Surgeon-Major Logie had received for making a report (confirmed by two other Surgeons and other independent witnesses) to the effect that, owing to effluvia from drains, part at least of Windsor Cavalry Barracks was unfit for occupation.

Mr. Cardwell said he was not surprised that the House should have manifested some signs of impatience at a detailed question of that kind, because it was quite open to an officer who felt himself aggrieved by any reprimand which he might have received from the Field-Marshal Commanding-in-Chief to make a proper representation through his superiors, which would most certainly be attended to by his Royal Highness. He submitted to the noble lord, who had himself been an officer in the Guards, that it would be more likely to conduce to discipline in the army that such a course should be pursued, than that *ex parte* statements should be placed on the paper of the House in the form of a question addressed to him. As the question had been put, perhaps the House would allow him to give an answer. (Cries of "No, no.") Well, then, since the House did not wish that he should give an answer, he would suggest to the noble lord to advise Surgeon-Major Logie to make a representation through his commanding officer to the proper quarter.

Lord Garlies thought it would be satisfactory to the House if the right hon. gentleman answered the question. ("No, no," and "Hear.") He wished to know whether the right hon. gentleman declined to answer.

Mr. Cardwell: I can only repeat what I have already said. I collect from what has occurred that it was not the wish of the House that the question should be put, and it is not their wish that I should proceed to give an answer.

Lord Garlies: Well, then, I beg to give notice that I shall call the attention of the House to this subject on the earliest opportunity.

The Public Health (Scotland) Supplemental Bill passed through Committee.

The Infant Life Protection Bill was read a third time and passed.

On Friday, May 31, in reply to a question by Sir M. H. Beach,

Mr. Stansfeld said that the Public Health Bill contained no clause which imposed a fresh charge upon the public revenue. Whatever charges there were would be voted from year to year.

In Supply, some opposition was made to the votes for the Medical and Cattle Department expenses of the Privy Council. The votes were ultimately passed.

On Tuesday,

Colonel Corbett asked the Secretary of State for War whether he was now prepared to state how Militia Surgeons were to be remunerated for the losses they would sustain by the new regulations, which transfer those portions of their duties to the Army Surgeons for the performance of which the greater part of their emolument had hitherto been derived.

Mr. Campbell (in the absence of Mr. Cardwell) said his right hon. friend had nothing to add to what he had previously stated on the subject. If any claims were preferred on the part of Militia Surgeons, his right hon. friend would at all times be ready to give them due consideration, but he had not prepared a general scheme for compensation to those officers.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

PROFESSOR HOLMES commenced his series of lectures on "The Surgical Treatment of Aneurism in its various forms" at the Royal College of Surgeons on Monday, June 3. In his first lecture, after briefly acknowledging the honour which he felt had been done him by being appointed Professor of Surgery and Anatomy in the College, he stated that his reasons for selecting the subject of aneurisms for his lectures were chiefly three—viz., the length of time since it had been dealt with by any of the able Surgeons who had been his predecessors in that chair, and the great change—or, in fact, the revolution—which had been brought about in the meanwhile in the treatment of aneurisms; because the treatment of aneurisms, besides being a subject of immense importance, was one about which there was much doubt and difficulty; and because so much interesting and valuable material, both in the literature and the pathology of the disease, had accumulated within the last few years, that he thought if he could bring the whole together into a uniform and intelligible phase much good might arise therefrom. The Professor then referred to the treatment of aneurism—which, though admirable, is now obsolete—as described by Guthrie forty-three years ago in his work on "Diseases and Injuries of Arteries"—one of the English classics of Medical literature. At that time the treatment by

pressure was in its infancy, and Guthrie barely notices it; and though Wardrop's operation was more fully described, Hunter's method was regarded by him as the only important mode of treatment. Other plans now occupy important positions, such as that of flexion of joints, which has been sometimes rapidly effective; and the method of rapid pressure under chloroform.

In the treatment of thoracic aneurisms Mr. Holmes warns us that the various methods are not to be repudiated simply because hitherto they have been unsuccessful.

After mentioning that the time at his disposal would not permit him to discuss the pathology and symptoms of aneurism, nor enumerate statistics except for the purpose of supporting arguments which he used, and after acknowledging the services he had received in his investigations from a great many—especially the Dublin Surgeons, and more particularly Dr. William Stokes—the Professor went on to state the propositions which he intended to bring under notice in these lectures. The first was that no form of aneurism is to be regarded as incurable. Aneurisms of the arch of the aorta are not necessarily so, for judicious Medical treatment is almost always attended with good results, and the partial consolidation of the tumours by these means by delaying their progress amounts well-nigh to a temporary cure. The objection which has been sometimes raised to such partial consolidation—viz., that it causes a corresponding increase in some other part of the sac—is theoretically and practically untenable, because the increase of an aneurism is a process of actual growth attended with softening, and sometimes of inflammation of the sac, and is not due merely to the mechanical influence of the blood.

In admitting the difficulties attached to any attempt to cure a *fusiform* aneurism, especially such an one as was exhibited extending from the innominate to the axillary artery, the Professor pointed out that aneurisms of this shape were fortunately less painful than other forms. Regarding growing aneurisms of the great vessels of the thorax as fit and fair cases for treatment, the question arises, What means have we at our disposal? The answer given is, Three—first, Medical treatment; second, Brasdor's operation; and third, galvano-puncture, omitting, however, all consideration of the method of the late Mr. Moore, which besides being ineffective is unquestionably dangerous. Mr. Jolliffe Tufnell has exhausted the subject, first prominently brought forward by Valsalva, of the Medical treatment of aneurisms; but as to the effect of drugs, Dr. Bristowe's opinion must receive sanction—viz., that there is no Medicine which can bring about spontaneous coagulation of blood in an aneurismal sac—for were this the case, such a Medicine would be itself dangerous, as being liable to effect coagulation in other parts of the vascular system. Moreover, aneurisms have been known to develop themselves while the subjects of them have been under the influence of lead, or undergoing a course of treatment by iodide of potassium.

No Surgical treatment of any kind is justifiable for internal aneurisms until Medical means have been fairly tried and failed.

The second proposition advanced was, that there is definite proof of the good effects of Brasdor's operation, when employed for innominate aneurisms.

After alluding to the difference between Brasdor's operation and the method of Wardrop, the theoretical reasonings by which the adoption of Brasdor's mode has been recommended were stated. Hodgson, however, must have the credit of first employing it from a consideration of the pathology of the disease. The Professor produced some pathological facts showing the effect of the spontaneous distal obliteration of arteries in innominate aneurism; and he drew the conclusion that in those cases where the spontaneous distal obliteration of the subclavian artery has taken place, the distal ligature of the carotid may be trusted to produce complete obliteration of the sac. An instance of the cure of an innominate aneurism from the distal impaction of a clot in the carotid was given. This was exactly analogous with a case of the distal ligature of the carotid by Dr. Wright, of Montreal. Professor Holmes also pointed out the little advantage likely to ensue upon the ligation of the subclavian in the third part of its course. The large size of the branches which come off from the first part of the subclavian allow such a large quantity of blood to flow on through the sac, even after the direct supply to the upper extremity is cut off, that the aneurism is not put under the conditions necessary for the deposit of a laminated clot. Attention was drawn to the manner in which a clot extends into the aneurism from the ligatured or obstructed vessel, and drawings of specimens illustrated how the portion of the sac nearest to the mouth of the ligatured artery becomes gradually solid from deposited fibrine.

"THE LONDON HOSPITAL SCANDAL."

(From a Correspondent.)

SOME time has now elapsed since a correspondent suggested that all the facts and documents connected with the above subject should be published. These facts are stated by two of your contemporaries to be fully known to them. They, nevertheless, whilst studiously withholding their publication, have not hesitated to try to clear Mr. Rivington and to throw discredit on Mr. Maunder. They have thus assumed the position of irresponsible judges, who give their award without stating the grounds upon which it is based. By this suppression of the case they seek to impose their own decision upon the Medical Profession, giving their readers no opportunity of judging for themselves, or of knowing how far the decision is justified. This course of procedure is so entirely at variance with the course of law, of justice, and with the common practice of Englishmen, that it is impossible not to excite suspicion that the case is one that cannot conveniently be stated.

To burke the case, and then to declare that under no circumstances can one member of a Hospital staff be justified in giving information concerning the conduct of a colleague to those in whom the government of the Hospital is vested, is simply monstrous. There are two hypotheses, at least, under either of which such justification would exist:—First, there might arise circumstances so flagrantly dangerous to the reputation of the Hospital that they ought not for a moment to be concealed from the governing body. Secondly, the constitution of the Medical staff might be such that courageous and honest concerted action could not be counted upon, or might be too long delayed. We do not wish to insinuate that either of these hypotheses applies to this case. But the persistent suppression of the facts seems to suggest that one or the other, or both, are true. It is obvious that no man can be rightly condemned even for the perpetration of what *prima facie* is the most heinous offence, unless the whole facts leading up to it—the apparent crime—are investigated. For example, one man shoots another. *Prima facie* this is very wrong. But will it be said that under no circumstances it is justifiable to shoot a man down? It may be found, under a properly conducted trial, that the man so shot was trying to take the life of the man who shot him. To pretend to decide upon an act without reference to its causes is not very logical or scientific.

The position appears to be simple enough. If your contemporaries are anxious for the truth, and to enable their readers to form a just and satisfactory opinion, let them state the case, as well as their verdict. Mr. Maunder has openly and repeatedly challenged them to arbitration. From this they shrink. Why? They know best. It is not generally those who are confident of having done right who shrink from free inquiry. We cannot be expected to bow to the dictum of those Rhadamanthine journalists who first castigate, then hear.

It is quite certain, however, that open inquiry will be demanded by the public and by the governors of the London Hospital. In the interest of the Hospital it must take place. To be satisfactory and final, that inquiry must be full, fair, and open. The reference must not be limited to parts of the case, but must embrace the whole. The court of arbitration must fairly represent the public and the Hospital as well as the Medical Profession. Mr. Rivington and Mr. Maunder must both have the opportunity of being represented upon it. A court confined to Surgeons alone would not carry complete confidence; Physicians also must be represented. The question of the relations of the staff to the governors is a wide one, which cannot be decided by Medical men alone. A court from which laymen were excluded could not render a satisfactory or final decision.

A STARTLING statement is contained in the report of the Medical Officer of Health for Bermondsey, laid before the Vestry on Monday last. He says that for three months the Southwark and Vauxhall Water Company have been supplying water to the district contaminated with gas-tar. "As this is still continued," adds the Doctor, "I think the Company should be called upon for an explanation."

THE FIRST REPORT OF THE LOCAL GOVERNMENT BOARD.

(Continued from page 580.)

DISPENSARIES.

CONSIDERABLE additions have been made during the past year to the number of Dispensaries, and at the date of the Report there were thirty-seven in working order, six in course of construction, and seven more in contemplation, making a total of fifty. These were distributed through twenty-seven unions and parishes.

The report contains the following observations on the subject of the register which is required to be kept by the Medical Officer at each Dispensary:—"The Medical Register, with its alphabetical index, supplies an easy mode of referring to the treatment pursued in each case, and of testing the grounds for any complaint that may be made. It supplies, also, valuable material for the Medical Officer of Health of the district, to whom, during office hours, it is always open; and should an adequate registration of disease in public institutions hereafter be found possible, its utility will be still more apparent. Equally beneficial are its results to the District Medical Officer himself. Working in greater publicity than heretofore, his sense of responsibility is heightened, and his energies stimulated."

The Report refers to the regularity of the attendances of the Medical Officers generally at the Dispensaries, and also to the mode of establishing an adequate control over the expenditure of drugs.

We look in vain, however, for any indication of an intention to extend to the provinces, or at all events to large towns, the system which the Report admits to have answered well in the metropolis.

PUBLIC HEALTH.

We next turn to the administration of the laws relating to the public health. This is treated of in a separate report by Mr. Simon, who says of the epidemic of small-pox—"It was marked, first, by the extraordinary multitude of persons whom the disease attacked; and, secondly, by the extraordinary intensity of the disease in its individual cases. To illustrate the latter point, it may suffice to mention that at the London Small-pox Hospital, where 950 cases were treated during the year, the deaths in proportion to the cases were nearly twice as many as the average experience of the Hospital for thirty-two years would have prognosticated. . . . The present great epidemic of small-pox is not confined to our own country. In the chief towns of Holland, where vaccination is non-compulsory, and where, as a rule, the children are long left unvaccinated—in Hamburg, with non-compulsory vaccination—in Paris, where not only vaccination is non-compulsory, but where also, at least some years ago, there were strong grounds for suspecting the quality of much of the current vaccination—in all these places the epidemic seems to have raged with very much more severity than even in London; and it is stated that Hamburg, which, though having but a tenth part of our London population, suffered nearly two-thirds as many deaths as London, has now, under influence of this terrible suffering, been led for the first time to pass a law of compulsory vaccination."

The report then refers in detail to the proceedings taken by the department for securing the strict enforcement of the laws relating to vaccination and to the removal of nuisances and prevention of infectious diseases, with the view of stamping out the epidemic.

On the subject of the means for the prevention of disease the following observations are made:—"The extensive diffusion of small-pox in England, like the great scarlatinal epidemic of two years ago, brought into prominence the evil results of the general want throughout the country of Hospital accommodation for cases of dangerous infectious disease."

With regard to the steps which were taken with the view of securing revaccination when necessary, the Report remarks that "early in the London epidemic it became the duty of the department to issue for general information a memorandum on the use of revaccination, as an additional safeguard which persons who have been vaccinated in infancy ought in general to adopt at about the age of puberty; and with this memorandum were issued also some suggestions for Medical Practitioners with regard to the supply of lymph for revaccination. The epidemic brought into strong relief two popular errors with regard to revaccination—first, the error of

not having it performed on each person (irrespective of any immediate alarm of small-pox) on his attaining the above-mentioned age; and secondly, the error of seeking under panic to have it performed indiscriminately again and again."

Mr. Simon proceeds to comment upon the visitation of cholera to this country which was anticipated during last year:—"The second exceptional business of the Medical Department in the year 1871 depended on there being again in the summer some alarm of Asiatic cholera. Having for nearly two years been in Russia, and since August, 1870, more or less in St. Petersburg, the disease in the spring and early summer of 1871 spread somewhat considerably in the Baltic provinces of Russia, and at the end of July began to touch the contiguous parts of Germany, where soon afterwards Königsberg suffered most severely. With cholera actually epidemic at St. Petersburg, Cronstadt, and Riga, and likely soon to become epidemic at ports still nearer to England, it was evident that ships from the Baltic might in certain cases be a source of danger to this country. At first the danger was comparatively remote, in the sense that any sailor or passenger who had caught cholera in some Russian port of the Baltic would probably have ended the infectious stage of the disease in death or convalescence before the arrival of his ship in English waters; but afterwards, as more westerly points in succession got infected, including (early in September) Hamburg and Altona, the chances were greatly increased, not only that ships might arrive having had cholera on board, and with bedding and other things in need of disinfection, but also that an occasional patient, at the height of the disease, and pouring forth infective discharges, might be brought on shipboard into some English port; and it was therefore very satisfactory to know that, almost universally, fair provision for any such casualties had been made. The cases in which port authorities actually had to treat particular ship-arrivals as infectious were, I believe, very few; almost universally they were cases were death from cholera had taken place during the transit; and I know only of a single case—namely, at Hartlepool—where the authority had to receive into Hospital a cholera patient brought living into the port."

REVIEWS.

An Exposition of Fallacies in the Hypothesis of Mr. Darwin.

By C. R. BREE, M.D., F.Z.S., Senior Physician to the Essex and Colchester Hospital, &c. London: Longmans. 1872. Pp. 418.

THE author of this work shows himself to be an original observer in natural history, an acute critic, and impressed with deep religious feeling, although religion is not offensively obtruded, and there is none of the *odium* or bitterness which render theological controversy so painful to most persons. He attacks Darwinism root and branch, and gives us an elaborate and continuous criticism, not only of Darwin himself, but of all who have supported Darwinism. He begins with Tyndall, whose views he criticises so far as they uphold the correlation of physical and vital forces, or the view that the germination of a grain of wheat is but the modification of the physical force which governs crystallisation, and that life, as a whole, in all its processes of production and reproduction, is a necessary result of the existence of heat and motion. He next, under the title of the "Physico-Psychical Argument," takes up Mr. Herbert Spencer's biological views, and argues against evolution in favour of special creation. Mr. Darwin's own works then come under review, beginning with "Animals and Plants under Domestication," and going on to the latest essays on Sexual Selection. After this, Mr. Darwin's supporters in turn are weighed and found wanting, and amongst them Mr. Wallace, Professor Huxley, Sir C. Lyell, and Professor Hæckel. Mr. Darwin's supposed line of descent from the ascidians to man is analysed and condemned, and the work closes with an eloquent vindication of the teleological argument, enlivened and fortified with extracts from those eloquent lectures on the "Principle of Least Action in Nature," by Professor Houghton, which we had the gratification of printing in the *Medical Times and Gazette* of last year. When we add that there is a copious analysis of the views of Agassiz, Owen, Mivart, Flourens, Beale, and others, with a gallery of portraits and a genealogical tree of our Darwinian ancestors, it will be seen that Dr. Bree's work covers a great deal of ground, and enables persons who are not conversant with the subject to gather the gist of the arguments used on either side.

We can only indicate in general terms the line which Dr. Bree's arguments take. His work is an evidence of that

reaction which is now generally felt against any doctrine that is tainted with the slightest suspicion of atheism, materialism, or necessitarianism. He fights against "evolution" so far as it may be supposed to be governed by "Necessity," or by "Law," without the ever-present influence of the Lawgiver. If we understand him aright, however, he does not object to evolution *per se*, as inconsistent with our notions of the Divine Being, though he does not believe in it. "It will be noted," he says, "that there are two distinct kinds of evolution advocated by different schools. That which is taught by Mr. Darwin, Mr. Huxley, and Mr. Herbert Spencer is founded upon the operation of physical forces and secondary laws, without the supervision and guidance of an exterior power. The other kind of evolution is adopted by Owen, St. G. Mivart, and such able writers as the reviewers of Darwin's work in the *Edinburgh and Quarterly Reviews* for 1871; and this is simply an expression that evolution is the mode of creation, and that the Creator is the ever-present and guiding power by which it is perfected, and that such evolution may occur, and probably does occur, *per saltum*."

As a short practical comment on this, we cannot help saying that the safest plan is to regard the Deity, so far as we may venture to do so at all, as having both kinds of operation. It is difficult to conceive of an Eternal Being to whom past, present, and future are alike known and predetermined, acting *from time to time*, and not acting according to a settled law, which must be perfect; it is equally impossible to conceive of Him as absent from, or otherwise than perpetually upholding all things. To quote St. Ambrose's hymn,

"Rerum Deus tenax vigor
Innotus in se permanens,"

or, as it was Englished by Mason Neale,

"O God, Creation's secret force,
Thyself unmoved, all motion's source!"

If we understand Dr. Bree aright, his great contention is for the acknowledgment of a Creative Power, which shall "preside over all the changes of His creation," and who shall "guide, direct, and mould into shape, and call into being every living thing in the vast world." But whoever believes thus of the Creation and the Creator is surely at liberty, in the absence of Revelation to the contrary, to conceive of the Deity acting by secondary laws. "Let the waters bring forth," says the Book of Genesis. The Psalmist, too, says of the works of Creation, "He hath given them a law which shall not be broken."

The doctrines of natural selection, or survival of the fittest, and sexual selection are dismissed, as wholly unable to account for the origin of species, and as introducing into the plan of creation the notions of the "haphazard" and the tentative, where all is arranged on a plan, and perfect for its own end from the first. Certainly our author does not believe in evolution of a casual order; still, he intimates that the Creator has caused "some of the varied masses of life which people the earth" to become extinct, and "others to assume new and varied forms," and therefore countenances the idea that new animals are the offspring somehow of pre-existing ones.

There are many points which will strike the critical reader in perusing Dr. Bree's work, which we must not linger over. He repeats the old argument drawn from the Egyptian monuments against what is called "the transmutation of species," by showing that the animals depicted are such as flourish at the present day. This argument refutes itself, since, of course, the Egyptians could not have depicted any new animals developed since their time. On the subject of *species*, he clearly sees that some natural theologians would impose on us, and force us to believe that everything we may consider a species was created as such (p. 294). He speaks of the "difference between species as defined by man and those which are defined by Nature." Here, as elsewhere, some of the ultra-orthodox would put fetters on the human intellect, quite unsanctioned by authority. Some persons (as Gosse, in his book called "Omphalos") refuse even to argue with anyone who will not acknowledge "species" to be immutable from their creation to their extinction. But, for our own part, let us take any genus of plant, *P*, with many species, say *Pyrus* or *Plantago*. We conceive that a man may be a very good Christian, and yet believe that *Plantago major*, *P. minor*, *P. lanceolata*, *P. maritima*, *P. Alpina*, etc., may all have been developed out of one or more original *Plantago*. The same with cat, dog, and mouse, whether *per saltum* or gradually, but probably *per saltum*.

One of the strongest arguments of the evolutionists is the fact, not to be shirked, that variations of human structure are repetitions of structures common to animals—as was shown long ago by Tiedemann, by Professor Wood, and by Mr.

Beswick Perrin in our own pages. One of the weakest arguments used by Dr. Bree is that which accounts for animal-like variations of muscles, on the supposition that the skeleton is first of all abnormally formed, "the result of ancestral disease," and that "Nature steps in" and modifies the muscular structure. A pretty confession this for an anti-evolutionist! Lastly, we may refer to the argument from design, which has been ridiculously abused by men who gave fanciful explanations of structures they could not understand, and assumed that every structure must be of use to the individual bearing it. But for all that, it is irrefragable in itself, and the palpable evidences of it in Nature stultify all notions of necessitarianism. So, too, Dr. Bree nobly vindicates the doctrine that the world was created for intelligent men, and that beauty of colour and harmony of sound were designed for the delight of the senses, and the senses for them. Here we must end our notice of a work marked by great thoughtfulness, learning, and good taste.

NEW BOOKS, WITH SHORT CRITIQUES.

Epilepsy and its Cure. By G. BEAMAN, M.D. London: Renshaw.

*** This is the fourth edition of a practical little work on a disease often intractable, if not incurable. Dr. Beaman appears to have had considerable success in a plan of treatment he describes, and in this edition several new cases are added.

Guide to Trefriw and the Vale of Conway Spa. By Dr. JOHN HAYWARD. Second edition. London: Renshaw.

*** An account of a very pretty little village in the Vale of Conway, which contains chalybeate waters considered to be of much value in a great number of diseases. This little brochure is worthy of a perusal for those in search of health in many forms of chronic disease.

Spiritualism answered by Science, with Proofs of a Psychic Force.

By E. W. COX, S.L., etc. New edition. London: Longmans.

*** Serjeant Cox is a shrewd lawyer and an able judge; and we venture to say the "proofs" he adduces in this really clever book would not be received by him as evidence of the smallest fact at the Middlesex Sessions. We might parody a line of Pope without offence to the learned serjeant,—

"Simple at Highwood, wise at Clerkenwell."

The Influence of Vaccination, Age, Sex, and Occupation on the Mortality in Small-pox. By Dr. GRIEVE, M.D. London: J. and A. Churchill.

*** This is a very interesting paper on the existing epidemic. Dr. Grieve gives in a detailed form the statistics of a large number of cases, and shows the influence exercised by vaccination, age, sex, and occupation on the rate of mortality in small-pox, the result of his own personal experience.

FOREIGN AND COLONIAL CORRESPONDENCE.

AUSTRALIA.

MELBOURNE, March 28.

A LEGAL PARADISE: CLURSON *v.* BLAIR; MOORE *v.* MOTHERWELL; CROOKE *v.* VAN HEMERT.

THE action of Clurson *versus* Blair, tried in the Supreme Court of this city in the beginning of this month, was one of great significance to the whole Profession. It occupied the Court nearly a week, and the verdict was received with general satisfaction. The plaintiff was a woman of no personal attractions, who some years ago was a patient of Mr. John Blair, L.R.C.S. Edin., the defendant, when he practised in a suburb of Melbourne. The history of the relations between Mr. Blair and Mrs. Clurson extended over four years. She appeared to have contracted for him that utterly absurd but furious affection which mature women sometimes entertain for young men. Her regard had been manifested in a hundred different ways; and Mr. Blair, being of a good-natured, easy, jolly disposition, was only amused at the assiduity with which his elderly patient and admirer urged her love. In 1867 Mr. Blair married a lady to whom he had been long engaged, and from that time Mrs. Clurson pursued him with a relentless bitterness and a hatred that nothing seemed to appease. She told her husband that Mr. Blair had assailed her virtue on three different occasions, but that she had come triumphantly

out of the trial. Mr. Clurson believed her, and he had good reason, for she might safely have been left with the most unappeasable satyr that ever existed. The two, however, set to work to "devise engines" for the moral life of their victim. Letters of a filthy description were written to Mrs. Blair, to Mr. Blair's mother and sisters, to his private friends, and to all his patients, accusing him of infamous crimes. Mr. and Mrs. Clurson went into public wherever Mr. and Mrs. Blair were to be found—at balls, theatres, etc.—and grossly insulted them; and at last they brought an action, accusing Mr. Blair of three "indecent assaults," committed, as alleged, eight or nine years before, and of sending to them an indecent photograph. Never was there such a discomfiture of a conspiracy. The "indecent assaults" were found to have been nothing more than very ordinary Professional attentions when Mrs. Clurson had had hysterical seizures in Mr. Blair's consulting-room, and the indecent photograph was shown to have been made indecent by someone else than Mr. Blair. Altogether the scandal was a very rank offence against decency; but as all the indecency was shown to be on the side of the plaintiffs, Mr. Blair came out of the ordeal unharmed. But the trial has caused a good deal of consternation in the Profession, because it is felt that any Medical man may suffer a similar persecution to that of which Mr. Blair has been the victim.

Another action in which the Medical Profession was intimately concerned came off on the 19th. Dr. Moore, a suburban Practitioner, sued Dr. Motherwell, the Senior Physician of the Melbourne Hospital and a member of the Council of the University, for damages for an alleged slander committed in the course of a discussion in the Council of the University, when Dr. Moore, who had taken the M.B. degree of the Sydney University, applied for admission *ad eundem* in Melbourne. Dr. Motherwell had expressed some doubts as to the manner in which the degree had been obtained; and this being reported to Dr. Moore by Dr. Cutts, another member of the Council, the action was forthwith instituted. But when the trial came on, Dr. Cutts could not remember the words which had been used, and so the judge nonsuited the plaintiff. It was well understood, however, that the real reason why the action was brought was to air the grievance of the *ad eundem* being refused by the Council. The Sydney University are granting Medical degrees much as the Scottish universities used to grant them thirty years ago—namely, after a nominal examination—and it is felt that it would simply destroy the prestige of the Melbourne University if these easily acquired qualifications could insist upon recognition here.

Two other actions are pending—one by Mr. Crooke, M.R.C.S., against Mr. Van Hemert, M.R.C.S., for a libel contained in a pamphlet entitled "What a Surgeon may suffer in Victoria"; and another by a Dr. Lloyd against the publishers of the *Australian Medical Journal*, for an alleged libel contained in a leading article reflecting upon that person as a member of the Diphtheria Commission. And *à propos* of this Commission, it is now in full operation, and the Profession is being summoned right and left to give evidence before it. A feeling of general indignation is experienced at the humiliation to which this exercise of authority subjects those who are so summoned, for I suppose no official body was ever held in such thorough contempt as is this Commission; but as they have the law on their side, there is nothing for it but to submit.

The election of two additional Assistant-Physicians to the Melbourne Hospital took place on the 13th, the result being the success of Dr. Lilienfeld (a German) and Dr. Lawrence (lately the Senior Resident). Dr. Patrick Smith, who for four years and a half has been the Resident Surgeon of the Benevolent Asylum, resigned that appointment about a fortnight ago, in consequence of having been appointed Resident Medical Officer of the Ararat Lunatic Asylum. Dr. Little has been elected in his place.

THE COUNTY AND CITY OF WORCESTER PAUPER LUNATIC ASYLUM.—The nineteenth annual report of this asylum, just issued, states that the receipts for the past year were £16,782 17s. 9d., and the expenditure £15,316 2s., leaving in hand a balance of £1466 15s. 9d.; that at the beginning of the year there were 644 patients, and during its course the admissions had been 175, making the total number under treatment during the year 819—viz., 372 males, and 447 females; that 79 patients were discharged as recovered, 24 patients were removed relieved, 10 patients were removed unimproved, and 81 patients died during the year, which left, on December 31, 290 males and 335 females under care in the asylum.

PROVINCIAL CORRESPONDENCE.

IRELAND.

DUBLIN, June 4.

At last a decided step has been taken with a view of securing for the subject of sanitary legislation in Ireland the attention it deserves. In the laudable effort to improve the hygienic condition of this country the Medical Profession has taken the lead, a thoroughly representative deputation from the Irish Medical Association, the King and Queen's College of Physicians, and the Royal College of Surgeons, having waited on his Excellency the Lord Lieutenant on Friday, May 31, to urge the necessity of appointing a Royal Commission to inquire into the state of the public health.

Earl Spencer received the deputation in a very cordial manner, and expressed his opinion that the issuing of a commission might possibly cause too long a delay in effecting the necessary reform—a contingency which, especially in the present insanitary condition of the country, was to be avoided if practicable.

Dr. Stokes dwelt on the subject of epidemics in Ireland, and strongly advocated the issuing of a Royal Commission. Dr. Evory Kennedy, as President of the Irish Medical Association, and Dr. Hudson, President of the College of Physicians, supported Dr. Stokes's views. It is, indeed, much to be desired that, with the experience of the existing terrible epidemic of small-pox in some of the cities of Ireland, her Majesty's Government should proceed to deal with the question of sanitary reform in a comprehensive and thorough manner.

On Monday, the 3rd inst., the annual election of officers took place at the Royal College of Surgeons, with the following result:—*President*: Frederick Kirkpatrick. *Vice-President*: John Denham. *Council*: William Hargrave, Robert Adams, Wm. Colles, Hans Irvine, R. Butcher, Rawdon Macnamara, G. H. Porter, B. MacDowel, E. Ledwich, Alexander Carte, James H. Wharton, Geo. W. Hatchett, Albert J. Walsh, W. A. Elliott, John Morgan, Ed. Hamilton, Robert McDonnell, Geo. H. Kidd, and Philip Crampton Smyly. *Secretary*: Wm. Colles.

According to custom, on the same day several Medical Societies held their annual meetings, all of which were well attended by town and country members.

The Irish Medical Association, after having been entertained at breakfast by Dr. Henry Smith, of Borris-in-Ossory, Chairman of Council, afterwards assembled in the library of the Royal College of Surgeons. The chair was taken by Dr. Evory Kennedy, President of the Association. In his address the chairman said that the Profession, hitherto known chiefly for its retiring and unobtrusive habits of thought and action, was taking its place in the rôle of turmoil; and, under the guidance of a necessary political movement, preventive Medicine and the question of an improved sanitary code now occupied the attention of the Legislature, and the Medical Profession had come forward to aid in this great crisis by the knowledge and the proverbial humanity of its members. Dr. Kennedy then alluded to the labours of the Irish Poor-law Medical Officers, and to the action taken by the University of Dublin in founding a qualification for State Medicine. At the conclusion of an able address, Dr. E. J. Quinan read the report, which gave an account of the proceedings of the sub-committee in reference to the Local Government Bill; of communications with the Government respecting the effect on the salaries of Militia Surgeons in Ireland; of changes in arrangements for training proposed by the Army Department; of interviews with the Registrar-General touching the inadequate remuneration granted to registrars of births, deaths, and marriages throughout Ireland; and of proposed schemes for making provision for the widows of Medical men. The death of Dr. T. E. Beatty was deplored, and the report concluded with the expression of a hope that the Council might shortly have an opportunity of bringing the whole subject of the sanitary state of the country before a Royal Commission sitting in Dublin. Resolutions were then adopted relating to the urgent necessity for a Sanitary Royal Commission, and to the present very inadequate salaries granted to the Irish Poor-law and Dispensary Medical Officers. On the motion of Mr. Darby, of Bray, a resolution was passed to the effect that powers should be sought to establish a fund from which the widows and children of deceased Medical officers might be entitled to relief.

The second annual meeting of the Irish Poor-law Medical Officers' Association was held on Monday afternoon in the Hall of the King and Queen's College of Physicians. The chair was occupied by Sir Dominic Corrigan, Bart., M.D., M.P. Dr. D. T. Maunsell, hon. sec., read the report. In it allusion was made to an important object of the Association—the obtaining, namely, the payment of the salaries of Medical officers from the State—thus making them members of the Civil Service, and securing a certainty of promotion, increase of salary according to length of service, and compulsory superannuation. Various Bills affecting the interests of the Profession were also mentioned, and the report went on to show how efficiently the existing Poor-law Dispensary system was carried out in Ireland by the Medical officers attached to it. The organisation of a sanitary system was advocated, and suggestions were offered whereby such might be made economical, efficient, and compact. The amount now annually spent on preventive Medicine in Ireland was stated to be the paltry sum of £5240 12s. 11d., while the prevailing epidemic of small-pox had already cost Dublin some £30,000, irrespective of the loss of 1300 lives, including about 500 heads of families.

Dr. Rogers, President of the Poor-law Medical Officers' Association, England, moved the adoption of the report, and the two following important resolutions were carried unanimously:—

Moved by Dr. Grimshaw, seconded by Dr. Maunsell—"That the Council of the Association be requested to take means to impress upon the Government the importance of so constituting the board proposed in the Local Government Bill for Ireland, now before Parliament, that the board may include a member specially qualified in State Medicine and sanitary science, with the view of efficiently carrying out such sanitary measures as have been, or may hereafter be, sanctioned by the Legislature."

Dr. Speedy moved, and Dr. Hanrahan seconded—"That a committee be formed to memorialise the Chief Secretary on the part of the Poor-law Medical Officers of Ireland as to the injustice inflicted on them in receiving no payment for certifying in cases of dangerous lunacy; or, if practicable, to wait on Lord Hartington, and place the matter fully before him."

At 5 p.m. on the same evening, the thirtieth annual meeting of the Royal Medical Benevolent Fund Society for Ireland took place at the College of Physicians. The chair was taken by Dr. Alfred Hudson, President of the Society. After some remarks from the President, one of the hon. secretaries read the report, from which it appeared that the funded capital of the Society was now £14,500; that the number of applications during the year had been eighty-five—nine from Medical men disabled by age or ill-health, sixty from widows, and sixteen from orphans; and that the amount expended in grants for the year had been £839. It was to be regretted that considerable apathy still existed in the neighbourhood of some of the country branches, from which reports of by no means a cheering character had been received. The report concluded with an appeal from the central committee for continued efforts on behalf of the Society. It was stated that a sum of about £1100 was available for distribution.

Dr. Stokes moved the adoption of the report. Among the subsequent resolutions was one by Dr. Duncan, who proposed that a vote of thanks should be passed to the Medical students of Belfast for a generous contribution made by them to the funds.

Bearing in mind the adage that "Union is strength," the Medical officers attached to the Irish militia regiments have formed a society termed the "Irish Militia Surgeons' Association," and a preliminary meeting was held at the College of Surgeons on the 5th inst., Dr. William Stokes, jun., being chairman on the occasion.

It was proposed by Dr. Wilkinson, seconded by Dr. Jacob, and carried—"That the course proposed to be adopted towards Militia Surgeons by the Right Hon. the Secretary of State for War in his army organisation scheme, so seriously affects our interest and position that it is incumbent upon us to take immediate steps to secure a fair consideration of our claims."

The following were appointed officers of the Association:—*President*: Dr. Stokes, Co. Dublin Light Infantry. *Committee*: Drs. Irwin, Monaghan; Lynn, Armagh; Murphy, Limerick Artillery; Maybury, Kerry; Townsend, Cork; Nagle, Roscommon; Nolan, Galway; Wilkinson, Limerick; Peter, Longford Rifles; Jacob, Queen's County Rifles; Huston, Kildare Rifles; Drew, Wicklow Rifles; Malcolmson, Cavan; Wilson, Dublin Artillery. *Secretaries*: William Malcolmson and Henry Wilson. *Treasurer*: Henry Wilson.

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, MAY 28.

T. B. CURLING, F.R.S., President, in the Chair.

A PAPER by Sir WILLIAM GULL and Dr. HENRY G. SUTTON was read, "On the Pathology of the Morbid State commonly called Bright's Disease with Contracted Kidney (Arterio-Capillary Fibrosis)." The authors of this paper commence by stating that Dr. Bright and subsequent pathologists have fully recognised that the granular contracted kidney is usually associated with morbid changes in other organs of the body; and the disease in the kidney and the other coexistent morbid changes are commonly grouped and collectively termed "chronic Bright's disease." It is generally assumed that, in chronic Bright's disease, the kidneys themselves are the organs primarily affected; and, in consequence, a cachexia is induced through which other organs subsequently suffer and undergo chronic changes. The authors consider that the history of the disease does not support this opinion. The morbid changes in the kidneys themselves are first considered, the coarser anatomy being omitted. The microscopical appearances observed in granular contracted kidney are given in detail, and their conclusions on this point are as follows:—The visible morbid changes in granular contracted kidneys are due to the primary formation of a fibroid or hyalin-fibroid substance in the intertubular parts, including the vessels, and to atrophy of the tubular and intratubular structures of the kidney. On this point the authors confirm the observations of Dr. Dickinson and other observers. And they further state that this formation commences in different parts of the kidney, commonly near the surface; but it also seems to commence in the outer coats of the arterioles, and in the walls of the capillary vessels. From these parts it extends round the convoluted tubes and Malpighian bodies. This fibroid or hyalin-fibroid substance subsequently contracts and draws the Malpighian bodies together, compresses the urinary tubules and vessels, and may entirely obliterate them. This thickening of the capillary walls, and the diminished calibre of some of the arterioles, must naturally interfere with the nutrition of the tissues and tend to produce atrophy; and the blood-supply to the secreting cells, being in this manner reduced, probably causes diminished secretory function and atrophy from diminished use. The alteration in the renal epithelium, when great, is the result of the atrophy; and its slighter changes, such as granular appearance and desquamation of some of its cells, are not peculiar to granular disease of the kidney, such slighter changes being even consequent on the process of dying. The morbid changes in the vascular system are next considered. Dr. Bright and subsequent observers have recognised that atheromatous arterial disease is common with granular contracted kidney. In 1852, Dr. George Johnson, in his work on Kidney Disease, stated that the minute renal arteries are much thickened in chronic Bright's disease owing to hypertrophy of the muscular coats of the vessels. A few years ago the same writer pointed out that the arterioles, not only in the kidney, but in the skin and other parts of the body, are thickened and their muscular coat hypertrophied in chronic Bright's disease. Sir Wm. Gull and Dr. Sutton describe at considerable length the changes that they have found in the minute arteries and capillaries of the kidneys, pia mater, and other parts; and they state that their observations show that the minute arteries and capillaries are thickened in chronic Bright's disease, and they remark, "we gladly acknowledge the debt the science of Medicine owes to Dr. George Johnson for so distinctly insisting upon this fact." The microscopical observations of Sir Wm. Gull and Dr. Sutton show that the arterioles and capillaries are more or less altered in chronic Bright's disease. This alteration is due to a hyalin-fibroid formation in the walls of the minute arteries, and hyalin-granular change in the corresponding capillaries; that this formation occurs chiefly outside the muscular layer, but it also occurs, but to a less extent, in the tunica intima of some of the arterioles. Further, that the degree in which the affected vessels are altered, and the extent to which the morbid change is diffused over the vascular system of the different organs, vary very much in different cases. The muscular layer of the affected vessel is often atrophied in a variable

degree. The authors recognise that some pathologists may consider that the perivascular canals are the seat of these hyalin-fibroid changes. On the existence of such canals they express no opinion; they assert only that the morbid changes are chiefly outside the muscular layer of the arterioles. The arterio-capillary changes observed in chronic Bright's disease are not seen in the vessels of healthy persons who have been accidentally killed or who have died of phthisis and of other diseases not allied to chronic Bright's disease. The condition which induces the vascular change is next considered. Dr. George Johnson states that the general arterial thickening is due to muscular hypertrophy. He considers the blood is impure in consequence of the kidney disease, and the arterioles resist the passage of this impure, more or less noxious blood, and in doing this they become hypertrophied. The left ventricle of the heart, therefore, makes an increased effort to drive on the impure blood, and the result of this antagonism of forces is, that the muscular walls of the arteries and those of the left ventricle of the heart become in an equal degree hypertrophied. This theory Sir William Gull and Dr. Sutton do not accept, for their observations show that arterial changes are not dependent on muscular hypertrophy, but on hyalin-fibroid formation. They have found the heart and vessels healthy in cases of chronic disease of the kidneys, and, further, their inquiries show that the cardiac and vascular changes may occur independently of renal disease. Cases given in the appendix to this paper are next alluded to, which show that there is a general morbid state in which the kidneys may be contracted, the heart hypertrophied, and the minute arteries and capillaries altered by a hyalin-fibroid formation. The kidney changes are most often, but by no means always, part and parcel of this morbid state, and their absence shows that the renal changes are not an essential and indispensable part of the general process; but as the vascular system is at some part affected with this hyalin-fibroid change in all the cases, therefore they conclude that the vascular disease is to be regarded as the constant and essential part of this morbid state. The pathology of this hypertrophy of the left ventricle is next considered. Bright considered that the quality of the blood was altered by the kidney disease, and the heart, in consequence, had to contract with greater power to force the morbid blood through the vascular system, and became hypertrophied in order to accomplish this. Many pathologists have adopted Bright's explanation. Dr. Wells, in 1853, suggested that the hypertrophy might be dependent on atheromatous changes in the vessels. Against the explanation offered by Bright and others, the authors state that the frequent association of cardiac hypertrophy and renal disease does not prove that there is a causal relation between these two morbid states. Moreover, that in many cases where there is chronic disease of the kidneys, and the blood therefore presumably impure, the heart is not hypertrophied—instance, large white, lardaceous and scrofulous kidneys, as well as some cases of granular contracted kidneys. Dr. Johnson has endeavoured to account for the absence of the hypertrophy in such cases by assuming that the muscle of the heart is imperfectly nourished. The authors consider this suggestion, and state that this may explain a dilatation disproportionate to the hypertrophy, but it does not explain how a normal-sized heart acquires additional force requisite to overcome the supposed obstruction. Evidence is next brought forward to show that the cardiac hypertrophy is induced by the morbid changes referred to in the vascular system, the heart being found hypertrophied in all the cases in which the vessels were much and generally thickened by hyalin-fibroid change, slightly hypertrophied where the vessels were little thickened, and greatly hypertrophied where the vessels were much thickened, although there might be little or no kidney disease. The hyalin-fibroid change is assumed to impair the elasticity of the vessels, thus imposing upon the left ventricle a necessity to contract with greater force to carry on the circulation. The other conditions which make up the morbid state known as chronic Bright's disease are next noticed—namely, vesicular emphysema, retinitis albuminurica, atrophied brain, contracted spleen, and morbid changes in the intertubular parts of the stomach. In all these conditions it is shown that the arterioles are more or less thickened by fibroid or hyalin-fibroid changes. This general morbid state is shown to belong principally to the period of life at or after forty years of age, and after forty its frequency greatly increases as age advances. It is pointed out that the kidneys, even in children or in other young persons under adult age, are sometimes much contracted and death caused by uræmic poisoning, without the cardio-vascular changes alluded to.

But the general hyalin-fibroid change in the vessels may occur in early life; and, in proof, the case of a girl, aged 9 years, is mentioned, where the kidneys were granular and very contracted, the heart hypertrophied, and there were hyalin-fibroid changes in the arterioles of the pia mater. The authors desire to show that in the state known as chronic Bright's disease with contracted kidney, the morbid changes described do not arise in a constant order. In some cases the changes seem to commence in the kidneys or in the heart, sometimes in the lungs or in the brain, or in other organs; hence the symptom of the disease varies very much in different cases. In all cases, whether many or few organs are affected, the minute arteries and capillaries are altered by hyalin-fibroid formation, attended with atrophy of the adjacent textures. The authors cannot regard the functional disturbances which occur in many organs during chronic Bright's disease with contracted kidney as dependent on blood changes only or chiefly—as, for instance, pain in the head, discomfort after food, palpitation, dry skin, epistaxis, etc. These are probably due not so much to changes in the blood as to changes in the tissues themselves. The conclusions arrived at in the paper may be briefly summed up as follows:—1. There is a diseased state characterised by hyalin-fibroid formation in the arterioles and capillaries. 2. This morbid change is attended with atrophy of the adjacent tissues. 3. It is probable that this morbid change commonly begins in the kidney, but there is evidence of its beginning primarily in other organs. 4. The contraction and atrophy of the kidney are but part and parcel of the general morbid change. 5. The kidneys may be but little, if at all, affected, whilst the morbid change is far advanced in other organs. 6. This morbid change in the arterioles and capillaries is the primary and essential condition of the morbid state called chronic Bright's disease with contracted kidney. 7. The clinical history varies according to the organs primarily and chiefly affected. 8. In the present state of our knowledge we cannot refer the vascular changes to an antecedent change in the blood due to defective renal excretion. 9. The kidneys may undergo extreme degenerative changes without being attended by the cardio-vascular and other lesions characteristic of the condition known as chronic Bright's disease. 10. The morbid state under discussion is allied with the conditions of old age, and its area may be said hypothetically to correspond to the "area vasculosa." 11. The changes, though allied with senile alterations, are probably due to distinct causes not yet ascertained.

Dr. BROADBENT commenced the discussion by avowing his intention to confine himself to the question as to the nature of the changes in the minute arteries. Sir William Gull, Dr. G. Johnson, and Dr. Sutton were agreed that in contracted granular disease of the kidney there was hypertrophy of the heart and thickening of the arterioles, and that the cardiac hypertrophy was a true muscular hypertrophy due to changes in the arteries. But these Physicians differed as to the character of the thickening of the arterial walls, and as to its mode of production. Dr. Johnson believes it to be true hypertrophy of the muscular coat, caused by overwork in resisting the passage of impure blood. Sir William Gull and Dr. Sutton record their belief that it is a degenerative change in the tunica adventitia, the causation of which is unexplained. The ultimate appeal was naturally to the microscope, and Dr. Broadbent did not pretend to have traced the history and progress of the changes as closely as the authors. But he was so firmly convinced as to the existence of hypertrophy of the muscular coats of the walls of the minute arteries that, if compelled to relinquish this belief after what he had seen, he should cease to credit the existence of muscular fibre at all in the walls of normal arteries, for the appearances were identical in kind, differing only in degree. He proceeded to canvass the arguments advanced in support of Dr. Johnson's theory. That the cardio-vascular hypertrophy is not usual in other forms of diseased kidney, and has therefore some other cause than renal disease, and consequent deterioration of the blood, to be valid, involves the assumption that the effects in the blood are identical in all affections of the kidney. It is not sufficient that the blood is rendered impure, because one sort of impurity may, and another may not, provoke vascular resistance. But it is obvious that the deterioration of the blood in granulated contracted kidney cannot be the same as in waxy kidney. In one the urine is abundant, pale, of low specific gravity, and contains little albumen; in the other it is scanty, with colouring-matter present in the usual proportions, more albumen, and higher specific gravity. The blood cannot, as a mere matter of subtraction, be in the same state, to say nothing of the less tangible but more important distinction which the differential charac-

teristics of the urine indicate. In large kidney, too, the course of the disease is shorter, and hypertrophy requires time. Scrofulous kidney is attended with suppuration, which latter condition is associated with vascular relaxation. And, after all, the forms of renal disease other than contracted granular kidney are not uncommonly attended with arterial tension and thickening and cardiac hypertrophy, and this is only to be explained by Dr. Johnson's theory. The second objection, that the cardio-vascular changes are not constant in contracted granular kidney, again, is of no great weight, for exceptional cases are very rare, and absolute uniformity cannot be expected in conditions so complicated. The general vascular change indicated in the views of Sir W. Gull and Dr. Sutton is not consistent with Dr. Johnson's theory, as the former imply arterial resistance and consequent hypertrophy intermediate between the renal disease and the hypertrophy of the heart. The vascular changes, indeed, need not be proportionate to the degree of kidney disease, since a long-continued slight amount of kidney mischief may cause greater vascular hypertrophy than a more rapid and complete degeneration of these organs. And with reference to Dr. Johnson's theory, that the change in the arterioles is hypertrophy of their muscular fibre, which latter is induced by long-sustained resistance to the passage of impure blood, manifested clinically by high arterial tension, we ought occasionally to have the vascular change and cardiac hypertrophy independent of, or antecedent to, renal degeneration. In the gouty condition, for example, long recognised as a cause of contracted granular kidney, there is frequently, if not always, increased arterial tension, and therefore vascular resistance, with no indication in the urine of kidney changes. It must be remembered that the arterial tension comes and goes, so that it cannot be attributed to hyalin-fibroid degeneration. If, as the views of the authors indicate, the thickening of the walls of the arterioles is degenerative in character, the latter must be converted into unyielding tubes; and it is indeed in this way that the cardiac hypertrophy is said to be induced, and they cannot, therefore, be influenced by any of the causes which contract or dilate the vessels, and so there can be no variation in the character of the pulse other than as due to the greater or less frequency and more or less force of the heart's action. What are the facts? Pyrexia is clinically known to relax the arteries and lower vascular tension. It does so in Bright's disease, and the speaker's attention was particularly called to the fact (frequently indeed since) by the character of the pulse and the interesting modifications in the sounds of the heart shown by Dr. Sibson to be due to high arterial tension in a case which the post-mortem examination showed to be one of contracted kidney. He continually made use of the fact in clinical teaching, and, on one occasion, having arrived at the bedside and described the distinguishing peculiarities of the pulse, he found that this had entirely disappeared: the pulse was soft, the vessels relaxed as in ordinary pyrexia, and, in effect, the temperature was high, and the patient passing through an attack of pyrexia, on subsidence of which the arterial tension returned. It is well known that the effect of nitrite of amyl is to relax the arteries and to lower the vascular tension, and Dr. Broadbent experimented with it in a case of Bright's disease. If these vessels were thickened by a degenerated hyalin-fibroid deposit, it is obvious that no result could follow; but the speaker was enabled to exhibit a sphygmographic tracing, taken by Dr. Handfield Jones, showing that, whereas before inhalation the trace presented a convex rise, a round summit, a partial fall, and a vibrating slope to the lowest point (unmistakable indications of high arterial tension), after inhalation the height of the trace was more than doubled, the rise was concave, the apex pointed, the fall precipitate, and there was marked dirotism, and, in fact, the tension was exchanged for complete dilatation. Dr. Broadbent, therefore, felt it impossible to accept the conclusion arrived at by the authors, and his conviction remained unshaken that Dr. Johnson's theory was one of the most comprehensive and interesting links between Physiology and Medicine.

Dr. GEORGE JOHNSON said that the interest of the subject obviously centred in the question as to what is the nature of the thickening of the walls of the minute arteries in the kidney and in most of the tissues in chronic Bright's disease. He maintained that the thickening was a genuine hypertrophy of the muscular coats of the artery, while the authors denied the existence of hypertrophy, and declared that a hyalin-fibroid degeneration external to the muscular coat constituted the essential change. An appeal to actual specimens must decide the question. He invited attention to those on the table, which had been declared to be examples

of hypertrophy by many men, including Dr. Sharpey, Dr. Carpenter, Sir James Paget, and Dr. Rutherford. He was surprised to find that the authors had not produced their specimens, and he maintained that degeneration of the muscular coat of an artery must impair its contractile power, and therefore lessen its stopcock action. Hence the high arterial tension and the cardiac hypertrophy could not be explained on the theory of arterial degeneration. With reference to this point, Dr. Broadbent's experiment with nitrite of amyl was of great interest. He had specimens of arteries whose walls had undergone the so-called waxy degeneration, showing the canals irregularly dilated in consequence of their diminished power of resisting the blood-pressure. In opposition to Sir W. Gull and Dr. Sutton, he stated that the renal degeneration commences in the glandular structures, and not in the arteries; and that, with the exception of the Malpighian capillaries, the walls of the capillaries in all the tissues were entirely unaffected, and the walls of the veins also were free from structural change. Hence the statement that the area of the morbid change is that of the area vasculosa is inaccurate. The same hypertrophy of the arterial walls occurs in the large white as in the contracted kidney, and he failed to see how the authors explain this in their theory that atrophy of tissues results from the primary vascular changes. The authors gave no explanation of the assumed primary degeneration of the arteries, whereas the speaker's explanation of the various forms of renal disease, with the resulting cardiac and arterial hypertrophy, was physiologically complete and intelligible. In the absence of specimens, it was difficult to give any positive opinion as to the nature of the so-called hyalin-fibroid degeneration described by the authors; but judging from the description of the change as occurring in a hyalin form external to the muscular coat of the artery, and from the appearance of the drawings, he ventured to suggest that they described as pathological that swollen and translucent appearance of the tunica adventitia so commonly produced by the imbibition of fluid, especially when that fluid is mixed with glycerine or dilute acetic acid. This appearance is readily produced in the normal arteries of the pia mater, and may be seen in the arteries of the skin and mucous membranes. If these were not the appearances described and figured in the hyalin-fibroid degeneration, the speaker could not say to what the description applied until he had examined the authors' specimens.

Dr. SILVER felt diffidence in criticising the paper of two such distinguished Physicians, but assuredly there were other modes of origin for contracted kidney than that described, connected with the tubular epithelium and the intertubular connective tissue. But granted the atrophy, the symptoms produced were excess of urine of low specific gravity, and containing little albumen, and he thought that this theory, especially as it applied to the heart, did not help to explain the matter. As to the urine, it was peculiar, being neither blood-serum nor urine; and while it contained little of the elements of urine, it also contained little albumen. The filtering apparatus remained tolerably sound, otherwise more albumen would be present; but the amount of fluid filtered through served to show that the process went on under great blood-pressure, although enough urea was not got rid of. So the patient had little risk of dropsy, but great risk of uræmic convulsions, or of inflammation of the serous membranes. These probabilities showed that urea was formed, and it was known that crystals of urea had been seen on the skin of patients in an advanced stage of the disease. Life, however, could not be maintained unless some urea was carried off. It was necessary, therefore, to increase the pressure, and the hypertrophied left ventricle showed that this was done; and as the speaker did not believe that the hypertrophy was immediately due to the contracted kidney, so also he could not believe that it was due to the presence of any irritant in the blood. This was not the hypertrophy of a damaged organ, but hypertrophy due to blood driven under higher pressure. To increase the flow of urine resistance in the arteries was necessary, and he suggested that that might explain the muscular thickening of the vessels. He had accordingly given ergot in a case of chronic Bright's disease. This would act on the muscular coats of the vessels, cause them to contract, and so increase the pressure of blood in the kidney. The result was that the patient's urine steadily increased from twelve to upwards of 100 ounces; but in other cases the increase was less marked. He doubted whether, on the whole, this new theory helped much to elucidate the phenomena of the disease.

Mr. BRUDENELL CARTER said the authors of the paper had

referred to albuminuric retinitis, and that the history of this condition was calculated to support their general conclusions. The changes in the retina were once supposed to be pathognomonic of albuminuria, but it was now known that they might be present without that symptom. Again, there was no constant relation between the retinal and the renal affections. In many cases of Bright's disease the retina escaped for a long period; in some it escaped altogether. In many others, on the contrary, the troubled retina was the cause of the patient's seeking advice; and the ophthalmoscopic examination first led to the discovery of albumen in the urine. The retinal changes, again, differed greatly in different instances—the white patches sometimes preceding, sometimes following, the characteristic hæmorrhages. On the whole, the weight of evidence was opposed to the supposition that the retinal was an effect of the renal disorder, and was in favour of the supposition that both were the effects of some more general cause; and that each, for a certain time at least, might exist independently of the other.

Dr. ANSTIE wished to ask Dr. Broadbent whether he was aware of the extent to which the muscular tissue of the arterioles remained sufficiently intact to be sensible of the action of nitrite of amyl, even in very advanced states of degeneration. He (Dr. Anstie) had had occasion to try the effects of amyl in many patients in whom the arterioles must have been extremely degenerated by the effects of old age; nevertheless, the usual sudden dilatation was well marked—indeed, alarmingly so.

Mr. HULKE said the changes in the eye were of two kinds, and not one only, in Bright's disease.

Dr. RUTHERFORD, in remarking that the essence of the discussion was the nature of the thickening of the walls of the arterioles, averred his conviction that an examination of the microscopic specimens exhibited by Dr. Johnson was sufficient to satisfy any impartial observer that there is a positive increase in the number of muscular fibres in the walls of the vessel. He regretted the absence of microscopic specimens in connexion with the authors' paper; but observed that it was competent for them to point out in Dr. Johnson's preparations the appearances indicative of hyalin-fibroid as well as the results of the so-called capillary fibrosis.

Dr. SYMES THOMPSON briefly subscribed his belief in Dr. Johnson's views.

Sir WILLIAM GULL, in replying, remarked that the subject was important as to its bearing upon mortality at a certain period of life. The state called chronic Bright's disease with contracted kidney was a mode of death comprising a large percentage of cases, especially in males, after the middle period of life. When visiting Bath a few years ago the attention of the speaker was directed to the tablets on the walls of the Abbey Church, recording the deaths of persons who had come from many parts of the kingdom for the benefit of the waters. Deaths recorded on the tablets near him ranged from fifty-seven to sixty-three, and from later knowledge he did not doubt that nearly all these patients had gone to Bath for what is commonly termed latent or suppressed gout, or, in other words, for symptoms depending upon the state of cardio-vascular degeneration then under discussion. Hence the Bath waters had been humorously characterised as well calculated to lay the dust. But the object of the paper was important in a therapeutic sense. The somewhat antithetical views set forth in the paper deserved, and must receive, the fullest discussion, whether the affection began, according to former pathologists, locally in the kidney, and so, by extension of morbid influence through the blood, producing a change in the heart and arteries, or whether the disease had, as it was now attempted to show, a more general beginning in the arterioles, the kidneys becoming contracted as a part of the general morbid change. Dr. Broadbent's argument that the cardiac and vascular changes might be limited to one form of renal disease, and not producible by other forms of kidney degeneration, was at present an hypothesis only, and not supported by the fact that extreme contraction and degeneration of the kidneys in young persons did not produce the cardiac and vascular changes which on such supposition should occur with it. Dr. Bastian and Dr. Dickinson gave clinical evidence supporting the views advocated in the paper; the former pointedly stated that dyspnoea was one of the early symptoms, and the latter said that in the early stage of the disease the urine is free both from albumen and casts. The clinical history of chronic Bright's disease, though not included in this paper, seemed distinctly to show that the renal affection may be developed at different stages of the disease. Sir William Gull concluded by saying that it

had long been a dream of the authors of this paper that the lines of pathological change in later life, so far as they were essential in contradistinction to merely accidental influences, would be found to correspond with the lines of early development. Chronic Bright's disease with contracted kidney appeared to the writers of the paper to belong to the area vasculosa. Had there been time, it might have been possible to point out how the mucous layer and skin had its senile pathology corresponding to the mucous layer of the embryo, and so probably had the nervous layer. He also wished emphatically to record that his colleague, Dr. Sutton, must properly claim whatever credit was due with reference to the morbid anatomy of the subject.

Dr. SUTTON, in reply, said that he should be glad to show the specimens, and would have done so before the meeting had he been apprised of Dr. Johnson's demonstrations. He did not agree with Dr. Johnson's opinion that the changes observed in the vessels were dependent on some incidental and not upon a diseased condition, for a great number of specimens prepared in the same manner had been examined, and the vessels taken from persons accidentally killed, or who had died from tuberculosis, fever, or other acute diseases, did not present this hyalin-fibroid appearance, which showed the condition to be a morbid one. Where the vessels had undergone the hyalin-fibroid change, the kidneys were found diseased, or there were cardiac hypertrophy and the other morbid conditions commonly found in chronic Bright's disease. He thought that the thickening of the arterioles was not dependent on muscular hypertrophy, and was supported in this view by other observers. Bader and Pagenstecher had studied the changes which the retinal arterioles undergo in chronic Bright's disease, and had concluded that the alteration was due to fibroid formation in them.

At the conclusion of the meeting, Mr. JOHN WOOD exhibited a patient upon whom he had performed the operation of Remote Transplantation of a large patch of Skin from the abdomen to the forearm and wrist, to remedy the contraction caused by a severe burn, which had drawn the fingers backwards nearly up to the elbow.

OBITUARY.

CHARLES LEVER, M.D. DUBLIN.

THERE are few who will not learn with deep regret that Charles Lever is no more. The most gifted, perhaps—certainly the most popular—of Irish novelists of the present century, his death will be felt by a large portion of the public as the loss of a personal friend. "Men of the Time" gives the following particulars regarding the deceased novelist:—

"Charles James Lever, the son of an architect, was born in Dublin in 1809. At an early age he had been destined for the Medical Profession, and with a view to qualify himself for practice in that line, he was entered at Trinity College, Dublin, where he attended lectures, and eventually took the degree of Bachelor of Medicine, in 1831. He passed through a subsequent course of study at Göttingen, where he also took a degree. When cholera broke out in Ireland, in 1832, Mr. Lever was appointed Medical Superintendent of an extensive and populous district, which included the city of Londonderry and the towns of Newtownlimavady and Coleraine. In this position he rendered good service, and when the disease had abated, became attached to the British Legation at Brussels, in the capacity of Physician. Whilst occupying this post, he produced, first as a serial, his 'Harry Lorrequer,' a novel of Irish life and character, the success of which led to his writing other novels, mostly published in a serial form. 'Charles O'Malley,' 'Jack Hinton,' 'Our Mess,' 'The O'Donoghue,' 'St. Patrick's Eve,' 'Roland Cashel,' 'The Knight of Gwynne,' 'The Daltons,' 'The Dodd Family Abroad,' 'Arthur O'Leary,' and many others of a like kind, touching chiefly on the various phases of Irish military life, and which were illustrated by the pencil of Mr. Hablot K. Browne. Whilst engaged upon these productions he undertook the editorship of the *Dublin University Magazine*, between the years 1842 and 1845, largely contributing to its pages, after which he retired to the Continent, establishing himself first in a castle in the Tyrol, and afterwards at Florence. Amongst the best of his works published anonymously is his 'Diary of Horace Templeton,' and his 'Con Cregan, the Irish Gil Blas.' Mr. Lever was appointed by Lord Derby's Government to a consular post in the Mediterranean. His more recent produc-

tions are 'One of Them,' 'Barrington,' 'Luttrell of Arran,' and 'A Day's Ride, a Life's Romance.' Since the above sketch was published several new novels have appeared from Lever's pen—the last, 'Lord Kilgobbin,' having been published in its complete form only a few weeks ago. This work he dedicated in the following terms:—"To the memory of one whose companionship made the happiness of a long life, and whose loss has left me helpless, I dedicate these volumes, written in breaking health and broken spirits. The task that was once my joy and pride I have lived to find associated with my sorrow; it is not then without a cause I say, I hope this effort may be my last." This 'presentiment' has, unhappily, been realised, and the literary world has seen the 'last effort' of one with whose name it seems difficult to associate a single melancholy idea. The University of Dublin lately conferred on Lever the honorary degree of LL.D. His literary labours, we should add, were not confined to works of fiction, and during recent years he contributed to *Blackwood's Magazine* a series of brilliant 'Sketches, by Cornelius O'Dowd,' on social and political subjects."—*Dublin Daily Express*.

MEDICAL NEWS.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received Certificates to practise, on Thursday, May 30:—

Hewett, Frederick Charles, Twickenham.
Holder, William, Hull.
Preston, Augustus Richard, South Brent, Devon.
Price, Charles William, Merthyr Tydfil.
Swan, Richard Jocelyn, Northleach, Gloucester.

As Assistants in Compounding and Dispensing Medicines:—

Evans, Gwelym, Llandovery.
Watson, William, Rochester.

The following gentleman also on the same day passed his Primary Professional Examination:—

Cookson, Hugh Alexander, Guy's Hospital.

APPOINTMENTS.

* * * The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

GRAY, ROBERT, L.R.C.P. Edin., L.R.C.S.I., L.S.A. Lond., I.A.H. Dub.; L.M.—Medical Officer for the Dispensary District of Armagh Union, Ireland.

MAHOMED, F. A., M.R.C.S., L.S.A.—Assistant Medical Officer to the Central London Sick Asylum at Highgate.

PRENDERGAST, JOHN, L.K. & Q.C.P.I., L.R.C.S.I., L.M.—Medical Officer for the Crossabeg Dispensary District, Wexford, Ireland.

SEATON, JAMES, L.R.C.S. Edin., L.S.A.—Surgeon to the General Infirmary, Leeds.

BIRTHS.

APPLIN.—On May 13, at Star Elms Villa, Hoo, Kent, the wife of George Peek Applin, L.R.C.P.E., M.R.C.S.E., of a son.

CREW.—On May 23, at Higham Ferrers, Northamptonshire, the wife of John Crew, L.R.C.P. Lond., of a daughter.

CUNNINGHAM.—On May 29, at Trelington House, Southsea, the wife of Surgeon-Major Cunningham, M.D., 20th Hussars, of a daughter.

EDGELOW.—On June 2, at 3, Tavistock-square, the wife of G. Edgelow, M.D., of a son, prematurely.

GAITSKELL.—On June 3, at King's Sutton, Northamptonshire, the wife of Edward Forbes Gaitskell, L.R.C.P., of a daughter.

HILLIARD.—On June 2, at 5, Belgrave-terrace, Upper Holloway, the wife of R. Harvey Hilliard, M.D., of a daughter.

POCOCK.—On May 29, at 374, Brixton-road, the wife of Edward William Pockock, M.R.C.S.E., of a son.

RIMELL.—On May 31, at 18, Eardley-crescent, West Brompton, the wife of Thomas W. Rimell, L.R.C.P., M.R.C.S., of a daughter.

ROBERTSON.—On March 17, at East St. Kilda, Melbourne, the wife of Robert Robertson, M.R.C.S. Eng., of a son.

WELLS.—On May 30, at 20, Fitzroy-street, Fitzroy-square, W., the wife of John R. Wells, L.R.C.P., F.R.C.S., of a daughter.

MARRIAGES.

ATKINSON—ATKINSON.—On May 25, at Ardnaree Church, Ballina, co. Mayo, Edward Eastwood, eldest son of E. Atkinson, Esq., J.P., Ballina, to Harriette Marian, third daughter of Thomas Atkinson, Esq., late Inspector-General of Hospitals.

CROSS—GARWOOD.—On May 22, at Acomb, near York, Richard N. Cross, second son of Richard Cross, M.D.; Scarborough, to Rose C. Garwood, eldest daughter of the late Wm. Garwood, Esq., solicitor, York.

HOLLIS—LEVER.—On June 4, at St. James's Church, Norland, Notting-hill, William Ainslie Hollis, M.D., of New Cavendish-street, Cavendish-square, to Fanny, only child of Charles Lever, Esq., of Notting-hill.

KING—ATKINSON.—On May 25, at Ardmore Church, Ballina, co. Mayo, Allan Armstrong King, Ceylon Civil Service, youngest son of William King, D.Sc., Glenair, Galway, to Henrietta Louisa, youngest daughter of Thomas Atkinson, Esq., late Inspector-General of Hospitals.

KLENCKE—BENNETT.—On June 4, at the parish church of St. Marylebone, Franz Klencke, Esq., of 23, Elsham-road, Kensington, eldest son of Professor Herrmann Klencke, M.D., of Hanover, to Angelina, youngest daughter of the late William Bennett, Esq., of Aberdeen-park, Highbury.

LEET—D'ARCY.—On May 28, by special licence, at Churchtown House, Newcastle West, county Limerick, by the Rev. A. Wellesley Leet, A.M., brother of the bridegroom, assisted by the Rev. W. Eyre Massy, A.M., Rector of Rathoran, Edward W. Leet, R.N., Assistant-Surgeon to H.M.'s *Sultan*, youngest son of Charles Henry Leet, M.D., of Eversden, county Dublin, to Bessie Adams, only child of the late Conyers D'Arcy, Esq., of Ringwood, county Limerick.

MILLER—MORSE.—On June 1, at St. Philip's, Kennington-road, William, second son of Charles Miller, Esq., of Kennington-park, to Fanny, second daughter of Edward Morse, M.R.C.S., L.S.A., of Upper Kennington-lane.

MITCHELL—HYDE.—On June 4, at St. George's, Hanover-square, Sydney John Mitchell, of Solihull, Warwickshire, solicitor, to Emmeline, eldest daughter of the late Clarendon Hyde, Surgeon, and granddaughter of the late Abraham Hoskins, Esq., of Newtown-park, Derbyshire.

RENNICK—TOMSON.—On June 4, at Christ Church, Lancaster-gate, Albert De Clany Rennick, Esq., Bengal Staff Corps, Assistant Commissioner of Punjab, third son of R. H. Rennick, Esq., Inspector-General of Hospitals, late Madras Army, to Mimie, youngest daughter of the late Colonel George Tomson, Commissary-General, Bengal Army.

SHEARMAN—TURNER.—On June 4, at Aithorpe, near Doncaster, Edward James Shearman, M.D., F.R.S., etc., Consulting Physician to the Rotherham Hospital, to Anne, only daughter of the late John Turner, Esq., both of Rotherham.

SKEFFINGTON—BIRD.—On May 30, at St. George's, Bloomsbury, Charles Neville Skeffington, of Oporto, third son of W. Skeffington, Esq., of Kensington-square, to Ada Alice, second daughter of the late Golding Bird, M.D., F.R.S.

SMITH—FROGGATT.—On May 30, at St. John's, Croydon, Walter H. Smith, L.R.C.P., M.R.C.S., to Margaret J., daughter of the late T. Froggatt, Esq.

STOKES—CURRIE.—On May 4, at St. George's Cathedral, Madras, Henry Edward Stokes, Esq., Madras Civil Service, to Helena Amy, second daughter of Dr. Currie, C.B., Inspector-General of Hospitals.

SWEETAPPLE—PARSON.—On June 1, at Godalming, Thomas Sweetapple, of Eashing, youngest son of the late Thomas Sweetapple, Esq., of Cottes-hall, to Mary, second surviving daughter of the late Charles Alexander Parson, Surgeon, of Godalming.

WINSLOW—GRANT.—On June 1, at the parish church, Fulham, Henry Forbes Winslow, M.D., Sussex House, Hammersmith, youngest son of the late Thomas Forbes Winslow, Esq., of 21, Montague-place, Russell-square, to Mary, younger daughter of the late Captain Edward John Grant, of H.M.'s 17th Regiment of Foot.

WINSTANLEY—HOWITT.—On May 29, at the parish church, Preston, William Alfred, eldest son of William Winstanley, J.P., of Chaigley Manor and West Cliff, Preston, to Maria Elizabeth, only daughter of William Howitt, F.R.C.S.E., and J.P. for the County of Lancaster.

DEATHS.

ADDISON, ELIZABETH CATHERINE, widow of the late Dr. Thomas Addison, of Guy's Hospital, and Berkeley-square, W., at Brighton, on May 30, aged 72.

CANTON, JANE, the dearly loved wife of Alfred Canton, M.R.C.S. Eng., L.D.S., of 17, Great Marlborough-street, Regent-street, suddenly, on June 4, aged 55.

GILL, WILLIAM LETH, L.R.C.P. Edin., M.R.C.S. Eng., L.S.A., at his residence, 29, White Lion-street, Pentonville, on May 31, in his 72nd year.

HOLLINGSWORTH, JOHN, M.R.C.S., L.S.A., at Maidenstone House, Greenwich, S.E., on May 23, aged 52.

HUTCHINSON, JOSEPH, F.R.C.S., at his residence, Cheetham Hill, Manchester, on May 28, in his 64th year.

STRANGE, ROBERT, M.D., late of Naples, at 6, Elvaston-place, Queen's-gate, on June 4, in his 76th year.

VACANCIES.

In the following list the nature of the office vacant, the qualifications required in the Candidate, the person to whom application should be made, and the day of election (as far as known) are stated in succession.

ADDENBROOKE'S HOSPITAL, CAMBRIDGE.—House-Physician and House-Surgeon. Candidates must be duly qualified. Applications with testimonials to the Secretary, 60, St. Andrew's-street, Cambridge, before June 19.

AMERSHAM UNION.—Medical Officer for the Workhouse, and Medical Officer for the Amersham District. Candidates must possess the qualifications required by the Consolidated Orders of the Local Government Board. Applications and testimonials to be sent to Mr. Henry Bedford, Clerk to the Guardians, on or before June 11.

BIRMINGHAM AND MIDLAND HOSPITAL FOR WOMEN.—Resident Medical Officer and Secretary. Candidates must be duly qualified. Applications with testimonials to Arthur Chamberlain, Esq., Hon. Secretary, 8, The Crescent, Birmingham, on or before July 15.

DERBYSHIRE GENERAL INFIRMARY.—Assistant House-Surgeon. Candidates must be duly qualified. Also, a properly qualified Dispenser. Applications, with testimonials, to the Secretary, Samuel Whitaker, Infirmary, Derby, on or before June 15.

EAST LONDON HOSPITAL FOR CHILDREN AND DISPENSARY FOR WOMEN, RATCLIFFE-CROSS.—Visiting Physician. Candidates must be Fellows or Members of the Royal College of Physicians of London, or F.R.C.P. Edinburgh or Dublin, or Graduates in Medicine of a British University, or of the Universities of Paris, Vienna, Berlin, or other universities approved by the General Medical Council, and be legally qualified to practise Medicine in England. Applications to be sent to the Secretary, at the Hospital, before June 17.

ESSEX LUNATIC ASYLUM, BRENTWOOD.—Second Assistant Medical Officer and Dispenser. Candidates must be Licentiates of the Apothecaries' Company and possess a Surgical qualification. Applications, stating former occupation, to Dr. Campbell, Medical Superintendent, County Asylum, Brentwood.

GLOUCESTER DISPENSARY.—Dispenser, registered under the Pharmacy Act, and otherwise duly qualified. Apply to George Whitcombe, Esq., Gloucester, from whom further particulars may be obtained.

INFIRMARY FOR CONSUMPTION AND DISEASES OF THE CHEST, 26, MARGARET-STREET, CAVENDISH-SQUARE.—Visiting Physician. Candidates must be Members of the Royal College of Physicians, London. Testimonials to be sent to Francis Baily, Secretary.

LEEDS UNION.—Medical Officer for the Workhouse and Industrial School. Candidates must possess the qualifications laid down by the Local Government Board. Applications with testimonials to be sent on or before June 12.

LIVERPOOL NORTHERN HOSPITAL.—House-Surgeon. Candidates must possess a Medical and a Surgical qualification from one or more British Colleges or Institutions recognised under the Medical Act. Applications and testimonials to the Chairman of the Committee not later than June 15.

LONDON FEVER HOSPITAL, LIVERPOOL-ROAD, ISLINGTON.—Resident Medical Officer. Applications with testimonials to be sent to the Secretary, on or before June 11.

MIDDLESEX HOSPITAL.—Lectureship on Psychological Medicine. Applications must be sent to the Dean of the Hospital not later than June 13.

NEWPORT ODDFELLOWS' MEDICAL AID ASSOCIATION.—Assistant-Surgeon. Candidates must be doubly qualified and registered. Applications, with testimonials, to James Davis, Secretary, 21, Rupperra-street, Newport, Mon., on or before June 8.

NORTH RIDING INFIRMARY, MIDDLESBOROUGH-ON-TEES.—House-Surgeon. Candidates must be Fellows or Members of one of the Royal Colleges of Surgeons of the United Kingdom. Applications and testimonials to be sent to the Secretary, on or before June 12.

SALOP FRIENDLY SOCIETIES' AND GENERAL MEDICAL AID ASSOCIATION.—A duly qualified Practitioner. Candidates must be Members of one of the Royal Colleges of Surgeons, and Licentiates of the Apothecaries' Hall, London. Applications, with testimonials, to W. H. Williams, District Office, St. Mary's-street, Shrewsbury, on or before June 11.

UNION AND PAROCHIAL MEDICAL SERVICE.

** The area of each district is stated in acres. The population is computed according to the census of 1861.

RESIGNATIONS.

Elham Union.—Dr. Wildash has resigned the Hythe District; area 6398; population 4305; salary £50 per annum.

Portsea Island Union.—Dr. Simpson has resigned the Workhouse; salary £150 per annum.

APPOINTMENTS.

Dorchester Union.—Wm. T. Borcham, L.R.C.P., M.R.C.S., L.S.A., to the Longbredy District.

Malmesbury Union.—John Betts, M.R.C.S. Eng., L.S.A., to the Fourth District.

Reeth Union.—Henry Towle, M.R.C.S. Eng., L.S.A., to the Muker District.

Walsingham Union.—Francis Coomber, M.R.C.S. Eng., L.R.C.P. Lond., to the Raynham District.

THE ROYAL COLLEGE OF PHYSICIANS have issued cards for their annual *conversazione* on Saturday, June 29, at 9 p.m.

DR. SUTHERLAND has been appointed Lecturer on Insanity to the Westminster Hospital School of Medicine.

THE HARVEIAN ORATION will be delivered by Dr. Arthur Farre, F.R.S., at the Royal College of Physicians, on Wednesday, June 26, at 5 p.m.

AN examination of candidates for fifteen appointments as Assistant-Surgeons in her Majesty's Indian Medical Service will be held in London in August next.

Dr. MURRAY, of Forres, has just been presented with a handsome brougham and a purse of sovereigns by his friends in that town.

It is proposed to form a sanitary association for Barrow, to supplement the action of the local authorities, and to carry out the powers entrusted to them, as well as to assist and encourage the labours of individual workers.

THE Eleventh Annual Report of the Bourton-on-the-Water and Cotswold Village Hospital states that the in-patients during the past year had been forty-four—a number never before but once reached. The material prosperity of the Hospital increases, and the liberality of the public places the institution every successive year upon a firmer basis.

UNIVERSITY OF CAMBRIDGE.—Professor Humphry gives notice that the course of Practical Histology will commence on Wednesday, July 3, at twelve o'clock, and be continued on Mondays, Wednesdays, and Fridays during July and August. Fee for the course, one guinea. There will be classes for Practical Osteology in July and August. The course of lectures on Practical Anatomy, next term, will commence on Monday, October 7, at 9 a.m., and be continued daily, with a fortnight's intermission at Christmas, till the end of March. Students desirous of obtaining a certificate for the Royal College of Surgeons will be required to attend during the whole of that period.

ACADÉMIE DE MÉDECINE.—At the meeting of May 28 M. Bernutz was elected into the section of Internal Pathology by the suffrages of thirty-nine of the sixty-nine voters present.

ST. MARY'S HOSPITAL MEDICAL SCHOOL.—Thomas Hughes, Esq., M.P., has kindly consented to preside at the annual presentation of prizes to the successful students at the school, and to deliver an address on Thursday next, June 13, at four o'clock p.m.

WINGFIELD CONVALESCENT HOME.—This institution has been opened by Archdeacon Clerke. It is near the Warneford Asylum, and about a mile from Oxford. It will accommodate eight persons, and cost 1075*l*.

THE VILLAGE HOSPITAL, HAMBROOK, BRISTOL.—This Hospital was established in 1867. From the annual report just issued, we find that during the past year fifty-three cases were under Medical treatment, and that no death took place. The position and prospects of the Hospital continue in a healthy and flourishing condition.

BLACK SMOKE.—On the ground that it had not been satisfactorily proved that black smoke was injurious to health, the Bolton magistrates dismissed a number of summonses for smoke nuisances. They had not called Dr. Ballard before them.

THE STEWART LUNATIC ASYLUM, DUBLIN.—The half-yearly report just issued states that during the past six months five patients had been admitted, and three discharged, leaving eighty-two inmates, and that the establishment has been working in a very satisfactory manner.

PROFESSOR HOLMES.—The following is the programme of Professor Holmes's concluding three "Lectures on the Surgical Treatment of Aneurism in its various forms," to be delivered at the Royal College of Surgeons next Monday, Wednesday, and Friday, at 4 p.m.—Lecture IV. (June 10), *Thoracic and Subclavian Aneurisms*.—Galvano-puncture in thoracic aneurism. Ciniselli's table. Evidence, from this experience, that benefit has been produced in some cases. No evidence of complete cure in any, though this is possible. Is the benefit produced by galvanism in intrathoracic aneurism worth the risk incurred? Nature of the dangers in electro-puncture. These dangers are not very great at present, and may be in all probability much diminished in future. The method may also be used in order to avert the danger of the imminent rupture of the tumour, and so to postpone death, if not to cure the disease. *Subclavian Aneurism*.—Ill-success of Surgical treatment hitherto. Researches of Koch and Poland. Subclavian aneurisms usually tubular, and generally symptomatic of extensive arterial degeneration. Universal failure of the Hunterian operation internal to the scalenus, except in one case. Can this be obviated in future by improved methods of deligation? Acupressure, or temporary deligation, hitherto unsuccessful. In some cases, where the first part of the artery has been tied, its second part could perhaps have been secured. Can pressure be exercised upon the first part of the artery under chloroform? In some cases, where the third part of the artery has been tied, and usually with fatal results, compression might have been used. Instances of compression in subclavian or subclavio-axillary aneurism. The other justifiable modes of treatment are manipulation and galvano-puncture. These have been successful occasionally, and we may hope for better results when the methods become more clearly understood. Lectures V. and VI. (June 12, 14), *Abdominal Aneurism*.—These aneurisms divided into three classes for the purpose of Surgical treatment. In none of these, however, ought Surgical measures to be adopted until a fair trial has been given to internal treatment. Occasional spontaneous cure, or very slow progress of such aneurisms. 1. Aneurisms seated as high as the pancreas. Question of trying distal pressure in such aneurisms. Bryant's case. Case of distal ligature in abdominal aneurism. Mesenteric aneurism, its various forms. Some of these are probably curable by pressure. 2. Aneurisms of the lower part of the aorta. Murray's case. Durham's case. 3. Aneurisms of the iliac arteries. Mr. Syme's proposal to treat such aneurisms by the old operation of laying the sac open. Proofs that Mr. Syme over-estimated the facility and safety of this operation. Defence of the old doctrine, from which the superiority of the Hunterian operation is inferred. The operation recommended by Mr. Syme may, however, be justifiably tried in iliac aneurism on account of the great fatality of ligature of the common iliac artery. Hargrave's case. Compression of the abdominal aorta, or common iliac artery, in iliac aneurism. Its successes and dangers. Rapid and gradual coagulation in the cure of aneurism. Question of combining distal with proximal pressure.

CAMBRIDGE PHILOSOPHICAL SOCIETY.—At the meeting on Monday, the 27th ult., the following communication was made to the Society by Dr. Latham: "On some of the Symptoms produced by Uræmic Poisoning in Chronic Diseases of the Kidney." The object of this paper was to show that many of the symptoms, as to the mode of production of which in chronic Bright's disease much discussion has hitherto arisen, might reasonably be explained. That the factors involved were—(1) The impeded passage of the blood through the minute arteries of the system, caused by excessive contraction and hypertrophy of the muscular walls of these vessels, as has been demonstrated by Dr. George Johnson. (2) The hypertrophy of the heart developed by the resistance offered to the circulation from the contraction of these small arteries; and (3) The impoverished state of the blood, which is the necessary accompaniment of the disease. The author first dwelt upon the occurrence of paroxysmal dyspnoea or asthma, and after discussing the effects which would be produced if the minute branches of the pulmonary artery were suddenly contracted, and the general symptoms and physical signs which would accompany such an event, he showed by reference to cases recorded by other observers, and from instances which had come under his own observation, that the theory was supported by fact. He next referred to epileptiform convulsions and uræmic coma, and pointed out why in some cases convulsions might occur, and not in others, owing to the predominance of one or other of the above-mentioned factors. He then went on to say that although cerebral apoplexy not unfrequently occurred in chronic Bright's disease where there was atheromatous degeneration of the arteries, yet that, independently of this, the apoplexy might be caused by the velocity of the blood through the minute tubes being retarded (the velocity through a tube varying as the square of the radius of the section), and so leading to the formation of a small coagulum of fibrin or a thrombosis. There would then be complete obstruction, and consequently the greatest possible pressure would be brought to bear on the arterial wall, and result very probably in rupture. This, also, he contended, explained the production of pulmonary apoplexy, and minute apoplexies in the kidneys and spleen, or hæmorrhagic infarctions occurring in chronic Bright's disease, where no valvular mischief of the heart or endocardiac disease existed. Dr. Bradbury thought the symptoms mentioned by Dr. Latham were explicable on the supposition that, after Bright's disease had set in, thrombosis of the heart had taken place. He described a case of pulmonary apoplexy which he had recently examined, where a large blocking had been caused in the pulmonary artery, and commented upon one or two points in the paper. Dr. Latham thought the conditions found post-mortem in the case quoted by Dr. Bradbury supported the theory he had advanced; for, as there was no valvular disease of the heart, the obstruction had most probably been caused by some of the minute branches of the pulmonary artery contracting, so as to retard the velocity of the blood through them to such an extent as to allow it to coagulate.

THE ETON WICK SEWAGE FARM.—A writer in the *John Bull* of June 1 describes a visit paid to this farm, of which he says—"It consists of about fifty acres; is situated in the valley of the Thames, with a very slight fall to the river. The soil consists of sandy loam, and has been levelled, earth being taken from one part to fill up the hollows of the other. The land cost about £100 an acre, and was very unremunerative to those who previously farmed it. It is now held by the Board of Health of Eton, and receives the sewage of about 4000 people. The premises are separated from the neighbouring land by a narrow embankment, probably six feet high, under which pass the pipes carrying the sewage. At the distance of a mile and three-quarters (at Eton itself) is seen a tall chimney; this is the pumping station, and from this point, by means of two six-horse-power engines, the sewage of the town is sent through iron pipes on to the spot we stood on. It then passes through glazed earthenware pipes into cemented cisterns, about six feet diameter, sunk in the embankment at regular intervals; these last are covered over with wooden lids. On opening one a turbid dark fluid is seen passing in on one side, and going out of the earthenware pipe on the other; the smell arising from this is somewhat sickening. The manager carries a large key with him, and turns on and off the fluid. As he turns it on, the sewage rushes out at right angles with the embankment down a conduit composed of half earthenware pipes, six inches in diameter, which by means of joints fit one into another. The conduits are about thirty feet apart, and the sewage, as it passes out, soon overflows right and left, covering a surface of say fifteen feet on each side of the conduit; thus the whole

field becomes irrigated in a very complete way. As soon as the earth has received a sufficient dressing of the liquid, the fluid is turned off by the turncock's key, and passes on to another piece of land. As the sewage overflows on the surface of the soil a disagreeable smell is emitted, but the most fastidious must admit that it is not much worse than the scullery-sink smell which we occasionally notice in houses when cabbage-water has been thrown down the sinks. If we subsequently look at a part of the farm that has been irrigated some days, we see the surface covered with a thinnish pellicle of dark blue or greyish crust; this as it dries cracks, and we notice the crop appearing through a friable mould; there is no longer any smell, but I can imagine that in muggy weather there must be a very nauseous effluvia, lasting for some considerable time, after a piece of land has been irrigated. The reader will ask what becomes of all this turbid water? In the valley of the Thames, particularly in the portion in which this farm is situated, gravel is found immediately beneath the surface, and into this bed, or shingle, water finds its way, and ultimately falls into the Thames, but before doing so the fluid has become purified by passing through the best possible filter that nature furnishes. We inquired for the outfall, in order to test the water, but we were told that, although this farm had not been artificially drained, it was never supersaturated with moisture. . . . We must protest against other boards of health bringing what may become a great nuisance into the close proximity of dwelling-houses. We would, moreover, point to the risk in many soils of permanently damaging well-water if the fall of the ground inclines towards houses drawing their drinking-water from wells. With these precautions, and a good choice of soil, we see no reason why other towns, as well as Eton, should not do as it has done."

COMPOSITION AND QUALITY OF THE METROPOLITAN WATERS IN MAY, 1872.—The following are Dr. Letheby's returns to the Association of Medical Officers of Health:—

Names of Water Companies.	Total Solid Matter per Gallon.	Oxygen required by Organic Matter, &c.	Nitrogen.		Hardness.	
			As Nitrates &c.	As Ammonia.	Before Boiling.	After Boiling.
	Grains.	Grains.	Grains.	Grains.	Degs.	D. gs.
<i>Thames Water Companies.</i>						
Grand Junction . . .	18.17	0.070	0.110	0.002	14.6	3.6
West Middlesex . . .	17.93	0.039	0.147	0.000	15.1	4.0
Southwark & Vauxhall . . .	18.50	0.074	0.120	0.003	15.0	4.0
Chelsea . . .	18.37	0.079	0.147	0.002	14.8	4.0
Lambeth . . .	18.93	0.101	0.111	0.002	15.0	4.0
<i>Other Companies.</i>						
Kent . . .	26.93	0.013	0.217	0.000	20.1	6.0
New River . . .	17.93	0.035	0.131	0.002	14.8	3.8
East London . . .	18.33	0.052	0.166	0.002	15.0	4.2

Note.—The amount of oxygen required to oxidise the organic matter, nitrates, etc., is determined by a standard solution of permanganate of potash acting for three hours; and in the case of the metropolitan waters the quantity of organic matter is about eight times the amount of oxygen required by it.

The water was found to be clear and nearly colourless in all cases but the following, when it was more or less turbid—namely, in that of the Lambeth, the Chelsea, and the Southwark and Vauxhall Companies, that of the Lambeth being very turbid.

The average quantity of water supplied daily to the metropolis during the preceding month was, according to the returns of the Water Companies to the Association of Medical Officers of Health, 105,457,575 gallons; and the number of houses supplied was 495,677. This is at the rate of 32.3 gallons per head of the population daily.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—Bacon.

B. S. says that many Poor-law Officers were induced to sign petitions against Mr. Stansfeld's Public Health Bill before they had exactly mastered the subject. Our correspondent should read Professor Stokes's admirable address in the *Medical Times and Gazette*, p. 440, April 13, 1872.

Dr. A. P. Stewart is well known as a well meaning, puzzle-headed person, who shows his capacity for organising the sanitary administration of the country by indulging in personal abuse of anyone who differs from him. There is no need to refute Billingsgate.

E.—The *Dengue*, *Dandy*, *Breakbone*, or *Scarlatina Rheumatica*, is not a form of scarlatina properly so called, but a specific fever *per se*. It begins very abruptly; has an initial and a terminal rash. Its pyretological tracing differs from that of scarlatina, in having a lower temperature after the first exaltation. There is desquamation of the skin, and possible albuminuria. The blood has an abundance of *bioplasm*, as Beale calls it, though this is common to all fevers (see the *Indian Medical Gazette*).

B.—The question is *sub judice*, whether the poison of cholera enters the blood, deranges that fluid, and interferes with the action of the heart and lungs, causing intestinal flux as a secondary result; or whether it enters the intestinal canal, produces violent irritation, hyperæmia, shedding of epithelium, and hæmorrhage, as primary effects, with changes of the blood as secondary. The results of early treatment, the well-established facts of the benefit of seeking out and treating early cases of diarrhœa, give probability to the intestinal hypothesis. See (besides Niemeyer, translated by Latham) the Ninth Report of the Medical Officer of the Privy Council on the cholera of 1866. Mr. Simon's conclusions harmonise with Niemeyer's. The question of temperature is but broached; we do not grasp it as yet.

W.—We are grateful for the letter from a "Resident Medical Officer to a Workhouse," quoted from the *London Daily Chronicle and Clerkenwell News*. It overstates the case, and is too severe on certain amiable and public-spirited men; but it shows pretty conclusively how those persons have reckoned without their host who believe that the Poor-law Medical Officers are unable and unwilling to do sanitary duties. He is not just in calling the elaborators of certain schemes "an interested clique"; if he had said that they viewed men and things through tinted spectacles, it would have been enough.

The *Sin of the Century*.—The *Journal of the Gynecological Society of Boston* for May, 1872, contains the history of a curious development of this matter. We gave, three years ago, a full account from the pen of an eminent Parisian Physician of the practices resorted to in France for limiting population. Other practices, still more actively criminal, for the prevention of pregnancy have been invented in America, and are already known here. Dr. Storer and other eminent American obstetricians deserve credit for speaking out. So long as a crime is little known, it is better to hush it up, in order not to spread the knowledge of evil. But when such a crime becomes widely prevalent, and is deemed by the ignorant to be no crime—only a matter of personal convenience—then there can be no doubt that the Medical moralist should speak out, as Dr. Storer did in his well-known "*Why not?*" We were not aware that the matter had been brought before the late Council at Rome by a French priest, with a view of getting the Council to consent to a relaxation of church discipline. We had always admired the steadfastness with which the Catholic Church had set its face, as the Bible everywhere does, against these unnatural practices, and hope she will be firm. How singular that a misdemeanour should prevail in France, because, as is alleged, of the scarcity of land and the difficulty of living, and hatred of expatriation; and in America, where land wants occupation, and population is a source of wealth! It will be said that the crime prevails only in the more refined and luxurious Eastern States of the Union; but it is a result which centuries of aristocratic refinement have not inflicted on England. Our women are sometimes accused of neglecting lactation, but never of refusing the risks and duties of pregnancy and childbirth.

THE BAKER BROWN FUND.

This fund is being raised on behalf of Mr. Isaac Baker Brown, who is paralysed, and in great pecuniary distress.

VACCINATION ETIQUETTE.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I have to thank you for your kind opinion on the subject of "Vaccination Etiquette," and should now like to be informed of the way in which a District Vaccinator who invaded my district should be treated by his *confrères* for retaining to himself the whole of the fees he received from the Government, amounting to about £50 sterling, notwithstanding his being aware of the other vaccinators having acted differently. For instance, I vaccinated twelve persons myself by mistake, and I felt no regret in handing over the names to my *confrère* to whom the district belongs; and he in like manner sent me 150 names of persons vaccinated by him in my district, but as the service saved me a considerable amount of time and labour, I only accepted half the amount, besides allowing him the full amount for mileage. It is not the value of the money deprived that I care about, but the keeping up of the dignity of the Profession I have the honour to belong to that induces me to trouble you. I am, &c. K.

. Appeal to the highest Government Professional authority within reach, and unless redress be obtained, and an apology be made, cut the offender..

ANTIQUARIAN.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Charles Reade said that to save his neck from the halter or his soul from damnation many a critic could not write a chapter. An eminent publisher, the other day, expressed his opinion that a certain style of writing never succeeds if at all jocular. The cap and bells are sadly out of place in Medical literature, the slightest levity ill-timed—discordant. But as one Practitioner finds that every care vanishes the moment he enters under his own roof, and a second seeks solace in the bottle in the endeavour to distract the mind from worries, Professional as well as private, the third may incline to scribbling ephemeral nonsense, feeling very grateful to the editors of Medical journals who insert contributions.

such as they are. This evening, for the first time in life, the accident of laceration of the perineum occurred—a young primipara, rapid labour, the arch of the pubis too acute, the child cocoon-headed. Now before me are appeals for help, official wiggings, and unpaid bills. Taking thought will not add a cubit to one's stature, working ever so hard will not increase income, but it will add vexation and sorrow and several nails to the coffin. Why not mentally battle with the skeletons—shake off the old man of the sea? Why not for an hour find comfort in the pen? Here goes: Read in De Quincey that he used to take sixteen ounces of laudanum daily. Read in the "History of Domestic Manners and Sentiments in England during the Middle Ages," by Thomas Wright, the following facts:—Our ancestors went to bed perfectly naked, but covered up their heads; all audiences and gossip took place in ladies' bed-rooms; stays and umbrellas were introduced by the Anglo-Normans; hats were worn indoors; medicinal herbs grew in every garden; ladies were nurses, Doctors, and sometimes clever poisoners. A co-respondent not merely had to pay damages, but also supply another wife. A mother would be punished if her child was scalded. As a rule, the ladies appear to have been good, hard-working wives, fond of flowers and animals, music, and gossip, especially at the baths. They enjoyed good health, as the want of light prevented late hours. Many of these bold barons in the days of chivalry must have been sad rips, drunk every night, although warned that apoplexy, paralysis, colic, quinsy, jaundice, gravel, and gout would follow. Sir Harley de Wimpole, in his cups, knocked his lady down, broke her nose, and smashed two front teeth. A knight and his lady, dining in a garden, had a difficulty, she falling into the water; afraid of consequences, the husband chartered a boat, but pulled up the stream, stating that, contradicting to the last, her body would float against instead of with the current. The coachmen who refuse to drive Edinburgh Doctors on Sundays would be startled to hear that in the good old times they would have been thrashed and thrust into irons. Many tales of the gallantry, not to mention the gluttony, of the clergy, ever prominent at public dinners, where they had swans and peacocks dressed in their feathers, the beaks and the feet gilt. In one of the religious plays or mysteries, Noah and his wife are supposed to have had a terrible tiff—she insisting on taking her cronies into the ark, had to be forcibly fetched out of a public-house by a policeman at the very last moment when the bell was ringing. The practice of swaddling infants prevailed generally; but at a very early age a child would be dressed up as the West-end Practitioner of the period (stethoscope, clinical thermometer, "our obstetric bag") if his cruel parents intended him to physic, lather, and shave.

Rat-a-tat at the door. Wanted at the cottages some distance off—a case of hæmorrhage. The wind blows a hurricane, the rain pelts down in drenching torrents; the dogs, Harry and Toby, wag their tails affectionately; but, preferring the society of the kitten on the hearth-rug, steadily decline the invitation to follow their unhappy master this dark, tempestuous night. Well, duty is duty—*me miserum!*—KISMET.

At the Royal Observatory, Greenwich, the mean reading of the barometer in the week was 30.00 in. The highest was 30.20 in. on Sunday evening, the 26th ult., and the lowest 29.79 in. on Friday evening.

* The figures in this column, excepting those for London and Dublin, are the unrevised numbers enumerated in April, 1871, raised to the middle of 1872 by the addition of a year and a quarter's increase, calculated on the rate which prevailed between 1861 and 1871. The London population is now based upon the number enumerated in April, 1871, as revised at the Census Office; this revision added 2456 (principally shipping population) to the unrevised number published in the preliminary Census Report. The population of Dublin is taken as stationary.

ORIGINAL LECTURES.

CLINICAL LECTURES ON INTESTINAL OBSTRUCTION.

By THOMAS BRYANT, F.R.C.S.,
Surgeon to Guy's Hospital.

LECTURE IV.

ON LUMBAR COLOTOMY FOR THE RELIEF AND CURE OF RECTAL OBSTRUCTION AND DISEASE.(a)

(Concluded from page 566.)

I WILL now proceed to consider the operation of colotomy as a curative agent—as an operation by means of which repair may go on uninterruptedly in the seat of the disease, even to a cure, and by which relief to local pain may be given and life prolonged; for I have something more than a belief that this result may be looked for in many cases, if not all, of simple ulceration of the bowel, as well as in cases of syphilitic stricture.

In cancerous disease such a consequence of the operation can hardly be expected; and yet, in the case now to be related, it would appear as if a curative process has taken place—for the ulceration that existed before the operation has now ceased, and a smooth, non-ulcerating, nodular structure alone remains. The structure exists as it did before, but clearly no progressive mischief is present. The patient suffers no pain from the local affection. The ulceration that existed has skinned over, and presents a smooth, unbroken surface, and now secretes a clear mucus. No blood or broken-up tissue comes away after examination.

Stricture of Rectum—Colotomy—Recovery.

(Reported by Mr. BARNARD.)

Elijah B., aged 38, was admitted into Guy's Hospital on August 31, 1871, under Mr. Bryant, with stricture of the rectum. He had been a healthy man up to eighteen months ago, when he had diarrhoea, and this has never left him for long. He has never had any pain in the bowels. He has at times passed blood with his motions. He has lost flesh. At times his bowels do not act for several days; his stools are always small. A stricture of the rectum had been detected by a medical man before his admission. On admission the anus appeared very patulous, and a narrow stricture was detected about one inch and a half up the bowel. It was so small that the top of the finger could not be passed through it; it was also ulcerated.

Oct. 10.—Mr. Bryant performed colotomy in the left loin, making the oblique incision. No difficulty was experienced in the operation. The bowel was stitched to the margin of the wound and then opened.

On the second day after the operation the man said he felt greatly relieved; the wound did well in all respects, and in one month the man had so convalesced as to walk out of the Hospital.

February 23.—Quite comfortable in all ways. Ulceration apparently healed; surface smooth and painless. Pure clear mucus alone escaped after examination.

I took this case to be one of cancer, for it was difficult to come to any other conclusion; and if it be, it certainly speaks better for colotomy as a curative agent in this affection than I have hitherto regarded it, and it is an extra argument in favour of performing it at an early period of the disease.

Again, in cases of recto-vesical fistula, where ulceration takes place in the rectum and makes its way into the bladder, the relief given by colotomy is very striking; for I must remind you that patients the subjects of this condition are enduring the pain of ulceration of the rectum as well as that of a foreign body in the bladder. It seems, moreover, that this ulcerative action, although at times cancerous, is more frequently of a simple kind, and that, as a consequence, is quite capable of a complete cure. I have had four such cases to treat. In one (published in the *British and Foreign Review*, January, 1869) the ulceration completely healed after the operation. In two others, which I have related in detail at the Clinical Society, 1872, the same result seems to have taken place; for although in one the fistula is still clearly open, no signs of ulceration are present, and in the second, from recent intelligence, it appears that for the last three months the

fistula has closed. I operated upon him three years ago, and up to three months ago urine passed into the rectum downwards through the anus and upwards through the artificial anus in the left loin; for the last three months, however, no such escape has taken place. He can retain his urine as well as ever he could. He has no bladder irritation or rectal irritation. All his urine comes the right way, and all his motions pass through the loin. He suffers no pain whatever, locally or generally; and beyond the slight inconvenience—for the patient says it is only slight—of passing his motions through the loin, he is as well as ever he has been in his life.

The fourth case has only recently died, and I now show you the preparation removed after death. The disease is clearly villous and very extensive in its nature; it has made its way into the bladder. The operation in this case gave relief and prolonged life, but no more. Unlike the other three, it had no curative tendency; but the three are enough to support the views I would now wish you to bear in mind.

The same result may also be looked for in a certain class of cases of ulceration of the rectum that is not cancerous—a class that, if left alone, will go on to produce stricture, and that does not get well if left alone. I allude to severe examples of simple ulceration of the rectum, and to syphilitic disease. All Surgeons know the obstinacy of those affections, and the almost invariable tendency they have to progress and to end in a fatal stricture. The parts cannot heal for the same reason that an ulcer leading down to the muscles cannot heal so long as muscular movement is allowed, and that the painful ulceration of the rectum won't heal till the sphincter muscle is divided. Surgeons now also know how rapidly ulcers so placed do heal when splints are applied and muscular action is prohibited. When the fibres of the sphincter ani are paralysed by a superficial section of the sphincter muscle, surely the same result may be expected in those cases of ulceration of the rectum to which I now allude, when the bowel is left at rest, and the faeculent flow is diverted from the natural channel through an artificial opening as made by colotomy. In the case now upstairs in Naaman ward, in which cancerous disease was supposed to exist, this result has been already recorded to have partially taken place. In the case of recto-vesical fistula the same healthy action in kind, although more marked in degree, has likewise been recorded; and I believe that if colotomy were performed in many more examples of severe ulceration of the rectum, syphilitic and otherwise, the same result might be recorded.

With this object I performed the operation in February upon a young married lady, aged 24, a patient of Dr. Wise, of Plumstead, for extensive ulceration of the rectum and stricture of three years' standing, with so far excellent results. With the same object I hope to perform a like operation upon that woman in Astley Cooper ward whose case I have already read to you, with recto-vaginal and anal fistula, the result of stricture and ulceration. But remember that when the operation is performed with a curative object it must not be postponed to too late a period; it should be undertaken when all other means are clearly of little use, and when the disease, if left alone, must progress to its too certain end.

THE OPERATION OF COLOTOMY.

For irremediable stricture or mechanical obstruction of the rectum from any cause, *Callisen's* operation of opening the colon in the left loin should be followed. When the seat of obstruction is higher than the rectum, and it is a point of doubt whether it be in the sigmoid flexure or transverse colon, *Amussat's* operation in the right loin should be performed; for *Callisen* first suggested colotomy in 1796, and applied it to the descending colon, and *Amussat* revived the operation, and extended it to the ascending colon, in 1839.

The colon in this position lies behind the peritoneum, immediately beneath the transversalis fascia. The kidney is in close contact with it above; and in one case I operated upon this organ was placed so low down as to fill in the space between the rib and pelvis, and it had to be pushed upwards to allow of the colon to be seen and opened.

The operation is to be performed as follows, in the left loin:—The patient is to be placed upon his right side, with a pillow beneath the loin in order to arch somewhat the left flank, and turned two-thirds over on to his face. The outer border of the quadratus lumborum muscle is then to be made out, for this muscle is the Surgeon's main guide. An incision is then to be made, four or five inches long, beginning one inch and a half to the left of the spine, below the last rib, and passing downwards and forwards in front of the anterior spine of the crest of the ilium, the line of the incision passing obliquely across the external border

(a) Reported by Mr. Henry Clarke (student).

of the quadratus lumborum muscle about its centre, and taking the same direction as the nerves which traverse this part. By this incision the integuments and fascia are to be divided, and the external border of the quadratus muscle exposed; the abdominal muscles being laid open in a direction to the same extent as the external wound. All vessels are to be secured. The transversalis fascia will next come into view, and beneath this will be the colon; a layer of fat generally intervening. The fascia is to be opened with caution. In the loose fat and cellular tissue beneath the fascia the colon is to be found. When distended it comes at once into view on the Surgeon dividing the fascia; when empty some little trouble may be experienced in hooking it up with the finger. I have found on several occasions great help in doing this by rolling the patient over on to his back at this stage of the proceedings. The bowel falling into the finger is thus readily caught. Allingham says (St. Thomas's Hospital Reports, 1870) that from more than fifty dissections he has always found the descending colon to be situated half an inch posterior to the centre of the crest of the ilium; the centre being the point midway between the anterior superior and posterior superior spinous processes. He has never known this point to fail him. When difficulties are felt in the operation he believes they are from the colon being looked for too far from the spine; and in these views I cordially agree. When the bowel has been seized it should be partially rolled forwards, in order to expose its posterior surface; for if this be not done there is a risk of the Surgeon wounding the peritoneum, as it is reflected from its anterior surface on to the anterior abdominal walls. The bowel having been drawn up to the wound, is then to be secured to the integument by the passage of two double ligatures introduced through one margin of the wound, then through both sides of the bowel, and lastly through the second margin; these ligatures being firmly held by an assistant. The bowel should then be opened by a longitudinal incision about three-quarters of an inch long over the ligatures that have traversed its canal. The centre of the ligatures are then to be drawn out and divided into two portions; with these the two sides of the opening in the intestine are to be fixed to the margins of the wound. Two or more stitches may then be introduced to make the artificial anus secure.

The margins of the wound may be oiled, to guard against the irritation of fæces, and the patient placed in bed. At times the fæces escape in large quantities directly the bowel is opened; at others some slight fæculent discharge occurs at the time, the larger flow taking place later. This is not, however, a point of any importance, and the Surgeon should take no measures to get the bowels to act. Indeed it is better, as far as the operation is concerned, that the flow be postponed; for within an hour or so the parts about the wound become sealed with lymph, and thus the risks of extravasation are diminished.

After the operation a good sedative should be given, such as opium, morphia, or chloral, and the recumbent position maintained; a piece of oiled lint covered with oakum, and kept in place with a soft towel, being the best local application.

The sutures may be removed on the fourth or fifth day, according to circumstances, and the most perfect cleanliness observed. Good food and stimulants may be given within a day or so of the operation, repairs as a rule going on favourably.

When the wound has cicatrised the patient may get up, a folded napkin fastened on with a lumbar belt being a good application. The ivory ball or plug that has been advised appears to be a useless instrument; it cannot be kept in its place, and does not, therefore, prevent the prolapse of the bowel that is said to be so likely to follow the operation. An indiarubber ball, with enough of one of its sides taken away to cover in the wound, is an excellent application. It is capable of holding any little fæces or fluid that may pass; it retains wind, and is a good pad. Three of my patients are now wearing it, and express themselves as feeling great comfort from its use. With the oblique incision, as suggested, the prolapse of the bowel that is said so commonly to take place does not appear to be very troublesome; it takes place only to a very limited degree, the incision falling into the line of the lumbar integumental fold.

Should contraction of the orifice take place—a condition I have not yet met with—a sponge tent may be daily introduced. Mr. Pollock gives a case in Holmes's "System" where such treatment was a necessity.

After convalescence it is well occasionally to wash out the lower portion of the bowel with warm water, for some fæces are apt to pass the artificial opening and rest in the rectum, causing

irritation. When the anal end is open it is best to do this through the natural opening; when it is closed, through the artificial.

I have performed this operation now at least sixteen times—in four for vesico-intestinal fistula, in two for pelvic tumour, and in ten for stricture of the rectum. One of the cases of vesico-intestinal fistula lived four months after the operation, and died with suppurating kidney, but entirely relieved from all vesical and rectal distress (*British and Foreign Review*, January, 1869); two are now alive and enjoying life, suffering very little inconvenience indeed from the artificial anus (*Clinical Society*, 1872). One of the patients with pelvic tumour died on the third day from a rupture of the tumour; the second is in good health and comfort. Of the eleven other patients, one lived eighteen months after the operation in ease, dying from supposed cancer of the liver after a month's illness; four died within four months; and five others are alive, one having been operated upon in May, 1870, a second in November, 1872, and three this year.

Curling has performed and recommended the operation in seventeen cases, and in ten of these the patients survived over periods varying from two to eighteen months. Allingham has had ten cases. Two are now living, three and four years after the operation; one survived it four years and a half, and another nineteen months; five lived a few months, and one a few days.

These results cannot be regarded otherwise than with satisfaction; for it must be remembered that in all these cases the operation was undertaken when life was threatened, and the distress from the local disease was severe and otherwise irremediable. The operation is a good one in all cases of vesico-intestinal fistula, when solid fæces flow with the urine; in all cases of stricture of the rectum, as soon as the obstruction becomes serious and local distress great; in all other cases of mechanical obstruction to the rectum from pelvic causes, when no less severe measure for relief can be suggested; and last, but not least, in extensive ulceration of the rectum—cancerous, syphilitic, or simple—when local treatment fails to give relief, and local distress is great—when the general powers are evidently giving way from the local disease, and the suffering severe, quite irrespective of all mechanical obstruction.

In no case, however, should the operation be postponed till the patient's powers are failing, for the prospects of recovery are greatly lessened, and of convalescence rendered impossible.

LECTURES ON THE COMPARATIVE ANATOMY OF THE ORGANS OF DIGESTION OF THE MAMMALIA.

DELIVERED AT THE ROYAL COLLEGE OF SURGEONS OF ENGLAND IN
FEBRUARY AND MARCH, 1872,

By WILLIAM HENRY FLOWER, F.R.S.,
Hunterian Professor.

LECTURE VI.

(Concluded from page 622.)

THE tongue of the lion and of the other *Felidæ* is long, flat, and tolerably broad, with thin edges. It differs from that of the dog in the great development of the conical papillæ, which over the anterior fourth of the dorsal surface (except near the edges, where they are small and simple) are remarkably modified, resembling long compressed recurved horn spines or claws, at the front edge of the base of which on each side is a foliated tuft, softer in structure. The spines are largest near the median line, where they attain the length of one-fifth of an inch. They give the part of the tongue on which they are found the appearance and feel of a coarse rasp. Such papillæ cover the sides of the tongue, as far back as the circumvallate papillæ, their points being directed backwards and inwards, but in the middle part of the dorsum they become soft and simple. Behind the circumvallate papillæ, at the root of the tongue, are a group of very large, flattened, soft, and pointed papillæ. The fungiform papillæ are very small and inconspicuous. The circumvallate are disposed in two linear rows, four to six in each, converging posteriorly. A lytta, resembling that of the dog, but very much smaller, is found near the apex of the tongue. The faucial passage between the tongue and the glottis is remarkably elongated, and in connexion with the extensibility of this region, which is supposed to have something to do with the characteristic roar of the lion, as it is not found in the smaller members of the genus *Felis*,

the anterior cornu of the hyoid is in great part ligamentous. The salivary glands generally resemble those of the dog, the zygomatic, as described by Hunter, (a) being well developed. The lower end of the œsophagus, for a short distance before entering the stomach, has its mucous membrane elevated into transverse folds resembling *valvulæ conniventes*. The stomach is oval in form, the pyloric part sharply bent upon the cardiac sac, and the cæcum, as in all the *Felidæ*, is short, simple, and rather conical, not convoluted as in the dog. In a lion dissected by Hunter the small intestine was four times the length of the body, and the large intestine two-thirds that length. The cæcum was two inches long in one case and three inches in another.

The liver of the *Felidæ* resembles that of the dog in its general mode of division, though differing considerably in proportionate size of the lobes, the left central and the right lateral being both very small, while the right central is very largely developed. The caudate is of moderate size, and the Spigelian not divided by a fissure.

The other *Æluroid* or cat-like carnivores constitute the families *Cryptoproctidæ*, *Viverridæ*, *Hyenidæ*, and *Protelidæ*. Of the former, represented by a single species (*Cryptoprocta ferax*) from Madagascar, the visceral anatomy is at present unknown. The *Viverridæ* are the civets, genets, paradoxures, and ichneumons. The tongue in some of these is covered with simple conical papillæ of tolerably uniform characters, but in many (especially the herpestine or ichneumon-like forms) their papillæ are enlarged and otherwise modified over a limited area in the middle of the anterior part of the organ, forming a distinct rasp-like surface. They nearly all possess a simple conical or blunt cylindrical cæcum, but in one Indian form (*Arctictis*, the binturong), this part is exceedingly rudimentary, and in *Nandinia binotata*, a viverrine animal from the West Coast of Africa, it is wanting altogether.

The *Hyænas* resemble generally the *Viverridæ* in their visceral anatomy. The tongue has a circular patch of enlarged and pointed conical papillæ on its dorsal surface, and a small "lytta" within. The circumvallate papillæ are but two in number, and very small; the stomach is less elongated than in *Felis*, the fundus being very little developed. The small intestine is about eight times the length of the large, and the cæcum about eight inches long. (b)

The *Proteles* from South Africa is an animal closely allied to the hyænas in many characters, though differing greatly in habits and food, and interesting as presenting a corresponding modification in its organ of digestion. Although exceeding a common fox in size it seems to have no power of killing or eating entire vertebrated animals, but subsists chiefly on insects, larvæ, and the viscera or other soft parts of higher animals in a decomposing condition. Its molar teeth differ from those of all other carnivores, and more particularly from its nearest allies, the hyænas, by their exceeding small size and rudimentary characters. The tongue is large and spatulate, covered in front with very large, circular, boss-like, conical papillæ. The submaxillary glands are greatly developed, as in insectivorous animals generally; their ducts open on the inferior surface of a leaf-like projection of the mucous membrane of the base of the frænum, with a dentated anterior edge. The stomach is of globular form, with a very distinct pyloric portion, the muscular coat of which is greatly developed; and the pylorus is closed by a strong valve leaving a crescentic aperture, the whole organ closely resembling that of the armadillos, which the *proteles* resembles in the nature of its food, though so widely removed in zoological position. The intestinal canal is not five times the length of the body, and the cæcum short and globular. (c)

The *Arctoid* or bear-like carnivora include the true bears (*Ursidæ*), the racoons and their allies (*Procyonidæ*), and the great family of weasels, martens, gluttons, ratsels, badgers, otters, etc. (*Mustelidæ*). Though so different in external appearance and habits, these animals present many common characters in their organisation. The tongue is generally very extensile, and the conical papillæ are small and soft, the fungiform papillæ well marked, and the circumvallate papillæ numerous (seventeen in number, and forming a complete V in *Ursus labiatus*). The salivary glands resemble those of the dog, though the zygomatic may be very small, or wanting. A lytta is found in the tongue of most species, though not in all. (d) The

stomach has the usual characters of the other members of the order, but the cæcum is invariably absent, the only distinction between ileum and colon being the sudden change of character of the mucous membrane, especially the absence of villi in the latter, and the presence of a large patch of agminated glands at the lower end of the former. The absence of cæcum in this group is rather remarkable, as it contains the least purely carnivorous members of the order, and in other groups the development of the cæcum seems to bear some proportion to the more or less vegetable nature of the aliment. The liver is divided in the same manner as in other carnivora, but the relative size of the lobes varies much in different genera.

FIG. 24.

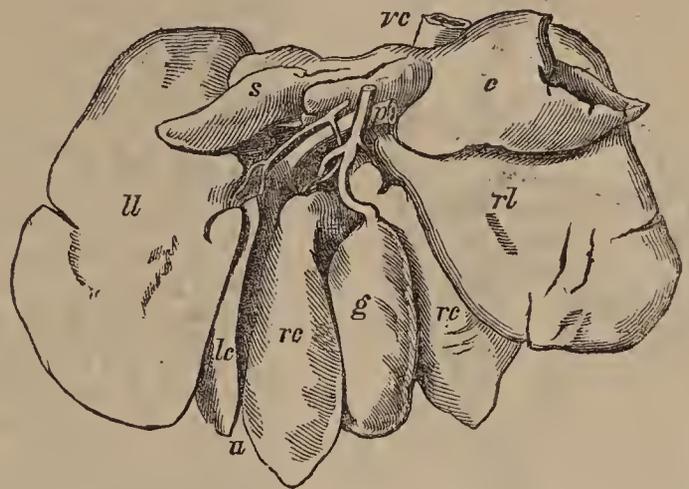

FIG. 24.—Under surface of the liver of the sloth bear (*Ursus labiatus*) u umbilical fissure, u left central lobe, rc right central lobe, rl right lateral lobe, c caudate lobe, s Spigelian lobe, g gall-bladder, vc vena cava, p vena portæ.

Associated with the ordinary carnivora is a group of animals which appear to be modifications of the same type adapted for an aquatic mode of life. These constitute the sub-order *Pinnipedia*, including the seals, sea-bears, and walrus. These are purely carnivorous, feeding mainly on fish, but also on marine invertebrates—as crustaceans and molluscs and annelids.

In the common seal (*Phoca vitulina*), taken as a type of the group, the characters of the mouth and teeth are in accordance with the habits of catching and swallowing slippery living prey—the gape being wide and the teeth much alike in character, sharp-pointed and recurved. The lips are thick and not very flexible, the lining membranes of the mouth smooth, the ridges of the hard palato very little developed and irregular. The tongue is short, broad, flat, and bifid at the apex, and has very little power of extension. The upper surface of the anterior two-thirds is covered with thick, short, soft, blunt conical papillæ; in the middle part of the dorsum they become pointed, with the apices directed backwards; at the tip and the sides they are round. Among them are scattered a few round fungiform papillæ, scarcely larger than the conical, and not very distinct from them. The posterior third of the dorsum is covered with greatly corrugated soft mucous membrane without papillæ, resembling that lining the mucous membrane and soft palate. A pair of papillæ with flattened round tops, which rise from among these corrugations, may be considered as rudimentary circumvallate papillæ, although they have no distinct surrounding wall. The tonsils are quite distinct, as lobulated oval protuberances of the mucous membrane, situated in a deep fossa with elevated walls, deeper and more distinct anteriorly than behind. The lining membrane of the pharynx and œsophagus is much folded, the latter in a longitudinal direction. There is no uvula.

The rudimentary condition of the salivary glands of the seal has often been noticed, and it is commonly stated in works on comparative anatomy that the parotid is absent. This is, however, far from being the case, as a preparation dissected by Mr. Lidderdale just added to the Museum shows. This gland has the usual situation just below the cartilaginous auditory meatus; it is very much flattened, of circular outline, about an inch in diameter, and much lobulated. The duct, formed by the union of three principal branches, runs directly forwards across the masseter muscle, and opens into the mouth opposite the hinder part of the crown of the posterior upper molar tooth. The submaxillary gland is solid, compact, and oval, flattened on its deeper surface, three-quarters of an inch in length, and of nearly the same breadth; its duct, accompanied at its commencement by several semi-detached glandular lobules, runs forward in the usual course, and opens in the floor of the mouth,

(d) It is wanting in the otter, but immensely developed in the kinkajou.

rather farther back and more distant from the middle line than usual, by the side of the root of the frænum of the tongue, and without any papilliform elevation of the mucous membrane. There is also a small and slender accessory submaxillary (or sublingual) gland, about half an inch long, placed on

Fig. 25.

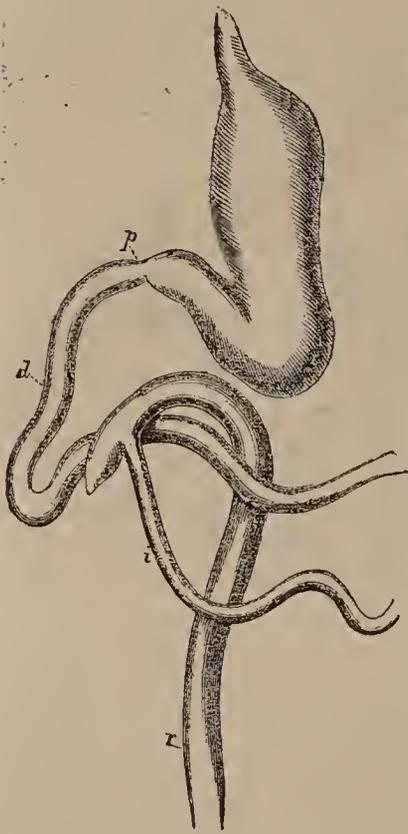

FIG. 25.—Diagrammatic view of the position of the abdominal alimentary canal of the seal (*Phoca vitulina*), the coils of small intestine being omitted. The lower end of the stomach is somewhat displaced to the left, so as to show the arch of the colon, which when *in situ* it conceals: *p* pylorus, *d* duodenum, *i* ileum, *r* rectum.

the same manner as in the other carnivora, but these lobes are partially subdivided by numerous notches and fissures, and their relations at the attached or posterior border somewhat modified by the dilatation of the vena cava at this spot into an immense sinus. The gall-bladder is present as in all carnivora, but it is peculiarly curved, its fundus being directed to the upper surface, and not the free edge of the liver. There are usually two or three small hepato-cystic ducts entering the gall-bladder near its neck. The common gall-duct has a considerable oval dilatation within the walls of the duodenum, into which the pancreatic duct enters.

The visceral anatomy of the sea bears (*Otariidæ*) and the walrus (*Trichichidæ*) appears to differ but little from that of the *Phocidæ*. They all have the same form of stomach, long narrow intestine, small cæcum, and short simple colon. (e)

THE NEW HOSPITAL AT PARIS.—The Administration of Public Assistance is about to erect a new Hospital, containing 550 beds, at Ménilmontant—one of the districts of Paris in which the poor abound, and which is too far removed from the other Hospitals. It is to consist of four separate pavilions, having spacious wards, which are not to contain more than twenty-two beds, while there are also to be numerous rooms with only one, two, three, or four beds. Each ward is to have its separate staircase, and the patients will be raised by lifts while lying in their beds. On the first stage of the pavilions there are to be galleries in the form of terraces, where convalescents may be in fine weather, protected by awnings. On one side of the four pavilions a lying-in establishment, one storey high, and surrounded by gardens, is to be erected. In another separate garden the small-pox patients are to be provided for. The total expense is estimated at 9,343,000 fr., of which 1,600,000 fr. have been expended in the acquisition of the site.—*Union Méd.*, June 4.

ORIGINAL COMMUNICATIONS.

CONSIDERATIONS RESPECTING THE PRODUCTION OF HEAD SYMPTOMS.

By C. HANDFIELD JONES, M.B., F.R.S.,
Physician to St. Mary's Hospital.

(Continued from page 655.)

10. DR. PEACOCK (*Pathological Transactions*, vol. xvii., p. 6) records the case of a boy, aged 4, who died with an abscess containing eight ounces of pus in the right middle cerebral lobe, extending close to the convolutions. It was surrounded by indurated tissue containing glomeruli, and a few similar corpuscles were present in the right corpus striatum and optic thalamus. Some lymph on the surface of right hemisphere; left side of brain, spinal cord, membranes, and other organs sound. The illness lasted about six months. The first symptom was a fit, which left him permanently and completely paralysed on left side. Three months before death there was right ptosis, dilatation of both pupils, loss of vision in right eye, and imperfect in left, pain in right temple. The ptosis disappeared. He died in convulsions. Was very intelligent. The record of this admirably observed case may be thought favourable to Dr. Hughlings-Jackson's view, as indications of material lesion were found in the right basal ganglia. Yet I think it can hardly be contended that the change in these ganglia was sufficient to produce complete hemiplegia, and, besides, it is quite possible that it might have been an indication of commencing decay in the centres from cessation of their function during six months. Possibly, as the abscess was of large size, the channels for the conveyance of the will to the motor centres were so extensively destroyed as to stop communication. Yet the abscess may have enlarged considerably in the last six months, and the induration have extended considerably beyond its limits at the time the hemiplegia occurred. Moreover, the latter, if produced by induration, should have occurred gradually, whereas it was complete from the first. I am therefore most disposed to attribute the hemiplegia to the irritation caused by the abscess, or to the arachnitis. The paralysis of the optic centres and of portions of the third nerves cannot be referred to any lesion of these districts. They seem to me, like the convulsions, to be results of irritation. This is the more probable as the ptosis disappeared. This case may be compared with Case 6—one of hydatid cysts. In both the intelligence was acute, there was blindness, head pain, and death by convulsions. But the paralysis differed much in the two cases, and this difference it does not seem possible to explain by any lesion that was detected.

11. Dr. Cholmeley (*Pathological Transactions*, vol. xix., p. 23) records the case of a female aged 24, who when admitted was quite unconscious and could not be roused; reflex movements and hurried breathing were produced by pinching and tickling. There appeared to be no paralysis of the limbs or face; the limbs were now and then slightly moved. The urine was non-albuminous. Axillary temperature last two days 100·8°. She died suddenly on the fourth day after admission; there was no stertor nor convulsion. She had been ailing for about six months with apparently chronic rheumatism; last nineteen days had severe and incessant headache. Four days before admission she suddenly became unconscious, and talked wildly; had fits of shivering for four days; the day after she seemed paralysed. Pia mater of hemispheres much congested, most on left. An abscess in left anterior lobe, two inches by one inch and a half, bounded behind by anterior commissure, with well-defined dark borders, not extending to base; adjacent cerebral tissue firm, not congested; nothing else morbid anywhere. No hemiplegia seems to have existed in this patient, only paralysis of both hemispheres and of the vaso-motor centres. As the disease was acute, this could hardly have been caused by any change of tissue proceeding from the abscess, and certainly not by anæmia. It was produced, I believe, much in the same way as it might have been had a clot occupied the site of the abscess. Was not the sudden death in like manner due to some morbid impression communicated to the vagal nuclei, and causing inhibitorily arrest of cardiac action? Such stoppage of respiration or of circulation is, I believe, by no means rare.

12. The following case is taken from my Lumleian Lectures:—P. S., aged 47, male, syphilitic, suffered with paraplegia coming on gradually; the palsy was blended with a good deal of rigidity and some sensory disorder, and much variation of temperature in the affected parts. Other symptoms were

hiccup, vomiting and headache, double vision, slight temporary ptosis, some paralysis of sphincter vesicæ, and latterly much delirium. Scarce any affection of upper limbs. The illness lasted about five months. The brain was healthy, with the exception of two tubercles situated at the antero-inferior part of the pons Varolii. The larger was about the size of a small bean, and lay just beneath the most superficial layer of transverse fibres, nearly on the median line; the smaller was the size of a pea, more superficial, and lay close to the median line. The cord was microscopically examined, but no exudation or granule cells were found anywhere. It appeared quite normal to the naked eye. The kidneys were tolerably healthy. There can be no question in this instance that the tumours were the cause of the symptoms, and yet it seems impossible to account for the latter by the local lesions. The tubercles caused irritation, which was conveyed upwards to the hemispheres and nuclei of the third, and downwards to the lumbar enlargement of the cord. The brachial escaped this morbid influence, just as it does so many others that cause paraplegia, probably by having a stronger organisation.

13. Dr. J. W. Ogle, in *Pathological Transactions*, iv., p. 23, relates the case of a female, aged 22, who had strumous disease of the shoulder-joint, left facial paralysis, and left ptosis, but answered rationally. Evacuations were passed involuntarily. Up to the day of her death she recognised those around her when roused. Gradually sank and died without any convulsion or paralysis of limbs having ensued. Brain not congested. Right optic thalamus occupied by a large mass of scrofulous deposit, which made it seem twice as large as normal; it pushed downwards, and displaced considerably the corpora albicantia and optic commissure. Right crus cerebri entirely involved in the malignant mass. There were pricking sensations in the upper extremities; no hemiplegia. At one time she had intense headaches and loss of consciousness.

14. G. P., aged 45, carpenter. Left hemiplegia commenced fourteen days before admission; got worse. There was right ptosis, left facial and left tongue paralysis, vision somewhat impaired; a history of constitutional syphilis. After admission he had much delirium at night; his speech was indistinct, but he remembered words well. The delirium and hemiplegia continued, and he died after seven weeks' illness. Inner surface of skull roughened; hemispheres normal; fornix diffuent; left optic thalamus normal, but right much enlarged and softened, extending quite across to left side, narrowing and displacing the third ventricle. In softened substance no glomeruli nor pus cells, only a *débris* of tissue and fine fibres. In substance of right crus a hard grey tumour of large hazel-nut size, consisting of imperfect fibres and granular matter. Both corpora striata normal. Right third nerve appeared discoloured and wasted.

In both these latter cases there was a tumour involving the right optic thalamus and right crus cerebri, and apparently no other disease except softening of the fornix. The tumour pressed downwards chiefly in Case 13, to the left in Case 14. The symptoms were remarkably different. Hemiplegia existed in 14, none in 13. Right ptosis in 14, left in 13. Tolerably clear intellect in 13, much nocturnal delirium in 14. Attacks of severe headache and unconsciousness in 13, none in 14. In the latter impairment of vision and of speech, which seem to have been absent in the former. In both there was left facial paralysis. The sphincters were paralysed in the first alone. The right ptosis may be explained by the state of the third nerve in Case 14, but the left ptosis, the facial paralysis, the impaired speech, the nocturnal delirium, the headaches and loss of consciousness, the palsy of sphincters, cannot be accounted for by local change. What was the effect produced by the softening of the fornix it is difficult to say, but we have no knowledge that would enable us to refer the phenomena occurring in Case 14 to this lesion. According to Lockhart Clarke, the facial nerve-roots do not decussate in their course to their nuclei, so that in right-sided lesion one would expect right facial paralysis. The delirium and the intense headaches clearly imply irritation, and the same cause must be assigned for the paralysis, I believe. These cases strongly illustrate how different may be the phenomena which occur with almost precisely similar lesions.

I do not assert that the evidence afforded by these cases is at all conclusive. I am aware that a more searching scrutiny than has been yet made is requisite to prove the point that the symptoms are not dependent on material lesion; and yet I must think that the facts strongly support the negative view. In admitting the necessity for careful scrutiny into the textural condition of secondarily paralysed centres, I would, however, observe that too much stress must not be laid on small amounts

of lesion. If a corpus striatum can function fairly well with a tumour or a small cavity in its substance, or a hemisphere with an abscess in it, we must not too readily conclude that microscopic lesions, unless very marked and extensive, are really the cause of morbid phenomena. Looking back at all the evidence that has been adduced, I can hardly doubt that the proposition will be found to hold true—viz., that a morbid state of a given centre may so affect other centres with which it is commissurally connected as to disorder or arrest their function. The latter, as well as the former, may, I conceive, be properly included among the results of irritation; for where derangement exists it is certainly not unreasonable to expect that it may in certain cases amount to such a pitch as to cause cessation of action. Thus a moderately strong electrical discharge merely irritates the nerves and muscles subjected to it, but a very strong one paralyzes. So with alcohol, digitalis, and other agents—in excessive doses they paralyze. But this term "irritation" is objected to as vague, and as affording no satisfactory explanation of the phenomena. I admit the charge, in so far as that we comprehend very imperfectly how the effect is produced; but that a morbid effect in some way is produced under the supposed conditions cannot be denied. Is it not a fact that a tapeworm in the bowels may cause headache, vertigo, or even epilepsy? Does not peritoneal irritation enfeeble and arrest the heart? May not sciatica paralyze the bladder, or facial neuralgia the muscles of the eye? These, and many like instances, show positively that unhealthy excitation of afferent nerves, or of tissues in which they ramify, can derange secondarily the working of the centres to which the morbid impressions are conveyed. The amount of secondary effect produced will vary *inversely* as the stability of nutrition of the elements of the recipient centre, and *directly* as the intensity of the impressions. A weak centre will be deranged by slight irritation, which takes no effect on a strong. This is a very important point to note, as it shows us that we must not expect the results of apparently similar irritations to be always the same. This is notorious as regards outside irritations; yet I may mention that I have seen the face very blanched and the heart's action greatly enfeebled in two females during the operation of vaccination, and that a friend was most gravely alarmed about one of his patients (a male, aged 22) after the same procedure. The syncope was so deep and persistent that he was not restored for an hour and a half. I saw this young man afterwards in consultation, and found his heart organically sound, but irritable and weak from over-rowing and over-smoking. In none of these instances was there any fear of the operation; but, nevertheless, the slight irritation produced more or less of cardiac paralysis. Such a result, though rare, seems to me very instructive; it teaches us that *morbid* stimulation may be essentially depressing—that, in fact, irritation may paralyze.

Now, the circumstance that the irritation originates, in such cases as we have been examining above, within the cranium, can make no material difference—we know that epilepsy may be equally produced from dental or intestinal irritation, or from a cranial endostosis. Why should we hesitate to admit that a focus of morbid action located in a far more highly organised and susceptible part should be capable of acting with injurious effects on those with which it is in close relation? Would it not, rather, be strange if no such effect occurred? And when we see a sudden lesion take place, as in hæmorrhage, and find that other centres besides the one directly injured are disabled, at the same time, it seems very difficult not to believe that some such morbid influence has operated on them as we endeavour to describe by the terms "shock" or "irritation"; the first implying probably only an acute degree of the second. As a speculation it may be suggested that what really happens in these cases is, that the state of the commissural nerve-fibres at the irritated ends is propagated to the cells of the healthy centre along the axis cylinders, and induces a like state in these cells to that which exists at the focus of disease—a state incompatible with healthy function. But this is a mere hypothesis, quite distinct from the *fact* which it seeks to explain. These views are essentially the same as those I have put forth in "Functional Nervous Disorders" (second edition, p. 16) and elsewhere. Some may prefer Brown-Séquard's explanation of the secondary paralyzes—viz., that they depend upon anæmiating spasm of the vessels produced by the morbid excitement—and though I do not adopt this opinion, it is very possible it may be correct. I have already referred to the writings of this eminent investigator on this topic, which seem to me not to have received the attention they deserve. Very noteworthy are also those of Andral, whose testimony is the more reliable as he makes no attempt to explain, but simply notices the facts. He more than once remarks to this effect: that beyond the

morbid states appreciable on the dead body there are others, quite as important, which escape the researches of the anatomist, and which add their all-powerful influence to the former in permitting or preventing the manifestations of functional disturbance. On page 164 he says, "the hemisphere opposite to that in which the softening is, may be affected in a manner altogether sympathetic, and it is thus we may conceive general disturbances of motion and sensation connected with a softening which occupies but a very circumscribed spot of one of the hemispheres."

It may now be worth while to see what bearing these views may have on the treatment of grave disorders of the brain; and considering our extreme poverty in this department, mere suggestions may be worth a hearing. If the symptoms evoked by intracranial mischief may be to an extent which it is difficult to determine beforehand due to irritation and functional disorder, it is clearly advisable to treat especially the latter, which is more remediable, and to let alone that which is beyond our reach. Suppose, the most common case, that blood has been extravasated into the corpus striatum and adjacent hemispheres. The bleeding is probably all over in ten minutes, before we get to the patient. But he is hemiplegic and very likely unconscious, with palsy of the tongue and face. What can we do to relieve these disorders? In so far as they depend on direct damage of nervous centres, we can do no more than put the system in a favourable condition to repair the injury. We can place the patient, as Mr. Bowles advises, on his side, and draw the tongue forward, so as to facilitate the breathing and obviate venous congestion of the head. Astringents suggest themselves as likely to promote the firm closure of torn vessels, the shrinking of the clot, and the consolidation of the lacerated tissue; and further, supposing the hæmorrhage to have occurred near the surface of the ventricles, may stave off the imminent risk of a rupture into their cavity, which is necessarily fatal. I think if I were attacked I should wish to be injected subcutaneously with ergotin, which has proved useful in dangerous hæmoptysis, and to take krameria tincture. I should like to have cool air blowing about my raised head, and probably some ice applied occasionally. But unless it was clear that my head was actively hyperæmic I would rather be spared the ordinary dose of croton oil, which can hardly fail to depress nerve power, and very seldom does any distinct good. Then as to the unconsciousness, the impending coma, and secondary paralysis which are dependent on shock, I would have restoratives administered; strong coffee, with or without a little brandy or wine, might do something to rally the nerve-centres from the depression caused by the internal concussion, or at least prevent its increase. Trousseau's experience led him to eschew all debilitating measures; he fed his apoplectic patients and gave them wine, and found that under this régime their symptoms yielded far more readily than when he acted differently. If convulsions ensue in any case from hæmorrhage having taken place into the membranes, or if violent delirium occur, the subcutaneous injection of bromide of potassium is likely to be of much service, although it is apt to cause a good deal of local inflammation. To more chronic cases the same views would apply, the principle of treatment in all being to sustain the power of the secondarily affected centres, and to protect them against the depressing inhibitory influence. This might justify the cautious use of opium or other so-called sedatives.

The suggestions now offered refer of course to cases where there is no marked evidence of active or passive cerebral hyperæmia, where the respiration is not oppressed or slow, the pulse not firm or retarded, and the blood-mass does not seem to exert undue intravascular pressure. When the reverse of this prevails we cannot do better than follow Sir Thomas Watson's counsels as to the use of bloodletting and purgation, which his most matured judgment by no means declines in appropriate cases. These, however, I strongly suspect are not the most frequent.

I ought to have mentioned that Dr. J. W. Ogle accepts the views of Brown-Séquard as to the production of the paralysis in certain cases by irritation conveyed from the original focus to other centres. He prefers the term "induced." (*Vide Medico-Chirurgical Transactions*, 1859.)

A LARGE and influentially attended preliminary meeting of the inhabitants of Clapham and Brixton took place last week to advocate the establishment of swimming and other baths, and to elicit the opinion of the public on this important question. The result of the meeting was highly satisfactory.

SHARK-BITE.

By J. FAYRER, M.D., C.S.I.

Hon. Physician to the Queen.

DENO, a muscular, healthy Oorya coolie, aged 30, was admitted into the Medical College Hospital on March 26, 1871, two days after having been severely bitten by a shark whilst bathing in the Mutlah. He had been rescued by his companions, but not before the savage creature had seized him three different times, inflicting most serious injury, tearing away a large portion of the left thigh and causing great effusion of blood. There was an enormous wound extending from about the middle of the left gluteal region to within three or four inches of the ham. It measured twenty inches in length, seven in breadth at the lower end, twelve inches in the gluteal region, and nine inches at its upper extremity. The depth was great, extending nearly to the bone, which could be felt only covered by a few muscular fibres. The flexors and great part of the glutæus maximus were torn away; the sciatic nerve divided, and several inches of it removed. The anterior aspect of the limb had escaped, and the femoral vessels and nerve were uninjured. He was depressed and feeble from shock, loss of blood, and pain; his pulse 112—better than might have been expected. He was restless and feverish. He appeared to have been a healthy and vigorous man before the accident. Notwithstanding the injury, he was able to move the limb slightly; he could approximate the knees and flex the limb, showing that some portions of the flexors were undivided. Sensibility seemed to be preserved in the integument of the leg and foot. In addition to the wound above described there were others—one on the right gluteal region six inches in length by four in breadth, the integument to this extent having been torn away and the subjacent tissues deeply lacerated; another on the right elbow, which had taken away a narrow strip of integument about two inches in length. There were also several deep punctures in the back, corresponding to the size of the shark's triangular teeth. These wounds were all superficially sloughing when he was admitted.

In consultation with my colleagues it was determined to attempt to preserve the limb. The loss of so much muscle, the division of the sciatic nerve, and the great extent of the wound were suggestive of immediate amputation at the hip-joint; but as the joint itself was uninjured, and his condition as favourable as could be expected under such circumstances—considering the shock and loss of blood (which is said by his companions to have been very great)—it was determined to attempt to save him without the amputation at the hip, itself a most dangerous alternative. His bowels being confined, a dose of oil was ordered, and acetate of ammonia with nitric and chloric ether prescribed with reference to his feverish condition. Opium was freely administered, to allay pain and give rest. The limb was supported on a splint, and the wound dressed with poultices and carbolic oil dressing. Subsequently decoction of cinchonæ with quinine were given, and chloric ether. He was slightly delirious on April 2. The pulse increased to 120. Temperature varied from 97.5° in the morning to 101° to 103° in the evening. But the wounds had cleaned and presented a healthy granulating surface on April 3, covered with well-formed pus. He was very restless at night, and could not sleep, complaining of burning in the wounds. Hydrate of chloral was given, but with little benefit. An abscess formed on the left shoulder about this time (April 9) which soon degenerated into a sloughing sore from which a slough of subcutaneous cellular tissue separated. The wrist and forearm became œdematous. From the 10th he again began to improve, and slept better. The discharge moderate; the wound looking pale and pink, with imperfect granulations, but evidently contracting. His pulse fell from 120 to 110, and the temperature from 103° to 101° to 100°. A slight burrowing of matter with sloughing of subcutaneous cellular tissue occurred; this being laid open on the 18th, the wound soon began to granulate, and he continued to improve. On the 25th the surface of the wound had contracted three inches in length and one inch in breadth on the thigh, and two inches in the loins. On May 3 he had slight diarrhœa, which was checked by astringents. He now began to look more pallid and puffy about the face and limbs, but the urine contained neither albumen nor sugar. The wounds, though inactive, continued to contract. Potassio-tartrate of iron and infusion of calumba were prescribed, with two grains of opium every fourth hour to allay irritability and promote capillary action. The puffiness diminished for a few days, but it again returned, and the pulse became weaker and more rapid, and he again began to complain of a burning sensation in the

wound; sleep was imperfect, and fever and cough supervened on May 16, which continuing for fifty-six hours, left him very weak. He never rallied from this condition, and he gradually sank on May 21.

On post-mortem examination the left lung was found to be congested throughout, the lower lobe being in a state of grey hepatisation, pus freely exuding from its cut surface. The right pleural cavity contained a quantity of sero-purulent fluid. The pericardium contained about four ounces of serum, and there was a small fibrinous clot in the right ventricle. The liver and kidneys were fatty, and the latter congested. The whole muscular system was pale and flabby. The wound was cicatrising throughout; that on the back had healed. On dissection it was found that about seven inches of the great sciatic nerve had been torn away. The muscles on the back of the thigh were also torn away. The semi-tendinosus and membranosus, the long head of the biceps, and the gracilis had suffered; their divided ends were found agglutinated together with the lower end of the sciatic about three or four inches above the ham. The surface of the sore was formed by the short head of the biceps, vastus externus, and outer surface of the trochanter major; the edge of the sartorius with the adductors on the inner side. In the gluteal region it was formed by the surface of the external rotator muscles of the thigh, the pectinæus and quadratus femoris below, the deep fibre of the glutæus maximus above. The gracilis was torn across at about an inch from its origin, and the upper end of the divided great sciatic nerve was on a level with the edge of the lower margin of the quadratus femoris, upon which it lay thickened and adherent. The end of the nerve was bulbous, and tied down by the cicatricial tissue that matted all together. The general condition of the patient and the reparative action in the wound all at one time seemed to promise a favourable termination of the case, but pyæmic mischief, resulting in suppurative pneumonia of the left lung, supervening in the seventh week proved rapidly fatal.

Calcutta.

EXPERIMENTS MADE ON ANIMALS, TO ASCERTAIN THE FUNCTIONS OF THE LARYNGEAL NERVES.

By Dr. EMMERICK NAVRATIL,
Member of the Pesth University.

The change in the opinions of the Faculty concerning paralysis of the vocal cords has been so complete since the practical application of the laryngeal mirror, that to refer to former perfectly unfounded opinions would be quite superfluous; nor is it necessary to discuss the importance of laryngoscopy.

In a work published by me in the Hungarian language, in the year 1866, entitled "Diseases of the Throat," and in a series of articles on paralysis of the vocal cords, published in 1869 in the *Berlin Weekly Clinical Journal*, I more fully discussed the subject of paralysis in so far as laryngoscopy could throw any light on it. I laid particular stress on the fact that a total paralysis of one side of the larynx, provided it were not of a decidedly local rheumatic origin, might be traced to an abnormal state of the vagus or of the recurrent nerve (compression through an aneurism of the arch of the aorta, or some other morbid growth). As a further guidance in the art of laryngoscopy, I thought it expedient to make experiments on animals, the results of which I shall briefly state. Nor can I here refrain from expressing my sense of gratitude to Professor Balogh, in whose institution the experiments were made, for his collegial assistance, and to Mr. Simbriger, Medical student, for his willing and skilful aid.

We made nine experiments: eight on dogs, and one on a cat.

Experiment 1.—On a middle-sized dog. A drachm of tincture of opium was injected into the jugular vein; this produced profound torpor. Then we divided the superior laryngeal nerve running off diagonally at the upper third of the thyroid cartilage, and examined the larynx. The examination of the larynx was effected as follows:—The animal was stretched out on the dissecting-table, its head being towards the window. By means of two cords fixed to the jaw-bones, one assistant held the mouth widely open, and a second assistant pulled the tongue as far forward as possible, whilst I raised the epiglottis with a pair of long pincettes, and drew it forward. By this means we obtained a clear and distinct view of the larynx, especially when favoured by the light of a clear sky. In dull weather we placed a lamp behind the head of the dog, and

directed the rays into the mouth. After dividing the superior laryngeal nerve, no apparent change took place, either in the vocal cord or the arytenoid cartilage of the side operated on—the former performed its functions as usual, the glottis closing and opening normally; the dilators, contractors, and expanders, too, continued their functions. The division of the laryngeus superior on the other side was attended with the same negative result. Then we divided the N. laryngeus inferior seu recurrens vagi at the lower third of the neck on the left side; thereupon total inaction of the left vocal cord and arytenoid cartilage, as well as of the left half of the epiglottis, ensued. Then we divided the vagus of the right side in its cervical situation. After this operation, the glottis assumed the position it does after death—i.e., an intermediate position between contraction and dilatation, presenting the shape of a triangle, with its point foremost and its base hindmost. Inspiration inaudible, expiration loud and convulsive.

Experiment 2.—On a middle-sized dog. A drachm of tincture of opium injected into the saphena vein produced torpor. First we divided the superior laryngeal nerve of the left side—no change in the larynx. Then we extracted the N. accessorius Willisii of the right side in the jugular foramen, and in this case also the muscles of the larynx performed their functions as before, normally. We could not make any further experiments on this animal, as it bled to death in consequence of the injuries the larger bloodvessels of the neck had sustained in the operation on the accessorius Willisii.

Experiment 3.—On a large dog. In this experiment, as well as in those following, the animals were operated on under the influence of chloroform. The division of the laryngeus superior had a negative result. The N. accessorius Willisii on the right side was divided as follows:—The skin and the soft parts of the back were stripped off, and the vertebral column laid bare. Then a long, thin, sickle-shaped knife was thrust in, between the atlas and epistropheus, and inserted diagonally into the right side of the spinal marrow, so as to make an incision of about a quarter of its transverse diameter. Then we examined the larynx, which continued to perform its functions normally as well during phonation as expiration. The dilatation and contraction of the glottis, as well as the tension of the vocal cord, took place regularly. Hence the result was negative: not a symptom of paralysis of the larynx. However, the extremities and trunk of the side operated upon were completely paralysed. To convince ourselves that the accessorius Willisii was actually divided, we opened the spinal canal with a pair of strong bone-scissors, and laid it bare. The spinal marrow of the side in question proved to have been incised to a quarter of its transverse diameter, and the nerve in this situation was divided.

Experiment 4.—On a large dog. Division of the laryngeus superior with negative result. In consequence of the division of the recurrens of the right side, total paralysis of that half of the larynx took place. During the operation on the recurrens on this plethoric animal (a greyhound), several large jugular veins were injured, and our unavailing attempts to staunch the blood prevented further experiments.

Experiment 5.—On a large cat. The result of the division of the laryngeus superior was negative. We then divided the recurrens of the left side, which produced inaction of the left half of the larynx; this, however, did not prevent the glottis closing, but the closure was effected in such a way that the right vocal cord and the corresponding arytenoid cartilage crossed the median line and rushed to the paralysed side, without producing any visibly oblique position of the glottis. The results of the above-mentioned experiments on dividing the vagi or the recurrens were the same. During the torpor the N. accessorius Willisii of the right side in that part of the throat connected with the spinal canal was divided in the manner described in the third experiment. It was proved by laryngoscopic examination that the right side of the larynx also was paralysed, and the glottis assumed the position it does after death, similar to that after dividing both vagi or recurrens. The trunk and extremities of the right side were likewise paralysed. The torpor, which during the whole time of this operation had continued unmitigated, now grew so profound that the animal gave no more signs of life, and lay there quite stiff. After several attempts at resuscitation, however, we succeeded in rallying the animal, and the laryngoscope again showed the normal action of the cord and arytenoid cartilage. Hence, it is evident that the paralysis of the right side, observed at the moment, was not in consequence of the division of the accessorius Willisii, but merely a consequence of the general torpor.

Experiment 6.—On a middle-sized dog. Division of the

laryngeus superior of the right side, with negative results. Division of the right recurrens, with a positive result—*i.e.*, paralysis of the right cord and arytenoid cartilage, and of the right half of the epiglottis. Division of the accessorius Willisii in the spinal canal on the left side, with a negative result on the larynx. The spinal marrow of the part pierced was taken out, which showed that the accessorius Willisii had been completely divided.

The above-named experiments were made with a view to ascertain the functions of the laryngeal nerves; those following will show the duration of life after the division of the vagi and the recurrens, as also the incidents consequent on those operations.

Experiment 7.—On a middle-sized dog. Division of both vagi. Pulsations of heart before division, 120 to 140; inspirations, 18 to 20 per minute. After division of one vagus, hoarseness; after that of the other, total aphonia—the dog was no longer able to bark. The speculum showed the posterior portion of the vocal cords to be in a fixed position five millimetres asunder. Four or five minutes after the operation the animal began to crouch and shiver as if from cold. Soon it grew restless, moving from place to place in a rotary way, till at length it settled down. It hardly heeded calls. Its eyes were dull and partially closed. Occasionally it would raise its drooping head, rise from its sitting posture, and seek another place. After the lapse of five or ten minutes saliva began to drop from the mouth, terminating soon in profuse salivation, accompanied by frequent micturitions and evacuations, retching and vomiting. Pulsations of the heart increased, being 160 to 180 per minute, but were more feeble; inspirations less frequent, 12 per minute. After the lapse of an hour and a half the above-named symptoms assumed a new form. On respiration the animal used efforts to widen the thorax. With regard to breathing, expiration only was distinctly perceptible. The intervals between inspiration and expiration were from four to six seconds, respirations decreased to eight; pulse faint, 180 per minute, only audible during respiratory sinking of the walls of chest, imperceptible on inspiratory expansion. After the lapse of two or three hours' salivation, evacuations continued, inspiration was wheezing and irregular, and accomplished with convulsive efforts, lasting eight seconds; then there was noiseless sudden expiration, the expirations being four per minute. About eighteen or twenty hours after the operation, respiration hardly perceptible, pulsations of the heart rapid but feeble, salivation in a high degree, temperature considerably decreased, general enervation; death. Dissection: Oedema of the lungs in a high degree, incipient pneumonia of one lung; heart dilated, much congealed blood in its cavities; brain and medulla oblongata containing a middling quantity of blood.

Experiment 8.—On a large dog. Division of one vagus nerve and one recurrens. The right vagus having been divided previously, hoarseness in this case, too, was the immediate consequence; after the division of the left recurrens, aphonia supervened, the animal being unable to bark. The symptoms were the same as the above-named. The dog lived for two days and a half. Enervation and collapse in somewhat higher degree than after the former experiment. Dissection: Both lungs very sanguineous, but especially the right, which was also oedematous; brain, medulla oblongata, and heart in the same state as after the seventh experiment.

Experiment 9.—On a middle-sized dog. Division of both recurrens. Hoarseness and aphonia as above. The animal barked loud at the least noise at first, but now became perfectly silent. Frequent evacuations and micturition, for a short time; restlessness and salivation of a little longer duration, but also terminating within four hours. Breathing hard, yet not with such efforts as on the division of the vagi; expiration also more distinct, yet not so suppressed as in the previous cases. The intervals between expiration and inspiration a little longer, yet not so long as after the division of the vagus. The operation was performed on March 10, and the animal is still living (May 7). Although a little debilitated, it eats and drinks well, whilst the former animals refused all food. Paralysis of the vocal cords remains to this day in the same state as after the operation, and does not in any respect differ from that produced by a division of the vagi. Respiration is abdominal, and rather prolonged. The dog is incapable of barking.

Based on the experiments above stated, the following conclusions may be drawn:—

1. The N. laryngeus superior has no influence whatever on the motary sphere of the larynx.
2. The N. laryngeus inferior seu recurrens vagi is that nerve which supplies the muscles of the larynx; the expanders, con-

tractors, and dilators of the vocal cords are under its influence. Hence any interruption of the functionary powers of this nerve causes paralysis of the corresponding half of the larynx. If both recurrens are interrupted in their functions, all the muscles of the vocal cords become inert, and the vocal cords assume the position seen after death.

3. The N. accessorius Willisii has no influence whatever on the muscles of the larynx.

4. The division of the vagi is attended with fatal consequences; but an animal may live for some time after the division of the recurrens.

In conclusion, we may further add that our object in dividing the accessorius Willisii having been to obtain a distinct picture, it was necessary to divide that nerve in the spinal cord before its communication in the jugular foramen with the motor fibres of the vagus.

From these experiments we may conclude that the assertions of Claude Bernard, according to whom the accessorius Willisii enervates the contractors of the vocal cord, are erroneous. The circumstance that Claude Bernard divided the accessorius Willisii in the jugular foramen, might lead one to conclude that that nerve inosculated with the motor fibres of the vagus nerve at that point, and that the observed paralysis of the glottis contractors was rather to be ascribed to this circumstance; whilst in our experiments Willis's nerve was divided in the spinal canal, consequently before any commixture took place.

REPORTS OF HOSPITAL PRACTICE

IN

MEDICINE AND SURGERY.

WEST LONDON HOSPITAL.

DISEASE OF THE WRIST-JOINT—AMPUTATION—RECOVERY.

(Under the care of Mr. TEEVAN.)

The following account is extracted from Mr. Lee's notes of the case:—C. A., aged 45, carpenter, was admitted into the Hospital on March 9, 1871. History: Whilst the patient was lifting a heavy weight last September he twisted the right wrist-joint, and experienced much pain at the time. The next day the joint was red, swollen, and painful, and could not be used. In about ten days' time the inflammation began to abate, but the joint remained abnormally large and useless for work. Last December the patient had a sharp attack of gout, which involved the joint. From this date the inflammation increased, and in the month of January an abscess formed on its palmar surface, which was succeeded by another close to the end of the ulna. Father suffered from gout and rheumatism, and his sister died of phthisis.

State on Admission.—Patient is a fair man, with florid cheeks; body well nourished. Face indicative of suffering; hand carried in a sling. The entire wrist-joint is greatly swollen and indurated, and of a dull purplish hue. There are two fistulous openings covered with fungous granulations. Grating can easily be felt between the carpal bones, and any pressure elicits pain. A probe passed into the upper opening extends to three inches above the joint, and if it be introduced into the other it goes right across the dorsum of the wrist-joint. Pus wells out freely from both apertures. The patient was put on a generous diet, the sinuses laid open and dressed with carbolic acid. The state of the joint, however, did not improve, and as the patient's health began to decline through want of rest and pain, Mr. Teevan amputated the hand immediately above the joint on April 20, making a long flap from the dorsum, but none from the palmar surface, as the state of integuments did not permit it; the lower ends of the radius and ulna were sliced off, as their articular surfaces were in several places destroyed. The wound was a very long time healing, and it was nearly six months before cicatrization was complete, when an artificial limb was provided for the patient.

May 11, 1872.—To-day the man came to the Hospital, and said he had been in very good health and able to follow his occupation till a few days ago, when a small abscess formed on the stump, and after it broke he felt a pricking sensation in it, and detected the point of a piece of wire. Mr. Teevan extracted the wire with the forceps; it was one inch and a half long, and it was evident that it was a suture which had become included in the stump in the process of cicatrization.

EXTENSIVE INJURY TO HAND AND FOREARM—AMPUTATION—RECOVERY.

(Under the care of Mr. TEEVAN.)

Mr. Read's notes of the case have supplied the following facts:—T. B., a muscular, healthy policeman, aged 26, was admitted into the Hospital at 9 p.m., August 31, 1867, having met with an accident an hour previously, whilst working at a threshing machine at Hampton, by getting his right arm drawn into the machinery. On admission, he was very blanched and suffering from severe shock. The limb was extensively damaged, as all the integuments were stripped off the dorsum nearly up to the elbow; the extensor tendons were exposed and torn away from their attachments; the anterior surface of the limb was swollen and of purplish hue from the extravasated blood. The radius and ulna were both fractured, as were also all the metacarpal bones except the first and fifth. When the patient was seen by Mr. Teevan, at 10.30 p.m., he had rallied considerably from the shock, and, accordingly, amputation was performed at the junction of the upper and middle thirds, a good long flap being made from the anterior surface of the limb, as the state of the integuments on the dorsum did not permit of their being utilised.

The patient made a rapid recovery, and by October 1 the wound was completely healed. A few days later he left the Hospital. The man had an artificial limb made for the stump, and he has ever since been employed as attendant at one of the cabstands.

HULL INFIRMARY.

CHRONIC LEAD POISONING—AMAUROSIS.

MARY ANN D., aged 21, was admitted into the Infirmary on April 4, 1872, under the care of Dr. Lunn. She sought admission on account of intense continuous pain in the brow, over the eyes. The history she gives is as follows:—She went to work at the lead mills for the first time five years ago, and she worked there irregularly for four years; never had lead colic. Twelve months ago had severe frontal headache for a fortnight, then had pain in the eyes, and a few days after noticed her sight failing. She says she had no photophobia; objects appeared smaller. When getting her tea she misjudged the distance from her of her cup, her hand passing beyond; the poker before the fire appeared as two. At the end of two months, to relieve her headache, had tied a handkerchief round her head; was asleep half an hour, and on waking was blind, and has since remained so. The ophthalmoscope showed simple white atrophy of right optic nerve; the vessels small. In the left eye the disc was woolly, and the vessels also small. Both irides were dilated and fixed. The headache was relieved by blisters behind ears, and by iodide of potassium. She was discharged on May 18.

Mary Ann W., aged 17, was admitted under the care of Dr. Elliott, February 7, 1872, as an out-patient. When first seen she was very anæmic, the lymphatic glands on each side of neck swollen, and she had a tremor of right hand and head. She was totally blind; both irides extremely dilated and fixed; the sclerotic coat white and glistening. She says she worked off and on at the lead mills for a year preceding the beginning of October last; had colic twice; once laid up four months with it. She worked in the mill up to the time of her sickness. In October she was taken suddenly giddy in the street; she did not vomit then, but did so shortly after her return home. At the end of five or six days, during which time she was light-headed and had illusions and pyrosis, though but little pain in head or eyes, she went to sleep for five hours in the daytime, and on waking was totally blind. During the fortnight following she lost the use of her limbs, and at the end of that time needed to be fed and carried about like a child. The sense of feeling was also in a measure lost. She then began to improve, and, although her sight did not in the least return, she lost the paralysis, and the sense of feeling returned in great part. The sensibility of the right hand is still low. For the first few weeks suffered great pains in limbs and joints. The ophthalmoscope showed simple white atrophy of both optic nerves, with diminution of size of vessels. She has gradually gained strength, but there is no return of sight. She was treated with iodide of potassium and citrate of iron and quinine.

Remarks.—The above cases are two of the four that have been under observation at the Hull Infirmary during the last three years. In all the cases loss of vision was complete; and in all cases treatment was useless, I need hardly say. Lead

amaurosis, if we are to believe the word of a workman whom Dr. Elliott interrogated, is not of such very infrequent occurrence here; he (the workman, who had been many years in the mills) had known several instances of loss of sight in lead workers. To what does Mackenzie refer when he says (edition of 1840)—“The purgative plan of curing lead colic is generally successful in removing the amaurosis which sometimes attends that complaint”?

WOLVERHAMPTON AND SOUTH STAFFORDSHIRE GENERAL HOSPITAL.

OPERATIONS ON THURSDAY, APRIL 18.

Enlarged Submaxillary Lymphatic Glands.

MR. VINCENT JACKSON stated that the patient, a young woman, had suffered for a long period with enlarged and indolent lymphatic glands beneath the left side of the lower jaw. They had resisted various kinds of treatment, and a quicker method of removing the eyesore was requested. Under chloroform an incision was made directly over them from symphysis to angle, and after they were fully exposed one by one they were disembedded. The edges of the wound were united by interrupted metallic sutures, and the patient removed.

Excision of the Left Elbow-joint.

Mr. Vincent Jackson narrated the history of this case. The man, a puddler by occupation, was admitted into the Hospital with a completely disorganised left elbow-joint about a fortnight ago. He stated that about twelve months back the joint received a severe blow with a large piece of iron; swelling and pain soon set in, but, in spite of both, he continued his work until he was obliged, from the excess of the symptoms, “to knock off.” Medical assistance was never obtained, an old woman bran-poulticing the part from time to time. Soon an abscess formed on the inner side, and burst and discharged itself, leaving a sinus which communicated with the articulation. The naked-eye appearance of the part was typical of irremediable disease, and, the physical examination being confirmatory, Mr. Jackson, with the consent of the patient, determined to remove the affected portions. It is worthy of note that twelve years back, in this Hospital, his right foot was amputated by Syme's method at the ankle-joint, on account of tarsal disease. The stump is a very good and serviceable one. The excision was performed by a central incision along the back of the joint, the soft parts being dissected off sideways, so as to allow of a liberal piece of the humerus, ulnar, and radius being sawn off. Afterwards some degenerated portions of synovial membrane were clipped away with scissors. The wound was brought together with interrupted metallic suture, and, in accordance with the practice and experience of this Hospital, the limb was placed upon a rectangular splint, until, in the course of a week or ten days, the acute symptoms involved by the operation having passed away, it is removed, and passive motion prudently employed.

Lateral Lithotomy.

A man, 46 years of age, was next placed upon the table and chloroformed, and Mr. Vincent Jackson then removed by lateral lithotomy a uric acid calculus, weighing nearly three ounces.

Stricture of the Urethra treated by Holt's Method.

A soldier was admitted into the Hospital a few days ago on account of the trouble which a twelve years' old stricture of the urethra of gonorrhœal origin gave him. It was found to be very tight, and with difficulty, twenty-four hours previously, a No. 1 gum-elastic catheter had been passed and tied in. On the table this was removed, and without chloroform Holt's dilator was pioneered into the bladder, and the stricture split with No. 12 tube. The dilator being withdrawn, the urine was drawn off by a No. 12 silver catheter, the instrument being taken out directly afterwards. Mr. Jackson stated that he had now treated 150 cases of urethral stricture (traumatic and gonorrhœal) by Holt's method, and no untoward symptom had ever caused him to regret doing so.

ST. THOMAS'S HOSPITAL.—The distribution of prizes to the students, by his Grace the Archbishop of Canterbury, will take place on Thursday, June 27, 1872, at three o'clock, in the Governors' Hall (entrance from Westminster-bridge). Seats will be reserved for ladies.

demand on the time of the scientific Practitioner. Now, we will not deny that in some impoverished districts it may be, on economical grounds, better to employ women, under the superintendence of Medical Practitioners, for the very poorest of the population; but we are certain that the state of things in this country is quite exceptional. The fact is that Medical practice will soon become a very dignified, scientific, exalted calling for men with large fortunes, but one entirely unsuitable for any who wish to earn their living and a maintenance for those dependent on them by their own exertions. Medical men have largely given up supplying their own medicines, and have thus thrown into the hands of the chemist not only a great amount of profitable dispensing, but a large share of absolute practice. It is now proposed that the Profession should relinquish to women the attendance on the midwifery of the masses—midwifery, for which fees average from half a guinea to one or two guineas. We have no hesitation in saying that such a policy, if it became general, would be most disastrous to the general Medical Practitioner. Fortunes in the Medical Profession are not built up as a rule by large fees, but by small ones. Fortunately, we do not believe the women of England would submit to the change; but we are certain that if they were so to do the Medical practice which has hitherto fallen to the general Practitioner would pass entirely into the hands of chemists and midwives, not to speak of charlatans.

We have left ourselves no space to enlarge upon the physical and mental attributes for a successful accoucheur, which are so apt to be wanting in women. This is a view of the subject which does not require to be enlarged on.

Our readers will see, from what has gone before, that our opinion is against the admission of women in any considerable numbers to obstetrical practice. Our reasons are—first, that long experience has proved that women do not make the best midwives; that female midwifery is likely to be attended with more accidents and a larger mortality than male; that the outcry which is now being raised in favour of female midwifery is a mere *vox et præterea nihil*; that there is no ethical objection to the present practice, as experience has amply proved; and that any transference on a large scale of midwifery from the General Practitioner to the female midwife, would do incalculable mischief to the Profession of Medicine and to those who are dependent upon it. At the same time, if it be urged on economic grounds that female midwives, in strict subordination to the Medical Practitioner, may be of use in certain localities, we cannot think that they could be tested in the rudiments of obstetric practice by any more suitable body than the Obstetrical Society—and the rather because that Society is likely to abstain from all pretensions to the examination and licensing of men.

THE DOCTOR IN THE WITNESS-BOX.

LAWYERS say the worst of all witnesses is a Medical witness. This was formerly the case more strikingly than at the present time, but still the dictum to a great extent holds good. The reason is clear enough: the Medical witness was not only in the habit of using technical and overlearned words, but he added opinions to the facts which he adduced—opinions biassed by his own views of the case before him, often very puzzling, and sometimes quite incomprehensible to the bench and jury. The struggle between the witness and the advocate was often a severe one, and the witness was subjected to as strict a cross-examination as it was possible to give him. Happily there has been some improvement of late in this matter; but still sufficient remains to be done to bring matters into a satisfactory condition.

We have read with much satisfaction a chapter entitled "Medical Men in Court" in a work just issued on "Law and Lunacy." (a) The article has reference chiefly to Medical

witnesses in cases relating to lunacy; but in its main features it is applicable to all cases in which Medical Practitioners are called upon to give evidence. At starting, the Medical Practitioner should recollect that he has no power to claim "privilege," as have the lawyers; whatever communication has been made to a Doctor, even in the strictest Professional confidence, is not protected from disclosure. This may seem a hardship, and to some extent it is; but on the whole it is probably better for all parties that the arrangement should be as it is. When the witnesses have been acting as special commissioners, as it were, to examine and report on an insane person, all the duty of the witness is to make his report clear and accurate—in other words, intelligible and truthful. The authors of "Law and Lunacy" do not object to the system pursued by some barristers, instructed by Medical Practitioners, of "baffling and confusing" Medical witnesses. Though this system has been strongly censured, they think that in questions involving insanity the utmost latitude should be given to the advocate. The answer of a Medical witness should be clear and direct—no "beating about the bush," or prefacing the fact sworn to by any unnecessary or doubtful sentence. "If the question is of such a nature as to elicit only half the truth, the Medical witness's duty is to answer it just as it had been put; and having done so, he may ask the judge's leave to explain in what way his answer, though true, may convey a false impression." The Medical witness ought never to argue with the counsel; he should, moreover, give his evidence without any bias or animus; and, above all, he should never take upon himself the functions of an advocate, "and he who does so injures the cause he would advance, and brings discredit upon himself and his Profession." This remark is particularly applicable to many cases in which Medical witnesses clearly go beyond their legitimate bounds, instances of which must be familiar to all. If a witness cannot answer a question, it is better for him to say so at once. "Thus, counsel will frequently ask Medical witnesses 'If they can define insanity?' The duty of the witness under such circumstances is to answer 'No' to the counsel, and to ask the permission of the judge to explain that he can describe insanity, but that its nature precludes the possibility of a satisfactory definition, although that does not prevent its invariable recognition." The witness, as a rule, has to undergo three examinations—"examination in chief," "cross-examination," "re-examination." He should adhere strictly to answering the questions put to him, and should avoid voluntary evidence—often a dangerous proceeding. Proving too much is often attended with great risk. When called upon to speak to facts—as, for instance, the facts he observed on visiting a lunatic in illness, or whilst in prison—he should be provided with notes of the dates before he enters the witness-box; to these he can refer to refresh his memory during his examination. "He may not, however, refresh his memory by extracts from a book, even though written by himself. If a Medical Practitioner is called to give his opinion on a matter of skill, and has made a report of the appearances or state of facts at the time, he will be allowed to read it—if his counsel require it—as part of his evidence." The practice in Scotland is somewhat different: the witness may read his report as a scientific document, on which he may be examined or cross-examined. In matters not of a scientific character he can only refer to the memoranda to refresh his memory. All attempts to raise a laugh or to crack a joke should be avoided as "unworthy of the character of a scientific witness." The witness should always speak clearly, and avoid the use of scientific words—such words as "dementia," "monomania," "puerperal insanity." The witness should describe in familiar terms the states here mentioned.

"It is scarcely necessary for a Medical witness to know, although it is important for a counsel to remember, that Medical books cannot be put in evidence, even though Medical witnesses state that they are works of authority; but at the same time Medical Practitioners may be asked their judgment

(a) "Handbook of Law and Lunacy." By Dr. J. T. Sabben and J. H. B. Browne. London: J. and A. Churchill.

and the grounds of it in relation to any Medical matter which may in some degree be founded on these books as part of their general knowledge."

Such is a general outline of the chapter on "Medical men in Court"; but the work has a wider significance and usefulness as an excellent manual for the Practitioner in all that relates to "Law and Lunacy."

THE WEEK.

TOPICS OF THE DAY.

THE arrangements for the partial Conjoint Board for England, which has received the sanction of the General Medical Council, are being pushed forward by the two Royal Colleges, and by the University of Cambridge. As we cannot but think that an imperfect combination of this kind—which, as far as present appearances go, will not be followed by any similar combination in Scotland, and until the law be altered cannot be rendered complete in England—must be productive of but little good, and may do infinite harm, both to the Profession and to the public, by introducing an inferior class of Practitioners, or at least by inducing English students to obtain their Surgical diplomas in Scotland rather than in England—we confess that we regard the action which the Colleges are taking as hasty rather than wise. By the present combination the one-portal system will not be obtained, and we cannot see that any real advantages will accrue. Supposing, indeed, that the Society of Apothecaries and the University of London can obtain such an alteration in the law as will enable them to take part in the scheme, and an arrangement with these bodies can be effected, the whole matter as regards England and Wales would assume a different complexion. But then the acquiescence and co-operation of Scotland and Ireland must be obtained before a satisfactory system can be inaugurated. It is true that the Scottish bodies adhere to their proposal of a "Conjoint Practical Examination," which differs from the English in every respect, and for passing which they hope to extract another fee of five guineas from the unfortunate student. We need not repeat that this is merely the addition of another and unnecessary examination to the long list. It adds to the evil instead of diminishing it. Patchwork legislation is proverbially bad, and we fear that these attempts to sew a new piece of cloth upon an old garment will only result in making the rent worse.

The complaint and remonstrance of "A Volunteer Surgeon," which we publish in our "Correspondence," have been called forth by so gratuitous a piece of insult on the part of the present "Liberal" Government that we do not think any comments of ours can strengthen the indignation which the bare facts have aroused. Volunteer Surgeons—specially educated Professional men, who, from patriotic feelings, at a large pecuniary expense to themselves, render their skilled services to their country—are to be compelled by the Government to attend in sickness, and find medicines for, the adjutant, the sergeant-major, and the instructors of their corps, with the families of these officers (in all an average of eighteen persons), for the munificent pay of 2d. per head per week, or £7 18s. per annum! To compel a volunteer is not a courteous act on the part of a paternal Government; but to insult an educated gentleman by offering him the dole of a crossing-sweeper is a height of effrontery which seems insurpassable, even by the combined talents of Messrs. Lowe and Cardwell.

There can be no doubt now, we believe, of the safety of Dr. Livingstone, although the telegrams respecting him have been enigmatical. The Governor of Bombay has informed by telegraph the Duke of Argyll that Livingstone has been to the northern end of Lake Tanganyika, and has found the rivers flowing into the lake. This is probably what Lieutenant Dawson meant when he telegraphed to Sir H. Rawlinson "Nile question appears settled." He adds—"Underground

village next attracts Livingstone's attention." We may evidently expect some anthropological and ethnological discoveries.

We have received a copy of the *Manchester Courier* of June 11, which contains an account of a special general meeting of the trustees of the Manchester Royal Infirmary, wherein some important changes in the staff and management of the Infirmary and Medical School were debated. A resolution was passed postponing the election of the honorary Medical staff until a complete scheme for the organisation of the staff has been prepared. We are glad to notice that a check has been given by the vote of the meeting to the system of expensive contests and canvassing for the Infirmary appointments which seems hitherto to have been the rule. The unenviable predicaments into which the system of canvassing may lead the Medical aspirant are exemplified in the following speech of one of the governors:—

"Mr. H. J. Leppoc said the reason which had induced the board of management to request the trustees to suspend this rule for some time was a very proper one. They had no vacancies before them on either the Medical or Surgical staff, but unfortunately there was too much fear that such a vacancy might occur. The Board of Management had been aware that an active canvass had been going on in various quarters; a canvass, he was sorry to say, which had not been conducted in the manner they would like to see. He was sure the trustees would be sorry to hear that a lady had been canvassed to give her proxy in favour of a candidate who desired to supplant her husband, who was still living. He thought that was a disgrace, if it was not done by a mistake. It was simply with the view to prevent disappointment and to prevent expense to those Medical gentlemen who wished to come forward that the Board thought it right to bring this matter forward."

Among the candidates for the chair of Psychological Medicine at the Middlesex Hospital is Dr. Rayner, who has been recently appointed Resident Physician at Hanwell.

THE ARTERIES IN CHRONIC BRIGHT'S DISEASE.

At the *conversazione* given by the Royal Medical and Chirurgical Society on Friday last, one great centre of attraction was the specimens exhibited by Dr. George Johnson and by Sir W. Gull and Dr. Sutton, illustrative of their views of the nature of the arterial change in chronic Bright's disease. Dr. George Johnson, as is well known, contends that in all the arteries of the body in chronic Bright's disease, and especially in those forms of it characterised by contracted kidney, there is muscular hypertrophy, meaning thereby an increase in the thickness of the muscular coat of the vessel, due to an increase in the number of the muscular elements. Sir W. Gull and Dr. Sutton, on the other hand, advanced the doctrine that the arteries were thickened indeed, but that this thickening was due to a hyaline-fibroid material, and that the muscular coat was in reality degenerated. Of course such a question could only be settled in one way, and that is by reference to actual specimens. Dr. George Johnson's specimens are well known, but Sir W. Gull and Dr. Sutton's were seen for the first time on the evening of the *conversazione*. Now, we are free to confess that it is dangerous to dogmatise after such an inspection of specimens as was possible on Friday evening. Men skilled in the use of the microscope as few men are skilled made mistakes in the hurry and had to look again, but on the whole the result was not doubtful—the verdict was in favour of Dr. Johnson.

As regards Dr. George Johnson's specimens, speaking with all due caution, and knowing well the difficulties in the way of judging aright, we are constrained to say that he exhibited specimens in which muscular hypertrophy, in the sense indicated above, was unmistakable—nay, some of the specimens exhibited by Sir W. Gull and Dr. Sutton showed the same thing as unmistakably as did any of Dr. George Johnson's. It is true most of these specimens seemed to show a marked

increase in the adventitia: in some purely fibroid, as might be expected; but in others the appearances were due to very different causes. Now, as we understand Dr. George Johnson's views, that gentleman is not prepared to deny that in certain cases the adventitia is hypertrophied in Bright's disease. His special contention—and on the whole he must be admitted to have proved it—is that the muscular coat is hypertrophied. With regard to any theories founded on either contention we meanwhile have nothing to say.

How comes it, then, that such men as Sir W. Gull and Dr. Sutton have been deceived?—for, speaking only by the specimens exhibited, it is clear they have been. The reason is not far to seek: they seem to have misinterpreted appearances artificially produced. A glance at these specimens showed the source of error. The first specimen we saw was the section of a large vessel cut apparently transversely—in reality, obliquely. Its walls seemed enormously hypertrophied; but it was not till after several inspections that we could see the cause. One cause was the oblique section; another was that all the elements were so soaked that they appeared of one kind only. In point of fact, it was only the discovery of the cut ends of the longitudinal muscular fibres which enabled the organ to be recognisable. And this was a type of the whole. Soaked in glycerine and water, the elements were so swollen and agglutinated that it was impossible to tell where one began and another ended; in short, the appearance was exactly as described by the authors—hyaline-fibroid. On the occasion of the reading of the paper, people complained of the vagueness of the expression—it was not couched in terms of modern histology, such as men accustomed to microscopical work are wont to express themselves in and to criticise. The specimens explained this; and Dr. George Johnson showed how the appearance might be begotten by causing the adventitia to swell with glycerine and water.

We are very far from saying that all Sir W. Gull and Dr. Sutton's specimens admit of this explanation—indeed, we do not think they do. However, we know now what the hyaline-fibroid change means. This is, so far, unfortunate for the authors of the paper, but it does not detract from the wonderful clinical acumen of the paper—that remains unassailed and unassailable.

CONVERSAZIONE AT THE ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

For the first time since its foundation, a *conversazione* was held on Friday last at the rooms of the Royal Medical and Chirurgical Society in Berners-street. The somewhat stately and venerable Society seemed a little out of place in its holiday garb; but we cannot help thinking that if in times past it had been somewhat more sociable, and somewhat less exclusive and aristocratic, it would have been better for it. However, it is "never too late to mend"; and we were well pleased to be present at the gathering on Friday evening. The numbers assembled were not large; but considering the weather, and the various other engagements of the night, it was successful. About 250 gentlemen assembled. The rooms were not overcrowded—often an evil—and there were excellent opportunities of viewing the various objects of art and science which abounded. The Society, by the alterations in its premises during the past year, has gained a large accession of library accommodation—probably sufficient to hold an additional 30,000 volumes; and the whole suite of rooms (the ground- and first-floors have been intimately connected by a new staircase of easy access) has an extensive and noble appearance, which the exterior of the Society's house would hardly lead us to expect. The meeting was confined chiefly to members of the Profession, and passed off most agreeably. The refreshments were abundant and *récherché*. Among the works of art arranged in the large meeting-room and the adjoining new reading-room, opened for the first time on this evening, were a very beautiful collection of Wedge-

wood medallions, lent by Dr. Sibson; Mr. Seymour Haden's finest etching, lent by Dr. Chambers; a fine picture by Constable, and specimens of Creswick and Bierstadt, lent by Sir H. Thompson; drawings by T. M. Richardson, J. Nash, jun. (View of Nice), etc., lent by the President; a beautiful selection of water-colour drawings from the well-known collection of Mr. Prescott Hewett (amongst which was the "Hastings Beach" of Turner, painted for Sir Anthony Carlisle for Medical attendance, and to which an amusing history of Turner's objection to receiving or paying for Medical advice is attached), lent by Mr. Vokins; a very fine T. M. Richardson, "Near Tivoli," and other pictures by Warren, Jenkins, etc., lent by Mr. H. Graves; some fine pictures, including the "Sabrina" of Frost, R.A., lent by Mr. E. Saunders; and Sir A. Calcott's "Venice" and McKewan's "Ludlow Castle," lent by Mr. S. Cartwright. Some autotypes from photographs by Mr. Vernon Heath, including his splendid effects in the photography of trees, were exhibited by the Autotype Company. Dr. Sutherland exhibited, for Dr. Crichton Browne, a collection of photographs of cases of mental aberration, chronic and recurrent mania, idiocy and imbecility, and general paralysis of the insane. Dr. Andrew Clark showed a collection of coloured drawings of pathological appearances of the lungs in cases of fibroid phthisis, pneumonia, etc. In the new reading-room Mr. Charles Baker, Mr. Ladd, and Mr. Browning exhibited their microscopes; and in the new library on the first-floor, now also opened for the first time to the Fellows, one of the events of the evening took place—viz., the exhibition, by Dr. George Johnson and by Sir W. Gull and Dr. Sutton, of microscopic specimens illustrative of the points in dispute between them on the condition of the coats of the arteries of the kidney in chronic Bright's disease, on which the discussion took place at the last meeting of the Society, on Tuesday, May 28. Other specimens illustrating the same subject were exhibited by Mr. Nettleship; some arteries from the pia-mater, by Dr. Beale; and Dr. Rutherford exhibited, from the Physiological Museum of King's College, his "Schema of the circulation intended to illustrate certain phenomena connected with the pulse and the blood-pressure," "Pitchforks for recording time upon revolving cylinders in order to ascertain the duration of various physiological movements," and "Helmholtz and Dubois-Reymond's myograph for studying muscular motion and the velocity of nerve-force." A selection from the Society's large collection of portraits of Medical men was shown on the long table in the front room, and two glass cases were filled with some of the more curious books in the Society's library.

THE MILITIA SURGEONS OF IRELAND.

REMONSTRANCE with the governing powers is vain, if the remonstrance be not backed with such a display of force as to show not only the wishes, but the power of the complainants. Acting upon this conviction, the Militia Surgeons of Ireland have determined to try the effects of combination for the obtainment of their just rights and privileges. They have founded an Irish Militia Surgeons' Association, and at a preliminary meeting held at the Royal College of Surgeons last week the following resolutions were unanimously carried:—

"The course proposed to be adopted towards the Militia Surgeons by the Right Hon. the Secretary of State for War in his army organisation scheme so seriously affects our interests and position, that it is incumbent upon us to take immediate steps to secure a fair consideration of our claims.

"That, in order to carry out the above object, it is desirable to form an Irish Militia Surgeons' Association, to bring these claims before the Secretary of State for War, and to co-operate with our English and Scotch brethren.

"That the president and committee be requested to take immediate steps to prepare a memorial for presentation to the Secretary of State for War, praying for a favourable consideration of our claims."

The subscription is at present limited to 5s.

DR. ROBERT FOWLER'S ELECTION AS A GUARDIAN OF ST. BOTOLPH, BISHOPSGATE.—QUESTION WHETHER A PENSION DISQUALIFIES.

The following letter needs little explanation. Dr. Fowler, a well-known Medical Officer, having been pensioned off, was elected to the Board of Guardians. The return was opposed. The decision of the Local Government Board, which gives him the seat, will settle all doubts as to the legal qualification for the post of guardian of many retired Medical men whose experience would render their services of the greatest value.

Local Government Board, Whitehall, S.W., June 10.

"Sir,—I am directed by the Local Government Board to state that they have had under their consideration your letter of April 10 last, respecting the decision of the Clerk to the Guardians of the City of London Union, as returning officer in the recent election of Guardians, in rejecting the nomination of yourself as Guardian for the parish of St. Botolph, Bishopsgate.

"The Board have been in communication with the Clerk on the subject, and they forward to you a copy of the letter which they have received from him.

"The question as to your qualification for the office of Guardian appears to depend upon the last part of the 5 and 6 Vic., cap. 57, sec. 14, which provides that 'No person receiving any fixed salary or emolument from the poor-rates, in any parish or union, shall be capable of serving as a guardian in such parish or union.'

"The Clerk considered that you were not qualified for the office of Guardian, on the ground that you are in receipt of an annuity of £61 from the poor-rates, such annuity being paid to you by the Guardians of the City of London Union, as awarded by the order of the Local Government Board of November 8, 1871, as compensation for the loss of your office of a District Medical Officer of the late East London Union.

"It is true that the payment is not made to you directly out of the poor-rates; it comes to you from the common fund of the City of London Union. But that fund is raised by contributions out of the poor-rates, so that it may be considered that in effect it is paid out of the poor-rates.

"The question then arises whether this compensation annuity is such an emolument as is contemplated by the provision above quoted of the Act 5 and 6 Vic., cap. 57, sec. 14; and it is one not free from doubt. The Board have given much attention to the point. They think that the Legislature, by the provision in question, contemplated the possibility of a guardian sitting in judgment upon his own conduct, which is involved in the payment of 'salary or emolument,' and passed the enactment to prevent such a consequence.

"In the present case, however, the reason for the disqualification fails. The compensation awarded to you for loss of office was settled, not by the Board of Guardians, but by extrinsic authority, and cannot be altered in any way by the Guardians of the Union, and perhaps by no other authority.

"The 'emolument' appears to them to be like the 'salary' dependent upon services rendered by the recipient, and applies to an officer or person who renders services, and is paid by a fixed salary or fixed emolument, such as a poundage, rations, or perhaps residence. Such, in the opinion of the Board, is the person contemplated by the statute, and not a person who is paid compensation for the loss of office, and is no longer connected with the Union otherwise than as a pensioner. The Board are, therefore, of opinion that the Clerk arrived at a wrong decision in rejecting your nomination, and that you should have been returned as an elected Guardian for the parish of St. Botolph, Bishopsgate.

"The Board have forwarded a copy of this letter to the Clerk to the Guardians, and trust that you will be allowed to take your seat at the Board without further trouble.

"I am, &c., JOHN T. HIBBERT, Secretary.

"To Robert Fowler, Esq., M.D.,

"145, Bishopsgate-street Without, E.C."

A JUBILEE DINNER.—THE ESPRIT DE CORPS.

It is pleasant to record an instance of good feeling and fellowship in the Profession like the following:—Dr. Lawrence, of Longside, last week completed the fiftieth year of his practice in that locality. A good knowledge of his Profession, a high and honourable career, had endeared him not only to his patients, but to his Medical brethren. They therefore determined to celebrate his jubilee of practice in a becoming manner. Accordingly, last week the members of the Buchan

Medical Society, with a number of friends, amounting to sixty, entertained him at dinner at Lamont's Hotel, Ellon. A right merry evening was spent. Good speeches were made, and good songs sung; and the worthy guest made his acknowledgments in a thoroughly sensible speech.

TESTIMONIAL TO MR. SAMPSON GAMGEE.

We have from time to time recorded the exertions of Mr. Sampson Gamgee with reference to the Working Men's Fund for the Extension of the Queen's Hospital, Birmingham. It is impossible not to acknowledge that Mr. Gamgee has acted with an energy and disinterestedness which entitle him to commendation. A testimonial was presented to him last week, which consisted of an illuminated address bound in red morocco with gold filigree ornamentation, and was signed by 250 of those who took part in the movement. Mr. Sampson Gamgee returned thanks in eloquent and feeling terms, and concluded a long address in the following words, which elicited much applause:—"By Profession a Surgeon, and not a politician—a healer of bodily pains and wounds, and not a prescriber for social ills and wrongs—I must be satisfied to look back upon my official connexion with you as an episode in a life which, in justice to yourselves and other well-wishers, shall be made useful, so far as will and work can make it, in faithful devotedness to a work which is above classes, and makes no distinction of persons."

SMALL-POX JOTTINGS.

Two fresh cases of small-pox were reported to have broken out in Camberwell last week. There had been no cases of the disease in the district for the previous three weeks.—Last week one death only occurred from small-pox in the Mile-end Old Town district.—Dr. McCormack, the Medical Officer of Health for Lambeth, in his report last week, stated that in the four weeks ending May 18 thirty-three deaths had occurred from small-pox; and he added that, were it not for the continued prevalence of small-pox, our standard of health would be most satisfactory, as there is an almost complete absence of all other zymotic or contagious diseases.—A lodging-house keeper was last week fined 20s. by the Thames Police-court magistrate for having neglected to give notice to the police that a person was on his premises suffering from small-pox.—Sixteen deaths are reported from small-pox in the Poplar Union during the past fortnight, and twenty-two new cases had been brought under notice. In the same period 122 persons were vaccinated at the public stations. There were five small-pox patients then under treatment in the North-street Infirmary.—The Aberdeen Small-pox Hospital return for the past week shows the total number of cases admitted since the opening, 218; number of patients in Hospital, 12; total discharged recovered, 169; total dead, 37.—Twenty-seven deaths occurred from the disease in the metropolis last week; in the two previous weeks they had been fifty-four and thirty-seven respectively.

PROTECTION TO A DOCTOR.

The Spanish Government with their usual intolerance lately arrested and tried before court-martial at Cuba an American Physician of the name of Howard, on the ground that he had supplied medicine-chests to the rebels. He was found guilty, and imprisoned. We learn that the American Government have made a peremptory demand on the Spanish authorities for the unconditional and immediate release of Dr. Howard. There is no doubt the demand will be immediately attended to. There was no proof that the medicine-chests were sold during the rebellion. Dr. Howard asserts that they were disposed of previously to the outbreak. In either case, the American Government would have acted properly in demanding the release of an American citizen.

COMPULSORY SERVICE FOR VOLUNTEER MEDICAL OFFICERS.

DR. JOHN MURRAY, Hon. Sec. of the Volunteer Medical Association, has requested us to intimate that a meeting of Volunteer Surgeons will take place at the Grosvenor Hotel, Victoria Station, London, on Thursday afternoon, June 20, at four o'clock (H. Spencer Smith, Esq., Surgeon Civil Service Volunteers in the chair), to consider the following and other important clauses in the new regulations for the auxiliary forces:—"Clause 43. *Medical Attendance*.—The Surgeon will attend the adjutant and his family professionally, and will receive an allowance of 2d. per week for each person for attendance and medicine. The word 'family' will include wife, unmarried daughters, and sons under sixteen. The Medical officer of a corps to which a drill instructor is attached will receive a similar allowance for attendance upon, and medicines for, such drill instructor and family. The word 'family' in this case will include wife and children under sixteen." All Volunteer Medical officers are urged to attend. Communications on the subject may be addressed to the Hon. Sec., 40, Bryanston-street, London, W.

EXHIBITION OF ARTS, INDUSTRIES, AND MANUFACTURES, DUBLIN.

ON Wednesday week the Exhibition was opened with great state by H.R.H. the Duke of Edinburgh, who represented her Majesty the Queen on the occasion. Loyal as the city was outside, it was not to be compared with the enthusiasm which greeted the "Sailor Prince" on his arrival within the Exhibition Palace, accompanied by his Excellency the Lord Lieutenant and the Countess Spencer. The ceremonial consisted in the performance of a programme of music, including selections from Haydn and Handel, and an ode composed for the inauguration by Sir Robert Stewart, and in the progress through the building of a procession in which the President of the King and Queen's College of Physicians in Ireland (Dr. Hudson), the President of the Royal College of Surgeons, Ireland (Dr. Frederick Kirkpatrick), Dr. Stokes and Sir Dominic Corrigan, Bart., M.P., Physicians to the Queen; Dr. George H. Porter, Surgeon to the Queen; and Sir William R. Wilde, Surgeon-Oculist to the Queen, took part.

CAN A PENSIONED POOR-LAW OFFICER ACT AS GUARDIAN?

IT has been decided by the Local Government Board that the fact of Dr. Robert Fowler being in receipt of a pension from the City Union in compensation for the loss of his post as a Medical officer to the Union, did not disqualify him for sitting as guardian for the parish of St. Botolph Without, to which he had been elected by the ratepayers. The Clerk to the Board of Guardians, however, though not a lawyer, chose to put his opinion against that of the Local Board: the consequence was that the following resolution was carried by a majority of 23 against 3:—"That the letter from the Local Board be referred to the Amalgamation Committee, with a view to proceedings being taken to test the legality of Dr. Fowler's election."

THE PUBLIC HEALTH BILL.

IT is understood that the consideration of the Public Health Bill in Committee will be deferred until the Scotch Education Bill and the Mines Regulation Bill, and probably also the Corrupt Practices at Elections Bill, have been disposed of.

THE HEALTHIEST MONTH.

THE present month ought to be the healthiest during the London year. Diseases of the respiratory organs, which always go up as the thermometer goes down, are coming to their lowest point in June, and the effects of the second week in May—which, Professor Corfield reminds us, is known as a cold week amongst meteorologists—have now left their last mark on the Registrar-General's tables. Summer diarrhoea has not

begun. Zymotic disease—that humiliation of modern science and morals—is on the decline. London is full, thought active, and wages high.

HONORARY DEGREES AT OXFORD.

IT is gratifying to announce that the authorities of Oxford did full justice to the members of our Profession at the meeting of Convocation on Thursday last, on which occasion the degree of D.C.L. was conferred on the following gentlemen:—Samuel David Gross, M.D. and L.L.D., Professor of Surgery in the Jeaffreson Medical College of Philadelphia; Sir Benj. Collins Brodie, Bart., M.A., F.R.S., late Waynflete Professor of Chemistry; George Burrows, M.D., of Caius College, Cambridge, F.R.S., President of the Royal College of Physicians of London, and formerly President of the General Medical Council.

PROMOTERS OF VACCINATION.

TWO examples of modes of promoting vaccination have been lately made public. These are widely different, both in respect to their authors and to their likelihood of success. The first is practical and to the point, and is in the form of a letter from the Bishop of Cork to the clergy of his diocese, recommending them to advise their respective flocks to submit themselves freely to revaccination, in order to arrest in some measure the small-pox epidemic at present existing amongst them. In the second a Californian editor offers to vaccinate, free of charge, all new prepaying subscribers to his paper.

FROM ABROAD.—MEETING OF THE AMERICAN MEDICAL ASSOCIATION.

THE twenty-third meeting of the American Medical Association, held at Philadelphia from May 7 to 10 under the presidency of Dr. Yandell, has proved, so far as the numbers present are concerned, a great success. The registered members exceeded 720, being more than one hundred in excess of those attending any former meeting of the Association. As a social gathering—which, after all, is one main object of meetings of Professional men—it seems to have been very satisfactory; but a reporter in the *New York Medical Record* greatly blames the body for spending its scanty three days in petty and futile disputations, instead of "listening to scientific addresses or discussing scientific problems." Probably for their own practical purposes, the Association considered what the reporter calls their "petty squabbles over the code of ethics" a not unimportant matter in the present transitional position of the Profession, so widely scattered over so immense a territory. Nor can we regard the efforts so persistently made by this Society for securing the adoption of a satisfactory scheme of Medical education as deserving the ridicule here attempted to be cast upon it. That improvement in this must constitute the basis of all future Professional advancement is acknowledged on all hands; and how this is to be secured, except by some widespread co-operation of this kind, it is difficult to imagine. That the *Record* has its own fits of sanguine expectation may be seen from an article (May 1) warmly commending the Bill for the Suppression of Quackery, presented to the Legislature by the New York Medico-Legal Society. This provides for the creation of "a board of censors" elected from the Medical men of the various counties of the State, the members of which shall have the power of examining and licensing in their respective districts all those who claim a right to practise Medicine. The licence thus obtained is to be considered a legal qualification, all who are already in possession of a regular diploma being of course exempted from examination. All others, whatever their previous character or present practices, who are willing to face an examination by their orthodox rivals in practice will be at liberty to do so. That few will consent we may readily imagine; but what seems strange is, that anyone can have credulity enough to suppose that refusal to submit will be

followed by submission to the dictates of the law which prohibits their continuing to practise. If ever a law was destined to remain a dead letter, such will be the fate of this one—if it is ever passed, which is not very probable. Even supposing it were to come into operation, and to some extent prove successful, we could scarcely congratulate the Profession upon the new recruits, or rather conscripts, of disreputable character it had thus forced into its ranks.

One excellent feature of the Association is the great pains taken by it in investigating the antecedents of those who seek to become members. To do this they must be registered, and the credentials they bring from the various Medical bodies and societies of the Union are submitted to committees on ethics and arrangements, who report to the Association concerning all objectionable or suspicious candidates. Without some such precaution as this, and if admission depended upon a mere money payment, many persons might gain admission who would bring discredit on the Association. It is true that this agency has been and still is used in a manner which seems to us oppressive for the exclusion of coloured Practitioners, even when well qualified. A strong minority of the Association is, however opposed to this restriction, and no doubt it will soon be removed. The veto is also brought into play in respect to the women-Doctor question, which in the States is a far more formidable one than with ourselves. Speaking of its policy in this matter, the *Medical Record*, which is a strong advocate of female claims, thus expresses itself:—

“On the question of recognising woman's place in the Profession, the Association manifests the same illiberal spirit which has characterised it heretofore. The first ground assigned by its Committee on Ethics for the exclusion of the delegates, Drs. Palmer and Reyburn, in a report endorsed by an overwhelming vote, is that they are connected with a College which admits female students and employs a woman teacher. The Association refuses to acknowledge that this question is practically settled, and continues to pass resolutions and make decisions as if it expected the country to respect them. It ignores the fact that the rule applied in the case of these Washington delegates would equally apply to the representatives of the Medical Society of the County of New York, and those of the New York Pathological Society, both of which have women as members; that it would exclude those of every Medical College of this city, since the College of Physicians and Surgeons, the Medical Department of the University of New York, and the Bellevue Hospital Medical College have each one or more of its Professors on the Examining Board of the Woman's Medical College at the New York Infirmary; that it would exclude those of Bellevue Hospital and of every other Hospital under the Department of Charities and Correction, since these all admit women to their clinics. In view of these facts it strikes us that the women will not be sorely disheartened by the action of the Association. Though not granted a voice in its councils, they are still likely to make themselves heard.”

On this last point we suppose no one can have any doubt, whatever the ultimate results of their success in forcing themselves on public attention may be. A motion proposed by Dr. Reese, of Brooklyn, but indefinitely postponed by the vote of the Association, would certainly meet with a better reception among ourselves, as offering a reasonable solution of the question. It was to the effect, “That whilst we admit the right of women to acquire a Medical education and to practise Medicine and Surgery in all their departments, we deem the public association of the sexes in our Medical schools and Hospital clinics as impracticable, unnecessary, and derogatory to the instincts of true modesty in either sex.” As one of the speakers observed, probably the most effectual check to the women-Doctor movement will be found in the great disinclination which those of their own sex exhibit to consult them.

Among other matters brought under the notice of the Association was the report of a committee proposing the formation of a National Health Council, or Department of Public Health, in connexion with the central government, and under the supervision of the Association. This was supported upon the same grounds which render the institution of a

Department of State Medicine so needed amongst ourselves. A more questionable recommendation was made by the Committee on Medical Literature, proposing to supersede the present annual volume of *Transactions* by a “national medical journal.” The present publication may be, as the Committee states, somewhat trashy, and capable of great improvement; but any attempt to found a journal by a body possessed of very limited funds and composed of the most heterogeneous elements is sure to end in failure. Some good papers were read in the Sections, and altogether the meeting must be regarded to have been highly successful.

PARLIAMENTARY.—THE GOVERNMENT LICENSING BILL—PUBLIC HEALTH (SCOTLAND)—AGRICULTURAL CHILDREN.

On Friday, June 7, the Government Licensing Bill passed through Committee in the House of Lords.

On Tuesday, in the House of Lords, the Public Health (Scotland) Supplemental Bill passed through Committee.

On Wednesday, the Agricultural Children Bill—a Bill for extending the principle of the Factory Act to agriculture—was read a second time in the House of Commons.

AN ART UNTAUGHT; OR, A TALE FOR THE TIMES.

(From a Correspondent.)

EVERYONE familiar with London practice and Practitioners during the last twenty-five years must have been acquainted with the handsome face and portly form of Harry Chowder, M.R.C.S., L.S.A. Chowder lived in a thriving neighbourhood—I need not say whether S.E. or N.W.—filled with well-to-do tradespeople living away from their shops, and so near to certain great manufacturing establishments that there was a large population of mechanics and artisans, able and willing to pay their Doctor's bill, spite of the well-advertised Hospital with its out-patient room not very far off. He had a good horse, lived in a solid and comfortable, but not ostentatious way, frequently attended meetings, especially those of the N. S. Medical Society, of which he was V.P. for one year, though he never spoke. He had a large midwifery practice, and, though he raised his fee from the half-guinea with which it began, seldom got more than three guineas, *tout compris*. Was esteemed judicious in the treatment of children, more especially as he could show seven lively ones of his own; was on excellent terms with monthly nurses and clergymen, though he kept District Visitors and Ladies Bountiful at arm's length; held no extreme “views”—in fact was the model of a prudent, thriving Practitioner, whose life seemed to be one easy-going jog-trot along a smooth tramway, with no impediment in sight.

However, spite of what the modern geologists say, cataclysms and convulsions, moral and physical, will come when least expected, and will divert the course of the most torpid current. So it happened to Chowder. Two evil things befell him in one year. His house and neat little garden were taken from him by the great N. S. Metropolitan Extension Railway Company; and whilst he was settling himself in a new abode his wife and only son were cut off by a dreadful attack of diphtheria at a farmhouse to which the family had gone for country air. Chowder was himself brought very low by the same disease, caught whilst he was endeavouring to save his poor wife; and so the members of the N. S. Medical Society, at their first meeting in November, were not surprised to learn that he had gone to live at a little cottage which he had been often heard to say he possessed at some out-of-the-way seaside place, and that his practice had been purchased by John Larraper, Esq., F.R.C.S. Eng. (Exam.), who had distinguished himself whilst House-Surgeon at St. Vitus's Hospital.

Chowder was a good deal missed at first; but

“*Quamvis digressu veteris confusus amici;*”

and I might say with Samuel Johnson—

“I praised the hermit whilst I mourned the friend.”

Still, time makes one forget heavier blows than the loss of a good neighbour, and I had almost forgotten him, when my family, one

day last month, received an invitation to a quiet garden party and croquet at Chudderton-on-the-Sea, which a lately-opened branch of the Kent and Suffolk line enables one to reach easily from London. Now, for my part (if your readers will not be shocked at such a societarian heresy), I hate and detest croquet. I look upon it as a thing invented by the devil, in the guise of an imbecile amusement, for the punishment in this world of idle clergymen. It involves standing about in the wet, stooping in ungainly attitudes, a worthless dexterity, and pernicious trial of temper. Neither do I agree with an ingenious and observant friend, who upholds it on Darwinian principles, as likely to improve the shapeliness of the legs of future generations of women by a process of "natural selection," for the game is most affected by old childless married men, confirmed bachelors, and inexpugnable virginites. However, one is always glad of an excuse for a holiday, and I was curious to see my old friend, and what kind of a hermitage he had chosen for his retreat. So we went on one of those few rare summer days at the beginning of this month, and a journey of a little more than two hours along the new branch loop-line brought us to a new railway station, where was a new railway hotel, and plenty of vehicles, one of which took us through what seemed to be the beginning of a prettily laid out little town on the edge of the sea, about two miles from the well-known old town of Sleepiton, which some say was a seaport in the time of King Stephen. Our friend's house—an old manor house, gentlemanly, but of no great pretension—was just through the new town site, and half a mile from the sea; and, by-the-by, we noticed in the waiting-room of the railway an elaborate plan and prospectus of the new "residential estate" belonging to the "Chudderton Villa and Freehold Improvement Company," with new roads, plots for villas, site of a new church, park, and public promenade, with a little burn running through to the sea; together with the names of the architect, surveyor, and solicitor, to whom application might be made by persons wishing to rent or purchase.

Well, we were warmly welcomed, along with a few other invited guests—mostly of our own craft—who had come down in the same train, including Larraper, who seemed to fancy that the eldest Miss C— would be a capital assistant in carrying on her father's old business. We saw the house, modest, quiet, and comfortable—nothing gaudy nor snobbish. We inspected the stables, hencoops, and piggeries; admired the yellow tea-roses just in full bloom with their exquisite perfume, and looked into the greenhouse; Chowder telling us with a quiet smile, as he quoted from *Punch*, that he did not pique himself on his flowers, but that he did love an early cucumber, and liked a few strawberries and early potatoes. Dr. Higgins, of St. Vitus's, who was one of the party, and not a good walker, vowed that he trotted us about till we were dead beat, and, as a Frenchman once said on a similar occasion, *il ne nous a pas épargné un seul chou*. However, as the afternoon grew on the girls were summoned from their croquet, and we all sat down to a capital cold repast, in the course of which Higgins recuperated himself on some particular sherry which had been disinterred when the railway destroyed the old house in London. After dinner the ladies went back to amuse themselves, whilst we men drew together to enjoy one more glass and a cigar.

Of course our chief talk was about our host. We praised his house, his grounds, and his establishment; and as most of us knew that he had begun the world upon little, and that his wife had no considerable fortune, curiosity grew rampant as we talked, till at last the Ulysses of the party was bold enough to say, "You must have played your cards deucedly well, Chowder, to be able to retire and live in this style."

Now, Chowder is one of those quiet fellows whom nothing disconcerts, and who seems not to hear what he don't choose to answer. However, he got warmed at last, and said—"I think there is one branch of Medical practice which is never taught, and unless a man finds it out by nature, he is apt to make a mess of things if he lives long enough. It goes to my heart to think of the numbers of our Professional brethren who toil and moil year after year in studying or practising their Profession, and who either make no money, or, if they do, don't know what to do with it. This is the art which is not taught in the schools. For my part (he continued), I consider myself a good Practitioner, though not a scientific one. I well remember when the 'reflex function' was first talked about, and a double spinal cord, and things of that sort, and I candidly confess I never could quite make that out; however, there were things I understood better. I always had a keen eye for what would cure troublesome symptoms, and a keen eye for the slightest

suspicion of danger, and, if so, always proposed a consultation. By this means I got on well in the world, and was popular with my patients and my Professional brethren. Then I had a pretty keen eye for business—did not charge much, but always kept my patients' shoulders to the collar as regards pay; nobody ever asked me twice for an account, for, as I said to myself, what is the use of fagging at one's work, and being idle in collecting one's pay? Then, as I lived very frugally, I found after a time that I had a little money to put by. And now came the difficulties. I found, on thinking the matter over, that with the ordinary savings of practice invested in the funds one had absolute security—of a sort, it is true; and you can always get your money, making allowance for the fact that when you want to sell out the funds may be ruinously low. But a man had need live to be 96 to provide for his family at this rate. Then, on probing the matter deeper, I found that when members of our own Profession have fallen into bad circumstances late in life, it was often not because they had not made money, but because they did not know how to keep and use it. Treacherous and unsafe investments run away with the fruits of a lifelong industry. Look at this month of June, 1872 (he continued), there is not one of us here who does not receive by post every day one, two, or three large oblong prospectuses, many of them accompanied with expensively got-up maps and plans. At one time mines abound—you are invited to invest your savings in the Grand Imposo Silver Mine, the Maritornes Lead and Copper Company (Limited), the Bottomless Mary Anne Whcal. Three times last week I got a prospectus from the Magyar and Transylvania United Coal, Iron, and Nickel Company, with an impudent announcement that after Friday residents in the country only would be permitted to subscribe. At another time foreign railways, loans to obscure foreign states, sewage and guano companies—limited companies, which always begin to the same tune: 'This company has been formed to purchase the well-established business of Messrs. —, with all its plant and appurtenances, and to carry on the same. Messrs. — consent to receive £10,000 in cash, and £20,000 in fully paid-up shares; and the Directors have much gratification in stating that Messrs. — have consented to continue the management of the affairs,' etc. Some of these companies are better, some worse. The best are those that acquire a tangible property—houses, land, and the like; the worst are those that consist really in a subscription, to enable the directors to deal in stocks and shares, or to 'finance' various undertakings; and it is almost amusing to see how they count and divide their chickens before a single egg is laid. Such are the 'United Trust Endowment and Security Corporation,' of which I have received two prospectuses this week, which, by some miraculous gift of foresight, promises its subscribers a speedy return of £200 for every £94 invested, and from 7 to 10 per cent. interest in the meantime. Gambling is gambling, and it does not matter whether people do it themselves or whether they subscribe the cash for abler hands to play with. For my own part (he continued), I always keep clear of bargains which assume that the seller must be a liar or a fool. What Yankees, for example, would be such fools as to sell to the Britishers a silver mine worth £1,000,000 for £200,000? and who but Britishers would be such fools as to buy a mine in the Mormon Settlements?"

"You cast a damp upon all investments," we said.

"Not a bit of it," he replied; "of course I don't speak of the men at the top of the tree, whose legitimate savings grow into a fortune. But I repeat, that as things are it is only by a dexterous or lucky employment of money saved that an ordinary member of our Profession can attain to anything like independence. Keeping your money in the funds is not free from some risk, for you may be obliged to sell at a loss. Investments of all sorts are liable to uncertainty, as all other earthly things are; but there are some which are sure to end in a loss, unless the investor use them like a cold bath—just dip in, and sell out at a premium, and wipe himself dry. But it's ill playing with edge tools, and one diamond can cut another. In many a 'limited' company all the possible 'profits' are booked and divided amongst the 'promoters' before a share is issued. Some things are sure to be ruinous on the face of them; some have a good chance of success if due allowance is made for the uncertainty of human affairs. I learned early under an excellent teacher that population and gold increase, whilst land does not increase; therefore, that it must rise in value in time, and more be required for human habitations. Finding that this out-of-the-way place was to be sold cheap, I bought it; but now the new railway has brought it into easy reach, and I have sold my

indifferent pasture land to a company, who are going to erect a town which will make my daughters rich. Here I stop; but let me say again that bad investments cause as much poverty and misery as mere idleness—that the best may be fallacious, but that the safest are those based on the gradual rise in the value of land, and the policy of improving land, side by side with increase of people and gold.”

We felt that our host had given us a pretty good glimpse at the secret of his prosperity, and refrained from pushing our inquiries further. But on our way home, as may be imagined, the subject did not drop, and most of us had a story to tell of the ignorance of business matters and business habits which mark some members of two, at least, out of the three learned professions; how they are absorbed in their practice, and let their accounts fall into confusion; and how they become weary of adding sixpence to sixpence, and become bitten with credulity as to the possibility of becoming rich at a jump by merely investing in such or such a clever swindle. I know by sad experience how that all the respectable inhabitants of a midland cathedral city—clergy, Doctors, ladies of limited income, and all the denizens of the “Close” had been inveigled into a German iron mine; and how, long after the capital had been lost, there were heartbreaking “calls” for the winding-up, under circumstances of “unforeseen” difficulty. Many were the fatherless children and widows that cursed the “Nisterdale” Iron Company. Let us invoke the *Medical Times and Gazette*, in the hope that the knack of taking care of one's money may not be always “an art untaught.”

PROFESSOR HOLMES'S LECTURES AT THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

MR. HOLMES, Professor of Pathology and Surgery to the Royal College of Surgeons, continued his lectures on “The Surgical Treatment of Aneurism in its various forms” on Wednesday, June 5. In his first lecture, a brief abstract of which appeared in our columns last week, he stated that the main propositions to be brought forward in this course of lectures were the following:—

1. That aneurisms of whatever form, or however near the heart they may be, ought not to be regarded as incurable, but should be made the objects of definite methodical treatment, internal or external.

2. That there is definite proof, from pathological anatomy and from Surgical experience, of the curative influence of Brasdor's operation in innominate aneurism, and of its beneficial effects in some cases of aortic aneurism.

3. That arteries may be successfully tied and obliterated without their continuity being interrupted; and that this modification of the ligature, whilst affording much security against secondary hæmorrhage, and thus much diminishing the danger of the operation in general, may very probably in future enable Surgeons to deal successfully with cases in which it may be necessary to tie the first part of the subclavian (whether on the distal or proximal side of an aneurism) or the innominate artery.

4. That galvano-puncture may be used with, at any rate temporary, benefit in thoracic aneurism. That its use is not so dangerous as to render further trials of it inexpedient; and that there is good hope that the method may be so far perfected as to make it a safe and regular plan for the treatment of thoracic, subclavian, and other forms of aneurism.

5. That many cases, such as those in which ligature of the artery near to the heart has been resorted to for the cure of subclavian and subclavio-axillary aneurisms, may be made amenable to improved methods of pressure.

6. That aneurismal tumours, situated even as high as the lower part of the abdominal aorta, those of the mesenteric and other branches of the aorta, and of the iliac arteries, may be treated with success by rapid coagulation of blood under pressure; but that this method is a dangerous one, and should not be used until internal treatment has failed.

7. That there are cases of abdominal aneurism in which Mr. Syme's suggestion of reviving the old operation is worthy of further trial.

Having shown, too, in his first lecture that there are some cases of innominate aneurism which may be completely cured by Brasdor's operation, the Professor commenced his second lecture by expressing a doubt whether one may fairly expect

complete obliteration of the sac from distal obliteration of the arteries when the tumour is partly aortic. Cases were, however, cited which justify the conclusion that in an aortic aneurism, as well as in those of the innominate artery, the obliteration of any of the arteries, such as the right or the left carotid—which lead directly out of the sac—will be followed by consolidation in that part of the sac which is distended by the stream of blood formerly passing up the obliterated vessel.

It should always be borne in mind that it is not usually the existence of an aneurism, however large, which is dangerous to life, but the growth of an aneurism, however small, in some definite direction. To stop this growth would preserve a patient from a danger which cannot be over-estimated, and would be worth more risk than is involved in tying the common carotid or the subclavian artery. Again, to line any portion of the sac of an aneurism which is growing and threatening to burst is a reasonable object for operation, even if this involves danger, and if the rest of the sac remains unconsolidated. These results are obtained by the obstruction of the arteries or artery leaving an aneurismal sac, as has been shown. Mr. Guthrie, however, endeavoured to show, from preparations in the College museum, that the distal operation of an artery would not cure an aneurism. Mr. Guthrie, even in advancing this argument, was obliged to admit that distal impaction is an effort of nature to cure the disease, though he did not believe that the disease could be entirely cured by it; and he further endeavoured to show that in cases where Brasdor's operation has been entirely successful, this success has been produced by inflammation propagated from the seat of ligature to the artery, and thence to the walls of the sac. Professor Holmes thinks that in this particular Mr. Guthrie's judgment was misled; for in one of the cases (Evans's) upon which Mr. Guthrie based his conclusions, the inflammation was caused by imprudent exposure and intoxication long after the immediate results of the operation had passed away; and though the same cannot be said of the other case—the negro operated on by Mr. Montgomery—yet suppuration in the sac follows occasionally after the Hunterian as well as after all other modes of treating aneurism, apparently as the results rather of imperfect coagulation within the aneurism than of inflammation of its parietes. It seems clear that coagulation in the sac has been more extensive and complete in cases where no inflammatory symptoms have been recorded.

The distal impaction of clot, in cases of aneurism, often produces very severe symptoms, and is followed by rapid and extensive coagulation in the aneurismal tumour. A case illustrative of these facts occurred under the care of Dr. S. Hughes, of Dublin, in which death took place in a few minutes from convulsions, and after death the dilated aorta and the left ventricle of the heart were found full of recent coagula.

In passing from the *à priori* reasons for believing that Brasdor's operation may be entirely or partially successful in some cases of innominate or aortic aneurisms to the practical results of distal ligature, the Professor drew attention to a table which he had constructed, and which comprises all the cases of innominate and aortic aneurisms which he has met with. For reasons which were stated at length, the Professor refused to use this table in a statistical manner. Though the death-rate is enormous, and though evidence of sound and permanent cure is wanting in all save three out of the whole forty-three cases, the early history of ovariotomy ought to convince us that these facts are not of themselves sufficient as a basis of a trustworthy judgment as to the future applicability of the distal ligature. Instead of the statistical method of reasoning, therefore, those cases of which there are reliable histories or preparations were selected and discussed so as to learn the lessons which each teaches.

The first part of the table refers to cases in which the carotid was tied first and the subclavian afterwards, the intervals being two years, six months, ten weeks, and seven weeks. The well-known case of Mr. Fearn is the first of these, and this case may be accepted as proof that it is possible by double distal ligature to check the progress of an innominate aneurism and restore the patient to a state of health. In each of these four cases the ligature of the carotid was, in the judgment of the operator, productive of relief, especially when symptoms of pressure on the trachea existed. In all these cases the aneurism was innominate, but in one the aorta also was affected. In all four the carotid artery was tied first.

The second part of the table contains eight cases of double simultaneous ligature, two of which were strictly on Brasdor's principle—*i.e.*, distal ligature, with no branch between sac and

ligature—and six in which Wardrop's plan was adopted. Death happened in both cases where Brasdor's operation was employed, but one of them (Hobart's) is a case of unique interest, for it was found upon post-mortem examination that perfect union had taken place where the ligature had been applied on the subclavian artery, but a small opening was found in the carotid, through which hæmorrhage had occurred. In spite of these two cases—the only two on Brasdor's method—being fatal, Professor Holmes cannot doubt that the operation, if it could be successfully performed, would cure the disease.

Wardrop's operation is justified, and its repetition encouraged, by Mr. Heath's case, in which this plan of treatment was adopted, and much relief to the dyspnoea and diminution in the size of the tumour resulted. The ease of innominate aneurism, in which the sac opened by a very large orifice into the aorta, and which was operated upon by Professor Holmes himself—catgut ligatures being employed, and afterwards galvano-puncture—points to the following conclusions:—1. That the double distal ligature will not produce consolidation in an innominate aneurism if it is partly aortic. 2. That galvano-puncture may be employed in such a tumour with the effect of producing great consolidation, but that if this consolidation is very rapid there is risk of inflammation. 3. That arteries may be tied as securely with the carbolised catgut ligature as with silk. 4. That such ligatures melt away in the wound without being discharged from it. 5. That an artery under such circumstances may preserve its continuity whilst its lumen is obliterated at the part tied, and thus the chief risk of secondary hæmorrhage is obviated.

From the cases contained in the third part of the table, in which the carotid alone has been tied on the distal side of an aneurism, the Professor thinks there is evidence enough of the benefit derived from the operation in some cases, and to justify the inference that this operation is urgently indicated in any instance which may prove appropriate. Of these recorded cases, there were 11 in which the innominate alone was affected, 4 where the innominate and carotid, 3 where the innominate and subclavian, and 11 where the aorta alone, or with one of the large vessels coming off from the arch, were involved.

Of those cases where the aorta was diseased, the right carotid was tied in four, and the left carotid in seven cases.

The Professor then quoted Velpeau's remarks upon two of these seven cases from "Nouveaux Eléments de Médecine," in which he says—"It would appear, *a priori*, that ligature in the hyoid region might suffice in all cases in which the aneurism occupies the carotid only, but that it would be necessary to join to this the ligature of the subclavian when the innominate trunk is itself affected. These two cases, together with those of Evans and Montgomery, prove incontestably that the ligature of the carotid alone may arrest the development not only of aneurisms of the innominate, but also of those of the arch of the aorta." Velpeau goes on to say—"Ligature of the carotid on the method of Brasdor deserves trial, even in cases where the aneurism appears to be prolonged down to the aorta. I must, however, still doubt whether the chances of success would not be notably increased by the ligature, simultaneous or consecutive, of the subclavian, only there remains the doubt whether the internal mammary, vertebral, and thyroid axis would not keep up the circulation in the root of this vessel, and thus destroy all the effect of the ligature upon the aneurismal sac."

The table concludes with two cases in which the subclavian artery has been tied in its third part for innominate aneurism. The first is the well-known case of Mrs. Denmark, operated upon by Wardrop; the other case that by Broca, the details of which are given in Holmes's "System of Surgery."

THE BELFAST DISTRICT HOSPITAL FOR THE INSANE.—The forty-second report of this institution for the past year states that the admissions during the year had been 130; discharged recovered, 82; relieved, 6; deaths, 21; and there remained, on December 31, 335. The receipts had been £7332 8s. 2d., and the expenditure £7061 2s. 7d., leaving a balance in hand of £263 5s. 7d.

THE INDIAN DENGUE.—Dr. Christie, Physician to Synd Bargash, the Sultan of Zanzibar, thus describes the Indian epidemic dengue, which is now raging severely among the European population of Calcutta:—"The first symptoms are those of severe muscular and articular pains, accompanied with fever, and on the fifth day an eruption, resembling erysipelas, followed by swelling of the joints and glands, and subsequent shedding of the cuticle. The disease seemed to be communicable." Dengue is not known as an epidemic in Europe.

REVIEWS.

Remarks on the Healthy and Morbid Anatomy of the Perivascular System of the Brain. By W. W. WAGSTAFFE, F.R.C.S.

AMONG the contents of the St. Thomas's Hospital Reports for the present year will be found a very interesting paper, by Mr. Wagstaffe, on the perivascular canals of the brain. Although this system was discovered some sixteen or seventeen years ago by Robin, no great amount of attention was given to it for some years, and so recently as 1866 these very sheaths were described and figured as morbid states of the vessels in cases of general paralysis of the insane. Just before and since this date, however, several histologists were working at the subject.

His showed by his injections that these sheaths or canals, from the regularity of their calibre, were produced neither by extravasation from nor collapse of the bloodvessels themselves; and it is now by general consent established that the presence of these sheaths in the pia mater as well as in the brain and spinal cord is not morbid but quite a normal condition.

The experiments of His were conclusive enough; but it was soon found that nature, or perverted nature, was in the habit of providing an injected view of these canals, for those who sought them, in cases of tubercular meningitis. First Virchow, then Rindfleisch, and then Bastian drew attention to this fact, though the latter differed from the others in his interpretation of the cause of the swelling of the sheaths—he regarding them as due to the altered condition of the epithelial lining of the canals, they to proliferation of the connective tissue of the outer coat of the artery.

His pointed out the connexion which exists between these canals and the lymphatics through the medium of the epicerebral lacunæ between pia mater and brain surface; though he denied that there was any connexion between the sub-arachnoid space and the lymphatics of the pia mater. He also showed the mechanical uses of the perivascular system as a protective to the brain substance, and as compensatory for the varying amounts of pressure, which reduces to a minimum the action of the bloodvessels upon the nervous substance.

Another disputed point respecting these canals is as to the structure of the sheaths themselves; and with the consideration of this question the remarks in the paper referred to upon the "Healthy Anatomy" of the perivascular system commences. Mr. Wagstaffe states that his investigations convince him that the structure of the sheaths differs in canals of different sizes, as well as in those of the same size examined at varying intervals of time after death. He says—"It may be easily shown that a description of a sheath surrounding a small vessel will not at all apply to that enclosing a large one. If a small vessel be examined after removal from the human brain ten or twelve hours after death, the wall of the sheath appears to be structureless or only faintly granular, and no epithelial lining is visible when a one-sixteenth object-glass is used; but if such a vessel be examined immediately after death, the transparent membrane is lined by a very definite layer of epithelium. . . . The transparent membranous wall, too, gives indication of a transverse and longitudinal striation."

Corresponding differences are observed in vessels of different sizes, the general conclusion we draw being that in perivascular sheaths of medium-sized and large vessels, in the recent state, the walls are seen to be composed of an outer set of longitudinal wavy fibres, within which is a set of delicate circular fibres, and within this again a third layer, either of corpuscular material or "with longitudinal markings distinct from the proper coat of the artery contained within the sheath." After a delay of twelve hours from the time of death the two inner layers are very much less distinct, and the striated appearance of the outer fibres more faint.

With reference to the morbid anatomy of this system of lymph spaces, Mr. Wagstaffe alludes to two cases of tubercular meningitis which bear forcibly upon the pathology of this disease. The first case was an advanced one in a child 1½ year old, and the second one of acute tuberculosis of the lungs and kidneys in a man aged 30, in whom no cerebral symptoms had shown themselves. At the examination of the body of this man no indication of tubercle of the brain or membranes was visible to the naked eye.

In both these cases the perivascular canals of the meninges (which in health are very difficult to be seen) were observed distended with nuclei, of pretty uniform size, surrounded by an irregular amount of plasma; but that, in the first case, besides this appearance, clusters of miliary deposits of various sizes, and always related definitely to the vessels, and in some

places undergoing degenerative changes, were also noticeable. Hence, then, the inference that the presence of these nuclei or nucleated corpuscles in the perivascular canals of the brain and membranes represents the early stage of tubercular meningitis.

In answer to the question "What is the nature of the deposit, and whence is it derived?" Mr. Wagstaffe adopts Bastian's view that its source is the epithelium normally lining the sheaths, and which is intermediate between spheroidal and tessellated.

In a third case—one of tumour of the brain and membranes—attention is drawn to a point in the pathology of the perivascular canals not hitherto noticed—viz., the probability of disease, such as a tumour of the sarcoma type, commencing in the connective tissue of a membrane in communication with these canals, and spreading rapidly along their course. The seat of morbid change in this case was different to that in tubercular meningitis, as there was no deposit within the canals; but their sheaths were "apparently thickened, and from their outer surface started an abundant cellular growth, consisting of caudate nucleated cells of pretty uniform character, together with an abundance of free nuclei."

Our space will not allow us to quote more fully from this paper, but we recommend its perusal to our readers as being instructive and suggestive, with the extra merit of being brief.

The author expresses his belief in the existence of these perivascular sheaths in others besides nerve tissues, and thinks he has traced them in muscular and fibrous tissues, and in the ovary and elsewhere. We quite anticipate that several structures which at present are not reputed to possess this system will in time be proved to do so, and we are aware that Macgillivray found in injected preparations of the liver lymphatic sheaths around the bloodvessels, though he could not satisfy himself these were lined with epithelium. Langer's investigations in the frog show, in opposition to Stricker's observations, that instead of the presence of sheaths around the blood capillaries of the lower eyelid of this animal, there are only two lateral lymph-tubes lying close to the bloodvessel, and every now and again uniting by transverse anastomoses crossing the vessel.

These considerations ought to make us guarded against hastily admitting the existence of lymphatic sheaths around or within the tunica adventitia of the bloodvessels. One point upon which the author of this essay does not touch, but upon which we hope soon to have some observations recorded, is as to the variations produced by different reagents upon these canals. There can be no doubt but that these do cause great alterations in the appearances of tissues, and it is now beginning to be suspected that many characters attributed to structures are due to changes in those structures produced by modes of preparation.

His stated that in chronic congestion the perivascular canals may become permanently widened; but we have more than once been puzzled to know, when looking at hardened specimens, to what degree the calibre of the spaces as seen is due to the method of hardening.

NEW BOOKS, WITH SHORT CRITIQUES.

Elementary Treatise on Natural Philosophy. By A. PRIVAT DESCHANEL. Translated and edited, with extensive additions, by J. D. EVERETT, M.A., D.C.L., etc., Professor of Natural Philosophy, Queen's College, Belfast. In four parts. Part II., Heat; Part III., Electricity and Magnetism. London: Blackie and Son.

* * * Some time ago we had occasion to speak in terms of high approbation of this very admirable treatise on physics. The second and third parts, now before us, are deserving of even higher praise than the first. Good as Deschanel's work is—representing a good fair average in point of acquisitions in physics if fairly mastered—Professor Everett has materially improved it. Certain departments of physics have been especially studied by British physicists, perhaps in view of the requirements of our manufacturing genius. In this way the mechanical equivalent of heat has now many important functions necessitating the rigorous application of mathematics to the phenomena of the conversion of heat into energy. This has been fairly mastered in this country, and Joule's equivalent is now a well-known quantity, universally made use of in such computations.

So, too, our experience in laying ocean cables for telegraphic purposes has necessitated and given a more accurate knowledge

of the laws of electricity than could be otherwise obtained. It is, therefore, with reference to the subjects of thermodynamics and electricity that we find the superiority of this edition over the original work most marked, but it is elsewhere to skilled eyes equally apparent.

To our mind this work as nearly as possible hits the golden mean. As taught in many of our higher schools and Universities, physics have too much the guise of applied mathematics; as taught in some of our manuals and schools, mathematical accuracy is too much overlooked. Here we have mathematics applied when they can be with advantage, but omitted when they are not desirable for one who is not reading for the mathematical tripos. We can, therefore, cordially commend it to our students as a means of training the mind to vigorous thought as well as of acquiring a proper knowledge of natural philosophy. The fine woodcuts give the volumes a special value of their own.

The Medical Wants of the Potteries and Neighbourhood. By CHAS. ORTON. Dilworth, Newcastle.

* * * This little pamphlet contains some useful information, and offers some practical suggestions to meet the Medical wants of the district.

FOREIGN AND COLONIAL CORRESPONDENCE.

AMERICA.

PHILADELPHIA, April 20.

THE DIPLOMA TRADE—THE APPOINTMENT OF MEDICAL TEACHERS IN AMERICA—THE WHARTON POISONING CASE—THE AMERICAN MEDICAL ASSOCIATION.

THE result of the persistent efforts made by members of the Profession to effect legislative interference that would crush out the vicious diploma traffic has already been communicated to you. Strange that it should have been tolerated so long. In one instance a diploma was made out in the name of a child a year old. The two colleges engaged in the business have been deprived of their charter, and one of them is about to be brought to the auctioneer's hammer, but the men who thrived upon this vile traffic go unpunished, and are not likely to receive any greater castigation than that which morally follows from being held up to the public scorn and contempt.

I spoke in my last letter of Medical colleges and some of their regulations. Several changes have been made in the *personnel* of these institutions recently by death or resignation. The main point of interest to you abroad, however, would probably be a knowledge of the mode in which the appointments of Medical teachers are made in this country. Let us take one of these schools as an illustration of the usual method adopted in all. A distinguished and honoured Professor died, leaving behind him pleasant memories among thousands who have listened to words of wisdom and eloquence from his lips, or have been the recipients of his graceful friendly greetings. The earth is scarcely laid upon his silent dust—indeed, in some instances, his feverish brow is scarcely cooled by death—when the question of the succession begins to loom up in magnificent proportions. Cases have been known where some of the vacancies in "appointing boards" have been filled for several years before the anticipated death or resignation of a popular professor with relatives of a perpetual candidate, such as brothers or intimate friends, with the too evident object of foisting upon an honoured institution by petty political chicanery an oftentimes unworthy aspirant. Such candidates, who, it may be truly said, are equally fitted for any vacancy—being totally unfitted for any—have been described as men of great application, for they apply for any position which lies open, and their talents fit any groove. The board of trustees of some of these institutions is made up of men of greatly varying calibre; some of them mere politicians, who believe that a school once established will thrive, even if all the solid props that once supported it are gradually knocked from under it, and replaced by weaker substitutes. Others, however, are men of culture and intelligence, who have a warm interest in the prosperity of the school, and may always be relied on to vote for the best man for the position. The contest sometimes waxes very warm, and the unworthy candidate may, perhaps, be chosen; but the institution dates from such appointment a downward career, the current of which a little foresight could have easily changed. The

struggle for a professorship is interesting enough when the aspirants are almost evenly matched in Professional excellence; but it becomes painfully so when, as sometimes occurs, one of these, of strong pretensions and mediocre qualifications, is brought prominently into dangerous competition with a gentleman of recognised ability and worth as a lecturer, author, or teacher, the only field of personal competition in which they are ever again to figure. Such unequal contests are not unknown in this country. Few of these appointing boards have a sufficiently strong infusion of Medical Professional representation in them to influence in any way the verdict of the majority. In all these bodies, which govern Medical institutions in this country, the object seems to have been to keep out Medical men from the position of trustees; and if the name of an M.D. does appear, it is often that of some fossilised member of the Profession, whose interest in its progress dates back a large fractional part of a century, before he gave up its active pursuit.

I spoke to you in a recent letter of the Wharton poisoning case, which, although the topic of the hour at the time, is now a thing of the past. Still, the lessons flowing from it have not been lost upon the Profession. I mentioned how seriously the Medical and Chemical "experts," as they were loosely called, differed in the public expression of their views in the witness-box. It was assuredly a sorrowful spectacle, for it diminished the confidence of even reflecting people in the validity of technical testimony, and gave the weak doubters something on which to strengthen their incredulity. Dr. John J. Reese, Professor of Medical Jurisprudence and Toxicology in the University of Pennsylvania, who was one of the most intelligent and accomplished witnesses for the defence, has just published (*American Journal of the Medical Sciences*, April 1872) a review of this trial, which must be interesting to all Medical, and especially Medico-legal, men at home and abroad. Such cases have no local habitation peculiar to themselves, and should excite an equal degree of attention everywhere. I will not, therefore, offer any apology for analysing this contribution of Dr. Reese's, the chief points of which might not otherwise be brought before your readers. The history of the main facts of the case was given you in the letter referred to (*Medical Times and Gazette*, April 6, 1872), and need not be again detailed. Probably the strongest point against the accused was the fact that an analysis of the contents of the stomach by Professor Aikin satisfied him that at least twenty grains of tartar emetic were present there; and the bare assertion of this fact, without further inquiry as to the method of examination employed by him, for a while bore heavily against the prisoner's prospects of acquittal. A hypothetical case was made, in which one of the principal elements was the supposed finding of these twenty grains, and it is probable that the assumed fact materially influenced the testimony of the witnesses for the prosecution. It is supposed that some of them might otherwise have concluded, from the facts presented in this hypothetical case, that death resulted from purely natural causes. An attempt was made to establish tartar-emetic poisoning, but unfortunately for the prosecution most of the prominent toxic symptoms were absent. The argument of these witnesses, as Dr. Reese states, seemed to be that, because all the symptoms of the hypothetical case did not, in their opinion, correspond with certain diseases, and also because the generally recognised lesions of these diseases were not observed after death, therefore the death must have resulted from a non-natural cause—i.e., poison. This is virtually to admit that metallic or irritant poisons must prove fatal, without ever leaving any lesion behind, discoverable by post-mortem examination! None of the Medical witnesses for the State testified that tartar emetic was the occasion of death; all save one merely spoke of it as being produced by non-natural causes. The defence of course was designed to prove that death might have resulted from natural causes, and probably from cerebro-spinal meningitis, which in the fulminant form may prove fatal, without leaving behind any discoverable lesion.

After all, however, the chemical testimony constituted the main feature of the case. Here was a poison stated to be found on post-mortem examination, without any ante-mortem symptoms corresponding with its presence there. Professor Aikin gave a detailed account of his mode of testing for antimony, which awakened the lively criticism and animadversion of several of the chemical experts for the defence. He passed sulphuretted hydrogen through the solution obtained from the stomach, strongly acidified by tartaric acid, but still containing all the organic matter, and obtained a precipitate which, for aught he knew, might have contained only sulphur and organic matter. Instead of weighing the precipitate, he seems to have guessed

at it, comparing two separate precipitates by his eye alone. If one of these was made up of nothing but sulphur and organic matter, it might, as Dr. Reese suggests, have very considerable bulk, and yet possess but very little weight. Professor Aikin did not produce metallic antimony in court, for he did not get it; and his testimony was almost annihilated by that of the defence, demonstrating that the colour-test (the orange-red precipitate), with all its subsequent reactions, except in one single point, might be exactly imitated without the presence of an atom of antimony. Then, when the utter futility of Dr. Aikin's evidence for any practical purposes was clearly exhibited, the Commonwealth procured another analyst, and without the knowledge of the defence made a new chemical examination of the liver and other viscera, which were the second time disinterred for this purpose by order of the State; but the results were proved to be not infallible, from causes in some respects similar to those previously mentioned, which need not be detailed. Such delicate manipulations certainly require more care in weighing of fractional milligrammes than was given in this case. The chemical witnesses for the defence insisted on the production of the metal in court in sufficient quantity for them to operate upon it and prove or disprove the poison; and also on the absolute necessity of excluding all extraneous substances, such as sulphur and organic matter, in the precipitate, which was to be weighed for the purpose of estimating the actual amount of the discovered poison. The attempt was made by the prosecution to cover up their neglect of this precaution by flatly denying its necessity. The deceased had taken several doses of chloral and yellow jessamine, and the defence satisfactorily proved that not only is there a similarity between the yellow-brown precipitates produced by passing sulphuretted hydrogen through an acid solution containing organic matter, and the precipitated sulphide of antimony; but that if the organic substance in the solution acted on by the sulphuretted hydrogen be the tincture of yellow jessamine and chloral (the latter is not essential), and sufficient time be allowed—say several hours,—the colour of the precipitate is of a decided orange-red, which would defy any chemist to distinguish from the (supposed) characteristic orange-red sulphide of antimony. A still stronger coincidence is found, however, in the fact that when the orange-red precipitate is itself subjected to further proofs, almost every test used produces similar results, whether it was the organic precipitate from gelsemium, etc., or the chemical one already referred to. These are the main points in this very interesting case, as honestly and ably stated by Professor Reese, and I may be pardoned for dwelling on them so lengthily, as the features presented in this *cause célèbre* are likely to be the basis of many new toxicological researches, and to open a more extended field of inquiry in regard to the proper employment of chemical reagents in future similar cases of intense Medico-legal interest.

The American Medical Association, which meets in this city on May 7, is likely to be one of the most agreeable social reunions which this body has ever had. The Medical men of Philadelphia are determined that nothing but pleasant reminiscences of their visit shall cling around it; and no matter what difference of sentiment may enter into the discussion of mooted questions in the Convention, the spirit of genuine hospitality and cordial welcome will pervade all the arrangements for their comfort and enjoyment. I have previously said that I consider this the most important feature of these annual gatherings, and that the actual amount of benefit accruing to the Profession from work done in them is not very considerable. This is partly due to the fact that the action of the National Association has no legal or binding force even, on the colleges or societies represented in it. Everything is voluntary, and whatever resolution is adopted in it to influence these subordinate bodies may have a certain amount of moral effect, but that is all. Still, the course of this general representative mass of the American Medical Profession is eagerly watched by the societies of the states and counties, and by institutions for Medical instruction, who sometimes strengthen their own tendencies to the adoption of decisive measures of reform by basing them on the previous action of the larger body. Among the aids extended to the visiting delegates, a handsome little handbook or guide to the city has been issued for gratuitous distribution, which will be worth presenting as a memento of the annual meeting of 1872. Of the proceedings of this session I shall speak much more minutely in my next.

FROM the West Coast of Africa we learn that the health of the coast at all the ports was good.

GENERAL CORRESPONDENCE.

POOR-LAW MEDICAL OFFICERS AS OFFICERS OF HEALTH.

LETTER FROM DR. JOSEPH ROGERS.

[To the Editor of the Medical Times and Gazette.]

SIR,—I beg to forward a letter from Mr. Bridger, enclosing a copy of a resolution adopted at a conjoint meeting of members of the Poor-law Medical Officers' Association and of the British Medical Association held at Cambridge last March, and trust you will be so good as to publish the same in this week's issue. I make this request, as I am given to understand the impression exists that the Poor-law Medical Officers' Association will, of necessity, reverse the policy it has hitherto followed as regards Mr. Stansfeld's Public Health Bill in virtue of the resolution adopted by a majority of one at the meeting of the Association at the Medical Club on the 28th ult., the attendance on that occasion being the smallest ever recorded, nine gentlemen only having been present. I shall further be obliged if you will permit me to state that the action that has been taken (so far, at least, as I am concerned) has been mainly determined by the nature of the communications which have been sent me by a very large number of provincial members; of the character of these the Cambridge resolution gives a very fair idea. Surely the views of these gentlemen are entitled to the largest consideration, seeing the Bill as drawn affects the interests of Medical officers of the provincial service exclusively.

I am, &c., JOSEPH ROGERS,
Dean-street, June 11. President of the Association.

Resolution put and adopted by the Medical officers present in Cambridge at a conjoint meeting of the British Medical Association and Poor-law Medical Officers' Association of the counties of Cambridge and Huntingdon, held on March 26, 1872.

"We, the undersigned members of the Poor-law Medical Officers' Association, fully concur in the resolutions adopted by the Joint Committee on State Medicine of the British Medical and Social Science Associations. We also beg to call attention to resolution No. 6, as we consider it would be an extreme hardship to impose further duties, without extra pay, on the already overworked and underpaid Medical officers."—Signed by "JOHN BRIDGER, Cottenham, Honorary Secretary of the Poor-law Medical Officers' Association for the county of Cambridge, and Medical Officer of the Seventh District of the Chesterton Union; and thirty-seven others."

THE LONDON HOSPITAL.

LETTER FROM MR. WALTER RIVINGTON.

[To the Editor of the Medical Times and Gazette.]

SIR,—For many years I have made it a rule not to notice personal attacks of an anonymous character. Let your correspondent manfully emerge from his obscurity, and by publishing his name afford us a guarantee of his good faith, and I will at once offer a reply to observations which at present must be regarded as worse than valueless. The deep interest which he evidently takes in his subject would then entitle him to an answer.

I am, &c.,
WALTER RIVINGTON, M.S. Lond., F.R.C.S.,
Surgeon to the London Hospital.

MEDICAL OFFICERS OF HEALTH.

LETTER FROM DR. WOODWARD.

[To the Editor of the Medical Times and Gazette.]

SIR,—Will you kindly insert the following as the reasons why, in my opinion, Union Medical Officers should be appointed Deputy Medical Officers of Health:—

- 1st. Because they are already accustomed to render great service to the State for very small pecuniary profit.
- 2nd. Because they are called in to cases of epidemic diseases among the poor long before any other public official, and in many cases they alone are individually cognisant of the existence of such cases.
- 3rd. Because they are personally interested in reducing sickness and mortality in their heavily worked districts; and
- Lastly. Because every street, alley, and cottage in the kingdom would be under inspection by an educated body of men

already in working order, instead of a fresh staff being appointed.

I think I am quite within the mark when I state that any Union Medical Officer could, if vested with ordinary powers, reduce the sickness and mortality from epidemic and preventable diseases in his district by at least one-half within the first twelve months.

I am, &c.,
Worcester, June 10. WM. WOODWARD, M.D.

PRACTITIONERS, CHEMISTS, AND CO-OPERATIVE STORES.

[To the Editor of the Medical Times and Gazette.]

SIR,—Your correspondents have drawn attention to the altered relations between the public, the general Practitioners, and the chemists, and have rightly pointed out that there are certain changes, brought about by altered circumstances, which we may grumble at, but must submit to. What the public want they will have, and if the general Practitioner can't supply it they will go to the chemist. But it is quite out of reason to suppose that there are no "morbid changes" affecting the chemist. He suffers in his turn from the same popular caprice. John Bull goes to the chemist to buy a remedy, as a trade transaction, in order thereby to escape paying for the advice or skill by which the remedy was suggested. The patient knows, and so does the chemist, that (say) ammonia is good for a headache; so why should he not buy an ammonia mixture at the chemist's for two shillings, instead of going to the general Practitioner to whom he would pay (say) three and sixpence, or five or seven shillings for the medicine *plus* Professional skill? But John Bull finds that what is sauce for the Practitioner will baste the chemist as well. His ammonia mixture consists of a few grains of ammonia, a little tincture of cardanoms, and some camphor water. The cost of these ingredients is small; anyone who knows the trick can make them up; so why pay the chemist two shillings for the medicine *plus* his professional skill? and why not go to a co-operative store, where mere drugs may be had at wholesale price, and prescriptions be made up at low rates, because it is not necessary to charge for a separate plant and establishment?

In fact, Mr. Editor, the chemists are beginning to feel the effects of these co-operative stores, and I sympathise with them, for it is a public calamity that professional and scientific skill should be discredited and abandoned by the public, whether it be the case of the chemist supplanting the Practitioner, or the co-operative grocer supplanting the well-educated pharmaceutical chemist.

I am, &c., E.
London, June 5.

VOLUNTEER SURGEONS.

[To the Editor of the Medical Times and Gazette.]

SIR,—I have seen to-day the new regulations issued by the War Office respecting the duties, etc., of the auxiliary forces, under which are included volunteers. Under the head of "Volunteers" it is stated that the adjutant, the sergeant-major, and the instructors of any corps (being the permanent staff) are, together with their respective wives and families (with slight restrictions as to sons), entitled to the services of the Surgeon of their corps, who is to supply all necessary medicines; and that the Surgeon, complying with certain forms, is to be paid by the War Office, through the adjutant, at the rate of twopence per head per week. There is no restriction as to the nature or extent of the attendance, and, as the regulations stand, each member of the permanent staff can compel the attendance of the Surgeon on all occasions (including midwifery), who is to find all necessary medicines. The regulations mention the word "Surgeon" only, and do not name the Assistant-Surgeons; hence the former is responsible for the attendance, but he, in virtue of his rank, is in the position to command the services of his assistants; hence the whole Medical Volunteer Service is involved. Being Surgeon to a metropolitan corps, I find that I shall have eighteen persons thus placed under my care, for whom, whether ill or well, I can draw 3s. per week, which in the gross amounts to £7 18s. per annum. I need not say that this attendance on Government officials thus thrust upon me is not only unremunerative, but a dead loss to me, and the amount of remuneration offered simply an insult to the whole Profession. It behoves us all who hold Medical commissions to make some stand against the duties and the pay, or else to resign *en masse*—a course which I, for one, shall approach with much regret, since I have been long connected

with my corps, and have experienced and derived much pleasure from my intercourse and friendship with my brother officers. Surely Government cannot imagine for one moment that such a proposal can pass unchallenged, or that our Profession in the service will submit to be so called upon for such a paltry remuneration. For my part I have always been willing to render, and have rendered, service to my permanent staff; but I never anticipated that such service would be wrung from me under compulsion and under promise of a pay which is of itself so ridiculous and so insulting that, for one, if the regulations be insisted on, I must consult my own dignity, though with much unwillingness, by resigning my commission, trusting that all other Volunteer Medical Officers will follow my example.

The rest of the regulations as applied to Medical officers are fair and proper. I am, &c.

A VOLUNTEER SURGEON.

* * It will be seen in another column that a meeting of Volunteer Surgeons has been summoned to take the whole matter into consideration.

REPORTS OF SOCIETIES.

OBSTETRICAL SOCIETY OF LONDON.

WEDNESDAY, MAY 1.

J. BRAXTON HICKS, M.D., F.R.S., President, in the Chair.

THE following gentlemen were elected Fellows of the Society:—Michael Coote, M.D., Quebec; N. S. Kerr, M.D., Dunstable; Jos. McMonagle, M.D., St. John's, New Brunswick; W. K. McMudie, M.D., Portadown; F. D. Niblett, M.B., Hackney; and John Wallace, M.D., Liverpool.

Dr. WYNN WILLIAMS exhibited a large-sized Mucous Polypus he had removed from a patient who was seven months pregnant. The polypus protruded from the os uteri; it was ligatured and then cut off. Another small one was also removed by torsion, and the parts were swabbed with a saturated solution of tannin and spirits of wine, which completely arrested the slight bleeding.

Dr. PHILLIPS referred to a similar case, in which, a few days previously, he had been induced to remove a muco-cellular polypus from the cervix at the sixth month of pregnancy on account of the hæmorrhage it caused. It seemed necessary in deciding the question of the removal of a polypus during pregnancy to take into consideration the amount of disturbance to which it gave rise; but, generally, he thought that abortion was less likely to be induced by the removal of a polypus hanging from the os uteri than by allowing it to remain.

Dr. ROUTH mentioned a case which he had seen in the country. He advised that labour should be brought on, and then the polypus removed to prevent the bleeding. Labour, however, came on spontaneously, and the polypus was apparently torn away during the passage of the child's head. He thought it quite safe to remove a polypus attached to the external os only; but to remove a polypus with a pedicle attached within the cervix he considered hazardous, and very likely to bring on a miscarriage.

Dr. BARNES exhibited for Dr. James Blake, of San Francisco, a modification of Hodge's Pessary, consisting in the substitution of watch-spring for the usual solid side bars. This modification gave elasticity to the pessary, which, whilst it increased its leverage action, diminished the risk of shock and concussion.

The PRESIDENT exhibited for Mr. Greaves, of Stafford, a large Growth from the Mouth of a Fœtus. (Referred to Dr. Black and Dr. Potter for a report.)

Dr. WORSHIP, of Sevenoaks, showed a large Malformed Fœtus delivered by Craniotomy.

Dr. GODFREY, of Enfield, exhibited a Placenta with a very large Fibrinous Effusion, which, judging from the history of the case, was doubtless due to syphilis.

Dr. MADGE said that other causes besides syphilis would produce a similar appearance, and that an examination of the placenta, apart from the patient's history, would hardly lead to the conclusion that its morbid condition was due to syphilis.

Dr. BRUNTON and Dr. BARNES referred to the distinctive characters of fatty and fibrinous degeneration. Dr. Barnes said that in the syphilitic placenta the albuminous or fibrinous effusion was uniformly distributed. There was, as Virchow said, hyperplasia.

Mr. MILWARD, of Cardiff, read an account of an Anencephalous Fœtus, and of another Malformed Fœtus, supposed to be due to maternal mental impression at an early period of pregnancy.

Dr. NEWMAN read a paper (a sequel to one published in the Society's *Transactions* for 1867) on a case in which the Cæsarian Section was successfully performed, but in a subsequent pregnancy delivery was accomplished *per vias naturales*. The local conditions which obstructed labour in 1866 were believed to be due to malignant disease of the cervix uteri. In August, 1871, the patient presented herself, and she was found to be three months pregnant. The cervix felt hard, and there was a feeling of deep lines of hardness about the whole lower part of the uterus, but otherwise the parts were nearly natural. Pregnancy was allowed to go on to full term. The cervix was then dilated by Barnes's elastic bags, and the long forceps was applied to supplement ineffective uterine action. The child was born alive, and the mother's subsequent progress was uninterruptedly good.

Dr. BARNES said that when he saw the case there was no distinctive mark of malignant disease, only a cicatricial condition of the os uteri. The cure of extensive malignant disease was so rare, that a suggestion which had been made, that the disease was pelvic cellulitis, seemed worthy of observation. On the other hand, the uterus was movable, which was consistent with cancer affecting the cervix only, but hardly with cellulitis. Dr. Habit had related a case in which a mass of cancerous tissue was cast off by sloughing, and recovery with cicatricial atresia followed.

Dr. PLAYFAIR said that he had seen in Calcutta a case of labour in which the pelvic cavity was so blocked up with exudation, probably from pelvic cellulitis, that the Cæsarian section had to be performed. He thought that in Dr. Newman's case the condition was chronic inflammatory induration of the cervix.

Dr. ROGERS described a case which he had recently attended. The patient was 40 years old, and in labour with her first child. After partial dilatation with the elastic bags, the cervix was so thick and rigid that it was necessary to scarify and carefully incise it. The dilator was reapplied, and the cervical ring gave way, tearing into irregular warty pieces. A live child was born, and the patient was doing well.

Dr. ROUTH referred to a case of malignant disease he had seen at Vienna, in which the cervix uteri was torn off as a hard ring by the child's head, and another case in which it was torn across, and death soon followed. In Dr. Newman's case the description given would apply to ordinary carcinoma, but it would also equally apply to a chancre, which might have become phagedænic. Hard cervixes were frequently evidence, not of cancer, but of syphilis.

An abstract of a paper by the PRESIDENT, "On the Anatomy of the Human Placenta," was then read. The paper began by discussing the foundation of the sinus system as first propounded by John Hunter. It was shown how the injection he used would almost certainly produce an irruption of blood amongst the villi. The walls of the dilated vessels, as they ramify in the decidua serotina on its inner or ovular surface, are so very delicate that the force of the syringe, so unlike the action of nature, is nearly certain to break them down. A description of the arrangement and condition of the vessels formed a subsequent portion of the paper. The evidence of Goodsir and other observers was then reviewed. The second part of the paper proceeded to discuss the fact that blood being found amongst the villi after natural expulsion was no evidence in favour of or against a sinus system, because in the vast majority of placenta naturally shed there are lacerations and denudations of the decidua serotina which would admit blood into the so-called cavity of the placenta. The author then argued that, the placenta being examined *in situ* without any injury whatever, if no blood be found among the villi, this was conclusive against the existence of a sinus system. Dissection of four specimens was given. In two not a trace of blood was found; in the other two there was a trace—in one of these the origin was clearly traced to a small clot extravasated among the villi, in the other to a laceration of the villi themselves. Further evidence was added, derived from three placenta called "fatty"; in these, although the decidual vessels were highly distended with blood, yet the intervillal space was absolutely free. Dissections of ova were given to show that at no time of pregnancy is there a trace of a transition state, which is assumed by some authors. The openings of the uterine glands can be observed to full term, no membrane passing over them on the ovular aspect of the decidua serotina, and the opaque tips of the villi are traceable without any

membrane over them till full term. The author quoted also the behaviour of hæmorrhage; for if the placental cavity were fed necessarily by blood from the mother's vessels, then any rupture into its cavity ought to be attended by severe and continuous loss, which is contrary to fact. A sinus system is proved by extra-uterine gestation not to be a necessity. In the uterus the existence of decidual processes with large sinuses in them brings the blood half-way through the placental thickness, and the peristaltic movements of the uterus would doubtless facilitate the exchange of elements.

Dr. SNOW BECK said he had no doubt that the anatomy originally described by the Hunters and confirmed by subsequent anatomists was correct, and that there existed vascular communications between the uterine sinuses and the cells or great cavity of the placenta through which the maternal blood flowed. He denied that the openings apparent after the separation of the placenta are accidental lacerations. He undertook to show the openings which existed on the uterine surface of the placenta upon any recent placenta immersed in pure water.

Dr. MADGE, on the other hand, said that, after working a great deal at the subject, he was convinced that the Hunterian doctrine respecting the utero-placental vessels was a mistaken one.

LEGAL INTELLIGENCE.

IMPORTANT DECISION.

MARYLEBONE COUNTY COURT.

(Before H. T. J. MACNAMARA, Esq., Judge.)

STEVENSON v. GLIDDON.

THE MEDICAL ACTS.—RIGHT TO RECOVER FOR MEDICINES SUPPLIED.

THIS was an action brought by a Surgeon to recover fees, and for medicine supplied to the defendant. The case came on for hearing on April 10, and was then referred for arbitration to Mr. Bullock, an attorney, who disallowed the items in the claim for medicines. An application was then made to the judge by the plaintiff upon the point of law. On May 22 his Honour delivered the following judgment. After observing that the case was a most important one to the Medical Profession, he said: The plaintiff is a Member of the College of Surgeons in England, and is authorised to practise as a Physician by a diploma from the University of Edinburgh, but is not qualified as a Member of the Society of Apothecaries in London. He is registered under the Medical Act of 1858 as such Physician and Surgeon, but not as an apothecary. His bill contains charges for visits alone, for medicine alone, and for visits and medicine. The arbitrator disallowed the plaintiff's charges for medicine supplied alone, amounting to about £11, without advice or visits, on the ground that he could not recover for medicine supplied except as auxiliary to a Surgical case. It was admitted that this would have been so—at all events, in the case of an English Physician or Surgeon—prior to the Medical Act, 1858; but Section 31 of that Act was relied upon as having effected a change in that respect. Let us (said the judge), in order to arrive at a true construction of the statute, look at the state of the law at the time when it passed, and the mischief it was intended to remedy. The statute 55 Geo. III., c. 194 (Apothecaries' Act), enacts that persons practising as apothecaries without a certificate from the Society of Apothecaries of examination and qualification, shall be liable to penalties and disabled from recovering fees. That passed for the public good, and to ensure competency in that class of Medical Practitioners; but it was still found that unqualified persons practised. The Act of 1858 was intended to strengthen public security by requiring Medical Practitioners to be registered, so that unqualified persons might be prevented from practising. Registration under this Act is made evidence of qualification, but it is not substituted for it (see the preamble of the Act, and sections 4, 15, 18, 26, 30, and 32). Another object of section 31 is to enable Physicians to recover fees. Now, read section 31, and it is clear it is not intended to repeal the Act of Geo. III., or to allow those persons to practise as apothecaries who have not a certificate from the Society of Apothecaries, and who would be liable to penalties. (Attorney-General v. Royal College of Physicians, 30 *Law Journal*, 757, Chancery; Wilcocks' "Treatise on Laws relating to Medical Practitioners;" Weightman's "Medical Practitioners' Legal Guide," 1870.) It was then contended, and evidence was given to show that a practice exists in Scotland for Physicians or Surgeons to act as apothecaries, but no satis-

factory evidence was adduced as to the law of Scotland on this point. This, however, is immaterial, as a Medical Practitioner must be registered as an apothecary to practise as such in England. In the case of the Apothecaries' Company v. Collins (4 Barnewall and Adolphus, 604) it was expressly decided that a person authorised to practise as a Physician by a Scotch diploma was not exempt from the penalty for practising here as an apothecary without a certificate from the Society of Apothecaries.

Leave was given to apply for a case to the superior court if desired.

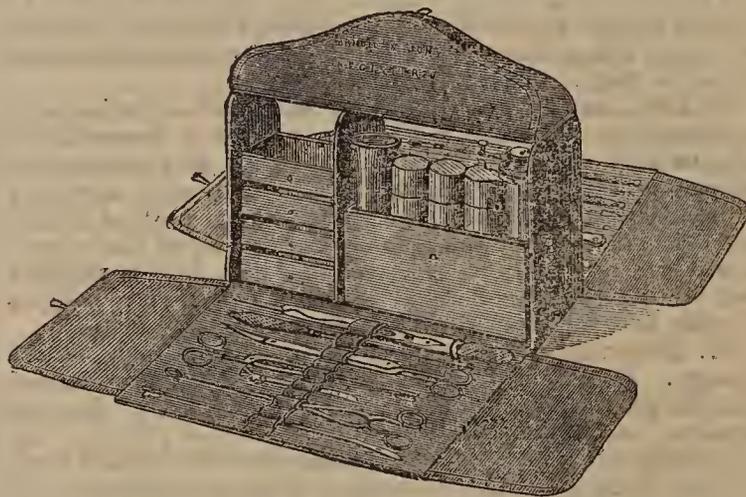

Mr. Macnamara, who has been only recently appointed to the County Court Bench, was long known in the legal profession as one of the most careful, painstaking, and experienced members of the bar. His decision will therefore carry much weight; but it will be observed that it does not affect the right of the Licentiates of the College of Physicians to practise pharmacy under their licences. The section 31 of the Medical Act relied upon by the plaintiff says that—"Every person registered under this Act shall be entitled, according to his qualification or qualifications, to practise Medicine or Surgery, or Medicine and Surgery, as the case may be, in any part of her Majesty's dominions, and to demand and recover in any court of law, with full costs of suit, reasonable charges for Professional aid, advice, and visits, and the cost of any medicines or other Medical or Surgical appliances rendered or supplied by him to his patients."

NEW INVENTIONS.

THE NEW GYNÆCOLOGICAL BAG (REGISTERED).

(Arnold and Sons, 35 and 36, West Smithfield.)

THIS bag, when closed, resembles an ordinary writing-case, or small portmanteau, of black morocco leather. Each side lets down, and reveals a centre compartment, which is a veritable apothecary's shop fitted with miniature drawers, bottles, etc. The lateral flaps contain loops and pockets for the reception of a great variety of instruments, which by this arrangement are

easily accessible. Such a bag, with due modifications, might be available for any department of practice—the Surgeon could carry in such a bag even the largest and weightiest instruments, together with chloroform, morphia, etc.; the accoucheur might take everything required in labour, ordinary or extraordinary; and, as in the present instance, the gynæcologist can take his formidable list of specula, forceps, scarificators, caustic-holders, pessaries, uterine sounds, tents of sponge and laminaria, scissors, catheters, chloroform apparatus, suppositories, etc. The fact that Dr. Greenhalgh approves this bag will be taken as evidence of its completeness.

DUST-PROOF AND WASHABLE CARPETING, OR ASPHALTE SUPERFICIAL FLOORING.

(G. P. Chiles and Co., 57, Belmont-place, London, N.W.)

WANTED, a material for covering the floors of offices, counting-houses, surgeries, etc., which shall be warm as Brussels carpet, without its dust, and cleanly as oilcloth, without its coldness. Such qualities are claimed by the inventors for the articles whose names we have given. The practical Physician is so well convinced of the mischief of stuffy, dirty, dusty old carpets, and of the still greater mischief of cold floors to persons engaged in indoor occupations—schools, and the like—that he will be induced to see whether the promises of the asphalte carpeting are justified by experience.

OBITUARY.

WILLIAM SETH GILL, L.R.C.P.E., M.R.C.S., L.S.A., Was born at Sandgate, Kent, and was the son of a respected Medical Practitioner there. Nearly fifty years since he commenced practice at Liddon, Norfolk, subsequently removed to Peckham, and later still to Pentonville, where he practised for nearly forty years. He early saw the advantage of imparting useful knowledge to the masses, and lectured on electricity (then in its infancy) nearly half a century ago. He was for many years Medical Officer to the Clerkenwell district. Among his contributions to Medical literature were articles "On Placenta Prævia," and "On the Action of *Secale Cornutum*." He died on May 31, at White Lion-street, Pentonville, aged 72, deeply regretted. His was an earnest and useful though laborious life, and within a few weeks of his death he was still engaged in the active duties of his Profession.

JOSEPH HUTCHINSON, M.R.C.S., ETC.,

DIED on the 23th ult., aged 63. He lost his father in 1830 from cholera, while studying Medicine at St. Thomas's Hospital School. He was the pupil of the late Dr. Camplin, of Islington, author of a work on "Diabetics." He became L.S.A. in 1833, M.R.C.S. in 1834, and F.R.C.S. by examination in 1846. He commenced practice at Cheetham Hill, near Manchester, where he continued for a period of thirty-eight years, and till within a few days of his death, with great success. He was for many years a Medical Officer of the Union; was kind, attentive, and conscientious towards his patients; upright and honourable in all his dealings. He paid special attention to obstetric practice, and was the inventor of a speculum. His skill in this branch of our art was widely known and appreciated. He was Medical referee to several insurance societies.

MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS.—The following Members of the College having undergone the necessary examinations for the Fellowship at the half-yearly meetings terminating on the 25th ultimo, were reported to have acquitted themselves to the satisfaction of the Court of Examiners, and, at a meeting of the Council on Thursday, the 13th inst., were admitted Fellows of the College, viz. :—

Cumberbatch, Alphonso Elkin, M.B. Lond., the College of St. Bartholomew's, diploma of Membership dated January 25, 1870, student of St. Bartholomew's Hospital.
 Durham, Frederic, M.B. Lond., Northampton, November 16, 1869, of Guy's Hospital.
 Elliott, Arthur Bowes, L.R.C.P. Lond. and L.S.A., Bartlett's-buildings, Holborn, April 25, 1867, of Guy's Hospital.
 Evans, George Harrison, M.B. Edin., Hagley-road, Birmingham, April 22, 1868, of St. Bartholomew's Hospital.
 Goodsall, David Henry, L.R.C.P. Lond., Finsbury-square, May 19, 1868, of St. Bartholomew's Hospital.
 Harvey, William, L.S.A., H.M. Indian Army, January 29, 1862, of the Charing-cross Hospital.
 Joubert, Charles Henry, M.B. Lond., Royal Victoria Hospital, Netley, Southampton, May 5, 1868, of St. Mary's Hospital.
 Raiton, Thomas Carleton, Manchester, January 20, 1869, of the Manchester School.
 Sympson, Thomas, L.R.C.P. Edin. and L.S.A., Lincoln, July 26, 1847, of St. Bartholomew's Hospital.
 Wells, John Soelberg, M.D. Edin., Savile-row, December 21, 1860, of King's College.

Six candidates having failed to acquit themselves to the satisfaction of the Court of Examiners, were referred to their Professional studies for twelve months.

The annual meeting of Fellows for election into the Council of the College will take place on Thursday, the 4th proximo, when Messrs. Henry Hancock, of the Charing-cross Hospital, Hunterian Orator, and Thomas Blizzard Curling, F.R.S., of the London Hospital, Vice-Presidents of the College, the retiring Members of Council, will offer themselves for re-election, and the vacancy caused by the death of Mr. Samuel Solly will be filled.

Collegiate Elections.—The annual meeting of the Fellows of the College for election into the Council will be held on Thursday, the 4th proximo, when Messrs. Henry Hancock, of the Charing-cross Hospital, and Thomas Blizzard Curling, of the London Hospital, the Vice-Presidents of the College, who retire in rotation, will deservedly be re-elected; and as on Monday evening last, at twelve o'clock, Mr. Barnard Wight Holt, of the Westminster Hospital, was the only candidate

nominated, it will be, to use a sporting term, "a walk over the course" for these three gentlemen, showing how highly they are esteemed by the Fellows generally. The names of three probable starters were mentioned, but they either declined coming forward on the present occasion, or were too late in their application. Sir William Fergusson, Bart., F.R.S., late President of the College, has consented to take the chair the same evening at the annual festival of the Fellows of the College. We are requested to state that tickets may be obtained of Mr. T. Carr Jackson, F.R.C.S., the Honorary Secretary.

At a meeting of the Council of the College on Thursday, the 13th inst., the following members having been elected Fellows at previous meetings of the Council, were admitted as such, viz. :—

Allen, Robert Marshall, of Welborne Hall, Grantham, Lincolnshire (retired), diploma of Membership dated June 26, 1840.
 Weekes, Henry, of Barnstaple, North Devon, July 1, 1836.

This was an adjourned meeting for the further consideration of the recommendations of the conjoint Committee of the Colleges of Physicians and Surgeons on the mode of carrying out the scheme for an Examining Board for England, and for discussing Mr. Charles Hawkins's motion, "That the four representatives of Surgery appointed by the Council as members of the Committee of Reference be selected from the present or past members of this Council," when the following gentlemen were elected, viz. :—Sir William Fergusson, Bart., F.R.S.; Sir James Paget, Bart., F.R.S.; George Busk, Esq., President of Royal College of Surgeons, F.R.S.; Richard Quain, F.R.S.

Collegiate Examinations.—The half-yearly examination in Arts, etc., for the diplomas of Fellowship and Membership of the Royal College of Surgeons will take place on Tuesday, the 18th instant, and following days, at the University of London, Burlington-gardens, and be conducted, as usual, by a staff of the College of Preceptors under the superintendence of Dr. Jacobs. It is stated that there are as many as 370 candidates—viz., 109 for the Fellowship, and 261 for the Membership. It may save the candidates some trouble by informing them that, owing to the large number of papers on so many various subjects to be read by the examiners, the result cannot be known for several weeks.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received Certificates to practise, on Thursday, June 6 :—

Anderson, William Henry, Theddlethorpe.
 Dixon, Thomas James, South Africa.
 Dobson, Joseph, Leeds.
 Edwards, Alfred, Scilly Isles.
 Gerrard, William Arthur, Ticknall, Derby.
 Greaves, Frank, Bishops Waltham.

APPOINTMENTS.

* * * The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

CHICKEN, RUPERT CECIL, M.R.C.S.—Registrar to the Evelina Hospital for Sick Children, Southwark-bridge-road.
 CLOUTING, JOHN REVETT, M.R.C.S.E. and L.S.A.L.—Medical Officer to No. 1 Medical District, Ongar Union.
 COURTNEY, DAVID, M.R.C.P. Edin. and M.R.C.S. Ire.—Medical Officer for the Workhouse, Amersham, Bucks.
 M'CALMAN, HUGH, M.B., C.M.—Parochial Medical Officer for Eddrachillis and Durness, Sutherlandshire.
 ROBERTS, W. L., M.R.C.S. Eng., L.S.A.—Senior House-Surgeon to the Bradford Infirmary, *vice* Dr. Robagliati, resigned.
 ROCHFORD, HUDSON H., L.K.Q.C.P.I., L.M., L.R.C.S.I.—Surgeon to the Odd-Fellows Medical Aid Association, Newport, Mon., *vice* Wasdale Watson, M.R.C.S. Eng. and L.A.C. Lond., resigned.
 SOUTTER, M. C., M.R.C.S. Eng.—Surgeon to the Islington and North London Provident Dispensary, Hornsey-road, N.

NAVAL AND MILITARY APPOINTMENTS.

MEDICAL DEPARTMENT.—Alexander Fisher, M.D., has been promoted to the rank of Staff Surgeon in her Majesty's Fleet, with seniority of May 24, 1872.
MEDICAL DEPARTMENT.—Surgeon-Major James Fraser, M.D., from the 50th Foot, to be Staff Surgeon-Major, *vice* Staff Surgeon Nicholas Ffolliott, appointed to the 50th Foot; Staff Assistant-Surgeon Alexander Crombie, M.D., resigns his commission.

BIRTHS.

BRICKWELL.—On May 25, at Stacey-place, Slough, the wife of John Brickwell, M.R.C.S. Eng., L.S.A., of a son.
 SCOTT.—On June 11, at Glyn Abbot, Holywell, the wife of R. R. Scott, Staff Surgeon, of a daughter.
 SHILLITOE.—On June 5, at Birch Mount, Sydenham-hill, the wife of Buxton Shillitoe, F.R.C.S., of a son.

STRANGE.—On June 1, at 13, Belsize-avenue, Hampstead, the wife of W. Heath Strange, M.D., of a son.

WHITMARSH.—On June 6, at Albemarle House, Hounslow, the wife of William Michael Whitmarsh, M.D., of a son.

WRIGHT.—On May 31, at Edinburgh, the wife of Surgeon Thomas Wright, of H.M.'s 93rd Highlanders, of twin daughters.

MARRIAGES.

AIRY—LANGTON.—On June 5, at St. John's, Keswick, Battersby Hubert Airy, M.D., second son of G. B. Airy, Esq., C.B., Astronomer Royal, to Susan Cecilia, youngest daughter of S. Z. Langton, Esq., of Barrow House, Keswick.

ANDREWS—CORBET.—On May 28, at Orsett, Essex, Thomas Corbitt Andrews, to Marion, elder daughter of the late David Corbet, M.D.

CALTHROP—THOMAS.—On May 4, at Kurnal, Punjab, India, Christopher William Calthrop, M.D., Professor of Anatomy and Materia Medica, Lahore Medical College, to Honor Cary, eldest daughter of R. W. Thomas, Esq., Deputy Commissioner, Kurnal.

COLLINS—JEUNE.—On June 6, at St. Mary's Church, West Horsley, Surrey, John C. Collins, M.D., Bengal Medical Service, to Augusta C., eldest surviving daughter of the late Col. T. S. H. Weston, C.B., Bengal Army, of West Horsley-place, and widow of Lieut. F. A. Jeune, Bengal Army.

CUTCLIFFE—PRICE.—On May 18, at Calcutta, Henry Charles Cutcliffe, M.D., to Louisa Mary, second daughter of Spencer Cosey Price, Esq.

GLANVILLE—CARTWRIGHT.—On June 6, at the parish church, Bradfield St. George, Usher Glanville Doyle Glanville, M.D., Spring-grove, Isleworth, to Edith Adeline, youngest daughter of the Rev. J. C. Cartwright, rector of Bradfield St. George.

LORIMER—LORIMER.—On June 11, at 9, Dryden-place, Edinburgh, John Archibald Lorimer, L.R.C.P. Lond., of Farnham, Surrey, son of the Rev. Professor Lorimer, D.D., to Harriett Annie, eldest daughter of James Lorimer, Esq., C.E.

OLIVER—HUNT.—On June 8, at St. Mary's Church, Barnard Castle, George Oliver, M.D., of Coatham, Yorkshire, to Alice Mary, daughter of John Hunt, Esq., of Barnard Castle, Durham.

READ—CORBETT.—On June 8, at Christ Church, Ealing, Reginald Read, F.R.C.P.E., Guildford-place, Russell-square, W.C., to Anna Maria, eldest daughter of George Corbett, Esq.

SKAIFE—PLATT.—On June 4, at the parish church, Brighton, John Skaipe, L.R.C.P. Edin., M.R.C.S. Eng., L.S.A., of Northampton-square, London, to Isabel Annette, daughter of the late Samuel Platt, D.L., of Belmont, Surrey, and 10, Hyde-park-gardens, W.

STRONG—OWEN.—On June 1, at All Saints' Church, Upper Norwood, Henry John Strong, M.D., of North-end, Croydon, to Elizabeth Ann, widow of Henry James Owen, and second daughter of the late Charles Brooks Teague, of The Lodge, South Lambeth, and Brighton.

THORNTON—CAUDLE.—On June 5, at St. Peter's Church, Henfield, Sussex, William West, third son of the late Thomas Thornton, of Brixton-hill, to Annie Homewood, third daughter of the late Adolphus Caudle, M.R.C.S. Eng., L.S.A., of Henfield.

DEATHS.

DICKSON, CHARLES FREDERICK LINDSAY, son of Lindsay F. Dickson, M.D., Bengal Army, at Jubbulpore, on May 12, aged 8 months.

DICKSON, JOHN, M.D., Medical Superintendent of the Government Lunatic Asylum, Port Louis, late of Dumfries, Scotland, at Port Louis, Mauritius, of malarious fever, on April 20.

LESTER, MARGARET HEARD, widow of the late Dr. C. S. Lester, R.N., at 13, Westbourne-park-villas, on June 9, aged 44.

MACDONNELL, J. W., M.D., eldest son of the late William Macdonnell, Esq., of Landsdown-place, Dublin, at Dublin, on June 3, aged 42.

ROY, MARY, wife of Henry Roy, M.D., and youngest daughter of the late James Steel, Tranent, East Lothian, at 20, Claremont-square, on June 4.

RUMBALL, JAMES QUILTER, M.R.C.S.E., L.S.A., late of Harpenden Hall, at The Limes, Harpenden, Herts, on June 4, aged 77.

SMITH, FANNY MATILDA MARY, the beloved eldest daughter of Septimus William Smith, L.F.P.S. Glasg., L.M., Surrey Villa, Kennington-road, on June 7, aged 7 years and 5 months.

VACANCIES.

In the following list the nature of the office vacant, the qualifications required in the Candidate, the person to whom application should be made, and the day of election (as far as known) are stated in succession.

ADDENBROOKE'S HOSPITAL, CAMBRIDGE.—House-Physician and House-Surgeon. Candidates must be duly qualified. Applications with testimonials to the Secretary, 60, St. Andrew's-street, Cambridge, before June 19.

BIRMINGHAM AND MIDLAND HOSPITAL FOR WOMEN.—Resident Medical Officer and Secretary. Candidates must be duly qualified. Applications with testimonials to Arthur Chamberlain, Esq., Hon. Secretary, 8, The Crescent, Birmingham, on or before July 15.

DERBYSHIRE GENERAL INFIRMARY.—Assistant House-Surgeon. Candidates must be duly qualified. Also, a properly qualified Dispenser. Applications, with testimonials, to the Secretary, Samuel Whitaker, Infirmary, Derby, on or before June 15.

EAST LONDON HOSPITAL FOR CHILDREN AND DISPENSARY FOR WOMEN, RATCLIFFE-CROSS.—Visiting Physician. Candidates must be Fellows or Members of the Royal College of Physicians of London, or F.R.C.P. Edinburgh or Dublin, or Graduates in Medicine of a British University, or of the Universities of Paris, Vienna, Berlin, or other universities approved by the General Medical Council, and be legally qualified to practise Medicine in England. Applications to be sent to the Secretary, at the Hospital, before June 17.

ESSEX LUNATIC ASYLUM, BRENTWOOD.—Second Assistant Medical Officer and Dispenser. Candidates must be Licentiates of the Apothecaries' Company and possess a Surgical qualification. Applications, stating former occupation, to Dr. Campbell, Medical Superintendent, County Asylum, Brentwood.

GLOUCESTER DISPENSARY.—Dispenser, registered under the Pharmacy Act, and otherwise duly qualified. Apply to George Whitcombe, Esq., Gloucester, from whom further particulars may be obtained.

GLOUCESTER INFIRMARY.—Assistant-Surgeon. Candidates must be Fellows or Members of the Royal College of Surgeons of London, Edinburgh, or Dublin. Applications, with testimonials, to T. H. Pitre, Secretary, on or before July 4.

HOSPITAL FOR SICK CHILDREN, 49, GREAT ORMOND-STREET, W.C.—Assistant-Physician. Candidates must be Fellows or Members of the Royal College of Physicians of London. Applications, with testimonials, to Samuel Whitford, Secretary, on or before June 26. Also, Medical Registrar. Candidates must possess some legal qualifications. Applications as above.

INFIRMARY FOR CONSUMPTION AND DISEASES OF THE CHEST, 26, MARGARET-STREET, CAVENDISH-SQUARE.—Visiting Physician. Candidates must be Members of the Royal College of Physicians, London. Testimonials to be sent to Francis Baily, Secretary.

LIVERPOOL NORTHERN HOSPITAL.—House-Surgeon. Candidates must possess a Medical and a Surgical qualification from one or more British Colleges or Institutions recognised under the Medical Act. Applications and testimonials to the Chairman of the Committee not later than June 15.

MIDDLESEX HOSPITAL.—Lectureship on Psychological Medicine. Applications must be sent to the Dean of the Hospital not later than June 18.

NORTH SURREY SCHOOL DISTRICT, ANERLEY, NORWOOD, S.E.—Medical Officer. Candidates must possess the qualification required by the Local Government Board. Applications, with testimonials, to "the Managers," at the School, on or before June 17.

SEAMEN'S HOSPITAL, GREENWICH.—House-Physician. Candidates must possess at least one qualification. Applications, with testimonials, to Kemball Cook, House-Governor and Secretary, on or before June 22.

YORK COUNTY HOSPITAL.—Non-resident Dispenser. Applications, with testimonials, to Robert Holtby, Secretary, 5, New-street, York, on or before June 29.

UNION AND PAROCHIAL MEDICAL SERVICE.

** The area of each district is stated in acres. The population is computed according to the census of 1861.

RESIGNATIONS.

Glendale Union.—The Ford District is vacant; area 11,727; population 2072; salary £10 per annum.

Mere Union.—Mr. Charles Rumsey has resigned the Workhouse; salary £10 per annum.

APPOINTMENTS.

Belper Union.—Thurstan Forshaw, L.R.C.P. Edin., L.S.A. Lond., to the Smalley District.

Bideford Union.—John Thompson, F.R.C.S. and M.R.C.S. Eng., L.S.A., M.D. St. And., to the Buckland Brewer District. Edgar Cox, M.R.C.S. Eng., L.S.A., to the Abbotsham District.

Dudley Union.—Hugh R. Ker, M.R.C.S. Eng., L.R.C.P. Edin., to the Second District.

Glandford Brigg Union.—Walter H. Paterson, M.D. and C.M. Univ. Edin., M.R.C.S. Eng., L.S.A., to the Broughton District.

Malton Union.—George Buckell, M.R.C.S. Eng., L.S.A., to the Leavening District.

Newcastle-upon-Tyne Union.—Thos. F. May, L.F.P. and S. Glasg., L.S.A., to the Seventh District.

Stokesley Union.—Andrew A. Boyle, L.R.C.P. Edin., L.R.C.S. Edin., to the Hutton District.

DR. MEADOWS has been elected a Corresponding Member of the Imperial Medical Society of Vilna.

The yellow fever is declining in Monte Video. There are no new cases, and confidence is returning.

UNIVERSITY OF CAMBRIDGE.—Pembroke College Lodge, June 10, 1872.—The Vice-Chancellor gives notice that the election of a Representative of Medicine, and of a Representative of Surgery, on the Examining Board for England, in accordance with Regulation 6 of the scheme approved on February 15, 1872, will take place on Friday, the 14th inst. The Vice-Chancellor and Proctors will attend in the Senate-House between the hours of 12 noon and 1 p.m., in order to receive the votes of members of the Senate.

KING'S COLLEGE HOSPITAL.—On Friday the festival of King's College Hospital took place at Willis's Rooms. General Sir Henry Daubeney presided. Since the opening of the Hospital in 1840 there have been 44,972 patients, and 821,658 out-patients; total, 866,630. The chairman stated that the expenses of the Hospital had been so great that the Council had been obliged to draw upon the funded property. During last year the assessment of the Hospital had been increased by the authorities from £860 to £1000 per annum, and the very uniforms of the hall-porters had now been taxed. An amateur dramatic performance under distinguished patronage will be given by the students of King's College, on behalf of this Hospital, early in July. Further particulars will be shortly announced.

MASONIC FEMALE ORPHAN SCHOOL, DUBLIN.—At a meeting of the Board of Governors, held on Tuesday the 4th inst., Dr. J. T. Banks was elected Consulting Physician, and Dr. George H. Kidd was appointed to the vacancy caused by the death of Dr. T. E. Beatty, for eleven years senior Medical Officer of the School.

THE sanitary condition of St. Mary, Islington, for May, 1872, was satisfactory. The total number of deaths registered in the parish during the four weeks ending May 25 was considerably less than the number for the corresponding four weeks in either of the last nine years, with the single exception of 1867. Along with the diminution in the death-rate from zymotic diseases, we find a remarkable diminution also in the number of deaths from diseases of the respiratory organs.

At the Dublin Police-court, last week, Charles Hammond and William Bailey, privates in the Army Hospital Corps, were brought up on remand charged with having caused the death of Edward Somerton, a private in the 68th Regiment, by cruelly ill-treating him. A private of the 4th Regiment deposed to having seen the prisoners, who were attendants in the lunatic asylum of the Military Hospital, put the deceased in a cold bath contrary to strict orders, and keep him there for a long time, and cruelly ill-use him so as to cause his death. The prisoners were committed for trial for murder.

THE value of the injection of ammonia, as recommended by Professor Halford, in cases of snake-bite and suspended animation, has been again demonstrated. A lady in Melbourne recently swallowed by accident an ounce of Brown's chlorodyne, which is a mixture of chloroform, morphia, and prussic acid. When seen by her Medical attendant, she was, as he imagined, on the point of death—cold, insensible to everything, and giving only occasional gasps as signs of breathing. Recollecting a former case in which a young man who had taken chloroform was revived after death had apparently occurred, the Doctor mixed half a drachm of the liq. ammon. fort. with one and a half of water, and within the space of one minute injected the whole into a vein of the arm. In a few minutes the pulse returned, the breathing became natural, and by twenty minutes the whole body had regained its natural warmth; but perfect consciousness did not return for some hours afterwards. The patient made a rapid recovery. Two further instances have also been reported in which the timely use of the injection saved the victims of snake-bite from the death which threatened them.—*Melbourne Argus*.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon*.

The *Moniteur Scientifique* can be obtained, by giving a few days' notice, from Messrs. Baillière, Tindall, and Cox, 20, King William-street, Strand.

Two Readers.—We do not doubt your title by courtesy and custom to assume whichever of the denominations may please you best; but as a matter of policy we should recommend the second. With that there is nothing of "false position"—nothing that an enemy could call in question, however unjustly; and it is always best to adopt that course which renders explanation unnecessary.

An Indian Surgeon.—There was a meeting of the Council for the admission of Fellows on Thursday last; you will therefore not be able to record your vote for the candidates, but can attend the festival the same evening by writing to Mr. T. Carr Jackson, F.R.C.S., the hon. secretary.

B. S., King's College.—Mr. Headington, of the London Hospital, died when President of the College of Surgeons. Mr. Cooke, in his interesting life of Sir William Blizard, states that on one occasion when going through the wards with the venerable Surgeon, he inquired of a student what was going forward in the operating-theatre. The young gentleman replied—"Mr. Headington, Sir William, is operating in a case of strangulated hernia, but the gut is quite rotten." He pleasantly remarked: "Pray, sir, do not call it *gut*, or say it is *rotten*, or you will be taken for a butcher; but call it *intestine*, and say it is *gangrenous*." Sir William Blizard and Sir Charles Blicke, his colleague at the College of Surgeons, were what were then called "Peg Nicholson's knights," having received the honour of knighthood from George III., at the Court of St. James's, March 16, 1803, for taking addresses of congratulation on the happy escape from the madwoman's dagger.

NEW PLAN OF EXTRACTING BODIES FROM THE EAR.

Dr. Loewenberg, of Paris, describes a new plan for extracting solid bodies from the ear, as follows:—"A very small brush is made by rolling and fixing a narrow strip of old linen around a thin wooden handle (a match, for instance), and unravelling its free border to the length of a quarter of an inch. The end of the so-obtained fringe is dipped into a warm and very concentrated solution of glue, applied to the visible part of the foreign body—or rather the operator leans it against the body by letting it glide very softly, and without exercising any pressure, over it. Previous to the application the patient seats himself comfortably in an arm-chair or on a sofa, and inclines his head towards the healthy ear. He remains in this posture for three-quarters of an hour to an hour after the introduction of the agglutinated brush. This time past, consolidation is generally accomplished, and the foreign body can be extracted by gentle pulling at the brush."

A Fellow.—The usual notices of the election were duly posted to all the Fellows of the College whose addresses were known to the secretary. That you have not received one is no fault of that gentleman's, as on inquiry we find that your letter was returned through the Dead Letter-office endorsed, "Gone away—address not known."

M.R.C.S.—The rumour has reached us. If the *clique* again attempt to injure the College they will again be defeated.

Ireland.—Nothing can show more strikingly the difficulty of dealing with the question of drunkenness than a habit lately sprung up in Ireland of drinking naphtha and methylated spirits for the purpose of intoxication. It would seem in this matter, as in most others, the old adage is applicable—"Where there's a will there's a way."

M.D. Edin.—We have seen the decision of Mr. Macnamara in the case of *Stevenson v. Gliddon*, in which he ruled that the plaintiff, M.D. of Edin. and M.R.C.S. Eng., could not legally charge for medicine supplied in a Medical case, inasmuch as he was not a Licentiate of the Apothecaries' Society of London. His Honour said that the Apothecaries' Act was not repealed by the Act of 1858, and as the plaintiff was registered as a Physician and Surgeon, and not as an Apothecary, he could not recover his charges for medicines. Of course the decision of the judge is not final, and is certainly open to grave doubt. A "case," we hope, will be submitted to a superior court to determine the question finally.

WILKS, not WELLS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Will you kindly favour me by stating in the next number of the *Medical Times and Gazette* that the name of Dr. Wells inserted in the abstract report of Sir William Gull and Dr. Sutton's paper was a misprint. It should have been—"Dr. Wilks, in 1853, suggested that the cardiac hypertrophy might be dependent on atheromatous changes in the vessels." By so doing you will greatly oblige,
Yours, &c.,
H. G. SUTTON.

W. C., Bodmin.—The Rev. George Crabbe, the celebrated poet, was apprenticed to Mr. Page, a Surgeon at Woodbridge, a market town seventeen miles from Aldborough, where he was born.

Archæologist, Birmingham.—The tables to which you allude are in the Museum of the Royal College of Surgeons. Professor Flower appears fully aware of their value, for he has had them lately thoroughly cleaned, varnished, and covered with plate glass. The amusing Evelyn mentions a curious circumstance with regard to Sir Charles Scarborough, who read the lecture founded by Dr. Caldwell at Barber-Surgeons' Hall, and who delivered lectures on mathematics at Cambridge, whose epitaph records that he was

"Inter Medicos Hippocrates,
Inter Mathematicos Euclides."

Evelyn's diary records that "My Italian collection being now arrived, came Meulins y^e great Chirurgeon to see and admire y^e Tables of Veines and Arteries which I purchased and caused to be drawn out of several humane bodies at Padua"; and November 5, 1652—"Dr. Scarborough was instant with me to give these Tables to y^e College of Physicians, pretending he would not onely reade upon them, but celebrate my curiositie as being the first who caused them to be compleated in that manner and with that cost; but I was not so willing yet to part with them as to lend them to y^e College."

QUERY AS TO THE VITAL PRINCIPLE.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—In cogitating over the various formulæ by which different scientific men endeavour to enunciate their conception of the forces that rule the living body, one is met with this difficulty:—Many diseases are attended by, or caused by, what great authorities call a great development of vitality. For instance, a late Surgical writer affirmed the cause of cancer to be a great abnormal residual quantity of vitality in certain organs—say womb or mamma—from which it happened that when the normal and ordinary growth and functions of those organs were diminished at the decline of life, the vitality, not having anything useful or regular to do, set to work to engender that abnormal and perishable tissue called "cancer." Dr. Beale, in his "Disease Germs," speaks of tissues "living too fast," and describes some inflammatory processes as overgrowths of the "germinal matter" of tissues, owing to their getting an excessive supply of *pabulum* in consequence of injury. Thus, it is evident that there is a local vitality inherent in each minutest part—such that one pus-corpuscle lodging in an appropriate seat can increase and multiply almost *ad infinitum*. But if the animal and vegetable body be such an aggregation of petty powers, there surely must be some general supervising vital principle to control them—something that shall direct the size, form, length of life, and properties of the whole organism. And the necessity of conceiving so many conflicting vital principles may, it seems to me, be used as an argument against the existence of any.
I am, &c.,
STUDENS.

Defence of the Study of the Classics.—The Rede Lecture in the Senate House of Cambridge was delivered this year by Mr. Edward A. Freeman, D.C.L., of Oxford. The subject was the "Unity of History." In the concluding sentences of an admirable lecture he thus defended the study of Greek and Roman history and literature from the attacks of Mr. Lowe and his imitators:—

"The fashion of the day, by a not unnatural reaction, seems to be turning against ancient and classical learning altogether. We are asked, what is the use of learning languages which are dead, what is the use of studying the records of times which have for ever passed away? Men who call themselves statesmen and historians are not ashamed to run up and down the land spreading abroad, wherever such assertions will win them a cheer, the daring falsehood that such studies, and no others, form the sole business of our ancient Universities. They ask in their pitiful

shallowness the utility of poring over the history of 'petty states,' of studying battles in which so few men were killed as on the field of Marathon. He need not stop to answer such transparent fallacies, but the use of such falsehoods and fallacies were signs of the times they could not afford to neglect. The answer was in their own hands. So long as the languages and histories of Greece and Rome were treated as something special and mysterious—something to be set apart from all other studies—something to be approached and handled in some peculiar method, the Universities were playing into the hands of the enemy. As long as we have classical instead of general schools of languages—schools of modern history instead of general schools of history—as long as the distinction implied in the words classical and ancient is recognised, we are acknowledging that, if not our whole attention, yet a chief share of it, is given to subjects which do stand apart from ourselves, cut off from all bearing on the intellect and life of modern days. The answer to such charges is to break down the barrier—to forget, if possible, the whole line of thought implied in the distinctions of ancient, classical, and modern; to proclaim boldly that no languages are more truly living than those which are falsely called dead; that no portions of history are more truly 'modern,' more full of practical lessons for our political and social state than the history of the times which in mere physical distance we look upon as ancient. If men ask whether French and German are not more useful languages than Latin and Greek, let us answer that in a direct manner of parentage and birth it is an imperfect knowledge of French which takes no heed to the steps by which it grows out of Latin, and that it is an imperfect knowledge of Latin which takes no heed to the steps by which it grew into French. As to the use of studying the history of petty states, the answer is that moral and intellectual greatness is not always measured by physical vigour; that the smallness of a state of itself heightens and quickens the power of its citizens, and makes the history of a small community a more instructive lesson of politics than the history of a huge empire. In this way we can make answer to gainsayers, and convince the unlearned and unbelieving that our studies are not vain gropings into what is dead and gone. Let us carry about with us the thought that the tongue which we still speak is, in truth, one with the tongue of Homer; that the Ecclesia of Athens, the Comitia of Rome, and the Parliament of England are all offshoots from one common stock; that Licinius and Simon of Montfort were fellow-workers in one common cause. Let all this be to us a living thought as we read the records either of the earlier or the later time, and we shall find that the studies of our youthful days will still keep an honoured place among the studies of later life; that the heroes of ancient legend, the worthies of ancient history lose not, but rather gain in true dignity by being made the objects of a reasonable homage instead of an exclusive superstition.'

APPOINTMENTS FOR THE WEEK.

June 15. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; King's, 2 p.m.; Charing-cross, 2 p.m.; Royal Free, 2 p.m.; Hospital for Women, 9½ a.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. Thomas's, 9½ a.m.

17. Monday.

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; St. Peter's Hospital for Stone, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

ANTHROPOLOGICAL INSTITUTE, 8 p.m. Meeting.

18. Tuesday.

Operations at Guy's, 1½ p.m.; Westminster, 2 p.m.; National Orthopædic, Great Portland-street, 2 p.m.; Royal Free, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; West London, 3 p.m.

19. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1¼ p.m.; Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.; St. Thomas's, 1½ p.m.; Samaritan, 2.30 p.m.; King's College Hospital (by Mr. Wood), 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. George's (ophthalmic operations), 1¼ p.m.

20. Thursday.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Royal Orthopædic, 2 p.m.; University College Hospital, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

21. Friday.

Operations at Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.

VITAL STATISTICS OF LONDON.

Week ending Saturday, June 8, 1872.

BIRTHS.

Births of Boys, 1118; Girls, 1081; Total, 2202.
 Average of 10 corresponding weeks, 1862-71, 1953.3.

DEATHS.

	Males.	Females.	Total.
Deaths during the week	673	616	1289
Average of the ten years 1862-71	647.4	608.9	1256.3
Average corrected to increased population	1382
Deaths of people aged 80 and upwards	42

DEATHS IN SUB-DISTRICTS FROM EPIDEMICS.

METEOROLOGY.

From Observations at the Greenwich Observatory.

Mean height of barometer 29.691 in.
 Mean temperature 52.6°
 Highest point of thermometer 72.1°
 Lowest point of thermometer 40.6°
 Mean dew-point temperature 47.3°
 General direction of wind Westerly
 Whole amount of rain in the week 0.77 in.

BIRTHS and DEATHS Registered and METEOROLOGY during the Week ending Saturday, June 8, 1872, in the following large Towns:—

Boroughs, etc. (Municipal bound- aries for all except London.)	Estimated Population to middle of the year 1872.*	Persons to an Acre. (1872.)	Births Registered during the week ending June 8.		Deaths Registered during the week ending June 8.		Temperature of Air (Fahr.)		Temp. of Air (Cent.)	Rain Fall.

At the Royal Observatory, Greenwich, the mean reading of the barometer in the week was 29.69 in. The lowest was 29.47 in. at the end of the week, and the highest 29.97 in. on Wednesday morning.

* The figures in this column, excepting those for London and Dublin, are the unrevised numbers enumerated in April, 1871, raised to the middle of 1872 by the addition of a year and a quarter's increase, calculated on the rate which prevailed between 1861 and 1871. The London population is now based upon the number enumerated in April, 1871, as revised at the Census Office; this revision added 2456 (principally shipping population) to the unrevised number published in the preliminary Census Report. The population of Dublin is taken as stationary.

PART X.

VESICULAR EMPHYSEMA OF THE LUNGS—HABITUAL ASTHMA.

Causes and Pathology. Contraction and Thickening of the Bronchi and Roots of the Lungs. Distinction of Emphysema into Tense (or Hypertrophous) and Flaccid (or Atrophous)—Effects and Signs of each. Reptile State of Circulation in Extreme Emphysema—Effects on Tissues and on the Blood in Lungs and other Organs. Treatment successful in Early Stages; in Extreme Cases more Palliative than Curative. Variations and Adaptations of Remedies. Climate—Compressed Air—Oxygenating Agents.

I HAVE alluded to emphysema of the lungs as a sequel of spasmodic asthma, but as a permanent disease it results from the change of structure which repeated and prolonged attacks of asthma induce, rather than from the spasm itself. It is quite true that a single severe fit of asthma often causes a temporary distension of the lungs, the inspiratory effort being more powerful, forcing more air into the lungs than the expiratory forces can get rid of; but this is only temporary, and the balance is soon restored after the spasm is removed. But when the spasm is frequent and prolonged, and when the narrowing of the tubes is further increased and perpetuated by congestion and thickening of the bronchial tissues, then the same change becomes permanent, and instead of temporary distension we have *permanent dilatation of the air-cells*, with various changes of structure in these and in adjoining parts.

Further, emphysema of the lungs is produced by other diseases besides spasmodic asthma. Bronchitis, either in the acute form, frequently recurring, or chronic, lasting for several months—the bronchial and pulmonary congestion connected with certain diseases of the heart, and attended with cough, viscid expectoration, and dyspnoea—naturally tends to cause the same distension of the lung, which by long continuance assumes the permanent form of pulmonary emphysema. Many years ago I pointed out (a) how commonly after death in chronic bronchitis the larger bronchi are found with their membranes and longitudinal fibres thicker and less extensible than usual, and that this comparative shortening of the tubes must have the effect of exposing the terminal cells to a greater amount of the inspiratory force. They thus become so permanently distended as to lose their elastic contractility, and then present the condition of pulmonary vesicular emphysema. The same thing occurs more partially in the vicinity of tubercles and other consolidations of the lung. In proportion as they prevent the entrance of air into one portion of the lung, the air is drawn with more force into the adjoining air-cells, and causes their permanent dilatation. The more extensive consolidation of the lung left by inflammation, if affecting the root of a lung, restrains the free expansion of this part, and the air passes with greater force through the still open tubes to the air-cells of the whole lobe beyond, and these become consequently dilated. In all these cases, too, be it remembered, the chronic deposits and thickenings of tissues have a tendency to still further contraction, as seen in the puckering of the lung and pleura, and the space thus diminished is partly made up by dilatation of the air-cells. Thus we see a sufficient explanation of the mechanical causation of emphysema of the lung, both general and partial, and we shall find some interest in tracing further its anatomical and pathological relations.

More than thirty years ago I directed the attention of the Profession to an important distinction in the anatomical characters of emphysema of the lung in different cases. In both varieties the dilatation of the air-cells is manifest, and the augmentation of the aerial contents of the lung is proved by the general lightness of the organ. But in one set of cases the texture of the lung is resistant and elastic—it does not collapse when the chest is opened; on the contrary, the lungs

bulge out as if they had been too large for the bony case which contained them, and they often encroach on the adjoining organs, pushing down the liver and diaphragm, covering the heart, and, projecting above the clavicles, fill up the hollows of the neck. When pressed with the fingers such bulky lungs offer a good deal of elastic resistance, in spite of their porosity; and when cut into they only partially collapse, and the resistance is found to increase more towards their root, and to depend much on an augmented toughness or density of the chief bronchial tubes, and of their surrounding tissues and vascular plexus. This is the *tense emphysema* attended with *hypertrophy* of the bronchi, and represents the common case of the habitual or chronic asthmatic.

In another class of cases the lung presents on its surface the same appearance of enlarged vesicles of many sizes and shapes, and is even lighter than the preceding variety, but with little, if any, augmented volume, and is especially characterised by the extreme flaccidity and tenuity of its textures, so that when a portion of the lung is pinched between the fingers it feels like a thin membranous bag, and when cut into collapses to a great extent. This is *flaccid emphysema*, or that accompanied with *atrophy* of all the tissues. In this case the bronchi are neither thickened nor much contracted; sometimes they are even dilated. This kind of emphysema is met with in the very aged and those worn down by wasting disease. I have also found it in lungs which have long been compressed by pleural effusion, which has eventually been absorbed. In a partial form it is met with in connexion with old phthisical lesions, and with chronic bronchitis attended with frequent purulent expectoration. In all these cases it has a clear connexion with a wasting process going on in the lung, together with some of the mechanical causes previously noticed as producing distension of the air-cells. In some such cases there are traces of fatty degeneration, as well as atrophy, in the vesicular texture, and the bronchial membrane is also in an attenuated state, having lost much of its characteristic epithelium, and with it the power of secreting mucus, which appears to be a proliferation of epithelial cells. In this may be remarked a close analogy with corresponding wasting diseases in the intestinal canal and in the uriniferous tubes of the kidney—in protracted diarrhoea and albuminuria respectively—the characteristic epithelial structure and properties of the parts become abraded and lost.

Differing as these forms of pulmonary emphysema do in anatomical characters and causes, it may be expected that they may during life be recognised by different signs and symptoms; and this is proved by clinical observation.

In *tense or hypertrophous emphysema* of the lungs we have most of the symptoms and signs of asthma in permanence—breathing always more or less laborious, the expiration being especially prolonged and difficult, whilst the increased volume of the lungs encroaches on the adjoining organs, swells out the walls of the chest, and by its pressure obstructs the passage of blood through the lungs. Hence outside the lungs there is great congestion and occasional lividity, especially in the lips, cheeks, gums, fauces, and trachea—and this may extend to the nails and other parts—with enlargement of the veins of the neck, chest, and subdiaphragmatic organs. The physical signs are those of the increase of the aerial contents of the chest, an unusually tympanic sound on percussion, often of raised pitch, over the whole lung, covering up the heart, and sometimes the liver, to the margins of the ribs; the same resonant fulness projecting above the clavicles, so as to form a ruff-like swelling at the root of the neck, and giving a rounded prominence to the intercostal spaces and the whole surface of the chest. As there is so little motion of air in and out of these distended cells, there is very little of the natural breath-sound heard, but rather a short wheeze in inspiration, followed by a long wheeze in expiration, loudest towards the roots of the lungs in the scapular regions. To this may be added more or less irregular crepitation, if there be liquid secretion in the cells or tubes, increasing from above downwards. The absence of all vocal sounds in the chest is very remarkable, and also the impaired transmission of the heart-sounds, from the decreased conducting power of the porous lung.

In cases of *flaccid emphysema*, on the contrary, the signs and effects of increased volume of the lung and obstruction of the tubes are absent. The stroke-sound is as tympanic as in the tense variety; but, being without tension, it is of lower pitch, and may even be more hollow. But it hardly, if at all, extends beyond the ordinary boundaries of the lung, which, so far from being enlarged, as in tense emphysema, may partake of the shrunken condition of the whole body. The motions and sounds of breathing are by no means much impaired; they may be

(a) "Lectures on the Physiology and Diseases of the Chest" (*London Medical Gazette*, 1838).

longer than usual, but are rather exaggerated in intensity, the breath-sound being puerile and of a peculiar dry and whiffing character, from the air passing freely through open and sometimes dilated tubes into a coarse, large-celled tissue; in fact, this flaccid emphysema—although, if extensive, it may impair the breathing power of the individual by diminishing the number of air-cells and the amount of action between the air and the blood—does not produce the tight, wheezy breathing of the asthmatic, but rather the panting breathlessness of the aged, emaciated, or anæmic; and it is in such subjects that this lesion is most commonly found.

To recur to the *tense, bulky, or asthmatic* form of emphysema, it will be interesting to trace the pathological history of its extreme degrees. The important feature of this lesion is the increased volume of the lung which the expiratory forces cannot reduce, in consequence of the impeded egress of air from the obstructed bronchial tubes; and this increased volume becomes in a measure an additional cause of the obstruction, for the stuffed cushion of lung is forced at each expiration, especially in the more forcible acts of coughing, against the bronchial tubes, trachea, and vessels of the neck, so as to compress them and cause those feelings of throat-swelling and choking so distressing in aggravated forms of emphysematous asthma. Dr. Jenner has lately propounded the notion that expiratory efforts are the chief cause of emphysema, by forcing the lung into those parts of the chest in which the walls are least resisting (b); but there is no proof that the walls over the apices of the lungs do yield until they are pushed out by the already increased volume of lung—that is, emphysema. Then, indeed, coughing or strong expiratory efforts will make the lung protrude into the neck; therefore these expiratory protrusions are to be viewed rather as a result and aggravating element of the emphysema than as its original cause. And it is this excessive stuffing of the chest with impure air which tends to impede equally the entry of the pure air and the passage of the blood through the lungs. Hence the congestion of dark blood, giving a purple or dusky hue to the lips, face, and other parts of the surface, and extending to the liver, kidneys, brain, and other extra-thoracic organs—in fact, the subjects of extensive emphysema are reduced to the imperfect respiration and circulation of reptile life; and, as might be expected, all the functions are deteriorated in proportion. (c) It is only because the change takes place by slow degrees that life is sustained. The lividity exhibited by an emphysematous subject would rightly be considered a mortal symptom in any other malady. And now comes out another illustration of what I said of pneumonia and other parenchymatous affections of the lungs: that they are not mere local diseases, but affect the blood also, and through it the whole system. The pressure of the distended lung in great measure shuts out the blood from it and from its arterialising function; and further results will sooner or later ensue in the gradual deterioration of the texture of the lung itself, and of the condition of the blood throughout the body. The lung-tissue, which in tense emphysema is more or less thickened, especially towards the root, under the influence of long-continued pressure and scanty supply of blood, wastes, and passes from the fibrous to the fatty state of degeneration, this change being most obvious in the aged asthmatic. It is remarkable how old deposits of tubercle or other cacoplastic matter are removed under the constant pressure of emphysema. I have seen the cicatrices of former cavities and the lining membrane of those actually remaining, or that containing the cretaceous *débris* of tubercle, reduced to the same tenuity with the other tissues of the lung.

The effect of extensive and long-continued emphysema on the blood and its vessels is manifest in the leaden pallor of the surface, contrasted with the dark congested state of the mouth, fauces, and larynx; the right cavities of the heart become enlarged; the liver, kidneys, and other organs partake in the livid congestion, and their degeneration not uncommonly follows; the arcus senilis generally appears early; and albuminuria, anasarca, and general dropsy usually precede death.

But it must not be supposed that these extreme results occur in all cases of emphysema. In more moderate degrees emphysema occurs in connexion with chronic bronchitis, and with the slight pulmonary congestion accompanying organic diseases of the heart, and, merely adding an habitual shortness of breath

and wheezy cough to these affections, may be regarded rather as an infirmity than as a very serious disease. The function of breathing and circulation in such individuals is reduced to a reptile standard; and if they can be contented to remain within their limited sphere of activity, slowly and quietly creeping their way, and not attempting in any sense to bustle, to run, or to hurry, they may live for many years in tolerable comfort.

It may be inferred, therefore, that the successes in the treatment of confirmed emphysema or chronic asthma will be chiefly of the minor class, amounting to mitigation or alleviation rather than perfect cure, and failures are to be expected in those intense and aggravated cases, in which the distension of the lung is so great and lasting as to cause much wasting and degeneration of its tissues. But there is a period in which the emphysematous distension of the lung is removable. If the causes which produce the incarceration of air in the cells (shortening and partial obstruction of the air-tubes, and thickening of the lung around them) can be taken away before the structure of the air-cells is altered by their continued distension, the lung may return to its natural condition and dimensions. Something of this kind commonly takes place after extensive bronchitis, in which there is more or less temporary emphysema. Still more does it occur after severe fits of spasmodic asthma, which induce more or less temporary emphysema; but the cause being transient, the lungs recover their normal dimensions. Now, it can be well understood that between these temporary varieties of emphysema and the confirmed and advanced disease there are intermediate degrees, which may be removed or ameliorated by appropriate treatment.

Among the remedies chiefly useful are those employed as expectorants of the more stimulating class—squill, salts of ammonia, ammoniacum, and other gum resins; benzoin, tolu, and other balsamics; creasote, and other terebinthines. Some of these exhibited through the stomach, others by way of inhalation with the vapour of hot water or in spray, tend to excite the secretion and expectoration of bronchial mucus, and thereby to diminish the obstruction to the egress of air from the distended cells. Often their operation may be aided by the iodides and bromides of potassium and ammonium and alkalis, before mentioned as useful in recurring asthma. The employment of stimulating expectorants in bronchitis and emphysema requires careful judgment and discrimination; for if given too soon, or during any inflammatory or febrile exacerbation or fresh spasm, they do harm instead of good. In fact their operation is always the opposite of that of the remedies for recent bronchitis or spasmodic asthma (salines, antimonials, belladonna, etc.), and it becomes beneficial in consequence of the bronchial muscles and membrane passing into somewhat of an opposite state—inflammatory irritation having given place to passive congestion, and spasmodic contraction to atonic or paralytic relaxation. So, too, with this change belladonna, stramonium, and salines fail to give relief, and are even hurtful. And yet the transition from one condition to another is neither constant nor uniform; and it often happens that at one time of the day there may be distressing cough with difficult expectoration and the long crepitant respiration of an atonic state of the tubes; and at another time the tight wheezy breathing, inspiration and expiration, of spasmodic asthma. Nay, sometimes these opposite conditions may co-exist in different parts of the same lungs, and entirely baffle our efforts to counteract them.

The most common case, however, of these opposing conditions is that the atonic state prevails throughout the day, and more or less of the spasm recurs at night; and therefore it often answers well to give stimulant expectorants and even tonics during the day, and a dose or two of antispasmodic or narcotic in the night.

I have just named tonics, and they require a little further notice with regard to their influence on these diseases. Like other affections which impair sleep and appetite, and exhaust strength, continued asthma or bronchitis wastes flesh and blood; and therefore ordinary reparative tonics, such as iron and quinine, may be often useful to sustain the failing general strength and structure of the frame. But certain tonics seem to have an invigorating influence on the muscles of respiration, external and internal, and may to a certain extent restore the breathing powers, when these have been impaired by prolonged attacks of dyspnoea and cough. I allude especially to strychnia, zinc, and arsenic. In several instances the continued use of strychnia (in doses of from 1-82nd to 1-24th of a grain three times daily, dissolved in an acid) has been followed by marked improvement in the breathing powers, and a diminished

(b) *Medico-Chirurgical Transactions*, 1857.

(c) This resemblance to the reptile standard of respiration and circulation is further shown in the fact manifest in some extreme cases of emphysema, that in proportion as the circulation is impeded and the bloodvessels shrink and waste in the lungs, a supplementary circulation takes place in the integuments of the chest-walls, which are marbled with enlarged bloodvessels, and in the mucous membranes of the upper air-passages, which are turgid and loaded with mucus.

tendency to the attacks of asthma. But if exhibited during attacks of spasmodic asthma, it seems rather to aggravate it than otherwise; and it is when these are over, and a state of exhaustion or atony follows, that this remedy proves beneficial. The same remark applies to the preparations of zinc, whether oxide, sulphate, or valerianate. In connexion with this operation of strychnia we may bear in mind its power to prevent vomiting and restore tone to the stomach in cases of nervous exhaustion from abuse of stimulants, or from hysteria, in which I have often found it the most efficacious of all remedies. Whether in all these cases it acts directly on the affected tissues, or through the medium of the nerves, we are hardly yet in a position to determine. Arsenic is another remedy which seems to improve the breathing powers in some cases of emphysema, and to diminish the frequency of attacks of asthma; but it is slow in its operation in the doses in which it may be safely given (three or four drops of arsenical solution twice daily), and patients will not often persevere with it long enough to derive benefit from its use. I have found it peculiarly efficacious in the not uncommon cases of asthma complicated with psoriasis or eczema; but its beneficial influence is not limited to these.

Asthmatic subjects are extremely sensitive to atmospheric changes, and to all influences which affect the purity and other qualities of the air. A person afflicted with extensive and confirmed emphysema, especially that of the tense kind, may be thrown into a state of severe suffering by a change in the wind, by the coming on of a fog, by impurities in the air, or a rise in its temperature, such as would not affect a person in health. It is only by avoiding all such deviations from the most salubrious standard that a patient thus affected can enjoy anything like ease and comfort, or indeed can hope to prolong life; and fortunate are those who can afford to migrate as the seasons change, and enjoy the pure air of a dry heath in the summer, and in the winter the equally pure but tempered air of the Nubian desert. Those who cannot afford to change their residence with the season should fix their abode in a sheltered spot, on as dry a soil, and in as pure an air, as they can find—in the summer much out of doors, strolling and basking in the sun; in winter, for the most part, shut up in well-ventilated, warm, but not overheated rooms. Such cases might be expected to derive much advantage from any means of increasing the oxygen in the air which they breathe, either by condensing the air by a forcing-pump in an air-tight room for the purpose, as has been practised at Montpellier and other places in France, and at Ben Rhydding in Yorkshire, or by the occasional inhalation of oxygen gas more or less diluted with common air. I have known several instances in which these means have been tried by asthmatic and emphysematous patients, and some have experienced considerable relief for a time, but not of sufficient extent or permanency to induce them to persevere long in the measures, which have many inconveniences, and are not always unattended with risk. Recently, oxygenated drinks have been recommended with the object of supplementing through the stomach what the lungs cannot receive; but it is very doubtful that either the so-called oxygen water or the diluted peroxide of hydrogen can introduce into the stomach a sufficient amount of oxygen to produce a perceptible effect in this way. But we have in nitric acid and chlorate of potass materials rich in oxygen, and readily parting with it, which may be given pretty freely without inconvenience. Twenty or thirty drops of the diluted acid with ten or fifteen grains of the chlorate in three or four tablespoonfuls of water may be taken three or four times daily. I have often prescribed this compound in cases of emphysema and other diseases in which the breathing powers were much impaired, and in some instances with apparent benefit. From some Hospital trials formerly made, it would appear that neither the chlorate nor the nitric acid can be detected in the urine. Therefore the oxygen is retained somewhere in the system; but further experiments are required to determine this point.

Note added in 1872.—The preceding remarks on pulmonary emphysema, prepared for the Lumleian Lectures in 1862, were for the most part the same as those which I delivered in my lectures on the Principles and Practice of Medicine at University College annually, from 1840 to 1850. The chief points, indeed, as to the origin of the disease and its distinction into the two forms—*tense* (or *hypertrophied*) and *flaccid* (or *atrophied*) emphysema—had been published before those dates in my lectures in the *London Medical Gazette* in 1838, and in my work on "Diseases of the Chest," and in "The Library of Medicine" in 1840. Since that period contributions on the subject have been made by Dr. G. Budd, Dr. Sibson, Dr.

Gairdner, Dr. Waters, and Sir W. Jenner; but although these several writers have added to our knowledge some interesting observations relating to the disease, I have found in them nothing to invalidate the views which I have given above. The most recent of these authors—Sir W. Jenner—has made the same distinctions between hypertrophous and atrophous emphysema that I had made long before; and although he applies the new terms *large-lunged* and *small-lunged* vesicular emphysema, his descriptions are so much the same as mine that it appears singular that he should have made no allusion to them.

Sir W. Jenner considers large-lunged vesicular emphysema to be most commonly caused by violent expiratory efforts, as in coughing with the glottis closed, which protrude and distend the air-cells in the directions in which there is least resistance, and the distension is rendered permanent by changes in the texture of the walls of the air-vesicles resulting from excess of blood in their capillaries. I quite admit that cough and other violent expiratory efforts are concerned in aggravating the effects of pulmonary emphysema, and I have long been in the habit of pointing out supraclavicular and intercostal protrusions during coughing as signs of emphysema, partial or general; but I consider that the chief initial cause of over-distension of the air-cells is the inspiratory act in some of the modes already described; and it is when the volume of air in the lung is already so much increased as to render its escape through the bronchi difficult, that it forms a full cushion, protruding all the more yielding walls of the chest. And these very acts of protrusion may add to the dilatation of the air-cells, and to the consequent obstruction to respiration and circulation.

ORIGINAL COMMUNICATIONS.

ON ANTISEPTIC DRESSING AFTER AMPUTATION OF THE BREAST.

(CASES UNDER THE CARE OF MR. SPENCER WELLS AND MR. COUPER.)

The following cases of amputation of the breast show how surely suppuration can be prevented in large wounds by Lister's antiseptic dressing. They comprise *all* the cases of this amputation in which the two Surgeons concerned have resorted to the antiseptic method, and place its advantages in a more striking light than selected cases can do. Although the details of the dressing have undergone many variations since its origin seven years ago, the principles on which it is based remain unchanged. The latter may be thus epitomised:—

- 1st. To destroy all particles capable of initiating putrefaction within the wound; and, having thoroughly done so,
- 2nd. To conduct the subsequent dressings with a view to the exclusion of such particles during the process of healing.

It is a common error to suppose that air must be excluded from the wound. Air may be and is freely admitted without causing putrefaction after being deprived of the septic particles which it happens to contain. All modifications of the method have been devised solely with a view to the better securing of these ends.

In some instances the operations were done in an atmosphere of carbolised spray (1 to 100), while in others a saturated watery solution of carbolic acid was freely injected through the wound after insertion of the sutures. The vessels were secured either by torsion or by ligatures of prepared silk or catgut, of which both ends were cut off close to the knot. In all instances the entire mammary gland was removed with the tumour, and the wound closed by deep and superficial stitches. Deep sutures of catgut were employed for the purpose of lessening strain on the superficial stitches, and of bringing the deep surfaces more completely in contact. When they were adjusted the edges of the skin lay in contact without tension, and were thus maintained by fine continuous suture. A little gap was left at the lower end of each wound, into which a shred of lint, saturated in a mixture of one part of carbolic acid to ten of olive oil, was introduced as a drain to any blood or serum that might exude during the first twenty-four hours. Carbolised gauze was the dressing used. Owing to the great surface presented by its interstices, it prevents putrefaction with greater certainty than the lae plaster. When much discharge was anticipated the thickness of gauze was increased, and a piece of thin mackintosh was interposed

between the outer two layers, in order to prevent discharge reaching the surface directly over the wound.

The following three cases of amputation of the breast, under the care of Mr. Spencer Wells, are communicated by Wm. Thomson, M.B., M.C., M.R.C.S. :—

Case 1.—Large Scirrhus Tumour of the Right Mamma—Firm Primary Union four days after Removal.

A married lady, aged 50, came under observation last summer. The tumour was of large size, and of more than two years' standing. The axillary glands were not affected, but the skin was closely adherent to it. It was removed under chloroform by Mr. Wells on September 27, together with the mamma and the affected skin.

On the following day the dressing was hardly stained, and the removal of the drain was not followed by the escape of any fluid from the wound. The patient had slept, and was in all respects comfortable.

On September 29 she was able to sit up in an arm-chair. On removing the dressing about a thimbleful of serum was found to have escaped from the lower end of the wound. Redness, pain, and tension were entirely absent.

On 30th there was perfect union of the skin edges, and the superficial stitches (which had not occasioned suppuration) were removed. The gauze was unstained, except at the spot where the drain had been.

On October 2 one deep stitch was withdrawn. The remaining two were left until the following day to give support to the deeper parts in case their union should not be perfect. They had not irritated the tissues nor produced discharge. Perfect primary union was then found throughout the whole extent of the wound excepting at the spot at which the drain had been; one or two granulations made their appearance there. They had all but skinned over on October 7, when the patient went by rail to Bath, and was seen in London last week, the cicatrix being a mere line and with no induration around it, although there were two or three suspicious-looking nodules in the skin at some little distance from the scar.

Case 2.—Adenocele of the Right Mamma, Removed by Operation—Primary Union in Five Days.

An unmarried lady, aged 41, had had an adenocele of the right mamma for many years. It, together with the mammary gland, was removed by Mr. Spencer Wells on February 19, and weighed three pounds and a half after removal. The drain was not withdrawn for forty-eight hours, when one drachm of bloody serum issued from the wound. The superficial stitches were extracted on the fourth day, and the deep on the fifth day from the operation. The whole wound had then united by first intention excepting at the spot where the drain had been. The innermost layer of gauze was slightly stained by serum at the end of the first and second days; otherwise the healing was entirely dry. The patient was able to leave her bed on the third day, and to go out of doors in a bath chair on the seventh day. She is now quite well, and with a freely movable soft cicatrix.

Case 3.—Fibro-plastic Tumour of Mamma—Excision, followed by Primary Union.

The third case was that of a widow-lady, aged 40, suffering from a recurrent fibro-plastic tumour of the mamma. It had been removed by Dr. Bell about a year previously, by the application of strong sulphuric acid, but had speedily grown again. Mr. Spencer Wells excised it on April 12, 1872. The tumour weighed a pound and a half after removal. The skin being implicated to a considerable extent, and the incisions being carried quite clear of the affected parts, a wide gap remained to be closed. So much tension was produced when the deep and superficial stitches were adjusted, that, although the skin edges were in accurate apposition, there appeared but little prospect of primary union. This, nevertheless, occurred in a most satisfactory manner in the whole extent of the wound, with the exception, as in the preceding cases, of the small opening by which the drain was inserted. The superficial stitches were removed on the fourth day; the deep ones on the sixth day after the operation. Unfortunately, on the latter day the patient ventured to brush her own hair, moving her arms very freely in so doing. The middle part of the scar, although quite closed on the previous day, gave way to the extent of two inches. As the gauze-dressing was undisturbed, no suppuration followed at first. A fortnight elapsed before this part had completely closed again. It closed by granulations, which, however, could scarcely be said to exude pus. A little gummy discharge stained the under layer of gauze, at the edge of the

green protective which covered the granulations, on each second or third day, when the dressings were removed to admit of the wound being inspected.

On the seventeenth day from the operation the patient left town for Brighton.

The following two cases of amputation of the breast were under the care of Mr. Couper :—

Case 1.—Scirrhus Tumour of Right Mamma—Excision, followed by Primary Union.

This case was that of a woman, aged 50, admitted into the London Hospital, last autumn, with a large scirrhus tumour of the right mamma. It had been growing for about two years. The skin was adherent to it, and puckered in at one spot; but the axillary glands were not indurated, and the tumour glided freely on the pectoral muscle. She was very fat, of an active, vigorous disposition, and in the enjoyment of good health. Mr. Couper removed the tumour, together with the mamma, nipple, and a large piece of skin. The wound was dealt with as in the preceding cases. A drop or two of serum oozed from the wound when the drain was withdrawn, at the end of twenty-four hours. With this exception, a perfectly dry healing took place throughout. The deep and the superficial stitches were removed on the fourth and fifth days. One of the former had been so tightly applied that on division the ends sprang more than an inch apart. A momentary darting pain accompanied this sudden release of tension, but no fluid issued from the emptied track of it or of the other deep sutures. By that time the entire wound had firmly closed. On the seventh day the patient, who, but for severe chloroform nausea of twenty-four hours' duration, had experienced no feeling of illness, was allowed to dress and leave her bed. The pressure of her dress, together with the weight and resilience of the parts about the scar, caused a portion of the latter to give way. The skin wounded opened to a very small extent. A probe introduced here showed that the deep wound had reopened to the extent of about an inch. The adhesion of the subcutaneous adipose layer had proved less resistant than that of the skin, the cicatrix of which was to some extent undermined. Serum continued to exude for several days. On the eleventh day from operation the damage had been repaired, and the wound was closed from end to end. Her temperature reached 100° on one occasion only. Eight months later the scar exhibited no trace of a recurrence of the disease, and the patient continued in the enjoyment of perfect health.

Case 2.—Excision of Mamma with a Scirrhus Tumour and Three Cancerous Axillary Glands—Death on the Third Day from the Action of Shock upon a Heart enfeebled by Fatty Degeneration.

The history of this, the last case, is required to complete the series. As it terminated fatally, before any healing had commenced in the wound, it is valueless as regards antiseptic dressing. The tumour at the date of the operation had been noticed eighteen months. Its existence must, however, date still further back, as it had attained the size of a walnut before it attracted attention. Since then it had grown very slowly. In January last it implicated only the extreme upper and outer border of the gland, and glided freely on the pectoral muscle. A small patch of skin over its centre was adherent, and three superficial axillary glands were stony hard, and evidently carcinomatous. The woman had enjoyed good health for years, and her aspect confirmed this statement. This circumstance, together with the small size, slow growth, and superficial position of the diseased parts, favoured a successful issue to a cutting operation. On the other hand, the implication of glands was unfavourable, from the diminished chance of removing all the diseased parts. The precise bearing of these several circumstances, as also the nature and usual course of the affection, were fully explained, in order that she might exercise a choice in the matter. After a fortnight's deliberation she elected to undergo the operation. It was accordingly performed by Mr. Couper on January 17. The mamma, a piece of skin including the adherent part, and the affected axillary glands were removed with the tumour. Neither the pectoral muscle nor the deep fascia investing it were cut. The wound was dealt with as in the preceding cases. Although the hæmorrhage was trifling (six vessels were secured by catgut), the patient became blanched, and had a very small pulse on recovering from chloroform, which she took well. This shock partially disappeared after the administration of two ounces of brandy, and a further reaction was determined by a full opiate. In the evening there was some (? chloroform) vomiting, followed by free oozing of blood from the wound, and the dressing had to be renewed. She passed a good night, and on the morning

of the 18th had a temperature of 100°. The wound was free from pain or tension; bleeding had ceased with the vomiting, and only a little serum exuded when the drain was removed. The pulse was still weak, and the countenance pale. The shock was greater than could be accounted for by the wound. Stimulants were given in small hourly doses.

On the 19th she appeared to be progressing. She had a better pulse, and was able to take some nourishment. The wound continued dry and antiseptic. At 5 p.m. she suddenly began to sink, and died two hours later.

Dr. Sutton made a post-mortem examination twenty hours after death. Very rapid decomposition had occurred, causing an abundant evolution of gas throughout the body. So copious was it, that all the limbs were resonant to percussion. The belly was tense from gas within the bowel and in the peritoneal cavity. There was no pus or other fluid within the wound. Any adhesion that might have occurred had been dissolved by decomposition. The ribs were found covered by an unbroken layer of muscle and fascia, which formed the floor of the wound. There were old adhesions of both pleuræ—a good deal of serous œdema of both lungs, such as is not infrequent in cases of sudden death. No branches of the pulmonary artery were plugged; no collapse of lung. There were complete old adhesions of the pericardium. There was a thick layer of fat on the surface of the heart, which was rather large. Its valves were healthy. The left ventricle was somewhat dilated and quite flaccid. All the muscular substance of the heart was exceedingly soft and friable, and its section had a greasy look. Sudden failure of the heart had been the immediate cause of death. The state of other organs corroborated this view. The section of the liver had a homogeneous look due to serous œdema, and there were patches of passively dilated vessels in the mucous membrane of the stomach. The kidneys exhibited no nephritic changes, and there were no cancerous deposits in any internal organs. All the morbid growth had been removed. The liver substance was soft, friable, and had a pale greasy look. The spleen was small. No other morbid appearances were noted. The heart, enfeebled by fatty degeneration, only partially rallied from the shock of the operation, and ultimately failed very suddenly. Dr. Sutton remarked that in all probability the structural degeneration of the heart could not have been detected during life. Occasionally a double second with prolonged and muffled first sound was heard in a heart with much fatty change of its muscular substance, owing to the contractions of the ventricles not being synchronous, and the aortic valves not closing simultaneously with those of the pulmonary artery.

ON THE PATHOLOGY AND TREATMENT OF SMALL-POX.

By ROBERT H. BAKEWELL, M.D.,

Medical Attendant of the Small-pox Hospital, Port of Spain, Trinidad; late Medical Officer of Health for the Colony, etc., etc.

It may seem an ambitious project to attempt to write anything new about small-pox after the publication of such treatises as those of Copland, Gregory, and Marson. These men, writing from an immense clinical experience, would seem to have exhausted all that can be said about a disease apparently so simple in its phenomena as small-pox; nor should I, a year ago, have presumed to attempt such a task. In the interval, however, I have had a considerable experience of an epidemic unexampled in severity even in the West Indies, and my appointment as Resident Medical Attendant of the Small-pox Hospital, of which I have had the entire charge during the whole of the epidemic, have given me opportunities of investigating the pathology of the disease such as cannot be obtained in outdoor practice. Of these I have availed myself to make daily microscopical examinations of the contents of the pocks. It is singular that in none of the treatises to which I have access here can I find any microscopical observations on this disease. Of all my cases (about 250) I possess careful notes. Of these, 203 were treated in Hospital, and the remainder out of doors. Through the kindness of some of my *confrères* I was permitted to see a considerable number of other cases, and to compare them with my own. Besides these I have had experience of three English epidemics. Of cases then treated I possess no notes, and they only serve as a rather vague standard of comparison for those recently seen.

The number of cases may seem ludicrously small when compared with the vast experience of Mr. Marson, for instance;

but the 250 cases *here* represent a far larger proportion of severe cases than the same number would in England. Out of 203 Hospital cases only 50 were discrete, more than 17 per cent. were of the hæmorrhagic type, and above half were unvaccinated. Now, an attack of small-pox in an unvaccinated negro or Spanish American, living in a wretched hut in a West Indian town, is in a general way a bad one. But I have no absolute conclusions as to treatment in these cases; my observations are chiefly pathological, and the treatment followed is deduced from those observations, but is not meant to supersede the results obtained by a larger clinical experience. As, however, there can be no rational treatment which is not based on sound pathological knowledge, I venture to think that some improvements may be made in the treatment of small-pox when its pathology is better understood.

I shall not take up the reader's time by any historical review of small-pox, or of its laws as an epidemic disease. Suffice it to say that in every inhabited region of the world it can flourish, and in every climate; that it attacks every known race of human beings; and that while its ravages are dreaded in crowded cities, they are even more terrible among tribes of wandering savages, living in the open air, and changing their abode whenever it suits their caprice.

It may seem superfluous to describe the course of a disease so well known as discrete small-pox, but yet the reader will find that it is probably because the symptoms are all apparently so simple, that they have not been studied as they ought to have been, and that the import of some of the phenomena has been misunderstood. The following description is taken from the records written down at the bedside of patients.

An apparently healthy person who has never been successfully vaccinated, and has been exposed to the contagion of small-pox, after a period of incubation usually stated as from twelve to fourteen days,^(a) is attacked rather suddenly with fever, headache, pain in the loins, and often vomiting; the pulse varies from 100 to 120, the temperature from 101° m.—103° e. to 102° m.—105° e. On the third day of the fever an eruption of minute vesicles (usually called papules) appears on the face and back of the hands and wrists; the fever abates. The next day the eruption is more copious, and the vesicles of the first day are more prominent. The fever in the slighter cases now ceases altogether; the temperature falls to 98·4°, the pulse to 76. Every day until the fifth or sixth the vesicles become larger, their contents remaining clear and transparent; an umbilicated depression is observed in those on the face, trunk, and upper extremities; those on the lower extremities, particularly about the feet, are often convex from the commencement. On the fifth day a slight degree of secondary fever occurs, marked by a temperature of 100° to 102°, and lasting for two or three days. During this stage the vesicles become rounded or convex, the central depression disappears, their contents become thicker, cream-coloured, and by degrees quite opaque. On the seventh day the vesicles on the face begin to burst, and then scab and dry up; the same process goes on a little later on the upper extremities and trunk. On the feet and legs, however, it often happens that the vesicles dry up without bursting, and the scab contains an unbroken vesicle, which may be separated as a closed sac from the outer layer of the epidermis above, and from the upper layer of the cutis below.

After the bursting of the vesicles, all febrile symptoms disappear (in discrete cases), the patient suffers only from slight debility, his appetite becomes more than good—even voracious—and he simply gets well without a symptom to record.

On dissection of pocks in various stages, it is found that they are formed upon, but not in the substance of, the cutis vera, below the rete mucosum. The presence of pigment in the cells of this latter membrane in the dark-skinned races has enabled me very accurately to ascertain the exact position of the pock, a matter which is of considerable importance pathologically and in relation to treatment. I have a preparation, taken from the body of a Hindoo, who died on the second day of the eruption from acute dysentery, which shows very well the anatomical position of the pock in the early stage of the eruption. By drying a portion of the skin in the sun, I was enabled to obtain a thin perpendicular section, in which can be seen the outer epidermic layer, which can be easily separated by tearing from the pock, the rete mucosum forming the outer wall of the pock, and the dilated capillaries with their stagnant red corpuscles, which in the dry specimen mark even to the naked eye the position of the vesicle. I say "vesicle," for, though commonly considered as papular at this early stage of the

(a) I am not sure that the period of incubation is invariable.

eruption, they are in reality vesicles—that is to say, they consist on the very first day, and from the first hour at which they become perceptible to the touch, of a membranous sac containing fluid. If carefully punctured with a sharp and fine needle, a minute drop of transparent colourless fluid will exude.

If this apparently homogeneous fluid be placed under the microscope, and magnified 200 or 220 diameters, it will be found to contain epidermic cells, and floating about a few rounded corpuscles, somewhat like pus corpuscles, containing two, three, or four bright, well-defined nuclei, or two larger nuclei with nucleoli, or sometimes a number of bright granules. These corpuscles may be somewhat smaller than a red corpuscle of the blood, or they may be, and most often are, larger than a white corpuscle. (b) I am speaking of them now only as they appear on the first or second day of the eruption. In addition to these corpuscles, there are some bright nuclei about half the size of red corpuscles, and some minute granules whose nature I have not been able to determine for want of a sufficiently high microscopic power, but which appear like the contents of some of the nuclei.

If the contents of the vesicles be examined daily, as I have done in twenty-seven cases, it will be found that the variolous corpuscles increase in number daily, and that a new form, not to be found on the first or second day, appears. This is a proliferous cell, large enough to contain three, four, or even five of the smaller corpuscles. These proliferous cells apparently burst and discharge their contents, as there are always to be found with them flat circular bodies of the same size, of an absolutely structureless membrane, and without any contents. I have also seen in many cases one of the proliferous cells ruptured at one part, with one or two corpuscles just escaped from its cavity, lying by its side, and others remaining within it.

Acetic acid brings out the nuclei more brightly; but as the corpuscles are filled, or nearly so, with nuclei, there is not that striking difference produced by acetic acid which we see in some cells treated by this reagent.

When the fluid of a vesicle is kept in a capillary glass tube without any preservative fluid for two or three days, or is allowed to dry up under a thin slip of glass, nothing but brightly refractive nuclei and granules are to be seen. If in the latter case a drop of water be carefully added without disturbing the thin glass cover, so as to insinuate itself underneath by capillary attraction, the forms of the corpuscles will be again perceived.

On the seventh and subsequent days, when the contents of the *variole* (to use a French term which is more convenient than “pock,” and has the advantage over “vesicle” or “papule,” of not committing one to any pathological theory) become thick and opaque, or, as the books call them, “purulent,” it will be found that this opacity is caused entirely by the multitude of these solid bodies, which fill the fluid so as hardly to be able to float about in it. On the seventh and eighth days they are most abundant, and the proliferous cells are most numerous. On and after the ninth day the proportion of free nuclei or bright granules (or nucleoli?) and of proliferous cells diminishes gradually, the medium-sized corpuscles predominating; and on the tenth or eleventh day the corpuscles are all found to be of much the same size, having then arrived at what I believe to be their full growth. The tenth or eleventh is, in a normal *variole*, the latest day on which they can be observed without the addition of some fluid.

I have been obliged to give this description of the *variole* before entering upon the symptomatology of small-pox, because the course of that disease cannot be rightly understood without first understanding the life of the *variole*. It will be observed that in describing a case of small-pox I have carefully avoided the use of the word “pustule.” There are no pustules in small-pox. The contents of what the books call “vesicles” do not become “pustular.” The same elements are found in the “papules” of the first and second days; in the “vesicles” of the third, fourth, and fifth; and in the “pustules” of the sixth or seventh and subsequent days—only at the commencement of the eruption they are few in proportion to the fluid in which they float, and at the close they are so numerous that the fluid is only sufficient to moisten them and keep them alive.

As regards the question as to what is the actual contagium of small-pox—that is to say, what is the thing which, introduced into the body of an unprotected person, will reproduce in him the same phenomena which attended its own growth and development—I feel no doubt that the corpuscles I have

called “variolous” are that contagium: they are so abundant in the only fluid which has hitherto been employed for the purpose of reproducing small-pox artificially by inoculation, and they seem to contain within themselves that reproductive power which is essential to the contagium of a disease like small-pox. (c)

My observations on the blood of patients in the stage of eruptive fever are, I regret to say, very few. It rarely happened that patients were brought to the Hospital until the second day of the eruption, and at the time when I had the greatest number of cases in an early stage I was too busy to undertake microscopical observations. The few I have made are quite insufficient to enable me to speak with any degree of certainty as to the existence of variolous corpuscles in the blood during the stage of eruptive fever. It seems to me very probable that they are to be found in the blood at that time; in severe cases probably in large numbers. One thing is certain: that in three cases in which I made observations, corpuscles exactly resembling those contained in the *varioles* were to be found abundantly in the blood of a patient on the first day of the eruption, when it was very slight, and that none were to be found on the third day, when the eruption had become extremely copious and confluent. Moreover, in a case of hæmorrhagic or malignant small-pox which was under my care for a few hours previous to death, when there was no proper variolous eruption, but only patches of epidermis separated from the cutis by bloody serum, and the patient died with symptoms of intense blood-poisoning, the blood one hour and a half after death was perfectly fluid, and ran out of an opened vein as rapidly as it would have done from the living subject, but in *two distinct strata*, one of colourless serum, the other dark purple. The colourless serum was found to be as rich in (apparently) variolous corpuscles as a vesicle of the third day. These were certainly not the white corpuscles of the blood. That the petechiæ on the skin were not caused by a deficiency of fibrine was shown by the firm coagulation of the blood a few minutes after it was removed from the body. The temperature of the corpse at the same time was 106.9° in the axilla.

However this may be, there is no doubt that careful chemical and microscopical investigations into the state of the blood during the eruptive fever of small-pox and the allied diseases would be of great value, and are much needed.

My own belief is that the variolous contagium enters the system through the mouth and lungs chiefly. That entering, generally in a dry condition—in a state of suspended animation, as it were—it must first return to the condition in which it was previous to the drying up of the *variole* in which it was formed. It then rapidly grows, and the reproductive process goes on in a way as yet unknown, until the variolous corpuscles in the blood become so numerous as to interfere with the normal nutrition of the nervous system, and more especially of the ganglionic system. Hence the febrile symptoms, which increase in severity until the offending matter, foreign to the blood, is thrown out of it in the eruption. Until the eruption is complete, as far as the number of *varioles* is concerned, the fever, though mitigated, does not entirely cease.

When the eruption is once complete—that is to say, when fresh *varioles* cease to appear, which usually happens in discrete cases within twenty-four hours of the appearance of the first *variole*—the fever, as marked by pulse and temperature, disappears. The irritating matter, the poison of small-pox, is by means of the eruption removed from the blood, and placed as it were outside the body. Being but few in number, the *varioles* do not for the first few days occasion any local inconvenience. About the fifth day, by their distension and pressure on the sensitive surface of the true skin, they give rise to an irritative or surgical fever, called the secondary fever. It is important to remember that this secondary fever is not from blood-poisoning. It has nothing to do with small-pox as a blood-poison; it is caused by the local pressure and local irritation, just as a grain of sand in the eye might occasion fever by setting up acute conjunctivitis. In discrete cases with few *varioles* this fever does not commence until the fifth day, and ceases on the seventh or eighth, its length and severity depending on the number of the *varioles* and the treatment adopted. The secondary fever must be treated as a purely surgical fever; but on this point more will be said when we have to speak of the secondary fever of the severer forms.

We have, then, in an ordinary case of discrete small-pox four stages—1st. The incubative stage marked by a *malaise* so

(c) I shall describe hereafter the results of some experiments on their reproductive powers, and also the contents of *varioles* in hæmorrhagic and abortive cases of small-pox.

(b) Nothing more is seen under a magnifying power of 700 diameters.

slight as not unfrequently to pass unnoticed; 2nd, the stage of eruptive fever lasting three days; 3rd, the stage of quiescence after the full appearance of the eruption; and, 4th, the stage of secondary or surgical fever.

The incubative period requires—and would doubtless repay—investigation; the period of eruptive fever is one of blood-poisoning, not easily distinguishable from several other fevers caused by blood-poisoning. The foreign matter eliminated from the blood by the eruption ceases to produce any poisonous effects, and a period of almost perfect quiescence follows. As, however, the variolous corpuscles grow and multiply, nourishing themselves in that mysterious *something* which apparently exists in the blood of almost every human being at birth, and upon which alone the variolous corpuscle can live, grow, and reproduce its like, they create some irritation by their mechanical pressure. When they burst or are opened this latter fever entirely disappears.

Such is the type of small-pox as it appears in a healthy unvaccinated person, living under good sanitary conditions, and not under the influence of panic.

REPORTS OF HOSPITAL PRACTICE

IN

MEDICINE AND SURGERY.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.

TREATMENT OF PTERYGIUM BY TRANS- PLANTATION.

(Under the care of Mr. GEORGE LAWSON.)

THE following case is illustrative of a very efficient method of treating pterygium, and as four years have elapsed since the operation was performed on the one eye of this patient, there is reason to believe that the cure is likely to be permanent.

John K., a young man, aged 34, came to the Royal London Ophthalmic Hospital four years ago with a well-marked pterygium in the right eye, and one commencing in the left. Mr. Lawson treated the pterygium in the right eye by transplanting the apex of the growth from the cornea to the conjunctiva in the lower region of the eye. This operation is easily and rapidly performed, and the result most satisfactory. The man suffered only a few days' inconvenience from the operation; the pterygium in its new locality steadily shrunk away, and has never since given any annoyance. The pterygium in the left eye, which four years ago was very small, had now considerably increased, and it was for the purpose of having this eye similarly treated that the man again applied to the Hospital. Mr. Lawson accordingly adopted the same method of transplantation, and in a week the patient was able to return to his work.

The great advantage which transplantation of the pterygium offers over excising the growth is, that there is no loss of conjunctiva, and consequently no cicatrix on the inner side of the eye to cause a limitation of the movements of the globe outwards.

EDINBURGH ROYAL INFIRMARY.

UNUNITED FRACTURE OF THE HUMERUS, SUCCESSFULLY TREATED BY RESECTION.

(Under the care of Professor SPENCE.)

JAMES W., aged 40, labourer, admitted into the Royal Infirmary, March 7, 1871, suffering from an ununited fracture of the humerus. The original injury was sustained twelve weeks before admission, from a fall upon the ice. The limb was set, but never united. Patient is a healthy-looking man, but of rather intemperate habits.

March 21.—To-day Mr. Spence made an incision, three inches in length, over the seat of fracture, exposed the ends of the bone, and, without removing them from their bed of soft parts, cut off with the bone-pliers the rounded extremities of the bones. The arm was then put up in rectangular splints. It need only be remarked, further, that the wound healed well, without a single bad symptom supervening. The discharge was never copious, and the bone showed a great tendency to unite from the first.

On May 9, "wound almost healed; bone quite firm; patient gets up every day."

A few days subsequently he was sent to the Convalescent House, with the splint still applied, instructions being given him to make passive movement of fingers and wrist-joint. After being at the Convalescent House he returned to show himself. The bone was firmly united; the thickening considerable. He feels it quite strong, but the movements of the elbow are not yet free.

He was dismissed, but strictly enjoined to continue passive motion and the use of the warm douche, as he had been doing whilst in the Hospital.

Remarks.—The foregoing case affords a favourable example of the good results of a method or modification of resection in cases of ununited fracture, which I first practised in a case of false joint of the humerus in 1854, which was published in the *Edinburgh Medical Journal* for that year. In regard to that case I remarked:—"In deciding on resection of the ends of the fractured bone, I determined to remove no more than the rounded and atrophied ends, and to do so with as little disturbance of the surrounding parts as possible. . . Having often observed in cases which had come under my notice, in which resection had failed, that fully two inches, or even more, had been removed, it always seemed to me that not only the amount of bone thus removed, but also the great denudation required to effect its removal, might account for the failure, besides increasing the risk of severe constitutional disturbance." The principle of this method of resection is one in which I have great confidence; and considerable experience in performing it since 1854 has confirmed me in the opinion I then formed.

SCHOOL DISEASES.

A MUCH-ESTEEMED foreign correspondent sent us, some little time ago, a copy of Dr. L. Guillaume's treatise on school hygiene, believing that it might be usefully made known to the functionaries now employed in promoting elementary education in England.(a) Hence we have great pleasure in making known its merits as a guide on many points that should be attended to in the construction and management of schools—the aspect, the warming and ventilation, the height

(a) *Hygiène Scolaire: Considérations sur l'Etat Hygiénique des Ecoles Publiques.* Par L. Guillaume, Docteur en Médecine, Membre de la Commission d'Education de Neuchâtel. 2^{ème} ed. Genève and Paris: J. Cherbuliez.

depth and breadth of desks and forms—on all of which matters Dr. Guillaume is clearly of opinion that the education of the young is materially smoothed by whatever makes education physically more healthy and comfortable.

What we desire to bring before our readers notice now, however, are some short comments on the sins which our systems of education often perpetrate on children of tender age, and on the hecatombs of children who must have been sacrificed to this modern Moloch in the last three centuries; and we take Dr. Guillaume's statements as our basis, because his evidence, coming from a country to which we are wont to look as to a model, is the more emphatic and above suspicion. Who is there, that cares for children, who can fail to be touched with the following passage?—

"I think," says Dr. Guillaume, "that the habit of making children of from 7 to 10 years begin school at eight o'clock in the winter is deadly and tyrannical. These poor little creatures, hastily wakened, with an insufficient breakfast, may be seen running to school scarcely washed and combed, hastily bolting, as they run, the remains of their meal, and trembling with the fear of being too late. Very often the schoolmaster, worried by their late arrival, shuts the door against them: then they may be seen timidly clustered on the threshold, exposed to the bleak wind, till a hard and scolding voice bids them come in, and gives them a punishment-task as they enter, perhaps making them stand upright in a corner. Then suppose such children, whom their evening lessons may have kept up late, thus deprived of their morning sleep, fatigued and hungry and depressed by punishment: how can they lend a ready ear to their teacher? The extra tasks inflicted on laggards are the more reprehensible, as they fall to the lot of weakly children, to whom longer rest and a leisurely breakfast are essential. All punishments which consist in obliging a child to maintain a forced attitude, which cause veritable torture to a muscularly weak child, ought to be suppressed."

Not only, according to our benevolent Doctor, does school begin too early, but the hours are too long. The blood becomes impoverished and the brain irritable, both of pupils and master. "*Hungry belly has no ears.*" That is a proverb that holds good everywhere. Even the *hum* of the school—*le babil et le bruit*—gives place to a sullen silence till twelve o'clock strikes, when the scholars hurry off to gobble up their dinners; often compelled by the rules of the school to begin work again at one.

Dr. Guillaume protests against the quackery which would multiply the number of subjects taught. Scarcely, he says, has any branch of human culture become sufficiently emancipated from doubt to become a branch of "science," so-called, than some fanatic proposes that it shall be added to the school curriculum. We have remonstrated against the absurdity of physiological lessons in a school where the scholars do not understand "literary," much less "scientific," English. Dr. Guillaume says that an attempt has been made to have "shorthand" added to the Swiss curriculum. Fewer lessons, but a more profound and leisurely way of teaching, are recommended. Competitive examinations on a multiplicity of subjects are denounced, with the diseased emulation and feverish application which attend them; and which are sure to produce those precocious and self-satisfied prigs whose heads, as Dr. Guillaume says, are stuffed with historic dates, but who lack personal activity, vigour, spontaneity, and *sève*—in fact, a set of human abortions who are rotten ere they are ripe. St. Vitus's dance is not unknown as a result of the strain of these examinations. Pauses are recommended between different lessons. Holidays need not be so absurdly long as they are if the school work were less intense. Home tasks, which poor little children are compelled to do in the evenings in addition to their school attendance in the day, are sharply criticised: so is the practice of requiring clean copies of tasks, and of setting arithmetical sums of impossible dimensions, and altogether alien to the demands of practical life. Who is ever compelled to add or multiply figures of ten or twelve places? The custom of requiring long and

abstruse passages of the Bible and Catechism to be learned by heart, the dry and unpractical mode of teaching history and geography, all of which form parts of the *home tasks*, are also condemned. Dr. Guillaume's chapter on punishments is that which will cause the most disagreeable surprise to those persons who look upon "Continental" systems of education as models. Schoolmasters and mistresses are formally forbidden to inflict corporal punishment; yet, says Dr. Guillaume, this injunction is but too often disregarded. In fact, he candidly confesses that the rod is the logical result of the existing curriculum; that without it the requisite quiet and appearance of attention during the long school hours cannot scarcely be maintained; and that the true mode of diminishing punishment is to make the lessons less fatiguing to teachers and pupils. Boxing the ears, pulling the ears till they are torn, pulling the hair till it comes out, rapping the knuckles with a cane (for bad writing!); humiliating punishments, such as making the children stand as objects of ridicule, making them kneel "during whole hours" on a sharp-angled piece of wood; the "black hole," cold in winter, suffocating in summer; "keeping in" after school-hours, so as to deprive the culprit of exercise and food; tasks to be done at home, such as writing out the word "*pareseux*" four or five hundred times—are evidently used in the Swiss schools, and are all condemned as useless for the purpose, and as tending to harden rather than to reform the culprit; moreover, they are sure to fall to the lot of the weakest children, and of the poorest, whose parents would dread being brought into conflict with the school authorities. All the existing punishments, says Dr. Guillaume, are hurtful to health and character; the best means would be the deprivation of some little indulgence—but then there are no indulgences to deprive them of. School boards are slaves to routine, and oppose every reform, even that of giving backs to the seats. Short sight, muscular debility, crooked spines, bleeding at the nose, headaches (*cephalalgies scolaires*), and goitre (*goître scolaire*), are diseases which the Swiss system of education is accused of producing. The great inference we draw is, that there are a multitude of children too delicate for the rough, old-fashioned modes of teaching, discipline, and punishments.

THE CONJOINT EXAMINATION SCHEME IN SCOTLAND.

WE understand that on Friday, June 14, the Senatus of the University of Edinburgh resolved to have nothing to do with the proposed scheme for a Conjoint Examining-Board for Scotland. This determination of the Senatus must be admitted to be equivalent to an entire disruption of the whole scheme of Conjoint Examinations as far as Scotland is concerned; for a Conjoint Board of Medical Examination in Scotland without the University of Edinburgh—*par excellence* the great British Medical Teaching and Licensing University—would be comparable only to the play of *Hamlet*, with the character of the Prince of Denmark omitted.

On reflection, we cannot but affirm that the Senatus of the University of Edinburgh has acted wisely, and with a due consideration both for the interests of the University and of Medical education in this matter. The arguments for a Conjoint Board for each division of the kingdom, which would constitute an equivalent and worthy portal to the Medical Profession for each, remain indeed unaltered, and must be allowed to be weighty. But it has long been quite clear that the thing is simply unattainable without legislation. On the other hand, the arguments for a Conjoint Examination, although weighty, are confronted by other arguments against it, which gather force on scrutiny, and which become overwhelming against a partial scheme or any proposal that would set up and continue a different standard of examination in the three kingdoms.

If the English scheme were a complete one—which it is not; if its machinery were perfect, or its chief advocates agreed

upon the purposes to be fulfilled by it—which the recent debate of the Fellows of the Royal College of Physicians has proved is not the case—the establishment of one Board for England, whilst Scotland or Ireland hold aloof, or only set up a sham supplemental examination to satisfy the demands of the General Medical Council, would be most detrimental to the interests of Medicine, both as a science and a profession. It is not for the interests of Medical teaching or progress that a student should have to pay in England the full price of examinations conducted by a complete Conjoint Board in every subject of Medical education, besides a large pecuniary fee; whereas his next-door neighbour would be at perfect liberty to go to Glasgow, pass the pleasant and cheap examination of the Faculty of Physicians and Surgeons of that canny city, and get a licence from the College of Surgeons of Edinburgh, including the *imprimatur* of the Conjoint “practical” Examiners, for one-half the expenditure of money, and we will not say how much less of brains. To encourage or inaugurate such a system of Dutch auction between the three kingdoms would be a crime on the part of the General Medical Council, for which the repeal of the Act of 1858 would be a light punishment.

We therefore can only applaud the Senatus of the University of Edinburgh for openly declaring its dissent by the position it has taken up—for saying in effect that the movement as at present directed is a false one; that it can lead to no good, but must only be productive of harm to the Profession and to the public; and that it (the Senatus) refuses to part with the ancient privileges and rights of the University of Edinburgh—privileges and rights which have been confirmed to it by the Act of 1858, and used since its foundation for the benefit of the whole civilised world—as a price for, at the best, a very partial and unsatisfactory co-operation with other Medical Examining Bodies, and in order to institute an examination which will be an additional burthen and an insult to the students who have graduated in the University, and which will not in any degree be equivalent to or represent the expensive and elaborate system of Conjoint Examinations which it is sought to establish in England.

Before, however, quitting the subject we may furnish our readers with a sketch of some of the arguments which we may presume led the Senatus to arrive at its recent decision. The first one which presents itself is the depressing effect which the establishment of a theoretically equivalent Conjoint Examining Board in each of the three kingdoms may possibly exercise on the standard of Medical education. The examination of the Conjoint Examining Board being a common portal through which all students would have to enter the Profession, it must necessarily be a minimum examination. Its standard could not be higher than that which can be reached with moderate effort by students who possess neither the advantage of genius, talent, extraordinary industry, or money to help them in the acquirement of knowledge. It will confessedly be a minimum test for a mere licence to practise. All will be obliged to pass it, and the obtaining of any higher qualification will be purely optional, voluntary, and unnecessary—in fact, a work of supererogation. It is impossible to deny that a depreciation in the standard of Medical education may be a very probable result of such a measure. All honourable rivalry between Examining Bodies for the maintenance of the value of their degrees will be practically at an end, for those degrees will only be sought by the select few, who, in consequence of the possession of larger pecuniary means or higher connexions, may wish to be decorated with commercially useless honours. In a country like Scotland, where a very large proportion of the whole of the Medical students become pupils of one of the three Universities, to which a Medical school is attached, and where, therefore, there is a healthy rivalry maintained both between the Universities and students—where, moreover, students, as a rule, are not of a

wealthy class, and have no money to waste on unnecessary diplomas—it is clear that in a great majority of cases the minimum examination of the Conjoint Board will be made to take the place of the University degree. Such a change can hardly be introduced without at least a danger of deteriorating Medical education, and consequently Medical science, throughout the country. In the case of Scotland, students who determine to obtain both a University degree and to pass the Conjoint Examination, would be subjected to more examinations than at present. In other words, in their case there would be an increase of the very evil which the Conjoint Examination Scheme was intended to remedy.

An argument in favour of a Conjoint Scheme has been found in the fact that in the Scottish Universities the Professors who teach are also the Professors who examine. This, if it be so, is a system which has many advantages—such as that the Professor who has taught is the best judge of what the student ought to know; and his personal knowledge of the student may often be of great avail in coming to a just conclusion in a doubtful case. That there are disadvantages in the plan we are fully ready to allow, but these are, or may be, completely removed by the provision of the Scottish Universities Act, which provides that assessors unconnected with the University, and appointed by the University Court, should take a part in all examinations.

Again, the General Medical Council is responsible for the efficiency of all examinations conducted by the present Licensing Bodies. This is a truth which cannot be too clearly borne in mind in these discussions. The General Medical Council has the power of visiting and inspecting all examinations. The slight experience it has already had of the value of this power which was given by the Act of 1858 is more than sufficient to show that it is fully equal to the requirement of keeping examinations at a high point of excellence. It is much to be regretted that this Scheme of Conjoint Examining Boards has been permitted to divert the Council from the exercise of the highest and most useful function the law has placed in its hands.

There is one argument against a Conjoint Board which applies especially to the cases of Scotland and Ireland. It is that which may be called the argument of locality. Take the case of Scotland, for instance. Three of its Universities are situated in three great towns, in each of which there is a large Medical school—Edinburgh, Glasgow, and Aberdeen. In each of these Universities a large number of Medical students is educated, and can obtain the highest Medical degree. They are situated far apart. If, then, their students are all to be reduced to the necessity of passing one Conjoint Board, one of three things must happen: either two of the Universities—say Glasgow and Aberdeen—will dwindle, and become in a short time deserted, and students will flock to Edinburgh, where not only education, but examination is to be obtained—and thus a grave injury and injustice will be inflicted on two British Universities of unimpeachable character and standing; or, secondly, the students will still obtain their education at the three universities, but go to Edinburgh alone for examination—in this way an injustice of extra expense and trouble and annoyance will be inflicted on the student; or, thirdly, the Board of Examiners may be peripatetic, and visit each of the Universities in turn—a plan which would be a very expensive one, and the expense of which, having to be provided for by the fees for examination and licence, will again inflict an injustice on the unfortunate student.

Lastly, in the case of the University of Edinburgh, there is the fact that a large number of the students who graduate at Edinburgh come from the colonies and foreign countries. It is manifestly an injustice for the General Medical Council to endeavour to impose on these gentlemen the tax of an extra payment to, and an extra examination by, a Conjoint Board.

We have already expressed our opinion of the Scottish scheme

of a Conjoint "practical" Examination. It is a mere sham, only intended to throw dust in the eyes of the General Medical Council, and in no way equivalent or analogous to the Conjoint Board which was contemplated for England.

From the arguments adduced on both sides we have come to the deliberate conclusion that it is far better that things should go on as they are, with a strict system of inspection of examinations by the General Medical Council, than that the present machinery should be destroyed, and different standards of qualification and examination in different parts of the United Kingdom be introduced of far greater divergence than any that at present exist, or that all grades in the Profession should be abolished by levelling education and examination down to a minimum. A perfect Conjoint Board for each division of the kingdom, with due provisions for the maintenance of its efficiency and standard of examination, can only be obtained by a new Medical Act, and by some public provision for its maintenance, which would make the examiner independent of the fees of the students. This will never be conceded by Parliament and Government unless the examination be made a *bonâ fide* State examination under the direction of some member of the Government for the time being. To any such plan of State interference and State control in the affairs of Medicine there are insuperable objections, and we express our firm conviction when we say there is no such evil in our present system as to render it necessary.

THE MEDICAL ACT AND THE QUACK FRATERNITY.

O'CONNELL used to say that he could drive a coach-and-six through an Act of Parliament. Certainly, the language used in some of our Acts is so vague that an astute lawyer may be able to make anything of them. This would appear to be the case with the Medical Act of 1858, for magistrates have refused to convict on what would appear to be the clearest evidence, and the legality of their refusal has been confirmed by the superior courts. The 40th clause of the Act runs thus:—

"Any person who shall wilfully and falsely pretend to be or take or use the name or title of a Physician, Doctor of Medicine, Licentiate in Medicine and Surgery, Bachelor of Medicine, Surgeon, General Practitioner, or apothecary, or any name, title, addition, or description implying that he is registered under this Act, or that he is recognised by law as a Physician, or Surgeon, or Licentiate in Medicine and Surgery, or a Practitioner in Medicine, or an apothecary, shall, upon a summary conviction for any such offence, pay a sum not exceeding twenty pounds."

Now, at first sight this clause would appear to be perfectly clear and unambiguous. It would be held—looking at the Act in a common-sense light—that a man unregistered, and holding no diploma or qualification that could be legally registered, by assuming a title implying that he was registered under the Act, would be liable to "pay a sum not exceeding £20." Of course if he used the title, knowing that he had no right to do so, he would be wilfully and falsely pretending. The lawyers, however, do not construe the clause with regard to its meaning, but only in regard to its literal sense. Being a penal clause, they argue, such is the duty of the judge. The consequence has been, the 40th clause has been all but a dead letter. A case came before Mr. Knox at the Marlborough-street Police-court on Saturday last, which is one of so much importance that we quote it entire at page 726. It will be seen that the magistrate felt that he had no alternative but to convict Mr. Hamilton, which he did in the mitigated penalty of forty shillings and costs. Now, it is by no means certain that the decision of the magistrate will be confirmed by a superior court; but the discussion of the subject cannot fail of being of great advantage to the public interests. Publicity given to such cases must have a tendency to impress upon the minds of our legislators the vast importance of having laws so framed that they shall act as a complete protection to the

public, and not be of that flimsy kind that a butterfly can break through them almost as easily as a coach-and-six.

It is well known that great efforts have been made for some years past to substitute a more stringent, more comprehensible, and clearer clause for the 40th in the Medical Act. It is difficult to understand, if law-makers are really in earnest, what objection they should raise to the proposed clause. If it is not intended to make "a delusion and a snare" of the "protection" clause, then we say the Legislature is bound to make that clause to answer the purpose for which it is intended. Here is the clause which the General Medical Council have proposed to substitute for the effete and unsatisfactory 40th clause of the Medical Act. We cannot understand what valid or just objection can be taken to it, and we trust that ere long it may pass both Houses of Parliament:—

"If any person practising Medicine or Surgery, or engaged in the cure or treatment of diseases or injuries, not being registered under the Medical Acts, takes or uses any of the designations enumerated in Schedule (A) to the Medical Act (1858) as amended by this Act or by any other of the Medical Acts, or the designation of Physician, Surgeon, Doctor, or Apothecary, or any other designation used by or used to distinguish duly qualified Practitioners of Medicine or Surgery, or any class thereof, or the designation of Professor of Medicine or of Professor of Surgery, he shall for every such offence be liable on summary conviction to a penalty not exceeding twenty pounds."

In the meantime the efforts made by Mr. Deakin are worthy of all commendation, and we trust he will persevere in these efforts to put down one of the greatest of our social evils.

THE WEEK.

TOPICS OF THE DAY.

THE UNIVERSITY OF CAMBRIDGE has appointed Professor Paget and Professor Humphry representative of Medicine and representative of Surgery at the partial Conjoint Board. As we said last week, we think that this action on the part of the University is entirely premature. The paucity of distinguished available Medical talent in the University comes out very clearly in this election. If the University require a representative in the Medical Council, they have to send Professor Paget; or, when he is made Chairman of the Council, Professor Humphry. If they then think themselves called on to send representatives to this imperfect Examining Board, they have no one to choose but the two same distinguished Professors, one of whom is already in office at the Council of the Royal College of Surgeons, and is known to have greatly influenced the Council in exchanging the independent privileges of the College for this imperfect scheme. Personally, we have the greatest respect for Professor Paget and Professor Humphry; but we cannot think it wise that these offices should all be vested in the same persons. The whole facts are evidence of the folly of placing a University, which grants perhaps half a dozen, or half a score, Medical degrees in a year, in the same position of power with one of the great Medical Corporations.

The case of *Booth v. Forsyth*, recently tried in the Court of Common Pleas, was one in which a druggist of East Greenwich, named Booth, brought an action against Mr. Forsyth, a Surgeon, for slander, Mr. Forsyth having accused the druggist of supplying medicine to produce abortion. As the jury found for the plaintiff, with £50 damages, we may presume they were thoroughly of opinion that there was no ground for the accusation which the Surgeon brought against the druggist. But there were certain matters given in evidence which at the present juncture have great interest for the Profession generally. In the first place, it seems that women are in the habit of buying "pilacotia" to produce abortion; in the second place, it seems, according to the summing-up of Baron Martin, that for a chemist to consult with a patient, and, having heard

the symptoms, to refer to a Physician's work (Dr. Lee "On the Practice of Midwifery"), and make up one of the prescriptions contained in the book, and sell it to the patient for 1s. 3d., is a transaction within the legitimate business of chemists; thirdly, that a chemist may prescribe and sell a lotion containing prussic acid, or sell strychnia to kill bugs, without giving any written instructions; and, fourthly, identify "pilacotia" pills with "the refuse of a chemist's shop—horse physic—refuse of aloes which could not be used in pharmacy." It is also worthy of note that the verdict obtained by the plaintiff seems partly to have been due to the suggestion of the plaintiff's counsel, that the defendant was actuated in making the charge against the plaintiff "by the fact that his practice was more or less prejudiced by the legitimate business of chemists, who were nowadays so much resorted to by the poorer classes."

The rejection of the Birmingham Sewerage Bill at the third reading by the House of Commons is a matter of no mere passing interest. The question of what is to be done with the sewage of our great towns seems as far off being settled as ever. In Birmingham, for instance, where the population is 350,000, and rapidly increasing, the Corporation have been prevented, and rightly prevented, by the Court of Chancery from polluting the river with it. They then resolve to utilise it by applying it to the soil. If this were done by irrigation, the estimate of the land required would be 10,000 acres. They therefore propose to do it by the process of intermittent filtration—a process by which the fluid part of the sewage would ultimately find its way purified to the river, and the solid would mix with the soil. For this 1060 acres of land would suffice. Of this, 300 acres formed part of the estate of Sir Robert Peel, who moved the rejection of the Bill, and, being supported by Sir C. Adderley, Mr. B. Osborne, and others, his motion was carried by a majority of three. Intermittent infiltration is an experiment, and it was probably as well that the House of Commons should not sanction the experiment being tried on so large a scale. The old plan of irrigation was carried out on the principle of obtaining the benefit of the sewage as a manure, and enriching as much land as possible by it; the new plan of intermittent filtration has quite a different object in view—viz., that of getting rid of as much sewage on as little land as possible. The former is philosophical and economical; the latter, if sewage is of value, is wasteful, and its benefits problematical. But we can only regard the rejection of the Birmingham Bill as a temporary respite. The demands of the towns for an outcome are increasing at an enormous rate, and will not admit temporising measures. The water-closet system is being introduced most unnecessarily all over the country, and the result is not difficult to foresee. Sewage to the soil and rainfall to the river is the only philosophical and common-sense principle to meet the difficulty.

Professor Odling, F.R.S., has been elected to the Waynflete Professorship of Chemistry in the University of Oxford, and has been elected to a Fellowship at Worcester College.

Dr. Gavin Milroy has returned from the West Indies, whither he was sent as a Commissioner by Government, on the advice of the Royal College of Physicians, to investigate leprosy and its treatment.

THE NIGHTINGALE FUND.

It is gratifying to state that the fund is in a prosperous condition. The report of the past year states that the building which has been erected for the accommodation of the probationers at St. Thomas's Hospital, and called the "Nightingale Home," comprises every convenience for thirty-five probationers. At the end of the year 1870 there were eighteen probationers in residence. During 1871 thirty-one were admitted, one was dismissed, three resigned or were found unsuited to the work, and eighteen having been recommended

to appointments, twenty-two was the number in residence at the end of the year. Further admissions have since taken place, increasing the total number to thirty-three. The Committee call attention to a work recently published by Miss Nightingale, entitled "Notes on Lying-in-Institutions." The facts which are there collected and commented on will explain the difficulties which stand in the way of any scheme for the re-establishment of a school for midwifery nurses, while they at the same time afford the strongest proof of the great necessity which exists for such an institution. The receipts for the year had been £2204 12s. 1d., and the expenditure £1808 2s. 4d., leaving £396 9s. 9d. in hand. The invested funds amount to £53,000.

LIGATURE OF COMMON CAROTID FOR SECONDARY HÆMORRHAGE.

On Wednesday, the 12th inst., Mr. Le Gros Clark operated upon a tumour of the upper jaw. A portion of the growth was so deeply situated as to necessitate a partial excision. Secondary hæmorrhage occurred on Monday evening, when the patient suddenly lost about twenty ounces of arterial blood. Mr. Wagstaffe tied the common carotid artery. Up to the time of going to press the patient was progressing favourably. The carbolised catgut ligature was used, and cut short in the wound. We hope to publish a full account of this case at some future time.

THE HARVEY TERCENTENARY MEMORIAL.

THE efforts now being made to form in London a committee to act in unison with the Folkestone Committee give every prospect of eventual success. Within the last few days a sum of £300 has been subscribed; and the Archbishop of Canterbury, Lord Granville, the President and Censors of the Royal College of Physicians, the President of the Royal College of Surgeons, Sir Thomas Watson, Sir Henry Holland, Sir William Fergusson, Sir William Gull, Sir James Paget, Dr. Quain, Dr. Bence Jones, Mr. John Simon, Mr. Skey, C.B., Mr. Curling, Dr. Owen Rees, and numerous other gentlemen, have already notified their support. His Royal Highness the Prince of Wales will be asked to preside at a public meeting at the Royal College of Physicians, kindly offered for the purpose by the President and Fellows. Meanwhile, the Committee are desirous of filling the subscription-list, in order to show the Prince that the memorial, which is fast assuming national proportions, will be worthy of his patronage. We are requested to state that donations may be sent to the Harvey Tercentenary Memorial Fund at the Western Branch of the Bank of England, Burlington-gardens; or to the Treasurer, Dr. Bence Jones, F.R.S.; or to the Hon. Secretaries, Mr. G. Eastes, M.B., 5, Albion-place, Hyde-park-square, London, and Mr. W. G. S. Harrison, Town Clerk, Folkestone.

MANCHESTER MEDICAL SCHOOL AND OWEN'S COLLEGE.

It has been determined to amalgamate the Manchester School of Medicine with Owen's College, now a most important and influential institution. Accordingly, a large meeting of past and present students of the school was held last week in order to form a committee to obtain subscriptions from past and present students, and others interested in the cause of education, towards defraying the expenses of the amalgamation. Resolutions were adopted to effect the object in view, and an executive committee was appointed.

THE NEW GOVERNOR OF INDIA AND MEDICAL STUDENTS.

LORD NORTHBROOK, who has already given evidence of the interest he feels in most matters concerning our Indian Empire, has given another instance of his desire to encourage the arts and sciences. He presided last month at the annual distribution of prizes to the students of the Calcutta Medical College, and made an excellent address to the assembly.

ARMY MEDICAL DEPARTMENT.

THE annual general meetings of the Army Medical Officers Friendly and Benevolent Societies were held on the 30th ult., at the Army Medical Board, Whitehall-yard. On this occasion the actuary's report of the last quinquennial examination of the Friendly Society was presented to the meeting, and proved to be of a highly satisfactory character; so much so, that it was unanimously resolved that the widows' annuities be increased from £44 to £48 for the first class, and from £22 to £24 for the second class. The donations and subscriptions to the Benevolent Society for the past year had been very liberal, enabling the meeting to distribute the sum of £705 among the different applicants.

INDIAN MEDICAL OFFICERS.

SOME misunderstanding having arisen on this subject, and much discussion having ensued, it is now announced that it has been decided that a commissioned Medical officer of the Indian army holding a civil Medical appointment is subject to the rules applicable to other military officers in civil employ, in regard to privileges as well as to leave.

THE MEDICAL OFFICER OF HEALTH AT GLASGOW.

THE Glasgow Police Board have determined to adopt a minute of their Health Committee of April 15. They propose to elect a Medical Officer of Health, who shall devote the whole of his time to the duties of the office, and that Dr. Gairdner should be retained as Consulting Medical Officer at a salary of £100 per annum. "We are not sure," says the *Glasgow Herald*, "that the course adopted is the wisest."

MANSLAUGHTER IN A LUNATIC ASYLUM.

AT the Dublin Assizes two soldier attendants at the Royal Military Hospital were found guilty of causing the death of an inmate. Mr. Justice Lawson, in sentencing the prisoners, said the charge of manslaughter had been proved by overwhelming testimony. "Two cold baths had been prepared for the unfortunate man. He had been beaten, terrified, tortured, and kept under cold water until benumbed and almost suffocated. It was impossible for any man to conceive a more barbarous and shocking procedure than that which had been proved against the prisoners. It was with some truth asserted that no evil passion to which our nature was subject more rapidly gained a mastery of the individual who indulged it than the practice of cruelty and acts of torture. He had often heard of such practices being carried on in lunatic asylums. He had read of them in novels; but he never believed that they existed in real life until they were disclosed to him in evidence. He believed that people in the position of the prisoners were entrusted with too much power; and the Court, to mark its sense of the enormities perpetrated in the present instance, in which the life of a man had been cut short, felt bound to sentence the prisoners each to penal servitude for five years."

PROFESSOR VIRCHOW.

A BERLIN correspondent tells us that—

"Virchow is devoting much more time than formerly to science. He gives a great deal of time to a collection of crania and specimens of bone disease. I believe when the new museum is completed the osteological collection will be the most valuable in the world, in a pathological point of view. Virchow continues to lecture every day, except Saturday, on 'Diseases of Bone,' so you see he is going very fully into the subject. The heat in Berlin is now very intense. They are using Lister's method in the Charité. Dr. Wegener recently made a post-mortem on a male upon whom an amputation had been performed after the manner of Lister, with catgut ligature. The wound healed by first intention, without pus, and no trace of catgut could be found. I may remark the man died of tubercular disease, associated with amyloid degeneration."

SANITARY REGULATIONS IN CHINA.

THANKS to the energy and ability of the Inspector-General of Customs of China, Mr. Robert Hart, we are in receipt of a second batch of half-yearly reports respecting the health of the seaports of that empire. These reports, which are of great value, and ten in number, had their origin in a circular dated Peking, December 31, 1870. The Inspector-General, in addressing the Medical officers of the various ports, speaks of the importance of obtaining information on various points respecting the public health in the various seaports. Amongst others he particularly invited attention to—(a) The general health of ——— during the period reported on; the death-rate amongst foreigners; and, as far as possible, a classification of the causes of death. (b) Diseases prevalent at ———. (c) General type of disease; peculiarities and complications encountered; special treatment demanded. (d) Relation of disease to season; alteration in local conditions, such as drainage, etc.; alteration in climatic conditions. (e) Peculiar diseases, especially leprosy. (f) Epidemics: Absence or presence; causes; course and treatment; fatality. Other points, of a general or special kind, will naturally suggest themselves to Medical men; what are above called attention to, will serve to fix the general scope of the undertaking. Dr. R. C. Jamieson, of Shanghai, was charged with arranging the reports for publication, so that they may be made available in a convenient form. The ten reports before us are of great value, comprehending as they do many points besides those indicated by Mr. Hart, such as meteorological observations, etc. The "Medical Reports" of the Inspector-General of Customs have already been productive of a vast mass of most useful information.

WOMEN-DOCTORS AT ZURICH.

PROFESSOR HERMANN, on conferring a diploma on an English lady, is reported to have said:—"The brilliant result of an examination is not the chief point; it is possible to attain a certain amount of knowledge by mechanical means. The lady Medicals have yet to prove that their knowledge is of any utility to society." M. Hermann added that "so great a concourse of female students at Zurich filled himself and his colleagues with apprehensions, and that so much the more inasmuch as the Government, in allowing free course to the scientific tastes of these ladies, did not at the same time supply the Professors with the means of exerting over them a sure control, and of removing certain suspicious elements." The students greatly cheered the Professor's remarks.

FROM ABROAD.—LYONS *v.* CHLOROFORM—HYGIENE IN FRENCH LYCEUMS.

THE narration of a case in which death occurred while under the influence of chloroform gave rise to a discussion at the Lyons Society of Medicine upon the subject of the dangers of chloroform and the innocuity of ether. Lyons, as is well known, is the only place in Europe in which the inhalation of ether is still preferred and largely practised. Why it should be so it would be difficult to conjecture, there not being there the same historical and national reason which has led to the same preference being still maintained in Boston, U.S.

The present case was not a very strong one to build an argument upon, for the patient might easily have died even if chloroform had not been given, and no post-mortem was instituted. He was an officer who, at one of the battles round Sedan, had, on September 1, his leg completely carried away by a shell, losing much blood, and being greatly prostrated. Amputation could only be resorted to several hours after the occurrence, a small quantity of chloroform being administered on charpie, which quickly induced resolution, without any previous agitation or loquacity or stertor. The operation lasted scarcely three minutes, when the patient was found pulseless, and, after two or three feeble expirations, he died,

the restorative means, which were tried during half an hour, proving of no avail.

M. Desgranges observed that with chloroform even in a state of purity, and in the most skilful hands, there was no security from danger, and the Paris Surgeons operate before complete anæsthesia is established, arousing the patient as soon as possible afterwards. Ether suffices for all operations, and no patients are refractory to it, provided ether at 65° is used—which, indeed, is not obtainable at Paris. M. Diday cautioned the Society not to remain under any illusions on the subject, for, in spite of the goodness of the cause, ether will not triumph until the law or the Legislature intervenes and snatches chloroform from the hands of the Surgeon. One of the members, a little startled at such a conclusion as this, asked M. Diday whether he did not think a law interdicting the use of chloroform would not infringe upon the immunities of the Profession. Ovariectomy might in this way be interdicted, for it produces far more victims than chloroform. M. Diday, however, held firm to his proposition. M. Pétrequin, whose influence has been one of the chief causes of the Lyonnese chloroform-phobia, declared that the Society possessed an authority which it ought to bring to bear on this question, and it must not believe that its prior efforts have been useless. After each of his three works on the subject M. Pétrequin has received approbatory letters from a large number of Practitioners. The fatal results from chloroform have in turn been attributed to impurity, want of skill, or the dose employed, and all without reason. "Chloroform is mortal in itself, and it alone is to be blamed." No preventive measures offer any security, and sometimes the operation put into force to meet these accidents is more formidable—tracheotomy—for the most part uselessly performed) than that for which the chloroform was resorted to. There has been no improvement in the administration of chloroform since its discovery, while, as regards etherisation, the agent has so improved that rectified ether of 63° or 64° may easily be procured, and the instrument now used is employed with the utmost facility—the operator himself, indeed, being able to watch his patient. The number of deaths which have occurred from it is quite insignificant, so that the Society, if it induce only some Practitioners to abandon chloroform, will have conferred a boon on humanity.

M. Marduel felt somewhat diffident in uttering a discordant note amidst this harmonious paean in favour of ether; but he could not forbear calling to mind that at Lyons as well as at Boston there had been several deaths from ether. He would not say that chloroform is an innocent agent and does not want more *surveillance* and precautions than ether; but he much doubts whether, if a rigorous statistical account could be obtained, it would not be found that ether in its comparatively small number of applications had given rise to relatively as many deaths as chloroform. Dr. Richardson had to count up 15,000 chloroformations in English Hospitals before he met with a fatal case; and M. Elser, of Strasburg, has practised more than 16,000 chloroformations without a single death. M. Delore, although he has had pretty extensive practice with chloroform, prefers ether because he is then less preoccupied with the anæsthesia. In explanation of deaths from ether, idiosyncrasies must be taken into account, the existence of which nothing could lead to suspect. The deaths that have been recorded as resulting from ether in nowise resemble those from chloroform. They are not so sudden (*foudroyants*), and a certain number of them should be attributed to hæmorrhage, epilepsy, etc. M. Marduel, on the contrary, maintained that several of the deaths from ether had been just as *foudroyants* as those from chloroform. M. Vezu observed that one advantage of ether was that once pure it remained pure; while chloroform, however pure and whatever care be taken, undergoes chemical change.

M. Jules Simon, Minister of Public Instruction, has just issued a circular to the Rectors of the Lycæums of France

announcing that in future lectures on hygiene are to be delivered to advanced schoolboys, and furnishing the programme (*vide Medical Times and Gazette*, May 4, p. 520) agreed upon by the Académie de Médecine. After alluding to the reports he had received concerning the fulfilment of his directions as to the teaching of gymnastics, living languages, history, and geography, he goes on to say:—

"With gymnastics are connected all questions relating to hygiene, all that concerns the development of the body and health. Very few persons in France have just ideas on this subject, and I have thought that five or six lectures, delivered at the end of their other studies, would suffice to make our pupils understand that health and strength, in a great measure, depend upon food, clothing, habitations, and a due regulation of life. Five or six lectures will scarcely require five or six hours; and as lectures on hygiene call for no effort of the mind, we may render them compulsory without interfering with the preparations for the examinations. If this teaching be well executed, as I hope, it will prove attractive, and these youths will easily understand its importance. I count upon the goodwill of the Medical attendants of our establishments leading them to undertake these lectures according to the enclosed programme. I shall make no apology for this slight increase of labour which I impose upon our Doctors. They are true fathers of family for our pupils, and I am sure will enter upon my views with pleasure."

The following is the programme:—"1st lecture: Hygiene, its object and its means. Atmospheric agents, with reference to their influence on health (air, light, heat, electricity, drought, humidity, and winds); the chief changes in the air (climates, epidemics, and endemics). 2nd: Habitations, with reference to soil, exposure, ventilation, warming, lighting, and cleanliness; clothing as modified by age, seasons, climate, and weather; cosmetics, baths, and cleanliness in general. 3rd: Food—nature and qualities of the different alimentary substances, and their appropriation to temperaments, professions, and climates; the conditions of a good digestion; preserved meats; adulteration and falsification of foods; alimentary regimen. 4th: Drinks—potable waters, their characters and their deteriorations, with the means of preventing and correcting these; the preservation of potable waters; fermented liquids, wine, cider, beer, spirits, tea, and coffee. 5th: Hygiene of the senses—sleeping and waking; intellectual and manual labour. 6th: Exercise and repose; gymnastics; special exercises—swimming, riding, fencing, and dancing.

We have transcribed this as a very good specimen of what persons in Ministerial authority in France believe can be done merely by prescribing that it shall be attempted. We do not know which to pity most—the unfortunate Doctors attached to these schools, thus suddenly called upon to prepare amidst all their other avocations an elaborate course of hygiene, to be delivered to a listless and wearied compulsory audience; or the audience itself, having this tacked on to the end of a laborious term, and, when anxious to prepare for impending examinations, obliged to listen to what must seem to them singularly ill-timed addresses. The career of a French schoolboy has much about it to call for sympathetic compassion, and may offer some excuse and explanation of the wildness of his subsequent student years.

PARLIAMENTARY.—THE BROADMOOR ASYLUM—BIRMINGHAM SEWERAGE BILL.

On Monday, June 17, there was a long conversation on the vote for the Criminal Lunatic Asylum at Broadmoor, which Mr. M. Henry moved to reduce by 15,000*l.*, sharply attacking the management of the Asylum, and contrasting it unfavourably with the general success and economical management of Dunderum Asylum. Broadmoor was warmly defended by Mr. Bruce and Mr. Walter, and, in the end, the amendment was withdrawn.

On Tuesday Sir R. Peel attacked the Birmingham Sewage Bill, which stood for a third reading, in which he was warmly seconded by Sir C. B. Adderley, Mr. Osborne, and Mr. Bouverie. On the other hand, Lord Henley, Mr. Marling, and Mr. Mifford supported the members for Birmingham, Mr. Dixon and Mr.

Muntz, in advocating the Bill, but in the end the arguments against the Bill prevailed, and it was thrown out by the narrow majority of three—148 to 145.

PROFESSOR HOLMES'S LECTURES AT THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

IN continuing his lectures on "The Surgical Treatment of Aneurism in its various forms," Professor Holmes said that the conclusions justified by present experience as to the applicability of Brasdor's operation in innominate aneurism appeared to him to be as follows:—

1. That the distal ligature of the carotid alone, or in conjunction with that of the third part of the subclavian, cannot be trusted to produce the complete consolidation of the tumour.

2. That the natural effect of the ligature of the carotid artery is to produce coagulation in that part of the sac directly connected with the mouth of that artery.

3. That this may suffice practically for the cure of the aneurism when the subclavian part of the aneurism is small and shows no disposition to grow.

4. That in other cases where the mouth of the subclavian artery is previously obliterated by impacted clot, the ligature of the carotid only may effect a radical cure.

5. That for these reasons it is better in any case which appears to require distal ligature to commence with the operation on the carotid alone, and afterwards to consider the propriety of securing the subclavian either in its first or third part.

As to the justifiability of operating on the first part of the subclavian, the Professor made the following remarks:—

The ligature of the first part of the subclavian has hitherto failed on account of the almost uniform occurrence of secondary hæmorrhage. There are dangers in the operation—viz., anatomical difficulties, and the possibility of wounding the sac or of finding the vessel diseased. Still, most Surgeons would allow that if the ligature of a large artery involved little or no risk of secondary hæmorrhage, the operation might be repeated under similar indications to those which would justify any other operation of equal importance. The less or greater risk of secondary hæmorrhage depends on the possibility or impossibility of securing an artery so as to obliterate without dividing it. Now, this has been an object with Surgeons since the first case in which John Hunter tied the femoral for popliteal aneurism; and the methods by which the attainment of the object has been attempted are the temporary ligature, the *presse artère* or acupressure, and the silver ligature. None of these, except the *presse artère*, has as yet afforded definite proof of success, and this only exceptionally.

A case lent by the College of Surgeons of Ireland, showing the obliteration of the femoral by this method for popliteal aneurism, proves, however, that an artery may be obliterated and an aneurism cured without division of the vessel. The only thoroughly satisfactory case of silver ligature is one in which Mr. Holmes employed the wire on the femoral artery for popliteal aneurism. In this instance the wound healed in a fortnight, and though suppuration occurred, the ligature was not discharged from the wound. But silver wire is dangerous, for if tied tightly it cuts the coats of the vessel more deeply, and produces more and more rapid ulceration than the silk thread. In preventing secondary hæmorrhage its use is too uncertain to be preferable to silk. Carbolised catgut, when properly prepared, may be used for the ligature of a large artery with perfect success without dividing the external coat of the vessel or interrupting its continuity, while the ligature itself is absorbed, and the wounds made over the vessels so tied often unite by first intention. This rapid union of the deep parts of the wound is a necessary condition for success.

The Professor then gave the history of the use of catgut for this purpose, mentioning especially the experience and comments of Sir A. Cooper (given in the "Surgical Essays" by Cooper and Travers, and in the 12mo edition of his lectures published in 1829) and of Porta, who gives in his work nine cases in which the operation was performed by himself, and two in which he assisted others. Porta nowhere, however, contemplates the occlusion of the vessel without its division; and, speaking of secondary hæmorrhage, says "that we shall never be able to annihilate its possibility by any method, or to reduce it within the limits which we observe in the lower animals." In the case where Sir P. Crampton used a ligature

of moistened catgut in tying the common iliac in 1828, if the catgut had been properly prepared, the ligature tied firmly and cut off correctly, and the wound and the patient been so treated as to produce speedy consolidation of the deep parts, there would probably have been no hæmorrhage.

After referring to Mr. Lister's tract "On Ligature of Arteries on the Antiseptic System," Professor Holmes remarked that, whether Mr. Lister's explanation of his method of dressing wounds be or be not the correct one, that method is very frequently successful in producing rapid union, especially in the deep parts of the wound. This being granted, and as it can be demonstrated that catgut ligature, under favourable circumstances, will gradually melt away in the tissues without causing ulceration, it cannot be denied that the object which John Hunter and his followers so sought after has been discovered. A preparation of the lecturer's own case showing successful ligature of the carotid and subclavian arteries with carbolised catgut, and with no interruption of the continuity of either vessel, was exhibited. This specimen affords anatomical proof that a large artery in the human subject may be tied in such a manner that the wound may unite by first intention, and the patient never be in any danger of secondary hæmorrhage; and, further, the case shows that the catgut ligature may be removed by absorption, the vessel remaining undivided. Mr. Holmes expresses his opinion of the carbolised catgut in these words:—"No material can be imagined better adapted for a ligature than catgut long steeped in carbolised oil; it is perfectly tough, perfectly flexible, and perfectly smooth. It excites no irritation, absorbs no putrescent fluid, and, though it gradually melts away, yet holds the artery firmly enough to close its tube permanently. Having used it in all large operations for about two years, I can testify to the latter fact, and I can say that I have never seen any sign of irritation produced by it, nor witnessed the escape of any of the little knots from the wound, and that I hold it to be a very much better and more convenient hæmostatic than torsion, and infinitely superior to acupressure. In fact, I have found it to possess all the comfort of the silk ligature, without its disadvantages. I do not, however, imagine that catgut or any other ligature can be applied to an artery with perfect success unless the tissues around become rapidly coagulated by first intention. An artery exposed in the middle of a suppurating cavity will, I believe, always soften and give way, and it was most probably because they failed to secure this prompt union of the deep parts of the wound that Porta in most of his experiments and operations, and Sir A. Cooper in the operations which he performed after his first successful one, failed to obtain this perfect result." The inference, then, is that the subclavian may be justifiably ligatured in the first part of its course in those innominate aneurisms which advance after distal ligature of the carotid.

The applicability of the distal operation in the treatment of aortic aneurism, and the probable reasons of its beneficial effect in this form of the disease, were next discussed. With respect to the ligature of the left carotid for aneurism of the arch of the aorta, there is no doubt that there are cases in which it is very beneficial, though there are no theoretical grounds for believing that cure can be effected by this operation. The beneficial result no doubt is produced by the obliteration of that part of the sac which was previously distended by the current of blood passing into the left carotid. When, then, the growth of the tumour can be traced upwards towards the trachea on the left side this operation is indicated, and when on the right side the distal operation on the same side will suggest itself. Finally, the treatment of aortic and mixed aortic aneurisms by galvano-puncture was considered, and the difference in the clot produced in any albuminous fluid according as the positive or negative pole is used was mentioned; the positive pole producing a firm coagulum, and the negative a large frothy mass formed of minute coagula.

Mr. Poland's summary of Abeille's case proves that the clots produced by electricity may be as efficacious in the cure of an aneurism as those produced by other means; but it must be allowed that there is at present much uncertainty as to the value of the method, and as to the effects of any given operation, and many details as to the method of employing this agent have to be cleared up before our estimate of the value of it can be formed with certainty. Professor Holmes is disposed to think that both poles should be used, that the action should continue for a considerable time under anæsthesia, and that the needle should be partly coated with vulcanite, so as to defend the soft parts covering the tumour. The uncertainties connected with its employment, however, are sufficient for discarding

electro-puncture in cases of aneurism of arteries accessible to pressure or ligature, as these methods are safer and more reliable.

REVIEWS.

The Origin of Cancer, considered with reference to the Treatment of the Disease. By CAMPBELL DE MORGAN, F.R.S., Surgeon to the Middlesex Hospital. London: J. and A. Churchill. 1872. Pp. 87.

A SMALL book, thoughtful, and elaborately argued. The issue is, whether operations on cancerous tumours are expedient and beneficial. The author affirms that they are, because he believes cancer in its origin is local—like one ill weed that may have sprung up in a garden—and that it ought to be extirpated before it has had time to scatter its seeds broadcast; for if allowed to do so, it becomes a “general” or constitutional or infecting disease in good earnest. As to the local origin of cancer, Mr. De Morgan pleads against the notion that it is a blood disease manifesting itself in a part, just as gout is a blood disease manifesting itself in the toe. He admits that cancer is very often hereditary, but denies that the “terrible grasp” of the disease, the difficulty of eradicating it, the outburst of tumours in various parts of the body at once, and the so-called cachexia, are sufficient evidence of its inherent primary constitutionality. The constitutional character which the author admits is an inherent congenital tendency, which may be inherited—just as anyone may have a tendency to warts, or fatty tumours, or wens. The difference is, that a fatty tumour has no tendency to “infect”—i.e., to diffuse its elements over the body—whilst cancer has, each tumour being as much constitutional at first as any other in its origin, but differing in the accidents of its structure. “The general conclusion at which I should arrive,” says Mr. De Morgan, “is, that in some persons and in some parts there is a tendency, local in its origin, to the formation of tumours; that this tendency may in some have been implanted in the tissue, even in its embryonic condition, though the actual development may not take place till years after birth—in others, although there may be a disposition to morbid growth, the actual tumour will not be developed unless under some irritation; that the morbid growth having once taken place, it will remain localised or become diffused in proportion to the facility with which its elements can be taken up and carried off by the structures amongst which it lies; that the period during which these elements may remain dormant is indefinite; that, save in degree, there is no real difference between the malignancy of cancer and of some other forms of tumour; and that even the line between malignant and non-malignant growths is not clearly defined. I should place cancer, then, at the top of a scale, at the lowest point of which might be placed the simplest forms of outgrowth, identical in structure to the affected parts.” There is in this statement nothing that has not been before the Profession these twenty years. The lesson it reads is, that a Surgeon of considerable powers of invention and great experience in this particular disease falls back upon early and ample operation with care to eradicate every possible germ of the disease, as the wisest and most merciful plan. Mr. De Morgan has full experience of the various plans in which the knife is replaced by what is infinitely more cruel; and his work produces the impression of the vast superiority of the confession of an honest man that he can do little good over the pretensions of the charlatans, whose “tender mercies are cruel,” as Solomon said.

NEW BOOKS, WITH SHORT CRITIQUES.

Our Lord's Miracles of Healing, considered in relation to some Modern Objections and to Medical Science. By T. W. BELCHER, M.D., M.A., Master in Surgery, Trinity College, Dublin; Fellow and sometime Censor, Examiner, and Chief Librarian, Royal College of Physicians of Ireland; Curate in charge of the Mission Church and District of St. Faith, Stoke Newington. With preface by the Most Reverend Richard Chenevix Trench, D.D., Lord Archbishop of Dublin. London and Oxford: James Parker. 1872. Pp. 168.

* * * We well remember Dr. Belcher's early essays on the “Nature and Treatment of Fever,” and the promise they gave of a successful Medical career; and we must concur in the admiration which Archbishop Trench expresses at the self-

devotion of a man who can exchange the practice of Medicine for the obscure position of a missionary amongst a depraved suburban population. Of the book itself we would rather not speak, as we doubt if the writer has given the full study and consideration to the subject which it demands. Such a book is unnecessary to the true Christian, whose faith is founded on a Rock—not to be disturbed by any petty difficulties of detail. A discussion of particulars would not be suitable to our pages; but we would respectfully call the writer's attention to the case of Surgical injury at page 163, and to his commentary at page 164, which is contradicted by the experience of every Surgeon, and the authority of every book, and the treatment of every Hospital. We are sorry to speak thus disparagingly of a work which we should gladly praise if we could; but Criticism must be honest, or else hold her tongue.

Timely Counsel and Short Essays on Social Subjects. By Surgeon-Major T. ARCHISON, M.R.C.S.E., etc., H.M. Bengal Army. Second Series. (Pamphlet.) London: Richards. 1872.

* * * A set of dashing, trenchant essays, by the writer whose most useful suggestion of “encampments” for the isolation of small-pox and cholera patients will not have been forgotten by our readers. In this series he pleads for freedom to visit wild scenery, condemns that demoralising penny-seeking habit which marks the idle classes of sea-side denizens, and pleads for opening the London squares, and for preserving historic remains. He combats Mr. Oldham's theory of the non-existence of malaria, and gives some weighty remarks on the alliance of variola and vaccinia. We except an article on the clergy from our commendation; for, to speak mildly, it does not exhibit the writer's good taste and charity.

Livret de Spencer Wells pour les Cas de Tumeurs des Ovaries et de l'Abdomen. Traduit de l'Anglais par le Dr. GUSTAVE BODDAERT, Chirurgien-Adjoint de l'Hôpital Civil de Gand. Gand: Hoste. Paris: Baillière. 1872. Pp. 32.

* * * This is a French version of the little “Note-book” in which Mr. Spencer Wells enters every point in the previous history, the treatment, and the results, of every patient who comes under his care for abdominal tumour. The advantage of such a note-book, with its copious blank forms, is that it suggests to the Practitioner the various inquiries which he ought to make, and supplies him with convenient forms for filling in and tabulating the results. The translation has a highly complimentary preface, and does justice to the great success of Mr. Wells as an operator, and more especially to the increasingly favourable results of each series of cases.

A Handbook of Medical Microscopy. By JOSEPH G. RICHARDSON, M.D., Microscopist to the Pennsylvania Hospital, etc. Philadelphia: J. B. Lippincott. Loudon: Trübner and Co., 60, Paternoster-row. 1871. Pp. 332.

* * * This book begins with a chapter on the microscope, and another on auxiliary instruments, manipulations, and reagents. This part is cleverly done, and whilst, of course, adapted to American readers and describing American instruments, shows the author to be well acquainted with instruments and observers on this side of the Atlantic. Then comes a series of chapters on the examination of the urine, pus, blood, discharges, Medico-legal questions, and morbid growths, in which, together with full instructions for the microscopic investigation, there is a good deal of information as to the nature and treatment of the diseases referred to. The author justly expresses his obligations to Beale, G. Harley, Roberts, Hughes Bennett, and McCall Anderson, and shows that Medical microscopy is in a very advanced condition in the United States. He gives especial praise to the microscopic photography of the War Department, whose sumptuous reports have often been held up by us to the admiration of our readers.

The Fallacies of Teetotalism, or the Duty of the Legislature in Dealing with Personal Freedom; and an Elucidation of the Dietetic and Medicinal Virtues of Alcoholic Liquors: comprehending an Exposure of the False Doctrines of the United Kingdom Alliance, and of the Detestable Tyranny of the Maine Law or Permissive Bill. By ROBERT WARD, Editor of the *North of England Advertiser*. London: Simpkin, Marshall, and Co. Newcastle-on-Tyne: R. Ward. 1872. Pp. 410.

* * * Mr. Ward is more than a match for his teetotal antagonists, and successfully controverts most of the positions of the “United Kingdom Alliance.” In particular, he shows with unanswerable force and great vivacity that whilst teetotalers carefully treasure up and parade every instance of crime committed by persons under the influence of liquor, they obstinately ignore, not only the palpable good effects of alcoholic liquors in debility and disease, but the good moral effects, the

reconciliation of estranged friends, the promotion of good feeling and kindheartedness which ensue from a temperate use of the "glass." In treating of the dietetic virtues, he takes the common-sense view, without entangling himself in the question, more curious than useful, whether alcohol is "food." His philosophy is that of King Solomon and the other Biblical writers, and of St. Jerome, to the effect that whilst persons in health, strength, and spirits may reasonably abstain from wine as unnecessary, the feeble, sick, and downhearted may derive infinite good from it. We must remind Mr. Ward, however, that there is one thing more tyrannical than the American Maine Law, and that is the English Poor Law; and if the ratepayers of any district find that destitution and poor-rates are enhanced by tippling, they have a perfect right to suppress both if they can.

FOREIGN AND COLONIAL CORRESPONDENCE.

FRANCE.

PARIS, June 18.

DEATH OF DR. ADOLPHE RICHARD—MEDICAL MEN AND THE COMMUNE—PARIS BEGGARS—DECREASE OF POPULATION IN FRANCE—BULLOCK'S BLOOD IN ANEMIA.

IT is with deep regret that I announce the death of Dr. Adolphe Richard on the 12th inst. He was born on June 13, 1822, and was the son and grandson of the illustrious men who bore the same name. Both his immediate ancestors were Professors of Natural History at the Faculty of Medicine; but he and his brother preferred the more extensive field of the science and art of Medicine and Surgery. Adolphe took to the latter, and his brother Xavier is a distinguished Physician now practising in Paris. The attainments of Adolphe Richard were of a very high order, and his death is a great loss not only to science, but to the Profession at large. He was—besides being a thorough scholar—an accomplished Anatomist and Surgeon. At a very early age he became Assistant to the Professor of Anatomy, and subsequently Dissector at the School of Medicine. In 1853 he obtained by *concours* the sub-Professorship, and was appointed Hospital Surgeon. He was for his distinguished services rewarded with the title of Chevalier de la Légion d'Honneur, and was for a long time attached to the Hôpital Beaujon; and whilst in the active performance of his duties there he was (about two years ago) struck with the melancholy affection which put an end to his brilliant career. He was the true type of a French gentleman, and appeared much younger than he really was. His malady is attributed to over-study, and to the sore disappointment he felt at not being appointed to the Chair of Surgery, for which he presented himself as a candidate, and which M. Dolbeau, his junior, now fills at the Faculty of Medicine. This was too great a blow for him, and he had never since been the same man. He was the author of a most excellent work, entitled "Pratique journalière de la Chirurgie," which was published in 1868. It is a most practical work, and contains observations of his own Hospital and private practice. His funeral took place on Friday, the 14th, attended by several Professors of the Faculty and not a few of his pupils, and a most touching discourse was pronounced over his grave by Dr. Guibourt, one of his greatest friends and admirers.

You will have seen, by the newspapers, that a Dr. Pillot was lately convicted as an accomplice in the murder of hostages and in the burnings that were perpetrated by the Communists last year; but as there were "extenuating circumstances" in his favour, and owing to his advanced age (he being 63), he was condemned to simple imprisonment for life. I have not been able to ascertain what this man's calling was, but he certainly did not belong to the Medical Profession; and, if I speak of him here, it is to repudiate the fellowship of such a monster. He appears to have been one of those restless characters so commonly seen in France, and before becoming a member of the famous Commune he had several times been condemned for political offences. Almost every calling in life was represented in the ranks of the Commune—even the clergy; but, to the honour of our Profession be it said, not one of its members, as far as I am aware, joined the lawless set. The names of many respectable Physicians and Surgeons were borne on the strength of the Commune, but this was done without their will and consent, and without acting under their orders or pay they afforded Medical and Surgical aid to all who required

their services in a most disinterested manner and without reference to position or creed.

Paris is just now so thronged with beggars that the Prefect of Police has added to his staff a Medical officer, whose special duty is to examine the blind and maimed so as to prevent imposture; but I would suggest the more salutary measure of sending all away to their native town or village, where they ought to be supported at the public expense, and thus relieve the already overcrowded capital to which workmen and others flock to obtain a livelihood. Among the maimed may be seen a number of armless and legless young men, the greater part being no doubt victims of the late war and insurrection; but, as they are otherwise strong and able-bodied, it strikes me that they may in some way be utilised for the public good. I would therefore venture to submit this as a problem worthy the consideration of political economists.

But while Paris is being thronged the authorities are alarmed at the decrease of the population throughout France from causes independent of the war, but said to have existed for the last twenty years. This period has been maliciously fixed upon as corresponding with that of the Empire, to which, besides other misdemeanours, the vile practice resorted to for limited population is ascribed. A certain Deputy lately went so far as to declare in open assembly that the republican form of government was the most favourable for the propagation of the species. How he came to this absurd conclusion it is not for me to say; but the worthy Deputy lost sight of the fact that there was one monarchy at least in the world in which the subjects were as prolific as any people can be, and, notwithstanding the efforts of the followers of Malthus, who lived before the Empire, these subjects carry out the divine precept, "increase and multiply"—the sovereign and royal family setting in this respect the best example. I need hardly say I here refer to old England. But, according to a report lately submitted to the Academy of Sciences by Dr. Decaisne, England is not the only country that has the advantage over France in this respect; and the latter has only to compare her population with that of other States, and she will find that she stands lowest in the scale as regards the fecundity of marriages, the number of births, and the proportion of these to deaths. Taking Prussia as his standard of comparison, Dr. Decaisne has found that in that kingdom to 100 marriages there were 460 births, whilst in France there were only 300; in the former country the number of births annually to each 100 inhabitants amounts to 398, whereas in France it is only 255; and, lastly, the proportion of births annually to each million inhabitants in Prussia is 13,300, whilst in France it is only 2400. These figures speak for themselves, and the cause of the progressive depopulation of France must be sought elsewhere than in the particular form of government.

In my last I mentioned as one of the results of the late war the discovery that France was the most favoured country in Europe. I have now to announce another, and that is that "the Prussians are not Germans." The French have discovered not only that the Prussians are not Germans, but, at a meeting of the Anthropological Society, it was shown by no less an authority than M. de Quatrefages that they were not even Europeans in the strict sense of the term; they are Asiatics, and belong to the Mongol race. It is therefore preposterous, he added, to talk about German unity, and still more so to constitute nations or political groups on ethnological grounds.

In the practice of Medicine, as in other worldly matters, certain things are in fashion for a certain time. Bleeding and mercury have had their day, cod-liver oil and chloral hydrate are already on the wane, alcohol and bullock's blood are now in vogue among the Parisians—the former for fevers and all inflammatory affections, and the latter for anæmia and pulmonary phthisis. It is a curious sight to see the number of patients of both sexes and of all ranks and ages who flock to the slaughter-house every morning to drink of the still fuming blood of the oxen slaughtered for the table. I was struck at the facility with which young ladies take to it, and I have heard many say that they prefer it to cod-liver oil. I shall not enter into any theoretical speculations as to its *modus operandi*, but what I can vouch for is, I know of several cases of anæmia that have been cured, and some of phthisis pulmonalis greatly benefited by the treatment—at least, as much as they would be under cod-liver oil. For the more fastidious, however, a pharmacion has prepared an extract of blood, which is administered in the form of pills, each of which, weighing about three grains, is said to be equivalent to about half an ounce of pure blood.

M. Boussingault, a distinguished chemist, lately read a paper

before the Academy of Sciences, giving an account of his researches on the composition of the blood, and expressed his surprise that, containing as it does all the constituents of a perfect aliment, it is not more generally employed as food. This is a subject worthy the consideration of philanthropists, especially in these days, when the price of meat is everywhere steadily increasing—at least, among the meat-eating population; and it strikes me that the rivers of blood that are daily spilt on the ground in the slaughter-houses might be utilised as food. In Europe, pig's blood is the most generally consumed in the form of sausages, but that of all animals, without distinction, might in this way be more usefully employed. It is well known that in the steppes of South America the natives have for a long time used as food the blood of the animals they chased, which they previously coagulate and season with different condiments.

According to M. Boussingault, of all nutritive substances the blood of animals contains the greatest quantity of iron, and, although varying in different animals, it is in physiological conditions found in certain fixed proportions in the blood. In man, to 100 grammes of blood, M. Boussingault found 51 milligrammes (a) of iron; in that of the ox, 55 milligrammes; of the pig, 59 milligrammes; and in that of the frog, 42 milligrammes. But it was not only in red blood that iron was found: the worthy *savant* detected it even in colourless blood; and after some experiments he found that the blood of snails contained as much iron as that of the ox or calf, and this he thought was sufficient to demonstrate that the red colour of the blood is not due, as is generally supposed, to the presence of iron in that liquid.

GENERAL CORRESPONDENCE.

PUBLIC HEALTH BILL.—MEDICAL OFFICERS OF HEALTH.

LETTER FROM DR. W. WOODWARD.

[To the Editor of the Medical Times and Gazette.]

SIR,—The importance of this subject at the present time will I trust be a sufficient apology for my again troubling you with it. I gave last week three or four reasons why I consider Union Medical Officers are unusually well qualified to undertake the duties of Officers of Health. Allow me to say in addition, that by giving the Union Medical Officers a higher status, the opprobrium which is generally attached to them (and through them to the Profession generally), especially in large provincial towns, will in great measure be removed. I might enlarge on this subject, but will content myself with reminding you that they are about 4000 in number, and represent about one-fourth of the Profession in the kingdom.

To show the importance of some change being made, I will merely remark that in Worcester the death-rate is now exactly the same as it was in the year 1850—viz., 23 per 1000—notwithstanding that we have spent £71,000 or £72,000 in public matters, and are now just landed in a Chancery suit.

The opposition to the Public Health Bill altogether will I am sure be very great, and I trust the Profession will rise as one man and support it. Domestic reforms are generally postponed until *next* session, when war breaks out, or Mr. Gladstone again mounts his political hobbyhorse, or some calamity occurs—when domestic reforms again go to the wall.

We all know the saving of life and money, and other good, which has attended the Contagious Diseases Act (animals.) If Mr. Stansfeld will give us dispensaries in large towns, and make an adequate arrangement for the appointment of Union Medical Officers as Officers of Health, we shall then have a Contagious Diseases Act (human beings), which will doubtless be attended with the same happy result as the former.

Worcester, June 17. I am, &c., W. WOODWARD, M.D.

LETTER FROM MR. J. WICKHAM BARNES.

[To the Editor of the Medical Times and Gazette.]

SIR,—I wish kindly to ask all Poor-law Medical Officers to send me, on post-card, an answer to the following inquiry, mentioning the Union to which they are attached:—

Do you prefer being appointed sole Health Officers under inspectorial supervision of Local Government Boards, or Deputy Health Officers having one of your local Medical

(a) A milligramme is the one-thousandth part of a gramme, which is equal to about fifteen grains.

men appointed as Medical Officer of Health between you and the Board?

I may take the present opportunity of assuring Poor-law Medical Officers that Mr. Stansfeld has given a complete denial to the erroneous statement which has been made, and which has had the injurious effect of getting up petitions against the Bill, that the additional sanitary duties will not be attended by increased remuneration. I am, &c.,

J. WICKHAM BARNES.

12, George-street, Mansion-house, June 18.

EXAMINATIONS AT THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

[To the Editor of the Medical Times and Gazette.]

SIR,—“There must be something rotten in the state of Denmark.” The examiners of the Royal College of Surgeons of England are pursuing a course equally disastrous to the College and to the Profession. The rejections for some time past of candidates for their diploma have attracted the attention not only of students, but of their parents and guardians. The number of these rejections has of late been without parallel in the history of the College. When Astley Cooper, Benjamin Brodie, Robert Keate, and Robert Liston were examiners, it was admitted that candidates were not rejected on merely technical points—and I mean by this on microscopical questions, and others equally useless to Surgeons in general practice. How is it, I will ask—and I am prepared to prove the fact—that the best men of the best schools have been rejected? The answer is clear. Either the best men have received honours to which they were not entitled, or some of the examiners of the Royal College of Surgeons of England are not capable to discharge their duties in a manner which is satisfactory to the Profession. I, for one, am so satisfied of this conclusion, that for the future no pupil of mine shall present himself for examination at the College in Lincoln's-inn-fields. I shall send them to the College of the “modern Athens,” where I shall know, if they be rejected, it will be on practical and just grounds.

I am, &c.,

A FATHER.

P.S.—I enclose my card, as a guarantee of good faith.

HAY FEVER NON-ESTIVAL.

LETTER FROM DR. R. BARRATT.

[To the Editor of the Medical Times and Gazette.]

SIR,—A month ago I was requested by a lady, at midnight, to see her coachman, no great distance from my house. I found a married man, of 26 years of age, hardly able to describe his feelings from incessant paroxysms of sneezing, intense lachrymation, and of course much nose-bleeding with it. Veins of head very turgid, conjunctivæ injected, pulse rapid, much dyspnoea, and sense of oppression about heart. With difficulty he asked me to look at his neck, for there I should find an eruption; and also he stated that if he could only lie in bed, his body would be covered with the same eruption, to the immediate relief of his more urgent symptoms; and that this was one of many attacks before during two or three years. Further, he added, “They come on at a minute's notice; I may be mounting the coachbox, and then must give it up.” No season of the year gives him impunity from the malady. I prescribed a brisk powder of hyd. chlorid., and some diaphoretics and pot. carbonat. I stated my views to him, and tried to get him to have some prophylactic treatment next morning when I saw him—but no; he was quite well, and “Sufficient unto the day” was his motto.

I have one or two clinical remarks to make. I never in a long experience in town and country saw a counterpart of this case.

I know the mews is healthy and well drained. I know the ill did not arise from any food, as shell-fish, etc. I know he is a temperate and well-conducted young man. And here *certainly* ends, and my theory begins. I should just think it probable some neuro-pathologists might hint, “Malarial miasm somewhere caught your patient.”

My opinion is that it is a case of “hay fever non-estival.” That he has a *latent susceptibility*, and after opening, as is his duty, hay-bundles from different sources of supply, the pollen of some plant is imbibed, and develops the intensely catarrhal condition of the mucous membranes of head and lungs.

Hitherto I should have believed hay fever never began before June.

The news is very healthy, and has no kindred cases, and never has had.

The rapid retirement of the symptoms by twelve o'clock next day surprised me as much as the invasion. Had he responded to my advice I should have prescribed empirically arsenic for him. I should add, the eruption was something like urticaria wheals.

I am, &c.,
R. BARRATT, M.D., F.R.C.S., etc.

"PITYRIASIS RUBRA."

LETTER FROM DR. SPENDER.

[To the Editor of the Medical Times and Gazette.]

SIR,—A letter from Dr. H. S. Purdon on the above subject appears in the *Medical Times and Gazette* for April 20.

I have seen only one case of this rare form of skin disease, and it ended in death after many months of suffering. The following is a clinical sketch of the case so far as it was under my own care:—Mr. K., a gentleman residing in Wiltshire, came to Bath to consult me in September, 1869. His health was then tolerably good, and the skin irritation not extensive; but there were certain tracts over the thigh and abdomen which were very red, and gave rise to a quantity of branny scales. He bathed in the Bath thermal waters on alternate days, and took an effervescent dose of citrate of potash every six hours, and tranquil nights were obtained by a moderate dose of morphia, administered subcutaneously.

After staying a month in Bath he returned home with no decided benefit. Very quickly, with the approach of winter, the redness and irritation of skin increased, both in extent and intensity. Small doses of arsenic were now given, and a sulphur-vapour bath was used once a week, but the suffering was appeased only by subcutaneous injections of morphia, which were resorted to by the patient's friends much more frequently than was at all justifiable. Twice in December, 1869, and once in January, 1870, I had the advantage of a consultation at the patient's house with Mr. Barrett, of Pewsey. Nothing gave any permanent relief, but a weak tar ointment was the best local application. I did not see Mr. K. any more, nor have I ever heard from Mr. Barrett about him; but I learned from other sources that he lingered in much misery, and died, quite worn out, in the spring of 1871.

Bath, June 1. I am, &c., JOHN K. SPENDER, M.D.

REPORTS OF SOCIETIES.

THE PATHOLOGICAL SOCIETY.

TUESDAY, MAY 21.

Mr. HILTON, F.R.C.S., in the Chair.

THE Morbid Growth Committee presented reports on various tumours submitted to their examination, including one from Mr. Waren Tay, which was pronounced to be a lymphadenoma; a breast from Mr. Cooper Forster, which was a fibroma; and a specimen from Mr. Squire of recurrent disease of the breast carcinomatous in character.

Dr. SANDERSON then exhibited some Microscopical Specimens illustrative of his views on Pyæmia, and to answer objections, especially that some foreign matter had been produced of a septic nature. The liquid from the peritoneum contained minute organisms of a rounded form. This was most intensely active. Bacteria also existed in the blood of the animal whence this was taken. Another slide was intended to show that this was due to ordinary inflammation only. A third showed fluid from an abscess in the thigh of an infective kind; in this organisms were found on removal.

Mr. JOHN WOOD exhibited the Genitals and Pelvis of a Hermaphrodite, aged 60. This person had passed as a female all her life; she had been married, but her husband deserted her. The general appearance was feminine, and the mammae were very well developed. The pelvis was broad, but its breadth was due to eversion of the upper iliac spines. The sacrum was broad. On the whole the pelvis transversely was female, antero-posteriorly it was male. The subject had very large labia majora, and each contained a well-formed testicle. In the median line was a clitoris, or penis, of some size; below it was a cul-de-sac, an inch in diameter and an inch and a half deep. It lay between the rectum and a well-formed prostate. There was a true vas deferens and vesiculae seminales. The

individual died of cancer. The vas deferens ended in the urethra.

Dr. WILKS thought they were hardly justified in calling this person a male, even though testes were found. If these were not developed the individual always remained feminine. There were other cases reported like this.

Mr. HULKE asked if the cul-de-sac was natural or acquired.

Mr. WOOD said the testes in this case were well developed. He could not say what was the origin of the cul-de-sac.

Dr. EDWARDS-CRISP showed some specimens and models illustrative of Tubercle in Fowls produced by vaccination.

Mr. HOLMES exhibited a specimen of Melanosis of the Penis spreading down the urethra. The man had been ill for several years. He did well after removal. (Referred to Morbid Growth Committee.) Also, a Tumour of the Scalp, apparently sebaceous in nature and diffuse in character, ulcerating all over. At first it seemed epithelioma, but Mr. Hewitt thought it sebaceous. It emitted a peculiar odour. It was removed; pyæmia followed, and death. Microscopical examination said the tumour was epitheliomatous. (Referred to Morbid Growth Committee.)

Mr. JOHN GAY said he had seen a whole family troubled with sebaceous tumours. One he saw with a tumour on the back; he attempted to remove it, but did not quite succeed. The part took on a malignant aspect, and the patient died.

Mr. GAY also showed a Cyst from the Neck of a lady, apparently sebaceous in character. It mainly consisted of epithelium, and contained some leucin and tyrosin. Also, a Sequestrum from the Tibia of an individual who fourteen years before had broken his leg. Since that time there had been pain, and latterly an abscess formed. He trephined, and found a sequestrum of bone in the centre of the tibia where it had been fractured.

Dr. CRISP exhibited a specimen of Softened Cerebellum. The patient was a lady of middle age, who had suffered from recurrent pain in the back of the neck. She died suddenly, and the roof of the fourth ventricle was found softened. The vessels were plugged.

Dr. BARNES asked if she recently had any children. It had been shown that growths inside the brain sometimes originated during pregnancy.

Mr. PADDON, who attended the case, said there had been no child for twenty-three years; and in reply to Dr. Cholmeley, he said there was no diabetes.

Dr. CRISP showed a specimen of Intussusception from an infant, of which it died. After death he could not pull the cæcum and small intestine from the great intestine, in which they were invaginated, even though no lymph was effused.

Mr. HUTCHINSON asked what, then, was the reason why he could not withdraw the invaginated portion. In one case he saw the cæcum projecting at the anus. He opened the abdomen, hooked up the gut with his finger, easily drew it out, and the child recovered.

Mr. ARNOTT exhibited a specimen of Multiple Exostoses removed from the Thigh of a servant girl aged 17. She complained of pain in the knee shooting down the leg. The exostoses were removed by a chain-saw, but the patient did not do well, and ultimately died of erysipelas. There were exostoses on most bones of the body. They could see the structure and nature of such growth in this specimen. It was no outgrowth of the epiphyseal cartilage, as asserted by some; but a kind of cartilage was formed on the surface of the bone, and this ossified.

Mr. T. SMITH asked if the patient was rickety, as such growths were not very infrequent in such.

Mr. ARNOTT said there was no rickety, syphilitic, or other hereditary taint.

Mr. HOLMES said such specimens were not very rare. He asked if it were desirable to interfere with them surgically. He had often seen them terminate fatally. Usually they ceased to grow after attaining a moderate size.

Mr. HUTCHINSON'S view was quite the same as Mr. Holmes's. He had seen patients die after the operation, and he would not interfere again. They were not limited to the epiphyseal line.

Mr. HULKE had no reason to regret removing any. He always fixed the knee, and applied ice after operating.

Mr. DE MORGAN confirmed what was said by Mr. Hulke. It was different when the bursa was interfered with.

Mr. WOOD also concurred in this opinion.

Mr. HOLMES asked if there was any reason for putting the patient to any risk. He thought not.

Mr. ARNOTT said he was unwilling to operate in this case, but the girl was in great pain, and asked to have it removed.

Mr. ADAMS said he removed one from the popliteal space of a boy, as it interfered with motion. He removed it partly subcutaneously. The patient was doing well.

Mr. SUTTON TOWNSEND exhibited a specimen of Ossified Aneurism of the Heart. The organ was large, the left ventricle being larger than the right. In its apex was the tumour shown. There were no signs of it during life.

Mr. SEBASTIAN WILKINSON showed some specimens of Malignant Disease affecting the Eyeball and Brain, from a child aged 3. The eyeball was removed, but the disease extended by the nerve to the brain, affecting the meninges and bones of the skull. There was not very much pain.

Mr. W. ADAMS exhibited the Limbs of a Club-footed Child, on whom he had divided the tendons of the tibialis posticus. The tendons were perfectly repaired. The death took place six or eight months after the operation.

This concluded the work of the session, and after a few words from the Chairman, urging all to send in their contributions to the *Transactions* as speedily as possible, the Society adjourned till October.

CLINICAL SOCIETY OF LONDON.

FRIDAY, MAY 24.

Sir WILLIAM GULL, Bart., M.D., F.R.S., in the Chair.

Dr. BROADBENT related a case in which tumours in the occipital lobe and in the posterior ascending parietal convolution of the right hemisphere had given rise to convulsion and paralysis of the left half of the body. The patient, a boot-maker, aged 65, was admitted into St. Mary's Hospital on October 15, 1871. He had been in good health up to October 7, when he had convulsive movements of the left arm; afterwards he had pain in the head, and on the day before his admission the entire left half of the body was violently convulsed, and he was sick, but never lost consciousness. The convulsions ceased in a few days, leaving the limbs incompletely paralysed, and sensation was diminished. Afterwards he had painful nervous shocks in the left arm and leg, but they gradually recovered power, till on November 10 he had pain in the head, and torpor, gradually deepening into coma, came on. He regained consciousness, however, after the application of a blister to the forehead, but remained very weak, and the paralysis of the left limbs was almost complete. He died on November 30. His mind was quite clear, except for a short time. The back of the eye could not be examined, on account of opacities in the lens. Two gliomatous tumours were found; one about the size of a cob-nut in the upper part of the second ascending parietal convolution of the right hemisphere, projecting from its surface; the other, about the size of a small orange, was embedded in the occipital lobe, not appearing on the surface at any point. Dr. Broadbent thought the tumour in the parietal convolution was probably the cause of the unilateral convulsion and paralysis. Interesting points in the case were the short time during which symptoms had existed, only seven weeks; the instant relief of stertor when the patient was turned on his side, as recommended by Mr. Bowles of Folkestone; and the recovery from coma after the application of a blister to the forehead; the tumours of course remaining, and probably increasing.

Dr. HUGHLINGS-JACKSON thought the case one of very great importance. It was especially interesting with regard to the localisation of changes which produce epileptiform seizures of different varieties. He agreed with Dr. Broadbent that in all probability the hemiplegia resulted indirectly from the anterior of the two lesions, and mentioned a case in support of this opinion. He referred to a case he had recently examined, in which a tubercle the size of a hazel-nut, lying in the third right frontal convolution, was associated with epileptiform seizures beginning in the left thumb. Another interesting point in Dr. Broadbent's case was the absence of mental symptoms. It was well known that a large quantity of one cerebral hemisphere may be destroyed when there are no obvious mental symptoms, but the exact locality damaged has to be taken into account. Dr. Charlton Bastian had brought forward evidence to show that the posterior lobes are the parts concerned in the highest intellectual operations, and Rosenthal has remarked that the psychical disturbance was incomparably more frequent in cases of tumour of the posterior lobes. He (Dr. Hughlings-Jackson) had been led to the conclusion that the right posterior lobe is more important in mental operations than the left, just as the left anterior is than the right. But

he admitted that Dr. Broadbent's case tells very strongly against this hypothesis.

The PRESIDENT had recorded a case of encysted tumour in that situation. The tumour was large and of long standing; there were no mental symptoms. The arm and leg had been in a condition of spasm, but when seen that had ceased. Repeated attacks of convulsions ending in coma carried the patient off. There was a large encysted abscess in the right posterior lobe of the cerebrum.

Dr. ANDREW read a paper "On Wide Daily Range of Temperature in connexion with Vegetations on the Mitral Valves (Rheumatic Disease) and Separation of the Spleen." Wm. Henry C., aged 16, was admitted into Victoria-park Hospital, under the care of Dr. Andrew, on October 27, and died on December 6, 1871. He had had a severe attack of rheumatic fever two years previously, and had never been well since; he had a slighter attack three weeks ago. On admission, he had still pains in the hips; was very pale and thin; pulse 120; tongue coated. His appetite was bad, and he was thirsty. The bowels were confined. He had a slight hacking cough. The dyspnoea was generally worse at night. The urine was of specific gravity 1020, containing a trace of albumen, which was never again found. The lungs were normal. The heart was greatly hypertrophical. A blowing systolic murmur, loudest at the apex and towards the axilla, was also heard posteriorly. The liver was slightly, the spleen greatly, enlarged. For the first ten days after admission the evening temperature ranged from 103° to 105°, the morning temperature from 98° to 101°. He had a slight attack of tonsillitis, and for two days the temperature remained at 103° to 104°; after this the daily variation returned and gradually diminished, the minimum rising and the maximum falling; on the whole, however, the mean temperature was somewhat increased. On December 1 the temperature began to fall, rising again for a few hours on the 4th. On the 6th, an hour or two before death, it was only 94°. At the post-mortem examination nothing was found except the disease of the heart and of the spleen, with one or two small fibrinous wedges on the kidneys also. The spleen grew larger for some time after admission, the gradual diminution in the daily variation of temperature coinciding with the subsequent gradual decrease in its size. The microscopic examination of the blood showed no increase of white corpuscles, but a pale shrivelled state of the red discs. The prominent features of the case were dyspnoea, without any physical evidence of pulmonary or pleural change, the extreme anæmia and muscular weakness, the constant drowsiness, and the absence of rigors and of any form of delirium. He seemed to die at last from cold.

Dr. WILKS had long been looking for a case of blood-poisoning from an arterial source. Before the thermometer was used he had seen such cases, and the temperature seemed to vary day by day. Dr. Ray, of Dulwich, suffered from such a malady. His only symptom was rigors. He had seen another case which occurred in a lady. He had seen several altogether, but had not taken temperatures exactly. The symptoms were mainly pain in the joints and varying temperature, and really depended on blood-poisoning. Kirkes had alluded to them in his paper, but the fact had been overlooked.

Dr. CHOLMELEY said he had now a case—that of a girl supposed to be the subject of rheumatic fever—but the only marked thing was variations in the daily temperature. Certainly there was no typhoid or heart affection.

The PRESIDENT said this was one of the most important pages in modern pathology. The condition gave rise to all kinds of doubts.

Dr. HUGHLINGS-JACKSON had seen a case of right hemiplegia with loss of speech, in which, as there had been a history of periodical shiverings, it was contended by one Physician that the cause of the palsy was malarious poisoning, and this notwithstanding that there was valvular disease of the heart. Besides blocking of a branch of the left middle cerebral artery, infarcts were found in the spleen post-mortem.

Dr. POWELL asked if there was anything in the appearances to show that the date of the one corresponded with that of the other.

Dr. BAÜMLER asked if there was pain in the spleen. In a case of embolism of that organ collapse and pain followed, but no variation of temperature. He had seen a case with these variations. The diagnosis was doubtful. Acute endocarditis was found after death. In pyæmia you might reduce the temperature by quinine, but this did the patient no good.

Dr. WEBER thought such conditions were more frequent than was generally acknowledged. Some cases of so-called

rheumatic fever were of this kind. He remembered a case of tonsillitis where the organs suppurated. It was almost healed when symptoms of rheumatic fever occurred, with great variation of temperature. This terminated by pneumonia and pleurisy. There was no apparent disease of the heart. In another case it was apparently a pneumonia which gave rise to the poisoning. Symptoms of fever came on, and the spleen was affected. This was really a case of chronic embolism. In another case we might have tuberculosis; there is only a step between the two.

Mr. CALLENDER referred to the case of a boy subject to repeated attacks of erysipelas. His temperature varied from normal to 106° F. in twenty-four hours. When the temperature went up they were sure to find next day a patch of erysipelas. They removed some necrosed bone from his tibia a few days after his temperature went up. He predicted an attack of erysipelas; next day it was out.

Dr. ANDREWS, in reply, said the range of temperature corresponded with the condition of the spleen. It was greatest when it was largest, and diminished with it. Some infarcts remained as cicatrices. Some years ago he had seen a case like this in the person of a lady. Often there was an extensive daily range when nothing could be made out.

Mr. THOMAS SMITH read a paper on a case of Strictured Oesophagus, for which Gastrostomy was performed. The patient, A.B., aged 38, was under Dr. Black's care at St. Bartholomew's Hospital. He had suffered from difficulty in swallowing for eight months. For a fortnight before admission he could take no solids, and for a week (as he said) no food of any kind. Treatment by bougies proved of no avail, as nothing would pass the stricture. There was no external evidence of disease of any kind; no swelling, tenderness, or pain; no expectoration of blood or matter. On March 21, 1872, gastrostomy was performed, and an indiarubber tube was introduced. Through this tube he was fed. The patient went on well for four days; and then was troubled by cough, which seemed to set up peritonitis, of which he died at the end of a week. On examination after death, the cause of obstruction was found to be a ring of epithelial cancer surrounding the oesophagus opposite the bifurcation of the trachea, producing complete obstruction, and involving the pneumogastric nerves. The stomach was firmly adherent to the skin and to the parietal peritoneum. Death was caused by peritonitis. Mr. Smith remarked that in this case the operation had been done under circumstances as favourable as were ever likely again to occur. The patient was not excessively exhausted. There was nothing in the local disease to have caused or even accelerated his death at the time when that occurred. The operation was easily performed. There was no failure in the process of union afterwards, and no hindrance to the administration of food; yet the case terminated as have all cases of gastrostomy for obstruction of the oesophagus. The author stated that there were now twelve recorded cases, all of which had ended fatally; and he expressed an opinion that, with our present experience of the dangers of the operation, it ought not to be undertaken when death is imminent from any other cause than starvation.

Mr. MACCORMAC gave the particulars of two cases in which Gastrostomy had been recently performed in St. Thomas's Hospital for Oesophageal Obstruction. In the first case, the patient was operated on by the author on March 19. He survived forty-five hours. In the other, Mr. Le Gros Clark operated on May 7, the patient living for six days afterwards. H. S., aged 40, was admitted to St. Thomas's Hospital under the care of Dr. Clapton. Up till the commencement of the present illness, about twelve months before, he had enjoyed excellent health. No history of syphilis or of cancer was obtained. One day he suddenly experienced difficulty in swallowing. This difficulty, with periodical remissions, steadily increased until he sought Hospital treatment. On admission, he was weak, emaciated, and scarcely able to swallow even small quantities of fluid. He did not complain of pain except when trying to swallow food, but the effort to do so always induced most distressing retching and cough. There had never been either pus or blood in the discharges. After consultation, it was deemed expedient to try to feed the man through an artificial opening made in the stomach, through the abdominal wall. Accordingly, at ten o'clock on March 19, Mr. MacCormac made an opening into the stomach, securing the cut edges of the viscus to the wound in the abdominal parietes by means of interrupted suture. The patient bore the operation well. There was no shock, and the vomiting and cough completely disappeared, giving him very marked relief. Food was introduced into the stomach by an indiarubber tube with a funnel, which allowed the fluid to gravitate into the organ. Surgical interference came too late,

however, to make any material change in the patient's condition. It did not, perhaps, hasten his end; but he became weaker, and died on May 21, forty-five hours after the operation. An examination after death showed that a cancerous stricture existed low down in the oesophagus, and that by the spread of the disease the lung, in which was found a gangrenous abscess cavity, had become seriously implicated. The edges of the stomach were glued by lymph to the parietes, and in the abdominal cavity there was no trace of peritonitis. In Mr. Clark's patient the antecedent history was very similar to that of the last. Difficulty of swallowing suddenly appeared during eating, and this steadily increased until he came to Hospital, when he finally became unable to swallow almost anything. Some attempts were unsuccessfully made in each case to pass a small elastic bougie. After consultation, the operation of gastrostomy was performed by Mr. Clark on May 7. Food was first introduced into the stomach thirty hours after the operation. The patient experienced great relief for four days by reason of the cough and efforts to vomit completely ceasing; but then the cough returned, the adhesions partly gave way, and he died six days after the operation. Very extensive epithelial disease was found in the oesophagus, and an ulcerated opening had been formed between it and the lower part of the trachea. There was some peritonitis, but it was limited to the neighbourhood of the wound. Mr. MacCormac considered that the operation itself was not necessarily dangerous, and that the relief from the great distress, inducing coughing and retching, caused by futile efforts to swallow, which was observed in a marked degree to follow the operation in both these cases, was encouraging. Even although the operation only prolonged life a little, it seemed possible to give great comfort by it, just as in a similar way the operation of colotomy gave great relief in cancerous disease of the rectum. He did not consider that Surgeons were as yet quite in a position to decide whether or not gastrostomy was a proper operation to perform for impassable stricture of the oesophagus. He thought further experience, especially of operations performed in an earlier period of the disease, desirable, and would not on another occasion hesitate to perform gastrostomy in a suitable case.

Dr. WILKS said there was not on record a single case of recovery from this operation, and he had never known a single case of non-malignant stricture which required such treatment. Even a single exception to the fatal termination would be encouraging, but there was none. The patients in such maladies did not die of starvation. The disease spread to the lung, the vagus, or something of the kind carried them off.

The PRESIDENT said it was really a question of easy death: Which was the easiest?

Mr. T. SMITH said some had lived after such an operation for other maladies. The patients after it were terribly shaken by cough. He threw a doubt on the successful cases of gastrostomy for foreign bodies. There were now twelve fatal cases from this operation on record.

OBSTETRICAL SOCIETY OF LONDON.

WEDNESDAY, JUNE 5.

J. BRAXTON HICKS, M.D., F.R.S., President, in the Chair.

THE following gentlemen were elected Fellows of the Society:—C. J. Bracey, M.B., Birmingham; G. B. Denton, Esq., Liverpool; H. M. Fernie, Esq., Macclesfield; C. Leonard, Esq., Bristol; M. Tuchmann, M.D.; and C. B. Waller, Esq.

A report by Drs. BLACK and POTTER on the growth attached to the mouth of a fœtus, and exhibited at the last meeting, was read. It was found to spring from the body of the sphenoid bone, and was composed of numerous pieces of bone and cartilage united together into a compact mass, with here and there little deposits of fat. The reporters believed that it probably represented a secondary fœtus.

Dr. SQUAREY read an account of the cases of three sisters in whom the Uterus and Ovaries were absent. The congenital defect seemed to have been derived from the mother's family. The first patient was 26 years of age, and had never menstruated. She suffered from pain across the back occasionally, but not regularly. The vagina was represented by a cul-de-sac one inch and a half or two inches long. No sign of uterus by vaginal or rectal examination. The pubes was devoid of hair. The breasts were well developed. The second patient was 18 years old. Menstruation had never appeared. A vaginal examination disclosed exactly the same condition as in her sister, except that the vaginal cul-de-sac was shorter and

smaller. The third sister, aged 16, was also the subject of a similar deformity. There was nothing in the external appearance of either of these to lead anyone to expect that such a malformation existed.

Dr. PHILLIPS said that in 1870 there were two sisters under his care at Guy's Hospital, in whom no trace of a uterus could be found. One was 20 years of age, rather diminutive in stature. The external genitals were well formed, and the mammary glands were well developed. The vagina was represented by a short canal, about an inch long, terminating as a cul-de-sac. So far as an examination during life could decide, there was no uterus, and the ovaries could not be felt. Her sister, aged 21, was found to be the subject of a malformation similar in every respect. Neither of them had ever menstruated. It was worthy of notice that in Dr. Squarey's cases and his own the breasts were developed. It was, of course, possible that the ovaries existed; but in one case he saw, the breasts were large, though it was in the highest degree probable that all the internal genital organs were absent. There was no opening between the urethra and the rectum, and the intervening septum was about the natural thickness of the urethro-vaginal septum. The finger in the rectum and the hand above the pubes met easily.

Dr. HEYWOOD SMITH referred to the case of a woman, aged 30, who had not menstruated, and in whom there was found merely a small knob, about the size of half a filbert, to represent the uterus. In another case there was no uterus, as far as he could ascertain; a very short vagina existed, and a wide urethra, through which menstruation occurred. In a third case there was a normal uterus, but total absence of menstruation, and she had full whiskers and beard.

Dr. ROGERS had had under his care three cases of absence of the uterus in otherwise well-formed and healthy women. The vulva, the labia, and the mammae were well developed, but the most careful examination, even with the hand in the rectum, the patient being under the influence of chloroform, failed to find any trace of a uterus.

Dr. TILT was not prepared to admit that the ovaries were absent in women who owned to sexual feelings and presented a normal development of the mammary glands; probably in such cases the ovaries were placed beyond the reach of the observer's finger.

Dr. BARNES said that Kussmaul declared that the uterus and ovaries were rarely altogether absent. There was a specimen, however, in University College Hospital, from a girl, aged 21, who had never menstruated. No ovaries could be seen, and the uterus retained the characters of that of a young child. In one case he had dissected up an artificial vagina a year ago, and by means of an elastic dilator this was well preserved.

Dr. WILTSHIRE agreed with Dr. Phillips that cases of various degrees of malformation of the female genitals were not very rare. He suggested that some information might be obtained by external measurements of the pelvis, and by the condition of the breasts. He mentioned cases where patients had borne children after treatment of malformations supposed to be irremediable.

Dr. MATTHEWS DUNCAN read a paper on "Long Delay of Labour after discharge of Liquor Amnii." A patient was expecting her confinement in June, 1872. On March 10 there occurred during the night a copious flow of liquor amnii, and slight irregular pains were felt. The liquor continued to discharge freely but not constantly. The uterus gradually diminished in bulk, and in a fortnight's time it felt not much bigger than a large adult foetal head. On April 25 regular pains came on, and the child was born alive, but survived a very short time. There appeared no doubt that pregnancy continued for forty-five days after the discharge of some of the liquor amnii, and the foetus continued to live for several weeks in a very contracted uterus. The author considered that the hypothesis resorted to by Burns in explanation of such cases—that the torn membranes may be healed—was not only without rational grounds, but contrary to all we know. Among the conditions which may be mistaken for premature evacuation of liquor amnii he mentioned discharges of urine, watery discharges, such as are sometimes observed in virgins, and whose source may be Cowper's gland or the cervix uteri, discharges from the uterus of a fluid occupying the anatomical position of hydroperionic fluid, discharge of liquor chorii, discharge of the liquor amnii of one ovum in a case of plural pregnancy, discharge of the fluid in a cyst described as occurring between the chorion and the amnion. In the above case, however, that the discharge was liquor amnii was proved by the subsidence of the uterine tumour, by the diminution of its bulk, by the

increase of its hardness, by the complete absence of discharge of liquor amnii at the time of labour, by the compressed state of the child, and by the almost complete rubbing off of the vernix caseosa. Here the discharge of liquor amnii in occasional gushes took place till labour came on, and long after it was evident that the uterus had been for the time as completely evacuated of this fluid as it could be. But this circumstance was easily explained by the accumulation of newly secreted liquor amnii. Winkler's researches proved that the amniotic membrane has the power of secretion and absorption in a high degree. The author believed that firm compression of the foetus may take place without active uterine contraction, and it is firm compression by active uterine contraction that is incompatible with the continuance of pregnancy, or of foetal life; not such mere firm compression as is seen in a case of missed miscarriage or missed labour. The explanation of the partial and repeated discharges of liquor amnii by a high position of the rent in the membranes and some sort of valvular action seemed to the author chimerical. The great question suggested was, Why do conditions which generally induce labour fail to do so in these rare cases? In our present state of utter ignorance as to the cause of the coming on of natural labour, it is not to be wondered at that we cannot tell the cause of its failing to come on. It is highly probable that he who discovers the cause of the coming on of natural labour will also be able to explain why in these abnormal cases labour does not come on.

Dr. SNOW BECK mentioned the case of a lady who, when six months pregnant, had a copious discharge of clear watery fluid. Labour came on at the natural term, and there was no escape of liquor amnii. Also another case in which at the fourth or fifth month there was a sudden discharge of two or three quarts of perfectly clear fluid, which continued more or less all night. This recurred every evening (except during one week) for ten weeks, when she was prematurely confined, and died from hæmorrhage two hours after the removal of the placenta. Dr. Beck believed this to be an exudation from the vagina, and perhaps the great venous congestion was relieved by rest during the night, and again increased by being about all day. He did not think that either set of glands in the uterus was involved in its production.

Dr. BARNES believed that hydrorrhœa, especially in early pregnancy, resulted from a hypertrophied condition of the glands of the uterine mucous membrane, and this might explain Dr. Beck's second case. He did not believe in the rupture of the membranes and the rent healing. He might offer a speculation in relation to the cause of labour. Why labour did not so readily come on under provocation before the natural term of gestation was because the nervous centres had not yet attained that remarkable degree of irritability which characterised them at full time. There was a less ready response to excito-motor stimulus.

Dr. RASCH said he found the characteristic smell of the liquor amnii a very valuable help to diagnosis in cases of alleged discharge of the waters.

Dr. MADGE read an account of an interesting case of Uterine Fibroids complicating Pregnancy. The patient was 40 years old, pregnant for the first time. Eight distinct swellings could be made out. All the tumours except one increased in size during pregnancy. Labour tedious; delivery by forceps; hæmorrhage from imperfect contraction. The hand in the uterus detected its walls to be full of nodosities. In three months one tumour was still the size of a cocoanut; all the other tumours were much smaller. In six months three of the smaller ones had disappeared. In sixteen months the uterus and the large fibroid were still but slightly lessened in bulk, and two of the smaller tumours were distinctly made out, but only traces of the others remained.

Dr. MUNDE exhibited for Professor Simon, of Heidelberg, a Scoop for removing the superficial portions of uterine cancer when more complete measures could not be entertained.

The PRESIDENT, Dr. BARNES, and Dr. RASCH assented generally to the principle of dealing with cancer by removing the superficial proliferating portions which were the seat of hæmorrhage and foul discharges. Dr. Rasch had used Simon's instrument. Dr. Barnes said it did not differ in its use from Marion Sims's eurette which he used.

Dr. LÖWENFELD, says a German correspondent, has purchased for the University of Strasburg the whole scientific apparatus and all the instruments which belonged to Alexander von Humboldt at the time of his death. The collection is said to be most valuable.

LEGAL INTELLIGENCE.

CONVICTION UNDER THE MEDICAL ACT.

At Marlborough-street, Dr. John Hamilton, of 494, Oxford-street, was summoned before Mr. Knox for unlawfully pretending to be, and taking and using the name and title of, a Doctor of Medicine, Surgeon, and General Practitioner, implying that he was registered under the Medical Act. Mr. Froggatt appeared for the prosecution, and Mr. Ricketts for the defence. Mr. Froggatt said the prosecution was instituted under the 40th section of the Medical Act, for improperly holding himself out as a Doctor of Medicine. The defendant had a shop in Oxford-street, and on the door and on a plate under the window, and on the window itself, there was "Dr. Hamilton, Surgeon, &c., Medical advice"; and he otherwise held out that he was a Medical Practitioner, and a printed book would be produced, issued by the defendant, in which he described himself as M.D., Surgeon and Accoucheur, and professed to give Medical advice. He should show that the defendant was not entitled to do so, that his name was not on the "Medical Register" issued by the Medical Council, and that he had rendered himself liable to a penalty of £20. Mr. Deakin, House-Surgeon at the Male Lock Hospital, Dean-street, proved that the defendant had on his lamp "J. Hamilton, M.D., Accoucheur"; on a brass plate under the window, "J. Hamilton, M.D., Surgeon;" and on the window, "Medical advice." The place had the appearance of a Surgical appliance shop. He bought a book at the shop with "J. Hamilton, M.D., Surgeon," on it. He did not know that the defendant was a graduate of the Metropolitan College of New York. (Diploma produced.) Dr. Francis Hawkins, M.D., Registrar of the Medical Council, produced the "Medical Register" referred to in the Medical Act, and stated that the name of John Hamilton, 494, Oxford-street, was not in it. In reply to Mr. Ricketts, Dr. Hawkins said the names of Kirk and Richardson were on the Register, they being Members of the Metropolitan College of New York; but if they were not Members before 1858, when the Act passed, they could not be registered, as the diplomas of foreign and colonial colleges were not recognised by the Act. The defendant had never applied to be registered. He knew that Mr. Mansfield and Mr. Raffles, at Liverpool, refused to convict in a similar case, and that the refusal on appeal was confirmed by the judges. Mr. Henry Chandler, Surgeon, Berners-street, had made a complaint to the Medical Council several times, and asked them to prosecute the defendant. He received a letter from the Council, and this summons was taken out. In reply to Mr. Ricketts, witness said he used the title of Doctor as a right, being a Member of the Royal College of Surgeons, and registered. Dr. Hawkins, when appealed to, said the witness had no right to call himself Dr. Chandler, as he was not a Member of the Royal College of Physicians. Mr. Chandler had asked for protection against the defendant, who called himself a Doctor, and who had set up in opposition to him. Mr. Ricketts said witness also improperly assumed the title of Doctor. His client had a diploma as Doctor, and had undergone a severe examination before he obtained it. Mr. Froggatt said it was well known that any number of documents called diplomas were offered for a payment of £10 to £17. Mr. Ricketts said the kind of diploma which the defendant possessed had been sanctioned by an Act of Congress. Mr. Knox had nothing to do with that. Mr. Ricketts then argued that the summons must fail, inasmuch as the defendant had done nothing more than he was entitled to do under the diploma he had obtained after undergoing a thorough examination as to his Medical qualifications. He did not find anything in the Medical Act which prohibited him from practising, if holding a foreign diploma, and if duly qualified, although he might not be registered. The case had already been twice decided at Liverpool, to the effect that a person so qualified might practise, and that decision of the magistrates had been confirmed on a special case by the judges. He submitted that the mere assumption of the title "Doctor" did not imply or intend to imply that the defendant was registered under the Act. Unless, then, it was found that the defendant falsely assumed the title of "Doctor," he submitted there was no offence. Mr. Froggatt contended for the other view, and quoted authorities in support of his argument. Mr. Knox said that this was a summons taken out under the Act of 1858 for the regulation of the qualifications of Practitioners in Medicine and Surgery. The object of the Act, as stated in the preamble, was that persons requiring Medical aid should be able to distinguish qualified from unqualified Prac-

tioners. The 40th section supplied us with the test appointed by the Legislature. It was this—"Any person wilfully and falsely pretending to be, or taking or using the name or title of Physician, Surgeon, General Practitioner, etc., implying that he is registered under the Act or is recognised by law as a Physician, Surgeon, etc., shall upon summary conviction for any such offence pay a sum not exceeding £20." Again, in the 37th section it is enacted that no certificate required from any Practitioner be valid except the person signing the same be registered under the Act. It is not pretended that the defendant is either registered or that he has applied to be registered under the Act. But a diploma from New York College (which is admitted by consent) is set up as entitling him to use the qualification of "Doctor, Surgeon, etc.," without registration. Allowing for argument's sake the validity of this document, he took it that the defendant was out of court by the very date of the diploma he had set up. By the 11th clause of Schedule (A) the Medical Council were permitted to grant registration to Doctors of Medicine of any foreign and colonial university who had actually practised in the United Kingdom before 1858, the date of the Act. No power is given to grant registration to gentlemen of this class save as thus provided. The Council could not, if they would, have granted registration to the defendant; and, as it appeared to him, under the 40th section, without registration he cannot legally use any of the names or titles mentioned in the section, the defendant must be fined forty shillings and costs. Mr. Ricketts gave notice in writing that he applied for a case for the Queen's Bench. It was arranged that a case should be agreed upon between the solicitors, and then Mr. Knox said he would grant the application.

NEW INVENTIONS.

DR. CLERTAN'S PEARLS.

(L. Frère, 19, Rue Jacob, Paris; and Jozeau, 49, Haymarket, London.)

UNDER the title "*Perles*" Dr. Clertan, of Dijon, some years ago introduced little gelatine globules, containing various medicaments, and especially those of a nauseous order, of which most patients desire to avoid the taste. The peculiar advantages claimed for Dr. Clertan's "pearls" over similar preparations are that they are smaller, rounder, and more easily digested; and we may add, as a recommendation of the capsule form of preparations in general, that they convey a drug to the organ fitted to absorb it, without wasting any upon the mucous membrane of the mouth and fauces. The contents of the "pearls" before us are ether, chloroform, turpentine, and the ethereal tinctures of assafoetida, castor, valerian, and digitalis. Their finished workmanship is a strong recommendation.

TWO NEW FORMS OF ENEMA APPARATUS.

Most of the enema apparatus hitherto invented present some disadvantages which militate against their usefulness. The ordinary brass enema apparatus is cumbersome, and extremely inconvenient to use alone, as it needs both hands to work it, so that it is difficult to keep the canula *in situ*. Again, if not often used, the packing on the piston is sure to get very dry, and in hot climates especially the instrument is in this way often rendered useless, it being no easy matter to pack a piston properly. The "irrigateur" of Dr. Eguisier is easy to manipulate, but it is very bulky, very liable to get out of order, and could only be repaired by an instrument maker. Perhaps the best form of apparatus yet made is either the Higgenson or Kennedy. They are both of them portable, and can be used with one hand, but they have also both of them one radical defect—namely, the vulcanised indiarubber ball. However good this may be when first manufactured, after a time it undergoes some molecular change and becomes worthless. Again, if the ball be made thin it fills but slowly; and if made thick it is very tiring to the hand; but, worse than all, oil or turpentine (so often used in enemata) soon destroy the indiarubber. Mr. Shepard has endeavoured to remedy all these various defects in two forms of enema apparatus made by Messrs. Arnold of 35 and 36, West Smithfield, E.C. It is proposed to call that depicted in Fig. 1 the "Simplex," and the other, Fig 2, the "Facilis."

The "Simplex" consists of two cylinders, sliding easily the one within the other. The upper and smaller of the two is

closed at the top as shown in the engraving, and is kept raised by means of a spiral spring which rests against the bottom of the lower cylinder. This latter is closed at its lower end by the solid base on which the instrument stands, and its upper end is made of rather larger diameter than the rest, so as to form a circular chamber, which has holes pierced at its under surface. An inlet-valve is fitted into the base of the lower cylinder, and an outlet-valve to an opening leading to a space between the inner and outer surfaces of the lower cylinder, which space is continuous with the discharge-pipe. To use the apparatus, it is placed in a basin or other vessel containing the liquid, the upper cylinder is pressed down by the hand, and then allowed to rise again by the action of the spring; it thus acts as a piston, and the fluid is drawn through the inlet-valve into the lower cylinder. On again depressing, the greater part is forced through the outlet-valve, and the little that escapes between the cylinders is forced into the circular chamber, from whence it runs through the holes on its under surface back into the vessel.

The "Facilis" is made essentially on the same principle, but it is constructed to feed itself from any vessel, and is intended to be used in cases where it would be inconvenient to stand the apparatus in the fluid—for instance, when it is required to be used in bed, or with delirious or unruly patients. It consists

FIG. 1.

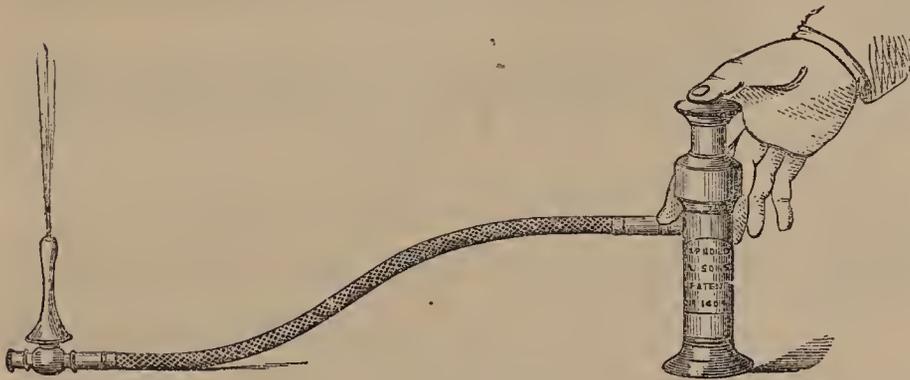

FIG. 1.—The Simplex.

of a cylinder, having the upper part of larger diameter than the lower, and fitted with a water-tight cover, which is pierced with an opening fitted with a stuffing box.

FIG. 2.

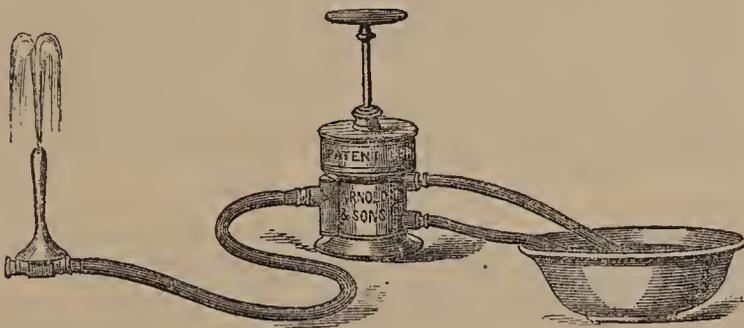

FIG. 2.—The Facilis.

Inside the cylinder is a *loosely-fitting* metallic piston, without packing, kept pressed against the cover by means of a spiral spring. In the centre of the upper surface of the piston is a depression corresponding with the opening in the cover. The piston-rod, which is loose, drops into this. An inlet valve is fitted to an opening in the lower part of the cylinder, to which the feed-tube (the lower of the two shown in the engraving) is attached. The upper tube is fitted to an opening on the under surface of the enlarged part of the cylinder, and acts as a waste-pipe. An outlet-valve is fitted to the opposite side of the cylinder, and is connected with the discharge-pipe. To use this apparatus the feed-pipe and waste-pipe are both allowed to dip into the vessel containing the fluid. Then, on alternately depressing the piston and allowing the spring to raise it, the liquid is drawn into the cylinder through the inlet-valve, and forced through the outlet-valve. What little makes its way beside the loosely-fitting piston gets into the large upper part, and runs through the waste-pipe back into the vessel.

The advantages which these apparatus are supposed to possess are—

1st. They are very easy to use, needing only one hand to work them.

2nd. They are eminently portable, the "Simplex" being only

four inches high and an inch and three-quarters in diameter at its widest part. The "Facilis" is three inches high and two inches in diameter.

3rd. There is no packing on the piston, and they are so simple in construction that it is next to impossible they should get out of order.

4th. They can be taken to pieces to clean, and put together again in a few seconds, and without trouble.

5th. They are made entirely of metal, and the springs are of plated steel, so they are not likely either to rust or become weakened.

OBITUARY.

DR. JOHN BAYLDON.

It is with regret that we record the death of Dr. John Bayldon, Acting Superintendent of the Ararat Lunatic Asylum, Dr. Bayldon was a man of very rare attainments. He was Bachelor of Medicine and Bachelor of Science of the University of London, and Licentiate of the Colleges of Physicians and Surgeons of Edinburgh. In 1860, when he passed his first M.B. examination, he not only graduated in honours, but obtained the exhibition in anatomy and physiology and the gold medal in the same subjects. Indeed, as a physiologist, he was rapidly obtaining distinction, quite at the outset of his career in the Profession, when the malady to which he eventually owed his death commenced to trouble him, and, acting under advice, he went to Melbourne in the early part of 1866. By the large circle of private friends who now regret his loss his death will be deeply felt, for no member of the Medical Profession was ever more thoroughly liked or more deservedly respected than was Dr. Bayldon. He leaves behind him a widow, but no children.

JOHN THOMAS, M.R.C.S., ETC.,

DIED on the 6th instant, after a few weeks' illness, at Hebden-bridge. He was born in 1795. He served his articles under the present Dr. Alexander's father, at Halifax, and shortly after he attained his majority he commenced business in Commercial-street, but many years since removed to the residence he last occupied. On July 1, 1837, he was appointed Registrar of Births and Deaths, which post he held until a few weeks ago. In 1855 he was appointed a Medical Officer to Todmorden Union. For many years he was Certifying Surgeon for the Hebden-bridge district. The two latter offices he held until his death. He was greatly respected throughout the neighbourhood, and is deeply regretted by a large circle of relatives and friends.

JAMES QUILTER RUMBALL, M.R.C.S., L.S.A.,

OF The Limes, Harpenden, Herts, died on the 4th instant. He was born in 1795. Was the son of Mr. John Rumball, Surgeon, of Abingdon. Admitted on September 5, 1817, as a M.R.C.S. Was a pupil at Bethlehem Hospital, 1819, under Sir George Tuthill and Dr. Edward T. Munro, and was a pupil of Dr. Spurzheim, from whom he imbibed a strong affection for phrenology. He was for a long period Surgeon to Harpenden Hall Asylum for the Insane, near St. Albans, Herts. He was the author of the "Mother's Monitor," "Address to the British Association on the Claims of Phrenology," "Letter to the Lord Chancellor on Insanity," "Essay on Reason and Instinct," "The Anti-Mesmerist," and other works. Testimonials were presented to Mr. Rumball by several societies to whom he had given lectures, as marks of their esteem.

A HEALTHY COUNTY.—Statistics published in a local paper (Alpine county, California) show that in nine years only twenty deaths have occurred in the settlement. These twenty are thus recorded:—Four were murdered, one fell from a tree, three were killed by an avalanche, one was suffocated in a mine, one perished in a cave, three were lost in the snow, three died of consumption, and of the other four—two have the word "infants" written after their names in the explanatory column, and two the word "whisky." The actual number of the population is not shown, but an approximate estimate may be formed from election times, when the county casts 1600 votes.

MEDICAL NEWS.

UNIVERSITY OF DUBLIN.—TRINITY COLLEGE.—At the Trinity Term Examination for the degree of Bachelor of Medicine, held on Monday and Tuesday, June 10 and 11, the following were successful:—

Moriarty, Matthew Denis.	Hamilton, James Charles.	
M'Munn, Charles Alexander.	McLaughlin, Frederick.	
Smyly, William Josiah.	Archer, Robert S.	
Mackesy, William Lewis.	Gubbins, William L.	
Kingston, William F.	Fullerton, John C.	
Allen, James Henry.	Pope, Frederick.	} equal.
Kerr, Elias William.	Goode, George.	
O'Meara, Thomas P.	Fleetwood, Thomas F.	} equal.
Wade, Arthur Law.	Marsden, Charles.	
Grandison, Alfred.	Chartres, John.	
Tuckey, Thomas P.		
Ball, Charles B.		

At the examination for the degree of Master in Surgery, held on Monday and Tuesday, June 17 and 18, the following candidates passed:—

McLaughlin, Frederick.	} equal.	Archer, Robert S.	} equal.
Ball, Charles B.		Hingston, William F.	

KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.—At the monthly examinations held on June 11, 12, and 13, the Licence to Practise Medicine was granted to—

Mahon, Charles J.	Smyly, William Josiah.
O'Keiffe, John Leonard.	Warren, Frederick W.
Ryau, John.	

The diploma in Midwifery was granted to—

Fullerton, John Campbell.	Ryan, John.
Mahon, Charles J.	Smyly, W. J.
O'Keiffe, J. L.	Warren, F. W.

APOTHECARIES' HALL.—The following gentlemen passed their Examination in the Science and Practice of Medicine, and received Certificates to practise, on Thursday, June 13, 1872:—

Godfray, Armiroux, Jersey.
Savage, George Henry, Nent Head, Cumberland.
Welchman, Edward, Winchester.

As Assistants in Compounding and Dispensing Medicines:—

Oxley, Herbert Lister, Palermo, Sicily.
Stansby, Charles John, Victoria Dock-road, E.
Young, John Rymer, Warrington.

APPOINTMENTS.

* * * The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

ALLFREY, C. H., M.D., F.R.C.S. (Exam).—Surgeon to the Asylum of the Governesses' Institution at Chislehurst.

BAILEY, G. H., M.R.C.S. Eng.—Additional Administrator of Anæsthetics to the Dental Hospital of London, Soho-square.

BARRIE, JOHN, M.D.—Medical Officer, etc., to the Central District of Govan, Lanarkshire.

BUCKLEY, SAMUEL, M.R.C.S., L.S.A.—Medical Officer to the Workhouse, and to the District comprising Crumpsall, Blackley, and Harpurhey.

FORREST, ROBERT W., M.D., C.M.—Medical Officer, etc., for the Eastern District of Govan, Lanarkshire.

GARRARD, WM. ARTHUR, L.S.A.—Assistant House-Surgeon to the Infirmary, Derby.

MAYNE, N., L.K. and Q.C.P.I., L.R.C.S.I., L.M.—Medical Officer for the Oughterard Dispensary District, Oughterard Union, county Galway.

PORTER, JOHN, M.R.C.S. Eng., L.S.A.—Medical Officer for the Blackpool District, Fylde Union, Lancashire.

RODMAN, ROBERT, M.B., C.M.—Medical Officer, etc., to the Western District of Govan, Lanarkshire.

TILEY, W. G., M.R.C.S. Eng., L.S.A.—Resident Medical Officer to the London Fever Hospital, Liverpool-road, N., *vice* W. R. Cheyne, M.R.C.S. Eng., resigned.

WILSON, J.—Dispenser to the Infirmary, Derby.

MILITARY APPOINTMENTS.

MEDICAL DEPARTMENT.—In accordance with the provisions of her Majesty's Order in Council of February 22, 1870, the undermentioned officer has been placed on the retired list of his rank from the 7th inst.:—Staff Surgeon Charles Forbes, M.D. Deputy Inspector-General of Hospitals: John Fraser, M.D., C.B., to be Inspector-General of Hospitals, *vice* Robert Lawson, who retires upon half-pay; Surgeon-Major James Macmillan Scott Fogo, from the Royal Artillery, to be Deputy Inspector-General of Hospitals, *vice* John Fraser, M.D., C.B., promoted. James Tucker, M.D., Surgeon to the Sligo Rifles.

BIRTHS.

COGMAN.—On June 16, at Heathfield, Sussex, the wife of Charles Cogman, of a son.

FEGEN.—On June 13, at 6, Jean d'Acre-terrace, Stoke, Devonport, the wife of W. Banks Fegen, Staff Surgeon R.N., of a daughter.

GOOD.—On June 12, the wife of Joseph Good, L.R.C.P. Edin., M.R.C.S. Eng., L.S.A., of Wilton, Wilts, of a daughter.

MACTIER.—On June 13, at Strone House, Blairgowrie, Perthshire, the wife of W. F. Mactier, M.D., late Bengal Service, of a son.

MOFFITT.—On June 14, at Woolston, the wife of A. Moffitt, L.R.C.S.I. Army Medical Staff, of a son.

TEMPLE.—On June 14, at the Royal Arsenal, Woolwich, the wife of Staff Assistant-Surgeon Wm. Temple, V.C., of a son.

MARRIAGES.

DRIVER—INSOLL.—On June 11, at the parish church, Eastbourne, George Vernon Driver, M.R.C.S. Eng., L.S.A., of Gordon-square, London, to Ann, only daughter of Robert Insoll, Esq., of the Old Orchard, Eastbourne.

FETZER—CAPPEL.—On June 18, at St. George's German Lutheran Church, Little Alie-street, Karl Berthold Fetzer, M.D., of Stuttgart, Würtemberg, to Mary Theresa, eldest daughter of the Rev. L. Cappel, D.D., of 4, Primrose-hill-road, N.W.

LYCETT—RADFORD.—On June 12, at the parish church, Tutbury, John Lycett, L.R.C.P., Lond., of Atherstone, to Ann, elder daughter of Edmund Radford, Esq., Tutbury.

NUNNELEY—OMMANNEY.—On June 12, at St. Andrew's Church, Chew Magna, Somerset, J. A. Nunneley, M.B., of Leeds, to Katherine Agnes, fourth surviving daughter of the Rev. E. A. Ommanney, M.A., Vicar of Chew Magna, and Prebendary of Wells.

SMITH—M'LEOD.—On June 11, at Bidstone Church, Professor Smith, M.D., of the University of Sydney, N.S.W., to Mary (Minnie), eldest surviving daughter of Norman M'Leod, Birkenhead-park.

SUTCLIFFE—HADEN.—On June 13, at South Hackney Church, John Sutcliffe, M.R.C.S. Eng., to Elizabeth, youngest daughter of William Haden, Esq., of Hackney.

TICEHURST—VENABLES.—On June 18, at St. Mary's-in-the-Castle, Hastings, Augustus Rowland Ticehurst, M.R.C.S.E., of St. Leonard's-on-Sea, son of Frederick Ticehurst, Esq., J.P., of Hastings, to Amy Sophia, second daughter of George Henry Venables, Esq., of Brondesbury, Middlesex.

DEATHS.

CHAPMAN, ANN, daughter of Richard Chapman, M.D., at Kirbymoorside, on June 17.

DALLAWAY, SARAH ANNE ELIZABETH, daughter of the late Joseph Dallaway, Surgeon R.N., at her residence, Broad-street, Deal, on June 17, in her 58th year.

JERDON, THOMAS CAVERHILL, late Surgeon-Major in the Madras Medical Service, and eldest son of the late Archibald Jerdon, Esq., of Bonjedward, Roxburghshire, at Upper Norwood, on June 12.

MAY, WILLIAM GORMLEY, Assistant-Surgeon Bengal Medical Service, at Kussowlie, East Indies, on May 12.

RICE, SARAH, wife of Surgeon Rice, at 206, Lancaster-road, W., on June 13.

SEATON, JULIA, wife of Edward C. Seaton, M.D., at Rochester House, Surbiton, on June 17.

SLEIGHT, ROBERT LEADEM, M.R.C.S., late of Hull, at Hornsea, Yorkshire, on June 12.

TAYLOR, WILLIAM, M.R.C.S. Eng., L.S.A., of 126, St. John-street-road, Clerkenwell, at St. Mary's Hospital, Paddington, on June 15.

VALLACK, ADONIAH, M.R.C.S. Eng., at Wringford, Rame, near Plymouth, on June 5, aged 59.

WRIGHT, G. A. W., M.D., Army Medical Staff, youngest son of the late James Wright, Esq., of Lawton, Perthshire, at Edinburgh, of consumption, in his 31st year.

VACANCIES.

In the following list the nature of the office vacant, the qualifications required in the Candidate, the person to whom application should be made, and the day of election (as far as known) are stated in succession.

BETHLEHEM HOSPITAL.—Assistant Medical Officer. Candidates must be Fellows or Members of one of the Royal Colleges of Surgeons, and also Members or Licentiates of one of the Royal Colleges of Physicians, or Licentiates of the Apothecaries' Society. Applications, with testimonials, to A. M. Jeaffreson, Clerk, Bridewell Hospital, New Bridge-street, Blackfriars, on or before June 27.

CARNARVONSHIRE AND ANGLESEA INFIRMARY.—House-Surgeon. Candidates must be registered Medical Practitioners, and acquainted with the Welsh language. Applications, with testimonials, to the Secretary, Infirmary, Bangor, on or before June 27.

GLOUCESTER INFIRMARY.—Assistant-Surgeon. Candidates must be Fellows or Members of the Royal College of Surgeons of London, Edinburgh, or Dublin. Applications, with testimonials, to T. H. Pitre, Secretary, on or before July 4.

HOSPITAL FOR SICK CHILDREN, 49, GREAT ORMOND-STREET, W.C.—Assistant-Physician. Candidates must be Fellows or Members of the Royal College of Physicians of London. Applications, with testimonials, to Samuel Whitford, Secretary, on or before June 26. Also, Medical Registrar. Candidates must possess some legal qualifications. Applications as above.

INFIRMARY FOR CONSUMPTION AND DISEASES OF THE CHEST, 26, MARGARET-STREET, CAVENDISH-SQUARE.—Visiting Physician. Candidates must be Members of the Royal College of Physicians, London. Testimonials to be sent to Francis Baily, Secretary.

LEWISHAM UNION.—Medical Officer for the Sydenham and Forest-hill District. Candidates must be registered under the Medical Act of 1868, and possess the double qualification prescribed by order of the Poor-law Board of December 10, 1859. Applications, with testimonials, to T. Watson Parker, 3, Greenaway-place, Lewisham, on or before June 26.

ROYAL NATIONAL HOSPITAL FOR CONSUMPTION, VENTNOR.—Resident Medical Officer. Applications, with testimonials, to Ernest Morgan, Secretary, 20, John-street, Adelphi.

SEAMEN'S HOSPITAL, GREENWICH.—House-Physician. Candidates must possess at least one qualification. Applications, with testimonials, to Kembell Cook, House-Governor and Secretary, on or before June 22.

TRIGNMOUTH, DAWLISH, AND NEWTON INFIRMARY.—House-Surgeon. Candidates must be duly qualified. Applications, with testimonials, to the Chairman of the Committee, on or before June 29.

YORK COUNTY HOSPITAL.—Non-resident Dispenser. Applications, with testimonials, to Robert Holtby, Secretary, 5, New-street, York, on or before June 29.

UNION AND PAROCHIAL MEDICAL SERVICE.

** The area of each district is stated in acres. The population is computed according to the census of 1861.

RESIGNATIONS.

Edmonton Union.—Dr. Rawlings has resigned the Stoke Newington District; salary £20 per annum.

Fylde Union.—The Blackpool District is vacant; area 7065; population 5693; salary £43 10s. per annum.

Honiton Union.—The First District is vacant; area 10,240; population 4914; salary £95 per annum.

Worksop Union.—M. Francis C. Crosslé has resigned the Whitwell District; area 9054; population 2222; salary £20 per annum.

APPOINTMENTS.

Mere Union.—Wilton Provis, M.R.C.S. Eng., L.R.C.P. Edin., to the Second District.

Sheffield Union.—Matthew Leach, M.R.C.S. Eng., L.S.A., to the South District.

Wandsworth and Clapham Union.—William H. Kempster, L.R.C.P. Edin., M.R.C.S.E., L.S.A., to the East Battersea District.

Westhampnett Union.—Alfred S. Bostock, M.R.C.S. Eng., L.S.A., to the Boxgrove and Rumboldswyke United Districts.

THE VOLUNTEER MEDICAL OFFICERS.—At the meeting of the Volunteer Medical Officers held at the Grosvenor Hotel on Thursday, the 20th inst., Mr. Spencer Smith in the chair, there were present Messrs. Cook, Cordy Burrows, and about twenty-five others. It was resolved that the obnoxious orders relative to the Volunteer Surgeons ought to be rescinded, that the proposed examination should not be retrospective, and that a deputation be appointed to wait on Mr. Cardwell with the above resolutions. We understand that a subscription in aid of this movement has been already commenced in Edinburgh.

ROYAL COLLEGE OF SURGEONS.—The following is an abstract of the unconfirmed proceedings of the last meeting of the Council, on the 13th inst.:—The Secretary submitted a report from the Court of Examiners of candidates passed and rejected at the Primary and Pass Examinations for the diploma of Member during the collegiate years 1868-69, 1869-70, and 1870-71; such report having been prepared in pursuance of the resolution of the Council on April 15 last. The Secretary laid before the Council a certificate of the conviction, at the Surrey sessions on the 6th ult., of William Brett (admitted a Member of the College in 1862), for stealing a book, and of his sentence to two months' imprisonment with hard labour, and stated that the said Brett had been identified by Mr. Stone in the Wandsworth House of Correction as the person so convicted and sentenced: whereupon it was resolved—"That in the opinion of this Council the criminal offence of which William Brett has been convicted is of such a nature as to render him unfit to remain a Member of the College, and that he accordingly be removed from being a Member thereof under section 17 of the by-laws." Mr. Hancock, in pursuance of his notice on the 28th ult., moved—"That in the opinion of this Council the conduct of Mr. Matthew Bass Smith, as shown by his own evidence in the case of Mr. Edmund Edmunds, of Newent, tried for manslaughter at the Central Criminal Court on May 8 and 9 last, was 'prejudicial to the interest and derogatory to the honour of the College, and disgraceful to the Profession of Surgery;' and that the solicitor be instructed to obtain a certified copy of the evidence in the case, with a view—should the same be found to have been correctly reported in the newspapers, and should the solicitor be of opinion that the offence committed is within the scope of the by-laws—to the removal of Matthew Bass Smith from being a member of the College, under section 17 of the by-laws." The motion having been seconded by Mr. South, and the votes of the Council having been taken thereon, the same was carried *nem. con.* Mr. Erichsen, in pursuance of his notice, moved—"That the Court of Examiners be requested to take steps to ascertain the manner in which 'Practical Surgery,' 'Practical Physiology,' and Anatomy have been taught in the different schools in the metropolis and in the provinces, and to report to the Council the result of such inquiry;" and the motion having been seconded by Mr. Hilton, and the votes of the Council taken thereon, a majority was in favour thereof. The Secretary then read a letter from Dr. Edwards-Crisp, of Beaufort-street, Chelsea, offering himself as a candidate for the officer of Professor; Messrs. Holmes,

Flower, Wilson, and Humphry were nominated for election in July to their respective offices of Professors and Lecturer for the ensuing year. Drs. Farrer, Barnes, and Priestley were nominated for election in July as members of the Midwifery Board; and Drs. Peacock and Wilks as Examiners in Medicine for the ensuing year.

COLLEGIATE ELECTION.—Notices have just been sent to the Fellows of the College that the only candidates for seats in the Council are Messrs. Hancock, Curling, and Holt.

ROYAL COLLEGE OF SURGEONS, EDINBURGH.—At the last meeting of the Council, Dr. Thomas Cawley, M.R.C.S. Eng., formerly of Guy's Hospital, Surgeon-Superintendent in H.M. Emigration Service, was elected a Fellow of the College. Dr. Cawley has proceeded to Sydney in the ship *La Hogue* in charge of emigrants.

ST. MARY'S HOSPITAL MEDICAL SCHOOL.—The prizes were presented to the successful students on Thursday, June 13, by Thomas Hughes, Esq., M.P., in the presence of an unusually large company of visitors. The Dean's report showed that the School was in a prosperous condition, there having been considerable increase in the number of students who had entered the School during the past year, and the foundation of open scholarships in Natural Science, and the appointment of a Medical tutor, having been attended with highly satisfactory results. After presenting the prizes, Mr. Hughes delivered an eloquent address, in which he urged that it was the clear duty of every true man to be searching and questioning in the field in which he had to work, with a fixed resolve to follow wherever his inquiries might lead him. The object of honest search must be the discovery of truth, and the pursuit was perfectly consistent with a spirit of reverence and toleration. The speaker then drew attention to the great disadvantages under which Medical students labour in having to enter upon a study so vast and comprehensive as that of Medicine, without having, as a rule, any general knowledge of natural science to start from. Although a great advance has been made of late years by the introduction of physical science as an integral portion of primary education in certain schools, he was of opinion that the only immediate and certain mode of securing that each student should be properly grounded in elementary science before entering a Medical school, would be for these institutions to agree upon the establishment of a matriculation examination in the elements of botany, chemistry, and physics. In conclusion Mr. Hughes dwelt upon the noble and beneficent nature of Medical work, and the obligation which rested upon all who undertook it to do so in no mere commercial spirit, but chiefly with regard to that highest reward of all high effort—a constantly widening insight into the great harvest-field of God in which they had been sent to labour.

SOCIETY OF ARTS.—The annual *conversazione* of the Society of Arts was held on Wednesday evening at the South Kensington Museum. Lord Henry Lennox, M.P., and the Council received the company in the South Court. The numerous corridors, courts, and galleries quickly became crowded, and the varied evening dresses of the ladies gave a grace and brilliancy to the scene. In the North Court a promenade concert was given by the band of the Coldstream Guards. In the lecture theatre a vocal concert was given every half-hour by the London Glee and Madrigal Union. The art library was specially opened, but it was too obvious there were greater attractions elsewhere. The picture-galleries were crowded—there were lingerers in front of well-known paintings to the last moment; nor were the refreshment-rooms forgotten, in spite of the innumerable objects of attraction contained in the museum.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.—The members of this Society dined at the Royal Hotel last week, to commemorate the termination of the winter session. Dr. Hall, the President, was in the chair. There was a good attendance of the members; several good speeches were made, and a very pleasant, jolly evening was spent in right good fellowship.

DR. CAMERON, of Dublin, has commenced a short course of lectures on "Public Health," at the Royal College of Surgeons. The auditory was large, including many ladies and distinguished members of our Profession.

THE following are the names appended to Mr. Barnard Holt's papers for the coming election at the College of Surgeons:—W. White Cooper, Berkeley-square; J. R. Martin, Upper Brook-street; John Marshall, Savile-row; James R. Lane, Berkeley-street; J. W. Hulke, Old Burlington-street; William S. Savory, Brook-street.

DR. PAGET, the Regius Professor of Physic, has been elected by the University of Cambridge representative of Medicine on the Medical Examining Board for England, and Professor Humphry as the representative of Surgery at the same Board.

DR. WILLIAM CARLOS, of Long Melford, was thrown from a dog-cart on Monday (caused by the pony shying), and sustained a fracture of the skull and other severe injuries, from which he died within half an hour.

THE ISLINGTON GUARDIANS are determined to rigidly put the law in force with reference to vaccination. Mr. Broome, the Vaccination Officer, has been instructed to continue to prosecute a man who had been three times prosecuted, convicted, and fined, but still remained recalcitrant; and he was further instructed to prosecute in every other case of a similar character.

THE ROYAL BERKSHIRE HOSPITAL.—We are glad to find by the annual report of this institution for the past year that the appeal of the Board of Management—not for donations only, but for increased annual subscriptions—was readily responded to, and that the total ordinary receipts amounted to nearly £920 more than those of the previous year, enabling the Committee to close the accounts of 1871 with a balance in hand of £11 3s. 11d., after clearing off the adverse balance (£32 3s. 6d.) of the previous year. The Committee draw especial attention to the appointment for the first time of a "Hospital Sunday," from which source alone the receipts amounted to £778 17s. 8d., being an increase of £257 3s. 5d. on the preceding year. There had been two more in-patients admitted during the year, making the number 862. The out-patient list shows an increase of twenty-two fresh cases; and the number treated is eighty-nine in excess of the former year, owing to a large number of out-patients of the previous year (1870) being still under treatment at the commencement of 1871.

IT is announced that the net result of the fancy fair in connexion with Prince Arthur's visit to Liverpool amounts to £20,000, which will be handed over to the new Southern Hospital.

THE outbreak of cholera at Cawnpore has been quite stamped out. No new cases had occurred for several days.

WE regret to announce that on Friday last a son of Dr. Atkinson, of Leeds, a youth 8 years old, and Miss Rodier, his governess, were both drowned in Morecambe Bay. The latter lost her life in attempting to save the boy, who got out of his depth in wading a dangerous pool.

HOW TO STAMP OUT SMALL-POX.—The Local Government Board has sanctioned a gratuity of £5 voted to Mr. George Stevens by the Board of Guardians of the Sudbury Union for services rendered during the prevalence of small-pox in his district. He had ten cases under his care, and although three had the disease in its worst form (confluent), they have all recovered, and there has been no fresh case for the past five weeks. Primary vaccination and revaccination were attended to. A cottage, situated in the midst of fields some distance from the village, was furnished at the expense of the guardians. This cottage is called the pest-house, and in years gone by was used for the reception of small-pox cases in the days of inoculation.

THE MONTHLY REPORT ON THE HEALTH OF ST. MARYLEBONE.—Dr. Whitmore states—"During the five weeks which ended on the 1st day of the present month, the number of deaths registered was 359—males 169, females 190. The consecutive weekly returns were 71, 84, 76, 51, 77, which in the aggregate were equivalent to an annual death-rate of 23.45 per 1000 of the living population of the parish. As compared with the rate of mortality of previous months in the year these returns are satisfactory, but they exceed by rather more than 2 per 1000 the death returns of the corresponding month of last year." Through the courtesy of Mr. Bedford, the clerk to the Board of Guardians, Dr. Whitmore will in his future reports be enabled to give the number of primary vaccinations performed in the parish by the public vaccinator, and also by private Practitioners. "These returns will be valuable, as showing the extent to which vaccination is carried out in this district of the metropolis. It may be estimated that of all the children born in St. Marylebone, from 12 to 15 per cent. of them die in the first few weeks of their existence—that is to say, before they are of sufficient age to undergo the operation of vaccination. If, therefore, it is found that during a period extending over six months the total number of vaccinations approximate to within 12 or 15 per cent. of the total births, it will be a proof that this necessary safeguard against small-pox has not been neglected."

A FANCY FAIR.—The financial result of the great fancy fair held during the week of Whitsuntide for the benefit of the funds of the new Royal Southern Hospital, has been eminently satisfactory. The total proceeds have been £25,035 18s. 2d.; and, after deducting all expenses, the Hospital has been benefited by £20,051 11s. 5d. A small additional sum will accrue from a few things that are not yet sold.

HEALTH OF SCOTLAND.—2609 deaths were registered in the eight principal towns during the month of May, of whom 1332 were males and 1277 females. Allowing for increase of population, this number is also 6 under the average for May during the last ten years. A comparison of the deaths registered in the eight principal towns shows that the annual rate of mortality was 18 deaths per thousand persons in Perth, 23 in Dundee, 24 in Aberdeen, 26 in Greenock, 27 in Leith, 31 in Glasgow, 32 in Paisley, and 33 in Edinburgh. Of the 2609 deaths registered, 1085, or 41 per cent., were of children under 5 years of age. In Perth, 15 per cent. of the persons who died were under 5 years of age; in Aberdeen and in Edinburgh, 33; in Paisley, 38; in Leith, 43; in Greenock, 44; in Glasgow, 46; and in Dundee, 47 per cent. The zymotic (epidemic and contagious) class of diseases proved fatal to 595 persons in the eight towns, and constituted 22.8 per cent. of the mortality. From the prevalence, however, of small-pox in Edinburgh and Leith, this rate was exceeded in each of these towns, the proportion of deaths from zymotic diseases being 36.0 in Edinburgh, and 33.6 in Leith. The most fatal epidemic was hooping-cough, which caused 185 deaths, or 7.1 per cent. of the mortality. In Glasgow 10.1, and in Paisley 10.8 per cent. of the deaths were caused by hooping-cough. Small-pox still continues on the decrease, the number of deaths from that cause being 149, or 5.7 per cent. of the mortality. As in last month, the towns which suffered most were Edinburgh, Leith, and Aberdeen, the proportion of deaths being respectively 18.6, 17.3, and 5.2 per cent. of the mortality in each of these towns. Fever caused 66 deaths. Of these, 37 were tabulated as typhus, 18 as enteric, 6 as relapsing, and 5 as infantile remittent fever. Scarletina caused 58 deaths (of which 38 occurred in Edinburgh), measles 28, croup 28, diarrhoea 26, diphtheria 23, dysentery 3, metria 2, and cholera 1. Forty-eight deaths were ascribed to apoplexy, 61 to paralysis, 117 to diseases of the heart, 83 to hydrocephalus, and 146 to premature birth debility. The deaths from inflammatory affections of the respiratory organs (not including consumption, hooping-cough, or croup) amounted to 469, or 18.0 per cent. Those from consumption alone numbered 366, or 14.0 per cent. of the total deaths. Seventy-eight deaths resulted from violent causes, one of which was a suicide. One death was caused by delirium tremens, and six by intemperance. Seven of the persons who died had passed the 90th year of life. They were all females, and the eldest was aged 98 years.

DR. SHORTT'S COBRA EXPERIMENTS.—I invariably keep a cobra or two for the purpose of experiments, and these snakes are attended to by a snakeman that I employ for the purpose. Once in every ten days or fortnight they are fed with sour milk or curds (*tyre*): a leaf funnel is placed in the open mouth of the snake, and the curds are poured in till the snake is filled out from end to end like a sack. By this method I have kept snakes alive for two years without any difficulty, in full vigour and quite effective for purposes of experiment. When an experiment is about to be conducted the snakeman pushes the cobra out of its receptacle by the end of a stick, and then seizing the snake by the tail, he places his stick on the neck as close to the head as possible, and now stamping the tail with his right foot, he seizes it by the head with his left hand, and I receive the snake from him by seizing its head with my left hand, placing the thumb on the top and the index finger under the head near to the base of the skull, so as to give the jaws free play. In the meantime the snake entwines itself around my forearm, and its struggles against my forearm are very powerful. In the case of a full-sized cobra the animal to be bitten being already thrown and held fast by assistants, I seize a part of the back of the thigh with the thumb and index finger of the right hand, and the part to be bitten is pushed out prominently, and with the left hand the mouth of the cobra is brought to bear against the part. In the case of a fresh cobra there is always some difficulty in getting the snake to bite at first, and I am obliged to pass a little stick into the mouth of the snake and open it by the aid of an assistant, and apply it thus to the part intended to be wounded, when it seizes the part. After an experiment or two the cobra seems to understand what is required of it, and it is quite ready to seize any

part presented to it, which it grasps with its jaws two or three times, or even oftener if allowed to do so, more especially when much irritated. There is a free relaxation of the jaws after each grasp, and the snake endeavours to extend its holding beyond the first wound, or to gather in its jaws as much of the part as it can at each subsequent grasp. These particulars I have here entered into to explain the whole process, which I have been repeatedly asked to do.—*Madras Monthly Journal of Medical Science.*

DR. REUBEN A. VANCE, of New York, says—"The careful observation of the intra-ocular structures with the ophthalmoscope, continued at short intervals for a length of time, will in certain cases reveal phenomena of great interest, both in a physiological and pathological point of view. This is especially true when the patients are women and the observations extend over such epochs as pregnancy and lactation, or menstruation and the climacteric period. We have then an opportunity of watching the effect upon the cerebral circulation of those bodily states which are notoriously competent to induce changes in the mental tone of the individual, and which, in certain cases, cause a most distressing form of insanity. The phenomena of menstruation may be attended by disordered vision, and it is possible that such visual disorders are due to the general commotion to which the female organisation is subjected at this time, yet such cases are rare; and Dr. T. Clifford Allbutt, of Leeds, in his recent work, says that he has never been able to satisfy himself of their existence. I have seen a number of cases in which photophobia and dimness of vision were complained of at the monthly periods, in which the ophthalmoscope did not reveal any disorder of the intra-ocular structures, and others again where hyperæmia of the disc and retina to a very marked degree, occurring at the same time, was unattended by any defect of vision. . . . The ophthalmoscopic appearances in the majority of cases in which symptoms referable to the cerebro-spinal system have been observed, are such as denote an increase in the quantity of blood in the intra-ocular structures. The retinal circulation is affected, but not to the same extent as that of the disc. The vessels of the latter are enlarged and their number increased. It may even assume a crimson appearance, and I have occasionally seen it so congested that the whole fundus oculi appeared of a uniform colour and the site of the papillæ could only be discovered by tracing the retinal vessels to their point of convergence. The arteries of the retina may be but slightly affected—as a rule they are not enlarged to any great extent—but the veins are increased in size and number, and their course becomes irregular and tortuous. It is the proper vessels of the disc which undergo the greatest change, and the chief evidences of congestion will be observed at the intra-ocular termination of the optic nerve."—*Boston Medical and Surgical Journal.*

DISCOLORATION OF CHINESE CHILDREN.—We have often observed over the sacral region of new-born children, and during infancy, but never once in adult life, a peculiar bluish mark of considerable size. The Chinese are all familiar with it, and call it, *par excellence*, the "black" (*tsing*). From the general belief in metempsychosis, old women assert that it is caused by the dead person lying upon the cash which is placed in the coffin of the deceased. Money is added by the friends and others we know in such circumstances with the view of giving wealth to the departed in the other world. Or this may probably have originated in the older idea of placing gold and other metals in coffins to prevent putrefaction. We have obtained no physiological explanation of this mark. It is not a "mother's mark."—*Report of the Peking Hospital, by Dr. John Dudgeon.*

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon.*

Mr. Bryant's Lecture on Ancurism next week.

Dr. Pears's Report on the Treatment of Small-pox shall appear as soon as possible.

We have received a copy of a letter addressed by Dr. Vans Bert, of Aberdeen, to the authorities of that city, with regard to Epidemic Hospitals. The remarks seem most sensible, and are certainly worthy of attention.

Dr. Johnson, Bayswater.—We think you will obtain all you require of Messrs. Butler and Co., Elm-street, Gray's-inn-road; or, if failing there, of Mr. E. Collier, 38, Myddelton-street, E.C.

We are sorry to see the announcement of the death of Mr. Thomas Edward Stainthorpe, a promising young Surgeon of Hexham. We shall give particulars next week.

W. P. S.—The late Sir William Blizard, of the London Hospital, suggested and first practised the operation of tying the superior thyroideal artery in bronchocele, and was one of the first Surgeons who secured the subclavian artery. He introduced the practice of large and repeated abstractions of blood in fractures of the ribs. See Mr. Cooke's memoir of this venerable gentleman, who died in his 93rd year.

GLYCERINED LYMPH.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Can you inform me how the "glycerined lymph" spoken of by Dr. Müller is prepared? I am, &c.,
June 11. A. S. B.

* Dr. Müller employs equal parts of chemically pure glycerine and distilled water. These are thoroughly mixed in a watch-glass by means of a fine pencil. The proportion of one part of lymph to five of this diluted glycerine forms a good inoculable matter. If immediate vaccination is desired the lancet should be charged by means of the pencil. If it be desired to keep the lymph it may be put either into capillary tubes or in a phial holding half or a whole drachm. This need not be filled, and has only to be secured by a cork; but before using the lymph it ought to be rubbed up again with a pencil. The lymph in this way may be kept for months, especially when placed between glass plates. It should not be exposed to the light, but warmth does not injure it.

CHROMIC ACID.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I have just now seen the *Medical Times and Gazette* for April 27, containing a notice of Dr. John Dougall's paper on "The Power of Various Substances in Preventing the Appearance of Animalcules in Organic Fluids," in which he praises chromic acid for being a powerful germicide, etc. I have merely to call your attention to a very interesting paper by Dr. H. S. Purdon, of this town, a few years since in the *Journal of Cutaneous Medicine*, vol. ii., where the same ideas are stated, and where its therapeutic action in different affections is clearly stated.
Belfast, June. I am, &c., GENERAL PRACTITIONER.

TINNITUS AURIUM.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Will any of your correspondents kindly inform me if they have met with a case similar to the following, or can suggest any hints as to treatment?—

E. G., aged 30; single female, healthy parents; two years since was revaccinated, being at the time in perfect health. The revaccination took well, but seems to have had rather a depressing effect on her mind. Within a month of the operation she complained of tinnitus aurium, and ever since she has never been for one moment—except when asleep—free from constant undefinable sounds in her head. The rushing of wind, or of a railway train in motion, or the roaring of the sea, are the comparisons she makes in describing them. Her wonder is that no one else hears them. In all other respects she is well, and I can discover nothing abnormal about her. She has had a slight paroxysm of hysteria since she has been under my observation. I have tried zinci val., steel, bromide of pot., arnica, nuxvomica, argenti nitras, a seton, change of air, without the slightest result.
Ilfracombe, June 14. I am, &c., EDWYN SLADE-KING, M.D.

* Our own experience is, that not a more intractable symptom has to be dealt with; but we pin our faith to steel, wine, and "recuperation." We assume that the physical state of the case has been explored.

THE DERBY.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—The white hat, the blue veil, the dust-coat, and the field-glasses laid out as on former occasions by the faithful Shadrach, alas! will not be required. If ever a plan is arranged—a ball, dinner, stall at the opera, rose show at the Crystal Palace, ladies down to lunch, archery and equestrian—some critical case invariably interferes. Supposing one participates in these sports, there is no enjoyment when the mind is full of anxiety.

This morning, at breakfast, I received one of those unpleasant notes winding up, "Come as soon as you can, and bring the instruments!" However, fortunately, the labour was easy—breech presentation, spina bifida, child alive; the mother frightened in seventh month of eighth pregnancy by a fire on board ship. In the last year six women (if not more), whose deliveries previously were instrumental, had natural labours. Still, Practitioners handy with the forceps are always to be envied. One patient states that her mother and three sisters died of puerperal fever. Another was a nurse six years in a Hospital where cholera, variola, scarlatina, and typhus were treated, she escaping until the last year, when attacked with the latter fever. In the early months of first pregnancy she was struck in the back by a drunkard, the child at birth similarly marked. Another attributes metritis to cold caught mending twenty pairs of damp stockings the day after labour, as her husband, who required three bottles of rum a day (tenpence a bottle in the colonies), was in pecuniary difficulties. Another, aged 36, gave birth to a girl fourteen years ago; no children since. Now she is pregnant, the fact being that a break occurred. Her husband was in gaol two months, and returned bloated with Indian meal. "Sir, I wish they had kept him in prison or even hung him, sooner than this misfortune should have happened," piteously cried the poor woman. A lady contracted scarlet fever badly after sixth labour; child removed did not take. Four years after, when delivered of eighth child, she again had scarlet fever, which extended to all the family, including the young infant and the child previously exempt. A woman marries at 24, and two years after, dancing at a ball, menstruates for the first time, but only once until another ball twelve months after, when she became a little more regular, but not sufficiently so until she left Malta and came to England. Another woman, vaccinated in infancy, had variola badly in India, yet when recently revaccinated healthy infantile vesicles were developed. She states that she had jungle fever from quickening to delivery; at times maniacal, beating people with sticks; labour easy. The child unaffected; took

cholera six months after, but recovered. States, also, that marching from Deoralle to Setaapore, a young officer, bitten by a favourite dog, died three days after of hydrophobia—a disease prevalent amongst the jackals, and, once recognised, never forgotten. In 1853, making a post-mortem, I cut my finger badly without any rabid results. Probably the Turkish bath and hypodermic injections of morphia, atropine, and belladonna along the spinal cord and nerve tracks would be of service. The other evening, Sir W. Gull and Dr. Sutton gave the results of four years' work in an elaborate paper, to prove that Bright's disease is a gradual, general, insidious, and fatal condition, depending on thickening of minute arteries (of fibroid character) in all parts of the body, especially in the pia mater—as far as I could understand—but, as the Yankees say, it is one of the subjects not posted in. However, other speakers primed to the muzzle all about muscular hypertrophy, arterioles, the left ventricle, the elimination of urea, the condition of the sclerotic, etc., aired their own views, damned the paper with faint praise, and, amidst ironical cheers, said, "Where are your specimens? here are ours." Dr. Johnson gallantly and cleverly defended his castle of theories now attacked in a short and interesting speech; Sir W. Gull, waiting until the arrows of criticism were expended, none of which appeared to have penetrated his armour of good nature, then advanced smiling, and, promising to show the specimens, told us, amongst other stories, of a young lady at Brighton, noticed at dinner to have an uræmic breath, and who died in a few days. Although it is very sad to think that diagnosis so often spells death, we are taught the lesson, in scarlet fever and other diseases, to direct more than ever extreme attention to the renal functions. At the present time, peculiar phases of insanity demanding research, it is curious to read of Howard the philanthropist as a tyrant at home, killing his wife by cruel treatment; and of Dean Swift, who, noticing the branches of a tree decay, truly prophesied that he would die at the top first. The telegram comes in—"Cremorne," the winner of the Derby. As a Medical student, I once visited pleasure-gardens of that name by mistake, endeavouring to find Exeter Hall. Arrayed like Solomon in all his glory, my wife will not figure at Scarborough this summer. Our weakly boys will lose the advantage of the πολυφλοισβοιο θαλασσης as well as the pleasure of grubbing and digging in the yellow sands. There will be "wigs on the green" presently. Mrs. Smith is right—it does not matter to bachelors; but the father of a family, having given hostages to fortune, should stick to his practice instead of stock-jobbing, gambling, and making a fool of himself by betting on scratched horses such as

WINSLOW.

THE LATE MR. McCHRISTIE.

An appeal is being made on behalf of the widow of the late T. Y. McChristie, Esq., Revising Barrister for the City of London for fourteen years. Mrs. McChristie, on the death of her husband, purchased an annuity in the European Assurance Society, and now, by the insolvency of that office, her annuity is entirely lost. The subscriptions already received amount to £131 8s.

Subscriptions will be received and acknowledged by A. C. McLaren, Esq., 60, Harley-street, Cavendish square, W.

Besides being a member of the Equity Bar, Lincoln's-inn-fields, Mr. McChristie had been, previous to being called to the bar, a Member of the Royal College of Surgeons of England since 1828. In the same year and subsequently he reported the well-known lectures of Mr. Abernethy.

COMMUNICATIONS have been received from—

MR. RUMBALL; DR. HUGHLINGS-JACKSON; DR. SLADE-KING; DR. PHILLIPS; MESSRS. ARNOLD and SONS; MR. TEEVAN; GENERAL PRACTITIONER; A. BAYSWATER M.D.; DR. ALLFREY; MR. J. CHATTO; MR. WILLIAM YEATS; PROFESSOR SPENCE; DR. C. J. B. WILLIAMS.

BOOKS RECEIVED—

Notes on Sanitary Reform—The Health of Towns, by a Member of the Association for the Promotion of Social Science—A Treatise on Diseases of the Bones, by Thomas M. Markoe, M.D.—On Diseases of Infancy and Childhood, by J. Lewis Smith, M.D.

PERTODICALS AND NEWSPAPERS RECEIVED—

Edinburgh Courant—Ormskirk Advertiser—British Trade Journal—New York Medical Journal—American Journal of Insanity.

APPOINTMENTS FOR THE WEEK.

June 22. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; King's, 2 p.m.; Charing-cross, 2 p.m.; Royal Free, 2 p.m.; Hospital for Women, 9½ a.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. Thomas's, 9½ a.m.

24. Monday.

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; St. Peter's Hospital for Stone, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

25. Tuesday.

Operations at Guy's, 1½ p.m.; Westminster, 2 p.m.; National Orthopædic, Great Portland-street, 2 p.m.; Royal Free, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; West London, 3 p.m.

26. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1¼ p.m.; Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.; St. Thomas's, 1½ p.m.; Samaritan, 2.30 p.m.; King's College Hospital (by Mr. Wood), 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. George's (ophthalmic operations), 1¼ p.m. SOCIETY OF ARTS, 4 p.m. Annual General Meeting. (No visitors.)

27. Thursday.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Royal Orthopædic, 2 p.m.; University College Hospital, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

28. Friday.

Operations at Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.

VITAL STATISTICS OF LONDON.

Week ending Saturday, June 15, 1872.

BIRTHS.

Births of Boys, 1103; Girls, 1086; Total, 2189. Average of 10 corresponding weeks, 1862-71, 1932.4.

DEATHS.

At the Royal Observatory, Greenwich, the mean reading of the barometer in the week was 29.64 in. The highest was 30.06 in. at the end of the week, and the lowest 29.28 in. on Sunday evening.

* The figures in this column, excepting those for London and Dublin, are the unrevised numbers enumerated in April, 1871, raised to the middle of 1872 by the addition of a year and a quarter's increase, calculated on the rate which prevailed between 1861 and 1871. The London population is now based upon the number enumerated in April, 1871, as revised at the Census Office; this revision added 2456 (principally shipping population) to the unrevised number published in the preliminary Census Report. The population of Dublin is taken as stationary.

ORIGINAL LECTURES.

ON THE TREATMENT OF ANEURISM.

By THOMAS BRYANT, F.R.C.S.,
Surgeon to Guy's Hospital.

LECTURE I. (a)

GENTLEMEN,—I propose to occupy the hour that is at our disposal to-day in considering the treatment of what is known as *aneurism*, and I shall make only just sufficient preliminary observations upon its pathology as to render the clinical remarks that are to follow intelligible.

In a practical point of view, aneurism may be divided into two classes—the *sacculated* and the *tubular* or *fusiform*. The sacculated consists of a sac communicating more or less freely with the artery, and a wall composed of some of the coats of the vessel or of the condensed tissues that surround it. As long as the aneurism is sacculated, it is immaterial whether one or more of the coats of the artery itself, the arterial sheath, or the parts around form the sac. When the sac ruptures, and the blood becomes effused into the surrounding tissues, a diffused aneurism is said to exist; but clinically it is well to regard such cases as these as examples of ruptured arteries, for they have practically to be treated on the same principles. For the present such cases may be dismissed from our consideration.

The tubular or fusiform aneurism is a general dilatation or expansion of the whole calibre of the vessel, and will possibly claim attention at a later period. The remarks I to-day intend to make are applicable only to the *sacculated aneurism*.

Pathologically, let us ask how such an aneurism is to be cured. What means does Nature adopt to cure such an affection when she is left to herself?—for upon such knowledge alone can a scientific treatment of the affection be based. Happily, our knowledge upon this point is tolerably definite; for in all cases of cured aneurisms the sac is found filled up with coagulum. And this coagulum we now know to be mechanically deposited in the sac by the stagnation of blood in it, or the feeble flow of blood through it. To obtain this feeble flow of blood or its stagnation are the objects of all our treatment, Medical and Surgical. In aneurisms that are beyond the reach of the Surgeon it is sought for by absolute rest and low diet, and sometimes bleeding—Valsalva in former days adopting such a practice very freely.

In aneurism of the extremities it is now sought for by arresting the flow of blood in the artery as it passes into the sac, and, when this cannot be successfully employed, by arresting the flow of blood in the vessel as it passes from it.

In the former cases the Surgeon's treatment is applied to the afferent vessel, in the latter to the efferent.

The treatment of an aneurism through the afferent vessel or artery by means of which the blood flows into the aneurism will now claim our attention. The treatment through the efferent will receive notice by-and-by.

Now what are the means at the Surgeon's disposal by which he can obtain the mechanical closure of the aneurismal sac by the deposition of coagulum? In what way can the circulation of the blood into the aneurism be arrested? In the extremities forced flexion of the joint will do this sometimes most effectually; and in certain cases, when it can be tolerated, nothing more is needed. Pressure upon the trunk of the vessel is the second way; and ligature of the artery is the third. By one or other of these means, or by the two former combined, most aneurisms of the extremities may be dealt with. We will now proceed to consider under what circumstances these three methods are applicable. But before doing so, let me remind you that they all act upon the same principle; by all the flow of blood through the aneurism is arrested, and the coagulation of blood, and formation of a clot in the aneurismal sac is favoured. In support of this assertion, I will just show you one or two specimens. This preparation was taken from a man whose case is as follows:—

Femoro-Popliteal Aneurism—Ligature of Femoral—Death from Pyæmia.

[Reported by Mr. HARRINGTON.]

George T., aged 37, a railway ticket collector, was admitted into Naaman Ward, Guy's Hospital, under Mr. Bryant's care, having been sent in by Mr. Brenchley, of Camberwell. He

reported that he had always been a healthy man up to sixteen days ago, when he strained his left knee when walking across the buffers of two railway trucks, which were moving slowly. He felt no ill effects at the time, and went on with his work. Three days after the accident a swelling appeared suddenly on the inner side of and behind the knee. The swelling was accompanied with some local pain. He walked home and went to bed, where he remained till he was sent to Guy's by Mr. Brenchley. On admission a large pulsating swelling occupied the inner side of the left thigh and popliteal space. The pulsations in the swelling were very marked both to the eye and hand; it expanded in all directions. Pressure upon the femoral artery above arrested it. Pulsation existed over a space of four or five inches vertically, and eight or nine transversely. The leg was œdematous. The circumference of the left limb was two inches greater than the right, over the tumour. Mr. Bryant, on account of the large size of the aneurism, its rapid progress, its expansive nature, and the œdema of the limb below the tumour, indicating vein pressure, determined to apply a ligature to the femoral artery. He feared delay, and that in such a case pressure was too hazardous.

This he did, therefore, on February 9, no difficulties being experienced in the operation. The artery was deep, as the man was fat.

On February 14 a slight blush appeared on the wound, and a rise of temperature—104.3°. Mr. Bryant opened its margins; some retained pus escaping.

18th.—Diarrhœa appeared. Temperature 103°.

19th.—Is in no pain; sleeps well; wound healthy; appetite indifferent. Temperature 103.9°. The aneurism has much diminished in size.

22nd.—Rigors and sweating appeared. Pulse 120; temperature 104.3°.

26th.—Died; having gradually sank.

Post-mortem.—Evidence of septicæmia. Aneurism divided after having been soaked in spirit. Aneurismal sac composed of muscle; artery ruptured, and the borders separated one inch and a half. Good clot in sac; efferent artery filled with clot. At seat of ligature inner coats divided, but not separated.

Now look at this preparation. Here is the artery divided; there is distinct rupture of all the coats of the vessel, the opening into the aneurism being at least an inch in length. The whole of the sac is composed only of condensed cellular tissue and muscle, none of the coats of the artery entering into its formation. As perfect a sacculated traumatic aneurism exists as any non-traumatic dilatation of the vessel you may imagine for yourselves. It is, moreover, filled with coagulum, which is indistinctly laminated. It was undergoing a cure, and had not pyæmia unfortunately appeared, a good result might have been expected. I should like to remind you in passing that, although so much is said about the laminated clot, you are not to look to obtain a clot like the one in this bottle; that specimen is the most perfectly laminated clot in existence, but that clot was taken out of an aneurism twelve years after Mr. Key had tied the subclavian artery for axillary aneurism. We can hardly say what process or changes that had undergone, considering it had been deposited for twelve years after ligature and cure had taken place. All clots, however, deposited during life are laminated to a degree. The slower the deposition the more laminated is the clot. An example of a rapidly formed clot you see in this preparation. This was cured by pressure in twelve hours; and here you see nothing but an irregular clot deposited in the aneurismal sac.

We will now proceed to consider these different modes of treatment; and first as to flexion. The advantages of arresting the flow of blood through an artery by flexion are not sufficiently recognised. It is not only useful in aneurisms, but it is most useful at times in hæmorrhage generally. For example, most of you in the course of practice will have cases of hæmorrhage from the palm of the hand—a punctured or deep wound that you cannot deal with; you cannot pick up the artery, you cannot cut into the palm of the hand, but you must adopt some means by which the hæmorrhage may be arrested. Most men would be contented with simple pressure and elevation of the limb; but in addition to this, and sometimes without it, you can do much better by flexing the arm upon the forearm and supinating it. You can thus completely arrest the flow of blood through the brachial artery. In some subjects, however, sufficient flexion cannot be obtained to produce such a result. In such you are perfectly justified in putting a small pad in the bend of the elbow, and thus effecting the desired end. In the leg we may get similar results by forcible flexion of the thigh upon the pelvis, so bending the artery upon itself as to produce its occlusion. In that way we may completely arrest the circulation through

the femoral artery, and produce the cure of a popliteal aneurism. Of course, that plan of treatment is only applicable in cases of aneurism of the extremities, and in only a certain class of aneurism of the extremities. Unhappily, however, this practice is not very applicable in the large majority of cases, and for these reasons:—The first objection is the extreme pain it very often causes—of course, by doubling up the artery you double up also the nerves which run with the artery. As a rule, the pain is so great that it is almost impossible to keep up the treatment. How far that may be neutralised by the administration of anæsthetics is a question not yet fully determined; but there is no doubt it can be done to a great extent. Again, by applying forcible flexion you are apt to get some injury to the sac itself—it may even rupture, and, as I have said, rupture of the aneurismal sac is equivalent to rupture of the artery, and must be dealt with as such. When such an accident occurs to the popliteal artery it generally means amputation. Therefore, in the treatment of, say, popliteal aneurism, such a mode of treatment is to be practised with care. I myself, unfortunately, have never been very successful in this mode of treatment. I have tried it in three or four cases, but in no one could the patient bear it. I must say in passing that the credit of introducing into England the treatment of aneurism by forced flexion must be given to Mr. E. Hart, although Dr. Maunoir, of Geneva, in 1857 recorded the first successful case. I will give you some of the numerical facts now as bearing upon this form of treatment, which I have abstracted from a paper by M. Liégeois. Out of 45 cases of popliteal aneurism treated by flexion, 11 were cured, 11 were cured by flexion and other measures, 23 failed, and in 7 of these rupture of the sac took place. Now, that is a large proportion in which to get rupture of the sac—7 out of 23. What became of the cases where it failed, I do not know. The success I have recorded, however, is enough, accompanied with the theory of treatment, to warrant its application in all cases of small aneurisms of the extremities, in aneurisms that are not rapidly developing. I will now read you a case in which the treatment by flexion and pressure combined proved successful.

Aneurism in the Calf of the Leg, cured by Pressure and Flexion.

[Reported by Mr. BETTANY.]

Thomas E., a stonemason, aged 40, was admitted into Guy's Hospital under the care of Mr. Bryant, on October 5, 1869. He was a muscular and healthy man in appearance. He had served in the army as an engineer during the Crimean campaign, and had received a severe injury to his skull from a rifle ball—the right frontal bone having been fractured and driven in at least half an inch. He had, however, no brain symptoms at the time, and even at present beyond the depression in the forehead feels no evil effects of the injury. When he came to England in 1857 he was discharged.

Three years since he observed a swelling at the back of his right leg, just under the knee. Six months after this he applied to St. Thomas's Hospital, where he was admitted under Mr. Simon for aneurism of the posterior tibial artery. It was treated by compression of the femoral artery in various ways for six months, when he was discharged as cured. Tourniquets, weights, and local pressure over the aneurism were employed at different times. The tumour became smaller and pulsated less by these means, but always "beat."

He returned to his trade on leaving St. Thomas's, when the swelling began to increase, and as this steadily progressed he came to Guy's. On admission a pulsating tumour was detected, three inches in diameter, in the upper part of the calf of the right leg. The leg at this part measured one inch more in circumference than the left. The aneurism was pulsatile and elastic; it could readily be emptied on the application of local pressure. Pressure upon the femoral artery having had its fair trial at St. Thomas's, Mr. Bryant wished to try flexion, as he found by flexing the leg upon the thigh all pulsation could be arrested in the aneurism. He accordingly so fixed the limb by means of a figure-of-eight bandage. The pain, however, in about an hour became so intolerable that the treatment had to be given up. The method was, however, re-employed on three different occasions, and on one with an air-pad over the aneurism, but with no success.

At 8 p.m., on October 8, Mr. Bryant placed the patient on his side with the leg and thigh flexed and raised upon a pillow. The patient with his hands forcibly flexed the knee, this action stopping all pulsation in the aneurism. At the same time he was told to apply digital pressure to the femoral artery in the groin when the crampy pain in the leg became intolerable.

October 9.—The patient kept up during last evening and

night the treatment advised, alternating every half-hour or so the treatment by flexion with the leg upon its side and digital compression in the groin of the femoral artery; and at 2 p.m., eighteen hours after it was commenced, when Mr. Bryant visited him, all pulsation had ceased in the aneurism—the tumour feeling more solid. Mr. Bryant advised, however, that the treatment should be maintained for another twenty-four hours, to make the cure certain. This was done, and as at that time the tumour was quite solid it was given up.

The man stayed in the Hospital another three weeks, when he left with the tumour a small indurated swelling. He was seen a month or six weeks later quite well.

Now, the case I have just read to you is a very good one; it well illustrates the effects of a combined form of treatment. It was in no way troublesome; the man understood what he had to do. I simply suggested it to him on account of a case I had about a year before, (b) where a man who had been under my care for aneurism previously, cured himself of a second large aneurism by pressure in four hours and a half. So you see this combined form of treatment answered admirably. The man simply rested upon his side, clasped his hands round his bent leg, and forcibly flexed the leg upon the thigh, and thigh upon the pelvis. He stood thus until the pain became unbearable, and then pressed the femoral artery in the groin, so alternating; and in eighteen hours a complete cure resulted.

We now come to the question of simple compression, and I will read you the history of a case most of you will have seen in Naaman Ward, and many of you have had a hand in its treatment.

Popliteal Aneurism—Digital Pressure—Cure in Forty Hours.

[Reported by Mr. HARRINGTON.]

Robert R., aged 31, a corn dealer, residing at Clapham, was admitted into Guy's Hospital, under Mr. Bryant's care, on February 15, 1872, with a popliteal aneurism in his right leg. He had been sent in by Mr. Cock. It appeared that three months previously, when lifting a sack of corn, he strained his right knee, but he thought little of the accident. For a month he felt occasional pain and numbness in the leg, and then discovered a swelling on the outer side of the right popliteal space. This swelling gradually increased, and on that account he sought Mr. Cock's advice. He was a strong and healthy man. He had never had syphilis or rheumatism. In the right popliteal space a tumour two inches long in its vertical diameter existed, which pulsated. By pressure upon the artery above pulsation could be arrested, and by pressure upon the tumour the swelling could be greatly diminished. On removing the pressure the swelling reappeared, expanding rapidly. There was no œdema of the leg.

Mr. Bryant thought it was a good case for pressure. At 4 p.m. on the 15th, consequently, digital pressure was commenced, a number of qualified students undertaking the task, under the direction of a responsible dresser (Mr. Burgess). The artery was compressed by means of a finger or thumb, Bellingham's weight of ten pounds being placed over the finger to save muscular exertion. This was kept up for eight hours, till twelve at night, when the patient was allowed to sleep. It was recommenced on the morning of the 16th at 8 a.m., and maintained till twelve at night, to be reapplied at 8 a.m. on the 17th. At 12 p.m. it was taken away, the aneurism having consolidated and ceased to be a pulsating tumour. Four hours before this the dresser stated that this result had been secured; but for safety it was maintained up to 12 p.m., pressure having been employed for forty hours altogether. The patient left the Hospital ten days later quite well—to keep quiet at home; the tumour being quite hard, and free from all pain. He has remained well since.

In this case the digital compression commenced the day after admission, two students watching the case for twenty minutes together, one pressing upon the artery with his thumb or finger; and to save muscular effort a weight (Bellingham's) was employed to press upon the thumb or finger, the weight being suspended to an iron bar placed across the bed. This was kept on for eight hours, then discontinued, and the man had a night's rest. The pressure was resumed the next morning, kept up for another sixteen hours, and again a night's rest followed. On the third day, when the pressure was removed, the whole thing had completely consolidated. No bad symptoms followed. The man returned home ten days later, and has since been quite well. Now, that is as good a case as you can possibly have for showing the effects of simple pressure. The treatment of aneurism in both these last cases, then, you see, was conducted upon precisely the same principle—the principle

(b) Guy's Hospital Reports. 1863.

I laid down at the beginning of the lecture: arresting the circulation of blood through the artery into the sac; and I want you to notice that in both the pressure was absolute, for upon this turns the question of the lamination of the clot. If we look for a laminated clot no doubt the process must be a slow one; but in these cases of rapid occlusion of the sac, it is not possible that a laminated clot can be formed. These cases I have given you—and I might give you more—are quite enough to prove that rapid cure is really the best; better than the slow. It is not so much pain and inconvenience to the patient, and it produces precisely the same result. So I think we may consider, pathologically, that an aneurism can be cured as well by rapid as by slow means; and there can be no doubt, in a clinical point of view, that the rapid method is much to be preferred.

(To be continued.)

ORIGINAL COMMUNICATIONS.

CASES OF FALSE ANEURISM, WITH REMARKS.

By JAMES SPENCE, F.R.C.S.,
Professor of Surgery, University of Edinburgh.

False Aneurism of the Posterior Tibial Artery.

History.—James A., admitted to Ward XVIII. this evening (March 2, 1871) suffering from the effects of an injury sustained six weeks ago. He was engaged in pruning a gooseberry bush with a large pocket-knife, when the knife slipped and entered the inner side of his left leg, burying itself in the calf for about two inches. He drew out the knife and went into the house, when he observed blood gushing from the wound; he tied a bandage round the limb and so stopped the bleeding. The patient first applied to a veterinary Surgeon. About eight days afterwards the patient called in a regular Practitioner, who attended him for three weeks; but as the wound bled repeatedly, he was at last recommended to apply to the Infirmary, and was accordingly admitted.

On Admission.—Patient very anæmic, conjunctivæ yellow, and numerous small vesicles about the leg. A small wound was found in the upper and inner part of the calf large enough to admit the tip of the forefinger. As there was some bleeding, Dr. Pitcairn plugged the wound with lint and applied a compress, which at once checked it.

March 3.—To-day Mr. Spence proceeded to examine the wound. Immediately the dressings were taken off a gush of blood followed. An assistant compressed the femoral, but still a good deal of venous hæmorrhage continued. On inserting his finger into the wound and feeling for the bleeding point, Mr. Spence was at once convinced that both the posterior tibial artery and vein were injured. A tourniquet was applied to the femoral, the patient carried into the theatre and put under chloroform. Mr. Spence then made an incision for about eight inches along the inner aspect of the calf, dividing the gastrocnemius and soleus muscles, and exposed the vessels. While doing so a quantity of clots and pus was evacuated from the large cavity near the wound, while the surrounding tissues were more or less disorganised. On exposing the vessels, it was seen that the posterior tibial artery was injured close to the bifurcation of the popliteal, and also one of the venæ comites. Mr. Spence applied a ligature above and below the wound on both artery and vein. A ligature was also applied upon the anterior tibial, just below the bifurcation of the popliteal. The ligatures were left hanging out, a piece of lint soaked in tepid water was applied over the incision, and the foot ordered to be covered with cotton-wool, and to be slightly elevated.

4th.—Patient has passed a quiet, painless night, but had not much sleep. The circulation in the foot is very good. Mr. Spence cleared out the wound and dressed it, supporting the edges of the incision with a many-tailed bandage of lint soaked in a weak solution of chloride of soda. A piece of carbolic lint was placed between the ligature and the skin to prevent undue irritation.

5th.—Patient doing well, but has passed a restless night, the wound causing him much pain.

10th.—A ligature came away this morning. Evening: All the ligatures remaining came away this evening while the limb was being dressed.

12th.—Wound looking very healthy. Dressed with a many-

tailed bandage soaked in camphorated lotion, the wound gently syringed out with weak carbolic acid lotion. General health much improved.

25th.—Wound healing rapidly. Limb still dressed with a many-tailed bandage of lint soaked in chloride of soda lotion. A bedsore, which the patient has had for the past week or ten days, on the outer ankle, is looking healthy now. Limb rests on water-pillow. General health good.

April 9th.—Wound gradually contracting. Edges kept together by plasters.

30th.—Wound healing rapidly, dressed with a narrow strip of dextrined oiled silk along line of incision and many-tailed bandage of lint. General health good.

May 8.—Wound almost healed.

14th.—To-day the patient was dismissed from the Infirmary cured.

Note (May, 1872).—When I last heard of this patient he had resumed his employment as postman in a country district, and was quite well.

False Aneurism of Radial Artery.

John A., aged 33, a farrier by trade, was engaged in shoeing a horse, when the animal suddenly withdrew its foot, and the point of the nail, which had not yet been twisted off, entered the patient's forearm, evidently wounding the radial artery. A gush of blood immediately followed, which he stopped by placing the point of his finger over the puncture until the arrival of a medical man, who applied graduated compression. The man feeling little or no inconvenience from the wound, returned to his work, and continued at it for some days, when he was obliged to cease on account of the pain and swelling which followed.

On admission, on December 18, 1871, about a fortnight afterwards, the external wound had healed, though only covered by a thin layer of newly formed tissue, while a considerable pulsating swelling, fusiform in shape, was apparent on the front of the left forearm. A piece of lint soaked in dextrine paste was applied over the seat of puncture to prevent any chance of the cicatrix giving way, perfect rest and quietness enjoined, and a gentle purgative administered.

19th.—The patient having been put under chloroform in the ward and taken to the theatre, Professor Spence cut down upon the radial artery, and, having turned out the coagula, tied the vessel above and below the wounded point with silk ligatures. Sutures were then inserted, the edges of the wound drawn together, and dressed with a saturated solution of boracic acid. On being carried to bed the arm was placed in the supine position on a pillow.

20th.—From this date the patient went on favourably; his pulse never rising above eighty beats per minute, while the last ligature came away on January 1.

January 3.—The wound shows a tendency to break up, and there is considerable swelling at the upper third of the forearm, probably owing to the patient injudiciously leaving bed. Pulse 88. Skin hot, and patient complains of headache.

6th.—For the last two days there has been no abatement in the feverish symptoms, nor in the swelling of the limb. There was also considerable discharge connected with the wound, which led Mr. Spence to make counter-openings to favour the escape of the pus.

11th.—There is a marked improvement in the appearance of the limb; the tension and œdema are steadily decreasing, and the patient expresses himself "much better." The wounds are dressed with the lotio sodæ chlor. and chloride of zinc.

16th.—The limb is nearly of the natural size and appearance, and the patient is able to get out of bed.

22nd.—There was now no swelling whatever, and the patient left the Hospital cured.

Remarks.—The cases of false aneurism just narrated are instructive as to the treatment of wounded arteries. I think they show the propriety of immediate ligature of the wounded vessel, even although there be no bleeding when the Surgeon sees the patient. It has been said that in the case of vessels such as the radial, ulnar, or tibial—or even in those of a larger size—that if bleeding has ceased or been controlled, it is not advisable to disturb the wound, but that we may trust to the natural hæmostatic processes to complete the cure. I have always looked on such doctrines as not only doubtful, but dangerous; and in my "Lectures on Surgery" I have stated my views strongly on this subject, instancing clinical cases corroborative of my opinions as to the practice to be adopted. In the case of the wounded posterior tibial artery, if a Surgeon had been called in at first, how much suffering and danger might the patient have been saved, had the circulation been commanded, the wound freely dilated with a probe-pointed bistoury, and the wounded

vessel been secured at once? In the other case we have an instance of a smaller vessel—the radial—in which the bleeding was at once efficiently arrested, graduated compression applied, and the punctured wound healed by the first intention, without any consecutive hæmorrhage. Yet we find a false aneurism arising some time after the injury, and requiring the vessel to be tied under less favourable conditions. Surely there can be little hesitation as to the safer plan of enlarging the wound, exposing and tying the injured vessel at once. Before leaving the case of the radial artery I would advert to the appearance of the false aneurism in that case. The swelling was of a bright red colour, and glazed exactly like an acuto abscess, and, as there was considerable pain, a superficial inspection might have led a careless Practitioner to plunge a knife into it. In another case of false aneurism of the radial, which was sent to my care by the late Dr. Cochrane, of Auchterarder, and in which the false aneurism arose after a comminuted fracture of the radius, which had united, the tumour presented precisely the same appearance as in the case narrated. The general appearance, together with the history, except for the pulsation, might easily have misled the Surgeon to suppose that the swelling was an abscess connected with disease of the injured bone.

The case of false aneurism of the posterior tibial presents some points of interest in regard to the treatment. Prior to admission the patient had suffered from repeated losses of blood, and was exceedingly anæmic; whilst, at the same time, the enormously swollen and painful state of the limb, and the severe irritative fever present at the time of admission, left little room for doubt that putrefaction and unhealthy suppuration were going on amongst the extravasated blood. Although, when the limb was examined by the resident Surgeon, on the arrival of the patient at the Hospital, there had been some bleeding, it was not of such a kind as to excite alarm or require more than a clean compress to be applied to replace the dressing removed. I was therefore unprepared for the forcible gush of blood which took place when the dressing was removed. I was looking at the general appearance of the limb, when the flat compress was gently lifted off, and in an instant I felt my face deluged with blood. I at once thrust my finger into the wound, and compression was made on the femoral. Of course there could be no hesitation as to immediate action, notwithstanding the very unfavourable condition of the patient. The procedure adopted has been already described. It was the direct method, which I have always advocated—viz., enlarging the wound upwards and downwards in the course of the vessel which we suppose to be wounded. The reason which led me to make such a very extensive incision in this case was not merely to expose the artery easily, but chiefly to lay open fully the collection of coagula and fetid pus, and thus get rid of the source of "the irritative fever," and avert if possible the pyæmia which seemed to be threatened. The point at which the posterior tibial was wounded, taken in connexion with the tender and swollen state of the leg and imperfect circulation in the foot, is a matter of interest, as showing how much we may trust to the vitality of tissue, even when not very healthy, and when the circulation must be carried on by the smaller arterial branches only. In this case the position of the wound necessitated ligature of the anterior as well as of the posterior tibial; indeed, properly speaking, the upper ligature embraced the lower part of the popliteal artery, and thus the arterial supply was chiefly dependent on the sural arteries and the anastomoses between the anterior tibial and articular branches of the popliteal and anastomica magna. When we consider, moreover, that one of the large veins had been wounded, and required to be tied, and that several of the branches of the sural arteries were necessarily divided in the long incision which I made—looking also at the state of the leg and the debilitated condition of the patient—I think it will be allowed that few cases could be conceived of as less promising for saving the limb; and yet the result of this and similar cases which I have seen and recorded convinces me that amputation should never be resorted to without giving a trial to conservative measures, carefully carried out.

MR. EDWIN RAY LANKESTER, B.A., late junior student, Christ Church, has been elected to a Natural Science Scholarship at Exeter College, Oxford. Mr. Lankester was elected to the Burdett Coutts Scholarship in 1869, and to the Radcliffe Travelling Fellowship in 1870. There were four candidates.—*Nature.*

SATURDAY, JUNE 29, 1872.

THE DIFFUSION OF CHOLERA IN EUROPE IN 1870-71.

A MOST important paper has recently been published by the Local Government Board from the pen of Mr. John Netten Radcliffe, prefaced by an epistle from Mr. John Simon, relative to the recent diffusion of cholera in Europe, and a new road to Europe for the invasion of Asiatic cholera.

In 1869 cholera prevailed, but not to a very great extent, in Southern Central Russia. In 1870 it broke out much more violently over all the country lying between Moscow and the Sea of Azov. At the same time it prevailed in St. Petersburg and along the line of the Caucasus to the Persian frontier.

In 1871 cholera became diffused through Russia in Europe, whence it extended into Siberia; but it did not extend westward except at four points. In July it attacked Königsberg in East Prussia, and thence it crept along the Baltic coast as far as Hamburg. In September it appeared in Sweden, and about the same date in Constantinople; and in October it had appeared at the mouths of the Danube. During the autumn, too, the disease prevailed in Asia Minor. In October an ill-furnished emigrant ship, sailing from Stettin, carried the infection with her. She was bound for America, and, the disease breaking out on the voyage, she had to put into Halifax, and introduced the contagion of cholera, of which some people died near Halifax. Two cases were imported in steamships into the port of Hartlepool from Hamburg; but being intercepted, though one of the cases terminated fatally, the disease did not spread. About this same period, too, cholera prevailed in Persia along the Euphrates and Tigris, and was introduced into Eastern Arabia; and cases occurred both at Mecca and Medina.

As to the origin of this very peculiar outbreak of cholera, Dr. Pelikan, the Director of the Medical Department of the Russian Government, as cited by Dr. Fauvel, holds that it was a recrudescence of the outbreak of 1865, which in 1866 sharply warned us of our liability to attack. This view, however, Mr. Radcliffe is not prepared to accept. As far as our knowledge goes, the former attack of cholera had entirely disappeared in Russia a year before this one broke

out. Further, ordinary experience shows that outbreaks in Russia are generally preceded by exacerbations of the disease in Northern Persia; and the outbreaks of 1830-31, 1847-48—probably also of 1852-56—seem to have passed from Persia into Russia following the ordinary lines of commerce. In all probability, therefore, the outbreak of 1869, corresponding as it did with an exacerbation of the disease in Northern Persia, followed the same rule, and broke out in Russia in a manner similar to previous attacks.

In Persia the disease has been more or less prevalent during the period of 1866-71, and some have come to the conclusion that it is beginning to be naturalised in Persia. But India, where the disease is undoubtedly endemic, had two great outbreaks within the period alluded to—one at the fair of Hurdwar, in 1867, whence it spread into Affghanistan with the pilgrims; and a somewhat similar eruption extended in 1869 as far as the Persian frontier. From Meshed, where it is known to have prevailed on both occasions, it might be easily distributed over Northern Persia, Meshed being a place of great resort both of merchants and pilgrims. In this way we can easily understand the possibility of the disease being renewed, though in the meantime it had never entirely disappeared, and so the source of the malady may still undoubtedly be referred to India.

The passage of cholera into Russia by way of Persia having been fairly made out on former occasions, it might be as well to search into the possibility of the same thing having occurred in 1869. At that time cholera was raging in Persia, and in that year it broke out in Russia, but at Kiev, far inland and remote from the Persian border. The course of cholera is always along well-defined routes of human transit—commercial or otherwise—and inquiry served to show that since 1864 the old trade routes had to a very considerable extent been disused, and a new one sprung up. Instead of going by way of Astrachan, much of the merchandise had been transmitted south of the Caucasus, between the Black Sea and the Caspian. This would readily account for cholera taking a new route from Persia to Europe, but why it should break out at Kiev does not at first sight appear. However, in that year two new lines of rail connecting Kiev with the Black Sea came into use, one of them going to Odessa, one to Taganrog on the Don. By either route communication between the centre of Russia and the Persian districts subject to cholera would be greatly facilitated. We are familiar with the fact that cholera may take great leaps, so to speak, between point and point, without, for the time, the mode of transmission being plain, though in others this is as unmistakable as the fact of the leap; and we are quite prepared to admit that such may have been the case in the outbreak of 1869. Meantime, certain links in the chain remain wanting, and no final verdict as to how these outbreaks began can as yet be given. Nevertheless, there can be but one opinion as to the immense value of Mr. Radcliffe's researches. It is well known that cholera follows the routes of human migration, and that it is most likely to follow the shortest routes. The starting up of a new trade route which is likely to bring a country like Persia—where for practical purposes cholera may be considered as naturalised, and where it is so much closer to Europe than is India—within easy reach, is fraught with danger to our Eastern neighbours. What steps should be taken to meet the danger have yet to be considered.

The opinions of Mr. Radcliffe, as given in this paper, are, we understand, calculated rather to elicit information than to lay down any absolute law. Either way it well deserves attention.

SLAUGHTER-HOUSES IN THE METROPOLIS.

In one of the clauses of the Metropolitan Building Act it is enacted that slaughter-houses in the metropolis should be closed after a certain date, now near at hand. The ground

taken for this is that slaughtering cattle is an offensive or noxious business, and inimical to the public health. The Act could not come into operation at a more inopportune time than the present, if we were to admit its expediency at any time. But we contend that there are certain advantages from slaughtering cattle and sheep in the metropolis which far outweigh the evils resulting from the system. We are pleased, therefore, to see that Dr. Brewer has a Bill before the House which contains the following clause:—"From and after the passing of this Act the slaughtering of cattle or sheep by a butcher in his private slaughter-house, duly licensed, shall not be held to be the carrying on of an offensive or noxious business within the meaning of the said Act"—i.e., the Metropolitan Building Act. In support of the view which we entertain on the subject we cannot do better than quote some passages from the "Quarterly Report of the Sickness and Mortality of St. George, Hanover-square, for the Quarter ending Christmas, 1858." This Report is so exhaustive, and treats the matter so ably, that we make no apologies for reproducing it here.

We may say that, though the Report was issued fourteen years back, the statements and arguments contained in it are even more applicable to the present time than then. The frightful price of meat, the diminution in the numbers of cattle and sheep in the country, make it of the utmost importance for us to economise in every way; and, above all, to prevent the waste arising from the slaughtering of cattle at a distance from the place where the meat is to be eaten. Of course it is to be understood that the metropolitan private slaughter-houses are to be duly licensed and strictly examined periodically. Under such supervision we have no hesitation in saying that the slaughtering of sheep may be carried on without the slightest injury to the public health, and that of cattle without any serious injury. We trust that Dr. Brewer will succeed in carrying his Bill. The following are the portions of the Report alluded to:—

"The question of the entire abolition of slaughter-houses from towns, and in particular from London, is one which we have carefully examined into; and as every circumstance connected with the supply and price of an article of prime necessity, like butchers' meat, is of importance to the whole community, we will venture to make a few remarks thereon.

"On abstract grounds, both of health and economy, no perishable matters ought to be brought into a town which will have to be carried out again as refuse, and be likely to be offensive or dangerous to health in the meanwhile. For thus the consumer has to pay double carriage, and is liable to nuisances into the bargain. As a rule, whatever is to be consumed should be brought into town; and all offal, even to pea-shells, be left behind.

"Vegetable refuse, as we know to our cost, creates trouble enough. Still more, then, does it seem unreasonable to bring a whole live animal into the heart of a town from a long distance, whereas only six-eighths of the animal are used as food, and the residue is a source of disgust and annoyance till it is carted away. Undoubtedly the consummation to be aimed at is, that animals should be killed in the country, fresh from pure air and wholesome food, without the loss of weight and fevered blood caused by driving, thirst, and ill-treatment on their way to a town slaughter-house. The eatable parts should be sent and the offal be left behind.

"But, on investigating the matter practically, we find that, under present arrangements, there is liable to be so much loss of country-killed meat from putrefaction in hot weather, and consequently such uncertainty in the supply, and such an increase of price, that we are compelled for the present to acquiesce in the expediency of maintaining some slaughter-houses in town.

"The question of the supply of meat is, as we have said, of such immense consequence in a social and political point of view, that we make no apology for introducing some of the scientific details involved therein; for it is only by public discussion that a better system can be brought about.

"After the death of an animal, whilst the body is cooling, there comes on the well known state of stiffness, technically called *rigor mortis*. This state consists in a partial solidification of matters in the flesh which were previously fluid, and is of the greatest value in hindering putrefaction, by prevent-

ing the admixture of the blood, which is alkaline, with the juice of the flesh, which is acid. This state is promoted by keeping the dead animal at perfect rest, and allowing it to become quite cold; and, so long as it lasts, putrefaction is absent.

"But, unfortunately, meat killed in the country in summer is packed whilst warm (and the natural heat is just that degree which is most conducive to putrefaction), and is kept in constant movement till it reaches the shop of the retail butcher. Hence it cannot *set*, and is often tainted before unpacked, or becomes so soon afterwards.

"Besides, there are many details in the killing and preparation of meat which ought to be attended to. For instance, if the animal be not entirely and quickly drained of blood; if it be allowed to rest on its side so that the blood may stagnate; if there be any defect in cleanliness; or even if the ripe, full-fed, juicy meat be too roughly handled, decomposition is apt to begin very early and suddenly—so that a parcel of meat which arrives fresh in appearance may become tainted in a few hours.

"Considering, then, what losses the town butchers would be exposed to from the careless manufacture of meat in the country; considering, moreover, that all the risk of loss from putrefaction at present belongs to the retail butcher, who purchases in the wholesale market, it cannot be wondered that the town butchers should desire to keep the management of the slaughtering in their own hands; and we believe that the summary abolition of town slaughter-houses might be attended with a most unpleasant rise in the price of meat.

"The real point to aim at, in order to procure the removal of these places from towns, is the introduction of a more careful system of killing, cooling, packing, and conveying meat from the country; and a proviso that, if the meat putrefies within a certain time after delivery in town, the loss shall fall on the vendor."

The *Times* of June 27 says that during the past fortnight "the enormous quantity of 35,799 lbs. of meat had been seized at the various City markets and slaughter-houses, and destroyed as unfit for human food. It consisted of 165 sheep, 58 pigs, 15 calves, 80 quarters and 466 joints of meat: 1072 lbs. were diseased, 33,972 lbs. putrid, and 755 lbs. had come from animals that had died from disease or accident." It will be noticed that nearly 34,000 lbs. out of the 35,799 lbs. were putrid—doubtless from the heat. Sanitarians must judge whether it be safer for a population to have empty bellies or to have their noses occasionally offended.

THE WEEK.

TOPICS OF THE DAY.

TIME does not allow us this week to go into the subject of the "Habitual Drunkards" Report; but we may say three words in commendation of the patience, the moderation, and the thoroughness of the investigation which led to it. The recommendations of the Committee offer to many a family the only means of safety from the ruin and disgrace liable to fall on them from the drinking habits of father or mother, whom neither religion, nor morality, nor self-respect, nor affection for children, nor the esteem of their neighbours suffices at present to restrain from this miserable bondage.

The Queen's University of Ireland has not yet given in its adhesion to the Conjoint Scheme, which has been accepted by the other Irish bodies. In Scotland, as our readers are aware, there is no Conjoint Scheme worthy of the name, and the University of Edinburgh will have nothing to say to any Conjoint Scheme at all. In England the University of London and the Apothecaries' Society, with the best wishes to join, are still without the legal power to do so. But, more fatal still, there is a growing conviction that due weight has not been given to the arguments which are against the reduction of the standard of Medical education to a minimum level; and many of the friends and *alumni* of the Royal College of Surgeons see with regret the dangers which beset the College—the danger of loss of *prestige*, for it will no longer be an independent body; the danger of loss of funds, for there can be no doubt, unless an

equal and a perfect Conjoint Board can be established in each kingdom, numbers of English students will flock to Edinburgh, where an equally useful, and much cheaper, Surgical diploma can be obtained; and the danger that, in consequence, the museum, the library, and the teaching in the College will be starved. As far as at present appears, the partial Board will satisfy nobody, lower the standard of Medical education directly or indirectly, or both, and mine the foundations of the Royal College of Surgeons of England.

Dr. H. W. Acland, Regius Professor of Medicine, and Dr. G. Rolleston, Linaere Professor of Physiology, have been nominated to represent the University of Oxford on the Committee of Reference for the Medical Examining Board for England.

The University of Durham, at the meeting of Convocation, on June 25, elected Dr. Philipson, of Newcastle-on-Tyne, as the representative of Medicine, and Dr. Heath, of Newcastle-on-Tyne, as the representative of Surgery, on the Committee of Reference under the proposed scheme for a Conjoint Examination for England.

The minutes of a meeting of the Executive Committee of the General Council of Medical Education and Registration held on the 16th of last month contain an important report from Dr. Francis Hawkins, Registrar to the Council, on the measures which are being and have been adopted to insure a greater accuracy in the Register. It appears from this report that no less than 3500 letters of inquiry were despatched at the latter end of the last and the beginning of the present year, with the result of correcting 2000 addresses in the Register of the present year. Six hundred letters were returned marked "Dead" or "Not known" or "Gone away." In the latter cases "registered letters" have been sent, to which if no answer be returned within six months, the names will be erased from the Register. Further efforts of the same kind are to be made; but it is clear that the officials of the Council are not the only persons responsible for the correctness of the Register. Members of the Medical Profession who change their residences are bound, for the sake of the Profession and of the public, and especially for their own sakes, to notify the change to the Registrar. It is surprising, considering the interests at stake, that this is not more regularly done, especially as no additional fee is payable for making an alteration in an address. We are glad to see that the extra work which has been thrown on the Clerks to the Council—Messrs. Bell and Roope—in connexion with the revision of the Register has been acknowledged by a gratuity of £10 to each of these gentlemen. The sum might, we think, have been larger. By a resolution of the Executive Committee, the President, Dr. Acland, and Dr. Quain have been requested to wait upon the Government on the subject of obtaining premises for the Medical Council. We do not think that the Medical Council have any right to apply to the nation to find them a home, and we cannot say that the public services they have hitherto rendered entitle them to do so. If we mistake not, the Medical Council have already sufficient funds invested to enable them to buy or rent a suitable house in one of the less modern parts of London, wherein their business of registration might be conducted, and their meetings held.

Mr. Jonathan Hutcheson is delivering a course of lectures on "Skin Diseases" at the Hospital for Skin Diseases, Blackfriars. They are delivered on Tuesday and Friday at 3 p.m.

The answer of Mr. Cardwell to Lord Elcho and Colonel Lindsay the other night, on the subject of the recent regulations for Volunteer Medical Officers, pledges, we think, the Government to rescind the distasteful orders. Mr. Cardwell said distinctly "if the proposal were unacceptable it need not be insisted on." That it should ever have been proposed proves the two faults with which Lord Elcho charged the Government—"the pedantry of officialism and absolute ignorance of

human nature." We hear, however, that up to the time of our going to press no answer has been received from Mr. Cardwell in reference to the reception of the deputation of the Volunteer Medical Officers to the War Office.

Dr. Rayner, of Hanwell, has been appointed Lecturer on Psychological Medicine at the Middlesex Hospital.

Dr. Nunneley having resigned his Assistant-Physiciancy at St. Mary's, we hear that among the candidates for the post are the following:—Drs. Gowers, Ralph, and Garrod, jun.

Dr. R. J. Lee has been appointed Assistant-Physician to the Hospital for Sick Children, Great Ormond-street.

We hear that Dr. Eustace Smith is a candidate for the post of Physician to the Eastern Hospital for Diseases of Children.

THE PUBLIC HEALTH BILL.

THE eleventh clause of Mr. Stansfeld's Public Health Bill makes it imperative on urban sanitary authorities, within three months from the enforcement of the Act, to proceed to the election of a Medical Officer of Health. It has been conceived that this clause necessitates the termination of existing appointments, and will render it necessary for gentlemen who now hold office to be re-elected; and this objection has been circulated, amongst other arguments, against the Bill. We are authorised to state, however, that no such grievance is contemplated, or will be inflicted, or is possible to be inflicted by Mr. Stansfeld's Bill.

THE ROYAL COLLEGE OF PHYSICIANS.

IT having been determined by the Royal College of Physicians that an abstract of the proceedings of the College shall be suspended in their Hall on the day after meeting, we shall from time to time furnish our readers with an account of such of the proceedings of the College as possess any interest for the Profession at large. An extraordinary meeting of the College took place on Wednesday, June 19. The principal business done was the election of Dr. C. J. B. Williams a Councillor of the College, in the place of Dr. Bence Jones, resigned. Apart from the high scientific and Professional standing of Dr. Williams, the active part which he took in obtaining a certain measure of reform in the mode of electing to the Fellowship will render his return to office a matter of congratulation amongst those who would wish to see the College placed upon a broader and fairer basis. Various communications were received; amongst others, a petition from the Medical Board of Trinidad, which, after stating that only those Practitioners can be admitted to the membership of the Trinidad Medical Board and licensed to practise in the island who hold a British qualification, or who are registered under the Medical Act (1858), prayed "that holders of foreign diplomas may be enabled to obtain the licence of the College after passing an examination in Medicine, to be conducted by means of sealed papers, under the supervision of the officers of the Medical Board, in a manner similar to that now pursued in regard to the Cambridge Local Examinations." This communication was referred to the Council, by whom we presume the legal power of the College to grant diplomas in the colonies will be ascertained. A letter from the Under-Secretary of State, conveying Lord Kimberley's thanks for the report of the College on the alleged "Spread of Leprosy by Contagion in the Island of Curieuse"; a letter from the Committee of the Harvey Tercentenary Memorial, accepting the offer of the use of the College for the purpose of meeting; and a letter from the University of Bishop's College, Montreal, asking for recognition, were also read. The College, in view of the probable formation of a Conjoint Examining Board, postpone the question of recognising any more Medical Schools and Universities. The report of the Council calls attention to the increase of work thrown on the Registrar since his

appointment to the office. The office of Bedell is vacant. Recommendation to the vacancy is in the hands of a committee, consisting of the President, Censors, Treasurer, and Registrar. Dr. Quain gave notice of his intention to move the following resolution at the next meeting of the College:—

"That it is desirable that the "recommendations" of the Conjoint Committee, laid on the table at the last Comitia, be submitted for consideration and approval by the College prior to their being transmitted to the Committee of Reference now about to be constituted."

THE HARVEIAN ORATION.

DR. ARTHUR FARRE delivered this annual address before a larger audience than usual, including many senior members of the Profession. The orator took for his subject the less known of the great works of Harvey—his seventy-two exercises on generation—and gave an interesting account of the circumstances of their publication. Harvey, tired of battling with prejudice and ignorance, reproached the friend who besought him to give up his manuscript, and remarked, with some bitterness, that it conduced far more to a man's comfort to keep his knowledge to himself than to make known truths which others are interested in suppressing; and, though he reluctantly gave his consent to the publication, it is clear that the papers were merely the materials for his intended great work, and not the work itself. Indeed, it appears that he never even revised the proofs. The opinions prevalent on the subject before Harvey, especially those of Aristotle and Galen, were glanced at, and Harvey's advocacy of "epigenesis" as against "metamorphosis" was explained. But the greater part of the lecture was occupied with a sketch of the additions made to our knowledge since Harvey's time, ending with a confession of our total inability to cope with the great problems of hereditary predisposition and atavism.

It is interesting to note that though the microscope was practically unknown, Harvey speaks, in discussing the then generally received doctrine of spontaneous generation, of ova so minute that they are borne through the air and evade our sight. And more distressing to Harvey than all the other losses which he had to endure was the destruction of his manuscript notes on the generation of insects, of which he was deprived in the civil war. Dr. Farre may be congratulated on having further illustrated the genius of Harvey by bringing to light a branch of his studies which previous orators had passed over.

ARMY SURGEONS IN PARLIAMENT.

WE are not entirely without friends in Parliament, and we are glad to see a member of our own Profession—Mr. Mitchell Henry—does not forget his *quondam* brethren. He took occasion on Monday evening, when a vote for the militia was proposed, to express his opinion that it was very hard that the Militia Surgeons should have their emoluments so seriously interfered with as they were by the new regulations. Major Arbuthnot remarked on a vote for the Army Medical Department that a great deal of dissatisfaction existed among Army Surgeons, and he inquired of the Secretary for War whether he could give these gentlemen hope of a better state of things? Mr. Cardwell, in replying, said that no doubt after the Crimean war and the Indian mutiny the large additions made to the Army Medical Department much retarded promotion, but he might say the whole subject was under the consideration of the War Office.

ACTION FOR MALPRAXIS.

AT the Winchcombe County Court, on the 12th inst., Mr. Samuel Smith, a Surgeon practising at Temple Guiting, was summoned by William Greening, a carrier, for injuries sustained by his wife through the defendant's Professional

negligence. The damages were laid at £50. The plaintiff's wife broke the fibula and dislocated her ankle by a fall on the slippery footway in the winter. Greening went to the defendant and told him of the accident. Instead of seeing her he sent word that she should have a poultice put on, and next day himself put on a pitch-plaster and bound the leg up in plain pieces of boards as splints. A fortnight later another Medical gentleman was called in, and it was then found that the dislocation had not been reduced, and that the broken bone had united so as to throw the foot out of its natural position. Medical evidence was called to prove that a Surgeon's first duty was the reduction of the dislocation, without which the proper union of the broken bone was impossible. The defendant, who exhibited considerable eccentricity in court, contended that he had treated the case properly; but a verdict was found for the plaintiff for the full amount claimed—£50.

ST. ANDREWS MEDICAL GRADUATES' ASSOCIATION.

The anniversary session and dinner of the Association will be held at Willis's Rooms on Saturday, July 6. Inspector-General Gordon, C.B., will deliver the presidential address at 5 p.m., and the dinner will be at 6.15 p.m. The time has been changed from December to July, to meet the convenience of country members.

SANITARY STATE OF CLERKENWELL.

WHILST some vestries are apathetic and others altogether negligent of their duties respecting sanitary matters, the Vestry of Clerkenwell seem to be in advance of their Officer of Health. At all events, at the meeting of that body held last week the following resolution was proposed and carried unanimously:—"That the sanitary state of the parish of Clerkenwell is in a most unsatisfactory condition, and that the vestry, therefore, call upon Dr. Griffith, the Medical Officer of this parish, to report fully thereon, and to suggest remedies for the same."

IN THE RIGHT WAY.

THE law is strong enough to remove some of the means to aid quackery and imposture which are resorted to by the filthy advertisers of "cures" and medicine. At the Clerkenwell Police-court last week a man was charged by the Clerkenwell Vestry with posting indecent bills in Owen-street. Mr. Cooke fined the accused twenty-one shillings, or twenty-one days' imprisonment. He was sent to prison in default.

A NEW COTTAGE HOSPITAL.

A HOSPITAL, to be called the North Cambridgeshire Cottage Hospital, is about to be erected at Wisbeach by Miss M. E. Watford Southwell, of Hyde-park. Miss Southwell will also endow the Hospital with £3000. This proposal has been supplemented by Mr. William Peckover, of Wisbeach, who has placed in the hands of trustees £2000, and Mr. Algernon Peckover, of the same town, £500, to permanently endow the Hospital.

TESTIMONIAL TO A SURGEON.

DR. PATRICK SMITH, who has been appointed Resident Medical Officer of the Ararat Lunatic Asylum, has been presented, on leaving the Benevolent Asylum in Melbourne, with an address signed by 500 of the inmates. The address expressed in emphatic terms the gratitude of the subscribers for the kindness and attention that had been shown them by him, and the regret felt at his having relinquished his connexion with the institution.

A MEDICAL GAZETTE IN TURKISH.

THE first number of a Medical journal in Turkish has just been published at Constantinople. Several Medical works have also been published there in the Turkish language.

THE MEDICINE OF THE FUTURE AT JAPAN.

THE Government of Japan, with a sagacity and foresight which promise well for her future position in the community of nations, has determined to lay the foundation of a good scientific Medical school. For this purpose they have rightly chosen the City of Nyaka (or, as it is otherwise called, Kioto)—the residence of the Mikado—and there they will establish a complete Medical school and clinical Hospital, making use of existing temples and other public buildings till new buildings can be constructed. The model for the Hospital is that of Leipsic, on the separate pavilion principle. They directed their agent in Germany to select for them, as the head or director of the whole establishment, a German Physician, whose qualifications and duties they defined with praiseworthy minuteness. He must be well versed in the theory and practice of Medicine and the allied sciences, but above all must have seen plenty of practice, and not be a mere theorist or bookworm. He must understand English, and be able to lecture in that language, inasmuch as English interpreters are more easily procured than others. He must learn the Japanese language, and be prepared to teach in it, in due time. He must be well versed in chemistry and physical science, and be ready to give information when appealed to. He must be a man of good general education, good manners, and kind-hearted; must love children, and be just such a man as children would take to readily. He must not be pedantic, or like a drill-sergeant; and must be of temperate habits. He must be in good health, sound in wind and limb and eyesight; not finicking, or of artificial manners, but upright, straightforward, and spontaneously courteous; if he saw military Surgery in the late war, so much the better. Lastly, the Japanese instructed their agent to choose out of two candidates (all other things being equal) the *shorter*, because, as they are not a tall people, they would expect more sympathy from a man who was not tall himself. The duties of this Physician are sufficiently ample and responsible. He has to superintend the erection of the Hospital and school; to instruct a body of assistants who begin with some knowledge which they have acquired under the Dutch at Nagasaki, and of students who begin *de novo*; to teach science in general and Medicine in particular; to treat the sick; and to lay the foundation of the Medicine of the future at Japan. We must not fail to add that the arrangements proposed for remuneration are liberal and thoughtful in the highest degree, and do the Japanese Government infinite credit. The task of selection was entrusted to the Professors of the University of Leipsic, and their choice fell on Dr. Junker, whose late essay on tracheotomy is well known to our readers. He is an M.D. of Vienna, M.R.C.S. England, and was attached to the Samaritan Hospital, which he resigned on the outbreak of the late war, during which he served at Bazeilles, and was afterwards Surgeon-in-Chief of the German Hospital at Saärbrücken.

ANCIENT USE OF ANTISEPTICS IN EGYPTIAN SURGERY.

"MEDICUS," who sends us a short article on antiseptics, which will be found in the "Notes and Queries," tells us in a private note that the earliest instance he has met with of the use of an antiseptic as such in Surgery, is the case of St. Syntellectica, an Egyptian Christian lady of the second century, of whom an account is preserved in the "Lives of the Saints," and whose "day" is observed in January. This lady, whose life was devoted to the good of the poor, died at last of cancer of the face, which was attended with so odious a smell that she used to have the ulcer bathed with the *liquid which was employed to mummify dead bodies*, in order that those about her might not be injured.

FROM ABROAD.—ERECTILE TUMOUR OF THE INTESTINAL CANAL—

NEW FRENCH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

M. LABOULBÈNE, one of the candidates at the Académie de

Médecine for the vacancy in the section of pathological anatomy, was fortunate enough, in the paper which it is customary to read announcing his pretensions, to be able to lay before the Academy, at its meeting on the 4th inst., an account of what he believed to be an entirely new fact in pathological anatomy—viz., the occurrence of erectile tumours in the alimentary canal. A patient, aged 74, having vomited blood and passed it by the anus, it was diagnosed, after a careful examination, that he was suffering from ulceration of the duodenum. He died in the course of some hours, presenting the signs of internal hæmorrhage. A most careful autopsy showed that almost all the organs were in a state of complete integrity, considering the age of the person. In the duodenum, however, a little lower than the orifices of the bile and pancreatic ducts, was found an oblong tumour the size of an almond, its projection being very visible when the blood which filled the duodenum had been washed out. Examined under water, the mucous membrane which covered the tumour presented a small, irregular ulceration, whence the recent discharge of blood had evidently issued. Two other blackish points seemed to indicate former orifices, which had undergone repair. On cutting through the tumour it was found to have invaded the entire substance of the mucous membrane, the muscular fibres and peritoneal coat being still recognisable. The mass consisted of capillary vessels of various sizes, which were dilated at several points, the dilatations being either uniform or only lateral. M. Laboulbène regards the tumour, in fact, as being precisely similar to erectile tumours met with on the surface of the body. Similar tumours, hitherto unobserved in this locality, may have given rise to fatal intestinal hæmorrhages, the causes of which have remained unknown.

The "French Association for the Advancement of Science" has just issued its programme, and we heartily wish it success. Its members are to consist of three classes, all, however, possessing equal rights. These are—1. Foundation members, who take 500-franc shares; 2. Perpetual members, compounding for 200 francs; and 3. Ordinary members, with an annual subscription of 20 francs. Already, besides a great number of annual subscribers, there are 158 foundation members, and these, together with 230 shares taken by the administration of large commercial companies, furnish a capital of 115,000 francs. The Administrative Council consists of Professor Claude Bernard, President; Professor Broca, MM. Delaunay, Quatrefages, and Wurtz, of the Institut; M. D'Eichthal, a former Deputy; Professor Cornil, of the Polytechnic School, Secretary; and M. G. Masson, publisher, Treasurer. The first meeting will be held at Bordeaux on September 5. In its address the Council states that its object is to follow in the steps of the successful British Association, seeking to encourage as far as possible both the advancement of theoretical science and the development of its practical applications. These aims it believes will be best brought about by interesting in scientific progress first the large towns of the kingdom, and then those of lesser importance; and annually, at one of these, "the first names in French science, without other aim than the love of science and of country, will expound recent discoveries and the advancement due to the industrial progress of theories; in a word, lighten up and support in all parts of the country scientific curiosity, the source of all labours and of all progress. The Association, entirely uninfluenced by the spirit of party, has no other object in view than that of contributing to the intellectual development of France. It solicits the co-operation of all those who love their country, and who believe that a nation should derive, from the assiduous investigation and diffusion of new truths, the moral energy which raises it, and the material prospects which assure its independence."

The programme contains no intimation of a desire for any foreign co-operation; and that there is some danger of

the Association becoming too exclusive an engine for the advancement of "French science" may be feared from the grossly partial accounts furnished by the French *savants* of the share their country had taken in the recent progress of science in the Reports which they prepared to illustrate this on the occasion of the Exposition of 1867.

PARLIAMENTARY.—INFANT LIFE PROTECTION BILL—THE EMPLOYMENT OF CHILDREN IN COAL MINES—ARMY MEDICAL OFFICERS—MILITIA SURGEONS—THE NEW REGULATIONS FOR VOLUNTEER MEDICAL OFFICERS.

In the House of Lords, on Friday, June 21,

The following noble lords were named of the Select Committee on the Infant Life Protection Bill:—Earl of Derby, Earl of Shaftesbury, Earl of Morley, Lord Bishop of London, Lord Boyle, Lord Saltersford, Lord Wharndcliffe, Lord Skelmersdale, Lord Portman, Lord Egerton, Lord Kesteven, and Lord Fitzwalter.

In the morning sitting of the House of Commons,

In Committee on the Coal Mines Regulation Bill, two attempts were made—one by Mr. Pease and the other by Mr. Kay-Shuttleworth—to extend the age below which boys shall not be employed underground. Mr. Pease moved that the age be extended from 10 to 12 years; Mr. Kay-Shuttleworth moved that in thin-seam mines the age be extended from 12 to 13 years. Both amendments were negatived.

On Monday, June 24,

In Committee of Supply on the Army Estimates, on the vote of £47,700 for the Medical Establishment, Mr. Cardwell stated, in reply to Major Arbuthnot, who asked if any steps were about to be taken to improve the flow of promotion among the Medical officers, that there had, no doubt, been a large addition made to the number of those officers during the Crimean war, which threatened to produce a retardation of promotion; but the subject was under consideration, with the view of seeing what could be done to remedy that state of things.

On the vote of £963,300 for pay and allowances to the militia, Mr. M. Henry complained that the new regulations dealt unfairly towards the Militia Surgeons. One of the grievances of those regulations was that they deprived them of the principal source of their income—the fees for the examination of recruits.

On the vote of £473,200 on account of the volunteers, Colonel C. Lindsay strongly objected to the regulations as to Medical officers, men of high Professional attainments, who, with few exceptions, held diplomas both in Medicine and Surgery. They were to be subjected to an examination highly unpalatable and derogatory to their Professional status. Clause 43, moreover, provided that Surgeons of corps and administrative regiments should attend on the adjutants and drill-sergeants, and their wives and young children, receiving 2d. per week for each person. Thus, for 8s. 8d. per annum they would have to attend an unlimited number of persons, scattered, perhaps, in the case of an administrative battalion, over thirty or forty miles. If their assistants did the work, it came to the same thing. Who was to pay their travelling expenses? A commanding officer who had written to him mentioned a case in which the adjutant lived at head-quarters, while the Surgeon was twenty miles off. It would be much better to give these officers the 2d. a week, and let them procure Medical attendance themselves. He was aware that this regulation had been framed on the rule as to Militia Surgeons, but the staff and adjutants of a militia regiment were a large body of men, and were all at head-quarters. Every time Volunteer Surgeons attended they did so at considerable loss, without the slightest equivalent, but the right hon. gentleman could not expect them to continue their gratuitous services if they were treated in the way proposed. He had dwelt at some length on this point, because it dealt with a class for whom we ought to have the highest respect, and whom we could not afford to lose.

Lord Elcho said this Government had two faults—the pedantry of officialism and absolute ignorance of human nature. The latter was exemplified by the Prime Minister early in the session, when he insisted upon his construction of the Washington Treaty on grammatical grounds. The same ignorance of human nature had been exhibited in this rule relating to the Surgeons of the volunteer corps. Men of great professional distinction volunteered for the service—men who had taken Medical degrees at the best universities. Was it to be supposed they would submit to an examination at the hands of Army Surgeons, whom they regarded as inferior in Professional standing?

Mr. Cardwell, in the course of his reply on the subject of the

vote for the volunteer force, said the main point appeared to be the mode of treating the Medical men. At present the Volunteer Medical Officers earned a capitation grant for their corps, but without any conditions of service. Now, two proposals had been made, neither of which, however, was intended to be injurious to the Medical Officers, and he did not know that either of them would be insisted upon if they should prove unacceptable to the Medical Profession or to the volunteers generally. One of them was that Medical Officers should be experienced in those parts of Medical science which had special reference to military duties. If a Medical Officer qualified in the manner specified in the regulations, he would be allowed to earn £2 10s. for his corps just like any other officer. It was thought that the permanent staff of the volunteers ought to be placed on the same level with that of the militia, and therefore it was proposed to allow the Medical Officers of volunteer regiments to attend them on the same terms as the Medical Officers attended the permanent staff of the militia; but if this proposal were unacceptable it need not be insisted upon. He supposed, however, his hon. friend wished that the attendance of the Medical Officer should be secured to the permanent staff.

PROFESSOR HUMPHRY ON HUMAN MYOLOGY.

PROFESSOR HUMPHRY gave his first lecture on "Human Myology" at the College of Surgeons on Monday, the 17th inst. After paying a tribute to the College for the good work done by it in promoting the science of Anatomy and Physiology, and so elevating the character and social status of the Profession, he stated that it was his intention to consider the muscular system of man morphologically and teleologically. Morphology and teleology are always associated in nature, and should therefore be associated in our study of nature. Every muscle, and also every fibre of muscle, is framed with relation to the work it has to do, and to the manner in which it may do that work best. The performance of work—*i.e.*, function—is the stimulus to the maintenance of its nutrition, but is not the stimulus to its formation. Each fibre is formed of a length proportionate to the range of action required. There are various provisions for lessening the range of action, and so for shortening the muscular fibres. Such are the obliquity of the

direction of the fibres, their crossing (as in the case of the pectoralis major), and the passage of tendons under loops or bands (as at the ankle), and the insertion of the tendons near the centre of motion. These, and other like provisions, diminish the operative force of the muscles concerned; but they compensate for this, inasmuch as they increase the motive effect produced by a given amount of contraction of the individual fibres. Hence the fibres can be shorter, and admit of being massed together in convenient positions, and of being so arranged that a great number can, through the medium of tendons, be brought to bear upon a given point. The osseo-muscular system of the trunk is composed of a series of alternating, transverse, skeletal and muscular planes. The skeletal parts may be membranous, cartilaginous, or osseous. This is best illustrated in the fish. In higher animals and in man the regularity of the alternation is much broken—in some instances by the obliteration of the skeletal intermuscular septa consequent on the extension or ankylosis of the muscular fibres through them; and in other instances by the prolongation and varying direction of the skeletal septa, which thus come to form the tendons. It was thus shown that the successive tendons of the dorsal muscles are modified intermuscular septa, and that they so correspond homologically with the transverse or oblique septa of the dorsal division of the lateral muscle of the fish.^(a) The dorsal muscles were described as divisible into three groups—first, a superficial oblique group passing from the spines towards the transverse processes, and including the splenii and the obliquus capitis inferior; second, a middle (rectus) group, including the erectores spinæ, the interspinales, and intertransversales, etc.; thirdly, a deep oblique group passing from the transverse processes towards the spines, and including the complexus and biventer, the semispinales, multifidus spinæ, and rotatores. In considering the ventral part of the lateral muscle of the trunk, the Professor showed how, by alteration of the direction of the fibres and the loss of the transverse septa, the oblique and transverse muscles of the abdomen are modified from the primitive simple pattern which is still to a great extent preserved in the rectus muscle. He entered into the purposes served by the septa in that muscle, as well as into the cause of their comparative absence below the umbilicus, and gave suggestions to account for the disposition of the oblique and transversalis tendons at the lower part of the abdomen being different from that higher up. The series of ventral muscles admit of being divided into three strata, as shown in the accompanying table:—

SCHEME OF VENTRAL MUSCLES.

<i>Superficial Stratum.</i>			
Gracilis	External oblique	Pectoralis	Digastric ant. Genio-hyoid
Sartorius	External oblique		
Tensor vaginae femoris			
Gluteus max.		Latissimus dorsi	Trapezius
<i>Middle Stratum.</i>			
Compressor urethrae	Internal oblique		Sterno-hyoid, Stylo-hyoid
Ischio-cavernosus	Rectus and Pyramidalis		Sterno-thyroid, Digastric post.
Transv. perinei			Omo-hyoid, Lingual
Sphincter ani int.			Thyro-hyoid, Pharyngeal
	Internal oblique	Intercostals ext.	Subclavius
Muscles from Pelvis to Femur		Serratus	Levator scapulae
	Quadratus lumborum	Intercostals ext.	Scaleni
<i>Deep Stratum.</i>			
	Transversalis	Diaphragm	Intercostals int.
Levator ani			Triangularis sterni
	Transversalis	Diaphragm	
Levator ani	Psoas and Crura of		Intercostals int.
			Longus colli
			Rectus capitis ant. major

In speaking of the intercostals, the Professor showed, by diagrammatic expositions of their arrangement with reference to the ribs in different positions, that both the external and internal fibres are in their whole extent agents in inspiration, and that there is not, as has been supposed by many observers,

an antagonism in the action of the different parts of the internal intercostal series. He gave also mechanical reasons for

(a) For the further elucidation of these views the Professor referred to papers recently published by him in the *Journal of Anatomy* and to his "Observations on Myology."

the absence of the external intercostals near the sternum, and of the internal intercostals near the spine. Speaking of the cervical muscles, he associated the form of the digastric muscle with its derivation from two strata of the ventral part of the lateral muscle—the anterior belly belonging to a superficial stratum, and the posterior belly being derived from a deep stratum; whereas the connecting tendon is a remnant of one of the connecting transverse septa of the lateral muscle—of that septum in which the hyoid bone is formed.

VOLUNTEER SURGEONS AND THE NEW WAR-OFFICE REGULATIONS.

(From a Correspondent.)

It was natural enough that the Volunteer Medical Officers who met on the 20th inst. at the Grosvenor Hotel, London, should express their indignation at the "twopence-a-week" clause of the regulations just issued. To attend a number of persons, varying from about ten to twenty, on these terms, when the persons live at considerable distances apart, would probably be a serious loss, and could not be remunerative—to say nothing of the supply of medicines, which many of the Medical officers would be prevented from undertaking on any terms. But the wonderful twopence is easily explained: it is the sum paid according to existing regulations to civil Surgeons who attend the staff of militia regiments, or other bodies of troops for whom no regular Medical officer is provided. This, which amounts to double the ordinary rate of clubs, has been accepted as fair average remuneration when given for a large number of healthy persons residing within a narrow compass; it is the application of the same scale to a totally different case that makes the injustice of the present proposal, against which Mr. Spencer Smith, the chairman, Mr. Cock, Dr. Squire, Dr. Carr, Mr. Cordy Burrows, and other speakers inveighed. The impracticability of the scheme is so patent on the face of it that discussion is scarcely needed. The question must be decided by the withdrawal either of the clause or of the present staff of Volunteer Medical Officers; and as the difficulty probably arose from nothing more than an office blunder, there is little doubt that the former alternative will be chosen.

The meeting objected to the proposal to make examinations in field Hospital and ambulance duties retrospective. It is probable, however, that the increased confidence placed by the volunteers in Medical officers who had made themselves acquainted with these indispensable matters would compensate the latter for the trouble which they underwent in doing so. This, however, is not a pressing question; but it will be well that the Volunteer Medical Officers should show—by joining the deputation which Dr. John Murray, the Honorary Secretary, was instructed to ask Mr. Cardwell to receive—that they object to become paid servants of the State at the rate of twopence a week.

FOREIGN AND COLONIAL CORRESPONDENCE.

FRANCE.

PARIS, June 18.

INFANT MORTALITY—PROPOSED PROHIBITION OF CERTAIN WORK TO WOMEN AND CHILDREN—NEW HOSPITALS—THORACENTESIS—HOSPITAL CASES: REDUCTION OF DISLOCATED HIP.

INFANT mortality continues to be very high in France, and at a meeting of the Society for the Protection of Infants I learned that one *nourrice* (which means dry or wet nurse) alone lost sixty-four nurslings within a few years. If this is not a "massacre of the innocents," I really do not know what it might be called; and the authorities, justly alarmed at this, have caused an investigation into the matter. You are aware that the Imperial Government and the Academy of Medicine had already taken the subject into consideration, and although the Republic is the ruling power in France, infant mortality does not seem to decrease; but to the praise of the National Assembly it must be said that legislative measures are being taken, not only for the better protection of infant life, but of children of a more advanced age. A project of law is under consideration for the regulation of the working hours of children, and also of women in the different manufactories, by

which no child is allowed to enter one of these before the age of 10, and until the age of 13 no child is to work more than six hours a day, and he cannot be called upon to do any night-work until past 16 years. Girls and women of any age are strictly forbidden to work at night, and are not on any account to be admitted into the mines or quarries, from which children under 13 are also excluded. Moreover, up to that age children are expected to attend school at certain hours of the day. Boys under 16, and girls and women of all ages, are not to work on festival days, Sundays being included; but as regards Sunday I would take the liberty of proposing the following amendment—"That men, women, and children of all ages be allowed to rest on that day."

Notwithstanding all that has been said against Hospitals, and against the new Hôtel-Dieu in particular, four millions of francs have been voted for its completion and for the construction of a Hospital in the twentieth arrondissement, in the Ménilmontant quarter, which is situated near the eastern boundary of Paris. It is high time that something should be done in that direction, for the number of Hospitals at present in Paris is far from being sufficient for the requirements of the population—indeed, it has long been in contemplation that each arrondissement or district should have its own Hospital, church, theatre, and market, with a multiplicity of schools, which in every point of view would be a most desirable arrangement. But one of the most sanitary measures that has been decided upon is the creation of new cemeteries outside the fortifications, the importance of which cannot be over-estimated.

You will have seen by the Medical journals that thoracentesis is *à la mode* in the Paris Hospitals, and the all-absorbing topic at the Academy of Medicine; but I have noticed that in the discussions that have taken place on this subject the expediency or results of the operation are set aside for personal consideration on the part of the speakers; and as each man has his own hobby, one may guess beforehand what his arguments and conclusions will be. For instance, Chassaignac prefers drainage, and Jules Guérin the subcutaneous method, to simple thoracentesis in empyema, and Loth can boast of about an equal number of champions on each side. But whatever may be said of this operation, it is impossible to refer to it without calling to mind that it is to the illustrious Trousseau that is due the honour of having popularised it, as it were, in Medicine; and M. Béhier, one of his disciples, has zealously perpetuated the practice.

In my walks through the Hospitals, I have, since my last, seen much to write about. Your readers will remember the case of corrosive poisoning I communicated in my letter which appeared in the *Medical Times and Gazette* of May 4. I have now to announce the death of the patient, which took place eight or ten days ago, in a state of extreme emaciation. He had not been able to take any solid food, and even liquids were with difficulty swallowed and retained. The fatal termination was immediately preceded by coma and a low muttering delirium. At the autopsy the œsophagus and stomach were found highly injected, and the former was studded with superficial ulcerations resembling those in the colon in dysentery; some of them had been cicatrised, and a stricture was found at each extremity of the tube. That at the pharyngeal end was overcome by catheterisation, but the cardiac extremity was so contracted as scarcely to admit of a probe. The stomach was the seat of an extensive but superficial ulcer, which occupied its great curve, and radiated towards its lesser curve and cardiac extremity. Nothing worthy of note was observed in the other organs, except that the vessels and substance of the brain were highly injected.

In the letter above referred to I made mention of a severe remedy which was employed by M. Béhier in a case of arthritic affection of the knee, but I have found its match at the Hôpital St. Louis, where M. Tillaux, one of the Surgeons, punched several holes with heated irons in an indolent bubo (a simple adenoid tumour of a strumous nature), which he said would never have supplicated nor been dissolved by other milder means. In my opinion, however, it is unnecessary to resort to such a painful remedy; I should give the preference to extirpation of the gland.

On the same day M. Tillaux reduced a recent dislocation of the hip-joint in a man of about 50, which was caused by a weight falling on him whilst in a position between kneeling and sitting, and which, M. Tillaux observed, would probably have broken the spine if the head of the thigh-bone had not given way. He said the dislocation was a modification of the fourth variety—that is to say, between the symphysis pubis and obturator foramen. The patient was placed under chloro-

form, and when the anæsthetic effect had reached the fourth degree he reduced the dislocation without any difficulty whatever, by simply flexing the thigh on the pelvis; then, with a combined movement of abduction and rotation, the bone slipped into its place. In his lesson on the subject, and with particular reference to the employment of chloroform in the reduction of dislocations, I was glad to find that he dwelt upon the necessity of pushing the anæsthetic to its fourth degree, when the muscles are perfectly relaxed, as French Surgeons are in general very timid in its administration, and I have seen cases where the Surgeon had attempted reduction before going so far, and had to give it up, owing to the violent involuntary resistance of the patients. Even as regards other Surgical operations I have seen the same mistake made, and, instead of waiting until the desirable effect is produced, patients have been cut and branded, thus depriving them of the benedictive influence of this valuable agent.

Owing to the death of Michel Lévy, Professor Laveran has been appointed Director of the Army Medical School of Val-de-Grâce. M. Laveran is very popular, and his administrative qualities well suit him for the exercise of his new functions.

M. Ulysse Trélat has been appointed Professor of Surgery at the Faculty of Medicine in the room of Professor Verneuil.

The following is the order in which the names of the candidates are inscribed for the vacancy caused by the death of Professor Laugier at the Academy of Sciences:—MM. Sédillot, Gosselin, Richet, Jules Guérin, Huguier, Piorry, Sappey, Marey, Vulpian—all well-known names; but disaffection prevails, owing to the candidature of those who are not Surgeons in the strict sense of the word, as the vacancy exists in that branch.

After the almost constant fall of rain we have had for nearly a month, and the consequent diminution of the temperature, the weather has become suddenly warm, and the thermometer, which only three days ago ranged between 55° and 60° Fahrenheit, now marks 75° in the shade.

The mortuary return exhibits a great fall in the number of deaths for the week ending June 14, but phthisis pulmonalis continues its ravages, the deaths from that affection alone amounting to 122, or about one-sixth of the general total, which is put down at 678.

GENERAL CORRESPONDENCE.

POOR-LAW MEDICAL OFFICERS AND OFFICERS OF HEALTH.

LETTER FROM MR. J. WICKHAM BARNES.

[To the Editor of the Medical Times and Gazette.]

SIR,—Since my letter of last week I have been reminded that one of the two propositions—namely, that Poor-law Medical Officers should be deputy officers under a local Medical Officer of Health—is only the idea of a certain few, in opposition to Mr. Stansfeld's carefully studied Bill, which will become law unless the Poor-law Medical Officers themselves follow the advice of others instead of consulting their own interests, and oppose it by their petitions.

Knowing from experience what Poor-law Medical practice is, both in town and country, I most strongly urge all Poor-law Medical Officers to fight well for the position which is now offered them, and which they may not get the chance of again. To my mind, this 13th clause seems to have been one of the chief objects our Association has been striving to obtain, as it will of necessity place the Poor-law Medical Officer in his proper position in the social scale, besides adding to his income, and he will treat with the contempt they deserve all such insinuations that duty will be sacrificed to interest. Trusting that all Poor-law Medical Officers will continue to respond to my letter of last week,

I am, &c., J. WICKHAM BARNES.

[To the Editor of the Medical Times and Gazette.]

SIR,—The differences of opinion which have arisen on this question ought to be not difficult of solution. It is agreed on all hands that the Poor-law Medical Officers ought to be the Medical Officers of Health of the first instance. They ought to report the existence of any nuisances they may observe, and any disease of the epidemic order; in fact, who but they can do it in scattered country districts?

The twaddle that is uttered about the "fear and unwillingness" of country Medical men to inform against nuisances on the territory of their squire or farmer patients is most ridiculous

and degrading. A Medical man afraid to do his duty? Turn him out! The duty in this case is to make a true report on those prevalent causes of disease which rob the national purse and murder the poor and their children. We have gone on far too long on the "make-it-pleasant" system, and the sooner a change comes the better.

One evil which I hope will be avoided is the employing Medical men to "take proceedings." This he should never do. It is a lawyer's work, and the Doctor should be a witness, not the complainant.

In cities many complex questions will arise, and then scope will be found for the consulting chemist or such a Physician as Dr. Gairdner, or both. But he ought to have full, early, and punctual information from the Medical attendants of the poor.

London, June 24. I am, &c., ANTI-MUDDLE.

* * * See Professor Acland's sentiments: "Sanitary Organisation," p. 748.

LETTER FROM DR. HENRY W. RUMSEY.

[To the Editor of the Medical Times and Gazette.]

SIR,—The alternative placed before Poor-law Medical Officers by Mr. Wickham Barnes in your last number is—doubtless unintentionally on his part—a singular perversion of the real points at issue in this controversy. He, being a Practitioner in the metropolis, which is hardly touched by this Bill, may be excused for ignorance of the question as regards the remaining six-sevenths of the population of England to which the Bill does apply. I beg leave, therefore, to ask every Poor-law Medical Officer in the provinces to send me, on a post-card, an answer to the following inquiry, which states correctly the rival propositions; and I promise every one who favours me with a reply that it shall be made good use of for the improvement of his position:—

"Which of these two alternatives do you prefer?"

"(a) In Urban Districts, the being set aside by the single Officer of Health, who is (by Clause 11) to be appointed by each urban authority, and who will generally be your rival in practice; and, in Rural Districts, being appointed sole Health Officers under the Board of Guardians, and occasionally inspected by an itinerant official from the Local Government Board; or

"(b) The being constituted, in town and country alike, Deputy Officers of Health, under (not 'one of your local medical men,' but) a County or Principal Officer of Health, debarred from private practice, who would be ready at all times to support you and to relieve you from the disagreeable duty of initiating proceedings against nuisances created by your private patients, and whose post, on a vacancy, would be filled by one selected for good service from your own ranks."

Mr. Wickham Barnes has secured an advantage by having been the first to put the question. But let me caution your readers against any conclusion which may be drawn from false premisses.

Cheltenham, June 22. I am, &c., HENRY W. RUMSEY.

OBITUARY.

ROBERT WIGHT, M.D., F.R.S., ETC.,

WAS born at Milton Dunca Hill, East Lothian, on July 6, 1796, and died on the 26th ult. at Grazeley Lodge, Reading. He took his degree at Edinburgh in 1816, and shortly afterwards entered the East India Company's service, first as Assistant-Surgeon, and then as full Surgeon in the 33rd Regiment. He paid great attention during his long residence in India to Indian plants. In 1834, whilst in Edinburgh on leave, he published, jointly with Professor Arnott, of Glasgow, the first and only volume of "Prodromus Floræ Peninsulae Orientalis"—a work of great value on Indian botany—but it was never completed, owing to Dr. Wight's return to India. After his return to Madras he published "Illustrations of Indian Botany," and subsequently a larger work, entitled "Icones Plantarum Indiae Orientalis," illustrated with 2101 plates; then a third illustrated work, on the flora of the Neilgherries, entitled "Spicilegium Neilgherrense." He was also the author of many memoirs published in various botanical journals. Dr. Wight bestowed considerable attention to the development of Indian products and to the introduction of tea, cinchona, and cotton. For several years he was superintendent of the cotton plantations at Coimbatore, and published several papers

on cotton. In 1853 Dr. Wight left India, and since that time has been employed at the Indian flora, and, by his great experience, largely assisting others engaged in the same field. Dr. Wight leaves a widow, four sons, and a daughter. He was one of the ablest Indian botanists, and may be honourably associated with Roxburgh, Griffith, Royle, and others.

THOMAS CAVERHILL JERDON, M.D.

DEATH has robbed us of another of the able band of Indian naturalists. Dr. Thomas Caverhill Jerdon died on Wednesday morning, June 12, after a long and weary illness. Having passed many years of Indian service with unbroken health, he contracted fever when at Gowhatty, in the Assam valley, in the spring of 1869, where he had been travelling to prosecute further researches into the fauna of that part of India. Diarrhœa and dysentery supervened, which, spite of his naturally strong constitution, he never shook off. Thus he overtaxed his strength by a still longer residence in India, and has really fallen in the pursuit of that early love of natural history which never died out even to the very last. He was the son of Archibald Jerdon, Esq., of Bonjedward, in the county of Roxburgh, Scotland, and was born in 1811, being thus only 60 at the time of his death. A student of the University of Edinburgh, which has produced such a long roll of distinguished naturalists, he received an appointment as Assistant-Surgeon in the service of the Hon. East India Company, in 1835, and proceeded to Madras. He early evinced a love of natural history, and commenced collecting the fauna of the above Presidency. Ornithology became his favourite study, and the first fruits of his labour were the publication in 1844 of the "Illustrations of Indian Ornithology," the plates turned out under his superintendence, the moiety by native artists. His name will be best known to the Indian collector and student of natural history associated with his work the "Birds of India," published, in 1862, under the auspices of the Government. No work has done more to familiarise the avi-fauna of India, or has led more students into the same field than this. His close study and long observation of the habits of the many species described are to be seen on every page. He possessed a wonderful knowledge "by eye mark" of every bird, and aided his memory by making rough tinted drawings of every species that came in his way or that he could obtain a drawing of. Of such sketches he had accumulated a very large and valuable series. It was a real pleasure to witness (as the writer often has) his ready discrimination of some dull, indistinctly marked form put into his hand, and hear the points detailed wherein it might differ from some other allied form. His other work, "The Mammals of India," was published in 1867, and it had been his design to bring out like text-books on the reptiles and fishes, and a great mass of materials had been collected. Had he been longer spared, a second edition of the "Birds of India," greatly enlarged, and with the addition of the forms of the eastern districts and Burmah would have been brought out. It is to be hoped that some competent naturalist will carry out Dr. Jerdon's intention. A supplementary list of Indian birds, lately published in the *Ibis*, and not completed, employed his time up to within a few days of his decease. Many of his other writings are to be found in various scientific journals. He was in his younger days a keen sportsman, and shooting, fishing, and hawking were his delight. He was a good specimen of the hard, wiry Scot, and his native country may be proud of her border son. His indefatigable energy was untiring, and few men take out to the full and employ the waking hours of life as did Surgeon-Major Jerdon. Of active service in the field he had not a very extended share. With the 2nd Madras Light Cavalry he took part in good and arduous duty in Central India during the days of the Indian mutiny. That he was not the man to spare himself on such service the writer can well imagine, and he and many other old friends who knew him well will long deplore his loss. In a scientific point of view it is also great.

WILLIAM CARLESS, M.B.

ON Monday last, while out visiting some of his patients, on his way home he stopped at a chemist's shop, where his driver alighted to give directions with regard to some medicines, when the horse, somehow taking fright, darted off, and Dr. Carless, failing to arrest its progress, was hurled out with great violence, his head coming in contact with a stone. The unfortunate gentleman never again spoke, and shortly afterwards breathed his last. He was the son of Dr. Carless, of

Stroude, finished his Medical studies in Aberdeen, and graduated only in May last, after which he proceeded to Leng Melford, Suffolk, as assistant to a Medical Practitioner there. Dr. Carless, during his last year of study at the University, was appointed (an appointment never before given to an unqualified man) Resident House-Physician at Elmlill Lunatic Asylum, and while there, as also throughout his whole Medical course, gained many friends, not among the members of the Profession and the students with whom he was coming in contact only, but among the citizens of Aberdeen, many of whom feel his death like the removal of a relative, and sincerely mourn his early and untimely fate, taking place, as it does, in the prime of life, and at the commencement of the practice of that Profession to which he had devoted himself.

ADONIAH WALLACK, M.R.C.S.,

DIED at Wringford, Rame, near Plymouth, on June 5. Mr. Wallack commenced his studies at the Aldersgate School of Medicine, where he obtained the gold and silver medals for his chemical acquirements; the former given and awarded by the late eminent Dr. Pereira. After passing his examination as Surgeon and Apothecary, he left England for New South Wales, and settled at Singleton, which place he left in 1848, and joined in an expedition undertaken for the relief of the explorers of "the Cape York Peninsula in tropical Australia," and, with two others, was successful, at great personal risk, in rescuing the survivors; the gallant leader, Mr. E. B. Kennedy, and others of the exploring party, having been speared by the aborigines, or starved to death. The account of the whole transaction was published at the time in a pamphlet printed in Sydney, and forms an interesting appendix to the second volume of a "Narrative of the Voyage of H.M.S. *Rattlesnake*," commanded by the late Captain Owen Stanley," by John Macgillivray, Esq., F.R.G.S., naturalist of that expedition, published in 1852 by T. and W. Boone, New Bond-street, under the sanction of the Lords Commissioners of the Admiralty. Mr. Wallack subsequently travelled much in California, Canada, etc., and wrote a description of the former country soon after the first gold discoveries, which was partly published in the Sydney newspapers. After an absence of between twenty and thirty years in the colonies, where, as a Medical man, and from his kindness of disposition, he was much appreciated, he retired from the active exercise of his Profession, and spent his latter days in rural occupations on a small family estate in his native county.

NEW INVENTIONS.

DOMESTIC HYDRAULICS.

A PATENT has been taken out by Mr. Thomas Morris, of Carlton-chambers, architect, for improved apparatus for the water service of buildings. By a concentrated system of pipes, with close cisterns, valves, and other contrivances, he proposes to effect saving in plumbing, and prevent the waste, exposure, and contamination of water.

Instead of making it the sole duty of the main pipe to feed a cistern with water, and employing other pipes for drawing it out again, one pipe is made to answer for the up and down service. It is qualified for this twofold use by a valve at the base that keeps it always charged, whether the supply be constant or intermittent. From this main, branch pipes are carried to the several points at which water is to be drawn, and are there terminated with suitable fittings. At the summit is a valve that admits air when there is not a perfect complement of water; but as the latter rises it drives the air out, and closes the valve without any waste whatever, though the contents of the pipe continue under atmospheric pressure. By this concentration the length of pipe in a building will be much reduced.

Another reform relates to cisterns. Nothing could well be more obnoxious than receptacles of the old box shape. A considerable part of every such cistern is sacrificed in giving requisite scope to the floating ball—an instrument, by the way, that now and then, with suicidal persistency, sticks vertically down, and so, as the plumbers say, gets "drowned." Frequently such a cistern is without a lid, and various abominations soon accumulate; or, if there be a lid, the consequences may be yet worse, for in order to guard against the known irregularities of the ball, there always stands close by it the capacious waste-pipe for carrying the overflow to the drains. This forms a direct channel for the sewer gases to rise up into the cistern to be there absorbed by the water. This mode of poison is,

perhaps, quite as prolific of disease as the direct emanations of the soil-pipe, and will be entirely got rid of under Mr. Morris's patent. He would prefer to dispense with cisterns *in toto*, but they will be kept in use by two causes. Where the quantity for the day is delivered in a single hour, the cistern must hold the day's supply, and the feed or main pipe must be of great diameter; but where the supply is constant, a smaller cistern will suffice, as the object is merely to accommodate the difference of velocity of the influx and that required for the drawing off. The main pipe may also be proportionately smaller.

It is not to be assumed that because the supply of water to the metropolis is to be constant it must necessarily be more copious. There will be a precise equation of velocity and time. If the daily consumption of a house amounts to 180 gallons, that quantity will be supplied at the rate of about a pint a minute. A cistern, therefore, is necessary to allow that to be drawn rapidly off that comes so slowly in. All the vices of the old cistern are, however, effectually cured, and it becomes, in fact, a mere enlargement of the pipe. The actual pressure on the main will be just as hitherto, and beyond the consumer's control; but the cistern, though filled to repletion and subject to the pressure of some surcharge, is to be under regulation, and excessive stress upon the vessel is to be avoided. Taking into account the general circumstances, it is seen that the cistern must be most effective when placed in the upper part of an edifice. The details, however, upon which the patentee is still engaged will embrace some novelties, and, whether much saving in expense be effected or not, we are prepared to welcome any plan by which the water we drink shall be presented to us pure and unpolluted.

MEDICAL NEWS.

UNIVERSITY OF DUBLIN.—At the Summer Commencements, held in the Examination Hall, Trinity College, on Wednesday, June 26, the following degrees and licences were conferred by Sir Joseph Napier, Bart., LL.D., Vice-Chancellor of the University:—

Doctor in utroque Jure, honoris causâ.

Armstrong, Alexander (eques ordinis honoratissimi de Balneo).

Baccalaurei in Medicinâ.

Alleu, Jacobus Henricus.
Archer, Robertus S.
Chartres, Johannes.
Fleetwood, Thomas Falkiner.
Goode, Georgius.
Grandison, Alfredus.
Gubbins, Gulielmus Laucelot.
Hamiltou, Jacobus Carolus.
Hingston, Gulielmus Josias.
Kerr, Elias Gulielmus.

Mackesy, Gulielmus Ludovicus.
McLaughlin, Fredericus Peard.
McMunn, Carolus Alexander.
Marsden, Carolus Georgius Wilson.
Moriarty, Matthæus Dionysius.
O'Meara, Thomas Patricius.
Pope, Fredericus Alexander.
Purefoy, Ricardus Dancer.
Smyly, Gulielmus Josias.
Wade, Arthur Law.

Magistri in Chirurgiâ.

Archer, Robertus S.
Ball, Carolus Bent.

Hingston, Gulielmus Freke.
McLaughlin, Fredericus Peard.

Doctores in Medicinâ.

Butler, Franciscus Theobaldus.
Cranny, Johannes Josephus.

Cooke, Edwardus Jones.

Licentiatius in Medicinâ.

Kelly, Thomas Josephus.

Sir Alexander Armstrong, K.C.B., Director-General Navy Medical Department, was much cheered on receiving the honorary degree of LL.D.

ROYAL COLLEGE OF SURGEONS.—Amongst the many valuable and important changes in the mode of conducting the examinations for the various diplomas and licence of this institution is that which was inaugurated on the 21st and 25th inst., for the diploma in Dental Surgery, when the candidates, in addition to the oral examination, were subjected to one in writing, having the following questions on Anatomy and Physiology, and on Pathology and Surgery, to answer from two to four o'clock, viz.:—Anatomy and Physiology: 1. Describe the process of mastication, enumerate the muscles which are concerned in it, and state their respective functions. 2. Describe the structure of the salivary glands, their situation and relative size, the course and terminations of their ducts, and the influence of the saliva on food. Pathology and Surgery: 1. Describe the situation, pathology, and treatment of an epulis. 2. What are the local symptoms of periostitis of the lower jaw? and what are its effects? The following were the questions on Dental Anatomy and Physiology, and on Dental Surgery, to be answered from five to eight o'clock, viz.:—Dental Anatomy and Physiology: 1. Where is the enamel pulp situated? and what is its structure? 2. Describe the anatomical condition of the lower jaw in relation to the teeth,

both temporary and permanent, in a child 5 years of age. 3. In what direction does calcification take place in the dentine, the enamel, and the cementum? Dental Surgery: 1. What symptoms, local and general, would lead you to diagnose between inflammation of the pulp and inflammation of the investing membrane of the root or roots of the teeth? 2. What conditions of the teeth give rise to chronic closure of the jaws? How would you treat such closure, and the conditions giving rise to it? 3. Describe the casts numbered 1, 2, 3, and 4; and state how you would treat the irregularities of the teeth which they exhibit.

The following gentlemen, having acquitted themselves to the satisfaction of the board of examiners, were admitted Licentiates in Dental Surgery after the oral examination on the 25th inst., viz.:—

Baylis, Leighton, Cheltenham, student of the Middlesex Hospital.
Coles, James Oakley, Wimpole-street, of King's College.
Harding, William Edward, Acton-crescent, Stafford, of the Middlesex Hospital.
Hutchinson, Samuel John, Manchester, of University and King's Colleges.
Poundall, William Lloyd, London-terrace, Derby, of King's College.

It is deserving of mention that all the candidates passed their examinations.

APOTHECARIES' HALL.—The following gentlemen passed their Examination in the Science and Practice of Medicine, and received Certificates to practise, on Thursday, June 20, 1872:—

Cartwright, John Peploe, Oswestry.
Dove, Henry, Norwich.
Laver, Arthur Henry, Rayleigh, Essex.
Paradise, Thomas Decimus, Stamford, Lincolnshire.
Pridmore, Campbell William, Abbey-street, Bermondsey.

As Assistants in Compounding and Dispensing Medicines:—

Jones, Owen, Long-acre, W.C.
Badcock, Daniel, Barnard Castle.

The following gentlemen also on the same day passed their Primary Professional Examination:—

Foster, Reginald Henry, Guy's Hospital.
Kirby, Samuel J. J., Middlesex Hospital.
Perrin, Alfred Charles, St. Thomas's Hospital.

APPOINTMENTS.

* * The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

BEACH, FLETCHER, M.R.C.S.—Medical Registrar to the Hospital for Sick Children, Great Ormond-street.

FLOYER, B. B., M.R.C.S.E., L.S.A.—Assistant House-Surgeon to the General Infirmary, Sheffield.

GORTON, WM., M.R.C.S., L.S.A.—House-Surgeon to St. Thomas's Hospital.

LAYER, ARTHUR HENRY, M.R.C.S., L.S.A.—House-Physician to St. Thomas's Hospital.

LEE, ROBERT JAMES, M.A., M.D., M.R.C.P.—Assistant-Physician to the Hospital for Sick Children, Great Ormond-street.

PUZEY, CHAUNCEY, L.R.C.P. Lond., M.R.C.S. Eng., L.S.A.—Assistant-Surgeon to the Eye and Ear Infirmary, Liverpool.

RAYNER, HENRY, M.D., M.B., M.R.C.S. Eng., L.S.A., Medical Superintendent of the Male Department of the Hanwell Lunatic Asylum—Lecturer on Psychological Medicine at Middlesex Hospital.

RICHARDS, J. PEEKE, M.R.C.S.E.—Medical Superintendent of the Female Department of the Middlesex County Asylum at Hanwell, *vice* Dr. J. Murray Lindsay, appointed Superintendent of the Derby County Asylum.

SERGEANT, EDWARD, M.R.C.S., M.R.C.P.—House-Surgeon to St. Thomas's Hospital.

STONE, RICHARD L., M.R.C.S. Eng., L.S.A.—Second Assistant Medical Officer to the Essex County Asylum, Brentwood.

SLATER, J. S. M.R.C.S., L.S.A.—Resident Accoucheur to St. Thomas's Hospital.

VERNON, BOWATER JOHN, L.R.C.P. Lond., F.R.C.S.—Ophthalmic Surgeon to the Great Northern Hospital, *vice* E. C. Hulme, Esq., resigned.

WATERS, A. T. H., M.D., F.R.C.P.—Lecturer on the Principles and Practice of Medicine at the Liverpool School of Medicine.

NAVAL APPOINTMENTS.

ADMIRALTY.—Staff Surgeon William Banks Fegen has been placed on the retired list of his rank from the 18th inst.

MEDICAL DEPARTMENT.—John A. Robertson, Assistant-Surgeon to the *Boscawen*.

BIRTHS.

BOWEN.—On June 15, at Birkenhead, the wife of Essex Bowen, M.D., of a son.

FOWLER.—On June 16, at Kennington-park, the wife of George Fowler, L.R.C.P. Edin., L.M., L.S.A., of a daughter.

HAYDEN.—On June 19, at Frogmoor House, High Wycombe, Bucks, the wife of W. G. Hayden, L.R.C.P. Lond., M.R.C.S. Edg., L.S.A., of a daughter.

HOPKINS.—On June 24, at 180, Shoreditch, the wife of Alfred Boyd Hopkins, M.R.C.S. Eng., L.S.A., of a daughter.

MEANE.—At Umballa, India, the wife of John Meane, M.D., Surgeon 72nd Highlanders, of a daughter.
 SOLOMON.—On June 8, at Malmo, Sweden, the wife of Ernest Solomon, M.D., of a daughter.
 TARRANT.—On June 14, at Lausanne Villa, Bath-road, Hounslow, the wife of Dr. Tarrant, Surgeon 12th Royal Lancers, of a daughter.

MARRIAGES.

NOAD—DIXON.—On June 20, at All Saints', Kensington-park, Henry Carden Noad, L.R.C.P. Lond., M.R.C.S.E., of Lower Norwood, only son of Dr. Henry M. Noad, F.R.S., of Bayswater, to Caroline White, youngest daughter of Edward Dixon, Surgeon-Major H.M.'s Madras 2nd Light Cavalry.
 PAYNE—FREEMAN.—On June 24, at the parish church, Edgbaston, David Payne, of Harborne, to Gertrude, daughter of James Freeman, M.D., of Birmingham.
 SWETE—ROYLE.—On June 18, at St. Ann's Church, Sale, Cheshire, Fanshawe Carrington Beaumont, only son of Henry John Beaumont Swete, Esq., late of Oxtou, Devon, to Mariana Fanshawe, only daughter of Peter Royle, M.D., J.P., of Vernon Lodge, Brooklands, Cheshire.
 WAKEFIELD—BROWN.—On June 25, at St. Andrew's, Plymouth, William Wakefield, M.D., 6th Dragoon Guards, eldest son of J. C. Wakefield, Esq., of Eastwood-park, Renfrewshire, to Amy, niece and adopted daughter of H. Brown, Esq., of North-hill House, Plymouth.

DEATHS.

BOWEN, CECILIA, the beloved wife of Essex Bowen, M.D., at Birkenhead, on June 18, aged 31.
 CARLESS, WILLIAM, M.B., C.M., eldest son of Dr. Carless, of Stratford Lodge, Stroud, at Long Melford, Suffolk, on June 17, aged 29.
 ELLIOTT, ROBERT, F.R.C.S. Eng., L.S.A., F.S.A., of North-street, Chichester, on June 20, aged 69.
 ELLIOT, SOPHIA, third daughter of the late Thomas Elliot, M.D., of Carlisle, at 3, Victoria-terrace, Weymouth, on June 19.
 FAWSETT, REBECCA, youngest daughter of the late John Fawcett, M.D., at Horncastle, Lincolnshire, on June 24.
 TRUSTRAM, CHARLES, M.R.C.S. Eng., L.S.A., at his residence at Tunbridge Wells, on June 25, suddenly, aged 64.

VACANCIES.

In the following list the nature of the office vacant, the qualifications required in the Candidate, the person to whom application should be made, and the day of election (as far as known) are stated in succession.
 BIRMINGHAM AND MIDLAND HOSPITAL FOR WOMEN.—Resident Medical Officer and Secretary. Candidates must be duly qualified. Applications, with testimonials, to Arthur Chamberlain, Esq., Hon. Secretary, 8, The Crescent, Birmingham, on or before July 15.
 DORSET LUNATIC ASYLUM.—Two Assistant Medical Officers. Candidates must be duly qualified and registered. Applications, with testimonials, to John Brown, Clerk to the Visitors, on or before July 10.
 GLOUCESTER INFIRMARY.—Assistant-Surgeon. Candidates must be Fellows or Members of the Royal College of Surgeons of London, Edinburgh, or Dublin. Applications, with testimonials, to T. H. Pitre, Secretary, on or before July 4.
 HOSPITAL FOR SICK CHILDREN, 49, GREAT ORMOND-STREET.—House-Surgeon. Candidates must possess some legal qualification to practice. Applications, with testimonials, to Samuel Whitford, Secretary, on or before July 9.
 INFIRMARY FOR CONSUMPTION AND DISEASES OF THE CHEST, 26, MARGARET-STREET, CAVENDISH-SQUARE.—Visiting Physician. Candidates must be Members of the Royal College of Physicians, London. Testimonials to be sent to Francis Baily, Secretary.
 LEEDS PUBLIC DISPENSARY.—Junior Resident Medical Officer. Candidates must possess at least one legal qualification (registered). Applications, with testimonials, to John Horsfall, 31, Albion-street, Leeds.
 LIVERPOOL ROYAL INFIRMARY SCHOOL OF MEDICINE.—Lecturer on Physiology; also, Demonstrator of Anatomy. Applications, with testimonials, to R. Harrison, Registrar (from whom further particulars may be obtained), on or before July 6.
 RAMSGATE AND ST. LAWRENCE ROYAL DISPENSARY.—Resident Medical Officer. Candidates must be doubly qualified and registered. Applications, with testimonials, to the Secretary, A. R. Emmerson, on or before July 15.
 ROYAL NATIONAL HOSPITAL FOR CONSUMPTION, VENTNOR.—Resident Medical Officer. Applications, with testimonials, to Ernest Morgan, Secretary, 20, John-street, Adelphi.
 SEAMEN'S HOSPITAL, GREENWICH.—House-Surgeon. Candidates must possess at least one qualification. Applications, with testimonials, to Kembell Cook, Secretary, on or before July 6.
 TEIGNMOUTH, DAWLISH, AND NEWTON INFIRMARY.—House-Surgeon. Candidates must be duly qualified. Applications, with testimonials, to the Chairman of the Committee, on or before June 29.
 WESTERN GENERAL DISPENSARY, 10, LISSON-GROVE, N.W.—Resident Surgeon and Apothecary.—Candidates must be Members of the Royal Colleges of Surgeons of London, Edinburgh, or Dublin, and Licentiates of the Apothecaries' Society. Applications, with testimonials, to W. Kimpston, Secretary, before July 15.
 YORK COUNTY HOSPITAL.—Non-resident Dispenser. Applications, with testimonials, to Robert Holtby, Secretary, 5, New-street, York, on or before June 29.

UNION AND PAROCHIAL MEDICAL SERVICE.

. The area of each district is stated in acres. The population is computed according to the census of 1861.

RESIGNATIONS.

Upton-on-Severn Union.—Mr. Wm. T. White has resigned the Fourth District; area 7613; population 2266; salary £60 per annum.

APPOINTMENTS.

Holbeach Union.—Alfred H. Haines, M.R.C.S. Eng., L.S.A., to the Long Sutton and Sutton-bridge Districts.
 Peterborough Union.—Joseph Baker Bodman, L.S.A., to the Castor District. Thomas Southam, M.R.C.S., L.S.A., to the Peterborough District.

MR. F. PORTER SMITH, M.B. Lond., has been elected an Honorary Fellow of King's College, London.

THE foundation-stone has been laid of an Hospital and Dispensary at Louth.

UNIVERSITY OF DUBLIN.—SCHOOL OF PHYSIC, TRINITY COLLEGE.—The Medical Travelling Prize, value £50, has been awarded to Mr. Matthew Denis Moriarty. The Surgical Travelling Prize, value £50, has been awarded to Mr. Charles B. Ball.

WE are informed that Dr. Sharpey, who has for so many years filled with such great advantage to science and personal distinction the post of Biological Secretary to the Royal Society, has recently sent in his resignation of that appointment. There is a very general hope among Fellows of the Royal Society that Professor Huxley may allow himself to be nominated as his successor.—*Nature*.

POISONING BY HEMLOCK.—The *Manchester Guardian* relates several cases of poisoning from eating the roots of wild hemlock. Two of the cases were fatal.

NOVEL AND ECONOMICAL, IF NOT COMPLIMENTARY TO THE PROFESSION.—The *Liverpool Mercury* contains an advertisement of a "Surgeon wanted," who will be required to act as purser for a steamer.

A MEETING of the National Health Society, which is intended to "unite men and women in a systematic effort to promote health amongst all classes of society," has been held in the rooms of the Social Science Association. Dr. W. H. Corfield read a paper, "How to keep Typhoid Fever out of Houses." The rooms were well filled. Mr. James Heywood, F.R.S., presided. Several speeches were made pertinent to the objects which the Society had in view.

ST. THOMAS'S HOSPITAL MEDICAL AND SURGICAL COLLEGE.—PRIZES FOR THE SESSION.—*First year's students*: H. C. Sanford, Brixton, College Prize, £20, and Hon. Certificate; J. Brock, Northwich, College Prize, £15, and Hon. Certificate; J. K. Pickford, Brixton, College Prize, £10, and Hon. Certificate; H. P. Potter, Denmark Hill, Hon. Certificate. *Second year's students*: C. M. Taylor, Wrawby, Brigg, College Prize, £20, and Hon. Certificate; G. F. Rossiter, Taunton, College Prize, £15, and Hon. Certificate; J. W. Clarkson, Surbiton, College Prize, £10, and Hon. Certificate; J. B. Pike, Leicester, Hon. Certificate. *Third year's students*: A. V. Maybury, Frimley, College Prize, £20, and Hon. Certificate; J. Boulger, Gravesend, Sir William Tite's Scholarship; A. H. Laver, Rayleigh, College Prize, £12 10s., and Hon. Certificate; G. Cleghorn, Bedford, Hon. Certificate; S. Taylor, Burton-on-Trent, Hon. Certificate.

THE LEVÉE.—At the *levée* held on Saturday, at St. James's Palace, by his Royal Highness the Prince of Wales, on behalf of her Majesty, the following presentations were made:—Surgeon Walter F. C. Bartlett, R.N., by the Director-General of the Medical Department of the Navy; H. Barber, M.D., 5th Administrative Lancashire Rifle Volunteers, by Lord Muncaster; Dr. Fleetwood Buckle, R.N., by Sir Francis Pettit Smith; Staff Surgeon-Major T. G. Fitzgerald, by the Director-General of the Army Medical Department; Dr. Frank, by Lord Richard Grosvenor; Surgeon-Major Dr. J. Fayrer, C.S.I., Bengal Army, by the Secretary of State for India; Professor Gross, D.C.L., of Philadelphia, by the United States' Minister; Mr. Samuel Grose, Surgeon R.N., by the Director-General of the Medical Department of the Navy; Deputy Inspector-General of Hospitals N. Hefferman, M.B., by the Director-General of the Army Medical Department; Dr. Thomas Sigertwood, M.D., Deputy Surgeon, by Sir Sydney Cotton, K.C.B.; Dr. J. A. Lush, M.P., by Mr. Thomas Fraser Grove, M.P.; Dr. Minter, Inspector-General of Hospitals, by the First Lord; Deputy Inspector-General of Hospitals W. Munro, M.D., C.B., by the Director-General of the Army Medical Department; Mr. MacCormac, by Colonel the Hon. W. J. Colville; Staff Surgeon William Ross, M.D., R.N., by the Director-General of the Medical Department of the Navy; Deputy Inspector-General Dr. Rutherford, C.B., on appointment as Companion of the Bath, by the Director-General of the Army Medical Department; Sir Henry Holland and Sir Galbraith Logan; Drs. Vernon Bell, Hickeys Bird, Brewer, Thomas King Chambers, Frederick Farre, Day-Goss, Gream, Jonas R. Leake, Lowe, MacCormac, Alexander Marsden, Minter, W. M. Muir, C.B., Nicoll, Charles D. F. Phillips,

Poore, Frederick G. Reed, and Swettenham; Messrs. Oscar Clayton, Du Pasquier, Robert Ellis, Fraser (Surgeon-Major), Cæsar Hawkins, Prescott Hewett, Leonard Sedgwick, and T. S. Wells.

CONFIDENTIAL VISITS OF MEDICAL MEN.—At the Quarter-sessions at Coleraine, co. Londonderry, on June 22, before Mr. J. C. Coffey, Q.C., an appeal was made from a decision of the Kilrea magistrates, by whom the defendant had been fined £2 and costs, with the forfeiture of his licence, for selling spirits to be consumed on the premises, contrary to the statute, he having only a grocer's licence. The chief witness for the prosecution before the magistrates was Dr. John M'Kay, who had been attending a patient in defendant's house. The Sessional Crown Solicitor explained that Dr. M'Kay did not volunteer information in the case—on the contrary, he only gave evidence when compelled to do so on summons by the police. His Worship, in confirming the conviction, but reducing the fine, said he wished it to be distinctly understood by those who instituted these prosecutions that, so far as his individual judgment was concerned, the production of Medical testimony in such cases was highly improper. He must repeat emphatically that he utterly disapproved of any one in charge of those prosecutions, or in any way connected with them, using the evidence of persons in the position of Medical men, or ministers of the gospel, who might happen to be upon the premises in attendance on patients or others requiring their attention. He entirely disapproved of their being taken up and made use of in carrying out convictions of this sort.

THE QUEEN'S UNIVERSITY IN IRELAND.—A stated meeting of the Senate of the Queen's University was held at Dublin Castle, on Wednesday, June 19, at which the following members of the Senate were present:—Sir D. J. Corrigan, Bart., M.P., Vice-Chancellor of the University; the President of Queen's College, Belfast; the President of Queen's College, Cork; the President of Queen's College, Galway; Professor Moffett, L.L.D.; and David Ross, M.A. The Secretary of the University was also present. A meeting of the University was held on the same day, in the Council Chamber, Dublin Castle, at which the Vice-Chancellor conferred the following degrees and diplomas:—*Doctor of Medicine*: John G. Adamson, Queen's College, Belfast; Archibald Adams, Queen's College, do.; James B. Bailey, Queen's College, do.; Robert Evans Burges, B.A., Queen's College, Cork; Richard Davis, Queen's College, Belfast; John G. Collis, Queen's College, Cork; Henry A. Fogarty, Queen's College, do.; James Graham, Queen's College, Belfast; John Hegarty, Queen's College, Galway; Wm. Hickman, Queen's College, do.; H. Maturin Johnston, Queen's College, Cork; Francis B. Kane, Queen's College, do.; John R. Leach, do.; Samuel M'Cutcheon, Queen's College, Belfast; Denis Peter Macdonald, Queen's College, Cork; Peter J. M'Quaid, Queen's College, Galway; Henry Madders, Queen's College, Cork; John A. Malcomson, Queen's College, Belfast; Timothy Moloney, Queen's College, Cork; W. E. Bonsall Moynan, Queen's College, Galway; Bartholomew O'Brien, Queen's College, Cork; Patrick O'Connell, do.; Bernard O'Connor, B.A., do.; Simeon Holgate Owen, Queen's College, Belfast; Thomas Patterson, B.A., do.; Richard Read, do.; James Ring, Queen's College, Cork; J. Nashville Ryan, Queen's College, Belfast; J. M. J. Scott, do.; Thomas Francis Sparrow, Queen's College, Cork; William F. Spencer, Queen's College, Galway; William Thomson, B.A., do.; Hugh Charles Wilson, Queen's College, Belfast. *Master in Surgery*: John George Adamson, Queen's College, Belfast; Archibald Adams, do.; Moses Black, M.D., do.; Robert Evans Burges, B.A., Queen's College, Cork; Richard Davis, Queen's College, Belfast; Wm. Fleming, M.D., Queen's College, Galway; Henry A. Fogarty, Queen's College, Cork; James Graham, Queen's College, Belfast; John Hegarty, Queen's College, Galway; William Hickman, do.; Francis B. Kane, Queen's College, Cork; John R. Leach, do.; Peter J. M'Quaid, Queen's College, Galway; Timothy Moloney, Queen's College, Cork; Bartholomew O'Brien, do.; Patrick O'Connell, do.; Thomas Patterson, B.A., Queen's College, Belfast; Richard Read, Queen's College, Belfast, and Galway; James Ring, Queen's College, Cork; J. M. Scott, Queen's College, Belfast; Wm. F. Spencer, do. *Diploma in Midwifery*: J. M'Mahon Brown, M.D., Queen's College, Cork; Ebenezer E. Sloane, M.D., Queen's College, Belfast; J. King Kerr, M.D., do.; Alexander Young, M.D., do.; Moses Black, M.D., do.; John Knox, M.D., do.; John G. Adamson, do.; Robert Evans Burges, B.A., Queen's College, Cork; John G. Collis, do.; Henry A. Fogarty, do.; James Graham, Queen's College, Belfast; Henry Madders, Queen's College, Cork; John A. Malcomson, Queen's

College, Belfast; W. E. Bonsall Moynan, Queen's College, Galway; Bernard O'Connor, B.A., Queen's College, Cork; Patrick O'Connell, do.; Simeon H. Owen, Queen's College, Belfast; Thomas Patterson, B.A., do.; James Ring, Queen's College, Cork; J. M. J. Scott, Queen's College, Belfast; William Thomson, B.A., Queen's College, Galway. The Secretary of the University announced that the following candidates had passed the first University Examination in Medicine, viz.:—R. C. Burke, Queen's College, Cork; Martin F. Cleary, do.; Ludlow T. Colthurst, B.A., do.; William Cranston, Queen's College, Belfast; Maurice Cremen, Queen's College, Cork; M. De Courcy Curtin, do.; Maurice Daly, B.A., do.; Francis Davison, Queen's College, Galway; Alexander Dempsey, do.; George Dougan, do.; J. E. Vaughan Foss, Queen's College, Cork; Patrick C. Gorham, Queen's College, Galway; George R. Gowland, do.; James C. Gray, Queen's College, Belfast; Henry Grier, do.; Christopher Gunn, Queen's College, Cork; John Wilson Hamill, Queen's College, Belfast; Joseph Henry, do.; Edmund Hemsted, do.; Edwin Hemsted, do.; Wm. R. Huggard, Queen's College, Galway; Wm. C. Jeffries, do.; Edward H. Kelly, Queen's College, Belfast; William M'Iver, do.; Horace Mansell Maybury, do.; William H. Milward, Queen's College, Galway; Jarlath J. Mullen, do.; Michael T. Munro, Queen's College, Belfast; John O'Callaghan, B.A., Queen's College, Galway; Simeon Holgate Owen, Queen's College, Belfast; Joseph Parker, Queen's College, Galway; Norman Pollock, Queen's College, Belfast; Caleb K. Powell, Queen's College, Cork; Michael Ronan, do.; D. J. Ross, do.; Charles E. Sharpe, Queen's College, Belfast; Edward Shipsey, Queen's College, Cork; Edward Smyth, Queen's College, Belfast; Michael Sweetman, Queen's College, Cork; Charles Wadsworth, Queen's College, Belfast; William Edward Warren, Queen's College, Galway; Michael White, do. The Secretary also announced that the following candidates had passed in special subjects, viz.:—Robert Talbot Beamish, Queen's College, Cork; John Bryans, Queen's College, Belfast; James Scott Dill, do.; Edmund J. Dowling, do.; Gerald Fitzgerald, Queen's College, Cork; Joseph R. Gormley, Queen's College, Galway; David M'Coubrey, Queen's College, Belfast; Hugh M'Millan, do.; Douglas Mullin, Queen's College, Galway; William Molloy, Queen's Colleges, Belfast and Cork; Charles Plowman, Queen's College, Cork; John Strahan, Queen's College, Belfast; Alexander Wylie, do.

I CONSIDER, indeed, that the cochlea represents a musical instrument, similar in nature to a harp or musical box, the strings of the one and the tooth of the other represented by the rods of Corti. The spiral bony lamina is simply a sounding-board; around the rods are placed the various nerve-cells and nerve-fibres, and from these cells the impressions are conveyed by the fibres to the brain itself. It is possible, therefore, to trace very completely the course of sounds or vibrations from a musical instrument or any other source to the brain, through the medium of the ear. First the vibrations are caught and collected by the auricle, and transmitted through the external meatus to the drum of the ear, next across the middle to the internal ear. Here the sound is appreciated, merely as a sound, by the vestibule; the direction is discovered by means of the semicircular canals; but to distinguish the note of the sound, it must pass on to the cochlea. The vibration, therefore, passes through the fluid of the cochlea and strikes the lamina spiralis, which intensifies and transmits the vibration to the system of rods. There is doubtless a rod not only for each tone or semitone, but even for much more minute subdivisions of the same; so that every sound causes its own particular rod to vibrate, and this rod vibrating, causes the nerve-cells in connexion with it to send a nerve-current to the brain.—*Urban Pritchard, M.D.*

NOTES, QUERIES, AND REPLIES.

Be that questioneth much shall learn much.—*Bacon.*

Sanitary Organisation.—On this subject, which elicits such a variety of opinion, and tries some men's scanty tempers so much, it is well to listen to the words of Dr. Acland—one of the earliest and most laborious and disinterested workers and thinkers on sanitary questions. In a lecture delivered last week at Oxford, he said that we ought to secure for the nation the best possible central Medical authorities for administration. They wanted such an authority as that at the head of affairs, and they wanted such local authorities as would well administer the wise conclusions of the central authorities. They wanted in the central authority to employ the highest intellect of the country. He would say one word as to experts. It was not necessary to have highly skilled persons to do

the ordinary work. It was necessary to have plain practical men—men who were living upright lives and who were on good terms with their neighbours. That was the sort of men they wanted for the local authority. . . . There was at this moment a Bill before the Legislature which was based on the true principle in this matter—that it was not for every corner of the country to dictate in these matters, but that they should be delegated to put in force the conclusions of the best intellect which the empire could provide. . . . The Home Office, the Privy Council, and the Poor-law Board were united in the formation of the Local Government Board, and now we had indeed a complete administrative office, the basis of a scheme for sending out a proper administration to every corner of the land, to every hamlet and every house. The central authority was already constituted. One word as to its duties. In the Bill now before the Legislature the central authority was to have power to do what they might think necessary. They were to have five experts if five were wanted, and fifty if fifty were wanted; but Mr. Stansfeld, with the sagacity of a practical man, declined to hamper himself with fifty or five. The Bill was based upon scientific knowledge, and had the requisite conditions; and he hoped before long we should have this perfectly practical Board supplied with the requisite power of meeting the wants which appeared on all sides.

The Bermondsey Water Famine.—There has been a great lack of water in Bermondsey, and one of our Medical correspondents in the Borough describes hundreds of persons as having been sent away unwashed from the baths and wash-houses for want of water. First-class bathers had only half-allowance of water. Other correspondents tell us that no specific damage to the health of the neighbourhood has yet occurred.

A Country Surgeon sends us the following advertisement. Of course it is a joke, but one that comes sadly near the truth:—

“Wanted a duly qualified Medical man to attend the paupers of five parishes. He will be expected to work by night as well as day; wages one shilling and threepence per day. Also, a few healthy labourers (on the nine hour system); wages three shillings per day. Apply to J. H. Willis, Lewdown, Exeter.”

Economy.—The following is the statement alluded to:—

Statement showing the cost of maintenance per week per head of patients for the half-year ending Lady-day, 1872, in the Central London Sick Asylum, Highgate.

	Rate per week.	
	s.	d.
Provisions	5	3½
Necessaries for wards	1	8
Clothing	0	3½
Total	7	3

Erratum.—On page 730, for “Dr. William Carlos,” read “Dr. William Carless.”

DISINFECTANTS AND ANTISEPTICS.

(From a Correspondent.)

I am often having inquiries as to what “antiseptic” is to be used in a case of small-pox, or what “disinfectant” in cholera; and I am tempted to ask my Medical brethren to use these words themselves, and teach their patients to use them, with more precision than is customary at present.

There seem to be three special and distinct actions performed by the substances which are loosely called “disinfectants” and “antiseptics.”

The first is the destruction or decomposition of an organic substance, so as to reduce it to its most stable condition—carbon into carbonic acid, sulphur compounds into sulphates, and (generally speaking) organised matter into inorganic. Amongst such substances we reckon oxygen, ozone, chlorine, chloride of lime or of soda, water, Condé’s fluid, charcoal filters, chromic acid, and other substances which part with oxygen readily. The common property of all these is, that they thoroughly oxidise, decompose, and reduce to a harmless state bodies whose existence or whose decomposition is hurtful. Thus, let us suppose a bit of putrid meat dipped into a solution of Condé’s fluid, or of chloride of lime: the first thing grappled with is the offensive gases in their nascent state, and the unstable matter which is undergoing decomposition into them. These are quickly oxidised, offensiveness ceases, decomposition is hastened and safened. It is believed that organic matter in a state of minute division, such as pus, contagious discharges, and diseased “germinal matter,” would by the same agency be first killed, next reduced to the inorganic state.

The second kind of operation is totally opposite. Instead of hurrying through, and completing the work of decomposition, so that the body acted on shall be reduced to a stable inorganic state, this stops decomposition and gives stability to the organic state. Such substances as carbolic acid, creasote, strong vinegar, common salt, and the like, hinder decay, and avert its consequences. Suppose some contagious matter represented by a lucifer match: how can it be made safe? (1) By burning it up, when it can do no more; or (2) by making it incombustible. This analogy may serve to explain the difference between Class I and 2.

A third operation there is, which consists in destroying the living germs which propagate fermentation; and this seems to be done by most substances of powerful chemical qualities—arsenic, sulphurous acid, etc.—and by chloride of lime, as well as by carbolic acid. We may look on this as a subsidiary affair—important, no doubt, but one which follows of itself when powerful agents are used. It is chiefly in the preservation of delicate organic matters—as milk in the dairy, meat in the larder, a woman in childbed, a patient after operation—that the interception or destruction of germs *per se* requires attention, by delicate agents which shall purify the air and not be noxious in themselves.

Now, it is clear that Class I. and Class II. are mutually incompatible. To use chloride of lime, which hastens decay, along with carbolic acid, is to neutralise both. If we spill carbolic acid, one uses Condé’s fluid or chloride of lime to get rid of the smell. Choose which you please, and use plenty, but don’t mix.

The decomposing powers of water are immense. It is the great putrefier; and when there is water enough, and in movement, the oxidising process is rapid and complete—as Lethby showed respecting sewage in

rivers. For the same reason, a water-closet is unsafe, because it hastens and furthers initial putrefaction.

There are some things which I am unable to classify with exactitude, though I believe them to belong to the oxidating group. Such are the essential oils, which have a real power of destroying (not of merely hiding) foul emanations. I was very ill some time ago, and unable to leave my room for any purpose, and various substances were used to mitigate the fumes of the *chaisepercée*. Condé’s fluid was very disappointing, carbolic acid unpleasant; chloralum did not purify the air, nor check the vapours given off at the critical moment. The best thing I found was lavender-water from Apothecaries’ Hall, which seems to have great pungency, and the virtue of destroying stinks. MEDICUS.

CARBOLIC ACID IN HOOPING-COUGH.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Having some reason to think that carbolic acid would be useful in the treatment of hooping-cough, I determined to try it, and had not long to wait for a favourable opportunity, as there was an epidemic in the neighbourhood. Three children in a family were ill with this neurosis, in whom there was no secondary lung complication, the only symptoms being the violent cough with the well-marked whoop—the paroxysm frequently terminating in vomiting, for which I exhibited small doses of carbolic acid—viz., one drop in three ounces of water, the youngest child (4 years old) to take a teaspoonful every four hours, the eldest (12 years) a table-spoonful every four hours. The children were quite well in twenty-*osc* days.

I have since then treated several cases of hooping-cough with carbolic acid with very great benefit. I find that if there is much congestion of the lungs, tartar emetic is generally the most useful drug; and when the pneumonia subsides I give the carbolic acid either alone, diluted with water, or combined with tonics or opium, and find that it always checks the whoop and the violence of the cough, altering the paroxysmal character, and reducing the state to that of convalescence from pneumonia or bronchitic inflammation. Altogether I have treated over ten cases, but have not yet had time to arrange them, as I hope soon to be able to do. At present I only wish to draw attention to the fact that I have found carbolic acid stop hooping-cough in a remarkable manner; and if any of your readers have found or tried the same they might render good service by mentioning the fact, with the manner of administration. I give it, usually, in doses of 1-24th to 1-36th of a drop, freely diluted with water, every four hours, to a child of 6 years old; though at present a child of 4 years is taking one-eighth of a drop three times a day with very great benefit.

Hoping this may elicit some more information on the subject,

I am, &c.,

Church House, Aveley, Romford, June 24.

C. GLEN BOTT.

“DISAPPEARANCE OF SMALL-POX IN PARIS.”

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Under the above heading, in your Journal for June 8, “The Paris correspondent of the *Daily News*” is at a loss to account for the disappearance of small-pox in “unvaccinated Paris, while the disease rages in vaccinated London.” Without discussing the subject of vaccination and revaccination, which testify the merciful hand of Providence, abused or neglected as it may be, I would suggest whether the combustion of thousands of tons of gunpowder purified the atmosphere of Paris to such an extent as to render the disease incapable of existing. An experiment on a small scale, if it could be performed with safety, might be worth a trial. We must not, however, forget that epidemics live for a certain time in every town they invade, and then disappear, owing probably to some atmospheric cause which science has not yet unfolded. But if the atmosphere of Paris is not at the present time in a state to favour the incubation of small-pox, it may be in a state to favour the incubation of epidemic cholera or some other disease. Time, however, will prove, and I watch with interest. We know that cases of small-pox have occurred from time to time in every town and village without becoming epidemic, even when sanitary measures have been neglected; but when such measures are neglected by those in authority or by private individuals during the prevalence of an epidemic, the disease is far more destructive to health and life. Hence the importance of being at all times prepared to meet an epidemic as an invading army—the one being a visible, the other an invisible foe.

I am, &c.,

Southampton, June 21.

HENRY OSBORN, M.R.C.P., Lond.

ON COMPOUNDED SURNAMES.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—In the pursuit of my humble occupation, I have of late met with a difficulty which I wish to lay before your learned readers. I think that one-half of the permanent value of a book consists in a good index, and in furnishing such we English have hitherto been pre-eminent. Anyone who doubts this can have had but little to do with referring to foreign works, or he would have learned that the French “Table des Matières,” or the German “Inhaltsverzeichnis,” (our table of contents in fact) forms but a sorry substitute for the English “Index.” When, as is almost always the case, this constitutes the sole means of discovering new or forgotten matters, loss of time and temper, and uncertainty of the results of searching naturally ensue. Even such aid is sometimes wanting, for I have seen large German books without the remotest indication of their contents, sometimes not even being divided into chapters.

But to return to our own indexes, or, as some term them more precisely, *indices* (why, I really cannot tell, for surely the word has become sufficiently naturalised amongst us to be entitled to a British plural)—the task of preparing these, until lately, if sometimes laborious, has been simple enough, the compiler having only to read the book and bring all the important points into alphabetical order, taking care not to omit those of an incidental character. It is desirable, indeed, that he should be conversant with the subject on which the book is written, for many indexes are superfluously minute without embracing all important matters. My difficulty, however, relates to names. Here, again, our practice is more simple than that pursued on the Continent; for even there, periodical literature is supplied with indexes, as without such it would remain inaccessible to students with the ordinary duration of life. But in France and Germany they seem to overdo the matter by having a separate index for authors and subjects, which possesses no advantage over our combined index, and consumes more space. Whether in a separate or combined index, the names have to be placed, and the difficulty I allude to consists in knowing how to deal with a modern practice that has sprung up—that is to say, if such names are to be arranged for reference in all times and countries, which probably is the desire of their proprietors. This practice consists in the assumption of two names and connecting them with a hyphen. It probably arose from the desire of distinguishing the possessors of very common names

from each other; and a man who is afflicted (in a literary sense) with one of the Smith, Jones, and Robinson class of names is justified, in the struggle for fame, taking any reasonable step to individualise himself. The depressing effect of this class of names is seen in the fact that, notwithstanding their commanding position in the "Directory," they have produced so few works of note. It has become a custom with all those who wish for some nominal distinction, to prefix to their ordinary surname that which has been adopted from godfathers or other source, in many instances dropping the christian name altogether. Like other fashions, it is being followed rather blindly, many persons assuming these names who find no reason for so doing in the commonness of their own proper names. Doubtless in future most children will be provided with one or more such names, to be hereafter brought into prominence if so desired.

But what is to be done with these new names in an index? This would seem to be simply enough settled; for a man does not cease to be Smith, etc., however remarkable the name may be which precedes this cognomen. This point, however, does not seem to be quite decided, for I find by the "Medical Directory," that while Mr. Fly Smith settles into his proper alphabetical position, Mr. Rye-Smith does nothing of the sort, but takes refuge among the R's. This last gentleman is at least consistent, and when he connects his two names by means of a hyphen he means what he says, and wishes his compounded name to be indexed under R. Not so others; and here is the difficulty which has given rise to this long discourse. Of course to the great bulk of writers it does not matter much where they are put in an index, as they are not very likely to be sought for; but others have a just right to expect that what they have written shall be hereafter consulted, and to be consulted it must be found. In these days of cosmopolitan learning, too, they may wish their fame to penetrate to countries beyond their own. But how are their names to be placed in an index when compounded by means of a hyphen? Ordinary words so treated are, (e.g., a garden-party, a tea-pot), we know, indexed in their order of writing; and why should the practice be different when a man seeks, as it would seem, to create an indissoluble union between his two names? On the Continent, too, where compound names are not of infrequent occurrence, this is the rule—the first name to go into the index. It is a sufficient puzzle for the foreign index-maker to find so many double names among our writers, but when these are wilfully connected with hyphens, they are naturally, and as I contend properly, indexed under the first name. Confusion is thus produced, and writers of (for example) the to us unknown names of Burdon and of Hughlings are sometimes on the Continent credited with the labours we have been accustomed to attribute to Drs. Sanderson and Jackson.

I am, &c., A MEDICAL INDEX-MAKER.

COMMUNICATIONS have been received from—

Mr. PILLEAU; Dr. VANCE; Dr. BEST; Mr. MARK OGDEN; Dr. WICKHAM BARNES; Mr. G. STEVENS; Dr. PEARSE; Dr. NEILD; A COUNTRY SURGEON; Dr. RUMSEY; Dr. PITMAN; Dr. H. OSBORN; Mr. LOWNDES; Mr. J. N. RADCLIFFE; Mr. C. GLEN BOTT; Dr. PLAYFAIR; Mr. J. P. RICHARDS; Mr. PAGE; Professor BENTLEY; Dr. CARLESS; Dr. PHILIPSON; Mr. GARTON; Mr. HUTCHINSON; Dr. SEDGWICK; Professor HUMPHRY; Professor FLOWER; Mr. J. CHIATTO.

BOOKS RECEIVED—

Contagion du Choléra démontrée par l'Epidémie de la Guadeloupe, par Dr. Pellarin—Traité de Chirurgie d'Armée, par L. Legouest—Injuries and Diseases of the Jaws, second edition, by Christopher Heath, F.R.C.S.—Affections of the Liver and Intestinal Canal, by Stephen H. Ward, M.D. Lond.—Cancer: its Varieties, their Histology, and Diagnosis, by Henry Arnott, F.R.C.S.—On Cerebralia and other Diseases of the Brain, by Charles Elam, M.D. Lond.—Report of the Sanitary Condition of Birkenhead for 1871, by C. O. Baylis, M.D., M.R.C.S.—On the Law which Regulates the Frequency of the Pulse, by A. H. Garrod, B.A.—Catalogue of the Museum of the Odontological Society of Great Britain.

PERIODICALS AND NEWSPAPERS RECEIVED—

Glasgow Herald—Hexham Courant—Western Lancet—Pharmaceutical Journal—Gazette Hebdomadaire—L'Union Médicale—Philadelphia Medical Times—Transactions of the Odontological Society of Great Britain, vol. iv., No. 7.

APPOINTMENTS FOR THE WEEK.

June 29. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; King's, 2 p.m.; Charing-cross, 2 p.m.; Royal Free, 2 p.m.; Hospital for Women, 9½ a.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. Thomas's, 9½ a.m.

July 1. Monday.

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; St. Peter's Hospital for Stone, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

ROYAL INSTITUTION, 2 p.m. General Monthly Meeting.

2. Tuesday.

Operations at Guy's, 1½ p.m.; Westminster, 2 p.m.; National Orthopædic, Great Portland-street, 2 p.m.; Royal Free, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; West London, 3 p.m.

3. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1¼ p.m.; Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.; St. Thomas's, 1½ p.m.; Samaritan, 2.30 p.m.; King's College Hospital (by Mr. Wood), 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; St. George's (ophthalmic operations), 1¼ p.m.

OBSTETRICAL SOCIETY, 8 p.m. Dr. Aveling, "On Post-mortem Parturition." Professor Trenholme (Montreal), "On Irregular Uterine Contractions." And other Papers.

4. Thursday.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Royal Orthopædic, 2 p.m.; University College Hospital, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

5. Friday.

Operations at Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.

VITAL STATISTICS OF LONDON.

Week ending Saturday, June 22, 1872.

BIRTHS.

Births of Boys, 1015; Girls, 982; Total, 1997.
Average of 10 corresponding weeks, 1862-71, 1935.1.

DEATHS.

	Males.	Females.	Total.
Deaths during the week	633	597	1230
Average of the ten years 1862-71	647.6	597.4	1245.0
Average corrected to increased population	1370
Deaths of people aged 80 and upwards.	45

At the Royal Observatory, Greenwich, the mean reading of the barometer in the week was 29.86 in. The highest was 30.12 in. at noon on Sunday, the 16th, and the lowest 29.64 in. on Wednesday afternoon.

* The figures in this column, excepting those for London and Dublin, are the unrevised numbers enumerated in April, 1871, raised to the middle of 1872 by the addition of a year and a quarter's increase, calculated on the rate which prevailed between 1861 and 1871. The London population is now based upon the number enumerated in April, 1871, as revised at the Census Office. The population of Dublin is taken as stationary at the number enumerated in April, 1871.
