HANDBOOK
OF
CONSTRUCTION COST

WORKS OF HALBERT P. GILLETTE AND RICHARD T. DANA

HANDBOOK OF CONSTRUCTION COST.
By Halbert P. Gillette
1733 *pages, illustrated,* 4¾ x 7 in., flexible binding

HANDBOOK OF MECHANICAL AND ELECTRICAL COST DATA.
By Halbert P. Gillette and Richard T. Dana.
1750 *pages, illustrated,* 4¾ x 7 in., flexible binding

HANDBOOK OF COST DATA, *by Gillette.*
A reference book, giving methods of construction and actual costs of materials and labor on numerous civil engineering works.
1878 *pages, illustrated,* flexible binding, 4¾ x 7 in.

HANDBOOK OF CONSTRUCTION EQUIPMENT.
By Richard T. Dana.
Gives net prices, shipping weights, capacities, outputs, etc., of all kinds of construction machinery.
Second edition, 850 *pages,* flexible binding, 4¾ x 7 in.

HANDBOOK OF ROCK EXCAVATION; METHODS AND COST, *by Gillette.*
840 *pages,* 184 *illustrations,* flexible binding, 4¾ x 7 in.

EARTHWORK AND ITS COST, *by Gillette.*
Third edition, 1362 *pages, illustrated,* flexible binding, 4¾ x 7 in.

HANDBOOK OF CLEARING AND GRUBBING; METHODS AND COST, *by Gillette.*
240 *pages,* 67 *illustrations,* 4¾ x 7 in.

CONSTRUCTION COST KEEPING AND MANAGEMENT.
By Halbert P. Gillette and Richard T. Dana.
A treatise for civil engineers and contractors.
572 *pages,* 264 *illustrations,* cloth, 6 x 9 in.

CONCRETE CONSTRUCTION; METHODS AND COST.
By Halbert P. Gillette and Charles S. Hill.
A treatise on concrete and reinforced concrete structures of every kind.
700 *pages,* 306 *illustrations,* cloth, 6 x 9 in.

THE TRACKMAN'S HELPER.
By Richard T. Dana and A. F. Trimble.
400 *pages,* cloth, 4½ x 6¾ in.

Note: For full descriptions of these books see the advertising pages at the end of this volume.

HANDBOOK OF CONSTRUCTION COST

BY

HALBERT POWERS GILLETTE

EDITOR OF ENGINEERING AND CONTRACTING, MEMBER AMERICAN SOCIETY OF CIVIL ENGINEERS, AMERICAN ASSOCIATION OF ENGINEERS, WESTERN SOCIETY OF ENGINEERS

FIRST EDITION

McGRAW-HILL BOOK COMPANY, INC.
NEW YORK: 370 SEVENTH AVENUE
LONDON: 6 & 8 BOUVERIE ST., E. C. 4
1922

THE MAPLE PRESS - YORK PA

PREFACE

Seventeen years ago the first edition of my Handbook of Cost Data was published; the second edition was published twelve years ago and has not been revised. When the question arose as to whether I should revise the Handbook of Cost Data now or produce an entirely new book on construction costs, I chose the latter alternative, for the following reasons:

Nearly three-fourths of the costs given in the Handbook of Cost Data are still applicable although published more than twelve years ago. This may surprise many people, for cost data are commonly supposed to be ephemeral. But, as stated in the prefaces to the Handbook of Cost Data and to the Handbook of Mechanical and Electrical Cost Data, unit costs can be so stated as to be applicable for a century or more, provided the methods of construction have not changed. If the number of hours of labor of each class and the number of units of materials are given for each unit of construction, then present rates of wages and present prices of materials can be applied to the old data, and the present cost of construction deduced.

Because of this fact I decided not to revise the Handbook of Cost Data for a few years longer, but to produce a new companion book under the title of Handbook of Construction Cost, thus preserving fully 1,800 pages of usable cost data in the old book, and adding thereto 1,700 pages in this new book. The owners of the old handbook will thus find no duplication of data in this new handbook and will not be put to the expense of buying a two volume revised edition.

The World War caused a great rise in prices and wages. So important did it become to know approximately what future price and wage levels would be that I decided to make a very thorough study of the factors that affect price and wage levels. This study was rewarded by the deduction first of a price level formula, and later of a wage level formula, both of which are discussed at some length in this book, where they are shown to be in agreement with the facts for so many years as to leave no doubt as to their substantial accuracy.

Several political economists had previously announced composite price and wage formulas, which purported to give a weighted average of commodity and security prices and of wages. My engineering training enabled me to discern that since the wage level curve had risen almost uniformly for a century, whereas the commodity price level curve had oscillated, no formula giving a composite of wages and prices would be of any value, even if it could be deduced. Accordingly, I devoted myself to deducing two distinct formulas, one for commodity price levels and one for wage levels. The first of these was published in Engineering and Contracting, April 7, 1920, and the second August 3, 1921, together with the proof of their substantial accuracy.

For compiling data for this book I am greatly indebted to James M. Kingsley.

HALBERT P. GILLETTE.

HANDBOOK OF CONSTRUCTION COST

CHAPTER I

ENGINEERING ECONOMICS

This chapter takes up briefly some of the principles and applications of engineering economics. Further matter on this subject is given in Section I of the "Handbook of Cost Data" by Gillette, which contains 112 pages dealing with the principles of engineering economics and cost keeping; and Chapter I of the "Handbook of Mechanical and Electrical Cost Data" by Gillette and Dana, which contains 81 pages on general economic principles. "Construction Cost Keeping and Management" by Gillette and Dana deals at greater length with the particular phases of engineering economics indicated by the book's title.

Engineering is the systematic application of science to problems of economic production and service. The engineer's ultimate aim, therefore, is to effect a desired result at a minimum cost and maximum profit. To this end, where it is feasible, the engineer should formulate a unit cost equation in which all dependent variables and constants are included, and he should then solve for a minimum unit cost. But whether he is able to employ this ideal method or must use cruder methods, he must eventually express all the items in terms of money.

Put differently, every economic problem resolves itself into the determination of quantities to which unit prices are applied. No economic problem can be solved merely by the use of qualitative terms; yet many a poor reasoner attempts to solve the most complex of economic problems without the use of a single item to which a definite cost is assignable. Volubility is vainly made to serve instead of valuation.

Imperfect Cost Data.—The term data is coming more and more to designate statistical facts rather than qualitative facts. Cost data are obviously essential in solving economic problems. Yet there still exists a prejudice against published cost data. If, however, each engineer were to rely solely on cost data gathered by his own meager pickings from his own little crab-apple tree of experience, economic progress would be decidedly restricted. Accordingly each year witnesses more complete and detailed publication of costs in most lines of engineering work. It is true that many of the cost data are incomplete, or insufficiently explained, and are therefore apt to be misleading. It is also true that a man entirely inexperienced in the use of cost data may misinterpret even the most complete data. But neither the deficiences in published data nor defective reasoning in their application should serve as an argument for restricting the publication of such information. In spite of the risk of misuse, "a half-loaf is better than none." Moreover a half-loaf of knowledge on a given subject is almost universally the precursor of a full loaf.

Prices and Costs.—Price is the quantity of money exchanged for property or service. *Cost* is usually, but not necessarily, expressed in terms of money, and, when so expressed, means the money outlay and debits incurred in securing property or service. Cost may also be expressed, at least partly, in terms of hours or days of labor required to produce a given commodity or service. But as materials that have been purchased usually enter into the cost of a product, and as the labor upon those materials is often unascertainable, the known labor-cost of product is rarely all the cost. The labor-cost of a product may be given in hours or days of labor expended upon it. The materials-cost of a product may likewise be expressed in units of each kind of materials used.

Although the money-cost of reproducing a given product or service vary with current prices and current wage rates, the labor-costs and the materials-costs of the given product may remain the same in different localities and in the same locality at different times. Indeed, unless methods of construction or machines change, the average labor-cost and materials-cost per unit of products or service may remain practically unchanged for a generation. When this is the case the present cost of reproducing a given product is ascertainable by multiplying the old labor-cost and material-cost by the present rates of wages and present prices of materials. In other words old money-costs can often be converted into present money-costs by the use of a little knowledge of prices, wages and arithmetic.

The Usefulness of Old Cost Data.—Obvious as all that has just been said may appear, nevertheless there continues to be some criticism of "old" cost data. It is clear, however, that part of this criticism springs from failure to distinguish between prices and costs. Part of the criticism springs from belief in a false generalization which usually takes some such form as this: "Modern progress is so rapid that cost data ten years old are inapplicable." We are rather proud of our industrial progress, and our pride has perhaps concealed from us how slow that progress really is. In Chapter II it is shown that during the years 1900 to 1919 there was practically no increase in per capita productivity in America. Prior to 1900 the annual increase had averaged about 1.5 per cent for 40 years. Surely this is not startlingly great industrial progress even at the best period. In the face of such facts what becomes of any sweeping assertion that modern progress makes useless all cost data that are ten years old?

When a generalization is shown to be false, it is not only natural but proper to narrow it so as to make it convey truth of a more limited sort. Hence the attempt may be made to qualify the generalization by confining it to the construction field. At first sight it does look plausible to say that construction methods and machines are revolutionized every ten years or so; but a little study of engineering literature shows that even this qualified generalization needs further qualification. There are countless instances of present use of very ancient tools and methods in construction work. The pick, the shovel, the cart, the wheelbarrow, the saw, the adz, the ax, the hammer, the block and tackle, the inclined plane, the lever and an almost endless list of primative tools still find an economic use, and most of them probably always will find such use.

The introduction of the method of chuting concrete, and of suitable new devices for chuting it long distances, is scarcely a decade old. But concrete is still handled in ways and by devices that are several decades old. Are we not apt to be so blinded by the latest devices as to ignore the fact that many of the oldest still have special fields of usefulness? A study of engineering literature convinces me that we are. Mere age, therefore, is not a sound reason for not studying old cost data. Frequently the best articles on methods and costs of construction of a given kind are the articles published 20 years or more ago.

Often an old article fails to give rates of wages, but gives the unit cost of labor. In such cases, the reader may still find the old data useful if he knows approximately the prevailing rates of wages at the time the old data were gathered. Accordingly I have left unchanged in every case, the rates of wages that were actually paid, so that the reader can, by searching this book and the Handbook of Cost Data, acquire a knowledge of what were the prevailing wages for different kinds of labor at different times and places. In order further to increase the reader's knowledge of wage rates, I have made a study of "wage indexes" for the past 80 years. This study, together with a formula for "wage levels," will be found in Chapter II.

For a similar reason I have also given prices of materials and "commodity price levels," together with a formula for "price levels."

Efficiency as Affecting Costs.—During periods of rapidly rising wage rates, employees tend to become less efficient. This springs from the fact that employers are bidding for employees to such an extent that employees take advantage of conditions. Hence, during the recent war there was a falling off in labor efficiency. But labor efficiency has returned again to normal. It follows that costs of work done during the years 1916 to 1920 inclusive are not so reliable as prior thereto, because of the unknown extent to which labor efficiency was below normal during those five years.

Engineering Economics.—The following reprint in Engineering and Contracting, May 30, 1917, is from a series of lectures delivered before the students of the School of Engineering, University of Kansas, by J. A. L. Waddell.

General Features of Engineering Economics.—When determining, from the standpoint of economy, which is the best of a number of proposed constructions or machines, one should compute for each case the four following quantities, and their sums:

A. The annual expense for operation.
B. The average annual cost of repairs.
C. The average annual cost of renewals.
D. The annual interest on the money invested.

That one for which this sum is least is the most economic of all the proposed constructions or machines; but this statement is truly correct only when the costs of operation, repairs, and renewals are averaged over a long term of years; or else, for a comparatively short period of time, when the conditions in respect to wear and deterioration at the end of that period are practically the same for all cases.

The principal economic investigation that occurs in engineering practice is that of determining the financial excellence of a proposed enterprise. It consists in showing by proper calculations its first cost, the probable total annual expense of maintenance, repairs, operation, and interest, the advisable allowance for deterioration or ultimate replacement, the probable gross income, and the resulting net income that can be used in paying dividends on the stock or other profits to the promoters. Whether any proposed enterprise, after being thus figured, will prove profitable will depend greatly on the state of the money market, the size of the project, the probabilities of future changes in governing conditions, and the personal equation of the investor. Generally speaking, if the computed net annual profits on the total cost of the investment (over and above all expenses of every kind, including maintenance, repairs, operation, sinking fund, and interest on all borrowed capital) do not exceed 5 per cent of the said total cost, the project is not attractive; if it be as high as 10 per cent, the enterprise is deemed ordinarily good; and if it be 15 per cent or more the scheme is termed "gilt-edged." Small projects necessitate greater probable percentages of net earnings than do large ones; and any possibility of a future reduction of income will call for a high estimate of net earning capacity. Finally, the measure of individual greed on the part of the investor will be found to be an important factor in the determination of the attractiveness of any suggested enterprise.

Such investigations as the economics of an important project should generally be entrusted only to engineers experienced in the line of activity to which the said project properly belongs; for if they be left to inexperienced investigators, it is more than likely that mistakes will be made and money lost in consequence. The professional men who generally do such work are the independent consulting engineers; certain specialists retained on salary solely for this purpose by important organizations, such as railroad companies; and engineers who are regularly in the employ of large banking houses. The work involved is of such importance that it usually commands large compensation—as, indeed, it should; because to do it effectively demands not only long experience but also good judgment and a vast amount of mental labor, both in order to make oneself capable in general and so as to consider thoroughly all the points embraced by the special problem in hand.

This fundamental economic problem is often one of extreme complication, involving, perhaps, a determination of the character of the proposed improvement, a choice of sites or routes, a selection of uses, a consideration of æsthetics, an option on type or style of construction, a question of ultimate durability, a study of greatest possible convenience, a prevision of serious opposition, a prognostication of future conditions, an anticipation of prospective structural modifications, and a safe estimate of cost.

General Features of Economics of Design and Construction

Anticipating the Future.—In all engineering work of both designing and construction, true economy necessitates a thorough consideration of future requirements and possible eventualities, also a provision for meeting the same. For instance, in designing a structure one should consider possible future additions of loading and how to accommodate them; and in construction one should anticipate delays, floods, storms, and other possible difficulties, and should prepare his programme so as to meet them effectively and without any unnecessary expenditure of time, labor, or money. Foresight of this kind is an important element of success in the career of every engineer.

Systemization.—Quoting from the speaker's treatise on "Bridge Engineering," "The systemization of all that one does in connection with his professional work is one of the most important steps that can be taken towards the attainment of success." Moreover, it is one of the fundamental elements of economics in all lines of work.

Time Versus Material.—Some designers in their endeavor to save a small amount of material expend a large amount of time, not only of their own but also of other people's, which time when properly evaluated is often greatly in excess of the cost of the material saved. Such economy as this is false; and its practice is unscientific.

Labor Versus Material.—Similarly some designers in an endeavor to cut down quantities in their structures increase the labor thereon to such an extent that the material saved is worth only a small portion of the value of the extra labor expended. For instance, if one were to make a small pier hollow, the concrete thus saved would not be worth anything like as much as the cost of the forms required to construct the hollow space.

Recording Diagrams.—The study of economics is greatly facilitated by the use of diagrams that record quantities of materials, costs of construction, times of operation, etc., for varying conditions. In general, it may be stated that American engineers do not use graphics for studying economics to the extent which is advisable; and that in this they might learn something from their European brethren.

Economics of Mental Effort.—Almost nothing concerning this important subject is taught in our technical schools; and but little is known about it by practicing engineers. To be a truly successful engineer, one has need to study deeply the matter of how best and most economically to utilize his mental forces; how to accomplish the greatest amount of work with the smallest expenditure of effort; how many hours of work per day for long-continued labor will effect the largest accomplishment; to what extent men in various lines of activity should take vacations, and how these should be spent; what are the effects upon one's working capacity from the use of liquor and tobacco in both small and large quantities, etc. All these are economic questions of great importance; and they need to be given proper attention by every engineer who aspires to efficiency in both himself and his employes. Again, the development of the faculty of concentration is an economic consideration of much importance.

Economics in Office Practice.—There are many conditions in ordinary office practice that are susceptible of considerable improvement from the economic point of view—for instance, unnecessary conversation, useless duplication of labor, and lack of proper checking; but this matter is too complicated and lengthy to warrant more than mere mention in a lecture of this kind.

Economics of Manufacture.—This is a subject of such complication and extent that it can merely be mentioned here; for upon it a large treatise might readily be written. It will suffice to say that the prime requisites are the prompt furnishing at all times of materials and tools; the keeping on hand of spare parts of machinery which are liable to breakage or wear; the proper upkeep of all machinery and apparatus; the systematic arrangement for carrying work through the shops, preferably always in one direction; the avoidance of duplication of labor; the prevention of errors, and the speedy correction of those which unavoidably occur; the development of individual efficiency in all employes; the maintenance of a contented spirit among the workmen; and the constant and intelligent supervision of all work.

Economics of Construction.—This subject like the one last discussed is of great complication, and in general principles the two have much in common.

For instance, there should be prepared for each piece of construction an elaborate programme, indicating the various steps to be taken and how the work should be carried out. Diagrams in this connection are most useful. Again, there should be prepared a time-schedule for the completion of the various divisions of the work; and this should invariably be lived up to when it is possible.

There should be a pre-arranged schedule for the furnishing of all materials and supplies; adequate means for the transportation thereof should be provided; the workmen should be well housed and fed; and should be made comfortable and contented; disagreements between heads of departments should be prevented; all possible difficulties should be anticipated, and means should be at hand to meet and overcome them; ample funds should be provided for paying promptly all bills for labor and materials; liquor should be kept away from the workmen; and strike organizers and other troublesome people should be run off the job.

All these matters are directly concerned with the economics of construction.

Labor.—The scientific handling of labor is an economic prolem of the utmost importance, and a treatise could well be written on the subject. The principal desideratum is to keep the workmen well, happy, and contented; and the best ways to do this are to treat them kindly, make them comfortable, feed and house them well, amuse them in their spare time, don't work them too long hours, pay them by piece-work when practicable, listen patiently to their complaints, right their wrongs, see that they are well taken care of when they are ill or injured, and evolve, if possible, some feasible method of sharing profits with them. On the other hand, though, drive them hard and continuously during working hours, insist upon their putting in overtime when the conditions truly require it, discharge instantly all insubordinate or otherwise troublesome men, dispense quietly with the services of all shirkers, and insist that everybody put forth his best and most intelligent effort to effect the maximum of accomplishment in the minimum of time.

Waste.—In all lines of activity the avoidance of waste or extravagance and the utilization of by-products are today burning questions; and upon their proper solution by American scientists will depend greatly the success of our country in its commercial struggle with the nations of Europe and Asia. This statement is just as true concerning engineering as it is of any other activity; and it is encouraging to see that a number of our leading technical institutions are inaugurating research departments for the furtherance of this object.

Efficiency Experts.—A very new type of specialist in engineering is the efficiency expert—the man who takes hold of moribund factories and other decaying enterprises, studies them thoroughly so as to determine the raison d'etre for their decline, evolves the proper remedies for their troubles, puts them again upon their feet, and starts them upon the high road to success. It is mainly in little matters, apparently of small importance, that such concerns fail; and it requires a high development of unusual talent in an engineer to become a truly successful efficiency expert. Such work as his no one can deny being "engineering economics" in the truest sense of the term; and the specialty is surely destined to become more and more popular and important as the years pass by.

The Art of Making Rapid and Reliable Preliminary Estimates of Cost.—Allen Hazen gives the following in Engineering and Contracting, March 18, 1914. Estimating the cost of constructing proposed or existing structures rapidly and surely is an art. It is a valuable art and deserves cultivation. The success of many undertakings depends upon its use. Some men have the knack of estimating; others can never learn it. But good methods are essential and these can be studied and perfected and applied to special problems.

Estimates made for different purposes, are prepared in quite different ways according to circumstances. They may be conveniently classified under three headings:

(1) Preliminary estimates, being estimates made in advance of the preparation of detailed plans and specifications for the purpose of discussing a project for deciding as to its adoption, and for making the necessary financial arrangements for carrying it out.

(2) Detailed estimates, being estimates based upon detailed plans for the execution of the work, and usually made shortly before bids are asked for the particular work covered, or in advance of undertaking to carry it out by day labor.

(3) Final estimates, being the estimates to the contractor at contract prices for the actual work done. The term "final estimate" may also properly be applied to a statement of the cost of a completed work based upon actual expenditures made for carrying it out.

That which follows relates only to preliminary estimates.

Preliminary estimates are made much more frequently than others because only a fraction of the projects for which estimates are made are carried out. Less precision is expected in preliminary estimates than in detailed or final estimates, but on the other hand all reasonably attainable accuracy is desirable, for many important matters depend upon it. The decision as to which of two or more alternate projects is to be adopted frequently turns upon the preliminary estimates of the respective costs. The decision as to whether or not to undertake a certain enterprise usually turns upon the preliminary estimate of the cost of the work. A certain degree of reliability is, therefore, essential in preliminary estimates. On the other hand, preliminary estimates must be made for many enterprises that will never be carried out, and it is necessary that they should be made rapidly and without undue expense to the client.

Basis for Preliminary Estimates.—There is only one real reliable basis for preliminary estimates. It is, the consideration of final estimates of work previously carried out, of a character and magnitude as nearly as may be similar to that of the proposed work. The more nearly the work represented by these final estimates approaches in all the conditions that for which estimates are being made, the more reliable, in general, are the preliminary estimates based upon it; and the more numerous and greater the points of divergence, the less reliable is the basis and the greater is the probable error in the resulting preliminary estimate.

Estimates in Valuation Proceedings.—When a property such as a water works property is to be valued for the purpose of sale, it is common for engineers to make estimates of the cost of reproduction for the structures. These estimates may be in the nature of final estimates when the structures were recently completed and the actual costs are shown by records. They may be in the nature of detailed estimates when full plans and quantity schedule are available. More often they are in the nature of preliminary estimates because such detailed information and cost are not available. Preliminary estimates made in this way are commonly subject to comparison with like estimates made by engineers representing the other party to the transaction, and it is frequently necessary to harmonize such estimates by arbitration or otherwise. If they are presented as evidence in court the engineers who made them must support them through a searching cross-examination. The criticism of preliminary estimates made in this way is likely to be more searching than that of estimates made in the ordinary course of business, where the estimates are made for the purpose of construction and comparison only. For this reason the experience gained in valuing properties for the purpose of sale and in condemnation cases is more useful than any other experience that an engineer can have in training him in the first elements of sound procedure in making preliminary estimates.

Methods of Comparison.—The problem presented in making preliminary estimates is this: given the final estimates of a certain number of works, more or less comparable to the one proposed, and a general outline of the works for which an estimate is to be made to find the probable fair reasonable cost of construction of the proposed works. The general procedure is to find the elements of cost in the work that is to be carried out, and the actual cost of those elements in the works for which final estimates are available, and to apply the latter to the former. In doing this all known differences that would affect, to an important extent, the probable cost of the work, must be taken into account and allowed for to the best of the estimator's ability.

Basis of Estimate.—An estimate may be said to be low, fair, or liberal, according to the methods used in making it. A fair estimate may be defined as one such that with the work carried out in a business-like way under average conditions, there is somewhat more than an even chance that the work could be completed within the estimate. In the case of structures of types that have been built frequently, and of which the elements of cost have been well determined, experience indicates that it is possible in most cases to approximate, in preliminary estimates, the cost of new structures within 10 per cent of the actual cost. With such structures a fair estimate would be somewhere between the most probable cost and 10 per cent more than this, or, in a general way, 5 per cent above the most probable cost. With an estimate made in this way, it should be possible to keep the actual cost of construction within the estimate three times out of four, and this is figuring as closely as an engineer can be expected to do.

In the case of structures of greater novelty, or structures involving undetermined underground conditions, greater fluctuations must be anticipated and the above-mentioned percentages should be increased.

Erroneous Methods of Reaching Estimates.—In a valuation proceeding, it is frequently surprising that reputable engineers will present on different sides, estimates differing so much for the same item. These differences must frequently grow out of the use of erroneous methods of procedure by the respective engineers. It may be well, therefore, to consider some of the commonest methods that are erroneous, and to point out the reasons why they should not be used.

The Contract Price Method.—The columns of the technical journals contain a record of the prices at which many contracts are awarded. By going through these columns and selecting the low bids and applying them to the proposed work, an estimate may be prepared which will probably be much below a fair estimate for the work. Among the reasons that it would probably be low are the following:

First, many of the low bidders have underestimated the difficulties to the work, and their bid are really too low. That is, they are not sufficient properly to carry out the work and make a fair profit. The contractor may not be able to complete the work under the contract and additional expense to the owner will have to be met.

Second, in applying the bid prices, or contract prices to new work, it is very easy to overlook entirely some items in the work. A price that relates to a part of the work may be taken as applying to the whole of it through ignorance or failure to make a fair and full comparison.

Third, the schedule of quantities prepared by the engineer for use in the specifications on which bids were obtained may be inaccurate and may not correspond with the final quantities when the work is completed.

Fourth, the items of extra work growing out of conditions that either were not anticipated, or that were intentionally excluded from the contract by the engineer as a matter of policy, are overlooked and ignored.

For these and similar reasons, estimates prepared from contract prices or from low bids reported are almost invariably too low and frequently may be too low by a very large percentage. An estimate made in this way is a low estimate. The figures may be arranged to make a very convincing showing in support of it, but it remains notwithstanding a low estimate.

Estimates Based on Averages.—In many municipal and corporate reports one may find records of the monies actually expended in carrying out certain developments. It is easy to find such records and to compile them and to deduce from them a figure which may be used as representing the probable cost of a proposed work of similar character. Some works represented by such figures may have been done in an efficient an economical manner, and the figures so obtained may be reliable and proper ones for use. Frequently, some or all of the work taken for use in this way was done under conditions that were not efficient, and the cost of doing it may include other items than those relating to the construction work. It is easy to select data in this way to back up a high estimate, and to make a showing that is convincing to those not familiar with the methods.

A Fair Basis of Estimate.—A fair basis of estimate does not exclude either of the above methods, but will take into account data secured under either for what it is worth, and will make allowances for the conditions, or supposed conditions, under which the bids were received, or the work was done. A fair basis of estimate will also give much greater weight to final estimates of work as comparable as may be to the work that is proposed where the work was done under conditions known to be careful and economical. The engineer in making such estimates will naturally and rightly give greatest attention to work done under his own direction, and will give second place to work done by his friends and acquaintances with which he is reasonably familiar as to conditions met and methods used in the construction.

The Weighted Price Method.—The number of different kinds of work for which unit prices may be obtained is very great. If an effort is made to keep track of the amount of work of each kind, and to estimate the amount of it in the proposed work, the schedule will be too complicated and the labor of applying the figures will be unduly increased. Moreover, if the schedule used for comparison is too complicated, some items are sure to be overlooked, with the result that too low a final figure will be reached. In order to prevent both of these conditions it is frequently best, in preparing preliminary estimates, to take only a limited number of the main items of work that are involved in the kind of construction that is contemplated, and to weight the unit prices for them in such a way that they will include the whole cost of all the incidental items naturally associated with them.

In proceeding in this way one selects first the items that are to be used. These items should be so selected as to include directly the major part of the work. The final estimates that are to be used as a basis are then taken for analysis. The whole cost of the work represented by each is then distributed among selected items. Considerable judgment is required in the distribution and each part of the construction should be included with the item to which it is most nearly related. The most important point is that every dollar spent should be charged under some one of the selected headings.

The sum of the costs reached in this way, divided by the quantities in the final estimate, gives new unit prices which are weighted to include all the minor items. Applying these unit prices to the main items of the proposed work gives a basis for preliminary estimate.

As illustrations of these methods, take the case of pipe-laying. The trenching, the lead, the cast iron pipe, the teaming and incidental expenses may all be represented by separate items in the final estimate that serves as a basis. These can obviously be consolidated into a single item per lineal foot of pipe of a given size. In this process the price for pipe is weighted to include the other expenses that naturally go with it. The process may be carried further and the pipe still further loaded to include the gates, the hydrants and all auxiliary structures.

In a similar way the cost of the reinforcing and of the forms for concrete construction first stated as separate items, may be consolidated, and all the different classes of concrete may be brought into one so that a unit price for masonry includes reinforcing and forms, and all the appurtenances that go with the masonry structures.

In estimating the cost of sand filters the writer has for years divided the whole cost of the construction into four parts, as follows:

(1) Excavation and earth work.
(2) Masonry.
(3) Filtering materials.
(4) Piping and auxiliaries.

The cost of each plant built worked out in this way on a uniform basis affords a basis for rapid and accurate comparisons, and allows the data to be applied in making preliminary estimates for new work where the prime conditions of cònstruction are known with comparatively little chance of large error.

Weighted unit prices of this kind must be carefully obtained and can only be used with caution. The amount of weighting must always be kept clearly in mind by those who use them. When properly deduced and used, they afford an extremely useful and rapid method of approximating the cost of many structures.

The Ratio Method.—There are many cases where the system of weighted unit prices cannot be used because the schedules in the final estimates that serve as a base are in such form that unit prices cannot be deduced from them. For example, there are many cases where the amount and character of work are known and the total cost of the work is known. but there is no way of sub-dividing it between the different items. To compare the costs of different pieces of work with each other, and to get a basis for estimating the probable cost of other similar work is then much more difficult.

A method of reaching an approximate and useful solution of this problem is one which may be called the ratio method. A schedule is made of a limited number of items of work which represent the greater part of the construction in the several cases. A simple schedule of unit prices is then formed, corresponding to the units. One fixed price is assumed for each kind of work. The price assumed should be a reasonable one, and as nearly as is known an average one, but precision is not to be expected and a round figure may always be used. The amount of work under each item in each job is ascertained and the assumed prices are applied to them. The sum of the amounts for each job represents what that job would have cost at the assumed prices. A comparison between the actual cost and the cost at the assumed prices gives an idea of the relative economy of the work. It may be found, for example, that one piece of work cost 20 per cent more than the amount obtained by applying the assumed prices; another piece of work cost 12 per cent more and a third, 7 per cent less. When the records of a number of known pieces of work are compared in this way it furnishes a basis for making a preliminary estimate for work of the same class. In doing this the quantities for the proposed work are ascertained, the base prices are applied to them and a ratio by which the sum so reached is to be increased or diminished is ascertained by consideration of the ratios actually found to have been obtained in the jobs for which cost records are at hand.

In arriving at the ratio to be used, the engineer will compare, perhaps in his mind and without written schedules, the ease or difficulty of the proposed work as compared with the ease or difficulty of the various works which served as a base; will take into account differences in labor conditions, in freights and deliveries; will take into account the known or assumed efficiency or lack of efficiency in the execution of the several pieces of work from which his basic data were derived, and will reach an estimate of the addition or subtraction to be made to or from the base price in each case.

This method is commonly combined with the preceding. That is to say, the base prices are usually loaded prices.

This method affords a convenient and efficient method of comparing the relative costs of different works where the loaded unit price method cannot be applied and in experienced hands it affords a rapid and reliable method of making preliminary estimates upon many classes of structures.

Extra Cost of Novel Designs.—Work on novel designs commonly costs more than work following standard designs. This is true even when well tried methods are first introduced in new places. Such work may be too small to attract bidders from a distance. The unit cost will then overrun anticipated prices. An under estimate of cost is frequently made on work because the estimator fails to realize what a great effect familiarity with the methods of performing work has upon the cost. To realize this, one has but to think of the difference between present methods and costs of building tunnels and subways and deep foundations, and the methods and costs of only 15 or 20 years ago. Not only is the risk which the contractor takes now less, but methods which have been thoroughly tried out are at his disposal as well as experienced foremen and laborers to do the work more economically. For a structure of new or novel design much caution in using prices that may be standard on other kinds of work must be used.

Small Jobs Cost More in Proportion than Large Ones.—Another common cause of under estimating costs is the use of figures on large pieces of work for estimating small work. The engineer often overlooks the large cost of overhead charges, the waste of labor and the cost of plant caused by organizing a force to perform a small piece of work. He too often forgets that for small work the work must be done by less efficient methods or the cost of plant prohibits the use of expensive machines. Perhaps the most common case of such underestimating is where the job, although a large one in the aggregate, consists of many small pieces of work of widely varied character. Such a job is troublesome and costly for the contractor and the experienced man knows it and puts in a corresponding bid.

It must be remembered that bids follow the law of supply and demand; that general slackness in construction work calls out bidders and low prices. The condition of the money market, the cost of materials and the general opinion of the condition of contract work are of course matters of much importance. It seems scarcely necessary to say that the engineer should know where and how the contractor is to obtain his materials and have a fairly definite idea of the cost either in dollars and cents or as a comparative figure to other work.

The engineer in estimating should try to look at the work from the standpoint of the contractor, should try to remember that no work runs as smoothly along as the contractor wishes, that labor conditions and other matters often spoil the best laid plans. He should endeavor to keep in mind the various work he has watched or performed and the numerous times when unexpected conditions added largely to the cost.

Generally speaking, estimates on proposed work by men of limited experience are too low, yet it is not unusual for an engineer to be so impressed with the difficulty of a piece of work that he overestimates the actual cost and it is more common to find that he has overestimated the bids of the contractors.

It is of much value to have two methods of arriving at estimates. If an independent check method can be made even though a rough one, a failure of the two results to agree often leads to the discovery of serious errors in the application of one or the other method.

Conditions of Success in Estimating.—One of the first requisites for successful estimating is a fair and unprejudiced, and moderately pessimistic mind. The estimator must be alert for new and cheaper processes and methods, and conservatively sceptical concerning their merits. Moreover a successful estimator must have had experience in actual construction. As a general rule an engineer should not make an estimate for a structure that he would not know how to build.

Next, as a requisite to successful estimating, may be mentioned a broad basis of cost records of actual work, more or less similar to that for which estimates are to be made. A good and safe method of using the cost data and adjusting it for application to new conditions is equally important. And, finally, the estimator must have the will to refuse to make estimates for work that he does not understand.

Cost Estimating; A Discussion of Principles with Actual Estimates for Contract Work.—Engineering and Contracting, July 14, 1909, publishes the following by J. B. Balcomb:

General Principles

Engineers rarely make a success of cost estimating. The same may be said of architects, contractors and others, to all of whom a reliable estimate is of the greatest importance. Many even go so far as to assert that it is not possible to do it satisfactorily. Yet it must needs be done, therefore the ability may be attained to do it; provided always, that it is undertaken with a complete understanding, not alone of its importance, but of its requirements and limitations as well.

Certain characteristics are essential: A man must be, (a) a logical thinker, (b) a constructive organizer; he must have, (a) an analytical mind, (b) an active imagination, well under the control of reason; he must acquire, (a) the habit of forming definite judgments and conclusions, (b) the practice of systematizing on paper.

In addition to these, it is imperative to have had shop or field experience, preferably both, and to have accumulated systematic notes and records of cost. A technical education is of advantage and some designing experience is helpful.

If one is to follow estimating professionally, as an architect, estimator or consulting engineer, his practical experience should be broad and diversified. While on field work he should have studied methods and collaborated cost data; both for future use in estimating, and as a guide in using information compiled by others.

In such records, it is not sufficient that quantities of work and their cost be given: he should note the rate of wages, the quality of work, the class of labor, the conditions regarding weather and the arrival of supplies and materials, as well as special conditions either favorable or unfavorable; so that in using this data he may be able to form a rational judgment as to how nearly other work, the cost of which he is called upon to estimate, will be controlled by like conditions.

As an illustration, let us assume that one is recording data on excavation. In such case it would be well to make note of how the work was done; whether with (a) steam shovel, (b) locomotive crane, (c) teams and wheelers, (d) teams and slips, or, (e) men with picks and shovels; whether the hauling was done with (a) locomotive and flat cars, (b) dinkies and dump cars, (c) teams and patent dumpers, (d) horses with carts, or, (e) men with wheelbarrows; and whether it was loosened by (a) men with picks, (b) teams with plows or rooters, or (c) blasting with dynamite or giant powder.

It is also necessary to give: (a) character of excavated material, (b) depth of cut and height of fill, (c) length of haul, (d) condition of roads or tracks, and (e) special features which either facilitated or hindered progress.

If the excavation is in rock, there will be, in addition, (a) method of drilling, (b) method of blasting, (c) method of loading and unloading.

There are other combinations than those suggested, but these cover the usual methods of handling earth. While no other form of construction is susceptible of being handled in so many different ways, yet this serves admirably to illustrate how meagre are the usual cost data as given in the periodicals or technical papers. To say that an excavation cost 40 cts. per cu. yd. means absolutely nothing, for it might have cost anywhere from 5 cts. to $5, and the work still have been handled to the best advantage. What is necessary, is not that we should know one or two but all of the above conditions.

When one is making up an estimate, he should know the relative cost of different methods of operation under like conditions. Then it is possible to select the most economical method, and having determined this, to estimate with a fair degree of probability the cost of the proposed work. To illustrate, where the haul is very short and the excavation shallow, buck scrapers or road graders are often used, while with longer haul and a deeper cut it is advantageous to use elevating graders and patent dumpers. In this latter case, teams with wheel or drag scrapers may be better, especially if the soil is sandy, stony or filled with roots. A locomotive crane presupposes a railroad track and a comparatively short haul, whereas a steam shovel may be used with an engine and cars, where a railroad track is used and the haul is long, or with teams and either dump wagons or scrapers. If the job is large, so that the unit cost of organizing the force and moving the plant is small, it is a safe rule to avoid manual labor wherever possible. The work is always recorded in cubic yards, preferably of excavation rather than of fill. This one kind of construction will serve to illustrate the others, the chief requisite being that all conditions affecting the cost be explicitly stated.

It has been said that the wise business man never ventures on a course of action without first submitting it to a detailed analysis on paper: certain it is that the wise estimator never prepares a bid without doing so. This of course does not apply to dwellings or other structures where the firm has already completed one or more similar buildings under like conditions. In other words, a detailed and itemized estimate is never presumed to be undertaken where identical cost data is available; cases of identical construction, however, occur far less frequently than is generally supposed.

In order to approximate actual costs, it is imperative for an estimator to outline a complete and rational plan of operation, while making an estimate. He should definitely formulate the requirements as to both equipment and men—how much and what kinds of machinery, how many superintendents, engineers, foremen, timekeepers, clerks, mechanics and laborers. In thus mentally organizing his force, he should estimate the size and makeup of each gang, and the time required for different portions of the work. These should be correlated as to their necessary sequence, both as regards the disposition of the working force, and the plant employed on each. That he may thus plan the work in detail, an estimator must have had actual field experience, the broader the better; a portion of the time, preferably, spending his own money. Few estimators, even of those who are without this experience, will question its advantage.

Although his plan may never be carried out, it is worth while to have it typewritten as a guide while making the estimate. Further, it will be helpful should he be called on to superintend the work or as a means of defending his estimate, in case of excessive costs.

It is of especial importance that an estimate be localized—adapted to the particular work in hand and none other—suiting the existing conditions only, because made for them. When another estimate is needed, even for similar work, take this one to pieces and build it up again in accordance with the new requirements and the new conditions. If a job is of sufficient importance to demand an estimate, it is worth a new analysis, an individual synthesis. This does not mean that the estimate shall be elaborate; if the work is simple, make the estimate so, but make it definite and detailed.

The chief items of the usual estimate consist of quotations on material and freight rates from the factory to the work—the theoretical cost of materials at the job. Before the true cost of materials is determined, allowance must be made for: (a) delays in shipment, (b) delays in transportation, (c) switching and demurrage charges, (d) unloading and storage, (e) hauling and reloading one or more times, (f) shortage and broken material, (g) wrong shipments and reordering.

Even then, this is but the beginning of an estimate, and the least difficult part

Frequently sub-contractors are asked for bids, with a view to sub-letting portions of the work, or as a check on the company's own estimate. It is often well to make it serve both purposes, for in many cases small contractors can handle specialized portions of the work for less money than large contractors.

Next to cost records on work practically identical, a man's own experience, properly classified and tabulated, is the most reliable asset of an estimator. In nearly all cases, however, this must be supplemented in order to cover the required field; even specialists finding a diversified knowledge none too broad to embrace the different forms of construction which will at times enter their work.

Since it is manifestly impossible for a man to have had experience in all lines of construction, even in all phases he may be called on to estimate, it becomes necessary to use published data to some extent. Books like Gillettes' "Handbook of Cost Data" are very helpful. Many valuable data are published in the technical journals, although few engineers classify and index them convenient for reference. General conceptions may be formed by noting contract prices, although this is of less value than would at first appear, owing partly to unbalanced bids, but mainly because one knows nothing of the specifications and local conditions.

Test pits are of great value in estimating the cost of excavation work and the necessary depths for foundations. The difficulty being that owners, to whom the work legitimately belongs, will seldom incur the necessary expense; and contractors usually prefer to "make a guess at it" rather than spend money for some one else to profit by. It would often be ultimate economy for owners to show the actual conditions underground rather than let bidders take chances, for the "gambler's chance" means high bidding or unsatisfactory work.

Where a considerable portion of any work is new to a bidding firm, or where its personnel is limited in numbers or experience, a consulting engineer, architect or construction superintendent is frequently called in consultation. This is a commendable practice and could more often be followed to advantage. The chief difficulty is that architects usually estimate by the cubic foot of building or square foot of floor area, thus making an approximation on the assumption of average conditions; construction superintendents have a better knowledge of methods than of costs, so can ordinarily give only general ideas; and comparatively few engineers have systematic cost records at their command. The present growing interest in this, the engineer's weakest point, promises to be of great economic advantage to the building public, and is an opportunity which should be embraced by all engineers who wish to see our profession occupy the preeminent position which rightfully belongs to it, as a result of the marvelous achievements which it has accomplished.

Main Features of Estimating

Materials.—In estimating the cost of machinery, materials and supplies, it is customary to ask for quotations; giving general requirements, approximate date of delivery and point of shipment. Only reliable dealers and manufacturers should be asked to quote. If freight rates are not included with the quotations, they should be secured from transportation companies.

These two items form an important, but by far the easiest, part of an estimate. Exclusive of a firm's reputation for fair dealing and prompt payment, any other company can secure as favorable figures; consequently, can bid equally low, so far as these items are concerned. The opportunity for difference in the bids of two contractors must lie in some place other than the cost of materials and the transportation charges. Usually it is to be found in the estimate of labor or in the question of profits.

Existing Conditions.—Aside from making a guess at the labor cost, which is by no means uncommon, the matter most often overlooked or ignored is that of existing conditions; natural, economic and legal. In forming a judgment regarding natural conditions, the following matters should receive due consideration: (a) amount and frequency of precipitation, (b) amount of surface water, (c) character of drainage, (d) depth to permanent water level, (e) kind of soil, (f) size and depths of excavations, (g) disposition of excavated material, (h) length of time pits will remain open, (i) amount of shoring and sheeting required, (j) effect of climate on materials, (k) effect of climate on plant, (l) effect of climate on labor.

While many of these conditions will be passed over as similar to those on work already done, and eliminated by the use of cost sheets on such work, it is well for an estimator to have such a list before him. On important work, each item should be given at least casual thought, considering fully such as are especially pertinent. The wide variations in these matters between different localities, states and countries, make their consideration imperative where close estimating is desired.

Of but little less importance are the economic conditions, regarding dealers and manufacturers, common carriers, and both skilled and common labor. The difference in service rendered by the same firm or individual in 1892 and the hard times immediately following was very great. Even more marked was the difference between the years immediately preceding and succeeding the Wall street panic of October, 1907, with its resulting aftermath. This should especially be borne in mind regarding the quantity and quality of labor performed both by mechanics and laborers, and the compensation paid therefor. Under this head should be considered the question of commissary and transportation facilities for the force employed, although it is also considered under the headings of plant and labor.

In this connection, the legal requirements should not be overlooked. This is of especial importance in large cities where the obligations imposed are often onerous to say the least. Such matters as not blocking street traffic, keeping the sidewalk clear, supporting adjacent buildings, the many police regulations, as well as the difficulties of not transporting materials, not forgetting the rules of labor unions, are matters which often wipe out the profit and leave a large deficit, when not duly considered in the estimate.

Even in rural communities, there are still the state laws regarding liabilities of employers, mechanic's liens, the collection of money due a contractor, and others, either favorable or unfavorable, which should have due weight in raising or lowering one's bid, before the final estimate is complete.

It is essential to go over the proposed contract carefully, noting the time limit and any burdensome clauses it may contain. Sometimes these may be altered before the bid is submitted, by using tact and diplomacy; if not, proper allowance can be made for them in the estimate.

Contractor's Plant.—The question of plant equipment with which to complete the work according to contract, in case one is the successful bidder, is of far reaching importance. It is an unfortunate custom among engineers and contractors to add a lump sum or a percentage for cost of plant, supplies and maintenance. One might almost as well add a percentage to cover the labor cost, after computing the cost of materials.

The only reliable way is to estimate the cost of plant for each proposed work, considering separately the requirements of each class of construction covered by the specifications. In order to do this, the estimator must outline a complete and rational plan for carrying on the work, as before suggested. Having outlined a plan, he is in position to determine with a fair degree of accuracy, the necessary plant, as well as the cost of supplies and maintenance. These latter will depend mainly on three things: (a) condition of plant, (b) character of work, (c) character of labor employed in operating it. In judging of these, the estimator should consider climatic conditions, facilities for repairs, and the company's attitude toward plant enlargement.

In addition to the tools and machinery with which to do the work, various temporary buildings ought to come under the head of plant equipment. These should embrace construction offices, commissary buildings, sheds and buildings for storage purposes, and such other structures as may be required by the plan of operation.

Labor Cost.—The most difficult, and at the same time most vital element of an estimate, is the labor cost. In order to make a fair approximation, one needs extensive records obtained by a wide and varied personal experience.

The first thing to be considered is the character, and perhaps personnel, of the staff; in other words, the efficiency of the superintendence. Where it is impossible to determine this with a fair degree of accuracy, it necessarily follows that the estimate of labor cost is an approximation only. Next after the general manager of the company, the superintendent will be the main factor in the success or failure of the work. While it is impossible to reduce such matters to mathematical formulas, an illustration by way of percentages will help to emphasize the need of forming a correct judgment on this point. Suppose a percentage of efficiency, giving what might be termed inherent values, is ascribed as follows:

	Illustration No. 1 Per cent.	Illustration No. 2 Per cent.
General Manager	100	70
Superintendent	90	80
Foremen	80	90
Laborers	70	100

At first glance one would assume that each is an 85 per cent organization, taking an average of the different values. This conclusion embraces two errors: first, the percentage value of each grade is affected by the one next above (a good foreman will increase the efficiency of men, a poor one will decrease it; likewise with the superintendent and foremen); second, the efficiency of the organization is the product, not the average of the different values. With a reasonable correction for the first, these would read:

	Illustration No. 1 Per cent.	Illustration No. 2 Per cent.
General Manager	100	70
Superintendent	95	75
Foremen	87½	82½
Laborers	79	91

Taking their products, we have,

Illustration No. 1.: $1 \times 0.95 \times 0.875 \times 0.79 = 66$ per cent organization.

Illustration No. 2: $0.70 \times 0.75 \times 0.825 \times 0.91 = 39$ per cent organization.

These illustrations serve merely to emphasize in a concrete way the importance of good superintendence, and are in no sense suggested as a practical method of arriving at the labor cost. In failing to estimate correctly the human element, especially "the man at the top," more than in all other factors combined, is to be found the reason why careful estimates so often fail utterly to agree with actual costs.

Following superintendence, the next matter to be considered is the quality and quantity of labor. Skilled and unskilled labor should be considered separately.

Superintendence, nationality, quarters and climate are the leading factors in forming an organization, and those which most largely affect the labor cost. The first of these is of prime importance and is usually greatly underestimated. For real economy in handling men and work, a good man is preferable to a poor one, although he demand twice the salary. It is safe to allow liberal salaries in estimating the cost of superintendence. The best contractors seldom permit the question of salary to stand in the way of retaining a really efficient superintendent or foreman.

The effect of commissary, climate and local conditions, as before mentioned, must be kept in mind. The proximity of saloons and dens of vice have a very noticeable effect, at times increasing the labor cost 10 to 25 per cent.

After determining the main features of labor cost, the experienced man knows that numerous items in addition will come to light during actual construction. These are almost impossible to compute previously, except by giving careful thought to every detail, as suggested above. Frequently a percentage is added to cover these contingencies; this is commendable, if each form of construction is considered on its merits, and the percentages varied according to the elements of uncertainty involved. The following are some of the more obvious of these features:

The commissary, which may prove either a debit or a credit, depending on its purpose and management.

Sanitation, including potable water, closets, sewers, drains and baths, and is always a debit.

Medical attendance, which usually produces a debit on small works and a credit on large ones.

Labor insurance, which is always a cost item, directly or indirectly.

Labor agency, which should produce a credit, if undertaken.

Walking delegates, each to be considered on his individual merits if known, otherwise on his reputation.

A Complete Cost Estimate

Losses and Margins of Safety.—In addition to, and supplementing the outline given in the previous sections, a series of items too often overlooked consists of what may be called losses and margins of safety. Among these may be mentioned: (a) lost and broken material, (b) delay in arrival of materials, (c) rehandling materials, (d) storage of materials, (e) cost of organizing the force.

The first item can best be offset by percentages on the labor and material cost, each class of work being considered separately. Regarding the second, it is often best to allow the salary and traveling expenses of a good man (on large works, two or more) to follow up shipments and see that they arrive on time. The unavoidable delay and consequent expense still remaining will be included in the percentage added for general expenses. The rehandling and storage of materials can be estimated only in conjunction with the plan of operation as outlined by the estimator; depending largely on local conditions as to space, buildings and character of the materials. The cost of necessary sheds and buildings will have been allowed for under plant.

The last item will depend largely on the nature of the work, condition of the labor market, character of the laborers, and maximum number employed. Other conditions being equal, it will be nearly a fixed cost, proportional to the maximum working force: the total amount being affected but slightly by the length of time required to complete the job.

Profits.—What constitutes a legitimate profit is an indeterminate proposition, since the number of correct answers is unlimited. A fair profit on one class of work is evident injustice on another. There should be a greater percentage on labor than on machinery; also, a varying per cent on the different classes of labor and the different kinds of machinery. A competent estimator never allows as great a percentage on a single unit that costs a large sum as on a multitude of small items aggregating the same amount; since the latter would be purchased from various manufacturers and dealers and cost much more to handle and install.

The adaptability of the company's plant to proposed work justly weighs somewhat in the element of risk and uncertainty; consequently, it helps determine the profit desired. A further factor is the proportion of the work of which the company makes a specialty. It is evident that a specialty can be handled more economically than general work; yet in so far as it may approach a monopoly, there is a desire for proportionately larger profits.

The aggregate of profit is also determined somewhat by the number and magnitude of contracts on hand; bidding always being higher by a company pretty well loaded up with contracts, and having most of its trained force already in the field. The final element entering into the estimate of profit is the policy of the company—a large amount of work at a low rate, or a few contracts at handsome figures.

Tabulation of Results.—Where a complete estimate is desired, the entire work should be divided into items or classes, each as separate and complete as possible. It is convenient to have a column for each of the following: (a) quotations on materials, (b) freight on same, (c) drayage of same, (d) estimated labor cost, (e) total for material and labor.

Instead of estimating the plant for each item, a better plan is to consider a group of items together; under each group allowing for: (a) repairs and maintenance, (b) supplies, (c) safety margins, (d) profits.

From the plan of operation, already alluded to, the cost of superintendence may now be computed; and than a lump sum or percentage added for general and office expense. This latter will be estimated from the company's monthly expense account, the amount of present and prospective business, and the past experience of the company.

The cost of surveys and expense incurred in the drafting room should be included in the general expense, unless these items are to be estimated separately. If the bid is to be by unit costs: the superintendence and surveying should be distributed proportionally to the labor cost; drafting, general and office expense, proportionally to the cost of both labor and materials.

With the estimate complete, it devolves upon the general manager, who is often the president also, to determine from conditions already mentioned the amount to increase or decrease this final figure before submitting the bid.

Realizing that contracting is an art, not an exact science, he will bear in mind the keenness of competition and the builder's reputation for fair dealing. If the latter is questionable, it is doubtful wisdom even to place a bid.

If the general manager does the estimating himself, it is well to remember that few contractors have become bankrupt because of not securing contracts; many because their work was not handled economically and honestly; while the vast majority who have failed have been able to secure contracts, have handled their work to fair advantage, but have been unable to secure reasonable acceptance and prompt payment; the situation most likely being aggravated by having taken the work too cheaply. For this reason, some managers add a small amount to cover interest on borrowed money to meet expenses while waiting on deferred payments.

With this in mind, two additional columns are sometimes added; one in which to place the percentage of work completed; the other, the cost of same to date. An estimate prepared as here outlined, with costs appended during the progress of the work, helps greatly in borrowing money with which to tide over unforseen emergencies.

These matters call for business ability rather than engineering training, and their successful handling is the final test of a man's ability to secure contracts advantageously. An intelligent estimate will preclude the probability of taking work at a loss, but will never enable a firm to secure work at a maximum profit.

Sewage Disposal Plant.—As an illustrative example, part of an estimate of cost for the sewage disposal plant at Washington, Pa., is given. (See Table I.)

The broken stone was to be quarried and crushed at a quarry belonging to the borough, which accounts for no allowance for rental. It was located at a distance of 500 ft. from, and at an elevation of 50 ft. above, the proposed plant.

A branch line of railroad runs next the site, accounting for the absence of drayage in most cases. General expense was estimated as follows:

	Per cent
Office	8
Drafting room	1
Labor insurance	1
Interest	1½
Adjustments	1½

This percentage, with minor exceptions, is computed on columns 1 to 9 inclusive.

Profit was estimated at from 5 per cent to 10 per cent on materials, including columns 1, 2, 6, 9 and 10, and 10 per cent to 15 per cent on labor, including columns 3, 4, 5, 7 and 8. Exceptions were made on item 45, where 2½ per cent on materials and 7 per cent on labor was used, as the company was desirous of underbidding machinery firms; 25 per cent on the different classes of concrete, as the company felt sure that bidding prices would be high; 30 per cent on the broken stone, as this still kept it below the price at which stone could be shipped in.

It will be noted that the mix is given in each of the concrete items immediately to the left of the ingredients. Where a figure is included in parenthesis, as (1) under freight, it signifies that the freight is included in the amount given in column 1. An x, as in column 3, means that there was no drayage on that item.

TABLE I.—COST ESTIMATE OF A SEWAGE DISPOSAL PLANT

Items and Quantities.	Material 1	Freight 2	Drayage 3	Superintendence 4	Labor 5	Lost and broken material 6	Rehandling material 7	Organizing the force 8	Plant 9	General expense 10	Profit 11	Total 12	Unit bid 13
Excavation, 7,500 cu. yds.							$467	$50	$100	$560	$650	$5,677	$0.76
Plow and scraper, 3,687, at .22				$180	$760								
Pick and shovel, 1.844, at .34				140	590								
Below creek level, 554, at .80				100	416								
Trench for pipes, 415, at .95				320	1,344								
Rolled embankment, 3,200 cu. yds.				250	1,056		106		20	185	210	1,827	0.57
Loam, 675 cu. yds.				65	270		41		5	50	85	516	0.76
Seeding, 17 acres				5	23		2			3	7	40	2.35
Sodding, 100 sq. yds.				4	13		2		5	3	5	32	0.32
Gravel for roads and walks, 560 cu. yds.	$470			45	190	$40	59		325	105	160	1,394	2.50
Concrete, Class "A," 325 cu. yds.				80	341	64	34	65	240	280	700	3,455	10.60
1. Cement, 520 bbls., at $1.58	822	(1)											
2. Sand, 147 yds., at $1.65	243	(1)											
4. Broken stone, 294 yds., at .84	235	(1)											
Forms at $1.08 per cu. yd.	351												
Concrete, Class "B," 1,200 cu. yds.				285	1,200	242	120	20	925	1,160	2,500	12,559	10.45
1. Cement, 1,920 bbls., at $1.58	3,040	(1)											
2. Sand, 592 yds., at $1.65	920	(1)											
4. Broken stone, 1,184 yds., at .84	947	(1)											
Forms at $1.00 per cu. yd.	1,200												
Concrete, Class "C," 1,300 cu. yds.				295	1,235	220	124	30	990	1,120	2,425	12,147	9.35
1. Cement, 1,625 bbls., at $1.58	2,574	(1)											
2½. Sand, 573 yds., at $1.65	956	(1)											
5½. Broken stone, 1,260 yds., at .84	1,008	(1)											
Forms at .90 per cu. yd.	1,170												
Concrete, Class "D," 1,525 cu. yds.				325	1,373	255	137	65	1,080	1,120	2,720	13,610	8.95
1. Cement, 1,906 bbls., at $1.58	3,020	(1)											
2½. Sand, 672 yds., at $1.65	1,111	(1)											
5½. Broken stone, 1,480 yds., at 84	1,184	(1)											
Forms at .80 per cu. yd.	1,220												

Owing to local conditions, the questions of commissary and medical attendance were not considered in this estimate.

The cost of plant is figured for each item, deducting its value as second-hand tools and machinery after the work was done.

The cost of organizing the force falls mainly on those items which would be undertaken in the earlier part of the construction work. The following table will be found helpful, *as a general guide only*, in estimating the cost of organizing a force; the actual amounts in all cases being dependent on many of the conditions previously noted.

	1st mo.	2d mo.	3d mo.	4th mo.
Max. force employed, 100 men.				
1 supt. at $100 per mo.	$ 50	$ 25	....	....
0–6 foreman at $60 per mo.	90	90	....	....
0–50 men at $1.75 a day	415	....	....	....
50–100 men at $1.75 a day	....	300	....	....
Field office help	100	50	....	....
Total, $1,120—$11.20 per man.				
Max. force employed, 500 men.				
1 supt. at $200	$100	$ 65	$ 50	....
0–15 foremen at $75	360	....	....	....
15–20 foremen at $75	....	440	....	....
20–25 foremen at $75	....	....	425	....
0–100 men at $1.75	440	....	....	....
100–300 men at $1.75	....	875	....	....
300–500 men at $1.75	....	....	700	....
1 asst. supt. at $150	100	75	50	....
Field office help	300	200	100	....
Total, $4,280–$8.56 per man.				
Max. force employed, 1,000 men.				
1 gen. supt. at $400	$200	$135	$100	$ 80
0–3 supts. at $175	235	....	....	....
3–5 supts. at $175	....	175	....	....
0–20 foremen at $75	375	....	....	....
10–30 foremen at $75	....	300	....	....
30–50 foremen at $75	....	....	250	100
0–200 men at $1.75	875	....	....	....
200–500 men at $1.75	....	875	....	....
500–800 men at $1.75	....	....	440	....
800–1,000 men at $1.75	....	....	....	440
Field office help	400	300	200	100
Total, $5,580—$5.58 per man.				

In the present instance, the company already had in its employ trained superintendents, foremen and mechanics; so the cost of organizing the force was estimated at a figure considerably less than suggested above. Like all other features of an estimate, it is evident that each case must be determined on its merits and considered accordingly.

Filtration Plant.—The estimate next given is that of a filtration plant at Roanoke, Va., of 4,000,000 gallons daily capacity. It was for a lump sum bid, consequently the arrangement is somewhat different than in the preceding estimate.

Near the end, under "Accessories," the amounts given in the columns for Material and Freight cover "Lost and Broken Material;" under Drayage and Labor, "Rehandling Material" and "Organizing the Force."

Unit bids not being called for, Plant, Superintendence, General Expense and Profit are not distributed, but added at the end to make up the final cost.

TABLE II.—ESTIMATE OF COST OF A FILTRATION PLANT

Coagulating Basin—	Material	Freight	Drayage	Labor
Excavation, 2,800 yds.				
Plow and scraper, 2,500 yds.........	......	...	....	$500
Pick and shovel, 300 yds............	......	...	....	90
Concrete, 596 cu. yds..............	......	...	....	892
Cement, 655 bbls. at $1.85...........	$1,207	(1)	$196	....
Broken stone and sand, 511 yds. at $2.	1,022	...	(1)	....
Forms, 4.6 M f. b. m..............	92	...	(1)	69
Water..............................	15	...	...	10
Reinforcement, 1,000 sq. ft. expand. metal at .04......................	40	2	2	20
Filter Tanks—				
Excavation, 685 yds.				
Plow and scraper, 625 yds...........	......	...	...	125
Pick and shovel, 60 yds............	......	...	...	18
Concrete, 269 yds.				
Materials and forms (as above)........	1,132	...	117	470
Reinforcement, 18,855 lbs. at .02......	377	43	15	204
Wrought iron railing, 80 ft. 180-lb. at .45 per ft........................	36	2	1	7
Clear Well—				
Excavation, 1,100 yds.				
Plow and scraper, 1,075 yds..........	......	...	...	215
Pick and shovel, 25 yds............	......	...	...	8
Concrete, 282 cu. yds.............	......	...	...	353
Materials and forms................	1,154	93	10	...
Reinforcement, none req'd.				
Roof,				
Framing, 25.7 M f. b. m.............	514	...	(1)	180
Sheathing, 9.7 M f. b. m............	194	...	(1)	68
Composition roofing, 81 sqs. at $3.50..	284	...	(1)	81
Building—				
Concrete, 48 yds. (same as filters)....	270	8	24	120
Brick (common), 235,000 lbs., 47,000 at $7.50.........................	352	(1)	176	376
Brick (pressed), 47,500 lbs., 9,500 at $24.............................	228	(1)	36	80
Mill work,				
12 windows at $3.75, 2 doors at $2.50..	50	...	2	35
Roof,				
Framing, 5 M. f. b. m...............	100	...	(1)	75
Sheathing, 3 M. f. b. m............	60	...	(1)	30
Slate, 9 T., 28 sqs. at $8............	224	(1)	14	168
Scaffolding, 3 M. f. b. m............	60	...	(1)	30
Painting...........................	25	...	(1)	50
Hardware,				
Openings, 14 at $1.50...............	21	...	...	...
Ridge, 36 ft. galv. iron..............	9	...	1	3
Conductors, 80 galv. iron............	20	...	1	8
Gutters, 215 galv. iron..............	54	...	2	23
Bearing plates and tie rods, 322 lbs. at .05............................	16	...	1	4
Treating Plant—				
Tanks, 4 req'd. (inc. under "Coag. Basin").				
Orifice boxes, 2 at $15...............	30	1	1	5
Brass pipe and fittings, as per list......	152	1	1	20
Merchant steel pipe and fit., as per list.	22	1	1	8
Depth gauges, 4 at $60..............	240	1	1	10
Brass orifice slides, 2 at $13..........	26	(1)	(1)	2

Machinery—				
Pelton wheel, ¼ ft.				
Centrifugal pump, 1-lb. 10 M.				
Blower, 1-lb. 2; 3.5 T. total..........	810	33	6	50
Pelton wheel, 1- like Lorain Cent. pumps, 2- like Lorain..............	260	9	2	40
Equipment—				
Inlet controller, 1-16 " butterfly valve and float..........................	91	3	1	6
Water manifold and strainers, 14,280 lbs., 1,428 sq. ft. at $1.25............	1,785	32	11	113
Air manifold, 4,450 lbs., 1,428 sq. ft. at .70..............................	1,000	10	3	18
Wash troughs, 8-168 ft., 8,400 lbs., $4.50 per ft......................	751	40	6	38
Gate Valves—				
4–6″ flanged at $8.10................	32	...	...	...
4–10″ flanged at $24.30..............	97	...	...	...
4–10″ angle at $43.50...............	174	...	...	...
3–10″ high pressur at $22.50........	68	...	...	...
4–5″ flanged at $6.75................	27	...	...	...
1–6″ flanged high pres. at $9.........	9	...	...	...
1–10″ flanged foot, at $21.28.........	21	...	...	...
6,700 lbs...........................	...	24	5	66
Sluice Gates—				
4–10″ flanged, at $19.50.............	78	...	...	...
4–12″ flanged, at $26.25.............	105	...	...	...
Valve stands, non-indicating, 20 at $5.	100	...	...	...
1–10″ regulator valve................	231	...	...	...
Loss of head gauges, 4 at $65.........	260	...	...	...
9,200 lbs., total	....	27	7	93
C. I. Pipe—				
B & S, 14,180 lbs.				
Heavy wt. 6″–50′, 1680 lbs...........	29	(1)	1	15
Heavy wt. 10″–200, 12,500 lbs........	219	(1)	10	8

Superintendence				500
General expense				2,500
Profit				5,000
Amount of bid				$33,027

Factors a Contractor Should Consider in Estimating.—The average contractor forgets a great many things which should be included in making up his estimate. It is true that many of these items are small and it might seem that they are insignificant, but when several are taken together the cost increases rapidly. In an interesting article in the January Contractor's Atlas, D. S.

Colburn points out certain of these matters that are commonly overlooked in estimating. The article, as abstracted in Engineering and Contracting, Jan. 28, 1920, follows:

It is probable that on an average about 6 per cent of the cost of the job is not taken into consideration when the estimate is made. The following table illustrates this point:

SCHOOL BUILDING 130′ 0″ × 200′ 0″—3 STORIES, NO BASEMENT

467	yds. rock excavation at $2	$ 934.00
880	yds. earth at 30 ct	240.00
9,900	cu. ft. concrete footing at 22 ct	2,178.00
11,880	cu. ft. concrete walls at 25 ct	2,970.00
13,524	sq. ft. reinforced concrete floor in corridors and toilets at 35 ct	4,733.40
13,524	sq. ft. terrazo floors at 25 ct	3,381.00
1,980	lineal ft. terrazzo base at 35 ct	693.00
7,914	sq. ft. plain cement floors at 10 ct	791.40
182,160	face brick at $35	6,375.62
1,339,240	common brick at $18	24,106.30
32,000	sq. ft. partition tile at 12 ct	3,840.00
3,960	cu. ft. cut stone trimmings at $1.75	6,930.00
58,000	enameled brick at $50	2,900.60
16,059	yd. lath and plaster at 40 ct	6,427.60
50	lineal ft. tile flue lining at 75 ct	33.00
6,000	lineal ft. corner beads at 6 ct	338.00
1,800	yd. metal lath at 45 ct	810.00
4,725	sq. ft. slate blackboards at 28 ct	1,325.00
2,160	sq. ft. cork tackboard at 28 ct	604.00
27,000	lineal ft. grounds at 1½ ct	405.00
96	squares steel ceilings at $7	672.00
	Moving picture booth with vent	
	Balcony in gymnasium	1,896.00
66,000	ft. maple floor at $65	4,290.00
500,000	ft. lumber at $45	22,500.00
260	squares roofing at $7.50	1,950.00
500	squares floor deadening at $2	1,000.00
47	tons structural steel at $115	5,405.00
3	iron stairs (sub-bid)	2,600.00
	Hardware trim	1,700.00
	Sheet metal ((sub-bid)	890.00
	Millwork, sash, doors, trim, etc. (sub-bid)	8,197.00
	Labor on millwork	3,278.80
	Painting (sub-bid)	1,890.00
	Usual estimate	$126,585.42
	10 per cent profit	12,658.54
	Usual bid	$139,243.96

FORGOTTEN ITEMS

Bond, 1 per cent	$ 1,490.00
Fire insurance, ½ per cent of $100,000	500.00
Liability insurance, 5 per cent of labor, $48,000	2,400.00
Telephone	160.00
Traveling expenses, board, etc	650.00
Temporary office, locker, sheds, etc	548.00
Water for building uses, temporary piping, hoists, etc	182.00
Lights, fences, barricades	80.00
Watchman, 6 months at $70	420.00
Timekeeper	350.00
Engineer, laying out, batter boards, etc	30.00
Protection of erected work	100.00
Temporary heating 6 months will burn 220 tons coal at $7	1,540.00
Cleaning out building	100.00
Carting debris	25.00
Cutting and jobbing for other trades	430.00
	$ 9,005.00

Bid Should Be

Usual estimate	$126,585.42
Plus items overlooked	9,005.00
Correct estimate	$135,590.42
Plus 10 per cent profit	13,559.04
Correct bid	$149,149.46

It frequently happens that the general specifications are glanced over in a superficial manner, the contractor immediately taking the plans and specific specifications and estimating all materials and workmanship. When the materials and labor have been figured from these, 99 per cent of the contractors think that nothing remains to be done except add the usual 10 per cent for profit. The trouble is that the general specifications are not carefully enough observed and studied.

As an example of this, there was a large contracting concern recently figuring on a drainage job of considerable magnitude. A close study of the specifications revealed the fact that the contractor was responsible in many ways which ordinarily would not involve any responsibility on his part. For instance, he had to guarantee the designer's work and if this job was done according to the plans and specifications, and it didn't work, then the contractor would receive no payment for the job. This happens in many cases.

In another instance, the specifications made the contractor responsible for the work under the specifications and plans as stated. In other words, the plans were prepared by the architect but the contractor was held responsible. One part of the specifications referred to a basement floor and stated that the contractor should guarantee the basement floor slab to stand a certain head of water. The slab has failed and it is a question now who is responsible.

There are certain matters that are commonly overlooked in estimating and these may be chiefly summarized as follows:

(1) Surety Bond—A surety bond guarantees the faithful performance of the contract and payment of all bills in connection therewith. One per cent is the amount commonly charged for this bond no matter how big or how small the job. Many contractors pass this up and think that they can take care of it out of their 10 per cent profit. It may seem that this is rather the exception than the rule and that very few contractors would neglect to take care of this feature. It is surprising how great a number and how many of all classes of contractors neglect to take this factor into consideration.

(2) Liability Insurance—Liability insurance usually amounts to from 5 per cent to 8 per cent of the total labor cost. This can be figured at that amount and should always be taken into consideration.

(3) Temporary Heating—Another item scarcely, if ever, figured in is temporary heating. Heating is required not only in winter work, but also in early spring or fall construction. While the job may start in the summer, it should be borne in mind that it may possibly run into the winter and, therefore, the problem and cost of providing temporary heating should be taken into consideration.

(4) Temporary Enclosures—These are frequently needed, especially in the case of winter work. They are often required to enclose a part of a building so as to afford public protection. Frequently in the case of a building located in the city, roofing is required above the sidewalks. Material sheds are always needed. These items are small but, of course, count up.

(5) Water for Building Use, Temporary Piping and Hoists—It should be taken into consideration that water will be required for various operations connected with the building, for instance, the mixing of concrete, in keeping the concrete wet, and in cleaning. Elevators or hoists are required for elevating the materials to the proper place. This is an item that is many times neglected. The contractor figures that it costs so much to lay so many bricks, but the means of getting them in place is not considered.

(6) Fire Insurance—During the process of construction the building is under joint ownership by the contractor and the individual or company for whom the building is being constructed and, in the event of loss of the building by fire, the loss is prorata. The fact remains that the contractor must pay the premiums on the job until finished.

(7) Engineer, Timekeeper, Watchman—A service engineer is required in connection with the layout and other details. This expense is, however, very slight. But the expense of the timekeeper and watchmen, in case of a large job, amounts to a very appreciable figure.

(8) Telephone Service—Sometimes telephone service is not required, while there are times when it is a great necessity and this item of expense should also be considered.

(9) Traveling Expenses—This item covers the cost of transporting the foremen or other laborers sent out of town away from their homes. The contractor must as a rule pay all of the railroad fares and board for these men as well as his own expenses.

(10) Cutting and Jobbing—Cutting and jobbing for other trades is a large item since the general contractor is usually required to cut all openings for electricians, plumbers and steamfitters and to patch these up after these workemen have finished.

(11) Guarantee—Often the architects require that the contractor guarantee the material and workmanship for two years or maybe more. This is an item of considerable importance and is never taken care of under the general overhead expense. The United States Government figures 1½ per cent depreciation per year on buildings, so it is an easy matter to gain an idea of how much this item alone amounts to.

How to Determine Whether a Crushed Stone Stock Pile Pays.—Engineering and Contracting, July 17, 1918, gives the following: In the production of crushed stone throughout the year it is usually profitable to provide a stock pile, in spite of the extra cost of rehandling the stone. The main reason for this is that a smaller quarrying and crushing plant working continuously will produce the desired annual output at less cost per ton, inclusive of stock pile costs, than the cost per ton incurred by a larger plant, without a stock pile, working below full capacity most of the time.

Electrical engineers use the term "load factor" to denote the ratio of the actual annual output of electricity to the possible full capacity output of a plant. Thus, an electric generator of 1,000 kilowatts capacity is capable of generating 8,760,000 kilowatt hours of current in a year of 8,760 hrs. (i. e., 24 hrs. daily for 365 days). If, then, such a generator is so run as to generate 2,190,000 kw. hrs. in a year, its load factor is 25 per cent.

Since all the annual "fixed charges" on a generating plant are independent of the output, it follows that if the load factor can be doubled, the fixed charges per kilowatt hour will be cut in two. In general, then, the cost of the "fixed charges" per unit of output vary inversely with the load factor. This holds true of all plants, and serves to explain the economy of providing a stock pile for a crushed stone plant that can be operated the year around at a uniform weekly output.

Stone can usually be delivered to and loaded from a stock pile at a cost of 5 to 10 ct. per ton, depending on the scale of operations and the kind of plant used for stock piling and rehandling. Assuming the first cost of a quarrying and crushing plant to be $80 per ton of daily capacity, and that interest, depreciation and taxes are 20 per cent annually, we have 5.3 ct. per ton for fixed charges on a plant when run continuously one shift every day for 300 days. But without a stock pile continuous operation is usually impossible. To meet the "peak demand" for stone the plant must usually be fully twice the capacity required under continuous (one-shift daily) operation. This alone adds 5.3 ct. per ton of stone for fixed charges on the plant, or enough to cover the cost of stock piling and rehandling under ordinary conditions. But this is not the only element of cost affected by the "load factor" or output factor. A plant large enough to take care of peak demands for stone must necessarily have a crew of men capable of running it at its capacity, and most of this crew must be kept on the pay roll when the plant is operating at but a fraction of its capacity. Some of the crew must be paid even when it is not operating at all. So that either failure to secure freight cars regularly or a falling off in immediate demand for the stone results in the paying of full wages to most of the crew, regardless of the low output of the plant.

In the solution of a problem of this character the first step is to estimate the total annual tonnage of stone to be delivered. The next step is to estimate the maximum delivery that will be required for any single day, also for any single week, and for any single month. Then estimate the first cost of a plant that will supply the maximum daily output aided by the storage capacity of the bins, but unaided by a stock pile. Estimate the operating expenses, interest and depreciation charges for such a plant for a year, under the fluctuating daily, weekly and monthly outputs. Divide this total cost by the total annual tonnage and ascertain the cost per ton. Compare this unit cost with the unit cost resulting from operating a smaller plant continuously with the aid of a stock pile, including therein the interest on the average amount of money tied up in the stone in the stock pile. If the smaller plant with the stock pile shows a lower cost per ton (as it usually will) than the larger plant without a stock pile, then it is obvious that the smaller plant is more economic.

Economic Considerations in Municipal Engineering Designs.—Clinton S. Burns gives the following in Engineering and Contracting, April 10, 1918: The designing engineer has for his guidance this motto: "Secure the maximum returns for the funds invested;" and if he be true to his chosen profession he will ever strive to bring his work to that standard, even though it may at times cause him much effort beyond that which may be appreciated by his clients. In many sections of the country with which the writer is familiar, especially in the more recently settled portions of the Middle West, city councils and officers in charge of municipal works have an extremely keen appreciation of the fact that they must accomplish the maximum results from the limited funds at their disposal, and they accordingly begin by engaging the engineer who will do their work for the least money; or else they save the engineering fee entirely by simply engaging some "practical contractor" to build the works and furnish the plans and specifications free of charge. That such a policy as this is directly the opposite to true economy is too well known to engineers to require discussion, but there may be others, some holding official positions, perhaps, who have not given this subject the attention its importance deserves. If public officers but realized the amount of work involved in determining the economic features of any engineering design, they would more readily appreciate the fact that true economy and cheap engineering are not companions.

Many of the municipal works throughout the country are built with so little respect to economic design as to require but a superficial examination to show where enough money has been wasted to more than pay the compensation which would have been required to secure the best engineering talent to prepare the plans and specifications. The firm of which the writer is a member has been called upon to examine plans for a sewerage system in which the plans called for flush tanks at the head of every lateral, regardless of grade or other local conditions of service. The general character of the specifications seemed to indicate that they had been copied largely from what was without doubt originally an excellent set of specifications for a level city in a wet country, where the sewers had to be laid in quicksand and water, for they provided for under-drains and other expensive accessories which could have no utility under any other conditions. It is not surprising to learn that the fee charged for these plans and specifications was about the proper compensation for a stenographer to copy the specifications and for a draftsman to make a few tracings.

The conditions in water works design are even worse than in sewer work, because many cities are unfortunate enough to possess six or eight councilmen, each of whom knows what size water pipe should be located on his own street. After a few hours' discussion they are able to combine their ideas, and the system of mains is adopted; no one dreams that possibly 5 per cent could have been expended for engineering fees, and much better results might have been accomplished with the remaining 95 per cent of the funds.

It is no doubt true that many contractors and practical builders of water works have the ability to plan excellent systems, but even if so, it is not to their interest to work out the economic features, and therefore in the absence of an engineer to look after the city's interest much public money is necessarily poorly invested.

As an illustration of some of the work involved in determining the economic relation between the different parts of a system of water works, the writer ventures to outline one or two of the points that must be considered in this connection. This can best be shown by a concrete example, using the local conditions as to price of fuel, cost of materials for construction, conditions of service, etc., all of which are taken from actual conditions for one particular plant, but which would, of course, be quite different for any other plant. In the case under consideration the rate of pumping is estimated as follows: 2,800 gal. per minute for 6 hours per day, 1,400 gal. per minute for 6 hours per day, 800 gal. per minute for 6 hours per day, and 300 gal. per minute for 6 hours per day. This is a total of approximately 2,000,000 gal. per day, supplied to a manufacturing city of 20,000 population. The pumping station is 4,000 ft. from the branching point of the distribution system. To determine the most economical size of main for this distance it is necessary to make comparison between the various commercial sizes of water pipe. Comparing 12-in. with 16-in. pipe the friction offered by each 1,000 ft. of 12-in. pipe for the above rates of flow is greater than that in the 16-in. pipe by the following amounts: 16.23 ft. for the 6 hours of maximum pumping, 4.06 ft. for the next 6 hours, 1.33 ft. for the next 6 hours, and 0.18 ft. for the 6 hours of minimum pumping. To overcome this friction requires the expenditure of 80 HP.

hours per day, which, with pumps operating at 80,000,000 duty, takes 320 lb. of coal daily, worth in the local market $2 per ton, representing an annual investment of $116.80. This assumes that no additional investment is required for the increased capacity of the power plant nor for attendance and small supplies, because in any ordinary plant of this capacity there is a large reserve power plant chargeable to the fire protection of the city.

At the time when these estimates were made the difference in cost between the 12-in. and the 16-in. pipe was 65 ct. per foot, or $650 per 1,000 ft. The interest and depreciation on this investment with money at 5 per cent, is only $33.45 per year, as against $116.80 for extra coal with the smaller size pipe, thus showing an annual saving of $83.35 in favor of the 16-in. pipe.

Again comparing the 16-in. pipe with one 20 in. in diameter, by a similar detailed calculation, the result shows an annual saving in coal equal to $23.15 per 1,000 ft. of pipe, due to the smaller friction in the larger pipe. But the extra cost of the larger pipe is 87 ct. per foot, or $870 per 1,000 ft. of pipe, requiring an annual investment of $46.11 for interest and depreciation, thus showing $22.96 annually in favor of the 16-in. pipe. Therefore, of these three sizes, the 16-in. is the most economical one to use for this particular service.

After having determined that so far as the domestic service is concerned, there is nothing to be gained by using a main larger than 16 in., a comparison should then be made between the 16-in. and 20-in. pipe with reference to the fire protection of the city. This brings up a question as to whether the city should resort to the use of steamers for this service; but since this point is not now under discussion, it will be assumed that the necessary pressure for ordinary fire service is to be furnished at the hydrants, and that sufficient water is to be provided for 10 streams of 250 gal. per minute each. Then if a fire occurs at the time of maximum domestic consumption, the total quantity of water that the mains must carry is 5,300 gal. per minute.

The difference in friction between the 16-in. and the 20-in. pipe is 12 ft. per 1,000 ft. of pipe, and therefore if the 16-in. be used there is required an additional investment of $300 for boiler plant and $20 for the room that it occupies in the power house. The life of this portion of the plant may be figured as almost indefinite, owing to the fact that it is so infrequently called into service. The maintenance charge, however, must be sufficient to provide for resetting the boiler when necessary and for the small supplies and repairs that are required to keep it in operating condition, a fair estimate for which would be 2 per cent of the cost of the boiler. For the purpose of comparison the life of the cast iron water pipe may be assumed at 60 years, and that of the reserve portion of the boiler plant the same. The two propositions are then compared as follows:

Interest on extra investment for 20-in. pipe	$43.50
Depreciation for a life of 60 years	2.61
Total annual charge against 20-in. in excess of 16-in. pipe	$46.11
Interest on extra investment, boiler and power house	16.00
Depreciation for a life of 60 years	.90
Maintenance, 2 per cent of the cost of the boiler	6.00
Extra coal used for domestic service as above	23.15
Total annual charge against 16-in. pipe for pumping	$46.05

It is thus seen that so far as the fire protection service is concerned there is nothing to be gained from the use of the larger pipe, and therefore the 16-in. is the most economical size to adopt for this particular location.

It will be noticed that in all of these calculations the rate of interest has been assumed at 5 per cent, which is the rate at which the city can secure money on bonds. However, in the matter of depreciation there is considerable uncertainty as to the proper rate of interest to be assumed. The depreciation of any particular machine may be defined as the annual sum that must be laid aside to amount to the cost of the machine at the end of its life. It then depends entirely upon the earning capacity of the funds laid aside annually, and is therefore independent of the rate of interest that is being paid on the original loan. If money can be invested in additional pipe to supply well settled streets it is likely that much more than 5 per cent can be realized on the investment, which will reduce the depreciation charge accordingly.

While such detailed calculations as are illustrated above are essential as a general guide in determining the important features of a system of water works, yet the writer does not wish to be understood as stating that they should always be followed with mathematical precision, because it often happens that the funds are limited by the statutory provisions, so that a city has only a limited amount to invest. In this case it becomes the engineer's duty to take into consideration the question of whether greater returns may not be secured by an increased pipe system rather than by larger and more efficient pipe lines or, in other words, the fact that large revenue may be derived from extending the mains may be sufficient reason for omitting condensers, using small pipes, and various other acts that would be entirely unjustifiable in designing a system for a private water company whose funds are invested for the purpose of securing the maximum rate of interest on the capital invested.

Another point where an attempt at economy is frequently made is in the spacing of fire hydrants. The popular impression seems to be quite general that since hydrants cost about $32 each they should be spaced about 500 or 600 ft. apart, so as to make a small number of hydrants serve as much territory as possible. This popular impression may be accounted for by the fact that the number of hydrants in a system owned by a private water company is universally accepted as the measure of the public tax for fire protection, and naturally, then, they are not closely spaced in such systems, and the precedent is thus established. In a system of water works owned by the municipality, designed to give fire protection without the use of steamers, there can be no possible justification for spacing the hydrants at such great distances apart as they frequently are.

The details will, of course, vary materially with the plan of the pipe system and other local conditions. In one system that has come under the observation of the writer the hydrants averaged from 500 to 600 ft. apart, but by increasing the number by 100 their distances apart could be reduced to 300 ft. This would effect a saving of about 100 ft. of hose for reaching the average fire, and aside from the convenience to the fire company, due to having a hydrant every 300 ft., there results a direct financial benefit to the city as shown below. To overcome the friction in this extra 100 ft. of hose requires an additional pressure of 13 lb. per square inch at the hydrant, and to provide sufficient power to throw 10 streams simultaneously in addition to the maximum daily consumption necessitates the installation of 50 HP. greater boiler capacity and pumps to correspond. This costs $800 for the extra investment in the power station, the annual charge against which is $57.25 for interest, maintenance and depreciation. There is also an increased pressure of 13 lb. per square inch on the pipes throughout the distribution system, which theoretically would require the use of heavier pipe, but for commercial reasons quite probably the pipe system would be of practically the same weight as though it were not called upon to meet this extra pressure. The financial benefits accruing from being able to secure the desired fire protection with less pressure will appear indirectly in the form of reduced maintenance charges, due to less frequency of bursting the mains, less leakage, and consequently greater efficiency of the pumps and quicker response to calls for fire pressure.

Again, the maintenance of the fire department is increased by the long spaces between the hydrants, since each hose cart must be equipped with at least 200 ft. more hose, which requires an investment of $600 for hose, the life of which will not exceed an average of 5 years. Therefore, with interest at 5 per cent the depreciation on the hose amounts to 18 per cent. The maintenance is largely a matter of time and attention of the fire department, and therefore no charge is figured for this item; however, for interest and depreciation the annual tax for the extra hose is $138. This makes a direct annual charge of $195.25 due to the effort to save $3,200 in hydrants, the annual charge against which would not exceed $200, leaving less than $5 to offset the benefits accruing from having twice the number of hydrants. These benefits must include the maintenance of the pipe system under the decreased pressure as mentioned above, the reduced risks in fire insurance, and the greater rapidity with which the fire department can couple the hose and turn on the stream, which means that a smaller fire company can perform the same service. After considering these points, it is clearly apparent that as a business investment it is inexpedient to economize in the first cost of a system by cutting down the number of hydrants, as is frequently done.

This brings up the question of hydrant spacing in systems owned by private companies, and suggests the fact that if a franchise provides for a certain stream to be maintained at the hydrant, it would be to the advantage of both parties concerned to put in more hydrants at a less rate per hydrant. It would be better for the company because it enables it to give the same service for less investment for power; and it is better for the city because it enables it to save in the maintenance of the fire department.

There are many other points that present themselves in planning an economic system of water works, such as the relative efficiency of the different classes of pumping machinery, proper proportioning of the boilers, motors or other machinery, cost of fuel as compared with condensers, etc.; but these are not unlike the points that should be considered in the design of every power plant, and therefore they will not be treated here.

The point that the writer wishes to bring out most clearly is the fact that without careful consideration of every detail there is but little probability that an investment is economically made, and that it should be the duty of those in charge of municipal improvements to exercise the same care in selecting professional advice that they would if they were investing their own capital.

It will be noticed that all of the above calculations of comparative costs are based on average or normal prices rather than upon the present war-time crest. This is as it should be, for any calculation to determine the economics of an engineering problem must be based upon data that will represent a fair average throughout the life of the project under consideration.

CHAPTER II

PRICES AND WAGES

Past and Future Price Levels.—The following discussion, pages 34 to 138, is in large part, very greatly condensed of two articles that I published in Engineering and Contracting, April 7 and May 5, 1920. My object was to deduce a formula for estimating commodity price levels or price indexes. As will be seen later, the formula gives results that agree very closely with the facts for every year since 1889. Data for years prior thereto are less reliable, but even back to 1859 the formula gives approximately correct results.

I know of no prior attempt to deduce a commodity price level formula. In 1907 Prof. E. K. Kemmer published "Money and Credit Instruments in Their Relation to Prices," in which he deduced a formula for the weighted average of three distinct things: (1) commodity prices, (2) wages and (3) prices of corporation stocks. It seemed to me that these three things (commodity prices, wages and stock prices) are not necessarily related one to the other. If this is so, only confusion would be likely to follow an attempt to average such unrelated things. Accordingly I confined my attempt to derive two separate formulas, one for commodity price levels, and one for wage levels. As will be seen later these formulas differ in one very important element, and since each of them corresponds closely with the facts, it follows that any formula that attempts to give a composite average of wages and prices is certain to be incorrect.

Prof. Irving Fisher, in his "Purchasing Power of Money" (1911) adopted Prof. Kemmerer's formula and attempted to bring its results up to date.

Price Indexes.—Before a correct understanding of the present subject can be secured, the meaning of certain terms must be learned. One of the most important of these terms is the expression "price index." Its technical sound, however, merely camouflages a very simple thing, namely, a relative average price.

"Index numbers" are relative numbers in which data for one year (or longer period) are taken as a base of 100, or 100 per cent, and upon which data for other years are computed as percentages. When the index numbers relate to prices, they are called "price indexes." Thus, if the year 1913 is taken as the base year, and average wholesale prices of, say, 300 commodities are taken, that average may be called 100 per cent. Then if the average wholesale price of the same 300 commodities is 1.96 times as high in 1918 as in 1913, the price index for 1918 is 196, or 196 per cent of the average price in 1913.

To take a simple illustration, let us assume that the wholesale price index of the four principal cereals is desired for the years 1914 and 1918. From the U. S. Statistical Abstract for 1918, we find that the average wholesale prices (on the farm) were as follows per bushel:

	1914	1918
Corn	$0.65	$1.37
Wheat	0.99	2.37
Oats	0.44	0.71
Barley	0.55	0.92
Simple average price	$0.658	$1.343

If we add the prices of these four grains and divide by four, we get a "simple average price" of $0.658 for the year 1914, and $1.343 for the year 1918. Hence, if we take the year 1914 as our standard year, we get $1.34 ÷ $0.66 = 203 as the index price for the year 1918, when the corresponding price index is 100 for the year 1914.

This method of calculating price indexes does not take into consideration the relative quantities of each of these four cereals produced in the given years. To give the proper "weight" to the quantities produced, the calculation of "weighted average prices" must be made as follows:

For the year 1914:

Corn	2,673,000,000 bu.	at $0.65 =	$1,737,450,000
Wheat	891,000,000 bu.	at 0.99 =	882,090,000
Oats	1,141,000,000 bu.	at 0.44 =	502,040,000
Barley	195,000,000 bu.	at 0.55 =	107,250,000
Total	4,900,000,000 bu.	at $0.659 =	$3,228,830,000

Dividing the total of $3,228,830,000 by 4,900,000,000, we get $0.659 as the "weighted average unit price" of these four cereals in 1914, as compared with the "simple (or unweighted) average price" of $0.658 previously deduced.

A similar calculation for 1918 is as follows:

Corn	2,583,000,000 bu.	at $1.37 =	$3,538,710,000
Wheat	917,000,000 bu.	at 2.37 =	2,173,290,000
Oats	1,538,000,000 bu.	at 0.71 =	1,091,980,000
Barley	256,000,000 bu.	at 0.92 =	235,520,000
Total	5,294,000,000 bu.	at $1.330 =	$7,039,500,000

This gives a "weighted average unit price" of $1.330 for these four grains, as compared with the "simple average price" of $1.343

Now if we divide the weighted average price of $1.330 (for the year 1918) by that of $0.659 (for the year 1914), we get 202, which is the weighted price index of these four cereals in 1918, as compared with weighted average price index of 100 for the year 1914.

Where several hundred commodities are thus treated, the weighted price indexes do not usually differ greatly from the unweighted price indexes, but the smaller the number of commodities thus grouped to secure an average price, the greater the range of differences between weighted and unweighted index prices. Hence, it is always preferable to use weighted price indexes when they are ascertainable.

Table I shows the weighted wholesale price index in the United States for every year from 1860 to 1920, the year 1913 being taken as 100 per cent.

The Author's Formula for Commodity Price Levels.—The price of every thing sold in competitive market is dependent upon the ratio of the realized demand to the effective supply. The realized demand is of course measurable only in terms of the total money spent; and the effective supply is measurable only in

TABLE I.—WHOLESALE PRICE INDEX OF COMMODITIES

Year	Price	Year	Price	Year	Price
1860	90	1880	93	1900	82
1861	86	1881	95	1901	80
1862	93	1882	96	1902	83
1863	110	1883	94	1903	84
1864	135	1884	92	1904	83
1865	172	1885	86	1905	86
1866	144	1886	86	1906	91
1867	131	1887	87	1907	96
1868	136	1888	88	1908	91
1869	122	1889	89	1909	94
1870	117	1890	84	1910	97
1871	112	1891	83	1911	95
1872	110	1892	78	1912	99
1873	108	1893	78	1913	100
1874	109	1894	71	1914	99
1875	108	1895	70	1915	100
1876	104	1896	67	1916	123
1877	99	1897	67	1917	175
1878	93	1898	69	1918	196
1879	87	1899	75	1919	212
				1920	243

The actual price indexes are those derived from two sources: (1) From 1859 to 1889, the price indexes are those given in Senate Report No. 1394 on "Wholesale Prices, Wages and Transportation," by Nelson W. Aldrich, March 3, 1893. The weighted average price indexes there given are multiplied by 0.9 to reduce them to the same base as the price indexes of the U. S. Bureau of Labor, the latter price indexes being those from 1890 to 1920, using the year 1913 as 100. The Aldrich report price indexes are based on the wholesale prices of 223 commodities, weighted in proportion to family budget expenses. The Bureau of Labor price indexes are based on the wholesale prices of 192 commodities in 1890, as given in Bulletin No. 173, and in the Monthly Labor Review, December, 1919, and January, 1920.

the total number of units of products sold. Hence we have this fundamental price formula:

$$\text{Average Unit Price} = \frac{\text{Demand}}{\text{Supply}} = \frac{\text{Money spent}}{\text{Number of units bought}}$$

In the case of lumber, wheat or any other given product, this formula, if applied to the transactions of a year, gives the average unit price for the year. This is simple enough, and may be called "self evident." But it is not "self evident" that this fundamental average price formula can be so treated as to yield a commodity price level formula.

The money spent in any nation during a year is equal to the average quantity of money in circulation multiplied by the number of times the money is "turned over" during the year (*i.e.* the "velocity of circulation"). Thus the numerator of the fundamental price formula is derived. The denominator of the formula is not so readily perceived to be susceptible of an equally simple analysis. The total number of units of product purchased in any year is practically equal to the total number produced in that year. But the total number of units produced is equal to the total population multiplied by the per capita productivity. Hence we have the following application of the supply and demand formula to a nation's entire annual output of commodities:

$$\text{Average Price} = \frac{\text{Money} \times \text{Vel. of Circulation}}{\text{Population} \times \text{Per Cap. Efficiency}} \times C$$

The factor C is practically a constant percentage, and is the ratio of the amount of money spent for commodities to the total amount of money spent for all things.

We may substitute letters for words in this formula, letting A stand for average price, M for money, V for velocity of circulation, P for population, and E for per capita efficiency of production. Then we may write the formula:

$$A = \frac{M \times V}{P \times E} \times C$$

This formula would give the absolute average unit price of all commodities for any given year, were we able to ascertain the value of E in units. But since this is impracticable, we must try to get the relative average price of commodities, or price index, which we shall indicate by the letter W. It will be seen later that it is practicable to ascertain the relative per capita productivity, or efficiency of production, E. When we insert its values for any given year in the formula, the formula then gives a relative price, or price level, or price index; and then may be written:

$$W = \frac{M \times V}{P \times E} \times C$$

Similarly we need not get the absolute value of V for each year, but only its relative value, and since this will introduce another constant factor analogous to the C, the final formula for commodity price index becomes:

$$W = \frac{M \times V}{P \times E} \times K$$

Based upon the standards for V and E that I shall use, the value of K is ½. Hence we have the following formula for practical use:

$$W = \frac{1}{2} \times \frac{M \times V}{P \times E}$$

This formula gives an average relative price of all commodities sold at wholesale and retail; but since there is at present available only wholesale price indexes, we must test the formula thereby, remembering that in normal times retail and wholesale prices move in unison, whereas in abnormal times wholesale prices change more rapidly than retail, and usually move through a wider range.

Applying the Price Formula.—In order to use the formula it is necessary to secure average values for each of the four variables (M, V, P and E) for each year. Currency in circulation (M) is obtainable from the Comptroller of the Currency, and his reports are abstracted in the annual Statistical Abstract of the U. S. and in the weekly and daily financial papers. Population (P) is reported by the U. S. Bureau of Census. This leaves only velocity of circulation (V) and efficiency of production (E) to be estimated.

Measuring the Rapidity of "Money Turnover."—Everyone is aware that when "business is good," bills are paid more promptly than when it is "poor." A little consideration of this fact makes it clear that "money is turned over" more rapidly in "good times" than in "bad times." It is also known that average prices of commodities rise in "good times." It follows from these two facts that there is a relationship between the rapidity of "money turnover" and average prices of commodities.

In seeking for a simple means of measuring the relative rapidity of "money turnover" I felt at the start of my study of this problem that it should be practicable to eliminate most, if not all, of the effect of speculative transactions upon bank clearings. My first step, therefore, was to take the bank clearings outside of New York City as being a better barometer of trade than the bank clearings in New York City. When I divided the annual bank

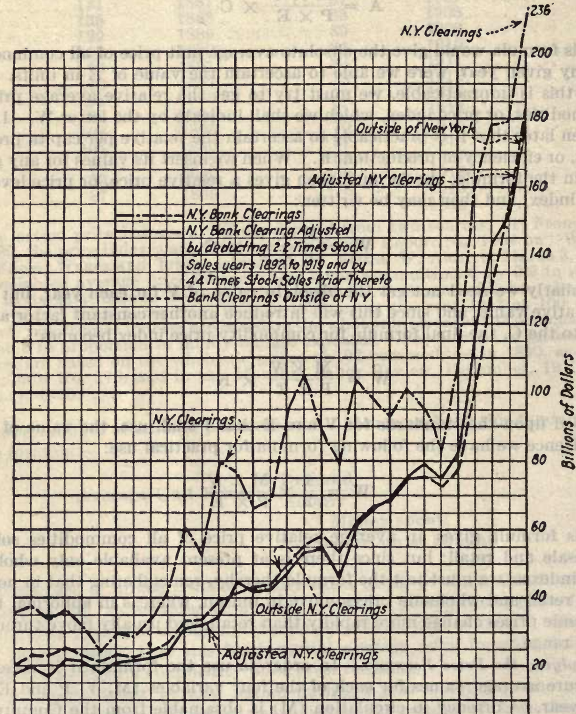

FIG. 1.—Bank clearings.

clearings outside of New York by the total bank deposits in the United States at the middle of any year, I found that the quotient was usually about 4.5 in years when business was "normal," that is, when there was neither a "boom" nor a "depression."

This result encouraged me in the belief that I might be able to "adjust" New York bank clearings, so as to eliminate the effect of stock and bond sales. I reasoned that in the case of an outright purchase of stock, a stock broker would deposit the check or draft received from his client, and would draw his own check for an almost equal amount payable to the person from whom the securities had been purchased. Hence there would appear in New York bank clearings \$2 for every \$1 of outright sales of stocks. In case of a purchase "on margin," a similar result would follow, because the broker would borrow from his bank the difference between the "margin" put up by his client and the purchase price of the stock.

Acting upon this theory, I deducted from the New York bank clearings twice the stock and bond sales for each year, from 1893 to 1919, and I found that the remainder was almost exactly equal to the bank clearings outside of New York City every year. This is well shown in Fig. 1, which is convincing evidence that my method of eliminating the effect of stock and bond sales from New York bank clearings is substantially correct.

It will be noted that when the stock and bond sales on the New York Stock Exchange are not available, all that is necessary to secure substantially correct results for total mercantile and industrial bank clearings in the United States is to double the total bank clearings outside of New York City.

Since the value of bonds sold is ordinarily about 10 per cent of the value of stocks sold on the New York Stock Exchange, and since the stocks usually sell at an average price of about \$90 a share, an approximate adjustment of bank clearings in New York City, to eliminate the effect of stock and bond sales, can be effected thus: multiply the total number of shares sold by \$90, and then multiply this product by 2.2 to get the total bank clearings due to both stock and bond sales. Deduct this product from the total bank clearings in New York City and the remained is the approximate total of New York bank clearings attributable to mercantile and industrial transactions. This is normally equal to the total bank clearings outside of New York City.

To calculate the relative rate of money turnover in a year, or velocity of money circulation, (V), divide the total annual bank clearings (after adjusting for N. Y. stock and bond sales, as above described) by the average bank deposits.

For all practical purposes the individual bank deposits as of July 1 can be used (See Table II). The adjusted bank clearings are given in Table V and Fig. 1 for each year. The resulting velocity of circulation (V) for each year is given in Table VI.

The values of V given in Table VI are relative only, for as a matter of fact only about 40 per cent of the total checks pass through bank clearing houses. Hence to get the actual rate of annual money turnover it is necessary to multiply the values of V given in Table VI by 2.5.

Adjustments of bank clearings for the effect of stock exchange transactions in Chicago, Philadelphia and Boston are unnecessary because of the relatively small volume of their transactions.

The following illustration may serve to make clear the soundness of the above given method of estimating velocity of circulation.

Practically all currency is constantly flowing into the banks and out again, the bank reserves being only part of the total. A bank, therefore, resembles a reservoir or lake into which water is flowing, only to flow out again. We may conceive all the banks in America to be like all the artificial and natural water reservoirs in America. We may conceive the clouds to be like the individual purses that carry the currency to the banks. We may conceive the rivers to be like the "pay envelopes" that carry the currency away from the banks. The average velocity of a given volume of water can be accurately calculated if we know the number of times that a reservoir is filled in a given period by the water In like manner the average velocity of currency circulation can be estimated by ascertaining the number of times the bank reserves are turned over in a year. But since bank deposits are normally about ten times the bank reserves, the relative rate of turnover of bank reserves is ordinarily about the same as the rate of turnover of bank deposits. Hence the relative rate of turnover of bank deposits is practically the same as the relative rate of turnover of all currency.

Productive Efficiency.—Prof. King, in his "Wealth and Income of the People of the U. S.," has given some estimates of the average annual incomes of several different classes of producers, expressed in buying power as well as in dollars. But he does not give the increase in average income per capita or per worker for all those classes of producers combined, and it was this general average that I was seeking. Moreover, I found that through not going to the original sources, Prof. King had made several errors both in the actual data and in his interpretation of them. For example, he did not realize that the statistics as given in the Statistical Abstract relating to the value of agricultural products are not at all comparable for the different census years, a fact that is pointed out in the volumes of the U. S. Census. In several instances Prof. King used incorrect index prices, e.g., simple averages where weighted averages should have been used.

In order to reduce to a minimum any errors that might arise from the use of incorrect price indexes, I decided to secure, as far as practicable, the number of units of product in each of the four grand classes of producers of commodities sold at wholesale, namely (1) Agriculture, (2) Mining, (3) Manufacturing, and (4) Transportation by Rail. I found it possible to secure all the needed data for every year back to 1869, except for manufactured products and for transportation. Steam railway transportation, however, could be carried back to the year 1882, for both the numbers of tons and ton-miles of freight were available.

Table X gives a general idea of the distribution of those engaged in gainful occupations, but too rigorous a comparison between successive census years should not be made, especially between 1899 and 1909, because of differences in the classification rules followed by the census takers in different years.

Since less than 3 per cent of all men engaged in gainfull occupation are classed as steam railway employes (under Transportation) in the U. S. Census, no appreciable error can result by omitting them entirely from consideration in seeking the general average productive efficiency of all workers. Moreover, it should be noted that for every railway employe there is an investment of more than $10,000 in the railway plant, or about four times as much per worker as is found either in manufacturing or in agriculture. All this railway plant has been built by workers classed under Manufacturing and Mechanical, and most of its renewals are made by them also. Hence, viewing the problem broadly, the productive efficiency of railway employes is mainly due to men not classed as railway employes.

The building trades employes must be excluded from consideration because no data as to the value of their total output are available since 1899. For 1899 and prior thereto the building trades output was included by the census with manufacturing output, but I have eliminated it from those years in order to derive a manufacturing output that will be comparable from 1869 to 1914. (Prof. King failed to take into account the above mentioned change in 1899.) The building trades constitute about 4 per cent of the total engaged in gainful occupations. The labor cost of buildings is only 40 to 50 per cent of the total cost, so that the omission of the building trades from the total of productive workers is even less important than the 4 per cent would indicate.

Finally, it should be remembered that we are seeking a productive efficiency factor to use in a wholesale commodity price formula, and the building trades employes have very little influence on this factor.

For similar reasons, workers classed under Domestic and Personal Service and Trade can be omitted from consideration. The same holds true of Professional service, for although a very large part of the increase of productive efficiency is attributable to professional men (educators, engineers, etc.), it finds its measure in the better work done by the workers, which is exactly what we are seeking to determine.

We have left, then, those engaged in Agriculture, Manufacturing and Mining. These occupations comprise about two-thirds of all people engaged in gainful occupations, and they comprise fully 85 per cent of all workers who produce wholesale commodities. Hence if we ascertain the average productive efficiency of these three classes, we shall have a very accurate measure of the productivity of all producers.

The census data for 1859 and earlier years are not comparable with those of later years, because slaves were not counted as being engaged in gainful occupations, although they were counted as part of the population. In 1859 negroes were about 15 per cent of the population.

The Efficiency of Miners.—Practically all the miners in America are engaged in producing seven minerals and metals: Coal, iron ore, copper, gold, silver, lead and zinc. Hence if we ascertain the annual number of units of each of these minerals and metals produced at intervals of 5 or 10 years, and multiply by standard unit prices we shall be able to compare one year's output with another. Then if we divide the total output in dollars for each year by the number of miners engaged in that year, we shall have the gross output in dollars per miner per year. But from this should be deducted the value of new equipment and of materials and supplies used in mining, which, according to the U. S. census, has averaged about 30 per cent of the gross value of the mineral output.

Table XIII gives two typical years, 1869 and 1918, for which I have calculated the gross value of the 7 minerals and metals, using prices that approximate to those of 1913. The gross mineral values for 1869, 1879, 1889, 1899, 1904, 1909, 1914 and 1918 being thus determined (always using the same standard unit prices), 70 per cent thereof was taken (to get the value after deducting raw materials, supplies and additions to plant), and the net values thus derived for each of these years were divided by the number of miners employed during that year. This gave net value produced per miner for each of the years, which is graphically shown in Fig. 2. A similar result is shown graphically in Fig. 3, but there expressed as percentages (instead of in dollars), taking the year 1879 as 100 per cent. Table XIV shows the same results, and the footnotes describe the methods of calculations. The numbers in column A of Table XIV, when multiplied by 70 per cent, give the dollars per miner per year shown in Fig. 2; the numbers in column E (or efficiency per miner) are shown in Fig. 3. It will be seen that the productive efficiency of the miners has more than doubled in 50 years, rising from 91.7 in 1869 to 187.8 in 1918. It is particularly noteworthy that their efficiency has increased more rapidly in the last 30 years of this 50-year period than in the first 20 years. In 1917 the coal miners (and they comprise 80 per cent of all the miners) broke all records for output per miner, mainly because they worked about 20 per cent more days per annum than in normal years. The output for 1918 also was abnormal. Had I used the abnormally high output that actually occurred for 1918, the result would have been a gross equated output of $1,902 per miner

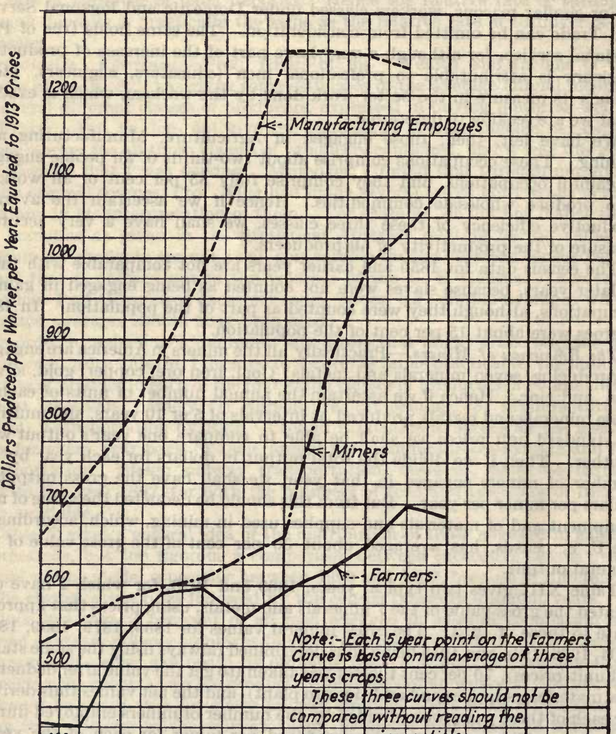

FIG. 2.—"Equated Productivity" per worker (dollars per annum).

instead of the $1,550 given in column A of Table XIV. But since we are seeking the average efficiency of all workers in America, this abnormal output of the coal miners for 1918 would give us a false result, so both in Table XIV and in Figs. 2 and 3, I have scaled down the mining output to that of a normal year.

With the same number of coal miners about 20 per cent more coal was mined in 1917 than in 1914. This achievement shows conclusively what may be accomplished in the way of improving the efficiency of the coal mining industry.

The data of annual output of the mines are to be found in the Statistical Abstract of the United States.

The standard unit prices of coal and iron that I have assumed in Table XIII, are the prices at the mines; but the rest of the prices are those of the

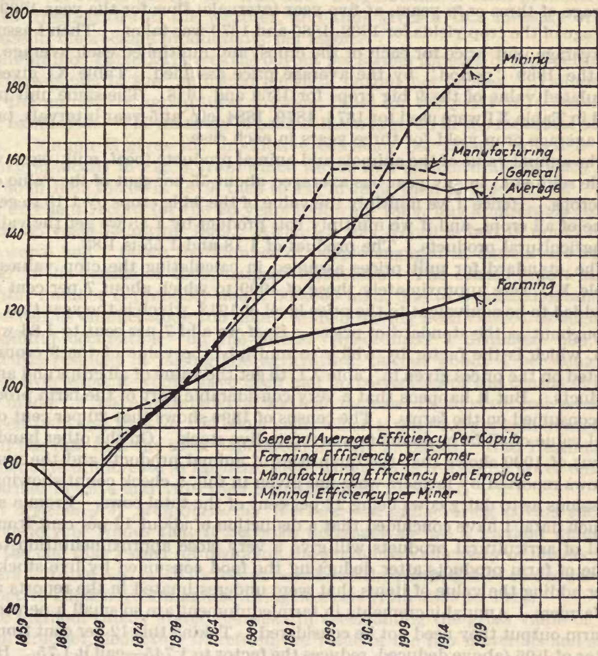

FIG. 3.—Productive efficiency.

metals in the primary wholesale markets. Since these metal prices include the cost of milling, smelting and freight, the resulting total values (Table XIII) for each year are in excess of the bare cost of mining. While this makes it impossible to contrast the dollars produced per miner with the dollars produced per farmer for a given year (Fig. 2), it does not prevent a comparison of the changes in their respective efficiency (Fig. 3), nor does it vitiate the final conclusions as to the per capita productive efficiency of all producers of wholesale commodities, as will be more clearly evident when we come to the discussion of that factor (E). The increased investment in plant per miner has already been taken into consideration, as above described.

Agricultural Efficiency.—In order to measure the productive efficiency of agricultural workers from 1869 to 1918 inclusive, I decided that the most exact method would be to secure the number of units of product of every important crop by years. Upon study of these crop data it became evident that 9 crops comprised 85 per cent of all crop values. Since the other (or minor) crops bear an almost constant ratio in value to the total value of these 9 crops, it is apparent that we need consider only the 9 crops in estimating crop productive efficiency for different years.

Since crops usually vary somewhat from year to year I decided to take the average of three crop years, at five year intervals; thus for the year 1869, the average of the crop yields for 1868, 1869 and 1870 was taken. Then I assumed an average unit price for each of the crops, and multiplied each average crop for the 1869 "period" by the average price assumed. Table XI gives the calculated value of the 9 big crops for 1869 and 1918. The same unit prices used in Table XI were used for 1874, 1879, 1884, etc. at 5-year intervals, taking the average crop yield for three years in each case.

The annual value of the animals and animal products (beef, milk, eggs, wool, cattle sold, etc.) in any year has averaged about 55 per cent of the value of all the crops. Hence if we multiply the value of the 9 big crops by 1.18 to get the value of all crops, and if we multiply this product by 1.55 we get the value of all agricultural products. The product of 1.18 and 1.55 is 1.83.

The standard for unit prices assumed in calculating the crop values (see Table XI) were approximately those of 1909 to which about 7 per cent must be added to be equivalent to the price level of 1913, which is the year that I use throughout as the standard of prices. So if we add 7 per cent to 1.83 we get 1.96, which is the factor by which to multiply the value of the 9 crops calculated on the prices given in Table XI, to get the value of all crops and animal products. But it happens that a very considerable part of the farm products are consumed on the farms. The census of 1899 shows that 20 per cent of the total value of all farm products was fed to live stock. On the other hand, the census of 1909 shows that the quantities of animal products and the number of cows reported by farmers were not given in full, a check count showing the omissions as to dairy cows being 22 per cent of the total cows. From a study of such data, I have concluded that a deduction of about 12 per cent from the total of agricultural products will give a very close approximentation to the value of farm products after deducting the food consumed by live stock and after adding the value of items that were underestimated in the reports made by farmers. Annual increments in farm equipment are so small a percentage of farm output they need not be considered. Taking this 12 per cent from the factor of 1.96 (above deduced, reduces the factor to 1.745—call it 1.75. Hence if we multiply the total values of the 9 big crops (as given in Table XI for 1869 and 1918, and as similarly calculated for intervals of 5 years between those years) we get the equated total value of farm products after deducting the value of food fed to livestock. The resulting totals for each year if divided by the numbers of agricultural workers give the "equated" annual productivity per agricultural worker.

The word "equated" here means reduced to the same standard prices for the standard year, the standard year in this case being 1913.

Fig. 2 shows the output in dollars per year per "farmer," for each of the 5-year points (each "point" being an average for three years' crops, as above explained), from 1869 to 1918 inclusive. Even though I had largely eliminated the effect of fluctuations in crop yield (by taking 3-year averages), it is evident that the effects of very bad crop failures were not entirely "ironed out." Since we are seeking average annual productive efficiency per capita, it is necessary to "iron out" all irregularities. Accordingly, it is necessary to omit the results for the year 1874 and 1894, for exceptionally large crop failures occurred at these "points." To do this "ironing out," draw a straight line on Fig. 2 from the farmer output in 1869 to that in 1879, thence to that in 1889, thence to that in 1918. This line (which is not shown in Fig. 2 but can be drawn by the reader) may be called the "adjusted curve of output per farmer." It serves merely to "iron out" irregularities of farm productivity due to irregularities in the weather, and thus gives a true measure of the increase in the average productivity per farmer.

Column B of Table XII gives the output per farmer for each of the "periods," and corresponds to the "adjusted curve of output per farmer." Column C gives the number of agricultural workers, those for the years 1914 and 1918 being estimated. The meaning of each column is given in the footnotes of the table. Column E gives the productive efficiency per farmer, which is also shown graphically in Fig. 3, from which we see that agricultural efficiency rose from 80 in 1869 to 100 in 1879, then to 111 in 1889, then to 125 in 1918. This in an excellent record for the 20 years following 1869, but a miserable record for the 30 years following 1889. Although this record is bad it would have been worse had I taken the number of people engaged in agriculture as reported in the census of 1909, namely 12,659,000. The census report states that this number is probably about 500,000 high, due to a misunderstanding by the census enumerarors, too many women having been classed as engaged in "gainful occupation" on the farms. Accordingly I deducted 500,000, which has resulted in raising the agricultural output about 4 per cent per worker over what it would have been had no correction of the census figures been made. I have estimated a 900,000 increase in agricultural workers between 1909 and 1918, or 100,000 a year, which is only 0.8 per cent yearly, or at half the rate that the total population usually increases. Had I estimated a higher rate of increase in farmers, there would have resulted a lower output per farmer in 1914 and 1918 then that shown in Table XI.

The Efficiency of Manufacturing Workers.—Manufacturing covers such a vast variety of trades that it becomes necessary to use a method differing from the one that I used for deducing the productive efficiency of miners and farmers. Table XV (with its footnotes) shows the method used to deduce the productive efficiency of manufacturing workers from 1869 to 1914.

The method, briefly stated, consists in ascertaining the gross value of the annual product, deducting therefrom the value of the raw materials and supplies, and dividing the net value thus obtained by the wholesale price index for the given year. The quotient (column E, Table XV) is the "equated" net value produced by the work of all those engaged in manufacture. If great exactitude is required, this result should be reduced by about 3 per cent, to allow for the annual increment in "equated" investment in manufacturing plant, but this refinement is unnecessary.

Dividing the value of a year's output by the price index for the given year gives an "equated" value that is comparable with that for any other year. By such a method we are able to reduce all values to a common basis, arriving at a result similar to that obtained by the method above described for "equating" the output of miners and farmers.

Fig. 2 shows graphically the data given in column H of Table XV; Fig. 3 shows the data in column I.

It will be seen that manufacturing workers' productive efficienct or out-put was 84 in 1869, and rose to 158 in 1899—almost doubling in 30 years. Following 1899 there was no improvement whatever for 15 years (up to 1914), and there is little doubt that some falling off in manufacturing workers' efficiency, per worker, has occurred since 1914. However, the per capita productive efficiency of the nation has not decreased materially since 1914, because farming and mining efficiency have risen sufficiently to offset any loss in manufacturing efficiency. The proof of this conclusion will now be given:

Productive Efficiency Per Capita.—Per capita productive efficiency has, so far as I know, never been ascertained before, yet its economic significance is of extreme importance, entirely aside from its use in my price index formula.

We have already considered the productivity of each of the three great classes of workers who produce raw materials and finished factory commodities. It remains now to secure the combined or composite efficiency of these workers. Before doing so it may be well to point out the economic part of the other classes of workers, namely those engaged in "professional service." "domestic and personal service," "trade and transportation." These three great classes comprise about one-third of all who are engaged in gainful occupations. As will be seen from Table X, this ratio of one-third has been fairly constant for the 40 years, from 1869 to 1909. It is apparent, therefore, that to the cost of producing commodities, there must be added about 50 per cent for transporting and distributing them and for the professional service (educatinal, engineering, etc.) and other services (government, etc.). This explains why retail prices average, on the whole, approximately 50 per cent in excess of wholesale prices, year after year. But the present significance of this constancy of the ratio of the number of "producers" to "distributors, etc.," namely, 2 to 1, is this: If we ascertain the efficiency of the "producers" of commodities sold at wholesale prices, that same efficiency will apply to the "distributors, etc."

Table X shows that the ratio of "workers" (all those engaged in gainful occupations) to total population has increased since 1869. Probably the rate of increase since 1914 has been greater than theretofore, because so many women who were called into gainful service during the war have continued in that service. This should be borne in mind when considering the productive efficiency of the nation as a whole, for it accounts largely for the fact that our per capita efficiency has not decreased during the past five years in spite of a decrease in individual efficiency in many industries and trades.

Table XVI gives my calculation of the per capita productivity and efficiency of the American people, from 1869 to 1918 inclusive.

It will be observed that I have estimated the "equated" value of manufactured products for 1918 at 10 per cent in excess of that for 1914. In arriving at this estimate, I studied all the data of annual production of different commodities, and made a "weighted average" estimate of the resulting percentage increase. Table VIII contains only a small fraction of the data that I used in making this estimate, but it should serve to silence anyone who argues that high prices are attributable to the reduced output of American workers.

Column G of Table XVI shows the per capita productive efficiency of the American people (the E in my index price formula) and Fig. 3 shows the same data graphically, from 1869 to 1918. Observe that per capita efficiency rose from 80 per cent in 1869, to 100 per cent in 1879 (the year taken as a standard for comparison), then to 146 in 1904, then to 152 in 1914, and finally to 153.5

in 1918. It will be seen that since 1909 there has been very little change in per capita efficiency. It will be seen that, contrary to general opinion, the productive output of the nation did not decrease as a result of the war.

The Effect of Exports Upon Price Levels.—There have been only three years since 1875 that out imports have exceeded our exports. During the fifteen years prior to the world war, the excess of merchandise exports over imports was as follows, by five-year periods:

	Millions
June 30, 1899, to June 30, 1904	$2,552
June 30, 1904, to June 30, 1909	2,381
June 30, 1909, to June 30, 1914	2,385
Total, millions of dollars	$7,318

Taking five years preceding the war, we see that out merchandise exports exceeded out imports by an average of 477 million dollars annually. In Table XVI will be seen that our average annual production of wholesale commodities during the same five-year period was 18,400 million dollars. Hence our annual excess of exports over imports averaged about 2.5 per cent of the total commodities that we produced. In my price formula this 2.5 per cent does not appear as a corrective factor, but it is automatically taken care of.

Table IX Column "A," gives the "balance of trade" for each of the last five calendar years in millions of dollars. To reduce these dollars to the same purchasing power as existed in 1913, the total for each year (as given in Column "A") is divided by the average price index for the corresponding year (as given in Column "B"), and quotient (as given in Column "C"). is the number of dollars of "balance of trade" expressed in terms of the buying power of a dollar in 1913. This "equated value" of the excess of exports over imports is 9,764 million dollars for this five-year period, or about 1,953 million dollars per annum, as compared with 477 million dollars per annum prior to the war.

Table XVI shows that the annual production of wholesale commodities averaged 19,770 for the years 1914 to 1918. Hence it follows that the excess of exports over imports during the years 1914 to 1919 averaged about 10 per cent of the total commodities produced during those years, as compared with 2.5 per cent during the prewar years; thus producing an abnormal deficiency of commodities for home consumption amounting to 7.5 per cent of the total annual production.

So far as its effect upon the American average wholesale commodity prices is concerned, this abnormal balance of trade of 7.5 per cent has acted precisely as if there had been a 7.5 per cent decrease in productivity. Hence the per-capita productivity coefficient (the E in the price formula) must be decreased 7.5 per cent for each of the five calendar years, 1915 to 1919, inclusive.

Some Imaginary Causes of High Prices.—Among the imaginary causes of higher average prices are: (1) Profiteering, (2) Extravagance, (3) Inefficiency of workers, (4) Scarcity of commodities in America, (5) High taxes.

"Profiteering," even where it exists, can not affect average prices, however much it may affect the prices of a given class of things. Profiteering merely serves to change the distribution of the total currency, but does not change the total. Profiteering does not change the total buying power of the nation, for that is measured by the product of the total currency and its rate of turnover. Profiteering diverts the currency into pockets and bank accounts that it would not otherwise have reached. Such a diversion may result in a greater buying of certain commodities by the profiteers. But by as much as those profiteers increase the demand for the things they purchase, by an exactly equal amount there occurs a decrease in the demand for the things that would otherwise have been purchased had there been no profiteering.

The very same sort of reasoning holds good as to extravagance. Extravagance diverts money from the purchase of, say, construction materials, to say, diamonds and silks; but extravagance alters not one whit the total annual buying power of a nation. Every nation always spends all that is earned annually.

High taxes have no effect on average prices, unless they cause a stagnation in industry. It is possible that this may yet occur to some extent, because the graduated income tax takes away a large part of the profits in business of a venturesome nature and therefore tends to a restriction of business enterprise. Also if high taxes lead to a permanent and large increase in government activities of an unproductive nature, there results a lowering in productive efficiency per capita (the E in my price formula) and a consequent rise of average prices of commodities.

A general scarcity of commodities in America does not exist. This also is a fictional reason for high prices.

Scarcity of commodities in Europe affects prices in America by: (1) Causing a shipment of gold to America, (2) by increasing the rate of money turnover, and (3) by decreasing the quantity of commodities available for domestic markets.

Modern political economists (with very few exceptions) have hitherto held that bank deposits against which checks may be drawn (often called "credit currency") are essentially the same as money, and that, therefore, an increase in bank deposits tends to raise the level of prices just as does an increase in money. It will be observed that my formula does not support that belief, unless it can be shown to be a fact that bank deposits subject to check have increased in the same proportion that money has increased. Table II shows that the ratio of bank deposits to total currency was 2.2 to 1 in the year 1880, and that it rose to 5.7 to 1 in 1919. The rise was steady and so rapid during those 40 years as to make it clear that, had total bank deposits had the same effect as currency in raising prices, there would have occurred a price increase several fold in excess of what actually did occur. Table VII shows that the ratio of total bank deposits to deposits subject to check has been constant for 30 years, so that it cannot be contended that the more rapid increase in total bank deposits has been offset by a decrease in the proportion of checking deposits to total deposits.

There remains only one other way in which the increase in total bank deposits could be offset, and that would be by a decrease in the rapidity of turnover of checking deposits. This, however, has not occurred. Prof. Fisher states that the contrary has occurred. But we need not use his estimates to prove this contention, for all that is necessary is to refer to Tables VI and VII. In Table VI we see that the ratio of bank deposits to total bank clearings "adjusted" for the effect of New York Stock Exchange transactions has averaged about 9 for the past 30 years oscillating, back and forth from this average. Table VII shows that during the same period the ratio of total deposits to checking deposits has averaged 2 to 1, and that there have been only slight departures from this average at any time. Hence it follows that the ratio of "adjusted" annual bank clearings to checking bank deposits (=

"credit currency") has averaged 18 to 1, and that there have been only relatively small departures from this average.

It is made clear from these facts that the rapid increase in bank deposits, as compared with the less rapid increase in total currency, has not been offset either by (1) a decrease in the ratio of checking deposits to total deposits or by (2) a decrease in the rapidity of annual turnover of checking deposits. This being so, it is conclusively established that average commodity prices would be nearly two times as high as they now are, were it a fact that checking deposits have the same effect as currency upon prices, it being remembered that per capita bank deposits have increased 2 times as rapidly as currency since 1890 (See Table II).

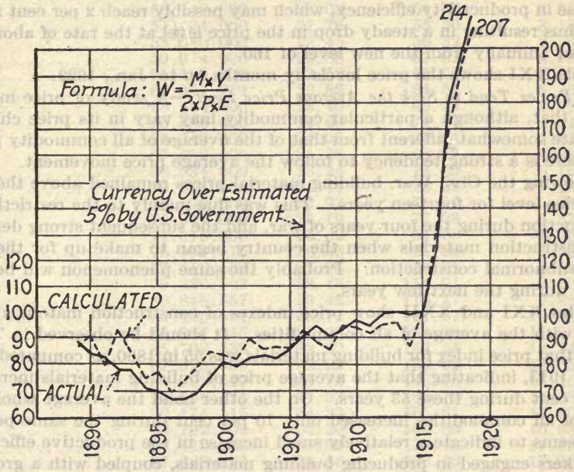

FIG. 4.—Comparison of actual and calculated wholesale price indexes, 1889 to 1919.

Predicting Price Levels by the Formula.—Table XVII and Fig. 4 show the actual wholesale price indexes for every year from 1889 to 1919 compared with price indexes calculated by the formula. The agreement is so close as to verify the accuracy of the formula, especially when consideration is given to the wide range not only of the price level during this period but the great variation in each of the four variables in the formula.

So long as the variables affecting price levels were not known quantitatively, it was impracticable to predict price levels with any degree of accuracy. But by considering the probable changes in each of the four variables in the price formula, it is possible to forecast price movements with considerable accuracy.

It is probable that the 50 per cent increase in gold that America secured during the war will not be materially reduced for several years, because Europe owes America 9 billion dollars, or more than all the gold in circulation in the world.

Table II shows that the per capita currency in circulation was $34.56 in July 1, 1913, and $54.74 six years later, or an increase of about 60 per cent.

There may be some decrease in this currency due to the retirement of Federal Reserve notes, but this shrinkage is likely to be nearly offset by increase in gold. Hence when the velocity of circulation (V) returns to normal, and when exports and imports again reach a normal relation of substantial equality, we shall have left only one factor that has changed, namely per capita currency. Since that has increased 60 per cent, and is not likely to change rapidly, the new price level, or new price plateau, will be about 60 per cent above the pre-war price level. This price plateau will probably slope gently downward as it did after 1867, following the two-year readjustment period when prices declined rapidly (see Table I). The factors that will tend to decrease price levels will be an increase in population (at about 1.5 per cent yearly), and an increase in productivity efficiency, which may possibly reach 2 per cent annually; thus resulting in a steady drop in the price level at the rate of about 3.5 per cent annually from the new level of 160.

Table XXI shows the price levels by months up to Jan., 1922.

All Prices Tend to Seek the Average Price Level.—A study of price indexes shows that, although a particular commodity may vary in its price changes at a rate somewhat different from that of the average of all commodity prices still there is a strong tendency to follow the average price movement.

Following the Civil War, building material prices remained above the general price level for fourteen years. This was due mainly to the restriction of construction during the four years of war, and the subsequent strong demand for construction materials when the country began to make up for the previous subnormal construction. Probably the same phenomenon will be witnessed during the next few years.

Tables XXI and XXII show price indexes of construction materials compared with the average of all commodities. It should be observed in Table XXII that price index for building materials was 55 in 1860, as compared with 100 in 1913, indicating that the average price of building materials increased 80 per cent during these 53 years. On the other hand the average wholesale price of all commodities increased only 10 per cent during the same period. This seems to indicate a relatively small increase in the productive efficiency of workers engaged in producing building materials, coupled with a growing scarcity of timber.

TABLE II.—POPULATION, CURRENCY AND BANK DEPOSITS

Year	Population (June 1)	Currency per capita	Bank deposits per capita (July 1)	Total bank deposits† (millions)
1895	30,822,000	$14.35	$35.80*	$1,098*
1860	31,443,321	13.85	34.60*	1,089*
1861	32,064,000	13.98	35.00*	1,121*
1862	32,704,000	10.23	25.60*	837*
1863	33,365,000	17.84	44.50*	1,488*
1864	34,046,000	19.67	49.20*	1,674*
1865	34,748,000	20.58	51.50*	1,787*

* For years following 1874 the data given by the comptroller of the currency in the Statistical Abstract of the U. S. are taken, except as to private banks, which (since 1877) have been estimated by multiplying the private bank deposits given in the Statistical Abstract by 4, because only one-fourth of the private banks have reported their deposits. The correctness of this estimate for private banks is confirmed by data given in Mitchell's "Business Cycles." The total deposits in private banks has been only about 0.6 per cent of the total deposits in all other banks for several years past.

These bank deposits are those known technically as "Individual Bank Deposits," which excludes the U. S. Govt. deposits.

TABLE III.—NEW YORK STOCK EXCHANGE SALES

Calendar year	No. of shares of stock	Stock value in millions	Bonds at par in millions
1889	72,014,600	$4,060	398

TABLE IV.—BANK CLEARINGS IN MILLIONS OF DOLLARS
(Calendar Years)

Year	New York	All U. S.	Year	New York	All U. S.
1889	$35,895	$56,175	1905	$93,822	$143,909
1890	37,458	60,623	1906	104,675	160,019
1891	33,749	56,718	1907	87,182	145,175
1892	36,662	62,109	1908	79,275	132,408
1893	31,261	54,323	1909	103,588	165,608
1894	24,387	45,686	1910	97,275	163,722
1895	29,841	53,348	1911	92,373	160,230
1896	28,870	51,333	1912	100,474	174,914
1897	33,427	57,403	1913	94,634	169,826
1898	41,971	68,931	1914	83,019	155,242
1899	60,761	94,178	1915	110,564	187,818
1900	52,634	86,205	1916	159,581	260,953
1901	79,420	118,579	1917	177,405	306,945
1902	76,328	118,023	1918	178,533	332,351
1903	65,970	109,209	1919	235,802	417,519
1904	68,649	112,621			

Foot Note: The bank clearings given in the Statistical Abstracts of the U. S. are for fiscal years ending Sept. 30. In ordinary times these do not differ greatly from those for calendar years ending Dec. 31, but in times of rapid business changes they may differ considerably.

TABLE V.—BANK CLEARINGS (MILLIONS OF DOLLARS)

Column	A	B	C*	D	E	F
	——New	York——		Adjusted	Clearings	Total
Calendar year	Clearings	Stock sales	Adjustment	N. Y. clearings (A − C)	outside N. Y.	adjusted clearings (D + E)

7	177,405	15,609	34,340	143,065	129,540	272,605
8	178,533	12,483	27,463	151,070	153,818	304,888
9	235,802	25,905	56,991	178,811	181,632	360,443

* The quantities in this column were calculated by multiplying the stock sales (column B) by the following factors: For the year 1891 and prior thereto, 4.4; for the year 1892, 3.0; for all subsequent years, 2.2. Prior to May 17, 1892, the N. Y. Stock Exchange clearings were merged with the N. Y. Bank Clearings, but thereafter there was no merger. If greater accuracy is desired, add the N. Y. stock sales to the bond sales and multiply by 2, instead of approximating the same result by multiplying the stock sales by 2.2.

TABLE VI.—VELOCITY OF CIRCULATION (V)

Year	(V)	Year	(V)	Year	(V)
1889	9.52	1900	8.75	1910	8.47
1890	9.89	1901	8.35	1911	8.32
1891	8.91	1902	9.13	1912	8.55
1892	9.61	1903	8.54	1913	8.60
1893	9.17	1904	8.36	1914	7.74
1894	8.02	1905	8.27	1915	8.15
1895	8.70	1906	8.65	1916	9.41
1896	8.60	1907	8.33	1917	10.18
1897	8.86	1908	7.50	1918	10.70
1898	8.67	1909	8.41	1919	10.89
1899	9.28				

Foot Note: The world war began early in Aug., 1914, and was followed immediately by an abnormal decrease in bank clearings due to failure to pay obligations. Hence the value of V for 1914 is below the real rate of money turnover, and accordingly it leads to an incorrect result for 1914 when used in the price formula.

TABLE VII.—TOTAL BANK DEPOSITS AND CHECKING DEPOSITS OR "CREDIT CURRENCY"

(Millions of Dollars)

Year	Total deposits	Checking deposits	Year	Total deposits	Checking deposits
1891	4,482	2,325	1901	8,817	4,935
1892	4,944	2,615	1902	9,501	5,367
1893	4,834	2,510	1903	9,953	5,853
1894	4,849	2,578	1904	10,288	6,559
1895	5,167	2,731	1905	11,735	6,860
1896	5,122	2,688	1906	12,546	7,103
1897	5,245	2,747	1907	13,553	6,522
1898	5,874	3,198	1908	13,166	6,888
1899	6,964	3,365	1909	14,687	7,713
1900	7,527	4,305	1910	15,658	8,242

Foot Note: Total bank deposits are taken from Table II. Checking Deposits are taken from Mitchell's "Business Cycles."

TABLE VIII.—PER CAPITA PRODUCTIVE EFFICIENCY (E)

Year	(E)	Year	(E)	Year	(E)

1884	1.11	1901	1.43	1918	1.55
1885	1.14	1902	1.44	1919	1.55

Foot Note: During the years 1915 to 1919 our exports exceeded our imports by an amount that was abnormal to an extent that is equivalent to reducing the quantity of goods available for domestic consumption by 7.5 per cent. Accordingly the factor E in this table must be reduced 7.5 per cent or to 1.43 for the years 1915 to 1919 inclusive.

TABLE IX.—EXCESS OF EXPORTS OVER IMPORTS

Calendar year	A Excess	B Price Index	C Column "A" ÷ column "B"
1915	$ 1,776	100	$1,775
1916	3,091	123	2,513
1917	3,282	175	1,818
1918	3,118	196	1,585
1919	4,017	212	1,872
Total	$15,284		$9,764

TABLE X.—GAINFUL OCCUPATION STATISTICS
(Thousands)

Year	1869	1879	1889	1899	1909
Agriculture	5,922	7,714	8,148	10,382	12,568
Professional	372	603	944	1,259	1,825
Domestic and personal	2,302	3,418	4,221	5,581	5,361
Trade and transportation[2]	1,240	1,872	3,326	4,766	7,606
Manufacturing and mechanical[1]	2,670	3,785	5,687	7,085	10,807
Total gainful occupation	12,507	17,392	22,318	29,073	38,167
Total population	37,756	48,866	61,289	74,318	90,557
Fishermen	......	41	60	69	68
Building trades	......	681	1,135	1,212	1,661
Mines and quarries	163	296	531	740	1,177
Transportation[2]	......	587	1,131	1,515	2,465

Foot Notes:

[1] Manufacturing and mechanical includes fishing, building trades, mines and quarries, railway shopmen.

[2] Transportation includes railways (exclusive of shopmen), telegraph and telephone linemen and operators.

TABLE XI.—CROP DATA FOR TWO PERIODS, 1869 AND 1918
Period of 1869

Crop	Millions of units	Unit price	Total millions, dollars
Corn, bu	958	$0.55	527
Wheat, bu	240	1.00	240
Oats, bu	263	0.40	105
Barley, bu	26	0.60	16
Hay, ton	25.70	12.00	308
Potatoes, bu	118	0.60	71
Cotton, bale	2.65	55.00	146
Tobacco, lb	393	0.10	39
Sugar, lb	80	0.025	2
Total			1,454
	Period of 1918		
Corn, bu	2,871	$0.55	1,579
Wheat, bu	784	1.00	784
Oats, bu	1,563	0.43	625
Barley, bu	278	0.60	167
Hay, ton	80.41	12.00	965
Potatoes, bu	422	0 60	253
Cotton, bale	11.50	55.0	633
Tobacco, lb	1,295	0.10	130
Sugar, lb	2,143	0.025	54
Total			5,190

Foot Note: The crop quantities for the "Period of 1869" are the average for the three years of 1868, 1869 and 1870. The crop quantities for the "Period of 1918" are the average for the two years of 1917 and 1918.

TABLE XII.—FARMING EFFICIENCY

"Period"	A Average per year per worker for 9 crops	B Average per year per worker for all products	C Number of workers in thousands	D Equated value of all crops in millions of dollars	E Efficiency per worker
1869	$246	$430	5,922	$2,545	80.4
1879	306	536	7,714	4,130	100.0
1889	340	595	8,566	5,103	111.1
1899	353	613	10,382	6,414	115.4
1904	359	629	11,522	7,238	117.3
1909	365	638	12,159	7,767	119.3
1914	375	647	12,660	8,309	122.5
1918	383	671	13,060	8,754	125.2

Foot Notes:

Column A gives the equated average annual gross output of agricultural workers, for the 9 leading crops per year per worker (see Table XI for two typical "Periods").

Column B is the value in column A multiplied by 1.75, giving the per worker equated value of all farm products.

Column D is one-thousandth of the product of the numbers in columns B and C.

Column E is derived by dividing the numbers in column A by 536, the 536 being the equated value of all farm products per farmer for the "period" of 1879; this year, 1879, being taken as a standard for comparing the output during each of the "periods."

The word "period" is used to designate the average crop for three years, as explained in the article and in Table XI.

TABLE XIII.—MINING DATA FOR TWO YEARS, 1869 AND 1918

Mineral	Millions of units	Unit price	Total millions of dollars
Year 1869			
Coal, long tons	29.38	$ 1.50	44.07
Copper, long tons	0.01	300.00	3.00
Iron ore, long tons	3.03	2.00	6.06
Gold, oz	2.39	20.70	49.47
Silver, oz	9.28	1.00	9.28
Lead, short tons	0.02	100.00	2.00
Zinc, short tons	0.01	120.00	1.20
Total			115.08
Year 1918			
Coal, long tons	581.61	$ 1.50	872.42
Copper, long tons	0.89	300.00	267.00
Iron ore, long tons	75.57	2.00	151.14
Gold, oz	3.31	20.70	68.52
Silver, oz	67.88	1.00	67.88
Lead, short tons	0.54	100.00	54.00
Zinc, short tons	0.58	120.00	69.60
Total			1,550.56

Table XIV.—Mining Efficiency

Year	A Equated output per miner	B Number of miners	C Total equated value, millions	D 70% total equated value, millions	E Efficiency
1869	$ 757	152,107	$ 115	$ 81	91.7
1879	825	234,228	193	135	100.0
1889	915	387,248	354	248	110.9
1899	1,112	563,406	627	439	134.8
1904	1,232	670,562	826	479	149.3
1909	1,393	777,719	1,084	759	168.8
1914	1,479	818,647	1,211	842	179.2
1918	1,550	815,230	1,264	885	187.8

Foot Notes:

Column A gives the equated average annual gross output of all miners engaged in producing the 7 leading minerals. (See Table XIII.)

Column B is the number of miners thus engaged.

Column C is one-millionth of the product of the numbers in columns A and B.

Column D is 70 per cent of column C, and this is the equated value produced by the miners after deducting 30 per cent for raw materials and supplies.

Column E is derived by dividing the numbers in column A by 825, the 825 being the equated value of minerals per miner for the year 1879; this year, 1879, being taken as a standard for comparing the output during each of the years.

Table XV.—Manufacturing Productivity and Efficiency

Year	A Total value of products, millions	B Total value of raw mtls., millions	C Value added by mfg, millions	D Weighted price index	E Equated value added by mfg.
1869	$ 4,232	$ 2,488	$1,744	1.22	$1,430
1879	5,370	3,397	1,973	0.87	2,268
1889	9,372	5,162	4,210	0.86	4,895
1899	13,000	7,344	5,656	0.76	7,442
1899	11,407	6,576	4,831	0.76	6,357
1904	14,794	8,500	6,294	0.84	7,493
1909	20,672	12,143	8,529	0.95	8,978
1914	24,246	14,368	9,878	1.00	9,878

Foot Notes:

Column A gives the total value of manufactured products in millions of dollars.

Column B gives the total value of raw materials and supplies.

Column C gives the difference between the values in columns A and B, or the value added by manufacture.

Column D gives the weighted actual index prices of all commodities, treated as a percentage.

Column E gives the "equated" value added by manufacture, which is derived by dividing the numbers in column C by those in column D.

Table XV.—Manufacturing Productivity and Efficiency—*Continued*

Year	F Employes, thousands	G Value per employe	H Adjusted value per employe	I Efficiency
1869	2,054	$ 696	$ 664	83.9
1879	2,733	830	791	100.0
1889	4,713	1,039	991	125.3
{ 1899	5,670	1,313		
{ 1899	5,077	1,252	1,252	158.3
1904	5,987	1,252	1,252	158.3
1909	7,405	1,212	1,212	153.2
1914	8,000	1,235	1,235	156.0

Column F gives the thousands of employes.

Column G gives the annual value created per employe, but for the years 1869, 1879 and 1889 this includes the buliding trades employes, whereas the years 1904, 1909 and 1914 exclude the building trades. Hence two sets of figures are given in the table for the year 1899; the upper set of figures includes the building trades, the lower set excludes them.

Column H gives the equated value created per employe after "adjusting" for the years 1869, 1879 and 1889 so as to exclude the building trades. This adjustment is made by taking 95.4 per cent of the numbers in column G for the years 1869, 1879 and 1899.

Column I gives the efficiency of manufacturing employes, obtained by dividing the numbers in column H by 791, which is the adjusted value created by the average manufacturing employe in 1879, this year being taken as a standard for comparative purposes.

Table XVI.—Per Capita Efficiency in the Production of Wholesale Commodities

(Column G gives values for E in the author's price formula.)

Year.	A Equated agricultural products, millions	B Equated mfg. products millions	C Equated mining products, millions	D Total of A, B, and C	E Total population, thousands	F Per capita products of A. B and C. efficiency	G Per capita
1869	$2,545	$1,222	$ 81	$3,849	37,756	$102	80.3
1879	4,130	1,937	135	6,202	48,866	127	100.0
1889	5,103	4,181	248	9,532	61,289	156	122.8
1899	6,414	6,357	439	13,210	74,318	178	140.2
1904	7,238	7,493	479	15,310	82,467	186	146.5
1909	7,767	9,241	759	17,767	90,557	196	154.3
1914	8,309	9,878	848	19,035	98,646	193	152.0
1918	8,754	10,866	885	20,505	105,118	195	153.5

Foot Notes:

Column A is taken from column D of Table XII.

Column B is derived from column E of Table XV, by taking 85 42 per cent of the numbers given there for the years 1869, 1879 and 1889, in order to eliminate the value created by the building trades. The $10,866,000,000 for 1918 is estimated in the assumption of a 10 per cent increase over 1914.

Column C is taken from column D of Table XIV.

Column D gives the total of columns A, B and C.

Column F gives the quotient found by dividing the numbers in column D by one-thousandth part of the numbers in column E.

Column G gives the quotients found by dividing the numbers in column F by 127, so as to express the per capita efficiency in terms of that in the year 1879 taken as 100 per cent.

TABLE XVII.—PRICE INDEXES CALCULATED BY FORMULA COMPARED WITH ACTUAL

Year	Calculated	Actual	Year	Calculated	Actual
1889	87	89	1905	86	86
1890	91	84	1906	93	91
1891	80	83	1907	89	96
1892	92	78	1908	86	91
1893	85	78	1909	95	94
1894	75	71	1910	94	97
1895	77	70	1911	92	95
1896	69	67	1912	95	99
1897	74	67	1913	96	100
1898	79	69	1914	86	99
1899	85	75	1915	100	100
1900	84	82	1916	128	123
1901	82	80	1917	163	175
1902	90	83	1918	190	196
1903	86	84	1919	207	212
1904	87	83			

The Relations of Prices of Different Commodities.—Prices of different commodities tend to rise and fall in harmony. But it should be remembered that this harmony of movement occurs only when there is a harmony of supply and demand, that is, when the changes or demand are relatively the same for each of the different classes of commodities. Furthermore (and the fact is rarely considered) the supply of commodities depends upon the productive efficiency of workers. If the productive efficiency in one field remains stationary while that in another field is rising, then we must look for relatively diverging prices in the two fields. Thus, if the efficiency of steel producers is rising while that of lumber producers is stationary, the price of steel will become relatively lower than that of lumber. This, in fact, is exactly what occurred after the Civil War, as shown in Table XVIII.

TABLE XVIII.—WHOLESALE PRICE INDEXES (UNWEIGHTED)
(Aldrich Senate Report)

Year	All commodities	Building materials	Metals	Food	Clothing
1860	100	100	100	100	100
1865	217	182	219	217	299
1870	142	148	139	154	139
1875	128	144	131	131	120
1880	107	131	105	108	105
1885	93	127	80	99	85
1890	92	124	78	105	82

It will be seen that while the four large classes of commodities moved in general harmony, there was a relative divergence between "building materials" and "metals." This was due to a more rapid increase in the average productive efficiency of miners and metal manufacturers than of producers of lumber, brick and other building materials. In the article on price levels in the Nov. 24, 1920 issue of Engineering and Contracting it was shown that the price indexes of "building materials," "metals" and "all commodities" were as follows (taking the average of the year 1913 at 100):

TABLE XIX.—WHOLESALE PRICE INDEXES*

Year	All commodities	Building materials	Metals
1840	89	64	166
1850	83	56	154
1860	90	55	134
1870	117	86	186
1880	93	76	141
1890	84	72	110
1900	82	76	106
1910	97	101	94
1913	100	100	100
1920	243	308	186

* These indexes are those of the Bureau of Labor and the Aldrich Senate Report, and are all weighted averages, except those for "building materials" and "metals" back of the year 1890 which are unweighted averages.

It is worthy of note that between 1860 and 1913, "building materials" increased 80 per cent in price, on the average, whereas "metals" decreased nearly 30 per cent. This could scarcely have occurred unless there had been a far greater increase in productive efficiency in mining and metallurgy than in the production of building materials taken as a whole.

Hence, while there is a general harmony of price movement of different classes of commodities, each class of commodities has its own economic factors that must be considered independently of the factors that affect all commodities in common.

Following our Civil War the pent up demand for building materials was released, and it served to hold the average price to such an extent that in 1880 when the price index of "all commodities" was down nearly to the prewar level (Tables XX and XXII), the price index of building materials never did return to the prewar level. Such facts must be borne in mind when forecasting the probable movement of building material prices.

TABLE XX.—WHOLESALE PRICE INDEXES OF BUILDING MATERIALS AND METALS
(The averages for the year 1860 being taken at 100 per cent)

Year	All commodities	Building materials	Metals and implements
1860	100	100	100
1865	191	182	219
1866	160	187	193
1867	145	179	179
1868	151	174	167
1869	136	166	158
1870	130	148	139
1871	124	151	132
1872	122	167	146
1873	120	172	149
1874	121	155	137
1879	97	115	90

Foot Note:
"All Commodities" is a weighted average wholesale price index of 223 commodities.
The index prices for "Lumber and Building Materials" and for "Metals and Implements" are simple averages.
These index prices are from the Aldrich Senate Report, No. 1394.

Principles upon which Six Different Price Indexes are Based.—Many users of price indexes have felt the need of a more thorough understanding of the details of construction of such tabulations, but have not found it easy to obtain the information desired.

There are radical and confusing differences among the commonly published indexes, leading even to the complete discredit of all index calculations in the minds of some people; and to supply the evident need of information upon this subject we present herewith brief explanations of the construction of each of the five most widely circulated and most commonly used indexes of wholesale commodity prices. Complete explanations including data would require a large amount of space, and readers desiring such information are therefore of necessity referred to the respective publishers.

General Principles of Price Indexes.—A price index is a device for showing the comparative changes in costs of certain groups of commodities over certain periods. Changes in the cost of any single commodity ordinarily require no special treatment or device, but it is often desired to measure an average change of price affecting an entire business—or in its largest sense, the average change in price of all commodities which are traded within a nation. Such an index of all commodities serves to measure the general price level, and thus to show (in reciprocal form) the value of money in terms of the amount of goods which a given quantity of money will buy.

Because of the difficulties in gathering complete data, indexes are usually based upon a limited number of commodities only, the numbers in the best known indexes ranging from 25 to more than 300, but these are selected with the intention that they shall afford a fair criterion of the business in all commodities. In some indexes the commodity prices are weighted according to their importance in the nation's trade: in others they are unweighted.

Indexes are most commonly stated in terms of percentage, the average price on some given date or for some given period being arbitrarily established as 100 per cent. It is now quite common to take the average for the year 1913, as 100 per cent, that being the last year for which prices were unaffected by conditions due to the great war.

A weighted index may be prepared as follows: The total money paid for all the index commodities sold during the base period (usually 1 year) is called 100%. Then the index for any other date or period is given by dividing the above total into the amount which the same quantities of goods would have cost at prices of the new date or period.

Unweighted indexes are prepared by adding together the unit prices of all the index commodities for the date chosen as base, and calling this sum 100 per cent. Then the sum of the unit prices of the same commodities on any other date, divided by the sum on the base date gives the index for the other date in terms of percentage. Since under this system a change in price of a little used commodity, such as pepper, produces an effect equal to a similar change in the price of an important commodity, such as flour, the unweighted index measures the price level much less accurately than does the weighted index.

Dun's Index, which is one of the best, is expressed in terms of dollars per capita consumption instead of in terms of percentage. This is explained later.

Altho indexes are of necessity approximations based upon partial data, when properly made and interpreted they possess sufficient accuracy for practical use, and they should not be criticised or discredited because of their lack of complete mathematical accuracy.

We treat here only of wholesale price indexes, altho the U. S. Bureau of Labor Statistics publishes a retail price index, and others have been computed. The greater difficulty in obtaining the necessary data for retail prices—particularly as affecting the nation as a whole—accounts for the greater attention which has been given to wholesale indexes, and for the general superiority of the wholesale to the retail index.

Index of U. S. Bureau of Labor Statistics.—This index covers each of 9 groups of important wholesale commodities, and a total for all commodities. It is calculated for each year from 1890 to the present, and for each month since January, 1913. It is based upon the sales of about 327 commodities —the number having varied slightly from time to time. The commodities selected cover, as nearly as is practicable, all the most important articles of wholesale trade. Difficulties in obtaining satisfactory units of comparison have kept out of the index such things as machinery and many other, sorts of manufactured goods; but the large proportion of the nations total transactions included in the commodities entering the index, and the tendency of price fluctuations in the omitted manufactured articles to follow the general tendency, leaves the index as a reasonably accurate picture of general variations in wholesale prices. In the figures as now published, the few changes in commodities used have been provided for, so that the figures are consistent for all the years covered.

Since it is necessary to deal with a constant basic quantity of each commodity, some average year's consumption is necessary. The quantities traded in the census year 1909 are at once the most easily obtained and the most accurate available, and are therefore used for multiplication by the prices of each index date or period.

For each commodity group the base is established by multiplying the total quantity of each article marketed in 1909 by the average price of that article in the year 1913, adding all the products so obtained for the group, and calling the total 100. The sum of the totals of the 9 groups gives the base of 100 for all commodities. For all other index dates similar calculations are made with prices as of those dates and total quantities the same as were used for 1913, so that the total of any group divided by the corresponding total for 1913 gives a true weighted average price expressed as a percentage of the weighted average price of 1913.

Information as to prices is obtained from both official and private sources. The same is true of the quantities marketed in 1909. Only products actually sold are used in the estimate, products not marketed, such as produce consumed on the farms where it was raised, or steel ingots made into other forms in the mills where they were produced being distinctly excluded.

The group classification and the number of commodities entering into each is as follows:

1. Farm Products	32 Commodities
2. Food, etc	91
3. Clothes & Clothing	77
4. Fuel and Lighting	21
5. Metal, etc	25
6. Lumber & Bldg. Materials	30
7. Chemical and Drugs	18
8. House-Furnishing Goods	12
9. Miscellaneous	21
Total All Commodities	327

Bulletin No. 269, "Wholesale Prices 1890 to 1919," published by the Bureau of Labor Statistics of the U. S. Bureau of Labor gives the indexes, data, and description of methods in much detail.

U. S. Federal Reserve Board Index.—This also is a weighted index, but as it is prepared primarily for purposes of international comparison, it relates chiefly to articles of foreign trade. It is based upon only 90 commodities as against 327 of the Bureau of Labor Index. Part of its figures are obtained from the Bureau of Labor Statistics, but its purpose is specifically different from that of the Bureau's index, and any comparison of the two should be with this fact definitely recognized.

The base of this index is 100 for the year 1913. It is calculated monthly. The classification of commodities is as follows—Goods produced, Goods imported, Goods exported, Raw materials, Producers' Goods, Consumers' Goods, All.

Dun's Review Index.—This index is based upon about 300 wholesale commodities divided into 7 groups. It is calculated for each year from 1860 to date, and for each month since Jan., 1898. In its preparation wholesale quotations on each commodity are obtained for the nearest business day to the first of each month, and are separately multiplied by figures determined upon as the estimated annual per capita consumption of the commodity. Therefore this also gives a truly weighted index.

The tabulation is on a different plan from the two indexes previously described, for instead of showing 100 per cent for each group of commodities and the total for the year 1913, it shows the worth in dollars of the estimated per capita consumption for the year. Thus the sum of the figures for the 7 groups for any given date gives the total for that date. Fortunately for purposes of the rough comparison of totals, the total per capita consumption of $116.319 estimated for the year 1913 is near enough to $100 to permit of a quick rough comparison with the Bureau of Labor Index with a base of 100% for the same year.

Percentage figures to a base of 100 in 1913 are obtainable by dividing any total from Dun's Index by 1.16319.

The classification is as follows: Breadstuffs, Meat, Dairy and Garden, Other food, Clothing, Metals, Miscellaneous, Total. The index figures from 1860 are published in pamphlet form by Dun's Review, New York. The number of commodities in each class is not stated.

Bradstreet's Index.—This is an unweighted index based upon the prices of 96 commodities at the first of each month. The index numbers are the totals in dollars and cents of the Costs of 1 pound of each of the 96 commodities. The classification and number of commodities used are as follows:

1. Breadstuffs	6 commodities
2. Live Stock	4
3. Provisions & Groceries	24
4. Fresh and Dried Fruits	5
5. Hides and Leather	4
6. Textiles	11
7. Metals	13
8. Coal & Coke	4
9. Oils	6
10. Naval Stores	3
11. Building Materials	8
12. Chemicals and Drugs	11
13. Miscellaneous	7
Total	106*

* 10 articles are omitted from the index computation, but what 10 is not stated.

The Annalist Index.—This is an unweighted index based upon 25 different articles of food only, mean prices for each week being used. These mean prices are converted to relatives of the prices of the period from 1890 to 1899, and simple averages of the relatives are then made. The Annalist is published weekly at New York City.

Canadian Index.—The Department of Labor of Canada publishes an index based upon 271 commodities corresponding quite closely with those of the U. S. Bureau of Labor. This index is not weighted like the Bureau's index, for it is stated that in the opinion of the compiler "an extended list of articles tends to weight itself" if judiciously selected. The method is similar to that of the Annalist but the calculation covers more than 10 times as many commodities. A quite close agreement between the Canadian index and the U. S. Bureau of Labor index indicates that there is some justification for the contention of the Canadian compiler as to weighting.

Table XXI gives wholesale price indexes compiled by U. S. Dept. of Labor, from 1913 to Jan., 1922. Averages for preceding years are given in Table I.

Foot Note.—The index prices for 1840 to 1889 are from the Senate Report No. 1394 on "Wholesale Prices," by Nelson W. Aldrich, Mar. 3, 1893. Those for "all commodities" (223 in number) are "weighted" in proportion to family budget expenses; but those for "building materials" and for "metals and metal products" are unweighted or simple averages, and therefore not so reliable, down to 1889.

The index prices from 1890 to 1919 are all "weighted" in proportion to annual consumption and are compiled by the U. S. Bureau of Labor. See Tables XXIII and XXIV.

TABLE XXIII.—GROUP 5, METALS AND METAL PRODUCTS, QUANTITIES AND WHOLESALE VALUES IN 1919

	Unit	Quantity (000 omitted)	Value (000 omitted)
Bar Iron:			
Best refined, Phila.	lb.	1,083,265	$ 41,381
Common, from mill, Pitts.	lb.	1,083,265	36,614
Copper:			
Ingot, electrolytic	lbs.	1,312,438	250,807
Wire, bare, No. 8	lb.	278,964	61,930
Iron Ore, Mesabi, Bessemer	Long ton	52,310	327,539
Lead, pig, désilverized	lb.	732,153	42,318
Lead pipe	100 lb.	1,058	7,688
Nails, wire	keg	13,916	48,961
Pig Iron:			
Basio	Long ton	1,742	48,248
Bessemer	do.	1,168	36,362
Foundry			
No. 2 northern	Long ton	2,557	77,512
No. 2 southern	do.	2,557	82,271
Pipe, cast iron, 6 in.	Ton	1,146	65,896
Silver, bar, fine	Ounce	151,969	170,935
Steel:			
Billets, Bessemer	Long ton	4,972	201,557
Plates, tank ¼ in. wide	lb.	5,256,756	142,458
Rails, standard—			
Bessemer	Ton	1,767	83,516
Open-hearth	Ton	1,257	61,925
Structural	lb.	4,996,876	139,413
Tin:			
Pig	lb.	94,248	61,742
Plate, coke	100 lb.	12,968	91,736
Wire:			
Barbed, galvanized	100 lb.	6,471	28,907
Plain annealed Nos. 0 to 9	do.	9,580	29,827
Zinc:			
Sheet	100 lb.	576	5,666
Spelter (pig zinc) western	lb.	464,903	34,403
Total			$2,179,612

This table compiled from Bulletin No. 269, U. S. Bureau of Labor Statistics.

TABLE XXIV.—GROUP 6, LUMBER AND BUILDING MATERIALS, QUANTITIES AND WHOLESALE VALUES IN 1919

	Unit	Quantity (000 omitted)	Value (000 omitted)
Brick, common: Chicago run of kiln salmon	1,000	3,264	$ 29,202
Cincinnati, red, building	1,000	3,264	44,336
New York, red, building	1,000	3,264	52,088
Cement, Portland, Domestic	bbl.	65,435	207,115
Glass:			
Plate, polished, glazing—			
3 to 5 sq. ft.	sq. ft.	24,861	11,498
50 to 10 sq. ft.	sq. ft.	24,861	14,482
Window, American, single, 25 inch:			
A	50 sq. ft.	3,461	24,951
B	50 sq. ft.	3,461	23,439
Lath, eastern spruce, 1½ in. slab	1,000	4,388	28,293
Lime, common	bbl.	23,278	62,224
Lumber:			
Douglas fir—			
No. 1	1,000 ft.	3,642	92,568
No. 2 and better	do.	1,214	48,155

Total.....................	$14,710	100.00	$35,149	100.00

From Bulletin No. 269, U. S. Bureau of Labor Statistics.

Average Wholesale Prices of Important Commodities, Used in Construction, 1890 to 1920.—Tables XXVI and XXVII are prepared from data given in Bulletin No. 269 of the Bureau of Labor Statistics, U. S. Department of labor and from further information obtained from the Bureau, by letter.

As stated in Bulletin No. 269, the average prices shown in the tables are, in all instances where this information could be obtained, based on first-hand transactions in primary markets. Thus the pig-iron prices are those to foundry operators and large steel makers. Steel prices are to jobbers or large manufacturing consumers.

In collecting prices for inclusion in these tables the aim was to secure quotations on those particular grades or qualities of an article that represent the bulk of sales within the class.

It is obvious that in order to arrive at a strictly scientific average price for any period one must know the precise quantity marketed and the price at which each unit of the quantity was sold. It is manifestly impossible to obtain such detail, and even if it were possible the labor and cost involved in such a compilation would be prohibitive. The method adopted here, which is the one usually employed in computing average prices, is believed to yield results quite satisfactory for all practical purposes.

In computing the averages shown in the tables the net cash price was used for all articles subject to large and varying discounts. In the cases of a few articles, such as steel plates, steel sheets, etc., the prices of which are subject to a small discount for cash within 10 days, no deduction has been made.

The name of city where price quotations were secured is given in every case.

TABLE XXVI.—AVERAGE PRICE OF METALS AND METAL PRODUCTS

Year	Bar iron: Best refined, from store (Philadelphia market) per pound	Bar iron: From mill (Pittsburgh market): Best refined, per pound	Bar iron: From mill (Pittsburgh market): Common, per pound	Copper: ingot (New York): Lake, per pound	Copper: ingot (New York): Electrolytic, per pound

Relation of Cast-Iron Water Pipe and Gray Forge Iron Prices.—Figs. 5 and 6, given in the Annual Review Section of Iron Age, published Jan. 6, 1921, show clearly the fluctuations in the prices over a period of 18 years and indicate, as might be expected, that the variations in price of cast iron pipe are largely due to the variations in the price of the pig iron from which the pipe is made.

Prices of Cast Iron Water Pipe During the Past 50 Years.—Interesting statistics on the price of cast iron pipe were presented by Burt B. Hodgman, Chief Engineer of the National Water Main Cleaning Co., in a paper presented at the 1917 annual meeting of the American Water Works Association. In his paper, an abstract of which is given in Engineering and Contracting, Aug. 29, 1917, Mr. Hodgman gives the prices actually paid for cast iron pipe by the city of Boston, Mass., during the past 50 years.

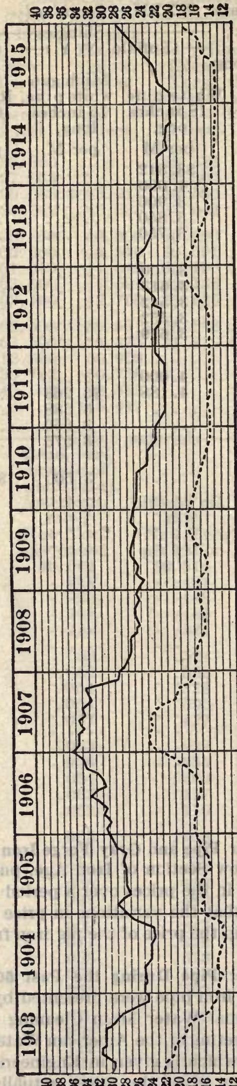

FIG. 5.—Fluctuation of prices of 6-in. cast iron water pipe at New York, per net ton of 2000 lbs. (car load lots) from 1903 to 1915, compared with gray forge pig iron at Philadelphia. Solid line, pipe; dotted line, pig iron.

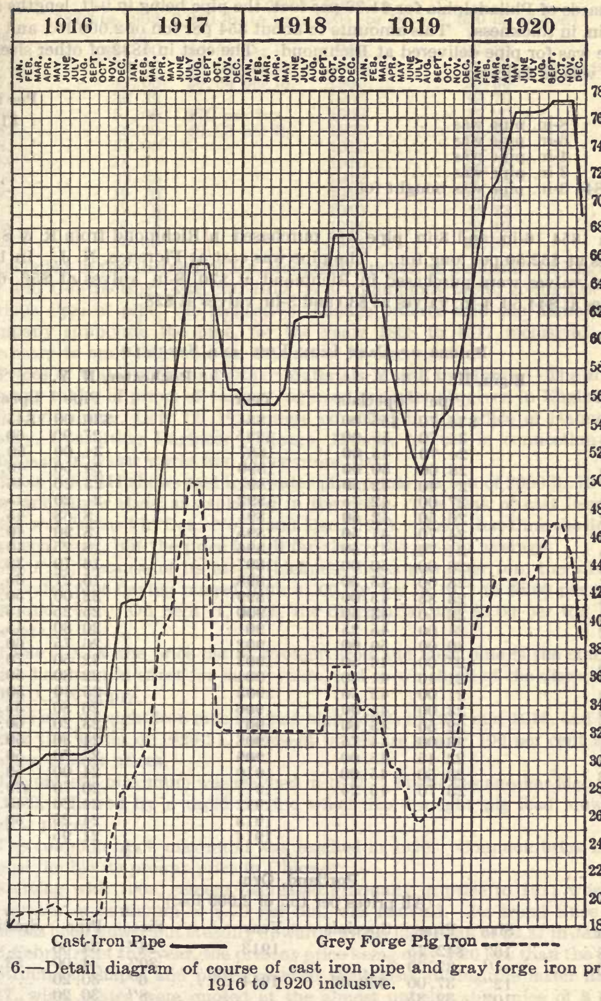

FIG. 6.—Detail diagram of course of cast iron pipe and gray forge iron prices 1916 to 1920 inclusive.

In 1832 Richmond, Va., purchased 10-in. pipe from Samuel & Thomas S. Richards of Philadelphia for $1.38 per foot, the pipe being in 9-ft. lengths and 9/16 in. in thickness. This amounts to about $54 per ton of 2,000 lb., and the price was for pipe delivered at Richmond. The cost in 1832 of other sizes of pipe was as follows:

	Per foot
8-in. pipe was	$1.25
6-in. pipe was	.70
4-in. pipe was	.45
3-in. pipe was	.37
In 1844 3-in. pipe was bought for	.30

In 1854 16-in. and 8-in. pipe was purchased in Richmond from R. & S. H. Jones at $52.50 per long ton. The pipe was cast at Florence, N. J. In 1832 10-in. valves were purchased in Richmond at $70, 8-in. valves at $56, 6-in. valves at $44.50, 4-in. valves at $30 and 3-in. valves at $28.

Included in the abstract of Mr. Hodgman's paper, as published in Engineering and Contracting, Aug. 29, 1917, is a voluminous table, giving prices on various sizes of pipe, the respective tonnage ordered and the name of the company supplying the pipe, for the years 1868 to 1917 inclusive. It is necessary to omit this table on account of its size.

Prices of Waterworks and Other Materials Month by Month.—The accompanying tables of prices of various engineering materials given in Engineering and Contracting, Oct. 12, 1921, were compiled in the office of Dabney H. Maury, Consulting Engineer, Chicago, Illinois, for use in connection with appraisals of water works and other properties.

Table XXVIII shows cast iron water pipe prices per ton of 2000 lb. in 4-in., 6-in. and larger sizes, as explained in the note. The peak of cast iron pipe prices was reached in Oct., Nov., and Dec., 1920. Since that time the decline has been rapid, but the price is still far above the prewar average.

Gas Pipe, because of its lesser thickness, costs more per ton, the advance over water pipe having ranged from $1.00 per ton in 1913 to $4.00 per ton in 1920 and 1921. On Sept. 1, 1921, the differential was $3.00 per ton in all markets.

Table XXIX the price list of wrought iron and steel pipe is the standard which has been in effect for many years, and to which all of the discounts of Table XXX apply.

Steel and wrought iron pipe reached high points in 1917 and 1918, and again during the winter of 1920-21. Present prices are nearly 100 per cent above average prewar prices.

The pig lead maximum was reached in 1917. There was another high point in 1920, followed by a rapid decline which has brought pig lead down to prewar prices.

The common brick maximum was reached in 1920. Common brick is still almost double its prewar price in Chicago.

Starting with 1903, cement decreased gradually in price to 1911 when, in November, a minimum of $.70 per bbl. was reached. Its trend since that time has been slowly but steadily upwards with a high peak of $2.37 in January and February of this year, the present price being only $.20 less than the peak.

Structural shapes and plates reached their peak during the latter half of 1917, when plates were quoted at the almost unbelievable price of $.10 at warehouse, Chicago. Since that time they have declined in price, reaching a point slightly below $.03 in August, 1921.

The range of prices of reinforcing bars has followed rather closely that of structural shapes.

Table XXVIII.—Prices per Short Ton of Cast Iron Water Pipe at Chicago, Ill.

(Quotations are from The Iron Age). See Footnote.

Foot Note: The prices given in the table are arranged according to size of pipe, the top figure for each month representing quotations on 4″ pipe. The sizes represented by the other figures are as follows:

Period	Middle figure	Lower figure
Jan., 1902 to July, 1903	6″	8″ & larger
Aug., 1903	6″ & larger	....
Sept., 1903	6″ & 8″	10″ & larger
Oct., 1903 to Jan., 1904	6″ & larger	....
Feb., 1904 to May, 1904	6″ to 12″	Larger than 12″
June, 1904 to June 1905	6″ & larger	....
July, 1905 to Sept., 1905	6″ to 10″	12″ & larger
Oct., 1905 to Aug., 1915	6″ to 12″	16″ larger
Sept., 1915 to Sept., 1921	6″ & larger	....

TABLE XXIX.—STANDARD PRICE LIST OF STEEL AND WROUGHT IRON PIPE—EITHER BLACK OR GALVANIZED

This list was established prior to 1900, and has since remained in general use throughout the United States.

Standard pipe is furnished with threads and couplings and in random lengths unless otherwise ordered. Weights are in pounds.

	Standard steam, gas and water pipe		
		Weight per foot	
Size, in.	Price per foot	Plain ends	Threads and couplings
⅛	$0.05½	.244	.245
¼	.06	.424	.425
⅜	.06	.567	.568
½	.08½	.850	.852
¾	.11½	1.130	1.134
1	.17	1.678	1.684
1¼	.23	2.272	2.281
1½	.27½	2.717	2.731
2	.37	3.652	3.678
2½	.58½	5.793	5.819
3	.76½	7.575	7.616
3½	.92	9.109	9.202
4	1.09	10.790	10.889
4½	1.27	12.538	12.642
5	1.48	14.617	14.810
6	1.92	18.974	19.185
7	2.38	23.544	23.769
8	2.50	24.696	25.000
8	2.88	28.554	28.809
9	3.45	33.907	34.188
10	3.20	31.201	32.000
10	3.50	34.240	35.000
10	4.12	40.483	41.132
11	4.63	45.557	46.247
12	4.50	43.773	45.000
12	5.07	49.562	50.706

Extra strong pipe for high pressure hydraulic installations, etc., takes a higher price.

Copper, Spelter, Lead, Tin and Sheet Steel Prices.—Tables XXXVII to XLIII, inc. are given in the Annual Review Section of The Iron Age, Jan. 6, 1921. The prices are the computed monthly averages of the prices of carloads, at New York, for metals and at Pittsburgh for tin plate and No. 28 galvanized and black sheets, given in the metal market reports of the Iron Age week by week.

TABLE XXXVII.—LAKE COPPER.

The highest prices realized for galvanized sheets, aside from the war peak in 1917, were obtained in April, 1916, following the spectacular performances of spelter, when prices of that metal soared to an unprecedented height. At that time, No. 28 galvanized sheets sold up to 5.30c. per lb., Pittsburgh, or higher, although the average for the month is placed, in the table, at 5c. It is interesting to know that in 1901, in a period of great activity in the steel trade, No. 28 galvanized sheets were regularly quoted at 5.10c., Pittsburgh, for two weeks, namely, the first half of September.

In making up the above table of prices the compiler has used for January,

February and March, 1919, up to March 21, the prices in effect to the latter date, and then used the 5.70c. price in effect all through the year from March 21. Premiums were paid during late November and all of December, but premiums have not been recorded above, as a large percentage of the sheets sold in 1919 were at the prices named in the table.

Pig Iron Steel, and Rail Prices for Twenty-one Years.—Tables XLIV to LV, inc., published in the Annual Review Section of the Iron Age, Jan. 6, 1921, give the monthly average prices computed from the weekly market quotations of the Iron Age.

Structural Steel Prices for 15 Years.—Fig. 7, given in Engineering and Contracting, Oct. 31, 1917, shows the average prices of structural steel at

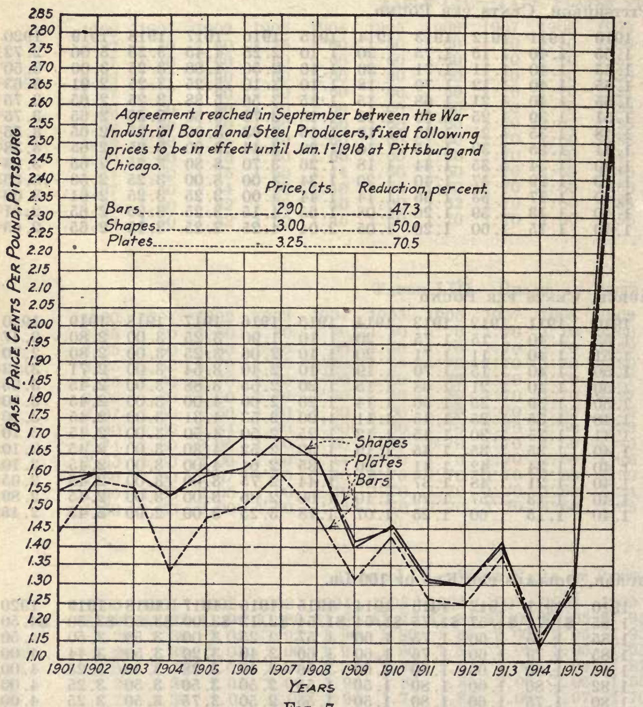

Fig. 7.

Pittsburgh for the years 1901 to 1916. The figures for structural shapes are base for beams and channels 3 in., to 15 in., and ångles 3 in. to 6 in. Prices for plates are f. o. b. Pittsburgh, and are for tank quality. Prices for bars are also Pittsburgh base and are for rounds and squares ¾ in. to $^3/_{16}$ in.

Structural Steel Prices, 1898 to 1917.—Fig. 8, reproduced in Engineering and Contracting, April 25, 1917, from the Dec., 1916, Bridge Manual of the Oregon State Highway Commission, shows price fluctuations in steel from year to year at various stages in its progress from furnace to the erected bridge. The lowest line in the diagram represents pig iron (Pittsburgh District), the next two lines steel bars and structural steel in the Pittsburgh District, the second line from the top fabricated steel at site (average for Oregon), and the top line steel in bridge erected in Oregon.

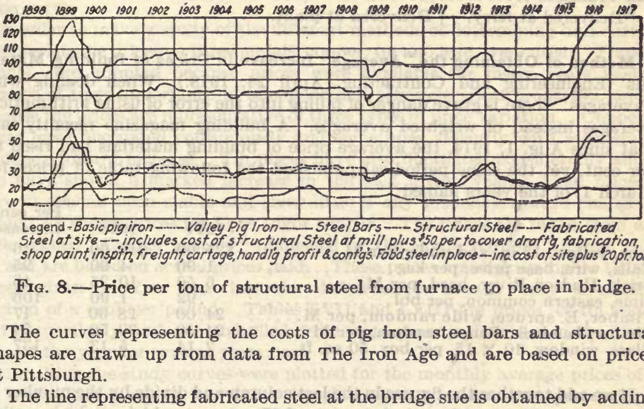

FIG. 8.—Price per ton of structural steel from furnace to place in bridge.

The curves representing the costs of pig iron, steel bars and structural shapes are drawn up from data from The Iron Age and are based on prices at Pittsburgh.

The line representing fabricated steel at the bridge site is obtained by adding $50 to these Eastern prices on structural shapes to provide for: Steel inspection, fabrication, shop inspection, waste in fabrication, draughting, shop painting, freight to Portland district, road haul and handling.

While this assumed figure of $50 is not a maximum, it is stated to be considerably higher than the mean or average cost of the sum of the items it is intended to cover, within the present zone of steel bridge construction in Oregon.

The line representing steel erected in place is obtained by adding $20 to the cost of the fabricated material at the site, to cover all costs of falsework, handling, erection and painting, and is a little better than a fair average price for steel bridge erection in Oregon. This line suggests in a graphical way, for the term of years which it covers, a base line about which, in comparative proximity to it, the prices paid for this work should have ranged themselves.

The costs from mill to site and for erection and painting are based on the cost of a large number of structures built in Oregon. The Manual states that actual costs should run under, rather than over, the figures given.

Teaming rates vary considerably according to the topography of the country and condition of the roads. They also are subject to conditions of supply and demand, but, according to the Manual, a fair average price for teaming throughout the state is 30 ct. per ton mile.

Price of Common Brick.—At the first annual convention of the Common Brick Manufacturers of America at Chicago, information was collected from the delegates regarding the prices of common brick in various cities. The following table shows the trend of prices for the years 1916–1919 in 9 large cities:

	1916	1917	1918	1919
Boston	$12.00	$14.00	$17.00	$18.00
Chicago	7.00	9.00	12.00	12.00
Cincinnati	10.00	13.00	15.00	16.75
Detroit	9.00	11.00	12.00	13.00
Los Angeles	6.00	8.00	14.00	12.50
Louisville	8.50	12.50	20.00	17.50
New York *	7.35	8.15	10.85	14.00
Philadelphia	8.50	12.50	14.00	19.00
San Francisco †	7.50	10.00	11.00	12.50

* Delivered at ferry. † Delivered at plant.

Method of Obtaining the "Average" Increase in Prices of Building Materials (Engineering and Contracting, April 24, 1918.) When dealing with "averages" there is grave danger of falling into the error of using arithmetical averages instead of weighted averages. A building magazine recently said that since Aug. 1, 1914, the average price of building materials had risen 84 per cent, yet the same periodical published the following table of prices for March 1, of the years named:

	1914	1918	Per cent increase
Pine, yellow, 12-in. and under per M	$25.00	$42.00	46
Nails, wire, base price, per keg	1.90	4.00	95
Brick, Hudson River, hard, per M	6.50	10.25	46
Lime, eastern common, per bbl	.92	1.90	106
Timber, E. spruce, wide random, per M	24.00	28.00	17
Timber, hemlock, Penn., random, per M	24.50	30.50	24
Glass, window, 10 × 15, per box, 50 sq. ft	2.14	5.13	137

If we add together the figures in the last column and divide by the number of items, 7, we get an arithmetical average of 67 per cent, which might be called an average increase in the prices of these building materials; but it should be apparent that such an average is really meaningless. Note that the quantities of each of these seven different materials that would be required in most buildings are such that brick and pine would greatly predominate; yet brick and pine have each risen only 46 per cent in price. On the other hand, nails, lime and glass are used in relatively small quantities, and they have risen 95, 106 and 137 per cent in price.

To ascertain the weighted average change in price of building materials in a building of a given class, multiply the quantities of each kind of material by the prices at the two different periods and ascertain the ratio of the two resulting totals. A rough application of this rule leads us to conclude that the average building cost has risen about 50 per cent since the war began.

Determination of Unit Prices of Material for Purposes of Valuation of Plant.—Engineering and Contracting, May 13, 1914, publishes the following article by R. V. Achatz.

One of the first questions which must be decided in making a valuation of a physical plant is what unit costs of material and labor are to be used. In making a valuation on the cost of reproduction basis, it is agreed that these costs should be present costs but there is a question of just what is present cost. In the case of labor present cost is a cost based on the current wage scale, but in the case of material it is quite generally agreed that the market price on a given date, particularly for those materials which are subject to constant fluctuations in price, cannot always be used with justice. Many writers in discussing this question have said that, in case of materials subject to price fluctuations, the market price on a given date should not be used but an average price over a number of years past, usually five or ten, should be adopted. There immediately arises a question as to the propriety of using an average of past prices in a valuation on the cost of reproduction basis, and there is also a large question as to whether such an average actually represents a fair present price. It has been proposed that the present normal price can be determined by plotting the prices for a number of years past and drawing a smooth curve representing an average of the prices as shown by the yearly price curve.

In order to make a study of the different methods of determining unit costs of materials the prices on three metals, copper, tin and lead, were used. These metals were adopted because prices were available for many years past, because of their importance in telephone and other electrical properties, and because the prices are representative of three types of price variation. Copper prices have fluctuated continuously and sometimes violently with a general tendency toward increase. Tin prices have also fluctuated considerably and also have shown a marked increase in the past fifteen years. Lead prices have in general been stable and show little if any tendency toward change. Table LVI shows prices for Lake Ingot copper. The prices are taken from a leaflet called "Copper History" published by the Rome Wire Co., Rome, N. Y., and are based on actual prices paid. These prices are slightly higher than prices given in *Iron Age* but the difference is usually only a small fraction of a cent per pound. Tables LVII and LVIII are prices of tin and lead respectively and are compiled from data given in *Iron Age* in the first issue of the year for several years past.

In making the study curves were plotted for the monthly average prices of the metal (not given in the tables) by plotting at the abscissa representing each month, the average price for that month and connecting the points by straight lines. In a similar way curves were plotted for the average prices for 5, 10 and 15 year periods by plotting at the close of each year the average of the prices for the period preceding and, as before, connecting the points by straight lines. A smooth curve was also drawn representing a mean between the higher and lower changes in the monthly average prices. Theoretically there should be equal areas, above and below, between this curve and the monthly average curve but in practice it can be drawn by eye with sufficient accuracy. This curve has been designated a "normal trend price" curve.

In Fig. 9 are shown the curves of copper prices. These prices extend from 1884, the earliest period that prices were available, to the present. It will be noted that the prices have had peaks at periods of from seven to ten years apart, the highest peaks occurring in 1889, 1899, and 1907, followed by periods of comparatively low prices. The dotted curve represents successive five years averages and was plotted as described in the preceding paragraph. This curve also has peaks coming at the frequency of the peaks in the monthly

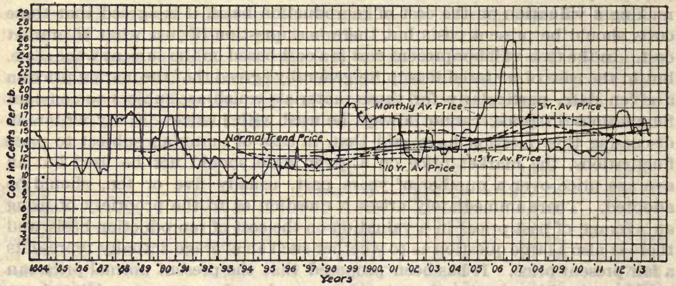

FIG. 9.—Variation and trend of prices for copper for period 1884 to 1913. inclusive.

average curve but displaced so that the maximum points in the five year average curve come later than those of the monthly average and occur during times of low market prices. For example, at the close of 1909 the market price of copper was 13.75 cts. per pound, while the five years average was

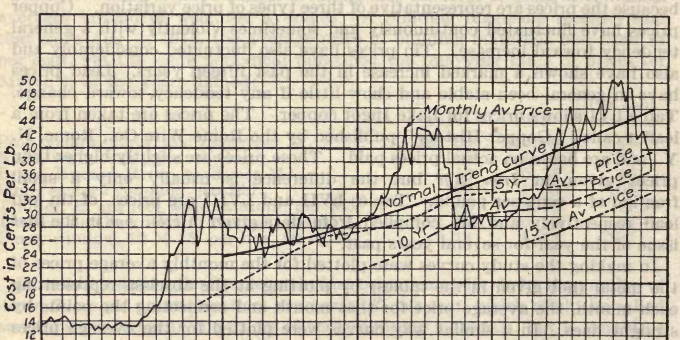

FIG. 10.—Variation and trend of prices for tin for period 1895 to 1913, inclusive.

16.808 cts. per pound. At the close of 1912 the market price was 17.75 cts. per pound, while the five year average was 13.91 cts. The high average for the five years ending with 1909 was due to the influence of the very high peak in the market in 1906–7 and the low average for the five years ending in 1912 was due to the abnormally low prices following the 1907 peak, the influence of that peak on the five year average having passed. It is at once seen that a five year average price at either of these times would be unjust, the price in 1909 being too high to be just to the public and the price in 1912 too low to be just to the utility.

The 10 year average prices of copper are shown in Fig. 9 by the broken line. This curve has peaks in much the same way as the 5 year average curve but the differences from time to time are not so great. The 10 year average at the close of 1911 is 1.1 cts. less than at the close of 1908. The use of this average would be less open to objection than the 5 year average on account of smaller variation from time to time.

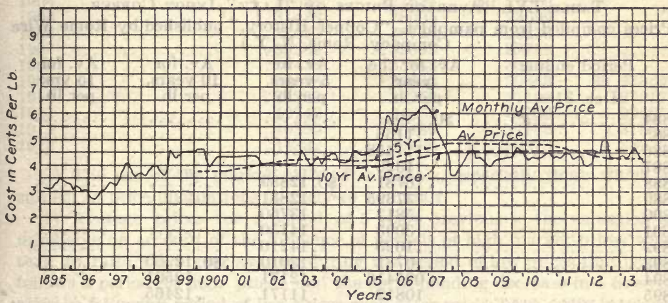

FIG. 11.—Variation and trend of prices for lead for period 1895 to 1913, inclusive.

The 15 year average is shown on Fig. 9 by the dot and dash line. It is entirely free from variation due to the influence of peaks in the market price and shows a general tendency upward. Its use might be objectionable on account of the influence of a period of low prices a long time ago.

The smooth curve which has been called the normal trend price has been drawn to represent an average of the market prices. At any given time the price read from this curve may be considered to be the price of copper under normal conditions. A buyer of copper in the future would expect to find prices following this curve more or less closely. The price as indicated by this curve was 15.2 cts. at the close of 1909, 15.8 cts. at close of 1911 and 16.3 cts. at close of 1913.

Fig. 10 shows the variation in prices of tin. This metal like copper has been subject to considerable fluctuation in price and has also more than doubled in price in the past fifteen years. The curves representing the 5, 10 and 15 year averages and the trend curve have been drawn in the same manner as in case of copper. The average curves are free from the variation from time to time noted in the average curves for copper but it will be noted that, with the exception of a few months in 1904 and the years 1908, 1909 and part of 1910 for the 5 year curve and a few months in 1908 and 1909 for the 10 year curve, the average curves are consistently lower than even the lowest points in the market prices. This brings out more clearly the objection mentioned above in the discussion of the prices of copper that average prices might be too greatly influenced by previous low prices to be used if the basis of the valuation is the cost of reproduction. If the basis is original cost of course this objection disappears. This discussion, however, has been predicated on the use of cost of reproduction. In the case of tin the normal trend curve at the close of 1913 shows a price of 45.9 cts. per pound while the 5 year average, the highest of the average curves, shows 39.468 cts. per pound. It is evident in this case that the use of any average price is unfair.

The variation in lead prices is shown in Fig. 11. The monthly average price curve shows that lead prices have been practically constant since 1899 with the exception of the abnormally high prices in 1906–7. This peak was caused by no particular condition of the lead market at that time but by the general inflation of commercial affairs during those years. The average price curves have been drawn as before. It will be noted that the 10 or 15 year curves

TABLE LVI.—AVERAGE PRICES OF "LAKE" INGOT COPPER
(Prices compiled from pamphlet, "Copper History," published by Rome Wire Company, Rome, N. Y.)

Period ending Dec. 31—	Av. for the year per lb.	Av. for 5 years, per lb.	Av. for 10 years, per lb.	Av. for 15 yrs. per lb.

1913	.15833	.14369	.15572	.15522

still show that influence of the 1907 high prices while the five year average has passed beyond this influence and has come very near to the normal price. The normal trend curve has not been drawn to avoid confusion in the figure but if it were drawn it would be a straight line parallel to the X-axis at 4.4 cts. This is exactly the same as the 5 year average at the close of 1913. There have been periods in the past, however, when the use of the five year average would have been incorrect. For instance, at the close of 1909 this average was 4.926 cts. per pound while at the close of 1912 it was 4.379 cts., a decrease of about 11 per cent.

From the study of the curves and the above discussion the following conclusions are drawn regarding the use of the different methods of determining unit costs of material for valuation purposes:

TABLE LVII.—AVERAGE PRICES OF TIN

(Prices compiled from *Iron Age* first issue of each year. Prices are on carload lots, New York market.)

1912	.46350	.36489	.34742	.31362
1913	.44332	.39468	.36378	.33276

(1) The use of the market price of materials, especially those which are subject to price fluctuations is likely to be unfair.

(2) Average prices for a period of 5 years previous to the valuation are unreliable on account of the influence of periods of high market prices which tend to raise the 5 year average during the period of low prices that usually follows a period of high prices and the corresponding decrease in 5 five year average following period of low prices even after prices have again increased.

(3) An average of the prices for a period of 10 years previous to the valuation fluctuates in a less degree than the average for 5 years, but may be lower than a fair price or higher than a fair price due to the influence of a period of low or high prices many years before.

(4) An average of the prices for 15 years may be unfair for the same reason as the second given under the ten year average, viz.: the effect of prices of many years previous.

(5) An average smooth curve can be drawn, taking into consideration market prices for a number of years past and also successive average prices for periods of 5, 10 and 15 years, which will represent the normal present price of the material. In general the use of this curve as a basis of unit price of material will be more fair and less open to objection than any average price.

(6) Before unit prices are adopted it is necessary to make a study of the past and present prices of materials, particularly the more important ones which may represent a large portion of the total cost of material in the plant. Such materials would be poles, copper wire, lead covered cable, duct materials and Portland cement in the case of telephone, street railway and other electrical properties, and cast iron pipe in case of gas and water plants.

There may be some objection to a price based on the trend curve on account of the fact that the judgment of the appraiser is brought into its determination, but it must be remembered that a valuation is an estimate of cost to reproduce a given plant and the entire result is based on engineering judgment. Furthermore a result arrived at by the use of well trained judgment after considering all the facts is more likely to be fair than an average over an arbitrary period without further consideration.

The use of such a trend curve as a basis for the unit price of a material is not new although little has been written concerning it. As far as the writer's knowledge goes the most important appraisal that has been made public in which this method was used is the appraisal of the property of the Chicago Telephone Co. made by H. M. Byllseby and Co. and the Arnold Co. in 1911. It is true that Prof. Edward W. Bemis, who was conducting the investigation of rates for the Chicago City Council in this case mentions the price of 16 cts. used in the appraisal as a doubtful point but he accepted the valuation based on this price. Prof. Bemis' comment is as follows:

Among the doubtful points in the appraisal may be mentioned the price of copper used by the appraisers. Copper was taken at 16 cts. a pound, as of Aug. 1, 1911. The following table gives the average price for each of the 19 years, 1893–1911, inclusive, as taken from the Iron Age by the Chicago Telephone Company. These prices are a little lower than those given in the Telephone Directory of the telephone industry, 1912 edition (page 333):

(Table of copper prices omitted.)

The above table would indicate that 16 cts. was high. The company has, however, established an elaborate trend curve of prices of copper to show that

1912	.04476	.04379	.04663	.04512
1913	.04401	.04415	.04676	.04556

16 cts. a pound is in line with the trend or tendency of prices, at the time of the appraisal. Since the earliest quotations on hand, beginning in 1883, copper has averaged less than 16 cents every year save in 1888, 1899–1901, inclusive, and 1905–1907, inclusive. During those years only 309,433 miles of wire out of 807,571 in use at the close of 1911, or 38 per cent, were laid. It would be easy to show that copper had not from the beginning averaged over 15 cts. per pound, and had not even averaged that for any period of 5 or more years before the appraisal. At the same time, if the test of value is not to be the actual cost or recent costs, but probable costs of material and labor during the next five years, then 16 cts, may be accepted as a probable price.

In advocating the use of the trend curve as a basis for determining the unit prices of material for purposes of valuation, it can not be said that this method will give, in every case, results which are absolutely fair and uniform. Judgment is required in its use and unforseen developments may change the trend of the price of any material but it is believed that the use of this method will give unit costs that are more fair to all parties concerned than any other method that has been used.

Past and Future Wage Levels.—The following is from an article of mine in Engineering and Contracting, Aug. 31, 1921.

In an article at the beginning of this Chapter I showed that average wholesale commodity prices, or price levels, are proportional to the money per capita; and to its velocity of circulation, and inversely to the productive efficiency per capita. In the present article it will be shown that the average wage, or wage level, is proportional to the money per capita and to its velocity of circulation, but that the productive efficiency has no effect upon the average wage except in so far as it may lead to an increase in the per capita money.

It will be shown that the buying power of the average wage (often called the "real" wage) was stationary in England for five centuries, but that beginning about the year 1800 it began to increase rapidly, until in 1914 it was nearly five times what it was in 1800. It will be shown that almost the same percentage of increase in buying power occurred in America during the same period.

It will be shown that the buying power of the average wage varies directly with the per capita efficiency of production, and that no other factor is involved.

It will be shown that in the building trades the average wage of common laborers has risen at the same rate as that of skilled workers and that for six centuries in England the average of common laborers has been almost exactly 60 per cent of the average wage of skilled workers.

It will be shown that per capita money has shown a rapid upward trend for more than a century, and that following a short halt in this tendency after each great war, the upward trend is resumed. Hence it is to be inferred that average wages in America will resume their upward trend, after the present wage readjustment is ended. Since per capita money in America is now 60 per cent above the prewar level of the year 1913, average wages will decline until they reach the new per capita money level. In other words, the average wage will be about 60 per cent above the average wage of 1913, after the present readjustments are completed.

The proof of the truth of the wage formula above mentioned is overwhelming, and the establishment of its truth necessarily demolishes the prevalent theory that inflation of bank deposits has the same effect upon wage levels as inflation of currency. The practical importance of overthrowing such a false theory can hardly be over-estimated, for every modern nation has hitherto acted upon the assumption that inflation of currency is not a serious evil compared with inflation of bank credits, whereas the contrary is true.

Money Wages and "Real" Wages.—Wherever the term wage is used in this article, the daily or weekly wage in currency is meant. The average yearly wage is given in Table LXVII for manufacturing employes, and it will be seen that it has usually varied almost exactly as the daily wage level (Table LIX) has varied.

The wage level (or wage index) is calculated by averaging the wages in different trades, and then taking the average wage during a selected year as a standard for comparison. The year 1913 is here taken as 100 per cent. The Aldrich Senate Report (No. 1394) is my authority for wage and price levels between the years 1840 and 1890. Prior to 1840 there was no published wage level, but from data given in the Annual Report of the Mass. Bureau of Statistics of Labor for 1885, I was able to deduce the wage levels back to 1790.

Fig. 12 and Table LIX give the daily wage level for almost every year for the last 130 years. Table LIX also gives the wage level at five year intervals prior to 1790.

The buying power of the average wage is ascertainable by dividing the average wage by the average commodity price, or, what amounts to the same thing, by dividing the wage level by the commodity price level. For this

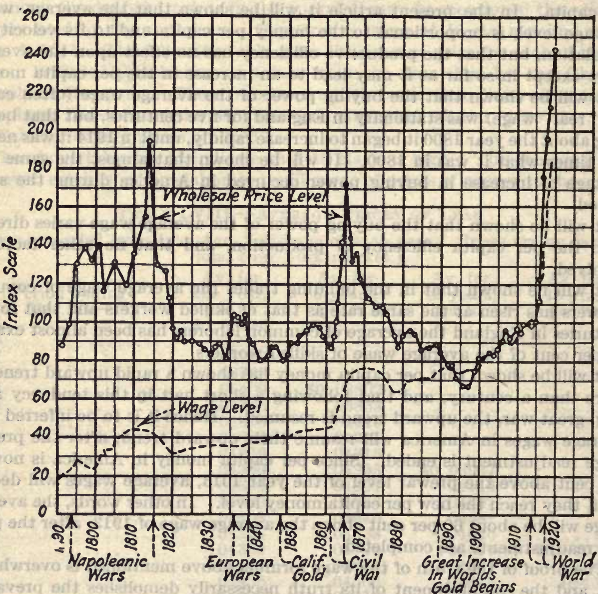

FIG. 12.—Wage and price levels.

(The Wage Levels are from Table LIX the footnote of which gives their source. The unweighted Price Levels from 1791 to 1840 are from an article by H. V. Roelse in the American Statistical Assoc. Quarterly, December, 1917; the weighted Price Levels from 1840 to 1890 are from the Aldrich Senate Report (No. 1394); the weighted Price Levels from 1890 to 1920 are from the U. S. Bureau of Labor).

purpose it would be desirable to use a retail price level, but since none is available, the wholesale price level must be used. Except during periods of very rapid changes in price levels, retail prices change in almost the same proportion as wholesale prices change. Hence, for the purpose of this article, no error occurs from using the wholesale price level.

The last column of Table LX gives the relative "real" wage, or the buying power of the average wage in America for the last 130 years. It is deduced by dividing the numbers in the second column by the corresponding numbers in the third column. The buying power of the average wage being 100 for

1845	39	1872	76	1899	77		

Note: From 1752 to 1840 these wage levels have been deduced by H. P. Gillette from wage statistics given in the annual report of the Massachusetts Bureau of Statistics of Labor for 1885, as compiled in "Comparative Wages, Prices and Cost of Living," by Carroll D. Wright, and are based mainly on New England wages paid to farm labor and to construction labor. From 1840 to 1890, the wage levels are those given in the Aldrich Senate Report, No. 1394, and are a weighted average of about 20 trades. According to that report, the average length of the working day was 11.4 hours in 1840; 11 hours in 1860, and 10 hours in 1890. From 1890 to 1920 these day wage levels have been deduced by H. P. Gillette from data in the monthly Labor Review of the U. S. Bureau of Labor, and in the monthly Labor Market Bulletin of the New York State Industrial Commission and in the monthly Crop Reporter of the U. S. Department of Agriculture.

TABLE LX.—BUYING POWER OF AVERAGE DAILY WAGE IN UNITED STATES

Year	Wage level	Wholesale price level	Buying power of wage
1790	18	88	20
1800	28	136	20
1810	45	136	33
1820	52	96	54
1830	36	83	43
1840	37	89	42
1850	41	83	49
1860	45	90	50
1870	76	117	65
1880	65	93	70
1890	76	84	90
1900	76	82	93
1910	93	97	97
1913	100	100	100
1920	220	243	91

Note: The Buying Power of the Wage is deduced by dividing the Wage Level by the Wholesale Price Level.

the year 1913, it was 50 for the year 1860; and 20 for the year 1800. In other words, within 113 years the "real" wage of the average worker in America had increased fourfold, until it was fivefold as great at the end of that period as at the beginning! The same astonishing increase occurred in Great Britain, as will be shown later.

In my price level article, I deduced the per capita efficiency of productiveness in America by 5-year periods, from 1859 to 1919; and it is there shown that this efficiency doubled between the years 1860 and 1910, which is in almost precise accord with the results shown in Table LX, although they were arrived at in an entirely different way.

Table LXI gives the changes in wages and in commodity prices in England, and its footnote gives the sources of the data. In connection it is important to observe that the weight of the pound sterling changed many times between the thirteenth and the nineteenth centuries, and that, therefore it is necessary to multiply English wages and prices prior to 1816 by factors to render them comparable with modern wages and prices. Accordingly, Table LXII has been prepared for this purpose. As silver was the common currency prior to the nineteenth century I have used the factors for silver (last column of Table LXII) in equating ancient English wages and prices. Prior to 1782 there are no British commodity price level or index data, but I have used average prices of wheat for periods of three years as the basis of price levels.

Table LXI shows that for five centuries the buying power of English wages was practically stationary. Then came a marvelous increase, beginning about the year 1800. In 114 years the buying power of the average wage rose from about 36 to 160.

Between the years 1600 and 1800 pure science made enormous strides. Then came its first fruits with the invention of an economic steam engine and scores of other labor-saving devices. The age of pure science dawned about the year 1600. The age of applied science (that is, engineering) dawned about the year 1800. What engineering has accomplished in a little more than a century is truly amazing. Yet the public is so ignorant of both the degree of the accomplishment and the primary cause of it that not one man in ten can name either one.

It was not labor unions that raised average money wages, for that occurred as a result of the increase in per capita money as will be shown later. Nor did labor unions raise "real" wages, for that was the result of applied science. Labor unions reached the apex of their strength in Britain two centuries ago, but without the slightest effect on the buying power of English wages. Skilled labor in England secured an average wage that was about 50 per cent greater than that of common labor as far back as the year 1400, and it has never been able to increase that ratio. In fact, during the recent war, skilled labor fell behind unskilled labor in the race. It is profoundly significant that the most completely organized labor in England has been unable during five centuries to increase its average wage more rapidly than that of unorganized or common labor.

Fortunately for Britain, its free trade policy during the last century has prevented any extensive curtailment of output by trades unions for any extensive period of time. America has always been almost free from such curtailment. Hence these two nations have progressed almost at the same rate in the increased buying power of the average wage.

Since economists are agreed that about three-fourths of all income goes to workers and one-fourth to capital, it is evident that future increases in "real"

TABLE LXI.—ENGLISH WAGES AND THEIR BUYING POWER

Year	Skilled worker	Laborer	Price level	Buying power of wage
1292	$0.36	$0.17	50	34
1400	0.29	0.17	45	38
1494	0.21	0.12	30	40
1601	0.28	0.19	75	26
1699	0.64	0.42	116	36
1778	0.70	0.45	120	37
1788	0.76	0.47	125	38
1797	0.89	0.57	159	36
1801	1.02	0.61	198	31
1803	1.25	0.61	178	34
1826–61	1.20	0.72	...	...
1861–65	1.40	0.85	...	...
1865–66	1.50	0.90	117	77
1866–72	1.60	0.95	...	...
1872–73	1.70	1.05	...	...
1873–78	1.80	1.15	129	81
1914	2.30	1.60	100	160
1920	5.60	5.00	290	172

Note: These wage data are based upon wages given by William Hardy in the London Times, Aug. 31, 1920, but the wages given by him have been multiplied by the factors given in the last column of Table LXII. The wages of "skilled workers" are the average wages paid to carpenters, masons, bricklayers and joiners engaged on public building construction and maintenance in London. The wages of "laborers" relate to the helpers of the "skilled workers." The wages of laborers correspond closely to those given for farm laborers in "A History of Agriculture and Prices in England, 1259 to 1793," by Rogers. This monumental treatise is my source of information as to the prices prior to 1788. The "price level" data from 1292 to 1778 are based upon the average price of wheat, which, as both Rogers and Adam Smith observe, was the greatest staple used by workers. The price of wheat, moreover, varied substantially as the prices of other foodstuffs varied. From 1788 to 1860, the price level is that of Jevons; from 1861 to 1872, that of Sauerbeck; from 1873 to 1920, that of the "Economist."

TABLE LXII.—FACTORS BY WHICH TO MULTIPLY ENGLISH PRICES AND WAGES TO EQUATE TO PRESENT STANDARD

Years	Factor for— Gold	Factor for— Silver
1066–1344	....	3.30
1344–1349	3.55	3.26
1349–1356	3.33	2.93
1356–1421	3.10	2.64
1421–1464	2.80	2.20
1464–1465	2.24	1.76
1465–1527	2.08	1.76
1527	1.73 to 1.95	1.47 to 1.65
1527–1543	1.86	1.47
1543–1545	1.62	1.37
1545–1549	1.55	1.37
1549–1551	1.37	0.92
1551	1.30 to 1.41	1.10
1551–1553	1.41	1.10
1553–1560	1.30	1.10
1560–1600	1.41	1.10
1600	1.28 to 1.39	1.06
1600–1604	1.39	1.06
1604–1626	1.25	1.06
1626–1666	1.14	1.06
1666–1717	1.05	1.06
1717–1816	1.00	1.06
1816–1920	1.00	1.00

Note: These factors have been deduced from data given in "History of Prices and the State of Circulation," by Thos. Tooke.

wages are infinitely more dependent upon increased productivity than upon securing a greater share of the total product. There is no reason why "real" wages can not be increased as greatly during the next century as during the past century. If this is accomplished the average common laborer in the year 2000 will have "real" wages as great as those of the average $6,000-a-year-man of today.

Up to 1824 the working day in America was from "sun up to sun down." By 1840 it had been reduced to an average of 11.4 hours, and by 1890 to 10 hours. It is now probably about 9 hours, possibly 8.5 hours. Since Table LX gives only the increase in the buying power of average daily wages, at least 40 per cent should be added to the buying power in 1913 in comparing it with that in 1800, if both are to be compared on the basis of wages per hour. When this is done, we see that the buying power of an hour's wages in 1913 was fully seven times that in 1800.

The Author's Wage Level Formula.—The average wage paid in any country during any given year would be ascertainable by dividing the total money spent for wages by the total number of workers. This may be expressed thus:

$$\text{Average wage} = \frac{\text{Money Spent for Wager}}{\text{Number of Workers}}$$

But the money spent for wages is a very constant percentage of the total expenditures, as a study of the census statistics indicates. The total annual expenditures are equal to the average number of dollars of currency multiplied by the number of times the money is "turned over" during the year. And the number of workers is a very constant percentage of the population; so if we indicate this percentage by the letter k, and the population by the letter P, the number of workers is $k \times P$. Similarly, if we indicate the wage percentage of the total expenditures by c the number of dollars of money in circulation by M, and the velocity of circulation by V, the total money spent for wages will be $c \times M \times V$. Hence the above given formula for the average wage becomes:

$$\text{Average wage} = \frac{c \times M \times V}{k \times P}$$

Since it is difficult to ascertain the exact value of c and, since we are mainly concerned in ascertaining a "relative wage," or "wage level" (W), we can pass at once to the desired wage level formula by substituting another constant (K) for the quotient of the constant c divided by the constant k. We then have:

$$\text{Wage level (W)} = K \times \frac{M \times V}{P}$$

This is the desired formula for wage levels, and an application of it to actual daily wage levels discloses that the constant K has a value of ⅓ when the wage level is taken at 100 for the year 1913. Hence we have:

$$W = \tfrac{1}{3} \times \frac{M \times V}{P}$$

This gives the annual wage level, but since the number of days worked annually is normally about constant, it also gives approximately the daily wage level.

It will be seen that this wage level formula differs from my commodity price level formula in not containing a factor for efficiency of production (E). The price level formula is:

$$w = \tfrac{1}{2} \times \frac{M \times V}{P \times E}$$

The buying power of the daily wage is measured by dividing the daily wage level (W) by the commodity price level (w). Hence, if we divide the last equation into the equation preceding it we get:

$$\text{Buying Power of Wage} \left(\frac{W}{w}\right) = \tfrac{2}{3} \times E$$

Expressed verbally this last formula means that the buying power of the average wage is proportional to the per capita efficiency of production. If the wage level formula is found to be correct, the conclusion is inevitable that the level of "real" wages rises or falls exactly in proportion to the rise or fall in

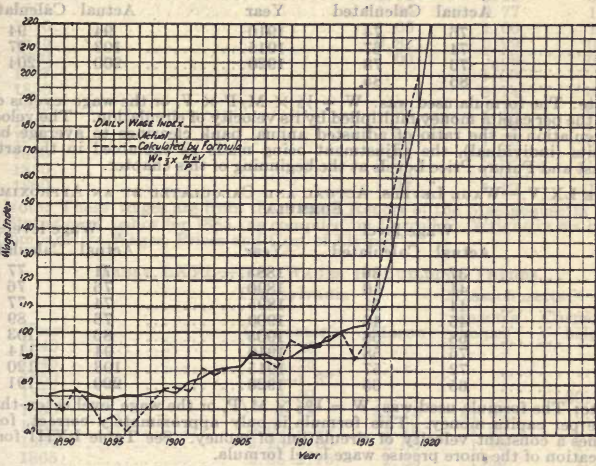

FIG. 13.—Actual compared with calculated wage levels.

per capita efficiency of production. I have established the correctness of the commodity price level formula by showing that it accords closely with commodity price levels. It now remains to prove the correctness of the wage level formula in the same manner. Table LXIII and Fig. 13 show such a comparison for the past 30 years. The agreement is very close. Unfortunately, values for velocity of circulation (V) cannot be very accurately estimated much back of 1889, but, since V has a value that oscillates between 8 and 11, we may assume it to have been 10 every year, and if the value for the wage level derived by substituting 10 for V in the wage level formula agree roughly with the actual wage levels for the past 80 years we may be certain that the wage level formula is substantially correct. Table XLIV shows such a comparison by 5-year intervals from 1840 to 1920. It is, I believe, a complete proof of the substantial truth of the wage level formula. Therefore, we reach this very imporant (and, so far as I know, novel) generalization:

Aside from the relatively minor fluctuations in the velocity of circulation of the currency, the general wage level is proportional to the per capita currency in circulation.

Having this information it becomes possible to forecast the future trend of daily wage levels, or wage indexes. Per capita gold is now 54 per cent above the 1913 level, and per capita currency of all kinds, including gold, is 60 per cent above the 1913 level. If we hold this increase in currency, the new wage level will be 60 per cent above the prewar level. The only question then is as to the probable future trend of our per capita currency.

For the past two years our per capita currency has been nearly constant. The decrease in paper money (Federal Reserve notes) has been offset by the

TABLE LXIII.—WAGE LEVELS, ACTUAL AND CALCULATED BY A CORRECT FORMULA

	Wage level			Wage level	
Year	Actual	Calculated	Year	Actual	Calculated
1890	76	74	1910	94	94
1895	74	67	1915	103	97
1900	76	78	1920	200	204
1905	86	85			

Note: The formula used was: $W = \frac{1}{3} \times M/P \times V$, or the wage level is one-third the per capita money multiplied by its velocity of circulation. The velocity of circulation is the ratio of adjusted annual bank clearings to average bank deposits (individual), the adjustment being made as explained in the article on Past and Future Price Levels at the beginning of this chapter.

TABLE LXIV.—WAGE LEVELS, ACTUAL AND CALCULATED BY AN APPROXIMATE FORMULA

	Wage level			Wage level	
Year	Actual	Calculated	Year	Actual	Calculated
1840	37	36	1885	71	77
1850	41	40	1890	76	76
1855	44	51	1895	74	77
1860	45	46	1900	76	89
1865	68	68	1905	86	103
1870	76	58	1910	94	114
1875	72	57	1915	103	120
1880	65	65	1920	220	191

Note: The formula used was: $W = {}^{10}\!/_{3} \times M/P$, or the wage level is ten-thirds of the per capita money. This formula is only approximately correct, for it assumes a constant velocity of circulation of money. See Table LXIII for an application of the more precise wage level formula.

inflow of gold. The great nations of Europe have issued huge quantities of paper money, which would normally drive out much of their gold to other nations, even were they not debtors to those other nations to begin with. But the victorious allied war nations are debtors to America to an enormous extent—about $9,000,000,000. The payment of the interest on this huge sum would alone increase our per capita currency 6 per cent annually. Although our per capita gold is already 54 per cent above the prewar level, it is almost certain to rise still more in the next few years, not merely because of interest payments from Europe, but because of the economic necessity of restoring the exchange equilibrium.

Every great per capita increase of currency in any nation results in a flow of its gold to countries whose per capita increase has not been so great. During and following our Civil War, most of our gold flowed away to Europe. The same phenomena is now occurring in a reverse direction, but for the same reason.

For these reasons, and based on the history of the flow of gold during and after previous great modern wars, it is safe to infer that our present per capita currency will not decrease materially during the next few years, and that it will ultimately increase.

TABLE LXV.—DAY WAGES IN NEW ENGLAND

Year	Carpenter	Laborer	Farm laborer
1752	.....	$0.33	$0.33
1755	.....	0.33	0.36
1760	.....	0.25	0.25

1855	1.55	1.00	....
1860	1.37	1.10	1.06

Note: These wages are from the Annual Report of the Massachusetts Bureau of Statistics of Labor for 1885, as compiled by Carroll D. Wright in his book on "Comparative Wages, Prices and Cost of Living."

TABLE LXVI.—DAY WAGES IN BUILDING TRADES

	Pennsylvania	Massachusetts		
Year	Carpenter's	Mason	Mason's helper	Carpenter's helper
1840	$1.25	.....	.....	.....
1845	1.25	.....	.....	.....
1850	1.25–1.37	.....	.....	.....
1855	1.50	.....	.....	$0.74
1860	1.75	$1.75	$1.05	0.83
1862	2.00–2.25	1.78	1.09	0.88
1864	2.25–3.00	2.03	1.43	1.00
1865	2.35–2.75	2.35	1.50	1.25
1866	2.50–2.64	2.91	1.75	1.62
1868	2.50–2.67	3.21	1.81	1.39
1870	2.50–2.65	3.62	2.06	1.42
1875	2.36–2.75	2.96	1.68	1.50
1880	2.30–2.75	2.41	1.75	1.18
1885	2.70–2.75	3.59	1.58	1.21
1890	2.70–2.88	3.40	1.56	1.12

Note: These wages are from the Aldrich Senate Report No. 1394.

In answering this important question of the flow of gold between countries, the price formula can be applied to advantage. It can be easily shown that the average prices in two countries that trade with one another on a large scale must become substantially equal. Hence we may deduce that the per capita money in each of two such countries must be proportional to their per capita efficiency of production. Also, it follows that gold must flow from the less efficient nation to the more efficient nation, also that it must flow from the nation that has increased its paper money to the country that has not increased its paper money so greatly. This is a disturbing factor that America has to reckon with for years to come, and it may result in a marked increase in our per capita currency, hence in our money wages within a few years.

Table LXVII.—Average Annual Wages and Salaries in Manufacturing Industries

Year	Salary	Salary level	Wage	Wage level	Salary and wage	Salary and wage level
1849	....	...	....	...	$ 248	37
1859	....	...	....	...	289	43
1869	....	...	....	...	378	56
1879	....	...	....	...	347	52
1889	$ 850	64	$ 444	76	484	72
1899	1,046	78	426	74	469	70
1904	1,103	82	477	82	532	79
1909	1,188	89	518	89	590	88
1914	1,380	100	580	100	671	100
1919*	1,941*	140	1,074*	185	1,178*	176

* For only 15 states.

Note: Prior to 1889 the U. S. Census reports do not give wages and salaries separately. The compensation is supposed to be given in currency throughout the entire period; but judging from the wage levels for 1869 and 1879, it would appear that many manufacturers reported wages paid in gold, which was then at a premium. Excepting for those two census years the wage levels in this table agree very well with those in Tables LIX and LXVIII. The census report for 1919 is not yet completed, so the data in this table for 1919 are merely indicative in a general way, as they apply only to 15 states.

Table LXVIII.—Hourly Wage Index. Year 1913 = 100%

Year	Wage index	Year	Wage index	Year	Wage index	Year	Wage index

1857	40	1877	61	1897	69	1917	128
1858	39	1878	60	1898	69	1918	162
1859	39	1879	59	1899	70	1919[1]	[1]184
						1920[2]	[2]234

[1] This index number applies to the spring of 1919. Wage rates advanced during the year.

[2] This index number applies to the summer of 1920, and probably represents the wage peak of the year.

Note: Wages are in currency throughout the entire period. This wage level table was compiled by the U. S. Bureau of Labor.

One of the most important conclusions to be drawn from the wage level formula is this: In the past 30 years per capita bank deposits have increased twice as rapidly as per capita money. Since bank deposits are nearly 6 times as great as currency, it would follow that if inflation of bank deposits (or "credit money") acts precisely as inflation of currency acts, then wages should have risen nearly twice as much as they actually did rise in the last 30 years. The failure of wage levels to follow increases in per capita bank deposits, therefore demolishes the theory that "credit currency" (bank deposits) affects wage levels in the same manner that real currency affects wage levels. I had already shown the fallacy of this theory in my article on price levels; but it is now shown again from this wage level study. It can no longer be successfully contended that changes in per capita currency are relatively immaterial so long as changes in the volume of credit occur. The truth is that "credit currency" is of comparatively minor importance as a factor in the changes in wage and price levels, its only effect being the relatively small fluctuations that it causes in the velocity of money circulation.

Table LXIX.—Indexes of Union Minimum Wage Rates and Hours of Labor. Year 1913 = 100%

	Index of—		
Year	Rates of wages per hour	Full-time hours per week	Rates of wages per week, full-time
1907	90	103	92
1908	91	102	93
1909	92	102	93
1910	94	101	95
1911	96	101	96
1912	98	100	98
1913	100	100	100
1914	102	100	102
1915	103	99	102
1916	107	99	106
1917	114	98	112
1918	133	97	130
1919	155	95	148
1920	199	94	189

Note: Based on union minimum wage rates as of May 1 of each year, compiled by U. S. Bureau of Labor.

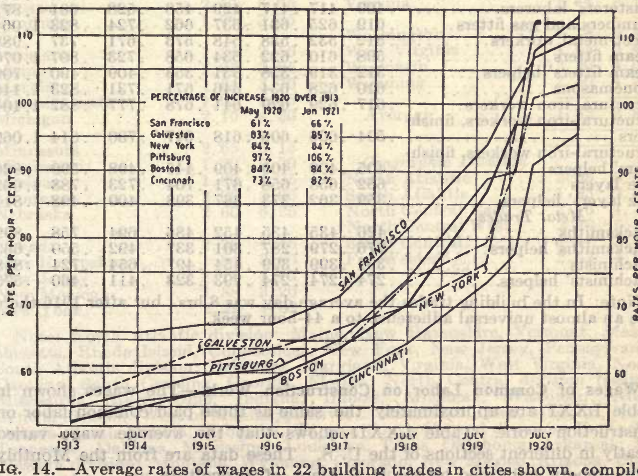

Fig. 14.—Average rates of wages in 22 building trades in cities shown, compiled from schedule of Chicago Builders' Association.

Wages in Building Trades.—W. N. Patten, in Stone and Webster Journal (reprinted in Engineering and Contracting, May 25, 1921) gives the following:

Fig. 14 shows increase in the average rates of wages for twenty-two representative trades in the construction industry for the period between July, 1913, and Jan. 1, 1921, for the cities of San Francisco, Galveston, New York, Pittsburgh, Boston and Cincinnati.

TABLE LXX.—AVERAGE BUILDING WAGES PER HOUR
(According to U. S. Bureau of Labor.)

Year	1913	1914	1915	1916	1917	1918	1919	1920
Building trades								
Bricklayers	.686	.699	.706	.713	.734	.789	.878	1.200
Bricklayers—sewer, tunnel, and caisson	.960	.960	.960	.960	.989	1.065	1.085	1.459
Building laborers	.309	.312	.312	.327	.361	.423	.482	.698
Carpenters	.530	.541	.546	.562	.610	.668	.774	1.034
Carpenters, parquetry-floor layers	.568	.603	.608	.614	.659	.739	.847	1.245
Cement finishers	.552	.557	.563	.568	.602	.662	.745	1.010
Cement finishers' helpers	.360	.364	.364	.367	.382	.447	.508	.814
Cement finishers' laborers	.418	.418	.418	.431	.460	.535	.606	.907
Engineers, portable and hoisting	.586	.592	.598	.604	.633	.727	.797	1.032
Hod carriers	.356	.359	.363	.373	.416	.487	.569	.825
Inside wiremen	.547	.564	.575	.586	.624	.695	.799	1.051
Inside wiremen, fixture hangers	.491	.521	.521	.540	.580	.634	.707	.953
Lathers	.485	.494	.499	.514	.533	.577	.640	.916
Marble setters	.665	.672	.678	.678	.685	.718	.798	1.051
Marble setters' helpers	.404	.408	.408	.408	.432	.453	.517	.873
Painters	.505	.520	.526	.571	.591	.652	.763	1.041
Painters, fresco	.544	.566	.566	.636	.642	.664	.778	1.115
Painters, sign	.629	.629	.629	.648	.674	.736	.888	1.196
Plasterers	.674	.680	.680	.707	728	.761	.883	1.152
Plasterers' laborers	.409	.417	.417	.429	.458	.528	.601	.871
Plumbers and gas fitters	.619	.625	.631	.637	.662	.724	.823	1.064
Sheet-metal workers	.512	.532	.538	.548	.573	.671	.737	.988
Steam fitters	.598	.610	.622	.634	.658	.723	.807	1.070
Steam fitters' helpers	.312	.319	.328	.331	.353	.409	.490	.709
Stonemasons	.610	.628	.634	.646	.671	.731	.823	1.146
Structural-iron workers	.617	.629	.629	.641	.678	.777	.882	1.104
Structural-iron workers, finishers	.594	.606	.606	.618	.647	.730	.814	1.069
Structural-iron workers, finishers' helpers	.405	.409	.409	.409	.445	.498	.599	.826
Tile layers	.652	.658	.658	.671	.704	.723	.788	1.062
Tile layers' helpers	.359	.362	.373	.387	.398	.409	.498	.814
Metal Trades								
Blacksmiths	.426	.435	.435	.452	.486	.694	.758	.899
Blacksmiths' helpers	.276	.279	.287	.301	.337	.492	.550	.663
Machinists	.391	.399	.399	.454	.497	.654	.724	.818
Machinists' helpers	.274	.274	.274	.293	.323	.411	.460	.575

Note: In the building trades the average day was 8 hrs., but after 1916 there was an almost universal adherence to a 44-hour week.

Wages of Common Labor on Construction Work.—The wages shown in Table LXXI are approximately the same as those paid common labor on construction work. Table LXXII shows that the average wage varied greatly in different sections of the U. S. These data are from the Monthly Crop Report, published by the U. S. Dept. of Agriculture.

TABLE LXXI.—AVERAGE DAY WAGES OF FARM LABOR IN U. S.
(Without board and during harvest time)

Year	Wage	Year	Wage	Year	Wage	Year	Wage
1866	2.20	1888	1.31	1898	1.30	1913	1.94
1869	2.20	1890	1.30	1899	1.37	1914	1.91
1875	1.70	1892	1.30	1902	1.53	1915	1.92
1879	1.30	1893	1.24	1910	1.82	1916	2.07
1882	1.48	1894	1.13	1911	1.85	1917	2.54
1885	1.40	1895	1.14	1912	1.87	1918	3.22
....	....	....	....	....	....	1919	3.83
....	....	....	....	....	....	1920	4.36

Note: These wages are for farm labor hired at harvest time; but at other times of the year the wages were less, being about 33% less in 1866, 25% less in 1914, and 20% less in 1919.

TABLE LXXII.—DAY WAGES OF FARM LABOR
(Without board and during harvest time.)

State	1910	1919
Alabama	1.26	2.30
Arizona	2.24	3.65
Arkansas	1.55	3.10
California	2.48	4.69
Colorado	2.47	4.60
Connecticut	2.00	3.75
Delaware	1.55	4.00
Florida	1.46	2.30
Georgia	1.23	2.30
Idaho	2.80	4.95
Illinois	2.30	4.63
Indiana	2.07	4.30
Iowa	2.51	5.20
Kansas	2.57	6.05
Kentucky	1.71	3.35
Louisiana	1.25	2.56
Maine	1.95	3.85
Maryland	1.64	3.70
Massachusetts	1.92	3.75
Michigan	2.10	4.30
Minnesota	2.65	5.15
Mississippi	1.22	2.30
Missouri	1.93	4.35
Montana	2.80	4.95
Nebraska	2.60	6.25
Nevada	2.38	4.45
New Hampshire	1.84	3.80
New Jersey	2.15	4.10
New Mexico	1.88	3.20
New York	2.22	4.02

State	1910	1919
North Carolina	1.28	3.01
North Dakota	3.03	5.85
Ohio	2.07	4.22
Oklahoma	1.97	4.80
Oregon	2.60	4.85
Pennsylvania	1.96	3.71
Rhode Island	2.05	3.50
South Carolina	1.12	2.40
South Dakota	2.95	6.00
Tennessee	1.44	2.70
Texas	1.57	3.68
Utah	2.20	4.10
Vermont	2.25	3.82
Virginia	1.44	3.10
Washington	2.78	5.40
West Virginia	1.65	3.40
Wisconsin	2.20	4.02
Wyoming	2.50	4.70
Average	1.82	3.83
Geographic Division		
North Atlantic	2.08	3.86
South Atlantic	1.33	2.82
North Central East	2.16	4.32
North Central West	2.43	5.33
South Central	1.47	3.14
Far Western	2.52	4.67

Note: North Atlantic division: Maine, New Hampshire, Vermont, Massachusetts, Rhode Island, Connecticut, New York, New Jersey, Pennsylvania; South Atlantic division; Delaware, Maryland, Virginia, West Virginia, North Carolina, South Carolina, Georgia, Florida; North Central division (east of Mississippi River): Ohio, Indiana, Illinois, Michigan, Wisconsin; North Central division (West of Mississippi River): Minnesota, Iowa, Missouri, North Dakota, South Dakota, Nebraska, Kansas; South Central division: Kentucky, Tennessee, Alabama, Mississippi, Louisiana, Texas, Oklahoma, Arkansas; Far Western division: Montana, Wyoming, Colorado, New Mexico, Arizona, Utah, Nevada, Idaho, Washington, Oregon, and California.

These wages are approximately the same as those paid for common labor on construction work. In the South Atlantic and South Central Divisions the laborers are mostly negroes.

Rate of Wages per Hour for Common Labor on Highway Work, 1912 to 1919.—Engineering and Contracting, March 19, 1919, reprints a committee report to the 1919 convention of the American Road Builder's Association, in regard to labor conditions as regards highway work, from which the following data are abstracted.

A questionnaire was sent out to all state highway departments, to the city engineer of all cities having a population in excess of 100,000 and to many of the large road-building contractors throughout the country. Replies to this questionnaire were received from 39 of the 48 state highway departments, from 54 of the 82 cities to which it was sent, and from 24 road contractors.

Summary of Replies from State Highway Departments.—Thirty-nine state highway departments made replies to the questionnaire. As some of the departments are only 2 years old their replies were not used in figuring average rates of wages.

In 1912 the average rate per hour as reported by 27 states was $ 188, while in the same year Georgia was paying $0.09 and Nevada was paying $.40 Only six states were paying $.25 or more and 10 states were paying $.15 or less—the most of them less. In 1913 the average as reported by 28 states was $.20. In 1914 the same states report an average of $.205, in 1915 of $.225, in 1916 of $.2585, in 1917 of $.303 and in 1918 of $.39. The highest rate for 1918 is reported by Oregon and is $.58. The lowest is by South Carolina and is $.18 per hour.

Summaries of Replies from Cities.—Fifty-four out of 82 cities replied to the questionnaire. Forty-six furnished information as to wages for all years from 1912 to 1918. Taking the year 1912, Spokane, Wash., reports $.37½ per hour, which was the highest, and Birmingham, Ala., with $.14 was the lowest, while the average rate for the year was $.234. In 1913 these 46 cities report an average wage of $.238 per hour. In 1914 the average was $.245; in 1915, $.255; in 1916, $.276; in 1917, $.312; in 1918, $.384. Boston, Mass., reported the highest rate for 1918. It is $.52½ per hour. San Antonio, Tex., had the lowest for the year, $.25, while Atlanta, Ga., and New Haven, Conn., both report a wage of $.28

Summaries of Replies from Contractors.—Twenty-four contracting firms, well distributed throughout the country, make replies, which may be summarized as follows: The average rate of wages they paid in 1912 was $.192; in 1913 it was $.20; in 1914, $.21; in 1915, $.23; in 1916, $.256; in 1917, $.315; in 1918, $.397.

Wages of Skilled and Common Labor Paid by Railroads 1896–1917.—Tables LXXIII and LXXIV have been prepared from the records of daily compensation given in the annual Reports of the Interstate Commerce Commission. These records start with the year ended June 30, 1892. The United States has been divided into territorial districts and all railroads (excepting terminal and switching companies) within each district are included.

From 1892–1910 inclusive the country was divided into 10 districts as shown in Fig. 15.

From July 1, 1910 the country has been divided into three districts and the roads classified as Class I, II or III depending upon the amount of gross earnings.

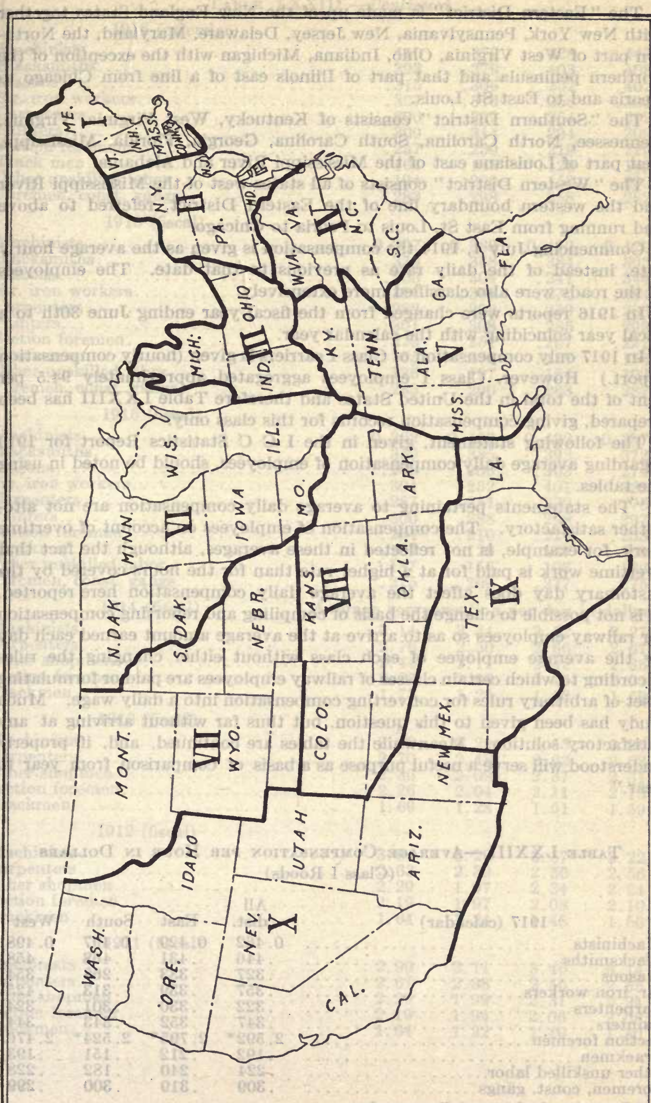

FIG. 15.—Territorial groups as per I. C. C. classification 1892–1910 incl.

The "Eastern District" is made up of the New England States together with New York, Pennsylvania, New Jersey, Delaware, Maryland, the Northern part of West Virginia, Ohio, Indiana, Michigan with the exception of the northern peninsula and that part of Illinois east of a line from Chicago to Peoria and to East St. Louis.

The "Southern District" consists of Kentucky, West Virginia, Virginia, Tennessee, North Carolina, South Carolina, Georgia, Florida, Mississippi, that part of Louisiana east of the Mississippi River and Alabama.

The "Western District" consists of all states west of the Mississippi River and the western boundary line of the Eastern District, referred to above and running from East St. Louis to Peoria to Chicago.

Commencing July 1, 1914 the compensation is given as the average hourly rate, instead of the daily rate as previous to that date. The employees of the roads were also classified more extensively.

In 1916 reports were changed from the fiscal year ending June 30th to a fiscal year coinciding with the calendar year.

In 1917 only compensation of Class I carriers is given (hourly compensation report.) However, Class I employees aggregated approximately 94.5 per cent of the total in the United States and therefore Table LXXIII has been prepared, giving compensation records for this class only.

The following statement, given in the I C C Statistics Report for 1910 regarding average daily compensation of employees, should be noted in using the tables.

"The statements pertaining to average daily compensation are not altogether satisfactory. The compensation of employees on account of overtime work, for example, is not reflected in these averages, although the fact that overtime work is paid for at a higher rate than for the hours covered by the customary day does affect the average daily compensation here reported. It is not possible to change the basis of compiling and reporting compensation for railway employees so as to arrive at the average amount earned each day by the average employee of each class without either changing the rules according to which certain classes of railway employees are paid or formulating a set of arbitrary rules for converting compensation into a daily wage. Much study has been given to this question, but thus far without arriving at any satisfactory solution. Meanwhile the tables are continued, and, if properly understood will serve a useful purpose as a basis of comparison from year to year."

Table LXXIII.—Average Compensation per Hour in Dollars (Class I Roods)

1917 (calendar)	All dist.	East	South	West
Machinists	0.462	0.429	0.497	0.498

NOTE: Due largely to the continuous character of the work, railway trackmen (or section men) receive less than the prevailing wages for common laborers on construction work. Adding 20% to the trackmen's wages gives approximately the wages of construction laborers.

Rental Prices for Construction Equipment.—A schedule, evolved from the records and experiences of contractors, manufacturers and rebuilders of equipment, and designed to furnish contractors with a practical means for estimating equipment expense and determining adequate rental charges has been approved by the Executive Board of the Associated General Contractors. The schedule, which was prepared by the Research Division under the direction of the Committee of Methods of the Association, is given in the Nov. Bulletin of the Associated General Contractors. The schedule and discussion of its application as abstracted in Engineering and contracting, Dec. 15, 1920, follow.

To use the schedule with safety, it is essential to understand how the amounts were obtained, how they are to be applied, and how they are limited for determining rental charges. Knowing these things, no great difficulty should be found in establishing the charges within the bounds of practical accuracy.

For the reason that arithmetical averages as obtained from available records, gave few rational values for depreciation and repairs, such averages were given less weight in establishing the tabular amounts than the practical experience of contractors. In fact, the strongest evidence that these amounts are reasonably safe and accurate lies in the endorsement given them by experienced general contractors.

A tentative draft of the schedule was submitted to members in the Weekly Bulletin of July 31. They were asked to criticise the amounts and offer suggestions. In accordance with the criticism received, which evinced considerable study upon the subject, some of the tabular amounts were changed. As it now stands, the schedule represents the consensus of opinion of many contractors, and with the proper understanding of what the percentage amounts mean, it should offer a safe means of estimating rental charges.

What the Values Mean.—The endless variation of job conditions, such as topography, ground formation and climate, indicate how great may be the error of any fixed equipment charge when applied to the exceptional job. But having figures which represent the mean of many projects, a starting point exists for ascertaining reasonable charges for the exceptional circumstances. Figures given in the standard schedule may be said to show equipment expense when machines are not required to operate continuously under either the worst or the best of operation strain. When no especially favorable or unfavorable circumstances attend a project, the tabular values probably give the expense within a permissible error.

To eliminate error as far as possible by permitting consideration and comparison of the individual items that make up equipment expense, the gross amounts are reduced to their component parts. Thus any item of the expense which is known to be unusually high in specific cases may be adjusted in the schedule to obtain a more appropriate rental rate.

Components of Expense.—Seven items of equipment expense constitute the total rental charge and require consideration in estimating a lump sum contract or in determining fixed rate rentals. An average value for each of these items which represents the expense of a general contractor's outfit as a whole, has been approved by the Executive Board. The items referred to and their annual proportions of the equipment's initial cost are as follows:

Schedule of Typical Rental Charge.—Items of expense are expressed as per cents of original capital investment for equipment having a useful life of 6 years and a salvage value of 25 per cent of the original cost.

	Per cent
1. Average depreciation	12½
2. Equivalent annual interest at 6½ per cent	4
3. Shop repairs	6
4. Field repairs	4
5. Storage and incidentals	3½
6. Insurance	1
7. Taxes	1
Total annual expense	32
Equivalent expense on basis of 8 months' working timer per year	48
Rental rate per month	4

How to Obtain Proper Percentage.—These percentages and those given in the detailed schedule were determined according to the following principles: The economical life of a machine is considered to end when its value has depreciated to 25 per cent of the original cost. The average annual depreciation then amounts to 75 per cent of the initial cost divided by the number of years it may be expected to give service. The initial cost of a machine is represented by the cost of that machine delivered at the contractor's yard.

Wagon loaders, power	5	15	10	6	3½	1	1	36½

Interest should naturally be charged at the prevailing rate. This may be computed in three ways:

1. By charging the prevailing rate each year on the depreciated value of the machine.

2. By charging the prevailing rate each year on the average value of the machine during economical life. For example, when the salvage rate value is 25 per cent the average value equals (100 per cent + 25 per cent) divided by 2 = 62½ per cent.

3. By finding the proportion which the average value is of the initial cost and charging this proportion of the prevailing rate each year. This proportion is called the equivalent annual interest and shows what interest rate on original cost will yield the same interest as the prevailing rate when applied to the depreciating value of the machine. This is the method used in the above schedule. The average value is 62½ per cent of the original; therefore the equivalent annual rate is 62½ per cent of the prevailing rate, or 62½ per cent of 6½ per cent = 4 per cent.

Shop and field repairs are separated by reason of a previous recommendation of the Committee on Methods that field repairs be considered a part of the cost under cost plus contracts and shop repairs be borne by the contractor and covered by the fixed rate rental charge. This recommendation was made on the ground that an owner should not be made to pay the total cost, for example, of re-fluing a boiler which may have been burned out principally on another owner's work.

The other items of cost require no special explanation.

Three Types of Charges.—Owners of equipment find occasion to establish rental rate as follows:

1. For a lump sum or unit price estimate.
2. To owners on cost plus work.
3. To others than client owners.

In these instances charges should be made as follows:

1. The rental charge or equipment expense for lump sum work includes all the items mentioned above.

2. The fixed rate to owners on cost plus work will include all but field repairs, if this item is paid as a cost of the work. To the amount thus determined may be added a service charge depending upon the policy of the contractor, *i.e.*, whether the service of equipment is included in the profit fee or carried in the rental charge.

3. The charge to persons other than client owners includes all of the items of expense and an additional amount for profit or payment for the machine's earning power.

A further consideration in each of these cases is the rate for double shift work, where the percentages for depreciation and repairs should be doubled, or nearly so.

Individual Judgment Essential.—The committee desires to emphasize the fact that the values presented in the table should not be considered absolute in determining a rental charge. A real danger presents itself in using any tabular percentage without investigating the conditions under which the equipment is to work. To illustrate: if the values here given for a standard gage shovel outfit were applied to such an outfit engaged constantly in excavating hard rock, the probability is that the charges allowed would not cover more than half the expense. The frequent dobey shots and the dropping of heavy boulders into cars entails a higher rate of depreciation and repairs than is given in the schedule. On the other hand, if this shovel outfit were steadily engaged in digging sandy loam, the values given in the table would probably cause the equipment charge to contain a fair per cent of profit.

It is with the understanding that individual judgment and experience

TABLE LXXVI.—RENTAL RATES FOR GRADING EQUIPMENT

Class of equipment	Original capital cost	Annual rate of depreciation on original cost, per cent.	Total annual rate of accrued charges on original cost, per cent.*	Total annual charge	Average earning days per year	Daily charge for int., dep., ins. and storage	General shop repairs daily	Daily rental	Est. cost field repairs daily	Total rental charge daily, incl. field repairs

* Except where noted this rate is made up of the percentage of depreciation, plus 3¾ per cent interest on original investment and 3¾ per cent of original investment allowed for insurance and storage.

† Interest = 3¾ per cent, insurance and storage charge = 15 per cent of the original investment.

‡ Interest = 3 per cent, insurance and storage charge = 3¾ per cent of the original investment.

should adjust the tabular values to meet unusual conditions that this schedule is offered to contractors.

Individual Equipment Rental Schedule.—The component expenses incurred by the ownership and maintenance of construction plant are expressed in this table as percentages of the initial cost for individual items of equipment. They indicate the probable annual expense without profit under ordinary job conditions and should be included in any lump sum estimate or in determining time rate rental charges. The salvage value in all cases is considered to be 25 per cent of the initial cost.

Total percentage amounts in the etreme right-hand column should be applied to the total cost of a machine, including charges for transportation from the factory. This gives the total annual charge which for a lump sum contract covering a full season, is the total equipment expense. For determining a monthly, weekly or daily rental rate the annual amount is divided by the number of such periods in the year during which construction work may be carried on.

Rental Rates for Grading Contractors Equipment.—(Engineering and Contracting, Feb. 18, 1920.)

F. J. Herlihy has compiled the following table (Table LXXVI.) giving the derivation of rental rates for grading equipment. The table shows the original capital cost of his equipment, depreciation charges, average earning days per year, daily charge for interest, depreciation, insurance and storage, and total daily rental charge.

CHAPTER III

HAULING

A fundamental cost entering into nearly every kind of construction is that for hauling. For some work, such as excavation, the cost of removing or hauling away the excavated material is often the controlling factor in arriving at the unit cost; while on practically all work if the transportation end "falls down," progress and costs are "shot to pieces." It is evident, therefore, that time may be well spent in determining the most economic method of hauling for each job.

The material in this chapter is, in general, grouped according to methods of hauling. For further data on this subject, the reader should refer to the index of this volume and also to Gillette's "Earthwork and Its Cost" and "Handbook of Rock Excavation."

Cost of Maintaining City Owned Teams is given in Engineering and Contracting, July 2, 1919, and is from a report by the Rochester Bureau of Municipal Research, Inc., on the collection of refuse in the city of Rochester, N. Y.:

Cost of Maintaining Horses at Columbus, O.—According to the report of Superintendent E. W. Stribling, of the Division of Garbage and Refuse Collection, the cost of maintaining 142 horses by the city of Columbus, O., in 1916 was 83.7 cts. per horse per day. This included a cost of 41.63 cts. for feed; 13.53 cts. for veterinary services, shoeing and supplies; and 28.54 cts. for stable labor. In 1915 the unit cost was 83 cts. per horse per day, including 45.77 cts. for feed, 11.98 cts. for veterinary services, shoeing, and supplies and 25.25 cts. for stable labor. The labor force consisted of 16 men and a night watchman. The cost of feed was about $14 per ton for hay, 75 cts. per bushel for corn and 50 cts. per bushel for oats. Straw cost about $7 per ton. In 1916 each horse consumed daily 30 lbs. of hay, and 13 lbs. of grain, 5.3 lbs. of straw were used in bedding each horse. In 1915 these quantities were 31 lbs., 12.75 lbs., and 6.3 lbs. respectively.

Cost of Horse Maintenance at Cincinnati.—Similar costs for 1916 in the city of Cincinnati, given in the report of Fred Maag, Superintendent of the Department of Street Cleaning, Sewer and Catch Basin Cleaning, indicate that 34.9 cts. per horse per day was the cost of feeding and 39.4 cts. was the cost of "other stable expenses," the total cost being 74.3 cts. per horse per day. Approximately 190 horses and 80 mules were maintained in 17 stables, practically one-half of this number being boarded in one stable. Each horse consumed 14.7 lbs. of hay, 11.5 lbs. of oats and 2.8 lbs. of nutritia daily. Hay cost about $18 per ton, oats 45 cts. per bushel and nutritia $1.50 per hundredweight. (No allowance apparently was made for bedding straw.)

Cost of Feeding Horse at Washington.—In Washington, D. C., according to the report of the Engineering Department for the fiscal year, 1915–16, the cost of feed amounted to 40.2 cts. per horse per day. The daily allowance per horse was 3.3 lbs. of dry straw, 7 lbs. of long timothy, 7 lbs. of mixed clover hay, 12.8 lbs. of oats and 1.7 lbs. of bran. Straw cost at the rate of

$16, long timothy at $20.80 and mixed clover hay at $20 per ton, oats at 54 cts. per bushel and bran at $1.27 per hundredweight. The cost of shoeing was stated to be 2.6 cts. per horse per day.

Cost of Maintaining Horses by New York Street Cleaning Department.—In the annual report of the Department of Street Cleaning of New York, in 1916, Commissioner J. T. Fetherston states that the cost of "labor, materials, supplies and consumable equipment used directly in the care of horses" amounted to $1.087 per horse per day and that this cost represents prices of forage and supplies considerably above normal. About 64 per cent of the total cost represents the cost of forage, 30 per cent the direct labor cost and 6 per cent the cost of maintaining stable equipment. In the 26 stables maintained by the department, 2,400 horses were cared for. One hostler and one stableman were employed for each 13 horses. In 1917, the daily allotment for each horse was 23 lbs. of oats, 18 lbs. of hay, 3¼ lbs. of bran and 3 lbs. of straw. In addition to this each horse was given 1½ lbs. of coarse salt and 2½ lbs. of rock salt per month. When idle the horses were given half ration of oats. In 1916, the daily ration was 21 lbs. of oats, 15 lbs. of hay and 1¼ lbs. of bran. The other items were practically the same as for 1917. This appears to be an unusually heavy ration and the cost of feed alone was practically 70 cts. per horse per day.

Stable Costs at Rochester.—For Rochester it was possible to obtain from James M. Harrison, formerly superintendent for the Genesee Reduction Co., data of the cost of maintaining horses employed in garbage collection from 1908 to 1916. On Jan. 1, 1917, the Department of Public Works took over the operation of the garbage plant stables and the 1917 costs, therefore, are available also.

In 1917 the 68 horses quartered at the garbage plant stables cost about 68 cts. per horse per day to maintain. The approximate cost of feed amounted to 50.7 cts.; the direct labor cost of stable operation, 9.4 cts.; and the estimated cost of barn supplies, shoeing and harness repairs, 7.9 cts. per horse per day. No exact ration allotment was made, but according to the total quantities purchased during the year each horse consumed about 11 lbs. of oats and 22 lbs. of hay per day. The approximate average cost of oats was 80 cts. per bushel and the cost of hay was about $18 per ton. The stable force consisted of one barnman and three helpers, the barnman and one helper working seven days and the other two helpers six days per week. The drivers cleaned and harnessed the horses and gave them their noon feeding.

The foregoing and certain additional data as to the cost of maintaining horses by the Genesee Reduction Co. before 1917, are shown in Tables I and II.

From the foregoing and other data it appears that a horse used in collection work should be fed on the average about 20 lbs. of hay and 14 lbs. of oats per day, in addition to possibly 2 lbs. of other feed, consisting principally of bran, salt, etc. Also each horse should be bedded with approximately 5 lbs. of dry straw daily. On this basis and with hay costing $18 per ton, oats 80 cts. per bushel, other feed $1.50 per hundredweight and straw $12 per ton, the total daily cost per horse of feed and bedding would amount to the following:

20 lb. of hay at $18 per ton	$0.18
14 lb. of oats at $0.80 per bu	.35
2 lb. of other feed at $1.50 per cwt	.03
5 lb. of straw at $12 per ton	.03
Total estimated cost of feed and bedding per horse per day	$0.59

In addition to this the cost of veterinary services, maintenance of stable equipment and supplies, shoeing, and harness repairs should not exceed 12 cts. per horse per day. If one hostler at $800 per year and one stableman at $750 per year were provided for every 20 horses, the direct labor cost of stable operation would amount to about 21 cts. per horse per day. This would include the cost of all work involved in feeding, bedding, cleaning and otherwise caring for horses, and all labor about the stables such as cleaning stables, handling feed and supplies, handling and moving equipment, cleaning equipment, etc.

The total cost per horse per day, therefore, might be estimated at 92 cts. distributed as follows:

Feed and bedding	$0.59
Veterinarian, shoeing, harness repairs, etc	0.12
Direct labor cost of stable operation	0.21
Total maintenance cost per horse per day	$0.92

The annual cost of maintaining horses at this figure would be $336.65 per horse, exclusive of the cost of overhead supervision, fixed charges on first cost of horses, stable sites and stable buildings, depreciation of horses, and depreciation and maintenance of stable buildings.

The annual (purchase) cost of the horses used in garbage collection in Rochester since 1912 has been about $31 per horse, which includes replacements as well as the purchase of three horses during the six years in addition to the number owned at the beginning of the period. (See Table II.)

TABLE I.—COST OF FEEDING HORSES EMPLOYED IN THE COLLECTION OF GARBAGE IN ROCHESTER, N. Y., 1908 TO 1916

Year	Total cost of feed (grain, hay, straw)	Approximate number horses fed	Average cost per horse per day
1908	$ 7,364.08	40	$0.505
1909	6,964.89	40	.477
1910	6,912.67	40	.474
1911	6,827.04	40	.467
1912	7,816.29	65	.330
1913	9,269.83	65	.395
1914	8,771.77	65	.370
1915	10,666.02	66	.443
1916	9,570.47	66	.397

TABLE II.—COST OF RENEWALS OF HORSES EMPLOYED IN THE COLLECTION OF GARBAGE IN ROCHESTER, N. Y., 1912 TO 1917

Year	Total expenditure for horses	Approximate number of horses	Average cost per horse per year
1912	$2,219	65	$34
1913	1,885	65	29
1914	4,205	65	65
1915	1,020	66	15
1916	1,575	66	24
1917	1,125	68	17

Estimates as to the economic life of a horse used in collection work vary from 4½ to 8 years. It is believed, however, that a good horse should give at least six years of useful service in this kind of work. Assuming a first cost of $275 and a salable value of $75 at the end of six years, the annual depreciation would be $33.33 per year per horse.

Depreciation in Value of Horses (Engineering and Contracting, Oct. 17, 1917).—Some interesting data on the depreciation in value of horses are given in a bulletin issued by the U. S. Department of Agriculture. This bulletin deals with the cost of keeping farm horses and the cost of horse labor. It is compiled from a study of records for 316 horses on 27 farms in Illinois, Ohio and New York.

In determining depreciation and appreciation in value of horses a yearly inventory value was placed on each horse on the farm by careful appraisal and a record was kept of each horse bought or sold. In Illinois 11 of the 18 yearly farm records showed a net depreciation of horses. In Ohio 7 of the 16 yearly records showed a net depreciation, and in New York 16 of the 18 yearly records showed a net depreciation.

The average net depreciation of the 316 horses was $4.50 per horse. Of this amount $2.70 per horse was due to the death of 9 horses, valued at $855. Depreciation varied from $11.60 per horse in New York to an appreciation of $2.10 per horse in Ohio.

Table III shows the percentage of horses that appreciated in value, the percentage that did not, and the factors influencing the aggregate depreciation or appreciation, by States.

TABLE III.—PERCENTAGE OF 316 HORSES THAT APPRECIATED IN VALUE, PERCENTAGE THAT DID NOT APPRECIATE, AND THE FACTORS INFLUENCING THE AGGREGATE DEPRECIATION OR APPRECIATION, BY STATES (27 FARMS, 316 HORSES)

	Percentage of horses that showed—							
State and number of horses	Appreciation	No appreciation	No. of deaths	No. bought	No. sold	No. colts bought	No. colts sold	No. colts fed
Illinois (154 horses)	18.75	81.25	3	21	21	2	..	43
Ohio (72 horses)	21.95	78.05	.	9	17	2	1	7
New York (90 horses)	4.95	95.05	6	6	3	1	2	18
The 3 states (316 horses)	15.60	84.40	9	36	41	5	3	68

On the Illinois and New York farms colts became work horses when from 2½ to 4 years of age. The age of work horses that depreciated in value varied considerably, depending on their usage and care. The average age of work horses that appreciated in value was about 4 years. The average age of those that neither appreciated nor depreciated in value was about 8 years, and the average of those that depreciated in value was about 11 years. In Ohio data showing the age of all the horses studied were not obtained; however, the data that were obtained along this line showed about the same results as those in Illinois and New York.

In Illinois about 19 per cent of the horses appreciated in value at the rate of $36.05 per head per year, while the average depreciation for the other 81 per cent was $12.55 per head. At this rate it will be seen that a $36 appreciation of one horse practically would offset the depreciation of three others. Thus the appreciation of one horse out of every 5.34 kept resulted in an average net depreciation for all horses of but $3.46 per head. Of the 154 horses included in the records from this State 3 died, causing a loss of $350. In other words, the death loss was about 1 out of every 51. In considering the reason for the number of young horses on these farms and the low depreciation of work horses it was found that there was an average of one colt for every four work horses kept. Further, no colts were sold, all being developed into work horses, 11 becoming work horses during the time in which data were collected. It also will be seen that the same number of horses was bought as was sold. Three died and had to be replaced, and a part of the farmers enlarged their business, thus requiring more horses. With the continued raising and developing of colts into work horses, however, it is safe to say that ordinarily a greater number of young horses will be developed than will be needed in the farm business.

On the Ohio farms about 22 per cent of the horses appreciated in value at the rate of $56.90 per head. The average depreciation of the remaining 78 per cent was $13.30 per head. At this rate the appreciation of 1 horse would offset the depreciation of more than 4 other horses. Thus the appreciation of 1 horse out of every 4.55 resulted in an average net appreciation of $2.10 per head for the total number of horses. While no deaths occurred in this group, 2 horses were severely injured, entailing a loss of $175.

On the Ohio farms there was an average of one colt for every 10 work horses kept. This was about two-thirds less than on the Illinois farms, and yet the depreciation of horses was $5.56 per head less than in Illinois. By this it will be seen that the net appreciation of horses in Ohio was not so much due to the raising of young horses as in Illinois. A study of the data shows that the reason for this was that on some farms a practice was made of buying young horses, and after working them for a time, selling them at an increase in value. During the years this study was made 9 horses were bought and 17 were sold, 8 of the 17 having been on the farms at the time this work was begun. The horses bought and sold were mostly young draft stock, which accounts for the high appreciation of $56.90 per horse. In following this practice, at times more horses were kept than were needed to do the farm work. Other data in this bulletin show that the average horse worked less hours per year on the Ohio farms than on the Illinois or New York farms.

On the New York farms the relative number of horses that appreciated in value was a great deal less than in each of the other States—less than 5 per cent—at the rate of $44.40 per head. The depreciation per head of the remaining 95 per cent was $14.48. At this rate, the appreciation of one horse would a little more than offset the depreciation of three other horses. Thus, the average net depreciation was $11.56 for all horses. One reason for this depreciation being higher than in the other two States was a loss of $505 due to the death of 6 horses, or about 1 out of every 15. Thus, more than 48½ per cent of the total depreciation was due to deaths. The number of colts on these farms was less than in Illinois. For every work horse sold two were bought. It seems that these farmers have but recently started to replace the old horses by raising colts.

Depreciation figures from other bulletins follow:

Bulletin 341 of the U. S. Department of Agriculture shows that the average depreciation of horses on 378 farms studied in Chester County, Pennsylvania, is $7 per head, and on 300 farms studied in Lenawee County, Michigan, $7.10 per head. These figures are largely determined by the practice of farmers in disposing of horses while they are still salable at a fairly satisfactory price, and would undoubtedly be much greater if all farm horses were kept until their usefulness was at an end.

Cornell University (N. Y.) bulletin 377 shows that the average annual depreciation of horses on 14 New York farms for the year 1912, and on 31 New York farms for 1913, was $14.03 and $12.10 per horse unit, respectively. Of the 45 farms studied, 12 showed an appreciation of horses.

Minnesota extension bulletin 15, covering a period of four years, 1904 to 1907, inclusive, gives figures for farms studied in three different counties. In Rice County depreciation varied from $0.98 in 1905 to $15.48 in 1904, averaging for the four years $5.56 per head. In Lyon County depreciation varied from $4.20 in 1905 to $9.86 in 1904, averaging per year $6.94 per head. In Norman County depreciation varied from $2.60 in 1907 to $7.37 in 1904, averaging per year $5.892 per head.

It is pointed out in the text that depreciation of the horse is an expensive item to farmers who are not able to control this expense by means of clever selling methods and by the use of young horses. Shrewd selling, however, does not affect the general principle of depreciation, since thus the loss is passed on to the buyer.

Minnesota experiment station bulletin 145 gives results of a further study of horse depreciation in the above-mentioned counties. Records for Rice County for the period 1908 to 1912 inclusive shows a variation in depreciation from $0.28 in 1910 to $5.10 in 1909, and an average per year of $3.05 per head. In Lyon County the study covers a period of three years, 1908 to 1910, inclusive. The depreciation varied from $1.47 in 1910 to $5.60 in 1909, averaging per year $3.06 per head. In Norman County the work covered a period of four years, 1908 to 1911, inclusive. The depreciation varied from $0.51 in 1910 to $3.42 in 1911, averaging per year $1.48 per head. It is pointed out in this bulletin that the annual depreciation as shown above is not high enough to represent a proper average charge through a long term of years. Abnormal conditions in the Minnesota horse market were largely responsible for the low depreciation charge.

Health Efficiency of Horses.—In Engineering and Contracting, Sept. 17, 1913, J. W. Paxton states that records are kept by the street cleaning department of Washington, showing the total number of horses cared for in each stable each day and the total number unable to work because of injury or sickness. The health efficiency of the stable is the ratio found by dividing the number of horses capable of working by the total number of horses. The health efficiency of all stables combined has been brought up to 98 per cent, although it was as low as 86 per cent one month shortly after the health records were initiated.

A health efficiency curve is plotted for each stable, and comparisons between different stables can be made at a glance. When in any case there is a drop in the curve, a conference with the stable boss discloses the reason.

In addition to a health record of this sort, it may be suggested that it would be wise, in many cases, to keep a record of all time lost by stock, and to plot curves showing the total "output factor," i.e., ratio of hours actually worked to hours that might have been worked had health, weather, etc., permitted. On construction work it frequently happens that many head of stock are idle for lack of drivers or equipment. Especially is this true when a job is being started. Time is also lost in shoeing, in moving from one camp to another, etc. It is certainly desirable to have daily records of all time losses, and the reasons therefor. Daily "output factor curves" and "health efficiency curves" will focus attention upon time losses and lead inevitably to a reduction of the losses.

Hauling Material with Mules.—The following data are taken from an article by William W. Hurlbut published in Engineering Record, July 19, 1913.

For hauling steel plates from Mojave to the Antelope Valley Siphon, Los Angeles Aqueduct, a distance of 35 miles, three stations were established 10 miles apart. Twelve mule teams were used for this hauling, the average load being 12.9 tons or a little more than 1 ton to the animal.

A team made 20 miles a day, loading at Mojave, arriving at the 10-mile station at noon; at the 20-mile station at night of the first day; at the 30-mile station at noon of the second day; leaving there and discharging the load at the siphon the afternoon of the second day; than returning to the 30-mile station the same night; returning the following day to the 10-mile station; and at noon of the fourth day reloading at Mojave, thus making the round trip in three and one-half days. The cost of this haul averaged 12 cents per ton mile.

Number of Wagons Required for Hauling from Steam Shovels.—The following data are reprinted from the Aug., 1919, issue of Successful Methods:

YARDAGE FOR VARIOUS HAULS

Haul in ft.	Round trips	Cu. yd. per day per team with 1½-yd. wagons
500	105	157
1,000	53	79
2,000	26	40
3,000	17	26
5,000	10	15
10,000	4	6

NUMBER OF TEAMS FOR VARIOUS OUTPUTS

Daily output in cu. yd.	Haul 1,000 ft.	Haul 3,000 ft.	Haul 10,000 ft.
250	3	10	41
300	4	12	50
500	8	20	84

On a road job in Minnesota 5 wagons are serving a ¾-yd. steam shovel on a 300-ft. haul and are kept busy.

At Hamilton, O., a steam shovel with a ¾-yd. bucket, loading gravel on a 3 to 10-ft. face, loaded 480 2-cu. yd. wagons in 9 hours, and 60 teams were estimated as necessary to keep the shovel busy on a 1-mile haul. The same shovel handled clay out of a 6 to 12-ft. face and should be able to load 360 2-yd. wagons in 9 hours. This would require 45 teams to haul the material away on a 1-mile haul, 8 trips to the team.

Average Loads in Team Hauling on Country Highways.—The following data are given in a paper by Seth A. Moulton (Engineering and Contracting, Jan. 4, 1911) before the Association of Cement Users. The observations were made during the construction of a storage dam at Aziscohos, Me., in 1910.

The round trip of 76 miles from Colebrook to the dam and return is made in 4 days, each team making two complete round trips without rest, and laying off the ninth day. Four, five, and six horse teams were employed, averaging 4½ horses to a team, and by a proper arrangement of the time schedule a maximum total of 180 horses could be accommodated on the road, making a total of 40 teams, which, on the basis of 4 days to a trip, gave an average of 10 teams arriving at the dam during each day of the toting season.

During the best period of toting, or for the 6 weeks from Dec. 1 to Jan. 15, the average loads were as follows:

Four horse team	6,650 lbs.
Five horse team	8,600 lbs.
Six horse team	10,400 lbs.

The average load per horse was 1,680 lbs.

During the best period of summer toting the average loads were as follows:

Four horse team	5,750 lbs.
Five horse team	None working
Six horse team	8,400 lbs.

The average load per horse was 1,430 lbs.

During the most adverse condition of toting the average loads were as follows:

Four horse team	4,800 lbs
Five horse team	6,200 lbs.
Six horse team	7,200 lbs.

The average load per horse was 1,220 lbs., or 20 per cent less than could be hauled during the best sledding.

Cost of Hauling with Teams.—Table IV, prepared by E. B. Hiatt, is published in Engineering and Contracting, Dec. 4, 1918. The figures are based on a rate of travel of 2 miles per hour with loads and 3 miles per hour returning empty. Forty minutes is allowed for loading and unloading 3,750 lbs. with shovels. This weight was the average load in Madison County, Iowa, during the 1918 season. The vehicle considered was a common farm wagon.

TABLE IV.—SCHEDULE OF PRICES FOR HAULING ONE TON

	Team rates per day of ten hours					
Miles	$5.00	$5.50	$6.00	$6.50	$7.00	$7.50
0.5	0.288	0.317	0.346	0.375	0.404	0.433

6.5	1.622	1.784	1.946	2.108	2.271	2.433
7.0	1.733	1.906	2.080	2.253	2.426	2.600
7.5	1.844	2.028	2.213	2.397	2.582	2.766
8.0	1.955	2.151	2.346	2.542	2.737	2.933
8.5	2.066	2.273	2.480	2.686	2.893	3.100
9.0	2.177	2.395	2.613	2.831	3.048	3.266
9.5	2.288	2.517	2.746	2.975	3.204	3.433
10.0	2.400	2.640	2.880	3.120	3.360	3.600
10.5	2.511	2.762	3.013	3.264	3.515	3.766
11.0	2.622	2.884	3.146	3.408	3.671	3.933
11.5	2.733	3.006	3.280	3.553	3.826	4.100
12.0	2.844	3.128	3.413	3.697	3.982	4.266
12.5	2.955	3.251	3.546	3.842	4.137	4.433
13.0	3.066	3.373	3.680	3.986	4.293	4.600
13.5	3.177	3.495	3.813	4.131	4.448	4.766
14.0	3.288	3.617	3.946	4.275	4.604	4.933
14.5	3.400	3.740	4.080	4.420	4.760	5.100
15.0	3.511	3.862	4.213	4.564	4.915	5.266
15.5	3.622	3.984	4.346	4.708	5.071	5.433
16.0	3.733	4.106	4.480	4.853	5.226	5.600
16.5	3.844	4.228	4.613	4.997	5.382	5.766
17.0	3.955	4.351	4.746	5.142	5.537	5.933
17.5	4.066	4.473	4.880	5.286	5.693	6.100
18.0	4.177	4.595	5.013	5.431	5.848	6.266
18.5	4.288	4.717	5.146	5.575	6.004	6.433
19.0	4.400	4.840	5.280	5.720	6.160	6.600

Similar tables can be prepared using different times for loading and unloadng which would depend upon methods employed and materials hauled. The average load would also vary with the type of wagon employed.

Cost and Service Comparisons of Motor Trucks and Horse-drawn Vehicles

are given by Clinton Brettell in "The School of Mines Quarterly," Columbia University, from which Engineering and Contracting, May 14, 1913, abstracts the following:

There are several ways of making a cost comparison. One is to reduce all costs to a "per day" basis. This method is of little value, for while the motor truck costs more per day, it also does more work per day. Then there is the "cost per mile" basis. This is a little better, but also shows but one phase of the question, as no account is taken of the tonnage moved. The third method, and the best one, considered from all sides, is the "cost per ton-mile." This is the method which will be employed in practically all cases throughout this paper. Data on the subject of transportation costs are abundant, but so many methods of bookkeeping and computation are used that it is not safe to accept any of them off-hand. Before adopting them for comparisons they should be carefully analyzed.

Motor Trucking.—To be accurate, the cost of operation for motor trucks should include the following items:

I. Fixed Charges.—Based on an average number of working days. A figure of 300 working days per year is often used, and approximates quite closely the actual working days for the average case.

A. Driver's Wages.—About $20 per week is a fair charge for this item.

B. Garage.—If the truck is stored in a public garage, about $25 per month is charged. This includes washing, polishing, inspection, heat, light, power, etc. If the owner maintains his own garage, this figure may be somewhat lower. In that case the charge for storage, to compare with the above, would be made up as follows: (*a*) Interest on investment, including building, property and equipment. (*b*) Insurance and taxes on same. (If the building is rented, the above, i. e., interest on investment, insurance and taxes on building, and an additional charge for depreciation on building would all be included in one item, rent.) (*c*) Depreciation on building and equipment, if owned by truck owner; on equipment only, if building is rented. (*d*) Wages of attendants, elevator men, washers and polishers, inspectors, superintendent or foreman. (*e*) Charges for heat, light and power. (*f*) Charges for maintenance of building and equipment.

C. Insurance.—Fire, liability, theft, property damage. These rates vary all over the country. As a rule they are unreasonably high. In most cases the same rates as for pleasure cars are applied to commercial vehicles, without taking account of the lessened liability with slow moving motor trucks. Insurance against fire and theft is generally at some percentage on a partial valuation, say, 2¼ per cent on 80 per cent valuation. Insurance against property damage depends on the horsepower of the truck and is arranged on a sliding scale basis, which is arbitrarily adopted without scientific basis. Liability is usually a flat sum, being greater the more hazardous the occupation. This item should also include taxes for licenses, etc.

D. Interest.—Opinion differs as to what rate of interest to use. One common method is to assume as a basis the rate offered by banks. Whatever the rate finally adopted, it is well to recognize that there is a regular depreciation in the amount of capital invested; so that while interest for the first year is chargeable on practically full value, for the second year it should be on less than full value, for the third year on still less, and so on. The easiest way of taking account of this is to use an average rate of interest, assuming full capital first year and entire dissipation of capital at the end of, say, the tenth year. The average rate will then be ½ the flat rate decided on, say ½ of 5 per cent. This method charges too little interest for the first five years and too much for the last five, the one balancing the other in the final result.

II. VARIABLE OR MILEAGE CHARGES. *A. Depreciation.*—To account for the gradual wearing out of the truck, even with the best possible care and maintenance, a certain amount must be charged off each year, so that at the end of the truck's life there will be a fund sufficient to purchase a new truck, identical with the old one. If a truck receives ordinary care and attention in the matter of upkeep, etc., and is not abused in operation, it will last as much as ten years before it is really worn out, and many will last longer. (*a*) One method of charging depreciation, then, is to write off one-tenth the original value of the truck each year. Opinion differs as to the life, but under present conditions it is not wise to figure over ten years. Naturally a truck which is run 25 miles a day should last longer than one operated 100 miles a day, with equal care and attention in both cases. (*b*) This suggests a second method of charging depreciation, i. e., on a mileage basis, figuring the life of a truck at 100,000 miles under average conditions. The latter method seems the more logical one to follow, since in fixing the rate for the former method it was necessary to consider, among other things, the daily mileage of the truck. Cost per mile is thus equal to total cost divided by total mileage.

B. Tires.—The life of tires is subject to practically the same discussion as given in connection with depreciation. The method generally employed is as follows: The tire maker guarantees his tires for a certain mileage (provided that rated capacities of tires are not exceeded, and in some cases that speeds are limited to certain specified values) usually around 8,000 miles. In addition, the time element is involved, because tires, being made of rubber, deteriorate even when standing idle. The tire maker covers this phase of the situation by stipulating (in most cases) that the guaranteed mileage must be covered within a given time, usually 12 months, to validate the guarantee. Hence cost per mile equals cost per set of tires divided by guaranteed (or actual) mileage, as the case may be.

C. Repairs (exclusive of tires).—This includes labor and material (and profit if work is done in a public garage). It is generally figured on a yearly basis and then converted to a mileage rate, by determining the yearly mileage. For electric trucks, this item includes renewals of plates, electrolyte, etc.

D. Gasoline or Current.—This cost is figured for a year and then reduced to a mileage basis. Cost of gasoline depends on the fuel consumption of the motor and the prevailing price of gasoline. Cost of current depends on type of motors, etc., and cost per kw.-hour for charging batteries. It is best to figure this on a yearly basis and then reduce to a mileage basis. The same discussion applies to oil.

Summary.—The total of items under I gives total cost per day for fixed charges. Assuming a certain daily mileage, and multiplying the rates for the various items under II by this mileage, we get the daily cost for each item. Total of these gives total variable costs per day. Adding daily fixed charges and daily variable charges, we obtain total daily operating cost. Ton-miles per day is the product of the tonnage, by the distance this tonnage was carried. Dividing average cost per day by ton-miles per day, we obtain "Cost per Ton-mile" which is the final result sought. As an example of the foregoing, see Table V, which shows costs for a 5-ton gasoline truck, figured for various daily mileages, and Fig. 1 plotted from these figures.

Horse Trucking.—Following out the same computation for horse drawn trucks, the costs would be determined as follows:

TABLE V.—ESTIMATED YEARLY COST OF OPERATING 5-TON GASOLINE TRUCK

Investment:										
Chassis........	$4,800.	Chassis, with stake body......$5,000.								
Miles per day...		20	25	30	35	40	45	50	60	70
Miles per annum		6,000	7,500	9,000	10,500	12,000	13,500	15,000	18,000	21,000
Fixed charges:	Cost per day.									
Driver........	**$3.466**	$1,040.	$1,040.	$1,040.	$1,040.	$1,040.	$1,040.	$1,040.	$1,040.	$1,040.
Garage........	**1.000**	300.	300.	300.	300.	300.	300.	300.	300.	300.
Insurance......	**.633**	190.	190.	190.	190.	190.	190.	190.	190.	190.
Interest........	**.416**	125.	125.	125.	125.	125.	125.	125.	125.	125.
Total fixed charges.	**$5.515**	$1,655.	$1,655.	$1,655.	$1,655.	$1,655.	$1,655.	$1,655.	$1,655.	$1,655.
Variable expenses:	Cost per mile.									
Depreciation....	**.044**	267.	333.	400.	467.	534.	601.	668.	802.	934.
Tires..........	**.068**	405.	506.	607.	709.	810.	911.	1,012.	1,215.	1,418.
Repairs........	**.033**	200.	250.	300.	350.	400.	450.	500.	600.	700.
Gasoline,.......	**.051**	308.	386.	463.	540.	617.	694.	771.	925.	1,079
Oil............	**.004**	24.	30.	36.	42.	48.	54.	60.	72.	84.
Total variable expense.......	**.200**	$1,205.	$1,505.	$1,806.	$2,108.	$2,409.	$2,710.	$3,011	$3,614.	$4,215.
Total cost per annum.......		2,860.	3,160.	3,461.	3,763.	4,064	4,365.	4,666.	5,269.	5,870.
Total cost per day..........		9.53	10.53	11.53	12.54	13.55	14.55	15.55	17.56	19.60
Total cost per mile..........		.476	.422	.384	.358	.339	.324	.311	.293	.280
Total cost per ton mile..........		.190	.168	.154	.143	.136	.129	.124	.117	.112

Number of working days, 300.
Full load carried half way.
Driver, $20 per week.
Garage, $25 per month.
Insurance: Fire, 2¼ per cent of $4,000; liability, $100.
Interest: The interest charge represents the average yearly interest at 5 per cent on principal.
NOTE.—Mileage costs shown in boldface should not be used in figuring yearly costs under "Variable Expenses," as they are only carried out to three decimal places and are therefore only approximate. The variable expenses shown under the various mileages were worked on yearly totals.

Depreciation (less cost of tires): Life of truck figured at 100,000 miles.
Tires, $540 per set for 8,000 miles guaranteed by tire manufacturer.
Repairs, $500 per annum for daily mileage of 50 miles (for 15,000 miles per annum), exclusive of tires.
Gasoline, 18c per gallon (3.5 miles per gallon).
Oil, 40c per gallon (100 miles per gallon).
NOTE.—The above yearly cost of tires does not take into account the tires on the truck when delivered. Accordingly $540 should be deducted in estimating tire cost for first year.

1. Fixed Charges. *A. Driver.*—In case the driver's wages are paid by the week, it is best to figure this item on the basis of a year and then reduce it to a daily basis. For average figures at Chicago, see Table VI.

B. Stable.—If a truck owner keeps a stable for his equipment the following items should be included in the cost account: (*a*) Feed, hay and straw, water and stable supplies. (*b*) Taxes, insurance, depreciation, interest; if the building is rented, rent includes all of these. (*c*) Light, heat and power. (*d*) Wages of stablemen, helpers, etc.; salary of manager.

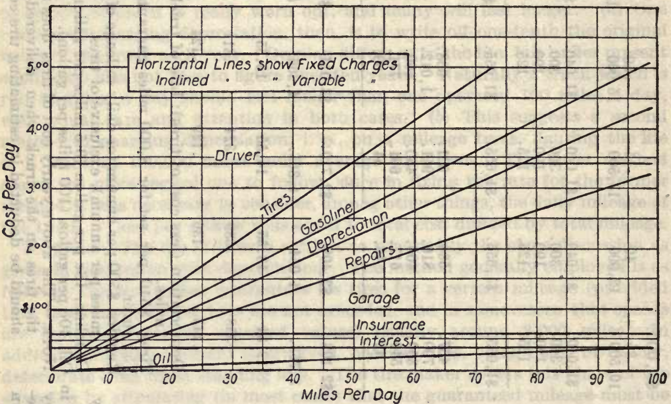

Fig. 1.—Estimated daily cost of operation of five-ton gasoline truck subdivided into its various items

If he boards his horses, a flat figure covers all of the above items. Record of costs should be kept for a year and then reduced to a daily basis by using the average days in service per year.

Table VI.—Costs Incident to Horse Transportation, Chicago

Commodity	1871	1881	1891	1901	1906	1911	1912
Corn, per bu...	$0.39	$0.635	$0.59	$0.675	$0.46	$0.70	$0.90
Oats, per bu...	.33	.468	.334	.483	.358	.474	.40
	1903	1907	1908	1909	1910	1911	1912
Hay, per ton.	$15.00	21.50	14.00	17.00	21.00	25.00	20.00

Chicago Truck Drivers, Wages Per Week

Type of wagon						
Single wagon	1902	1904	1906	1909	1910	1912
One horse............	$11.00	$11.25	$11.25	$11.50	$12.00	$13.50
Two horses..........	12.75	13.00	13.00	13.50	14.00	15.50
Double wagon						
Two horses..........	13.75	14.00	14.00	14.50	15.00	16.50
Three horses.........	15.50	15.75	15.75	16.00	17.00	18.50
Four horses..........	16.50	17.00	17.00	18.00	18.00	19.50
Six horses...........	18.50	19.00	19.00	20.00	20.50	21.50

Overtime (year 1912), 30 cents per hour up to 8 p. m.

D. Interest.—The same methods are applied as in connection with motor trucking. Interest on horses and equipment (harness, wagons, blankets, etc.).

E. Insurance.—No insurance is carried, as a rule.

F. Veterinary and Medicine.—Charges for a year are reduced to daily basis.

II. **Variable Charges.** *A. Depreciation.*—Distinctly a mileage charge, as horses are worn out much quicker by working long hours, and constantly, than by giving them plenty of rest. Under average conditions, horses are unfit for heavy trucking after more than a few years' service. Life of wagons, while somewhat longer, depends on the amount of service; also on nature of service and care as to upkeep. Yearly mileage under average conditions is based on average number of working days, and an average daily mileage (not over 18 miles for light work, considerably less for heavy work). The original cost must thus be divided over the total mileage for the working life of the horse. Cost of wagon is distributed in same way. This gives cost per mile.

B. Repairs.—Repairs on harness and wagons, painting, etc., are figured for a year and then reduced to a mileage basis by applying the total yearly mileage. For any given daily mileage, find total mileage cost per day.

The sum of fixed and variable charges gives total cost per day. Dividing by ton-miles per day gives the final result, cost per ton-mile. The curves shown in Fig. 2 give quite accurately the ton-mile costs for various capacities of trucks, gasoline, electric and horse drawn, figured for various mileages. Table VII shows another method of keeping the cost records for two-horse and three-horse wagons. The final result is cost per ton-mile.

Table VII.—Cost of Operating Horse Wagons
(On basis of five years' operation: loaded both ways.)

Two-horse wagon—	
Price of open express-body wagon	$300.00
Price of two horses	400.00
Price of double set harness	75.00
Total cost of equipment	$775.00
Working days	300
Average miles per day	20
Load in pounds	8,000

Items	Per year	Per working day	Per mile	Per ton mile	Per cent
Wagon expense—					
Maintenance, grease, repairs, etc	$ 125.00	$0.417	$0.0208	$0.0052	6.94
Depreciation, 10 per cent	30.00	.100	.0050	.0012	1.66
Rental value of space	25.00	.084	.0042	.0010	1.38

	$2,400.00	$8.001	$0.4380	$0.0739	100.

Comparative Economies.—The costs of horse transportation were calculated as follows: A one-horse truck with driver can be hired for $4 per day. Its maximum daily mileage would be 22 miles and its maximum capacity 1 ton. Hence, ton-miles per day (full load half way) = $\frac{1}{2} \times 22 \times 1 = 11$; and cost per ton-mile = $4.00 ÷ 11 = $0.364. Similarly:

Two-horse truck with driver, per day	$ 6.00
Maximum daily mileage, miles	20
Maximum capacity, tons	3
Maximum ton-miles per day = $\frac{1}{2} \times 20 \times 3$ =	30
Cost per ton-mile = $6.00 ÷ 30 =	$ 0.20

Three-horse truck with driver, per day	$ 8.00
Maximum daily mileage, miles	18
Maximum capacity, tons	5
Maximum ton-miles per day = $\frac{1}{2} \times 18 \times 5$ =	45
Cost per ton-mile = $8.00 ÷ 45 =	$0.178

These are the extreme points for the three curves. For lower mileages, the costs will be higher. The daily mileages given are much higher than would be obtained under average operating conditions. Hence, in most cases, the costs would be found further up on the curves.

The figures from which curves in Fig. 2 were plotted, for gasoline trucks, are from figures given in a table (see Table VIII) published in "Commercial Car Journal," Feb. 15, 1912, and are averages taken over a number of years, from records of trucks in actual service. They are based on the assumption that full load is carried half way.

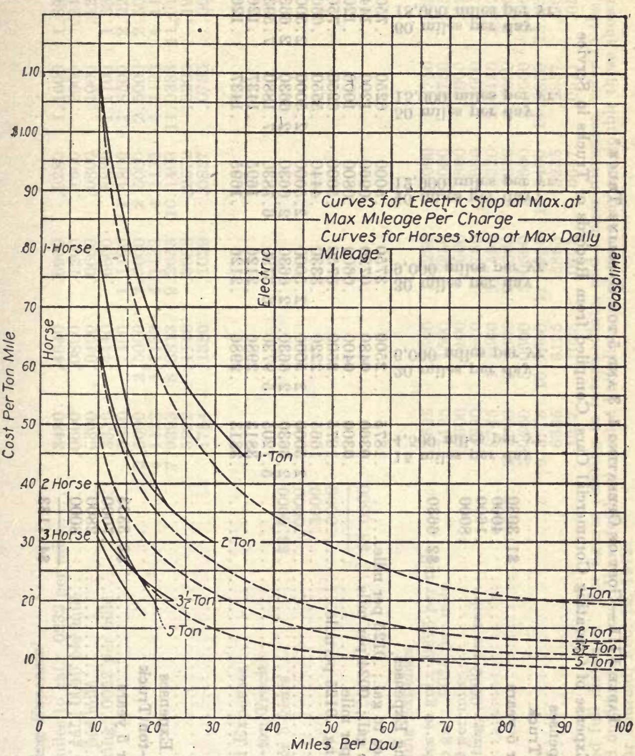

Fig. 2.—Comparative operating costs of gasoline, electric and horse trucks.

The figures for electric trucks of from 1 to 5 tons' capacity (see Table IX) were taken from a table published in February, 1912, by the Commonwealth Edison Co. of Chicago, a company operating a large force of electrics and supplying current to many others. Both these tables are thus from reliable sources.

In Fig. 3 is given another set of curves showing: (1) Horse-haulage costs collected by the National Association of Automobile Manufacturers, from professional truckmen. (2) Probable daily mileages for horse-trucks of various capacities. These are the results of actual practice. (3) Motor-truck speeds recommended by N. A. A. M. for trucks of various capacities.

TABLE VIII.—COST OF OPERATING 1, 3 AND 5-TON GASOLINE TRUCK*

Average Expense of Operating Commercial Cars, Compiled from Records of Trucks in Service

Fixed Expenses	
One-ton Truck	
Dep. on $2,000 at 20 % for 5 years	$1.3030
Interest at 6 %	.4000
Insurance	.1600
Garage	.8000
Total per day	$2.6630

Operating Expenses	15 miles per day; 4,500 miles per yr.	20 miles per day; 6,000 miles per yr.	30 miles per day; 9,000 miles per yr.	40 miles per day; 12,000 miles per yr.	50 miles per day; 15,000 miles per yr.	60 miles per day; 18,000 miles per yr.	70 miles per day; 21,000 miles per yr.

Note.—300 working days per year. For intermediate capacities, see original article in Power Wagon, February, 1912.

These speeds have been determined after considering all sides of the question, so that depreciation will not be too rapid, due to excessive speeds. (4) The costs shown in this curve for the operation of gasoline trucks of various capacities were plotted from figures published by the Knox and the Hewitt automobile companies. Part of the figures are averages of the two, the remainder being either Knox or Hewitt costs alone.

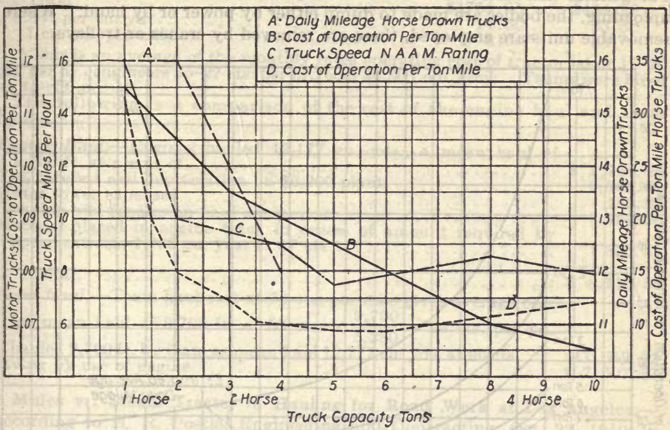

FIG. 3.—Comparative operating costs of motor and horse trucks.

In Fig. 2 truck capacities up to 5 tons were shown. In Fig. 4 additional curves are shown for capacities from 6 to 10 tons. The same rates of increase were maintained in figuring the unit costs in these trucks of larger capacity, the results being checked by estimating the various capacities. In addition, calculations were made, assuming average conditions as to running speeds and working hours, to determine what daily mileages trucks of these various capacities would accomplish under ordinary conditions. Results were compared with figures submitted by the N. A. A. M., and were found to check quite well. A curve was plotted from these values, between daily mileages and truck capacity, on the same sheet with the other curves. This curve cuts the cost curves, thereby marking out the working part of these curves for average conditions. The cost curves approach one another as capacity is increased; increase of daily costs begins to catch up to increase in daily ton-miles, so that it becomes less and less of an advantage to increase from one capacity to the next. This is true even when the mileages per day are kept constant. But in actual changing from seven to ten ton capacity there is practically no decrease in cost of hauling per ton mile.

Referring again to Fig. 2 we find that for low mileages, up to about 18 miles per day, the three-horse truck is the most economical means of transporting goods. This then is the field of usefulness of the horse-drawn vehicle, i.e., where traffic loading, unloading or other conditions are such that the conveyance is forced to remain idle a considerable portion of the day and would therefore be un-economical. Realizing the truth of this argument, the truck manufacturer is designing loading and unloading devices, by the use of which standing time is reduced to a minimum, and the motor truck is thus able to cope successfully with the horse, even in this short haul work. To reduce loading time, several means are resorted to, depending on the nature of the product to be transported. For building materials, coal, etc., cranes, scoops and other mechanical loading devices are employed with great success. For general merchandise, bodies made up of several units are used. For uploading, the bodies are made to dump either by power or by hand. Where removable units are employed, these are removed by cranes or trolleys.

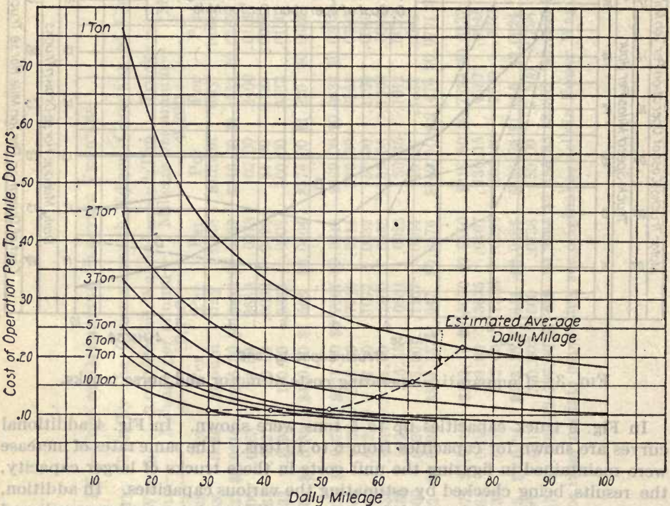

FIG. 4.—Cost of operation per ton-mile for average conditions, various truck capacities and daily mileages.

Comparative Costs of Hauling with Steam Tractor and Teams are given by K. I. Sawyer in Engineering and Contracting, March 13, 1912. The records were taken in 1911 on road extension work of Menominee County, Mich.

Owing to the fact that the steam haulers (75 h. p. Case Traction Engines) were a new part of the county plant a comparison was worked out to show the advantage of using this equipment. This comparison was taken directly from the schedule of actual costs of the road. In the work 12,177 cu. yds. of stone were handled by the engines and 1,912 cu. yds. by team. This work was under identical conditions and gives a good basis of comparison. The team haul rate was 53 cts. per yard-mile. This would be considered high under normal conditions, but it was good under existing conditions. The conditions under which the hauling was done were very stern as is shown by the fact that it was possible to load only about a ton to the load for teams at the start, and even then it was necessary to double the teams over considerable of the road now built. Only good teams weighing 2,900 lbs. to 3,400 lbs. each were used. Further details regarding the hauling are given in Table X.

TABLE X.—COST OF HAULING WITH TRACTOR AND TEAMS

Item	Steam tractor haul	Team haul
Av. haul, ft.	9,700	2,300
Total cu. yd.	12,177	1,912
Cost		
Labor	$ 940.87	....
Coal and oil	$ 814.08	....
Total	$1754.95	$454.26
Av. per cu. yd.	14.5c	23.8c
1 cu. yd. per mile	8.6c*	53.*

* This is an average of the monthly rates operating cost of tractor labor 17–20 cts. per hr., engineers 25–27 cts. per hr., coal $4.50 f.o.b. scow. Teams were hired at 45 cts. per hr.

The following is a comparison of the cost of the engine haul and team haul:

Engine Haul.—Engines hauled 12,177 cu. yds., a mean haul of 9,700 ft. at a cost of	$ 1,754.96
20% interest and depreciation on $6,200 plant	1,260.00
Water tower expenses	140.92
Cleaning and repairs on haul equipment	163.26
Material placed in engine track in excess of amount required by specifications, 1,703 cu. yds. at 47 cts	800.41
Total	$ 4,119.55

Team Haul.—Team haul cost at 53 cts. per mile gives average cost for mean haul of 9,700 ft. of 53 cts. $\times \frac{9,700}{5,280}$ = 96 cts. per yd.

hauled 9,700 ft. by team as mean haul 12,777 cu. yds. at 96 cts.	$11,689.92
Saving by use of engine	$ 7,507.37

Mules vs. Steam Tractor in Hauling for Road Work at Los Angeles.—According to H. R. Postle, Engineering and Contracting, Oct. 22, 1910, in hauling crushed rock from cars to the road, under construction at Los Angeles, Cal., it proved cheaper to haul rock with mules than with a traction engine, using the type of wagon ordinarily manufactured and sold to be drawn in train with an engine. The particular wagon used was the Port Huron 5-yd. or 6 ton wagon; each was fitted with a tongue, two mules being hitched alongside the tongue with three abreast in the lead. With a haul of about ½ mile, each wagon made 10 trips per day of 8 hours, thus delivering on the road 60 tons of rock at a cost of $7.50 (five mules at $1.00 per day and $2.50 per day for the driver) or $0.125 per ton. To have hauled 60 tons of rock with 2-yd. wagons would have required two and a half 2-yd. wagons costing $4.25 each (two horses $2.00, one driver $2.25) or $10.65, which would make the cost $0.177 per ton, which shows a saving of $0.052 per ton by hitching more stock to one wagon and using a large sized wagon. The saving will increase with the length of haul. The coupling of two or three wagons together, or using a wagon of large capacity, with 4 to 8 head of stock is a very common California practice, and is one which the writer has failed to observe in the east. It is the writer's experience that this method of hauling, unless the haul be a long one, will generally be found to be cheaper than hauling by engines for the following reasons:

1. To load a train of wagons quickly requires either a private or specially constructed railroad switch and loading bins, or two trains of wagons, one of which is loading while the other is on the road. Loading wagons continuously one by one does not require so much in the way of switches, bins or wagons.

2. Most contracts demand an equipment easily and cheaply movable from one switch to another. It is seldom that all of the loading can be done at one

switch, consequently expensive equipment which cannot be cheaply and quickly moved, is not justifiable.

3. Horse equipment is better adapted to torn-up and dusty roads, which are sure to be encountered where construction work is in progress.

4. Horse drawn wagons are more easily handled on the sub-grade where the rock is dumped. They pull in on the sub-grade more easily, do less damage, dump and pull out and turn around more quickly.

5. On very few contracts and on very few railroad switches can rock be delivered fast enough to justify the equipment required for engine hauling. The whole equipment, the necessary unloading devices and the number of wagons, more easily fit the general run of contracts where horse drawn wagons are used.

Of the numerous contracts now under construction in Los Angeles County, where $3,000,000 is being expended on macadam road construction, on only one is the rock being hauled by steam engines. They were tried on several others, but quickly abandoned.

Motor Truck Cheaper than Teams on Hauling Gravel.—F. P. Scott in Engineering News-Record, May 16, 1918, gives the following data on cost of hauling gravel for road constructing in Montana.

Teams and a 5-ton (5 cu. yd. capacity) truck were used. Late delivery of the truck prevented it doing its full share of the work.

Labor and supplies were paid for at the following rates: Common labor; $0.375 per hour; team and teamster, $0.75 per hour; foreman, $0.45 per hour, truck drivers, $100 per month; gasoline, $0.27 per gallon; oil, $0.52 per gal.

TABLE XI.—COMPARATIVE COST OF HAULING GRAVEL BY TEAMS AND MOTOR TRUCK

Item	Team hauling	Truck hauling
Total amount hauled, cu. yds.	21,952	2,937
Haul, miles ave.	1.588	2.079
max.	2.125	2.416
min.	0.704	1.805
Cost per yd. mi., ave.	$0.431	$0.235
max.	0.813	0.292
min.	0.349	0.158

The operating costs of the truck upon which the above units are based were as follows:

Operator	$292.05
Repairs	131.59
Fuel	320.63
Int. and Depr.	695.16

Economics and Costs of Motor Truck Operation.—The following matter, from a paper by W. H. Clapp in the Journal of the A. S. M. E., Oct., 1916, is given in Engineering and Contracting, Oct. 18, 1916.

Economics of Truck Operation.—For many kinds of haulage, covering a wide range of operation, the motor truck is distinctly superior to any other method of transportation. Given an active service at full load, with a terminal not definitely fixed and a radius of operation up to 30 miles, it is an exceptional condition which will justify any other method of goods haulage.

There are, however, special considerations which may have considerable bearing upon the employment of a truck. A committee of the Boston Chamber of Commerce, in a detailed report on street traffic in Boston, covering eighteen months of study, reported that "development of motor trucks will tend to relieve congestion by moving all merchandise in larger units and more rapidly," and that "the average speed of motor vehicles in getting into and away from railway terminals is from two to three times that of the horse."

Costs of Gasoline Trucks.—Fig. 5 gives curves of cost, weight and horsepower (average values) for all classes of gasoline trucks as listed by publishers of motor truck publications. The noticeable feature of these curves is the sudden break of each for the lighter trucks of less than 1 ton capacity. These show that the demand for a light truck has been met by making a vehicle which is much lighter for the rated load than the heavier trucks. This is possible because of the higher engine speed, a more simple final drive, torque and thrust taken through the vehicle springs, and by the generous use of

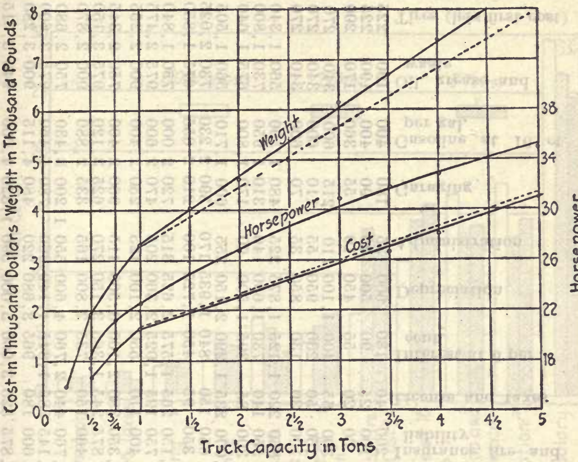

FIG. 5.—Average cost, weight, capacity and h.p. from all classes of gasoline motor trucks.

special alloys and heat-treated steels. The curves suggest that these trucks are too light for the load that they are rated to carry. That this is true is abundantly proved by the records of many light trucks which show that the average life of a light delivery truck is about 35,000 miles, whereas the heavier trucks when properly driven; and cared for can be depended upon to give 80,000 to 100,000 miles, or even more for the better grade of trucks, if they are carefully driven and ordinary maintenance is kept up.

Table XII is an itemized cost statement for various sizes of gasoline trucks under average service conditions on the roads of southern California. That these costs are somewhat lower than averages for other localities may be largely credited to good roads and an equable climate. In making this table three conditions of operation are assumed: the costs for each size of truck are computed for a daily run of 25, 50 and 75 miles, and for each condition the life of the truck is estimated, and depreciation is based on this life. Costs are given in dollars for the entire life of the truck. First costs are average chassis costs in Los Angeles, as follows; Light delivery wagon, 18 h. p., $600.; 1,500

TABLE XII.—TOTAL COST OF OPERATING GASOLINE MOTOR TRUCKS AT VARIOUS DAILY MILEAGES

Capacity of truck	Estimated life, years*	Total mileage	Costs for entire life of truck, in dollars: Insurance, fire and liability	License and taxes	Interest at 6 per cent	Depreciation	Administration	Garaging	Gasoline at 16 ct. per gal.	Oil, grease and waste	Tires (less first cost)	Driver's salary	Inspection and maintenance	Total	Cost per mile, dollars
Light delivery wagon.....	5	37,500	200	40	180	600	35	180	400	190	225	2,400	750	5,200	0.139

lbs. truck, 22 h. p., $1,100; 1 ton truck, 24 h. p., $1,875.; 1½ ton truck, 25 h. p., $2,150; 2 ton truck 26 h. p., $2,625.; 3½ ton, truck 32 h. p., $3,500.; 5 ton truck, 35 h. p., $4,600; 6½ ton truck, 40 h. p., $5,000.

In California distillate is being used to quite an extent as a substitute for gasoline. The cost per gallon is about half that of gasoline at the present time (1916), and the b. t. u. content somewhat greater. A supply gasoline is carried and used in starting. The consumption of distillate is about the same as that of gasoline. The success which has attended this innovation would seem to justify the claims that the use of distillate does not increase carbon trouble. The question of a lessened volumetric efficiency is a negligible consideration.

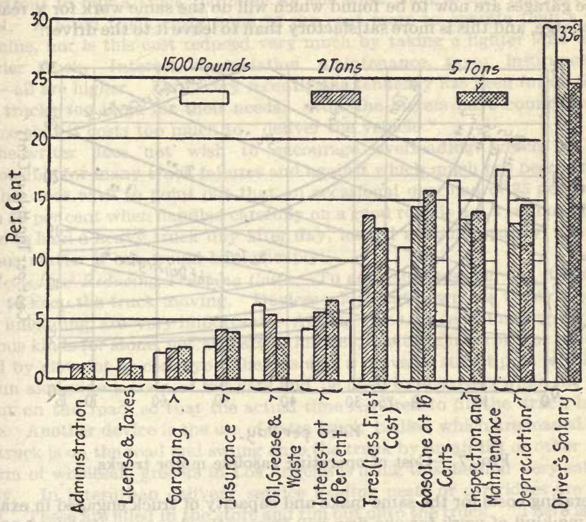

FIG. 6.—Division of truck costs.

Tires will outwear the manufacturers' guarantee at least 25 per cent when used on the good roads of southern California. Smooth roads, dry surfaces and an equable climate all contribute to this result. Overloading and overspeeding are the things that shorten tire life. However, the important consideration is not tire economy, but economy of truck operation per ton of material carried; therefore, durability is only one factor that must be taken into account. Resilience, which prevents the wasting of truck power; cushioning effect, which keeps the maintenance charges low on the whole truck; a good tractive grip and a reasonable cost are all properties which are required in a truck tire.

Operating Costs.—Fig. 6 gives a graphical view of percentage costs for a light, a medium and a heavyweight truck, each averaging 50 miles a day. The higher proportion which the light truck has in the items of labor, depreciation and maintenance is noticeable. Against this increase is the lower percentage of the entire cost charged to fuel and tires.

In discussing motor truck costs it is not possible to neglect the human factor, which here more than in most cases of machinery handling is one of the principal items. It is hardly too much to say that maintenance costs are chiefly driver. An expensive and intricate machine is put in charge of a low-paid employe who is not the owner and who ordinarily has but a limited knowledge of machinery. This is one reason why the life of a light truck is usually about two or three years.

Ownership of eight or ten trucks will justify an owner in employing a mechanic who, with a small outfit of tools and a helper, can keep the trucks clean and in adjustment and make many of the smaller repairs. Reliable service garages are now to be found which will do the same work for a reasonable charge, and this is more satisfactory than to leave it to the driver.

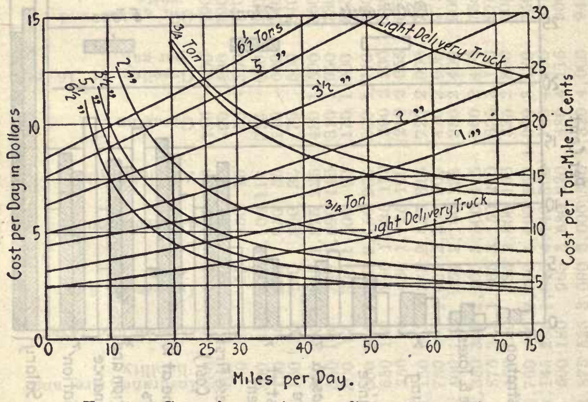

FIG. 7.—Cost of operating gasoline motor trucks.

Operating costs for the same make and capacity of truck engaged in exactly the same kind of work for one firm will frequently show a variation of 40 per cent in the items of gasoline, oil, tires and maintenance. It is easy to see how a poor driver will shorten the life of a truck.

The truck governor has helped to solve the speeding problem. Another aid is the recording speedometer, which gives a graphical log of each day's run—velocity plotted against time: thus every minute of the day is accounted for; the number of stops and time of each, maximum speed, etc. The chart will show, for example, whether it will pay to put on a second man to hasten deliveries or whether a rerouting of existing lines will give a better all-around service. A driver's record sheet, if it is brief and informing and filled out each day, is frequently helpful. It must be drawn off at the office and kept up to date. Records are of little use unless changed conditions can be recognized at once.

Fig. 7 gives curves for gasoline trucks plotted from the data of Table XII. These curves, if continued out to the line of zero miles per day, show the daily fixed charges for each truck. The cost per day increases quite uniformly with the increase in size of the truck, whether the daily run be a large or a small one. The cost per ton mile is based on a full load each way. This chart shows that under such favorable conditions of haulage a heavy truck may reach a ton-mile cost of as low as 5 ct., provided that the nature of the work is such that the truck can be run daily at the rate of 50 or 60 miles a day. This is a heavy mileage for a big truck, and such an ideal service as would be represented by a full haul each way on level roads, with loading and unloading time minimized so that the truck could be under way for six or seven hours each day and with no extra helper required, is not often found.

In deciding upon a truck one of the most important questions to settle is that of size. On the good roads of this section (California) it is more disastrous to buy a truck too large for the work than to buy one that is too small. A 5-ton truck costs some 25 per cent more to operate than a 3-ton machine, nor is this cost reduced very much by taking a lighter load on the heavier truck. Interest, depreciation, maintenance, taxes, insurance and fuel—all are higher. Until very recently the tendency has been for owners to buy trucks too large for their needs. Now the buyers have commenced to realize that it costs too much to "deliver the vehicle."

The writer does not wish to encourage overloading, which has been responsible for many truck failures and against which much has been written, but he does wish to point out that an occasional overload of 25 per cent, or even 50 per cent when handled carefully on a good road is not a serious matter. while to haul a heavy truck day after day, loaded at half capacity, is a very serious matter if one would haul cheaply.

Methods of Reducing Trucking Costs.—To get a low cost per ton it is necessary to keep the truck moving. Devices which cut down the time of loading and unloading are very important. Among these are self-dumping bodies of various kinds for stone, hot asphalt or lumber; loading chutes or bins which are filled by elevator or conveyor; there is also a movable steel tipple which can be run alongside a train of flat cars and be filled by shovelers while the truck is out on the road, so that the actual time required to fill the truck is very little. Another device is the use of extra truck bodies, which are loaded while the truck is on the road and swung onto the truck by an air lift or other hoist. A firm of wholesale grocers in Los Angeles is using this method very satisfactorily. In interurban delivery service loading nests or cartridges are being used. These are filled in the store and run out onto the truck. There is some promise in the extension of this device for relieving the congestion around freight stations and also for interurban service where a heavy truck can bring over all of the orders for an entire community and local deliveries be taken care of by light trucks, each with its especial cartridge. A scheme somewhat similar to this is now being tried out by the city of Los Angeles. The incombustible rubbish is gathered by a house-to-house collection, using wagons. The material is put in large cans which are carried to a central point and a heavy truck is used to haul all of the cans to the city dump.

Comparisons of Operating Costs of Horse-Drawn and Motor Trucks.—The use of an extra man to facilitate deliveries will often save enough time to make a good investment. One of the large department stores in Los Angeles found that on a certain route where one man had averaged 110 stops a day two men were able to make 190 deliveries. The use of self-starters on trucks of this type is also becoming common. These save a little time on each stop and also keep the driver out of the dirt, and particular customers appreciate this feature. At the plant of the Southern California Gas Company the night man unloads the trucks and stores the pipe and old meters that have been collected during the day, and then puts onto the truck the new supplies that have been requisitioned for the coming day.

Fig. 8 and Table XIII show a comparison between the cost of running a light gasoline delivery truck such as is used for close-in delivery work by grocers and the cost of running a one-horse delivery wagon. The costs are

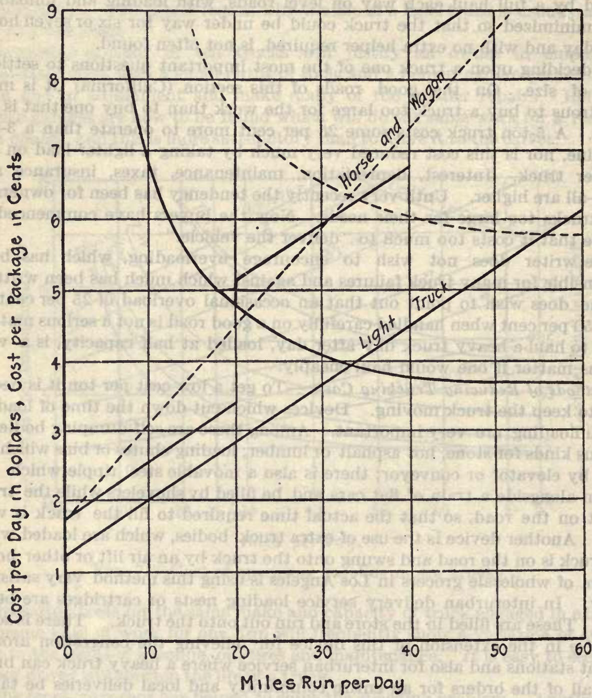

FIG. 8.—Comparison of single horse and wagon and light delivery truck costs.

from actual costs gathered in Los Angeles and vicinity and averaged. For each vehicle the cost is figured for the vehicle idle and again when running at a fair maximum daily average. The figures show that there is no excuse for using a horse for this kind of work, whether the number of deliveries be large or small. Twenty miles a day is a maximum for any delivery horse if used 300 days a year. If more than 20 miles a day are to be covered, it is necessary to duplicate equipment.

Fig. 9 and Table XIV give a similar comparison between the cost of operating a 5-ton gasoline truck and heavy teams used for such work as rock and dirt haulage and heavy transfer work generally. As in Fig. 9, the costs are figured from actual costs based on a maximum of service per day and an assumption as to what the costs would be if the vehicle did no work. The curves show that the truck should have enough work to do to occupy the time of more than one team, if it is to be the cheaper vehicle. The Pacific Electric Railway Co. uses heavy trucks for patching and paving along the line. They find that for work outside the business district the truck will do the work of two or three teams, depending upon the length of haul and the size of the job; for long-distance hauling the truck will do the work of four or five teams.

In paving Vernon Ave. the rock and crushed stone were delivered by teams, the average haul being about two miles. Each team delivered a 3-ton load

TABLE XIII.—COMPARISON OF OPERATING COSTS OF A SINGLE-HORSE WAGON AND A LIGHT DELIVERY TRUCK

Cost of wagon equipment (horse, $250; wagon, $140; harness, $40), $430.
Cost of 700-lb. capacity gasoline truck, $600.

Total cost { Per day	$2.45	$6.70	$3.46	$15.81

and averaged 5½ trips per day. When work on other contracts took the teams away the work was sublet to another contractor, who took the job at the same price per ton as the teams were figured to have cost. Three 5-ton trucks averaged 12 trips per day eaeh, and carried an average of 54.7 tons per day apiece. This makes each truck equivalent to 3.3 teams, which would represent a considerable saving by the use of trucks, provided they could be kept steadily employed.

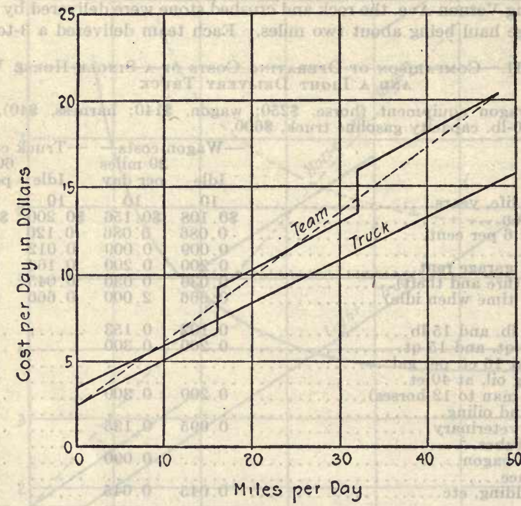

FIG. 9.—Comparison of costs for 5-ton gasoline truck and heavy teams.

The use of electric trucks for delivery service is not so general in Los Angeles as in most large cities. Two of the largest department stores in Los Angeles use no electrics, and other stores which do use them have usually a smaller percentage of the entire fleet of this type. There are two reasons for this: First, a smaller congested area than cities like Boston or Chicago; and, second, a smaller number of stops per mile. For light delivery service where the vehicles carry 1,000 lb. or less the higher first cost of the electrics is a serious objection; for vehicles in the 1,500-lb. class the difference in first cost is not so great, and the electric vehicle will show a lower cost per delivery than the gasoline truck where the latter is held down to the same number of miles per day. Table XV gives the average work and costs for one month for both classes of vehicles for one of the large department stores in Los Angeles. From

TABLE XV.—COMPARISON OF GASOLINE AND ELECTRIC DELIVERY TRUCKS (Averages for 1 month)

Type of truck	Gasoline	Electric
Miles traveled per day	75	36
Stops per mile	1.96	2.74
Stops per day	147	104
Cost per mile, cents	12	15.3
Cost per stop, cents	6.12	5.29

this it will be seen that, where the electric truck gives a cheaper delivery, it has the advantage of more stops per mile. It is probable that in spite of the close-in traffic conditions the gasoline truck would cover the same route in less time or give a larger number of deliveries per day in the same territory. These costs are based on the use of two men with the gasoline truck and one man on the electric. The comparison shows that the advantage in favor of the electric truck is a very small one, and may vanish altogether under comparative tests. On the other hand, there is an advantage for the electric in its quieter operation and greater cleanliness that is worth something in delivery service.

Operating Cost of 5-Ton Dump Truck (Engineering and Contracting, Aug. 6, 1919).—As the result of a questionnaire the Motor Truck Owners' Association of Philadelphia ascertained that the average daily cost of operation for a 5-ton truck of dump body type working under (1919) Philadelphia conditions was $26.09, itemized as follows:

	Per day	Per cent
Depreciation	$ 5.29	20.3
Interest	0.76	2.9
Insurance	1.25	4.8
License	0.11	0.4
Gasoline	3.42	13.1
Oil and grease	0.42	1.6
Repairs	5.11	19.6
Garage fees	0.74	2.8
Overhead expense	1.74	6.7
Driver	4.96	19.0
Tires	2.29	8.8
Total	$26.09	100.0

It also was found out that the fixed charge costs should be based on a 265-day year, and that the average daily mileage was 40½ miles.

Operating Costs of Motor Truck Delivering Sand and Gravel (Engineering and Contracting, March 21, 1917).—A Pacific Coast sand and gravel company is using a 5-ton truck for delivering sand and gravel. The material is nearly always mixed and usually is quite wet. It runs 4 yds. to the load and 3,400 lbs. to the yard, and is hauled over country roads of various kinds, about equally divided between gravel and dirt. There are many hills, some of them quite steep, necessitating going in first and second gears. Most of the trucking was for delivering gravel on county roads, and spreading it with the attachment on the truck. The operating costs, furnished by the company for a 5-months period are given in Table XVI.

TABLE XVI.—OPERATING COSTS, 5-TON TRUCK, 4-YARD CAPACITY

Article used	Amount gal	Miles per gal. or lb.	Av cost article	Total cost	Cost per mile
Distillate	1 655	3.494	11†	$ 182.05	$0.0153

For the Season

Average distance of delivery, miles	6.1
Cost per yard mile	$0.1055
Cost per ton mile	.0617
Total mileage	7,900
Yards delivered	5,190
Weight of gravel, 1 yd., lb	3,400
Yard miles hauled	15,800
Ton miles hauled	28,835

The truck was new last year. The driver was paid for an extra hour each day the truck was operated. This extra time he put in screwing down the grease cups and inspecting parts on the truck. The driver was, therefore, held responsible for anything happening that could have been prevented by his inspection. In several instances he discovered that there was a loose nut, missing bolt, cup gone or something of minor importance, which if neglected might cause lost time and more or less expense. These things were immediately attended to and as a consequence no time was lost on account of truck trouble.

Cost of Hauling with Motor Trucks.—The following figures, given by J. A. Broad, Luce County Engineer, in a paper presented at the Michigan Road School (1919). are published in Engineering and Contracting, April 2, 1919.

The cost of hauling with motor trucks in highway work in 1918 in Luce County, Michigan, averaged about 10 ct. per ton mile. Two 5-ton White trucks were employed. The interest on the truck investment was taken at 6 per cent per year and amounted to $288 for each truck. There was no insurance.

The charges for Truck No. 1 were as follows:

Depreciation 100,000 miles (truck value minus tires)	$ 255.16
Total wages of driver	319.74
Gasoline, 1,377 gal. at 25 ct	344.25
Lubricating oil, 117 gal. at 56 ct	65.52
Hard oil, 128.5 lb. at 6 ct	7.71
Waste, 20 lb. at 20 ct	4.00
Tire depreciation—5,316 miles at 3 ct	159.48
Repairs and renewals	160.00
Total operating charges	$1,315.86
Fixed charges (interest)	288.00
	$1,603.86
Average haul in miles	5.54
No. of yds. hauled	1.863
Total number of yd. miles performed, 10,321	$0.155 yd. mile
Total number of ton miles performed, 15,481	0.104 ton mile

The charges for Truck No. 2 were:

Depreciation 100,000 miles (truck value minus tires)	$ 237.40
Total wages paid driver	297.00
Gasoline, 1,235 gal. at 25 ct	308.75
Lubricating oils, 117 gal. at 65 ct	68.88
Hard oils, 128.5 lb. at 6 ct	4.08
Waste, 21.5 lb. at 20 ct	4.30
Tire depreciation, 4,946 miles at 3 ct	148.38
Repairs and renewals	131.00
Total operating charges	$1,199.79
Fixed charges (interest)	288.00
	$1,487.79
Average haul in miles	5.54
No. of yards hauled	1.780
Total number of yd. miles performed, 9,861	$0.151 yd. mile
Total number of ton miles performed, 14,791	0.101 ton mile

Operating Costs for 3½-Ton Truck (Engineering and Contracting, Aug. 6, 1919).—In an address before the Detroit Transportation Association, C. E. Stone gave the following figures taken from the cost records of a Detroit owner for the operation of a 3½-ton stake body truck:

INVESTMENT		
Chassis		$3,800.00
Body		350.00
		$4,150.00
Less tires ($74.25 each, 7,000 miles guaranteed)		445.50
		$3,704.50
Costs are based upon 300 working days in the year		
YEARLY FIXED CHARGES—		
Interest on $3,704.50 at 6 %	$	222.27
Insurance—		
Fire, 75 ct. per hundred		31.13
Collision, full coverage $152, $50 deductible		102.00
Liability (truckman)		135.00
License—		
15 ct. per horsepower (4½ × 5½ − 32.4)		4.86
Weight, 15 ct. per 100 lb., chassis 7,000 lb., body 1,800 lb., total 8,800 lb		13.20
City dray		1.00
Tax 3 % on 70 % of $4,150 ($2,905)		87.15
Garage, $15 per month		180.00
Driver, $5 per day (300 days)		1,500.00
Per year		$2,276.61
300 days $2,276.61, per day cost		$7.58
OPERATING COSTS—		
Fuel (25 ct. per gal., six miles per gal.) per mile	$	0.040
Lubricants (60 ct. gal., 150 miles per gal.) per mile		.004
Tires (7,000 miles set, $445.50) per mile		.064
Depreciation ($3,704.50 on 100,000 miles) per mile		.037
Per mile	$	0.145
Overhauling ($300 per year) per day		1.00
60 miles per day at .145		8.70
Total daily cost	$	17.28
Per ton mile cost	$	0.288

It will be noted that the above figures contain no allowance for the "cost of doing business," which includes general expenses, accidents, bad accounts, etc. To meet these charges this owner charges up $1 a day per truck which he finds about meets the figures. He also has a general sinking fund of 10 per cent of the daily gross receipts of each truck to take care of this matter.

Economic Motor Trucking over very Bad Roads (Engineering and Contracting, Dec. 20, 1916).—The Haskins Dolomite Co., of San Francisco, operates a 5-ton White truck with a Troy trailer from their dolomite quarry to the railway a distance of 10.5 miles, and the truck makes four round trips every 24 hrs., working two shifts. The road is one of the worst of mountain roads, full of chuck holes, covered with dust often 6 ins. deep, with grades up to 10 per cent, one of which (10 per cent) is 1.5 miles long. The truck requires 44 gals. of gasoline and 4 gals, of oil for the day's work of 84 miles. The daily operating expense is about $30, which is equivalent to 7 ct. per ton-mile, exclusive of interest and depreciation, but inclusive of tire renewals and current repairs.

Trailers for Use with Contractors' Motor Trucks.—According to Engineering and Contracting, Dec. 3, 1913, extensive experiments, made by the Troy

Wagon Works Co. in studying the problem of the ability of motor trucks to pull one or more trailers, show that the average truck loaded to its rated capacity, in addition to carrying its rated load, develops a drawbar pull equal to about one-half of its rated load. A team of horses will develop a maximum sustained drawbar pull equal to about one-fourth of their weight. It was estimated from the tests that the drawbar pull required to move a ton of material varies from 50 lbs. on a brick street to 150 lbs. on a hard surfaced country road, no grades of consequence considered. Further variations are in proportion to grades, road conditions, etc. On average roads with average

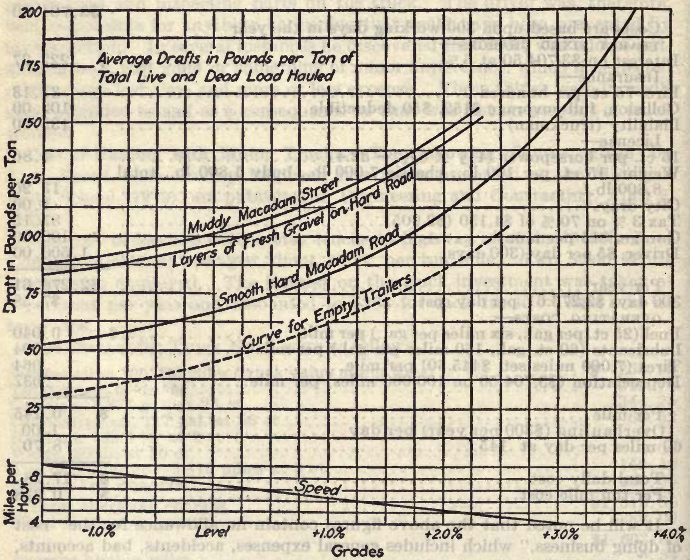

FIG. 10.—Draft per ton curves for various road conditions.

grades the drawbar pull required is about 250 lbs. per ton of live load moved on a properly constructed vehicle. This was another conclusion drawn from the tests. On this basis an average 3-ton truck will pull 10 tons live load in addition to the rated load on the truck proper, in other words the drawbar pull of the average 3-ton truck equals that of three 3,000-pound teams.

Fig. 10 shows "draft per ton curves for various road conditions" from actual tests. In order to take care of possible conditions not obtained in the actual tests, the per ton drawbar pull given in the paragraph above is placed considerably in excess of that shown by the tests.

The Troy Wagon Works Co. decided from the results of their tests that an average motor truck could develop the tractive power necessary to pull one or more loaded trailers. In the tests, in order to keep the motor truck from being delayed the trailer plant was three times the number being pulled, ⅓ of the plant at the loading point, ⅓ in transit and ⅓ being unloaded.

Table XVII shows the results of actual tests in tons delivered, comparing teams with motor alone, with motor hauling one trailer and motor hauling two trailers. In connection with Fig. 11, Table XVIII indicates ton-mile cost for various outfits and shows considerable economy by the use of trailers.

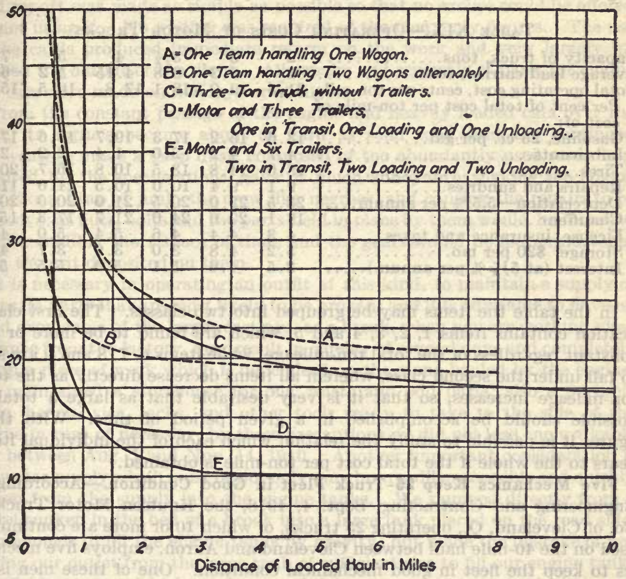

FIG. 11.—Curves showing comparative ton-mile costs for various outfits.

TABLE XVII.—DAILY TONNAGE DELIVERED

Length of haul	One team One wagon	Motor alone	Motor hauling one trailer	Motor hauling two trailers
½ mile	27	42	160	280
1 mile	18	36	140	260
2 miles	12	30	85	160
3 miles	9	21	60	110
4 miles	6	18	50	100
5 miles	6	18	35	70

TABLE XVIII.—COMPARATIVE TON-MILE COSTS

Distance of loaded haul in mines	One team One wagon	Motor hauling: Motor alone	One trailer	Two trailers
½	$0.444	$0.480	$0.210	$0.258
1	0.319	0.319	0.154	0.167
2	0.256	0.240	0.143	0.118
4	0.221	0.200	0.137	0.106
6	0.214	0.186	0.135	0.104
8	0.209	0.179	0.134	0.103
10	.....	0.176	0.134	0.103

Distribution of Average Operating Costs of Gasoline Trucks.—Table XIX, given by Ralph W. Horne in Engineering News-Record, Sept. 20, 1917, is prepared from data collected on the cost of motor-truck operation covering periods of from one to several years, and it is believed that all factors which might be affected by seasonal variations are properly averaged.

TABLE XIX.—OPERATING COSTS OF MOTOR TRUCKS

Capacity of truck, tons	2	3	3½	4	5	7
Average load carried, tons	2	3.3	3.8	4.15	5.2	6.5
Total operating cost, cents per ton-mile	21.5	19.0	18.1	17.8	16.5	15.0
Per cent of total cost per ton-mile of cost of:						
1 Gasoline, 25 ct. per gal	13.6	15.2	17.3	19.7	18.6	17.0
2 Lubricants	4.7	4.2	2.0	1.4	2.2	2.2
3 Tires	18.0	14.8	13.5	10.8	16.7	20.2
4 Repairs and sundries	9.1	9.4	10.0	10.5	11.0	11.1
5 Depreciation—5.5 % per annum	23.5	22.0	20.5	21.0	20.0	20.0
6 Chauffeur	18.1	20.6	24.0	21.7	17.3	15.4
7 License, insurance and taxes	4.3	4.4	4.6	5.4	5.0	4.8
8 Storage, $20 per mo	5.2	4.8	3.0	3.6	3.7	4.0
9 Interest (at 5½ % per annum)	3.5	4.6	5.1	5.9	5.5	5.3

In the table the items may be grouped into two classes. The first classification contains items 1, 2, 3, 4 and 5, which are found to be more or less constant regardless of the total ton-mileage; while items 6, 7, 8 and 9 are seen to fall under the second class, wherein all items decrease directly as the total ton-mileage increases, so that it is very desirable that as large a total as possible should be accomplished in a given period of time. With these figures it is possible to study the relation which each of the individual items bears to the whole if the total cost per ton-mile is obtained.

Five Mechanics Keep 25-Truck Fleet in Good Condition.—According to Engineering and Contracting, Sept. 4, 1918, the Knutsen Motor Trucking Co. of Cleveland, O., operating 25 trucks, of which 10 or more are continually used on the 40-mile haul between Cleveland and Akron, employs five mechanics to keep the fleet in good mechanical condition. One of these men is an expert capable of supervising all kinds of truck repair work, while the other four men are less skilled. The expert and three of the men work at the Cleveland repair shop and warehouse during the day. The other man is kept on duty at night to fix any emergency troubles that might arise, as the company operates a night service between Cleveland and Akron during the summer.

Cost of hauling stone with a 22-h.p. traction engine and stone spreading cars is given by John F. Hammond in Engineering and Contracting, March 27, 1912.

In building the Gatchellville Road, York County, Pa., 14,000 tons of 2-in. stone were required. Because of grades, team hauling was exceedingly expensive and slow, as a team of average weight usually found among the farmers could not move over two tons per day, for a wage of $3.50 or $1.75 per ton. An expert from a prominent traction engine company, who was called in and driven over the route, expressed himself as very doubtful if we could succeed with a traction engine, as the grades on the pitches of some of the hills were 30 per cent, and the traction surface was of a soapy clay nature. He advised us to begin our work at the southerly end beyond New Park and work over the finished road with the traction outfit; this course was finally adopted. The grades of the finished road were approximately 7 per cent on some of the hills for a considerable distance. The records on which this article is based were started on Aug. 1, 1910, after 2 miles, one-half of the road, had been built, and continued up to Nov. 14, 1910, when the road was completed. These records were kept as a means of information and to promote efficiency by compelling daily report of the materials used, wages paid and work done. The card report was made as simple as possible so that no excuse could be offered for not using it. No writing was required of the men, only figures. The use of the cards produced immediate reform on the work and very largely increased the output of the plant. All repairs and renewals of parts for engine and cars were made on holidays or at night.

From the constant passage of the engine and heavily loaded cars over the road, its surface became about as hard as solid rock, and the continued dry weather made a deep dust, composed of too abundantly used screenings required by the specifications, gave us much annoyance, making the engine look like a heap of junk, the crew like negroes, and causing the repairs to be excessive; as nuts, bolts and the parts held in place by them would be loosened in an incredibly short space of time, and the gears would be like grindstones from the grit deposited on them.

It is necessary in operating an outfit af this kind, to maintain a supply of the extra parts that are most likely to be broken; and it is advisable to have on hand even some of the larger castings, as a break, when you are working some distance from the factory, may result in a delay of several days and completely tie up a piece of work which is dependent on the stone hauled by the engine. We maintained a storehouse for oils, waste and odd parts; also a portable forge, bench, vice, jacks, and other tools ready to take to the side of the engine in case of necessity; by these precautions we did not lose one workable day between Aug. 1 and Nov. 14, 1910. Another important consideration is the water supply which must be not only pure but readily accessible and quickly gotten from the supply into the engine tanks. We pumped directly from a barrel sunken in the bed of a brook into a large tank placed on the road side, high enough to fill the engine tanks by gravity; but made the mistake of not having our outlet from the large tank of sufficient size to fill our engine tanks as quickly as we might have done, and delays occured at the tank that were needless and anoying. Water was pumped into the supply tank by a small one-cylinder gasoline pump which operated very cheaply, and only required the services of the engine driver to start and stop it as he passed on his trips. The wages paid to the engine crew was; Engineer, \$3.50 per day; fireman, \$1.75 per day, steady time for ten hours daily; overtime at same hourly rate. The fireman operated the stone spreadnig cars, making the spread of even thickness, which requires considerable experience and should be closely watched by the overseer as the tendency is to spread too deeply, and superfluous stone would have to be removed at an extra expense. Supervision in our case was figured at one-third of the superintendent's time, or \$2.28 per day with no extra time allowance. Interest and depreciation are figured on the new value of the machinery—\$5,050 on June 1, 1909, and on an estimated life of four years, or 25 per cent depreciation per year, with an interest charge on the capital invested of 5 per cent. The sum of the interest and depreciation, however, are figured for the whole year and divided into the days that we actually worked. This is hardly fair to the machine, as it might have done more days' work and thus reduced this item. The life of the machine is also very conservative, and probably should be eight to twelve years instead of four years.

The following tabulations show our conclusions and we think may be considered quite accurate. I have not thought it necessary to make an analysis of the repair account, which consisted of castings, bolts, nuts, valves, pipe elbows, engineer's and fireman's time and many small items:

Total Cost of Operation—93 days.

Operating	$ 945.67
Repairs	310.17
Depreciation and interest	686.15
Supervision	239.40
Total	$2,181.39

Analysis of Operating Account.

4.70 tons coal at $4.50	$ 21.15
3.49 tons coal at $5	17.45
913.4 tons coal at $3.26	297.77
Water	66.27
67 gal. cylinder oil at 30 cts	20.10
30½ gals. black oil at 9½ cts	2.94
333½ lbs. grease at 5½ cts	18.77
71 lbs. of waste at 7½ cts	5.35
Engineer's wages on operation	330.41
Fireman's wages on operation	164.83
3½ gals. kerosene at 10 cts	.35
1 can of tar at 28 cts	.28
Total	$ 945.67

Daily Expense.

Supervision wages	$ 2.28
Engineer's wages	3.50
Fireman's wages	1.75
Coal	3.55
Cylinder oil	.21
Black oil (gears)	.03
Grease (cups and gears)	.20
Kerosene	.003
Tar	.002
Waste	.06
Depreciation	6.417
Interest	0.961
Repairs	3.33
Total	$22.293

Tonnage Hauled.

August 1, 1910	1,681
Sept. 1, 1910	1,525
Oct. 1, 1910	1,176
Nov. 14, 1910	284
Total tons	4,666

Cost Per Ton Hauled.

Operation	$\frac{945.67}{4,666}$	$ 0.202
Repair	$\frac{310.17}{4,666}$	0.066
Depreciation	$\frac{596.78}{4,666}$	0.128
Interest	$\frac{89.37}{4,666}$	0.017
Supervision	$\frac{239.40}{4,666}$	0.051

Total.......$0.464 or 6.4 cts. per ton mile.

Extreme haul, 9.44 miles. Start, 5.00 miles.

Average length of haul, 7.22 miles round trip. 2.24 trips daily; 209 trips, or 1,508.98 miles in 93 days.

Costs of Industrial Railway in Road Building.—The following matter, given by R. P. Mason in a paper presented before the Road School of the University of Michigan (March 1919), is published in Engineering and Contracting, March 5, 1919.

The conditions necessary for the successful operation of an industrial railway in highway construction are as follows:

First fairly level country. We haul 30 car trains over grades up to 3 per cent and have worked over a 1,000-ft. hill of 5.1 per cent by cutting the train in three parts at the foot; in other cases we have used a roller to tow up, but many such hills would make it out of the question. If the hills were not too frequent other power could be provided.

Second, sufficient and continuous supply of material. As such an outfit will handle a large daily volume (at 8 trips per day 300 yd.) and as it requires a considerable crew to keep the work moving, it will not pay if there is much delay in the delivery of road material, or if the loading facilities are inadequate. I am considering the question of stock piling some matreial in order to keep going when deliveries are delayed, but this presents the further problem of loading from the stock pile. Our loader could not be utilized and another rig would have to be provided.

Third, a considerable mileage to be constructed from one set-up to avoid the expense of numerous moves. We figure on at least 8 miles at one set-up 4 miles each way. If the road is continuous and the move is only from the end of a completed section to a point 4 miles beyond, the moving cost will be a completed section to a point 4 miles beyond, the moving cost will be a minimum, but if the outfit has to be moved to a distance, the cost is heavy. Our maximum haul so far has been 4 miles as we have been fortunate in having our work along the railroad with frequent stations. Our outfit consists of a 30-HP. locomotive with underslung tank, 60 1½-yd. side dump steel cars, 1 tracklaying car, 1 hand car and 4 miles of 24-in. gage portable track with curves and switches. The track is 30-ft. rail made up in 15-ft. sections with 7 steel ties to the section.

The outfit cost about $16,000. We depreciate 10 per cent on all the machinery, but only 5 per cent on the track as, at the end of 10 years the salvage value will be at least half the first cost. It is also evident that there will be considerable value in the rest of the outfit at the end of the 10-year period. It is now 5 years old and practically as good as new.

Tracklaying is one of the large items in operating and this will vary considerably according to the character of the soil. In swamp sections where the shoulders have not much stability it is necessary to shim up frequently to keep the track in safe condition, but on a firm soil such as sand or gravel, it does not need much attention after laying. Our cost has varied from $100 to $150 per mile, with an average of about $132.

When the outfit is also used for grading it cuts the tracklaying cost as the track is then in position for the stone work. During a move and while the macadam work is on the short haul, some of the cars and track can be spared for grading without delaying the other work, using a team to haul the train. Especially in soft sections it is very useful and in heavy cuts, working with a small shovel it shows great economy. The fact that the outfit has to be there anyway should be considered as it involves no transportation to and from the job.

Hauling 30 car trains and loading one while the other is making a trip, should admit of an average of 10 trips per day on a haul up to 4 miles—2 miles average haul—and we have made this at times, but various delays, principally in the delivery of stone, have combined to cut the average down to 8 trips. I think the train should average 6 trips on a haul up to 8 miles as the delays in unloading and at the loader would be less and it would only mean an average of 48 miles per day actual running. At this rate, hauling 47 tons per trip would equal 282 tons per day. Speed of train is 8 to 10 miles per hour and time of unloading 10 to 15 minutes. Time of loading is about ½ hour, but of course this does not delay the train. At times when our stone supply was sufficient we have averaged over 400 yd. per day, or at the rate of a mile of road built in 6 days.

The following costs are an average of 3 years, 1914, 1915 and 1916, and cover about 20 miles of 16-ft. macadam construction:

	Per cu. yd.
Tracklaying	$0.055
Engineer	.025
Brakeman	.013
Watchman	.010
Fuel	.010
Oil, grease and waste	.002
Repairs	.015
Moving	.025
Total operating	$0.155
Depreciation	.055
Interest	.035
Total hauling	$0.245
Cost per yard mile	$0.1225
Cost per ton mile	$0.098

Delivering the stone on the road as above affords an opportunity of keeping the other construction costs at a minimum. Loading with an elevator is about the cheapest method and spreading the stone with a road machine is cheaper than by hand and planes the road at the same time, avoiding minor inequalities which so often occur. Rollers and sprinklers are kept up to their full capacity.

The other costs of the macadam construction follow:

	Per cu. yd.
Loading	$0.070
Spreading	.160
Sprinkling	.065
Rolling	.021
	$0.505
Hauling as above	.245
Total	$0.750

Portable Railways for Hauling Materials for Road Construction. — The following information concerning the method and cost of operating a portable railway on road construction near Lockport, N. Y. is given by Orenstein-Arthur Koppel Co., in Engineering and Contracting, March 14, 1914.

The equipment consisted of about four miles of narrow-gage portable track, 40 36 × 24-in. dump cars and two 5-ton dinky locomotives. The cars were hauled in trains of 12 cars each, the arrangement being so made that there was always one train of loaded cars on the way to the site of the work, one train of empties returning for material and one train of cars being loaded.

The cars were loaded from over-head bins at the crusher and the average amount transported was 80 cu. yds. per day.

Item—	Amount	Per cu. yd.
Materials:		
Fuel and oil for locomotives and cars	$ 8.00	$0.100
Labor:		
2 engineers at $2.75	5.50	0.069
2 brakemen at $1.75	3.50	0.044
1 track foreman at $3	3.00	0.037
1 track laborer at $1.75	1.75	0.022
Totals	$21.75	$0.272

As the material was hauled three miles the unit cost was 9 cts. per cubic yard per mile. The average cost of grading the shoulder or berm of the road ready for track laying and laying track was between 2 and 3 cts. per foot of track.

CHAPTER IV

EXCAVATION ECONOMICS

The matter included in this chapter deals with the economics of excavation and does not give costs for particular kinds of work. As most construction work requires excavation at some stage, by referring to the index, under excavation, itemized costs of many different kinds of work may be found.

For further data, on cost of excavation, the reader is referred to Gillette's "Earthwork and Its Cost," Handbook of Rock Excavation" and "Handbook of Clearing and Grubbing."

Rating Table for Excavation with Pick and Shovel.—L. K. Sherman gives the following data in Engineering and Contracting, May 27, 1914.

The accompanying diagram and tables represent the amount of excavation of various materials which will be performed in a ten-hour day by the average laborer working under good supervision. In making this compilation the writer has compared a large number of data from many sources with figures obtained in his own experience on construction. As might be expected there is wide divergence in such published data.

The curves in the diagram based on a rational relation of one class of material to another as regards the amount of work or power required in picking or shovel cutting and the power required in casting up materials of different weights. The output of excavation is proportional to the amount of power or work required to move a cubic yard of the material. Let the amount of work or power to cut into and fill the shovel with sand be called unity. Then for other materials the relative power to cut out and place on the shovel will from experience be as in Table I.

TABLE I.—POWER TO PICK, LOOSEN AND CUT ONTO SHOVEL

Sand	P = 1.0
Gravel, loose	P = 1.5
Earth, medium	P = 2.0
Clay, light	P = 3.0
Clay, dry, hard	P = 4.5
Clay, wet, heavy	P = 5.0
Hard pan	P = 6.0

The work or power to lift or cast up the material after the shovel is filled is proportional to the weight of material and height cost or which is the same, the depth of cut. Then if W is the weight, the relative power to cast up material to different heights H will be as follows:

Sand	W H where W = 1.0
Gravel	W H where W = 1 0
Earth, medium	W H where W = 0.8
Clay, light	W H where W = 1.1
Clay, dry	W H where W = 1.1
Clay, wet	W H where W = 1.3
Hard pan	W H where W = 1.12

The total power to shovel and cast any material is $P + WH$. The output is inversely proportional to the power or work required. The output of any material by hand excavation in cubic yards per man per 10 hours is

$$\text{Cubic yards} = \frac{30}{P + .3WH}$$

The constants 30 and .3 are empirical and like the relative values of P have been selected to correspond with the best data available on excavation of various materials at different depths of cut.

The curves in the diagram Fig. 1 are platted according to the above formula with coefficients P and W as previously noted. The letters represent observations from various published statements and are not equally reliable or comparable. The curves do not attempt to average the data but correspond with the writer's experience and some of the most definite of the published data. Table II shows the number of cubic yards an average laborer should excavate and cast out, at various depths in ten hours while working at the depths stated. Table III shows the average number of cubic yards per 10-hour day than an average laborer should excavate working from the surface to the depth stated. This figure for the same material is naturally somewhat greater than given in Table II. These figures may be increased by 30 per cent for rapid workers and may be decreased 30 per cent for inefficient workmen. The foregoing material may be now definitely classified as follows:

Sand.—Weight, 3,000 lbs. per cubic yard slightly damp. In natural bed. Not over 15 per cent clay.

Gravel.—Weight, 3,000 lbs. per cubic yard. Loose, as excavated material.

Earth.—Weight, 2,400 lbs. per cubic yard. Slightly damp, in natural bed, easily plowed, little or no pick work required. Would require some sheeting in trenches over 6 ft. deep.

Clay (light).—Weight, 3,300 lbs. per cubic yard. Slightly damp, easily plowed. Not stiff or very cohesive, corresponds to yellow clay lying below the black soil and above the blue clay in vicinity of Chicago. Would require some sheeting in trenches over 6 ft. deep. Little pick work required.

Clay (dry, hard).—Weight, 3,300 lbs. per cubic yard. Requires pick work equal to one-third time spent in shoveling and casting. No sheeting required at any depth. Corresponds to material on top of ravines along the lake shore in Lake County, Ill. Hard plowing. Abode in this class.

Clay (wet).—Weight, 3,900 lbs. per cubic yard. Tough and cohesive, has to be cut out in pieces. Slightly sticky, would require substantial sheeting. Corresponds to the underlying "blue clay" of Chicago. Gumbo in this class.

Hard Pan.—Weight, 3,360 lbs. per cubic yard. Requires picking equal to one-half the time spent in shoveling and casting.

The use of the relative coefficient P is suggested as a simple and definite means of describing or designating any class of earth excavation.

The jog in the curves (Fig. 1) at depth of 9 ft. represents an allowance of $P = 1$ on account of extra labor of shovel cutting done to recasting from a platform. As a matter of fact no recasting may be done at the 9 ft. depth or even 14 ft. depth but the output per man will not be increased over the quantity shown by the diagram.

TABLE II.—CUBIC YARDS PER MAN PER 10 HOURS AT STATED DEPTHS

	0 ft. to 3 ft.	3 ft. to 5 ft.	5 ft. to 8 ft.	8 ft. to 10 ft.	10 ft. to 15 ft.

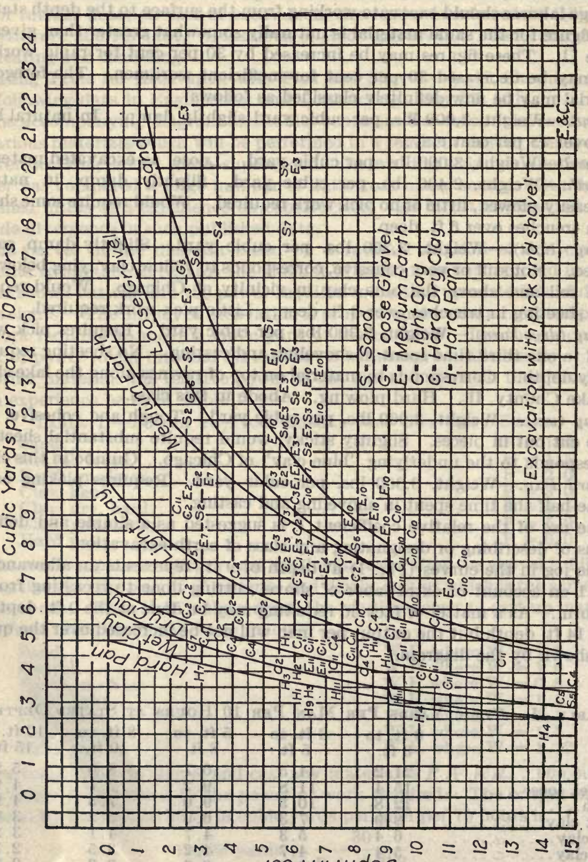

FIG. 1.—Excavation with pick and shovel.

The recorded data platted on Fig. 1 are designated by a letter for the class of material. The number following the letter refers to the source from which the data were obtained, as follows: (1) American Engineers' pocket Book; (2) Cost Data, Gillette; (3) Earth Work Cost, Gillette; (4) L. K. Sherman; (5) Windette. Journal West. Soc. Engrs.; (6) Concrete Costs, Taylor & Thompson; (7) Orrock; (8) Prelini; (9) Engineering and Contracting (December, 1908), Atlantic, Iowa, Sewers, M. A. Hall; Centerville, Ia., Sewers, M. A. Hall; (10) Engineering and Contracting; (11) Engineering and Contracting.

Application of Efficiency Engineering to Shoveling.—The following abstract of a paper, presented before the Feb. 1919 meeting of the A. I. M. E. at New York, by G. Townsend Harley is given in Engineering and Contracting, June 18, 1919.

At the mines of the Phelps Dodge Corporation at Tyrone, N. Mex., the cost of shoveling in all stopes during 1917 amounted to 24 ct. per ton. In the top-slice stopes for the same period shoveling cost 27 ct. per ton, or 16 per cent of the total cost of these stopes. The average wage per laborer shift was $2.67 during the year under review. The tonnage for shovelers from all stoping was 9.3 tons per man, and for top-slicing 8.2 tons per man per day. These stopes were not unduly hot, and there was not more than the usual amount of timber to interfere with the work of the men. The tonnages obtained per shoveler were considered low; first, because of a poor grade of Mexican labor, many of the men having come in from railroad-grading camps; and, second, because of a poor spacing of raises, especially in the top-slice stopes, where, in general, they were spaced 25 ft. by 66 ft. centers.

Preliminary Steps far Determining Shoveling Efficiency.—As a first step toward determining how the general efficiency of underground shoveling could be improved, several weeks were spent in a general survey of the field and making time studies on various men, to see what points would need to be determined for a full consideration of the subject. The following factors were soon recognized: The type, weight, size, and design of shovel giving the greatest shift tonnage without too much wear and tear on the man would have to be determined; a standard of comparison would be necessary if the ill effects of mine air, powder gas and smoke, temperature, humidity and poor light were to be estimated, and the layout and spacing of chutes would have to be studied with regard to their effect on shoveling directly into the chutes, or loading into wheelbarrows or cars and tramming to them. This latter work would determine the proper distance at which shoveling into a chute should cease and loading into a wheelbarrow or car would begin, and the information would also be of great value in planning the development of a stope. Further considerations were: Hindrances to work, such as timber standing in line of throw or closely spaced, and men and supplies passing back and forth through working space; manner of placing the shovelers to obtain maximum results from them, number of men in one working place, and size of working place required per man; the hours of actual work and the cause and amount of delays; capacity of a man for work as the day progresses; proper rest periods for men to maintain maximum efficiency; best means for instructing men and supervising work, and compensation received and manner of payment.

Three types of shovels were in general use at the mines: A No. 2 scoop, a No. 2 or No. 3 square-point D-handle shovel, and a No. 2 round-point long-handle shovel. In determining the average load that the various types and sizes of shovels would handle, so as to be able to decide the best load for the average Mexican laborer of the Southwest, average capacities were obtained by repeatedly shoveling a weighted pile of ore with each of the shovels and counting the number of shovel loads required to move it. It was determined that with Burro Mountain ore a specially made shovel with a 10 by 13-in. blade would hold a 21-lb. load, or 363 cu. in. In practice, however, a No. 4 square-point shovel holding 373 cu. in. and a No. 5 round-point shovel holding 340 cu. in. were used.

A time-study sheet was developed, which was used for all tests. In addition to the data placed on this sheet, an extensive log of the work was carried on, which undertook to explain, in detail, all delays, changes of work, rest periods, changes in conditions that would affect speed, high and low efficiency periods during the day, and other points to be considered.

Motion Studies Establish Standard Time and Performance of Structures.—During the period of preliminary work, it was discovered that the work of a shoveler can be classified into several divisions, each susceptible to comprehensive study and analysis, and to each of which a definite relative time value can be given.

These divisions, in general, may be classified into time spent actually shoveling, time spent other than shoveling, delays and resting periods. By studying each motion separately, it was possible to establish a standard time for each, and, consequently, a standard of performance for the whole. It was possible, also, to discover which were the most tiring motions and how each was affected by length of time worked, length and distribution of rest periods, size of shovel design of shovel, and length of throw.

To obtain some standard of comparison for the underground work, some of the mine shovelers were brought to the surface and a record of their work was made under ideal conditions; that is, with good air, good light, no timber to interfere, steady shoveling for various lengths of time and standard lengths of throw for the muck. In addition to obtaining the comparison standard, it was possible to form definite conclusions, which were later checked satisfactorily under actual conditions in the mine, as to the most advantageous size, type, weight, and design of shovels for general mine use, under the various conditions encountered.

Tests of Shoveling Performance.—Tests were carried on for two months, three different shovelers, taken from the mines, being observed. Each of these men was warned that he had to work at his best speed, all during the job, but that he was not to overtax himself. He was told that when he became tired he was to take a few moments' rest, as it was better for him to rest at intervals than to try to work all the time, at the expense of speed and capacity. Later the rest periods were regulated, to obtain the proper intervals at which they should occur, and their length.

All of the underground shoveling tests may be classified under one of three headings: Shoveling directly into chutes; shoveling into wheelbarrows and tramming to chutes, and shoveling into cars and tramming to chutes. Each of these series was conducted independently of the others, and was complete in itself. The men under observation worked for periods varying from 1 to 8 hours, and for each length of job they threw or trammed the muck over a wide range of distances, with various types and sizes of shovels. In all the underground tests, the work was done under the actual mining conditions, with the one exception that the men were always under observation, and, consequently, were working at a good speed for the full period of the test. In no case did the men overtax themselves, and it is believed that all tonnages recorded are easily obtainable by a good but not exceptional Mexican laborer after he had been properly instructed, and under close and intelligent supervision together with a wage paid in such a manner as to provide an adequate incentive to do good work.

It soon became evident that the great majority of shovels being tested were not suitable for efficient work, and only the work of the No. 4 shovel, which handles the 21-lb. load, together with that of the No. 2 scoop, which was held in high esteem by many of the men in the operating department was plotted on charts. The results obtained during the surface tests were plotted alongside of corresponding results from underground, to accentuate the adverse effects of underground conditions on shoveling capacity.

Effect of Type of Shovel and Length of Throw on Shoveling Speed.—The number of shovels per minute thrown into a chute at a distance of 8 ft. from the ore pile, for jobs varying in length from 1 to 8 hours, is greater with the No. 4 shovel than with the No. 2 scoop. Both on the surface and underground, the speed of shoveling decreases more rapidly with the scoop than with the shovel, as the length of the job increases. A man working with a scoop underground can perform at only 72 per cent at his speed on surface for 8 hours, whereas with a No. 4 shovel he can work at 82 per cent of his surface speed. The percentage reduction in speed between surface and underground work is the measure, in part, of the effect of mine air, powder gas and smoke, temperature, humidity, and poor light. Under the same condition of work, the difference in speed between the No. 4 shovel and the No. 2 scoop is due to the difference in the load handled.

The manner in which the length of throw will affect the speed of the shoveler was worked out for a uniform length of job of 6 hours and 12 minutes, and for varying distances. The decrease in shoveling speed on the surface amounted to an average of 2.5 per cent for every foot increase in distance thrown in the case of the scoop, and 1.8 per cent for the No. 4 shovel. Underground, the working speed was decreased more rapidly, being respectively 4.4 per cent and 3.2 per cent per foot increase in throw. The rate of decrease in shoveling speed, both on the surface and underground, was greater for the heavily loaded scoop than for the shovel.

In determining the amount of rest required for shoveling jobs of various lengths it was found that the scoop again has a negative effect both on surface and underground, causing a man to use up more time in resting than when working with a No. 4 shovel. The rest period, as considered, was made of the time consumed in delays, the time actually spent in resting, during which the man may smoke a cigarette and sit down for a few minutes, and the time used in loosening the muck pile, scraping up the dirt on the shoveling plat, or doing other light work, not actually shoveling, but closely related to it.

Determination of Actual Time Devoted to Shoveling.—Over a long period it was possible to demonstrate the feasibility of accurately determining the percentage of the working day that a man will actually devote to shoveling. The working day at the Burro Mountain mines is 8 hours, ½ hour of which is given up to the lunch period, leaving 7½ hours as the total possible working time. It was found that of this 7½ hours the man actually worked at shoveling for 82.5 per cent of the time. The remainder of the possible working time, or 17.5 per cent, is spent on other work, the man quitting early for lunch or leaving the mine or commencing to work late at beginning of the shift or after lunch. Observations of this character were gathered by some of the shift bosses, on several hundred-man shifts, and it is surprising how little the figures obtained by each have varied from the average finally obtained.

The average tonnage per hour to be expected of a man throwing the muck a distance of 8 ft. over any period of time is shown in Fig. 2. Experiments to determine the total tonnage shoveled for any period over the same distance showed that for a job lasting 5 hours and 30 minutes, with a No. 4 shovel underground, a man would be expected to shovel 26.0 tons a distance of 8 ft. Five representative tests actually gave the following tonnages under average conditions:

	Tonnage
Length of job 5 hours and 40 minutes	28.0
Length of job 5 hours and 10 minutes	23.0
Length of job 5 hours and 25 minutes	26.0
Length of job 5 hours and 50 minutes	34.0
Length of job 5 hours and 30 minutes	25.0
Average, 5 hours and 30 minutes, average	27.4

Comparison of Work Done with Scoop and by Shovel.—A careful study of Fig. 3 shows the following conditions: (1) The difference in tonnage handled by the same shovel, on the surface and underground, for any length of job, is the

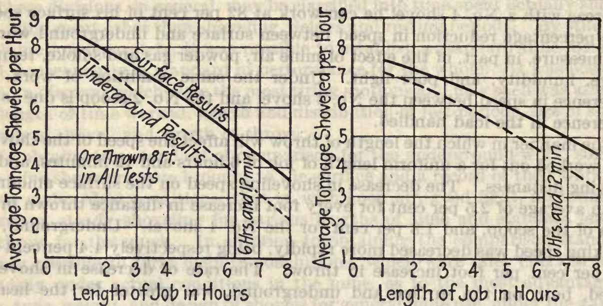

FIG. 2.—Average tonnage shoveled per hour.

measure of the bad effects of underground conditions. For a job of 6 hours and 12 minutes, with a No. 4 shovel, the underground work is 20.5 per cent less than on surface. (2) The difference between the amounts shoveled with the No. 2 scoop and the No. 4 shovel, under same conditions, is the measure of the effect of the difference in load handled by the man. (3) Each line on this chart shows a peak at some particular length of job, and the total tonnage shoveled for any greater period than this is actually less. (4) The presence of this peak accords with the experience of many superintendents and managers, who state that their men do more work in an 8-hour day than they did on the old 10-hour basis. (5) The "economic shoveling day" is about 6⅓ hours, with a No. 2 scoop on the surface, and 5⅓ hours underground. With a No. 4 shovel, on the surface 8 hours is about the proper length of day, whereas underground 6⅔ hours seems to be about correct. As the men actually shovel only 6⅙ hours per day on an average, and as their other work is generally of a light nature, the 8-hour day with the correctly proportioned shovel is probably the best; but with a scoop it is certainly too long. (6) For work on the surface, on jobs lasting longer than 4⅔ hours, the No. 4 shovel is superior to the scoop. Underground the No. 4 shovel demonstrates its superiority for jobs longer than 3⅜ hours. The scoop thus may be considered as a task shovel for short-time jobs, but even here its value is only slightly greater than the No. 4 shovel and it tires the man so that he is unfit for other work when the shoveling task is finished.

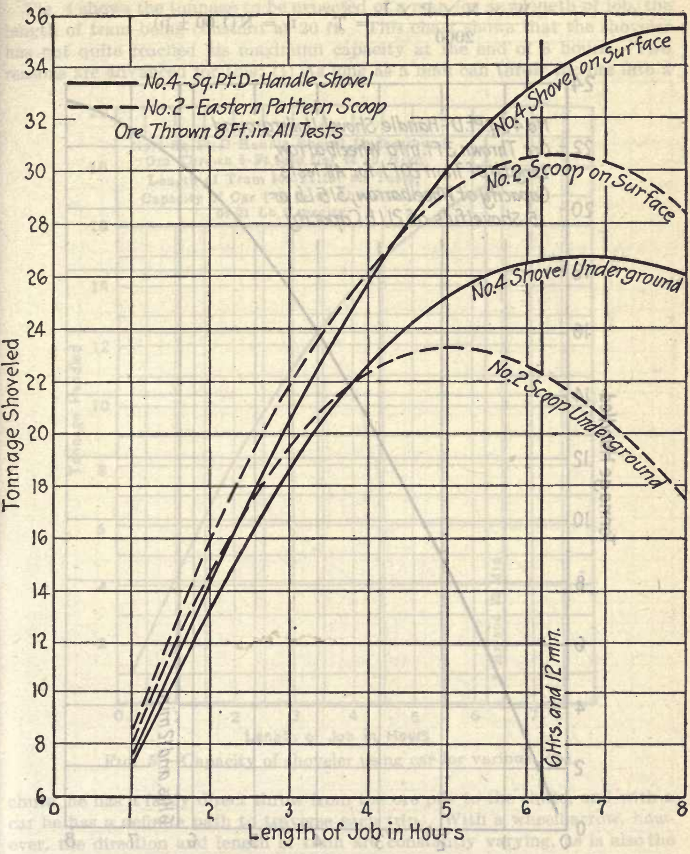

FIG. 3.—Comparison of work of No. 2 scoop and No. 4 shovel.

Effect of Height and Length of Throw on Shoveling Speed.—The following formulas show the manner in which use is made of the figures presented in the preceding diagrams:

Let W = weight of load on shovel, in pounds;

N = number of shovels per minute;

P = per cent time actually shoveling;

L = length of job, in minutes;
T = total tonnage shoveled;
n = number of shovels per minute for an 8-ft. throw;
p = per cent increase or decrease due to various lengths of throw.

$$\frac{W \times N \times P \times L}{2000} = T \qquad n = N(1.00 \pm p)$$

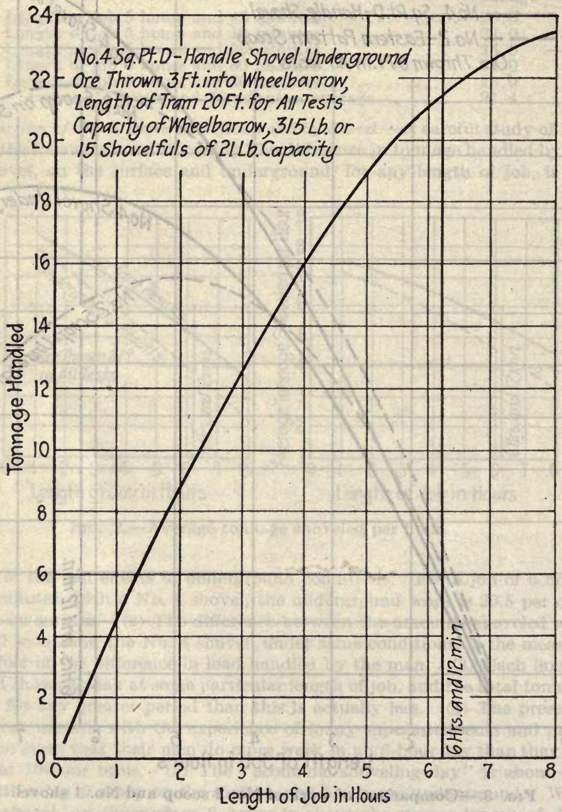

FIG. 4.—Capacity of shoveler using wheelbarrow for various jobs.

In using the No. 4 D-handle shovel it was discovered that a throw of 3 ft. to the wheelbarrow gave the best results as far as number of shovels per minute and rest periods required were concerned, and in all subsequent work the ore was thrown into the wheelbarrow from this distance. For any length of job, the number of shovels per minute is less than when throwing 8 ft. into a chute, and this is due to the fact that the shoveler must place each shovelful carefully to keep the wheelbarrow from spilling its contents and to make it ride easily.

Fig. 4 shows the tonnage to be expected of a man for any length of job, the length of tram being constant at 20 ft. This chart shows that the shoveler has not quite reached his maximum capacity at the end of 8 hours. Two reasons are advanced for this: (1) As long as a man can throw the ore into a

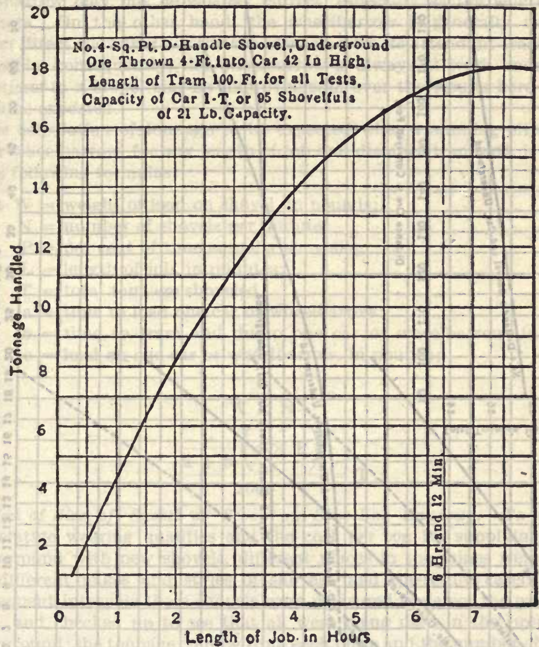

FIG. 5.—Capacity of shoveler using car for various jobs.

chute, he has a fairly direct throw from the ore pile to the chute, and with a car he has a definite path to traverse each trip. With a wheelbarrow, however, the direction and length of tram are constantly varying, as is also the amount of interference from other trammers, timbermen and machine men. The retarding influence of these factors increases as the length of the tram increases. (2) The sequence of operations, shoveling, tramming and dumping, is of such short duration and changes so often from one to the other than it is hard to keep up any pace that may be set, and probably an unnecessary amount of rest is indulged in for all periods.

From a series of tests during which the ore was thrown into a mine car 42 in. high, it was determined that a horizontal interspace of 4 ft. was the best distance to maintain between car and ore pile in order that a man might work to the best advantage. Owing to the height of the car, the capacity of a shoveler is decreased, as compared to his capacity in shovels per minute when loading into a wheelbarrow. This decrease in shoveling speed amounts to about 8 per cent per foot of height. The best type of car for a shoveler to use

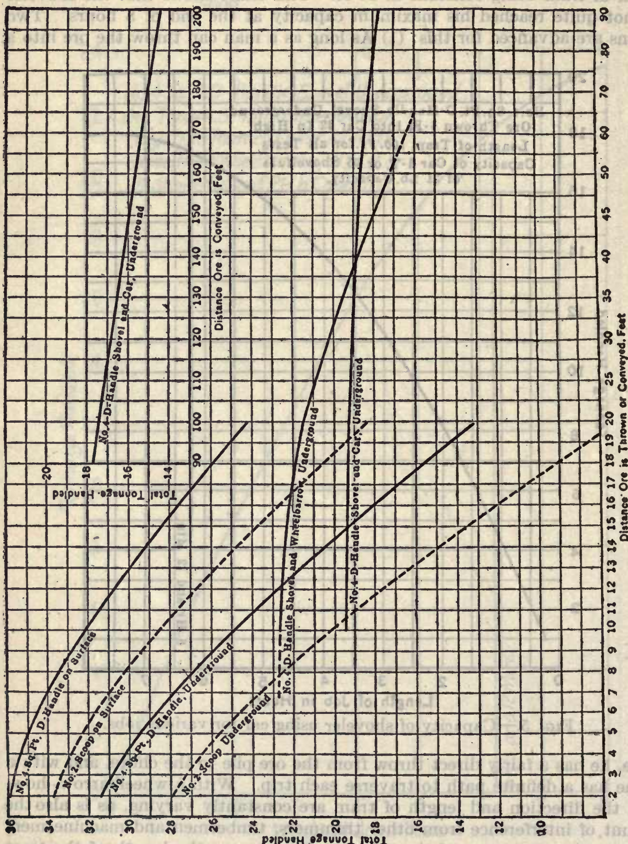

FIG. 6.—Comparative efficiency of different methods of handling ore in stopes with Mexican labor. Length of job constant at 6 hours and 12 minutes.

holds about a ton of ore, is as low as is consistent with good design—certainly not over 45 in. in height—and is equipped with roller bearings, which should be kept in the best of condition. Cars much larger than this are too hard to tram and cars much smaller use up too much of the shoveler's time tramming back and forth.

Tonnage to be Expected under Average Shoveling Conditions.—Fig. 5 shows the tonnage to be expected of a man mucking into a car and tramming a constant distance, for various lengths of jobs. It will be noticed that the economic shoveling day is between 7 and 8 hours long, and that the maximum average results to be expected of a mine shoveler under the given conditions have probably been reached. The tonnage to be expected under average shoveling conditions during a uniform shoveling day of 6 hours and 12 minutes and for any distance that the ore must be thrown or trammed is shown in Fig. 6. The graph representing the tonnage to be expected of a man with a wheelbarrow may not be entirely correct, especially as the length of tram increases. On the other hand, the wheelbarrow is generally used where neither direct shoveling nor the use of a car, with its attendant track expense, is feasible; consequently, the wheelbarrow is always at work under adverse conditions in a stope, and no improvements over the results here tabulated are to be expected.

The calculation of tonnage to be expected when tramming either with a car or wheelbarrow, for any length of job and distance trammed, is expressed in the following formulas:

Let W = weight of load on shovel, in pounds;
N = number of shovels per minute;
P = per cent of time actually shoveling;
L = length of job, in minutes;
T = total tonnage shoveled;
a = time to load one car or wheelbarrow;
b = time to tram and dump one car or wheelbarrow, in minutes;
c = load on one car or wheelbarrow, in pounds;

$$\frac{c}{W \times N} = a$$

$$\frac{\frac{L}{a+b}\left(c \times P\right)}{2000} = T$$

Effect of Size of Shovel or Scoop on Shoveling Capacity.—To determine the relative wearing qualities and the cost per ton for supplying the men underground with new shovels, different places in the mines were equipped with different makes and styles of shovels, and the results carefully noted. At frequent intervals these shovels were measured to detect the wear of each blade, and checked up to see that all were being used in the proper places underground; the tonnage coming from each place and the number of shovelers employed were also noted.

Tests were conducted with square and round-point shovels varying in size from No. 2 to No. 6 and with standard No. 2 scoops, to determine what size of shovel was best adapted to the work. For short jobs of less than 4 hours' duration, the No. 2 scoop and the No. 5 and 6 shovels were slightly superior from the standpoint of tonnage handled; but for jobs requiring more than 4 hours for their completion, the No. 4 shovel was greatly superior. From the standpoint of "number of shovels per minute," work with a scoop is at all times slower than with a No. 4 shovel, and as the day progresses the percentage of time required for resting becomes greater with the scoop than with the shovel. The result is that although, for short work periods, the larger capacity of the scoop brings the total tonnage handled above that of a No. 4 shovel, for long periods the increased amount of rest required when handling the heavier load serves to put the No. 4 shovel considerably in the lead as a tonnage mover. In general it may be said that for shovels smaller than the 21-lb. load shovel, the tonnage handled per shift is approximately directly proportional to the shovel capacity; that is if a man using a No. 4 shovel will handle 26 tons in an 8-hour shift, with a No. 3 shovel, which holds 91 per cent of the load of a No. 4 shovel, he would be expected to shovel about 24 tons a shift. If the increased cost of shoveling with a smaller shovel, or one that has been worn, is balanced against the cost per ton of putting a new shovel underground and discharding the old one, it will indicate economic limit of wear of the shovels in use.

Design of Shovel Best Adapted to Mining Work.—The design of shovel which was considered as being the best adapted to mining work, conforming to conditions under which the tests under review were made, should hold 21 lb. of broken ore as an average load. Both the square and the round-top blades should be of standard shape, of No. 15 gage at the point, and of such composition that the shovel will handle not less than 1,100 tons of medium hard ore when shoveled off a wooden mat. All blades should be of the plain-back type without rivets, the back strap being welded to the blade. Only best-grade, second-growth, northern white ash should be used for the handle, which should be bent to the proper shape and dimensions. On short-handle shovels, the Dirigo, or split D, handle is preferred, as it is much stronger than the ordinary D handle.

How to Obtain Greatest Shoveling Efficiency.—To obtain the highest shoveling efficiency underground, every man hired as a shoveler should be in a particular stope or working place that is directly in charge of a shoveling boss. This boss should have had considerable experience in shoveling.

Economic Choice of Shovels for Construction Work.—C. W. Hartley in Engineering and Contracting, March 31, 1915, gives the results of a study made to indicate the economic choice of shovels for handling different classes of material, from which the following is taken.

It is the custom, or has been in the past, among many large contracting firms and companies in New York City employing a great number of laborers on trench work, to require the men to furnish their own shovels. The principal reason for this is claimed to be that shovels furnished by the employers are very rapidly lost or stolen. While this may be true, it would appear that such procedure is a false economy, as I shall endeavor to show.

Frank B. Gilbreth, in his work on "Motion Study" (page 59) says:

No worker should ever be obliged to furnish his own tools, if large output is expected. When workmen are obliged to furnish their own tools (due to their having too much thrift, lack of money, or fear of having them stolen) they usually use one size only of the same kind of tool. On many kinds of work, greater output can be obtained by using two or more sizes of a tool.

Again, where workmen furnish their own tools, they use them after they are too much worn. A shovel with a worn blade will require several motions to push it into the material to fill it. It is cheaper in this case to cut off the handle of the shovel, so that the men cannot use it. Where no records are kept of their individual outputs, the men always choose the shovel with the small blade.

The statements contained in the last paragraph quoted have been most strikingly forced upon the writer's attention by reason of the following discovery:

In a gang of 38 men, at work in a trench, with shovels furnished by themselves, it was found that 92 per cent were using the smallest size shovel on the market, a No. 2, while the remaining 8 per cent were using the next size larger, a No. 3. These shovels, as will be shown later, are incapable of holding near the amount of material (if it be earth) that should constitute a shovelful. It was further observed that 50 per cent of these men were using shovels, the blades of which were worn down approximately 3 ins. from the point, or until but little over half the original blade remained.

By critical time observations it was demonstrated that the men using the worn shovels worked no faster than those using the good; further, that men will shovel at approximately the same speed whether they are working with a No. 2 shovel, or a No. 4, and, as a general rule, will fill the blade full whenever possible to do so. This being the case, it is self-evident that the use of small or worn shovels will entail the handling of less material, as follows:

A No. 2 shovel, in good condition, was found by many trials to hold, as an average load, 13 lbs., the material being common loam or earth, loose and dry. This same size shovel worn down, as were half of those in use by this aforementioned gang, was found to hold but 7 lbs. of earth or loam, which is, as will be noted, only one-third the amount Taylor has shown to be productive of the greatest shoveling efficiency.

These same data were obtained for shovels of other sizes, namely No. 3, No. 4, and No. 5, and Table IV gives the results of the tests made to determine the average amount of earth, sand, and stone that constitutes a shovelful.

TABLE IV.—SHOVEL LOADS OF VARIOUS MATERIALS IN POUNDS FOR SHOVELS OF DIFFERENT SIZES

		Worn			New		
Number	Dimensions of blade (inches)	Earth	Sand	¾-in. stone	Earth	Sand	¾-in. stone
2......	9¼ by 12¾	7.0	9.0	7.0	13.0	14.5	9.5
3......	9½ by 13¼	...	...	...	15.5	17.0	11.0
4......	9¾ by 13¾	...	...	...	18.0	19.0	12.0
5......	10½ by 14½	...	...	...	22.0	22.5	15.5

It has been my observation that the shovel most used in general contracting work is a No. 2, whether it is supplied by the employer, or by the laborer. That this is the fact is due, probably (in the case of the employer), to lack of consideration of the subject, and also to the fact that the use of this particular size is sanctioned by custom.

It will be noted, from Table IV that the No. 4 and No. 5 shovels approach most nearly, in the amount of material handled, the 21-lb. load. For trench and general shoveling work, however, the No. 5 is a trifle wide and cumbersome, while the No. 4, though appearing large and heavy in comparison with a No. 2, we found to be well adapted to use in the trench. Fortified, therefore, with the data presented at the beginning of this paper, it was decided to equip the laborers in the construction department with the No. 4 shovels, and at the beginning of the season, in April, 1914, this was done.

To quote from a report presented to the chief engineer:

I find that we started the season, on April 15, 1914, with 606 round-pointed No. 4 shovels, and 150 square-pointed No. 4 shovels, or a total of 756.

At the present time, Nov. 10, 1914, there are at the storeyard 311 round and 92 square shovels, leaving 295 round and 58 square, or a total of 353 shovels used during the season. Of these 353 shovels, 57 have been returned as worn out, and there are at present 251 in use on the work. The majority of these shovels now in use show considerable signs of wear, and might well be classed as worn out, so we have a total of 308 shovels worn out during the season. This leaves 45 shovels to be accounted for as lost, stolen, broken, etc.

In a season of 168 working days (up to the first of November) therefore, we have used 353 shovels, or an average of 2.10 per day. These shovels were of two different grades, costing $8.60 and $5.25 per dozen, respectively. The fact that the higher priced shovels outwear the lower has not been apparent, however, at least, not sufficiently so as to warrant the difference in cost.

Assuming, for sake of argument, that all the shovels cost us 72 cts. apiece (or at the rate of $8.60 per doz.) we find that it has cost $1.51 per day to supply our laborers with these No. 4 shovels. The daily average number of laborers at work during the season was 178, and the cost of the shovels per man per day was therefore .85 cts.

It was shown, by my previous reports, that the use of a No. 4 shovel, in place of a No. 2, increased the efficiency, and consequently the output of the shoveler, approximately 27 per cent. While it is practically impossible, on our work, to figure the actual increase in yardage shoveled, the balance seems to be unquestionably in favor of the No. 4 shovel. The cost of these shovels, as shown above, was less than 1 ct. per man per day, and there can be no doubt but that their use effected an increase in output far greater than that amount.

The item of 45 shovels lost, stolen, or unaccounted for is worthy of note. As remarked before, the statement has been made that shovels furnished by the employer are lost and stolen in great numbers. The fact that out of a total of 353 shovels used by 178 men through a season of over five months, only 45, or a percentage of 12.7, were unaccounted for, would tend to refute the argument.

There may be some who might question the practicability of equipping with the No. 4 shovel a number of men who have never used any other than a No. 2. This was done, however, and without the offering of any explanation, or a bonus for increased output. Such a step quite naturally created a great deal of comment and discussion among the men, for a few days, but after that time they apparently forgot that they were using a shovel which would hold half as much again as the one to which they had been accustomed.

A Study of the Application of Scientific Management to Trenching.—The following is a portion of an abstract, of a paper by B. M. Ferguson before the Michigan Gas Ass'n., Sept., 1911, given in Engineering and Contracting, Nov. 29, 1911.

"*High Wages and Low Labor Cost*" is Mr. Taylor's theme of scientific management. To increase the entire working efficiency of any industrial establishment, by putting into the hands of the management exact knowledge of *how long it takes to do work*, and carefully selecting and training men for each particular kind of work, together with improved methods of operation and a reward or bonus going to the operator, workman, mechanic, or laborer for an extra hard day's work, is the essence and direct object of the Taylor System of Scientific Management. "An extra hard day's work" must not be interpreted as meaning that men shall be worked to their limit of capacity or beyond that rate of speed which a man can maintain daily and throughout the year. It simply means a full day's work minus the time lost due to the evils connected with day work or the older and less efficient systems of management and the handling the labor.

The writer was assigned the task of studying the Taylor system with a view of testing its applicability to gas manufacture and distribution. A little study and investigation will develop the fact that *system* and *scientific or efficiency management* find just as big a field of application in the gas business as they do in any other industrial enterprise. What is necessary is a thorough investigation of the working conditions, and a *time study* of all the elements entering into each particular kind of work under consideration.

The Street Department, or more strictly speaking the laying of mains and services, offered the most prolific field of investigation to begin with, since upwards of 400 men were engaged in this kind of work. With the aid of a stop watch and note book the following data were gathered—Table V:

The time for removing this dirt was much too slow, and this for the following reasons:

1. The working capacity of the different men varies greatly due to lack of experience, old age, and a slow natural gait acquired by years of such work.

2. Good men, natural-born workers, and capable of much work, are slowed down or work at the pace set by the men next to them.

3. Men will soldier at every opportunity. They will work at a reasonable gait while the foreman stands over them and watches them, but just as soon as he turns his back and leaves the gang, the men will soldier. The foreman purposely picks a crew of mixed nationalities so as to avoid soldiering and waiting for each other as much as possible.

Two days later, after spending most of the time with the gang, I laid off 14 10-ft. sections, and timed the men on each section, with the results given in Table VI:

The average would be 59.8 minutes. The two men digging sections 4 and 5 are good men and work fast. They could easily earn $2.50 per day on the basis of $2 for

TABLE V—TIME OBSERVATIONS OF FIVE DIFFERENT MEN DIGGING 9-FT. SECTIONS OF 3.23 CUBIC YARDS

Minutes per yard	75.8	62.	83.6	72.7	72.7
Average per yard	73.3		(Average Cross-Section)		

TABLE VI

	No. 1	No. 2	No. 3	No. 4	No. 5	No. 6	No. 7	No. 8	No. 9	No. 10	No. 11	No. 12	No. 13	No. 14
Time taken	3:15	4:05	3:20	2:30	2:15	2:10	3:40	3:40	3:40	3:45	3:45	4:15	4:25	4:10
Time per yard	55.1	69.3	66.5	42.2	38.2	37.0	62.5	62.5	62.5	63.7	63.7	72.2	75.0	71.0

the average man. All the men knew that I was watching them closely, and hence worked more steadily than they would have had I not been there. I marked the sections off for them at the start, and measured them at the finish. Of course, there is always some variation in soil, and temperature conditions have a good deal to do with the manner in which the men can work. It grew hotter in the afternoon, and the men naturally weakened a little.

Similar observations were made with another gang working on the laying of a 4-in. main on Cameron Ave., north of Woodland.

Number of hours digging: 84. Yards of dirt removed: 86.85 = .967 hours or 58 minutes per yard as the average of 17 men digging.

When I came to this job I told the foreman that I was doing some inspecting for the Street Department. When he saw me taking notes in my book and frequently looking at my watch, he began to push the men along, muttering to them in their own language, most of them being Polish. He complained about the short run jobs, and said it was difficult to know how to place his men. The soil here is softer than that on Jefferson Ave., but wet and heavier below the first foot or two. In two different places the banks caved in in the same half block, while nothing like this happened on Jefferson Ave. in about four blocks or more.

Ratio of Time Required to Dig and Throw One Shovelful of Dirt to the Time Required to Backfill One Shovel of Dirt.—Allowing for variation in soil of section by considering the section as composed of $\frac{1}{3}$ soft soil and $\frac{2}{3}$ harder soil, and multiplying observed times by this ratio:

On Jefferson avenue, 1 ft. below surface:
Mean time per shovel..11.5 seconds
Do., 3 ft. below surface:
Mean time per shovel..16.41 seconds

$$
\begin{aligned}
11.5 \times \tfrac{1}{3} &= 3.83 \\
16.41 \times \tfrac{2}{3} &= 10.95 \\
\hline
&\ 14.78 \text{ seconds per shovel.}
\end{aligned}
$$

Mean of 51 other observations taken at random, 13 seconds per shovel. Average of the two (about), 14 seconds:

Time per shovel on backfilling:
8-in. main gang (mean of 180 observations), 5 seconds.
4-in, main gang (mean of 190 observations), 4.8 seconds.

$$\frac{\text{Time required to dig.....14}}{\text{Time required to backfill..5}} = 2.8$$

or a yard of dirt should be thrown back in .357 times required to dig it.

Taking the following as the average cross-section: One cubic yard = 33.4 lin. ins. or .928 lin. yds. Total time required to dig and backfill .928 lin. yds. of ditch of the above section = 59 minutes digging + 16.5 minutes backfilling, or 75.5 minutes per cubic yard.

Soil fairly hard, weather warm but not hot. Nos. 1026, 1031, 1655, 1001 and 1027 received bonus on the basis of 1½ hours overtime ($1.30 on basis of $1) for each 21-ft. section dug. No. 1655 was not a very good worker and it was too much physical exertion for him to keep up his pace. All others showed no special signs of fatigue, and were quite satisfied to apply the extra effort for the bonus offered. (Table VII.)

No. 1031 said he disliked "Piece-work," so took him off. No. 1001 dug two hard sections at a good rate but claimed too much was wanted for the bonus. In the afternoon, he slowed down (Table VIII). His particular sections

[1] These men received bonus as noted.

were harder than the average on account of the many tree roots and this necessitated the use of the pick and axe quite considerably. No. 1026, who is the best worker in the gang, also slowed up in the afternoon, but more on account of the influence of the other men than any other reason. The foreman had always given them 9-ft. sections to dig, and consequently the larger sections were not very popular at the start. For this reason I made the sections smaller temporarily.

Digging of the Average Man Under Close Supervision.—Soil rather hard, and ditch located about 5 ft. from row of trees. Digging in the morning—Table IX.

(1) Average time per yard for good men, 47.3 minutes.
(2) Average time per yard for average men 57.4 minutes.
(3) Average time per yard for good men with bonus, 38.3 minutes.
(4) Average time per yard for good men without bonus, 59.3 minutes.

Amount of work done by bonus men = 1.51 times work done by average man. This is equivalent to $3.03 on a basis of $2 per day. The bonus allowed was three hours overtime, making the day's pay $2.60 instead of $2. On the basis of 60 minutes for the average man and 40 minutes per yard for the bonus man, the men would be doing an excellent day's work. Even allowing this bonus for work at the rate of 45 minutes per yard ($2.66 on the basis of $2) would pay because of the influence of the good men on the other men.

Method of Keeping Cost of Earthwork so as to Show the Daily Unit Cost of Each Gang.—W. A. Gillette in Engineering and Contracting, July 24, 1912, gives the following:

Every dirt moving contractor knows the difficulty of ascertaining the unit cost of excavation during its progress, that is, before he secures his monthly estimate. I venture to say that not one contractor in fifty knows closely the cost per cubic yeard of the earth he moved yesterday or last week, unless it was moved in cars or wagons. Even then few contractors have adequate records of daily output.

Some time ago I conceived the idea that I would have my timekeepers "keep tabs" on the number of loads hauled by each gang during a period of about 20 minutes during the forenoon and for an equal period in the afternoon. Upon these two relatively short-time records, I determined to base an estimate of the full day's work of each gang and to test the accuracy of this method by comparison with the monthly estimates based on the engineers' cross-sections. I was astonished at the accuracy of my estimates of yardage. The first month I moved about 70,000 cu. yds., and my estimate was about 5 per cent higher than the engineers' estimate. The next month I was about an equal amount too low, so that I checked almost exactly with the engineers on the total yardage of the two months.

The timekeeper was given a statement of the estimated size of load of each kind of scraper and wagon. Thus, a No. 2½ wheeler was estimated to hold one-third cubic yard, measured in place. A three-up dump wagon was estimated to average 1¾ cu. yds. Fresnos were estimated at different capacities, according as the pull was up hill, or down hill, or level; and, in some cases, it might be desirable to vary the estimate according as the haul is short or long.

The important new feature of this method of cost keeping is the practice of counting the loads hauled by every gang during at least two periods of the day. One timekeeper can cover a lot of ground if he is provided with a saddle horse; and thus can report the output of a great many separate gangs.

His report is made out daily for each gang, and he also makes a summarized total daily cost report for all the gangs.

By following this plan I was able quickly to discover that my wheeler work was costing more than my fresno work. I also saw at once that for hauls of more than about 150 ft., the cheapest method was to load wagons with fresnos through a trap.

Methods of Analysis of Costs of Steam Shovel Work.—The following matter, published in Engineering and Contracting, Dec. 13, 1911, is an abstract of pages 5 to 30 of "Handbook of Steam Shovel Work" a report by Construction Service Co., to the Bucyrus Co.

There are so many factors entering into steam shovel work that the problem of determining the details of cost seems at first highly complex, but systematic analysis has resulted in so simplifying it that any man of field experience ought to be able, with the help of the data contained in these pages, to put his shovel work on a scientific basis. To determine what the work is costing day by day, is half the problem; to determine what it ought to cost is the other half.

To establish these factors it was necessary to observe a large number of shovels in operation, and the data given are the results of the observation of nearly 50 different shovels at work in various kinds of earth and rock.

The unit costs of working by hand will be nearly the same, field conditions being equal, whether the job is a large one or comparatively small. The steam shovel is dependent for its work upon so many factors, any one of which may greatly help or hinder it, that there is a far greater diversity of results than in the case of handwork. The question of how much work there must be to economically justify the use of a steam shovel is vital in a large percentage of all excavation contracts. To answer it, simply calculate the total cost, including the cost of installing the plant, and divide this by the number of cu. yds. of material to be handled.

General Conditions.—Repair costs should be apportioned to the work rather than considered a function of the age of the shovel. It will be higher for rock than earth and higher for poorly broken rock than for well blasted material. Time alone doesn't affect the unit cost of repairs.

In the item of *depreciation* the reverse of this proposition obtains. If the machine be kept in proper repair the depreciation is effected by time alone, regardless of the work the machine is doing. Many concerns class this item and repairs under one account, but this practice is inaccurate and misleading. There is a great disagreement among accountants as to how depreciation should be figured and there are many so-called depreciation formulae and curves. The simplest to use, and one which for steam shovel work is satisfactory if proper allowance is made for repairs, is the "right-line formula," which is as follows:

$$X = \frac{(a - b)c/d}{a},$$

where
a = original value,
b = value on removal,
c = time in use,
d = estimated life,
X = % of depreciation.

Then X divided by the output for the period c will be the cost of depreciation per unit of performance.

The working life of a shovel may be assumed to be 20 years, and assuming the first cost at $150 per ton, and its scrap value at $10 per ton, the value for X with a 10-year-old shovel, would be

$$\frac{(\$150 - \$10) \times \frac{10}{20}}{\$150} = 46.67\,\% \text{ in the 10 years or } 4\tfrac{2}{3}\,\% \text{ per year.}$$

The *interest* on all money invested in the work must be included in the costs of the work. In this discussion the interest is assumed as 6 per cent.

The *height of bank* to which a shovel can work has an important bearing upon the costs. The reason for this is that the higher the bank the larger amount of material that can be removed without moving the shovel.

Formulæ.—The following analysis of steam shovel work is based on the results of observations of about 50 shovels at work. The wages of the different classes of men were standardized as listed below for purpose of analytical comparison. In connection with this analysis the accompanying curves of cost are useful in enabling a rapid estimate to be made of the approximate cost of steam shovel work in progress or proposed:

d = time in minutes to load 1 cu. ft. with dipper (place measure).
c = capacity of 1 car in cu. ft. (place measure).
f = time shovel is interrupted while spotting 1 car.
e = time shovel is interrupted to change trains.
g = time to move shovel.
L = distance of 1 move of shovel.
N = number of shovel moves.
M = minutes per working day less time for accidental delays.
A or B = area in sq. ft. of section excavated.
R = cost in cents per cu. ft. on cars, for shovel work only (place measure).
LAN = cu. ft. excavated per day.
C = shovel expense in cents in 1 day, not including superintendence and overhead charges and not including preparatory charges.
n = number of cars in train.

(1) Time to load 1 car = dc.

(2) Time to load 1 train = ndc + nf + e.

(3) Number of trains for 1 shovel move $= \frac{LA}{nc}$

(4) Time between beginning of 1 shovel move and beginning of next $= (ndc + nf + e)\frac{LA}{nc} + g.$

$$(5)\quad N = \frac{M}{\left(dc + f + \frac{e}{n}\right)\frac{LA}{c} + g}$$

$$(6)\quad R = \frac{27Cd}{M} + \frac{27C}{M}\left(\frac{f}{c} + \frac{e}{nc} + \frac{g}{lA}\right)$$

This is equivalent to the equation R = md + b.

$$(7)\quad \text{Where } m = \frac{27C}{M}, \text{ and}$$

$$(8)\quad b = m\left(\frac{f}{c} + \frac{e}{nc} + \frac{g}{LA}\right)$$

It appears that the equation $R = md + b$ is that of a straight line. Now since the equation $m = \frac{27C}{M}$ and $b = m\left(\frac{f}{c} + \frac{e}{nc} + \frac{g}{LA}\right)$ all quantities involved in the equation excepting d are, or are assumed to be, constant. The data upon the value of these quantities have been represented in graphic form with all influencing factors by the Figures 7 to 10 incl.

The following standards have been assumed for a shovel valued at, say $14,000:

	Per year
Depreciation, 4⅜ %	$ 653.34
Interest, 6 %	840.00
Repairs, when working one shift	2,000.00
	$3,493.34

	Per day
Assuming year of 150[1] working days	$ 23.29
Shovel runner	5.00
Craneman	3.60
Fireman	2.40
½ watchman at $50 per mo	1.00
6 pitmen at $1.50	9.00
1 team hauling coal, water, etc., ½ day, say, at $5.00	2.50
2½ tons at $3.50	8.75
Oil, waste, etc., say	1.50
	$ 57.04

[1] For various reasons, such as lack of continuous work, weather, etc., 150 working days per year is assumed. This will vary greatly with local conditions.

TABLE X.—DATA FOR USE WITH COST CURVES

Values of e, n, c, f, involved in ordinary contracting work with side dump cars.

e = Average time shovel is interrupted to change trains.
n = Number of cars per train.
c = Capacity of cars in cubic feet (place mueasure).
f = Time to spot one car.
c′ = Capacity of cars in cubic feet (water measure).

	Values of n			Values of c				
	Min.	Avg.	Max.	Min.	Avg.	Max.	f	c′
Brick yard clay	1	1–2	2	54	72	81	Zero	...
R. R. borrow pits	7	11	15	83.7	126	270		151
Rock cuts	7	9	12	54	75	97.2		188
Crushed stone quarries	1	10	10	108	124	189		162
Earth and glacial drift	10	10–11	13	70	108	141		157
Iron ore	3	7	12	270	540	675		540
Sand and gravel pit	1	7	15	67.5	598	891		...

General average of e, n, c, f, c′, as follows

	No. of obs.	Minimum	Average	Maximum
c	35	.25 min.	4.00 min.	13.5 min.
n	35	5.0 cars	10.00 cars	15.0 cars
f	0	0	0	0
c	35	2 yards	4.00 yards	10.00 yards
c′	27	4 yards	5.00 yards	12.00 yards
c/c′	27	0.5	0.8	0.95

Fig. 7 indicates the time to load 1 cu. yd. place measure, in various kinds of material. Fig. 8 deals with the quantities e, average time shovel is interrupted to change trains. For use in plotting the equation above, those

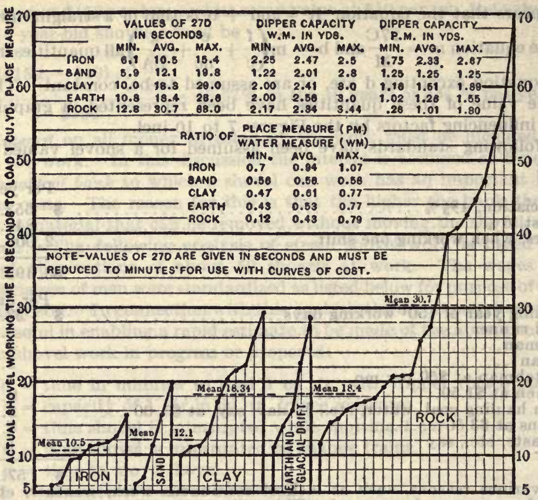

FIG. 7.—Diagram for use with cost curves.
(Value of 27d shown graphically.)

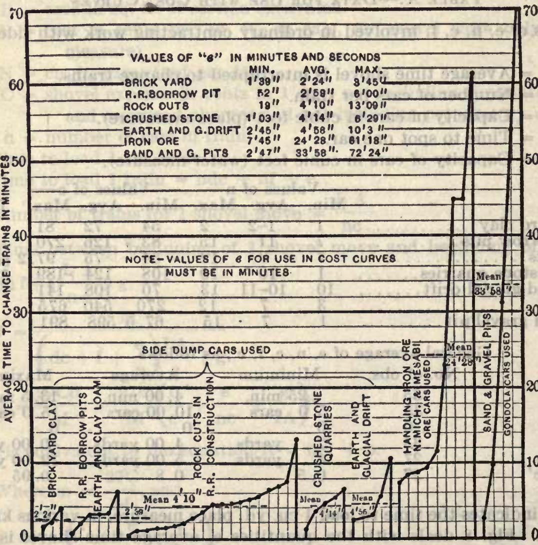

FIG. 8.—Diagram for use with cost curves.
(Value of e shown graphically.)

average values of e, n, c and f involved in ordinary contracting work where side dump cars are used, have been tabulated separately in Table X. It will there be seen that the average value for e, the time between trains is 4 minutes. The average number of cars per train, or n = 10. The commonest form of contractors' dump car is 4 yards water measure or 2.5 yards place measure, and therefore c is taken as 67.5 cubic feet. The ordinary value of f is zero, since the cars are almost invariably spotted while the shovel is swinging and digging. Fig. 9 deals with the value of M or the working

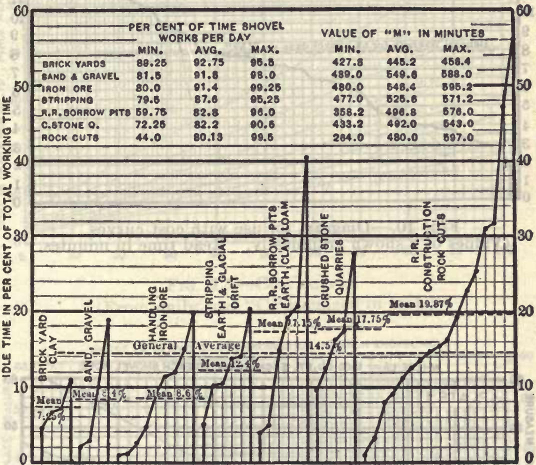

FIG. 9.—Diagram for use with cost curves.

(Idle time shown graphically in per cent of total time per day. Values of "M" to be taken from this diagram. To find "M" take value plotted below subtract from 100 per cent and multiply result by total working time per day (generally 10 hours).

time, including actual shovel time waiting for trains and moving up, but not accidental delays. Fig. 10 deals with the time of moving up, an average value for which is 8 minutes.

The constants having thus been established, three sets of curves have been plotted, Figs. 11, 12 and 13, which are cost curves. Each plate is plotted, with one of the three values of LA 1,500, 3,000 and 6,000 cu. ft. (L being the average shovel move, 6 ft. and A the area of the dug section in sq. ft.) Each of these sets of curves has been plotted for values of M, ranging from 2 hrs. to 10 hrs. by hourly intervals between which intervals the observed values (see Table X) fall.

Estimating.—There are two important uses to which these cost curves can conveniently be put, (1) estimating the cost of proposed work and (2) checking up the cost of work under way. In estimating we may proceed as follows: Assuming that the proposed work is to be a railroad cut in rock, with average equipment, there are then only three quantities to decide upon, namely, LA, 27d, and M. The area of the shovel section being assumed at 250 sq. ft. and

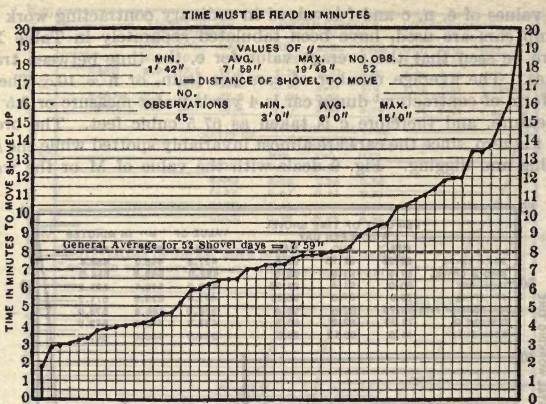

FIG. 10.—Diagram for use with cost curves.
(Values of g shown graphically. Read time in minutes.)

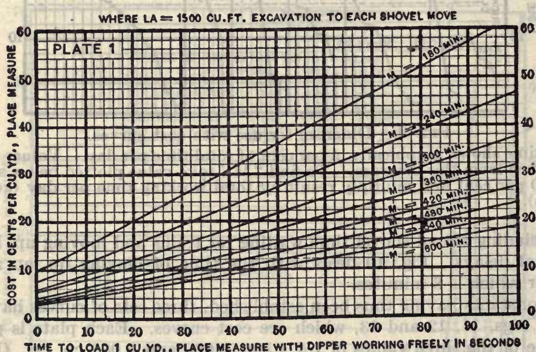

FIG. 11.—Cost curves.

$$\text{Formula } R = \frac{27Cd}{M} + \frac{27C}{M}\left(\frac{f}{c} + \frac{e}{nc} + \frac{g}{LA}\right)$$

Assume—

f = 0, interruption of shovel while spotting cars.
e = 4 min. time between trains.
n = 10, number of cars per train.
c = 2.5 yds. place measure = 67.5 cu. ft.
C = 5704 cents, daily cost.
M = actual working time of shovel.
g = 8 minutes, see Fig. 4.
d = Minutes to load 1 cu. ft. place measure.

the average distance of move being 6 ft., LA will equal 1,500 cu. ft. Now refer to Fig. 7 and select a fair value for the time of loading 1 cu. yd. in rock work. Suppose 30 seconds be chosen. Next refer to Fig. 9 for the proper value of M to use in rock work. The average value is 8 hrs. (80 per cent of 10 hrs.). The cost per yard in cents can now be read directly on cost curves

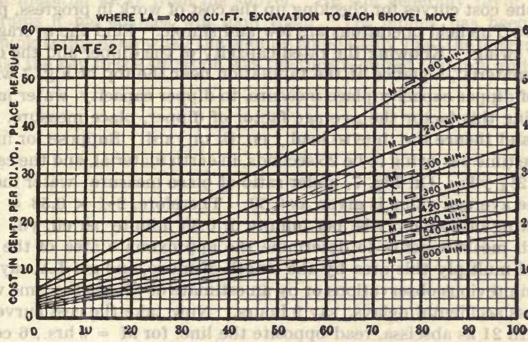

FIG. 12.—Cost curves.
(From daily cost "C" itemized in text.)

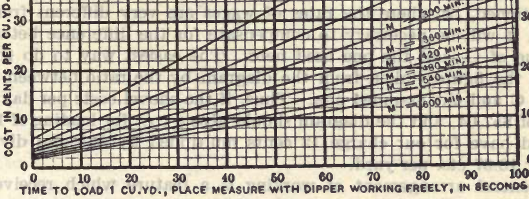

FIG. 13.—Cost curves.
(Values same as Figs. 11 and 12.)

Fig. 11. With abscissa (27d) as 30 seconds glance upward till the vertical line through 30 seconds intersects the 8 hr. M line. Then on the left, opposite this point of intersection read 9½ cents as the cost per cu. yd. loaded, place measure.

It may be noted here that with respect to the two important items of time to load 1 cu. yd. with dipper and values of M, the cost curves are perfectly flexible. Variation in the value of the constants may be allowed for by proper choice of M. In connection with the formula it is interesting to note the effect of decreasing the carrying capacity of each train, other conditions remaining the same. Suppose the carrying capacity be decreased from the average 10×2.5 yds. = 25 cu. yds. to $8 \times 2 = 16$ cu. yds., place measure, what would be the effect upon the cost per cu. yd. The new cost would be 10.6 cts. per cu. yd. as against the former 9½ cts., an increase of 10 per cent.

To use the cost curves for checking up the cost of work in progress, proceed as follows: The field operations are few and simple. Find the average time per dipper swing. Knowing the rated capacity of the dipper and the character of the material, a glance at the tabulation near the top of Fig. 7 will give the ratio of dipper capacity place measure, to dipper capacity, water measure and by using this factor the average factor of dipper, place measure, can be obtained, and thence the time to load 1 cu. ft. or yard. Suppose for instance the average time per swing to be 25 seconds, in earth material, and the capacity of dipper, 2¼ yds. On Fig. 7, under ratio of place measure: water measure, we find the average value is given as 0.53. Therefore, $2\frac{1}{4} \times 0.53 = 1.2$ cu. yds. per swing or 2.88 cu. yds. per minute or 0.35 minute per cu. yd. Make some rough measurements to determine the approximate area of the shovel section and multiply this area by the length of move, and get LA, say 3,000. Then, from previous observations or by an estimate of M, get the time worked per day, less accidental delays, say 9 hours. Now take the cost curves, Fig. 12, and with 21 as abscissa, read opposite the line, for M = 9 hrs., 6 cents as the cost per yard, place measure. If the contents in the formula do not agree close enough with the actual conditions, allow for this by choosing a suitable value of M, or substitute directly in the equation for cost.

It should be noted that the above does not include superintendence or overhead charges and cover only the cost of loading. It should be particularly noted that for plotting the two co-ordinates certain assumptions are necessary because there are a large number of variables in the theoretical steam shovel formula. Thus, the three plates are given—one for LA = 1,500, one when LA is 3,000 and one where it is 6,000. Also an assumption of $57.04 for the value of C is made. Where the shovel differs very much in type from the one mentioned, or where the rates of wages are very different from those assumed, it will be necessary to compensate for the difference between the new value of C, and the one used here. The easiest way to do this is to multiply the figures taken from the diagram by the ratio between the new value of C and the assumed one. Thus, if the shovel costs per day are $65 instead of $57.04, and the diagram should give a cost for loading of 12 cents, we would have for our charge 12 cents multiplied by $65 and divided by $57.04 or 13.67 cts. per yard.

The general arrangement of working is a feature which receives great attention from skillful managers; the "old line" contractor comes on a job and looks it over from the seat of his buggy, deciding on the ground, where he will begin operations and how he will transport the material from the shovels. The modern manager undertakes a job much as a professor attacks a mathematical problem. Sometimes there is only one place to "cut in" and only one way to handle the earth or rock, but generally there are several places to cut in and many ways available for handling the material. If there were only 3 ways—and there are seldom less than 23—he is a bold man who would decide offhand which is unquestionably the best of the three, until an economic study has conclusively established the facts.

The quality and amount of superintendence will greatly affect the unit costs of the work; and by superintendence is meant, not only the man in charge, but his whole directing organization. The work in the iron ore country is an example of the work which may be accomplished in the way of skilled organization. Pure observation alone without actual timing will not show a superintendent whether it is more economical for him to use 9 car or 10 car trains to haul material away from his shovel. He will generally favor the use of long trains if his engines will haul them. Yet money has been saved by shortening trains even when the engines could easily haul the longer ones. In this case the key to the situation was the time required to dump and transport.

CHAPTER V

CONCRETE CONSTRUCTION

This chapter is comprised of articles dealing with the economics of plain and reinforced concrete, in general. For costs on particular types of construction the reader is referred to chapters of this volume covering the subject in question and to the index at the back of the book. Further costs on concrete construction may be found in "Concrete Construction Methods and Cost" by Gillette and Hill and "Handbook of Cost Data" by Gillette.

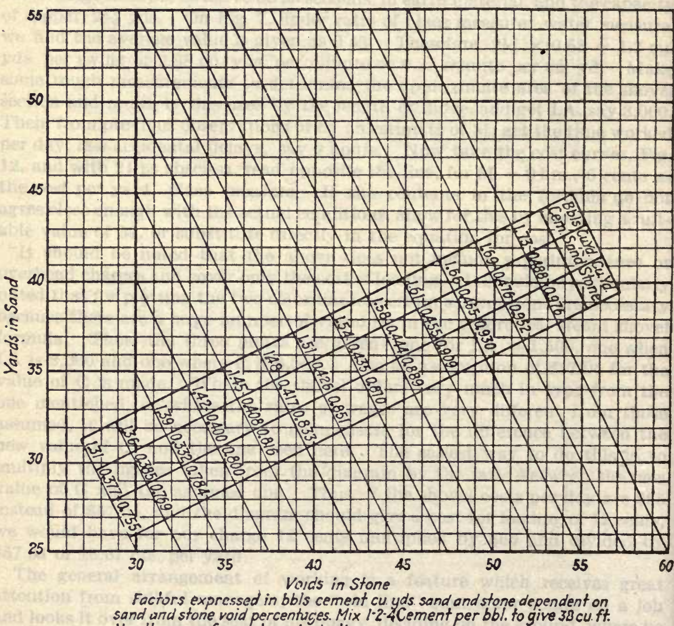

FIG. 1.—Diagram for obtaining interpolated values of factors when the voids in either of the coarse aggregates vary from a multiple of 5 per cent. Mix 1:2:4.

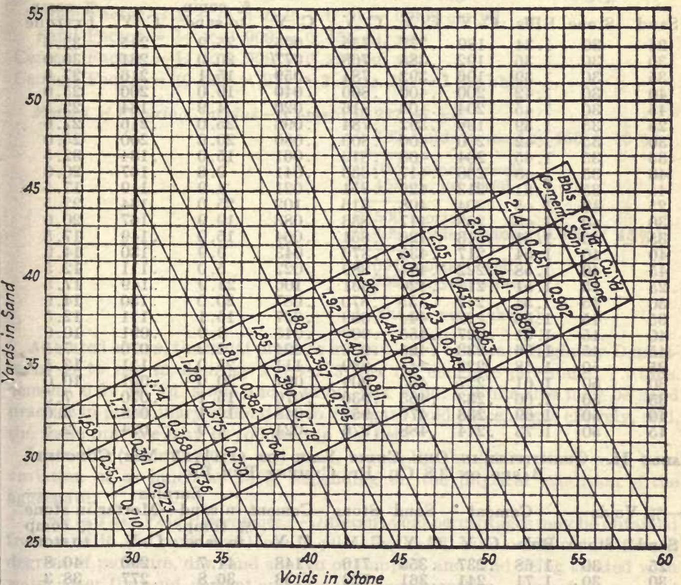
Value of Determining Void Percentages in Coarse Aggregate for Concrete.—W. G. Crandall gives the following discussion in Municipal and County Engineering, Dec. 1919.

In the New York State Highway Department, it has been and is the custom in preliminary estimating of concrete pavement for a mix of 1:1½:3 to figure

1.9 bbls. cement, 0.84 cu. yd. stone, and 0.42 cu. yd. sand as the factors to use in obtaining the cubic yard price of concrete. Inasmuch as the percentage of voids in the aggregates determines the value of the factors, and a variation in the factors means a difference in the cubic yard cost of concrete, it would seem that a field investigation of the voids in the aggregates would warrant itself, to determine whether or not a contractor would increase or decrease his bids on the engineer's estimate of the concrete pavement by varying the



Factors expressed in bbls. cement, cu. yds. sand and stone dependent on sand and stone void percentages. Mix 1-1½-3. Wt. cement per bbl. to give 3.8 cu ft. No allowance for waste or hydration.

FIG. 2.—Diagram for obtaining interpolated values of factors when the voids in either of the coarse aggregates vary from a multiple of 5 per cent. Mix 1:1½:3.

factors, all other items in the analysis being considered equal for the purpose of comparison. Before working out a comparative analysis to show in dollars and cents what this difference means, it is necessary to explain the accompanying tables and curves.

Tables and Curves.—The tables show the quantities in 1 cu. yd. of concrete based on 3.8 cu. ft. cement per barrel for proportions of 1:2:4 and 1:1½:3, the two mixes used by the New York State Highway Department in concrete pavement construction.

The purpose of these tables is to show at a glance what proportions of coarse and fine aggregate to use for either of the above mixes, based on the void percentages in the coarse aggregates. In the tables, the sand voids range from 25% to 45% and the stone voids from 30% to 50% by increments of 5% and the accompanying curves are used to obtain interpolated values of factors when the voids in either of the coarse aggregates vary from a multiple of 5%. The tables and curves show also the cubic yard and percentage excess of cement in sand and mortar in concrete.

Method of Figuring Quantities.—Following is the method of figuring quantities in one cubic yard of (1:2:4 mix) concrete based on 3.8 cu. ft. cement per barrel.

Take for instance a 40% sand and a 45% stone

Mix 1		Void %		Void	Swell
2	×	0.40	=	0.8	0.2
4	×	0.45	=	1.8	0.2

Stone Factor = 4 ÷ (4 + 0.2 + 0.2) = 0.909 cu. yd.
Sand Factor = ½ × 0.909 = 0.455 cu. yd.
Cement Factor = ¼ × 0.909 = 0.227 cu. yd.
Cement Factor = (0.227 × 27) ÷ 3.8 cu. ft. = 1.61 bbls.

Method of Figuring Surplus.—Cement 0.227 cu. yd.
0.182 Voids in sand (0.455 × 40%).

0.045 Cement swell.
0.455 cu. yd. sand.

0.500 mortar.
0.409 Voids in stone (0.909 × 45%).

0.091 mortar swell.
0.909 cu. yds. stone.

1,000 cu. yds. (check).

As stated above, the usual practice in the New York State Highway Department is to use in figuring a 1:1½:3 mix for concrete pavement, 1.9 bbls. cement, 0.84 cu. yd. stone and 0.42 cu. yds. sand. While this may be good practice in preliminary estimating to disregard void percentages entirely, still, the same practice may be followed in the field.

In testing voids in stone and sand, especially the latter, there may be a variation of as much as 25%, depending on the physical condition of the aggregate.

Time to Take Void Percentages.—Different void percentages may be obtained from sand in the bank and loose in piles, dry sand, sand containing different degrees of moisture, dry sand shaken or tamped, and sand being treated with water after the sand, cement and stone is mixed together. Therefore, especial precaution should be taken by the engineer on the road to take void percentages at the time directly previous to the actual mixing of the ingredients and in the physical state that the coarse aggregates exist directly previous to their incorporation to form the concrete. These void percentages should be taken every day and also when the character of the aggregate would tend to show a variation, as when a coarse pocket of sand would be evident in a bank from which a fine grade was being taken.

After these void percentages of sand and stone are derived the factors entering into the mixture may be obtained at a glance from the curve.

Example of Value of Void Determination.—Assume the following analysis of cement concrete pavement:

Cement		Stone		Sand	
F. O. B.	$2.35	Bin	$2.25	Royalty	$1.25
Handling	.08	Haul, 1 mi.	.45	Wash, screen,	
Haul, 1 mi.	.08			Haul, 1 mi.	.45
			$2.70		
	$2.51				$1.70

For 1:½:3 mix use 1.9 bbls. cement, 0.84 cu. yd. stone and 0.42 cu. yd. sand.

Cement $2.51 at 1.9	$ 4.77
Stone $2.70 at 0.84	2.27
Sand $1.70 at 0.42	.71
Manipulation	2.50
Water and joints	.30
	$10.55
Profit, 20%	2.11
Waste and overhead, 10%	1.06
	$13.72
	Say $13.75

Suppose a contractor made a void test of the coarse aggregates in the field under approximately the physical conditions the stone and sand would be, when mixed, and determined a sand void of 35% and a stone void of 40%. From the curve the factors entering into the computation would be cement, 1.88 bbls.; sand, 0.397 cu. yd.; Stone, .795 cu. yd.

Applying these factors to the above prices we have

Cement $2.51 at 1.88	$ 4.72
Stone $2.70 at 0.795	2.15
Sand $1.70 at 0.397	.67
Manipulation	2.50
Water and joints	.30
	$10.34
Profit, 20%	2.07
Waste and overhead, 10%	1.03
	$13.44
	Say $13.45

The difference is .30 per yd.

In a road 5 miles long, 18 ft. wide, section 6 in.-8 in.- 6 in., Parabolic, the number of cubic yards, 10,756, at $.30 would mean a saving of $3,226.80, which it seems would be worth a preliminary investigation before submitting bid on a concrete pavement.

Diagram for Cost of Placing Steel Reinforcement.—Labor cost in placing steel is usually estimated in dollars per ton, although it is recognized that such unit costs increase when light steel is being placed. The accompanying diagram Fig. 3, devised by Dan Patch of the Aberthan Construction Co., and published in Engineering Record, Aug. 26, 1916, shows chearly the effect of sizes of rods on the unit cost per ton.

Mr. Patch says:

The unit costs are usually obtained by dividing the labor cost figured from the time-keeper's sheets by the tons of steel reported placed by the quantity man. In order to obtain data for studying the effect of size of bars, only one more item must be recorded—the total length of bars placed. This is easily done by the use of a listing adding machine, by which the total running feet of each diameter of rods placed can be obtained. The daily totals are tabulated in terms of rod sizes and linear feet placed, the total length and total weight computed, and the average weight per running foot easily obtained. Knowing total cost and total tonnage, the cost per ton is found, and plotted on the diagrams as shown in Fig. 3.

The curves *A*, *B* and *C*, which are drawn through the fields of plotted points obtained for costs of placing in wall, columns, stairs, etc., in floor and roof slabs, and of bending and cutting respectively, indicate the large effects of average weight upon the cost of labor per ton.

If additional argument in favor of accounting for the weight variable is necessary it will be found in the curves of Fig. 4. This diagram shows on a larger scale the plotted costs for the same kind of work, but for different dates, the steel growing lighter as the roof is approached. Sections of the typical

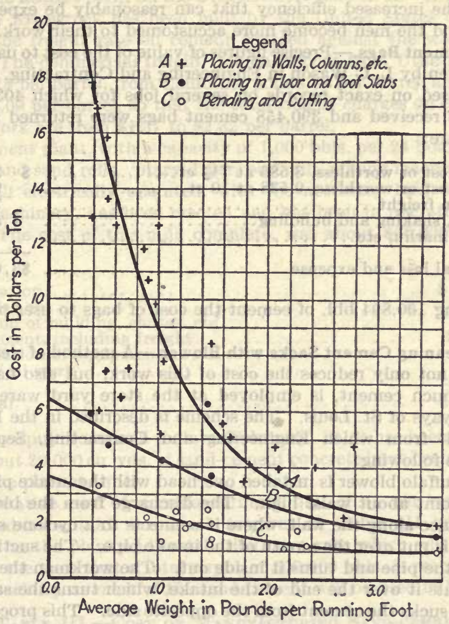

FIG. 3.—Chart for cost of reinforcing steel based on weight per foot.

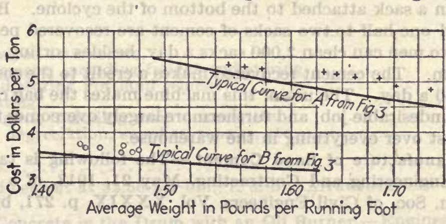

FIG. 4.—Typical examples of costs at various dates compared with curves in Fig. 3.

curves of Fig. 3 to this enlarged scale are shown, the costs of placing in walls, columns, etc. (Curve *A*), giving the clearer illustration.

Use of Typical Curves.—As an example of the value of these curves, consider the figures on the work recorded in Fig. 4. On Nov. 23 the cost per ton was \$4.83. By Jan. 19 this cost had risen to \$5.34 per ton. With these figures only and no knowledge of the weight of steel it would be assumed that the work was being less efficiently done, but with the typical curve as a basis of comparison it will be noted on Fig. 4 that while there has been a 10-per cent increase in the cost per ton, the typical cost curve *A* has been more nearly approached, indicating the increased efficiency that can reasonably be expected as a job progresses and the men become more accustomed to their work.

Cost of Cement Bags.—Precise figures of value of the cost to users of cement sacks are given by L. C Wason in Engineering and Contracting, Feb. 9, 1916. They are based on exact records on several jobs for which 403,576 bags of cement were received and 390,458 cement bags were returned and credited. The figures are:

Bags lost or worthless, 3,586 at 7½ ct	$ 268.50
Bags lost or worthless, 9,538 at 10 ct	953.80
Return freight	725.06
Labor, shaking and bundling	1,590.00
Wire, marlin, etc	66.50
Total loss and expense	$3,603.86

There being 100,894 bbl. of cement the cost of bags to user per barrel was 3.6 ct.

Cost of Cleaning Cement Sacks with Blower.—A method of cleaning cement sacks which not only reduces the cost of this work, but also has resulted in recovering much cement, is employed at the store yard warehouse of the United Railways of St. Louis. The scheme is described in the Electric Railway Journal, from which Engineering and Contracting, Sept. 22, 1920, abstracts the following:

A No. 5 Buffalo blower is installed overhead with the intake pipe extending down to a point about waist high. The discharge from the blower is piped a short distance along the wall, where it connects to a cyclone separator. A cement sack is put over the mouth of the intake pipe. The suction draws the bag up into the pipe and turns it inside out. The workman then pulls it out and again puts it over the end of the intake, which turns the sack the other way out and sucks the cement from the opposite side. This process leaves the sacks cleaner than it is possible to get them by hand. The cement recovered is deposited in a sack attached to the bottom of the cyclone. By this means from one and one-half to two sacks of cement are recovered per 1,000 sacks cleaned. Two men can clean 2,000 sacks a day, besides sorting, counting and bundling them. The cement recovered makes a credit to the cost of handling of about $2.50 a day. The use of this machine makes the bag cleaning not a particularly undesirable job, and furthermore largely overcomes the spreading of cement dust over everything in the warehouse.

Cost of Manufacture of Sand Cement.—The following is taken from an abstract in Engineering and Contracting, May 21, 1913, of a discussion in the Proc. Am. Soc. of Civil Engineers, Vol. XXXIX, p. 271, by Charles H. Paul.

The use of sand-cement in mass work, where the requirements are enough to justify the installation of the necessary grinding machinery, where suitable blending material is available, and where the transportation charges on Portland cement amount to a considerable portion of its cost laid down, will result in a marked saving in construction costs, and will give a product which is at least the equal of the Portland cement from which it was made, in fact, one which, for ordinary requirements, is not open to the least suspicion.

In the construction of the Arrowrock Dam—by the U. S. Reclamation Service to store the flood waters of the Boise River—about 550,000 cu. yds. of concrete will be laid, and the cost of cement is, of necessity, a most important item. The dam is about 22 miles above the city of Boise and 17 miles above Barberton, the nearest point on the Oregon Short Line R. R.. A railroad from Barberton to Arrowrock has been built by the United States Government, over which the freight rate on cement charged against the work is 23 cts. per barrel. The commercial freight rate on cement from Utah mills to Barberton is $1.14 per barrel, from California points $2 per barrel, and from Kansas points $2.09 per barrel, so that the total freight charges on cement to the Arrowrock work are from $1.37 to $2.32 per barrel.

A sand-cement plant, with a capacity of 1,000 bbls. per 24 hours, consisting of a crusher and sand rolls, rotary dryer, ball mill, mixing machine, and three tube mills, all electrically operated, with the necessary bins, hoppers, and conveying machinery, has been erected and has been in operation for about 2 months. The cost of this mill, complete, was about $46,000, itemized as follows:

Excavation	$ 1,500
Foundations	3,750
Erection of building, chutes, etc	8,150
Equipment, including freight	23,000
Installation of equipment	7,850
Electrical work	1,750
Total	$46,000

The total output of the mill to date (February, 1913) has been about 25,000 bbls. and about 20,000 cu. yds. of sand-cement concrete have been placed in the dam up to the present time.

A representative cost of manufacturing 1 bbl. of 45 per cent by weight blend of sand-cement at Arrowrock is given in Table III which includes depreciation on the plant and installation, at a rate which will wipe out the total cost at the time that a total ouput of 500,000 bbls. is reached. It does not include sacking, as most of the sand-cement will be used in bulk.

TABLE III.—COST OF MANUFACTURING SAND-CEMENT

Items	Unit cost of sand-cement per barrel
Granite delivered to crushers	$0.02
* Portland cement, including freight and storing	1.35
Handling and storing Portland cement	0.08
Labor, operating	0.10
Power and lights, including maintenance, etc	0.16
Installation, depreciation, supplies, repairs, etc	0.14
Total cost	$1.85

* Portland cement at $2.36 per bbl., f. o. b. Arrowrock.

Heating Concrete in the Drum with an Oil Burner.—Engineering and Contracting, Jan. 3, 1917, states that a concrete mixer with Hauck Oil Burner attached, designed and built at the request of several contractors engaged on the subway in New York City, gave the following results in the winter work of 1916:

½ cu. yd. batch heated to 50°F. in 2 minutes
½ cu. yd. batch heated to 60°F. in 3 minutes
½ cu. yd. batch heated to 80°F. in 4 minutes

The heater uses fuel oil or kerosene and is made in two types. The compressed air type is equipped with a 25-gal. oil storage tank and air regulating valves, filling pipe with plug and full union. The approximate oil consumption is 1½ gal. per hour.

The other type of heater is designed for use where compressed air is not available. It consists of a 20-gal. oil storage tank equipped inside with a powerful hand pump. The tank can be placed on the ground or on the engineer's platform. It is necessary for operating this vaporizing type of burner to carry oil pressure from 12 to 75 lb., which is obtained from the hand pump placed inside the tank and which requires about 90 seconds of pumping to obtain the above mentioned pressure. No air from the tank is necessary for vaporizing the kerosene in the burner and pressure is only used for forcing the oil to the burner. The burner is attached to a steel pipe, oval shaped at the lower end and bent so that flame shoots diagonally into the mixer. It is fastened to the frame of the mixer.

Additional Cost of Concreting in Winter.— In constructing ore dock No. 2 of the Duluth & Iron Range R. R. at Two Harbors, Minn., the Engineering News-Record, Aug. 9, 1917, states that an item of interest in connection with the winter concrete work on the deck slab was the extra cost of this over concrete placed in more favorable weather. Aside from the initial delay due to very severe cold, no unfavorable conditions were encountered. When started, the concreting progressed at the maximum rate, very smoothly and with an unusually efficient crew of men. Yet the extra cost amounted to about $2.50 per yd. This was due chiefly to the cost of the housing, the fuel and boiler-plant attendants increased concrete labor cost due to decreased production, cost of moving housing and cost of canvas. This is not considered excessive in view of the results achieved.

The heating plant consisted of a 40-hp. return-tubular boiler and two water tanks installed on a flat-car. One tank was for the boiler feed and the other, heated by steam, for hot-water supply for the concrete mixer. A locomotive tender delivered water to the tanks by means of a steam ejector. A steam connection was made to the mixer drum to inject live steam there.

With this equipment it was possible to turn out concrete heated to almost any temperature desired. If concrete is too hot, however, it will set up badly in the mixer, clogging this rapidly, and will also cause checking in the finished slab work. The contractors consider 90 to 100° about as warm as it is desirable to go.

Although a comparatively thin concrete slab on top of a high structure extending into Lake Superior would not seem a very favorable place for cold-weather concrete work, there were several advantages for this work. The bottoms, fronts and dividing walls of the pockets were all in place, thus shutting off the under side of the slab very effectually. The dock was provided with the four railway tracks, and there was also a substantial steel railing on each side of the dock. These points were all used to assist in housing in the deck-slab work.

The housing, 70 ft. wide and 75 ft. long, was mounted on 4 wooden ore cars. The roof and ends of the house were made of 1-in. boards covered with tar paper, the sides being closed with canvas. Steam coils were built completely around the sides of the house and connected to the boiler car.

A move of 72 ft. could be made in 5 min. after the canvas was loosened at the bottom. With weather varying from zero upward, it was found entirely feasible to put in the deck-slab concrete. With weather much below zero it was not found advisable to handle that class of work.

An Inexpensive Method for Testing the Strength of a Reinforced Concrete Floor Slab.—The following abstract, of an article by C. H. Weitz in the "Purdue Engineering Review," is taken from Engineering and Contracting, Jan. 17, 1912.

A number of materials have been tried out for loading floors to be tested; such as pig iron, rubble stone, and bags of cement, gravel or sand. Where cartage charges and wages are high, the cost of a single test, using any of the above materials, will run from $200 to as high as $700. The latter figure may look very high, but a little figuring will show that the amount is not excessive or unusual. In the first place two slabs which measure 18 × 20 ft. each, live load 250 lbs. per sq. ft., will require about 200 tons of material for the test load. Cartage on this material to and from the job will cost

Per ton	$1.00
Unloading and hoisting	1.50
Taking down and reloading	1.00
Total cost per ton	$3.50

This makes a total of $700 for handling the 200 tons of material and is a very low estimate of the cost where laborer's wages are $3 per day, hoisting engineers get $5.60 and teams cost $7 per day.

It was while casting about for some cheaper method for making these tests that the writer hit upon the use of torpedo sand in the bulk. Damp torpedo sand weighs about 110 lbs. per cubic foot as it is shoveled into a bin or pile. A 2-in. plank enclosure was built on the center line of columns, enclosing floor panels. The height of this enclosure in feet was just 9/10 of the hundreds of pounds per square foot of the test load. For instance, a test load of 400 lbs. per square foot requires a bin 3 ft. 7 ins. high.

The sand can be loaded into wheelbarrows and hoisted on a brick hoist, or, more cheaply, in a concrete skip; or, still more cheaply, if conditions permit, by means of a bucket elevator. The sand should be hoisted first to the highest floor to be tested, thrown into the bin and leveled off even with the sides of the bin with a straight edge. The cost of hoisting the sand by the first method will run about 75 cts. per ton; by the second method 30 cts. per ton; and, by the third method 15 cts. per ton. These prices include placing the sand in the bin provided it is located within 30 ft. of the place where the sand is delivered by the hoisting apparatus. There is usually one or more of the above mentioned hoisting mechanisms available on a job, so that it is unnecessary to erect a hoist especially for testing purposes.

As soon as one floor is tested and the load is wanted on a lower floor, it is not necessary to lower the sand by means of a hoist or to carry it down a stairway as is the case when pig iron, rubble, or ballast in bags is used. Instead, all that is needed is to cut a small hole in the slab from beneath and let the sand run through. The hole can then be patched at slight expense.

When as many tests are made as is required the sand may be dropped down a stair or elevator shaft, through a window, or down a rubbish chute directly into wagons. However, there are usually a number of things remaining to be done, such as basement floors, sidewalks, etc., for which a quantity of torpedo sand is needed so that it is seldom necessary to remove any of the sand from the premises.

On a recent job about 150 tons of sand were hoisted by means of a bucket elevator to the third floor and spouted through a window on to the floor. This sand was then shoveled into a bin covering two panels to the required depth. The load was allowed to remain 24 hours for the city inspector to make his observations. A hole was then cut in the slab and the sand allowed to run down to the second floor where a bin had been prepared. After the test of the second floor the sand was dropped to the ground and was all used for cinder concrete and for the first floor which was laid directly on the ground.

The entire cost of these two tests, which involved the handling of 150 tons of material three times, was slightly less than $50.

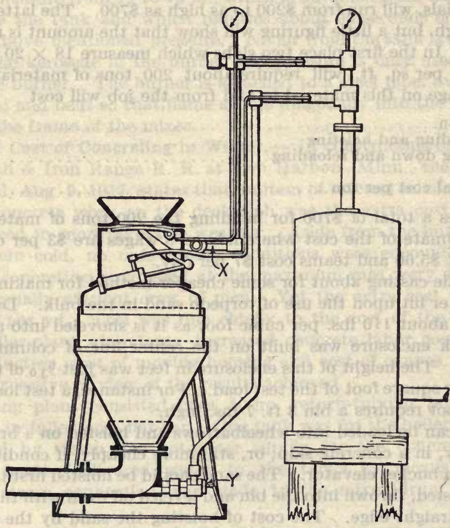

Fig. 5.—How to admit air to pneumatic concrete mixer.

Operating Cost of Concrete Mixer Reduced by Electric Motor.—Engineering and Contracting, May 2, 1917, gives the following:

By attaching an electric motor to a concrete mixer Ryberg Bros., contractors, Salt Lake City, Utah, effected an economy in the first month's operations amounting to more than the cost of the motor. The contractor had a Ransome 10-cu. ft. batch load mixer with a steam engine and boiler. The motor was mounted on timbers extending across the bed frame of the mixer and was connected by a belt to the flywheel of the engine, the piston rod and eccentric of the latter being disconnected from the crankshaft. The boiler was removed. The motor cost $65, and its installation and other work cost $6. The operating cost by electricity for a 25-day month, with the mixer averaging 60 cu. yd. per 8-hour day, was $45. When operating by steam, with coal at $1 per day and engineer at $3.50 per day, the cost was $112.50 per month.

Operation of Pneumatic Mixers.—H. A. Leeuw gives the following discussion and data in Engineering Record, Oct. 9, 1915.

Proper application of an ample supply of compressed air has overcome clogging in the conveying pipe in placing concrete by the pneumatic method.

This clogging has been the most serious drawback to the use of this method for mixing and placing concrete, which has developed until concrete has been placed at a distance of 2,800 ft. at the Mile Rock tunnel in San Francisco, and raised to a height of 60 ft. in building piers for a bridge at Magnolia, W. Va.

Owing to the way in which different aggregates behave in feeding into the conveying pipe, the air has to be supplied differently for stone and gravel. The illustration shows a cross-section of the mixer and inlet pipes, which are designated by *X* and *Y*. To illustrate the above statement, when gravel is used, it has been found that it was necessary to admit air only through the inlet marked *Y*, as an application through both would cause the material to feed too fast into the conveying pipe, and would result in a clogged pipe. When stone is used, however, it is necessary to apply the air through both inlets. If only the inlet *Y* is used, the material will arch and then suddenly all down to the discharge pipe, causing it to clog.

It is very important to have a sufficient volume of air to carry the concrete through the delivery pipe to the forms. When this has not been properly taken care of, the concrete will drop in the delivery pipe and the next batch will stick on this and clog the pipe. The tendency has been to under-estimate the number of cubic feet of free air per minute required. The following table shows the result of three years of study and practical experience. Present satisfactory installations are proving the correctness of these figures.

Cubic Yards of Concrete Per Hour, Mixer Capacity ½ Cu. Yd.

Actual amount of compressed air required. Cu. ft. of free air per minute	Length of horizontal discharge: 100 Lin. ft.	300 Lin. ft.	400 Lin. ft.	600 Lin. ft.	800 Lin. ft.	1,000 Lin. ft.
600	20	15	10	...	..	..
800	30	20	18	12	6	..
1,200	40	30	25	20	12	8

It has been found that the character of the sand plays a more important part, with reference to the speed with which the mixture is carried through the pipe, than does that of the stone or gravel. A sharp, clean sand will require less air to move concrete mixed with it than one in which the percentage of loam or oxide of iron is high.

It has also been found that a pressure of 90 lb. per square inch gives the best results. This pressure, expanding into a 6 or 8-in. pipe, depending on the size of stone or gravel used, is reduced to a pressure averaging about 25 lb.

Hose at Delivery End Reduces Kick.—This high pressure has presented an obstacle to be overcome, as the delivery end must be securely fastened to take care of the kick resulting from this pressure. After considerable experimenting, it has been found that a hose, the lining of which is made of pure rubber to withstand the wear, and reinforced to take care of the thrust, when connected a short distance from the delivery end, acts as a shock-absorber, and allows the discharge end to be handled, so that the concrete is not all deposited in one place, but may be distributed in even layers.

The mixture of the concrete placed in this way has been found to be as perfect as that delivered by any of the mechanical mixers on the market. When, however, the volume of compressed air falls below the amount required, as shown in the table, the mixture shows a tendency toward segregation.

The pneumatic method is well adapted to tunnel lining, as it is possible to secure an increase of at least 50 per cent in speed with a corresponding decrease in labor. Accurate cost data are difficult to get, but the following represents the average case:

	Cents per cubic yard
Labor	12
Compressed air	20
Pipe and equipment	10
Overhead	3
Cost for mixing and placing	45

The usual labor crew consists of six men for an outfit which is placing concrete at the rate of 100 cu. yd. in a 10-hr. day.

Placing Concrete in Wall and Dam of Water Supply Reservoir at Montreal by Compressed Air Method.—Engineering and Contracting, Feb. 10, 1915, gives the following:

Fig. 6 shows the arrangement of material handling plant employed in placing the concrete in the walls and dam of the new reservoir of the Montreal

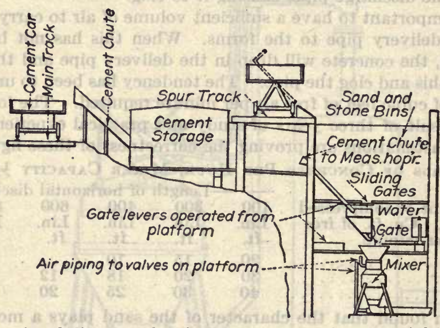

Fig. 6.—Sectional diagram showing arrangement for material handling plant and mixer for placing concrete walls and dam of new reservoir at Montreal by compressed air method.

Water and Power Co. by the compressed air (Mac Micheal) method. The cement used was unloaded from trolley cars on the track as shown. The sacks were unloaded by hand and were placed in the chute which carried them to the cement storage shed. A short siding on a trestle carried the aggregate past the cement shed. The crushed stone was dumped directly into the storage bin, over the mixer, from side-dump cars. The capacity of this bin was 80 and of the cars 6 cu. yds., respectively. The sand was shoveled from box cars into an auxiliary bin, at one side of the pneumatic mixer, of a capacity of 500 cu. yds. The 80-cu. yd. working sand bin, over the mixer, was gravity fed from the auxiliary sand bin mentioned. The sliding gates, hand operated, regulated the discharge of stone and sand into the proper compartments of the measuring hopper shown. Cement was gravity fed from its storage shed into the stone compartment of the hopper. Water was applied to the contents of the hopper as they were discharged into the mixer.

The discharge pipe from the mixer extended to the forms and varied in length from time to time. This was an 8-in. steel pipe provided with flange joints of a special design to facilitate adding or removing sections. The mixed concrete was discharged directly into the forms from the end of the conveying pipe or from a boot at the end of the pipe. At bends the pipe line was firmly secured to resist the side thrust produced by the inertia of the heavy moving mass of concrete. The sections were poured in three lifts of 15, 30 and 37 ft., respectively. The maximum length of discharge pipe was 600 ft., which included the 37-ft. ft. In this line the total curvature aggregated 400°. At this distance pauses were necessary between the discharge of successive batches to allow the air receiver to fill sufficiently. The wall was poured in alternate sections containing about 30 cu. yds. and this necessitated many shifts of forms and discharge piping thus delaying the work. Concrete was placed by the method described in zero weather without difficulty. the aggregate being heated.

TABLE IV.—DATA ON PLACING CONCRETE IN DAM OF MONTREAL RESERVOIR BY COMPRESSED AIR METHOD

No. of shifts	Distances transported, in ft.	* No. hours pouring	Cu. yds. poured	Cu. yds. per hr.	Cu. yds. per shift.	Ratio hrs. pouring to ttl. hrs.	Avg. labor, and power cost cts.
32	180–300	227	4,181	18.5	130	70%	21
22	100–180	126	3,941	31.5	180	58%	17
54	100–300	353	8,122	23	150	65%	19

* Includes pipe repairs and minor changes.

Concreting Dam.—Table IV gives a summary of the progress of the work in concreting the dam of the reservoir. Work was carried on in day and night shifts. In the work on the dam there were 54 shifts to place 8,122 cu. yds., or 150 cu. yds. per shift. The cost of labor on the day shift averaged $19 and on the night shift $27, or an average of $23 per shift. Thus the labor cost was 15½ cts. per cubic yard of concrete placed; the corresponding figure for power was 4.7 cts. per cubic yard. The average gang consisted of six men charging the mixer, including the operator, an extra cement wheeler, a foreman and from two to eight men on the pipe and forms. The best day's run was 436 cu. yds. in 7½ hours. On this run the cost of labor per cubic yard was 6.1 cts. and the cost of power was 1.6 cts.

Concreting Wall.—The wall contained 2,600 cu. yds. and was poured in 26 shifts. The average daily cost for labor was $17.50 and for power $7. This gave a cost for labor and power of 24½ cts. per cubic yard. The average gang on the wall concreting consisted of two men handling cement, three handling aggregate, one mixer operator, one water man, one foreman and one to three men on forms and pipe line. The distance transported ranged from 100 to 600 ft. All wall concrete was lifted 40 ft. Pouring was actually in progress 50 per cent of the time.

Plant.—The compressor used was a W. B. 2 Sullivan, steam driven, 705 cu. ft. machine. There were 1,100 ft. of 6-in. air pipe between the compressor and the mixer. There were two air receivers, one of 150-cu. ft. capacity at the compressor and one of 50 cu. ft. capacity at the mixer. The compressor was run from the boilers of the stone crushing plant and the cost of steam was prorated to the different engines on the basis of the horse-power required. Under this arrangement the power cost for the compressor per shift was $7.

Labor Saving Equipment for Depositing Concrete.—The following data are taken from an article in Engineering Record, Jan. 27, 1917, by W. P. Anderson.

The object of the two installations considered was to reduce the number of common laborers required by doing away with all hand shoveling, charging the mixers by gravity and decreasing the amount of labor needed in handling the chutes used to place concrete directly in the forms. At the plant of the Ubiko Milling Company this was accomplished by dumping the cars of concrete materials into a small bin under the track, from which a bucket elevator carried them to overhead storage bins feeding the mixer by gravity. Both sand and gravel were dumped into the track pit, the material being deflected at the top of the elevator into the sand or gravel compartment of the bins, as the case might be, by a gate between the bins.

At the East Side High School the concrete materials were unloaded from railway cars to overhead bins or into reserve storage piles by a derrick with a clamshell bucket. Stone and sand were drawn from the bins into a small measuring car with two marked compartments which ran along an elevated track in front of the bins and dumped directly into the charging hopper of the mixer. The cement at this plant was unloaded and handled on gravity rollers, and the form lumber, tile and other materials were unloaded in the same way.

Movable Hoppers on Concrete Towers.—At both plants the concrete, after being mixed, was hoisted to movable hoppers, which could be set at any desired height on the tower, and thus spouted to place. The main tower at the East Side High School plant was provided with two hoppers so that concrete could be spouted alternately for long and short distances without materially changing the rigging of the chutes. The amount of rigging required at this plant was further reduced by having drop chutes set in the main chute lines at convenient points. At both plants, the first length were supported from split booms. The upper chute line for the high-school buildings, however, which remained fixed during most of the work, was hung from a guy cable between the main tower and a centrally located tail tower. For supporting the lengths of chute within the lines of the buildings, tripods mounted on iron wheels about 30 in. in diameter were used. The large diameter of these wheels made it possible to roll the chutes around over reinforcing steel already in place, or on the forms or finished surface, with little labor. In addition to the wheeled towers a low "bicycle" frame on two similar wheels was used to carry the delivery end of the chute line at the Ubiko plant.

TABLE V.—LABOR COST OF CONCRETING

	—Ubiko Plant—		
	Mill	Warehouse	East Side High School
Installing and wrecking equipment	$0.426	$0.426	$0.350
Unloading sand, cement and gravel	.265	.265	.171
Mixing concrete	.272	.204	.263
Hoisting and placing concrete and handling chutes	.340	.356	.475
Cleaning up, care of sacks, and miscellaneous	.176	.140	.040
Protection on account of winter work	.003	......	......
Labor cost per cubic yard	1.482	1.391	1.299
Total yardage	2267	907	*4661

* Partial yardage; work not yet completed.

The labor costs given in Table V were realized with common labor at 25 to 30 cents per hour on the Ubiko job, most of the men receiving the lower rate, and at an average of 28.5 cents per hour on the high-school job. The yardage indicated in the table so far placed at the high-school job is considerably below the total quantity of concrete required; but as the total yardage has been considered in estimating the cost for installing and wrecking the equipment and for cleaning up and miscellaneous work, it is expected that the unit figures given will prove approximately correct at the close of the work. It is interesting to note that with the higher unit cost for installation on the smaller contract a lower cost for mixing and placing concrete was realized. The figures make it appear also that the grab-bucket rig has a considerable advantage over the bucket conveyor. It must be considered, however, that it was not always possible to secure materials in bottom-dump cars. Moreover, the design of the conveyor in this plant proved faulty, and a heavier one is now in use on the second contract.

Labor Costs on Foundation Work, Using Portable Plant.—The following data, published in Engineering and Contracting, July 5, 1911, are given in a table appended to a paper by Victor Windett, presented to the Western Society of Engineers on June 7th, 1911.

A portable concrete mixing and conveying plant, which was used by the Great Lakes Dredge & Dock Co. on foundation work for a blast furnace plant near Chicago, is built on a platform 20 ft. square which is mounted on rollers. On the platform a 75 h.p. horizontal boiler is mounted which furnishes steam for the operation of the Ransome mixer and Lidgerwood hoist. The 1-yd. mixer is placed near the rear of the platform and a hopper bin is erected above it, which has a capacity of 10 cu. yds. of stone and 5 cu. yds. of sand. The bins were filled from cars on a parallel track, by means of a locomotive crane and clamshell bucket. Storage is provided for 500 bags of cement on the platform at one side of the mixer. The material from the storage bins is dumped into a 1 yd. batch hopper. From the mixer the concrete is delivered to a Ransome tower bucket which is raised 75 ft. and delivered into the chute. The chute consists of a 12-in. galvanized pipe, supported by two 80 ft. booms. From the ends of the booms lines run to equidistant points on the chute thus supporting it uniformly and keeping it in a straight line. The booms are swung horizontally over the work by hand. The lower 60 ft. of pipe is made in movable lengths of 8 ft. The plant itself is pulled along on its rollers by attaching a line to a deadman and taking it in on the hoist.

The concrete work consisted of foundations for power house and blast furnace buildings. The work was started in 1910 and continued through the winter and spring of 1911.

Table VI gives data on 6 different operations in connection with this work designated as A, B, C. etc. The total work done amounted to 36,146 cu. yds. of concrete. The labor costs given include the placing of 500,000 lbs. of steel reinforcement or about 14 lbs. per cu. yd. of concrete also the labor for erecting and dismantling the plant for handling the concrete.

The rate of wages paid averaged $0.344 per man per hour including the entire force employed.

TABLE VI.—DATA ON CONCRETING FOUNDATIONS

	A	*B*	*C*	*D*	*E*	*F*	General average
Sq. ft. of forms per cu. yd...	7.57	9.74	12.8	14.2	6.1	8.69	9.0
Sq. ft. surface, without forms	8.54	16.1	14.4	.....	.....	14.7	13.0
Total days worked..........	110	79	75	17	24	70	375
Actual concreting time, days.	88	57	36	14	20	62	277
Total labor-days of 9 hours..	5,020	3,977	2,310	922	1,290	3,900	17,419
Cu. yds. of concrete per day (total time).............	98.5	128	49.6	72	139	100	96.5
Cu. yds. of concrete per day (conc. time).............	123	172	103.5	87.5	167.5	113	130
Labor days per cu. yd.......	0.46	0.40	0.62	0.75	0.39	0.56	0.482
Labor cost per cu. yd., dollars	1.43	1.24	1.92	2.32	1.21	1.74	1.49

A. The work on the blast furnace building was massive concrete work the blast foundations consisting of concrete slabs 50 × 70 ft. square, and having a firebrick core averaging 23 ft. in diameter. There were 10,809 cu. yds. of concrete placed at a complete labor cost as given above:

B. The work on the hot blast stove and boiler foundations was massive work, including 10,064 cu. yds. of concrete placed during the summer.

C. The power house foundations consisting of light piers, floors and some massive piers, including in all some 3,733 cu. yds., were placed. This work was done in the winter.

D. The casting machine building foundations were built in the spring. These consisted of light piers and walls amounting in all to 1,225 cu. yds. This concrete contained no reinforcement.

E. The work on the wharf consisted of 3,344 cu. yds. of concrete in massive work. Two rows of piles were capped with concrete forming a base for the walls supporting the rails of the unloading crane. This work was done in the winter and early spring.

F. The construction of the piers for the steel trestle consisted of moderately heavy work amounting in all to 6,971 cu. yds. of concrete. The work was done in the winter and the chuting system was not used. Instead the concrete was delivered in hand pushed Koppel cars of 1 cu. yd. capacity.

Wear of Pipe and Trough Conveyors for Concrete and Concrete Materials.—The following is taken from Engineering and Contracting, March 17, 1915.

In lining pressure tunnels on the Catskill Aqueduct concrete materials were in several places fed down shafts through steel pipe to mixers at the bottom. In one case an 8-in. pipe was used and in another case a 15-in. spiraly rivited steel pipe. In both cases excessive wear put pipe delivery out of competition as an economic means of conveying concrete aggregates great vertical distances. Incidentally clogging occurred so frequently that, putting excessive wear aside, pipe chutes were a failure.

On recent tunnel work in San Francisco, placing concrete lining by pneumatic mixer and conveyor, very interesting studies of pipe wear are reported. An 8-in. steel pipe was used for conveying and 16-cu. ft. charges were forced through the pipe under 120 lbs. air pressure with velocities of 75 to 100 ft. per second. On level straight lines ordinary 8-in. flanged connection steel pipe not quite new had a life of about 6,000 cu. yds. of concrete conveyed. The same pipe on an upgrade of 7 per cent wore through first on the top. Threaded connections proved least durable; the thinning of the section by threading resulted in rapid cutting through at the joints. At bends, 4-ft. radius, ½-in. steel pipe cut through in instances in 12 hours continuous conveying and averaged only 60 hours life.

Records of gravity conveying of concrete in open trough inclined chutes may be summarized about as follows: No. 14 gage blue annealed steel open trough chutes have in instances cut through small holes with 1,500 cu. yds. of concrete conveyed, and there are recorded instances of such chutes having carried 20,000 cu. yds. without wearing holes.

The examples selected, it must be remembered, are purposely examples of failures. They are chosen to show the worst results likely to be experienced in wear of pipe and trough conveyors. Ordinarily the contractor will not experience anything like such adverse conditions. Were this not true these conveying methods would never have attained the extensive use that they have. When excessive wear occurs the records, though they are unfortunately very meager, indicate that it occurs because of exceptional circumstances.

As indicated by the example cited, pipe line wear is greatest at bends, at thin spots like threaded joints and on up-grades. Trough chutes cut through first at dents or bumps or where there are "soft spots" in the rolled plate. Again the character of the aggregates affects greatly the rate of wear. For example pit run gravel will cause least wear, broken stone causes more rapid wear, and slag causes extremely rapid wear. Velocity of travel of the concrete is another factor of importance. Driving a batch of concrete through a closed pipe under crowding pressure at a speed of over a mile a minute is a severe abrasive action for any steel to resist. The wonder is that the destruction is so small as it is. Speed and pressure of flow increase materially the rate of wear of pipes and chutes.

The causes named for excessive wear indicate the possible remedies. At bends in pipe lines, for example, elbow sections of special pipe may be used. Cast manganese steel bends were finally adopted on the San Francisco tunnel work previously named and despite their greater expense proved more economical than ordinary steel elbows. It might even be economical when long use is expected to adopt alloy steel or special steel pipe for the line as a whole. Another remedy is a special joint construction, one which will not produce a thin spot or an irregularity which will intensify the wear locally.

Open trough chutes, inclined so that flow is by gravity, present a different problem. Good uniform quality steel plate shaped smooth and kept undistorted by denting or buckling is the first requisite. Where this will not serve, resort to interlining or to alloy steels is probably the only solution unless change is possible to a smoother aggregate or to reduced chuting speeds. Inquiry of one of the leading makers of concrete chutes, brings out data on relining chutes which contractors will be interested in noting.

For the ordinary job the relined chute is not advisable because of the increased weight. The standard untrussed unlined chute of No. 14 steel weighs from 20 to 30 lbs. per lineal foot so that the ordinary 30-ft. section weighs about 450 lbs. A 50-ft. trussed section without lining weighs 905 lbs. These weights are about as great as the contractor can handle well. No. 14 bottom liner plates 12 ins. wide add about 3½ lbs. per lineal foot or 165 lbs. to a 50-ft. section. Taking into account all the factors causing wear it is probable that a lined chute will wear three times as long as one without lining. Also relined chutes are less liable to become dented and if the plates contain soft spots they are not likely to coincide in locations. For work of considerable volume lined chutes are practically always advantageous.

Depositing Concrete in Bags Under Water.—H. R. Ferriss gives the following data in Engineering and Contracting, Feb. 10, 1915.

A 20-in. cast iron outfall, Fig. 7, was laid from a point on shore to a distance of 720 ft. out from shore, at which point the end was in 18 ft. depth and a swift off shore current. The outfall follows a channel between high rock reefs, and the pipe for its entire distance—with the exception of 120 ft. of the outfall end—is laid in a ditch dredged in clean sand. At the outfall end, the floor of the sea falls away somewhat faster than the grade of the pipe, and advantage is taken of this to hold the end of the pipe line off the floor of the sea. It was considered advisable by the engineer in charge to rest the pipe on concrete deposited in bags, and the outermost end, owing to the swift current and heavy winter storms, is heavily anchored with concrete in bags.

A 1:3:6 mixture was used. A scow was anchored near the outfall end, and aboard it the concrete was mixed and sacked dry. The sacks of concrete were then lowered in a sling, and placed one at a time, by the diver, who afterwards ripped them open with a knife as placed. The concrete showed no sign of setting up for two days. After the seventh day it was fairly well bonded. It is now, after one year, a fairly good mass of concrete, which shows no damage, either from the swift current or from storms, from whose action, except the fiercest, however, it is probably protected by its depth.

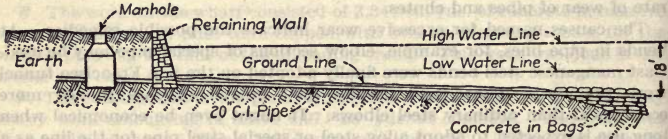

FIG. 7.—Anchorage of concrete in bags for submerged outfall.

It will be noted that the costs of labor only are given, and they depend considerably on locality and weather, which in this instance was exceptionally fine. The costs of materials are easily ascertained for any locality. The costs for the use of scows, engines, etc., will depend entirely on locality and weather conditions. The amount of concrete deposited was 80 cu. yds. and cost as follows:

	Total	Per cu. yd.
Sacking and mixing concrete:		
Foreman, 19 hrs. at 35 cts	$ 6.65	$0.082
Labor, 400 hrs. at 30 cts	120.00	1.500
Placing:		
Diver, 120 hrs. at $1.00	120.00	1.500
Tender, 120 hrs. at $0.50	60.00	0.750
Compressor eng., 60 hrs. at $0.40	24.00	0.300
Labor, 250 hrs. at $0.30	75.00	0.938
Total	$405.65	$5.070

Labor Cost of Forms for Reinforced Concrete Construction.—In a paper read before the American Concrete Institute, Feb. 14, 1916 and abstracted in Engineering and Contracting, Mar. 1, 1916, Sandford E. Thompson gives the following:

In reinforced concrete construction, the greatest discrepancy lies in the cost of forms. It is here that the contractor and also the engineer are apt to be fooled, unless either they are well provided with unit costs or else have handled work previously of an identical nature.

To illustrate the variations in labor costs of different members in form construction, Table VII presents a few values selected from "Concrete Costs" by Taylor and Thompson.

TABLE VII.—LABOR COSTS OF FORMS FOR COLUMNS, BEAMS, GIRDERS, AND SLABS

Costs include 10% for foreman and 15% for superintendence, contingencies, etc., but do not include profit or home office expense. Carpenter labor, 50c per hour; ordinary labor, 25c per hour. Material, 1-in. lumber.

Size	Make form	Place and remove form, first time	Place and re-move form after first time	Remake, place and re-move form
12-Foot Columns—Labor Cost per Member, Iron Clamps				
8-in. by 8-in.	$1.16	$4.68	$3.77	$5.53
16-in. by 16-in.	1.46	5.45	4.40	6.16
24-in. by 24-in.	1.80	6.20	5.14	6.86
36-in. by 36-in.	2.61	7.64	6.33	8.14
20-Foot Beams—Labor Cost per Member, Size Measured Below Slab				
4-in. by 8-in.	$0.92	$2.42	$1.97	$2.79
6-in. by 12-in.	1.09	2.75	2.31	3.23
8-in. by 16-in.	1.26	2.99	2.59	3.64
12-in. by 24-in.	1.75	3.41	3.09	4.29
20-Foot Girders—Labor Cost per Member, One Intersecting Beam				
8-in. by 16-in.	$1.38	$3.27	$2.75	$4.31
12-in. by 24-in.	1.82	3.86	3.20	5.02
Labor Cost of Slab Forms*				
Per 100 square feet of slab surface	$ .81	$2.53	$1.90	$2.06

* Based on slab built two panels per bay.

For inexperienced builders, increase costs 33⅓%.

For special design, add 10% to 50% to "Make Forms."

If no mill saw on job, add 50% to "Make Forms."

If old lumber is used, add 75% to 100% to "Make Forms."

For rectangular columns, select values for square columns having the larger dimension of the rectangle.

For wall columns, add 50% to all except "Make Forms."

Design and Costs of Sliding Forms for a Reinforced Concrete Grain Storage House.—The following data were published in Engineering and Contracting, Oct. 20, 1915, by Wm. Wren Hay and refer to the design, construction and costs of the sliding forms for a large reinforced concrete grain storage house located in Western Canada. The detailed costs of these forms were compiled in the field while the forms were under construction and were checked from the final costs after the concrete was placed and after the accounting had been totaled. The costs are the result of daily observations as to labor and materials in use, these costs being derived in part from the reports turned in by the foremen and in part by personal check of the amount of work completed each day. They were obtained for the purpose of checking the work against the contractor's estimate of cost, and were also used as a guide for the time of completion of the job, as all work was conducted on a rigid schedule to insure against delay in any part of it.

In estimating for such construction it is customary to figure the actual contact surface at so much per square foot, and to figure the flooring over the bins, the yokes, the jacking, and the maintenance of the forms while being lifted, together with their removal, each as a separate item. The cost data given will therefore be grouped in this manner. It is evident that the form surface is a function of the lineal feet of bin walls, and that the number of yokes will vary in a similar manner, although influenced by the contact of the bin arrangement. The flooring will vary as the area of the bins, while the jacking and the maintenance are further influenced by the height of the bins The item of removal depends largely upon the bin arrangement and the story overhead, from which are hung the blocks used for hoisting.

Design Features of Bins.—The bins cover an area of 11,850 sq. ft., their width being 74 ft. 4 ins. and their length 158 ft. 4 ins., including a projecting stairway and elevator tower 12 ft. wide by 17 ft. 10 ins. long. The bins proper consist of 50 circular tanks, each 13 ft. in inside diameter, arranged in five rows spaced 15 ft. 6 ins. on centers by ten rows spaced 16 ft. on centers, forming 23 inner bins and 13 leg openings. The exterior walls are run straight through tangent to the circular bins, these forming 26 additional outer bins The bins are 70 ft. in height, with a nominal capacity of 500,000 bushels. The bin walls are all 6 ins. thick. The contacts of the circular tanks across the structure were widened out, and upon them rest the columns which support the floors of the cupola above. Lengthwise of the bins the tanks are connected by 6-in. contact walls, each 2 ft. long, except where the elevating legs run between the pairs of tanks. This arrangement of bins is that commonly used for houses of this type where there is an additional storage annex.

Forms.—In general, the forms consisted of segments made up of 2-in. planks, spaced 28 ins. vertically, to which were nailed 1-in. sheathing. The large circular forms were braced by means of ½-in. rods bolted through the upper and lower segments at an inclination of 45°, forming a truss arrangement which effectually prevented distortion. The skeleton forms were placed on the bin-bottom girders, being nested together to form the 6-in. wall space. The yokes were then straddled across the opening. As fast as the floor was laid over the forms the latter were cut through at certain lines to provide slip joints, and were then tied horizontally by timbers bolted across the wall space on each side of the joints, by means of toggles at the cuts in the segments and by the rods bolted from one yoke to another across the cut. These joints divided the entire area into eight sections of six tanks each and one section consisting of two tanks and the tower. They were provided for the purpose of enabling each section to be adjusted for levels independent of the others, but the experience on this work did not seem to justify fully the additional expense.

Plant for Constructing Forms and Procedure.—The plant used in constructing the forms was centered in a large carpenter shop, 48 ft. wide by 72 ft. long, in which were set two combination, gasoline-driven saw rigs, with 24-in. gage industrial tracks for handling the lumber in and out of the shed. The lumber was routed from the trackage, where it was unloaded from the cars into the shops for cutting, and out on the opposite side onto a large, open-air platform, upon which the segments were nailed on templates and the sheeting erected. All of the segments were cut to shape on these saw rigs, and all of the sheathing boards were also cut to length on them. This work was done some time in advance of the actual operation of sheathing, and the segments were also nailed ready for the boards, in advance. The sheeting was actually commenced 20 working days before the forms were needed for concreting. To maintain the necessary schedule, and yet not crowd the carpenters, a curve of parabolic form was drawn through the points representing the first three days' unit progress, this curve terminating in the day specified for the total area to be sheeted. By accounting for the area sheeted during each five-hour period, and plotting the points, a very close account was kept of the progress. As a result the last segments were being covered when the first completed forms were started up to the top of the girders.

Detailed Costs of the Forms.—The following data give the unit costs, in the yard, of the forms, as determined from day to day:

Item	Cost per sq. ft. of contact surface
Carpenter labor	\$0.089
Superintendent	0.013
Bolts, etc., including labor	0.010
Oiling forms, total	0.002
Lumber	0.061
Total	\$0.175

The observed rates of labor were as follows:

Item	Labor force	Time required
Cutting segments, 27,500 ft. B. M.	1 carpenter 2 laborers	20 days
Nailing segments	4 carpenters 3 laborers	10 days
Sheathing segments, 18,200 sq. ft.	10 carpenters 2 laborers	20 days

The carpenters were paid 50 cts. per hour and the laborers 30 cts. per hour, working 10 hours per day. There was a total of 5,150 lin. ft. of bin wall, and the staves were 48 ins. in length. The actual contact area was 20,600 sq. ft. Of this amount only 18,200 sq. ft. were built in the yard, the remainder for the exterior perimeter of the storage house being cut and framed on the floor during erection. In the totals considered later, this contact area of 20,600 sq. ft. is used.

The lumber for the sheathing was a special 1 × 4-in. tongue-and-groove pine, with the grooved edge beveled slightly for the circular forms. Its cost was \$28 per M. The cost of the common lumber varied from \$17.50 to \$22 per M, depending upon the size. There was a total of about 11 ft. B. M. per square foot of building used in these forms, divided as follows:

	Ft. B. M.
Segments	2.2
Staves	1.1
Flooring	3.3
Miscellaneous, including gallery, staging, timber for joints, etc.	4.4

Oiling.—The form surface in contact with the concrete was oiled with two coats of light oil. There was no trouble whatever due to sticking or swelling, as the oil penetrated to a considerable depth and prevented the entrance of water. A paraffin oil, from which the small residue of kerosene remaining after "freezing" had not been removed, was used. This oil cost 22 cts. per gallon in barrel lots. One gallon of oil covered 160 sq. ft., two coats, one man applying it at the rate of from 350 to 400 sq. ft. per hour.

Yokes.—The yokes used on the forms were constructed of timber, the legs being 6 × 8-in. pieces, 8 ft. long. The jacks, which were of the pump type, were seated on two 6 × 6-in. pieces, through which ran the 1¼-in. jacking rod. The head piece was a 3 × 8-in. timber. Double ⅝-in. bolts were run across the top and middle, and the forms were hung from the yokes by means of ½-in. rods through both segments and the jack seat. Each yoke contained about 85 ft. B. M. of lumber and 25 lbs. of bolts and iron, and cost slightly over \$5 in place. There were used on this set of forms 244 yokes. In general, there were four yokes to each circular tank. Where the joints occurred a yoke was placed on each side of the joint.

The joints were made by overlapping pieces of 2 × 6-in. timbers where the face of the form was cut, the opening being covered with a piece of tin. The segments were held together by a toggle joint, consisting of a short section of 1½-in. pipe running through four steel plates bolted to both segments, on each side of the cut. There were 80 of these joints, the cost of each being about $12, of which $4.50 was for materials and $7.50 for labor.

Total Costs of Formwork.—The following are the final costs as returned for the various items discussed:

		Per sq. ft.
Forms, labor only:		
Carpenter shop and yard	$2,112	or 10½ cts.
Placing, including floor	1,439	or 7 cts.
Materials, incl. iron, etc	1,470	or 7¼ cts.
Total	$5,021	or 24¾ cts.
Maintenance, leveling, repairing, etc	$ 667	
Yokes, including setting jacks, bolts, plates, etc	1,220	
Joints, including timbers, bolts, plates, etc	960	
Total, no removal	$7,868	
Estimated cost to remove	500	
Total cost of forms	$8,368	

There were 54¼ cu. yds. of concrete per vertical foot of the bins. This concrete was placed at the rate of 10 cu. yds. per hour, in 17½ days of 20 hours each, requiring a vertical movement of 3 ft. 9½ ins. per day. The cost of the jacking gang was about $100 per day, with labor at 30 cts. per hour. The cost of placing and finishing the concrete walls was $1.00 per cubic yard, plus an overhead charge of 30 cts. per cubic yard, or a total of $1.30 per cubic yard. It cost about $10 per ton to place the ⅜-in. rods used for reinforcing and contacts, plus $6.50 per ton for handling in the yard, or a total of $16.50 per ton.

Movable Wall Forms Give Low Cost.—Fig. 8 indicates the type of forms employed in building two heavy concrete walls aggregating some 1,250 cu. ft. at Lock 9 on the New York State Barge Canal. The following costs, for this work, are taken from an article in Engineering and Contracting, Sept. 21, 1910.

The labor of building each form required 3 days' time for 6 carpenters. Two straight forms were built and one curved form. The cost of these, including labor and material used, was $525.00. Spruce dressed lumber was used, at $23 per M. ft. B. M. The labor of moving was accomplished by 6 men, including the foreman, in from 4 to 6 hours. This labor completed the moving and lining-up ready for concrete. The rate of wages for these men and cost of moving were as follows:

6 hrs.—Foreman at $3.52 per 8-hour day	$ 2.64
6 hrs.—2 men at $3.20 per 8-hour day	4.80
6 hrs.—2 men at $2.40 per 8-hour day	3.60
6 hrs.—1 man at $2.00 per 8-hour day	1.50
Total cost of knocking down and setting up	$12.54

The cost per cubic yard of forms and the setting up for the entire work may be estimated as follows:

Cost of material and building of 3 40 ft. forms	$525.00
36 setups at $12.54	451.44
Total	$976.44
Total cu. yds. + neatwork	4,370
Cost per cu. yd. concrete	$0.22

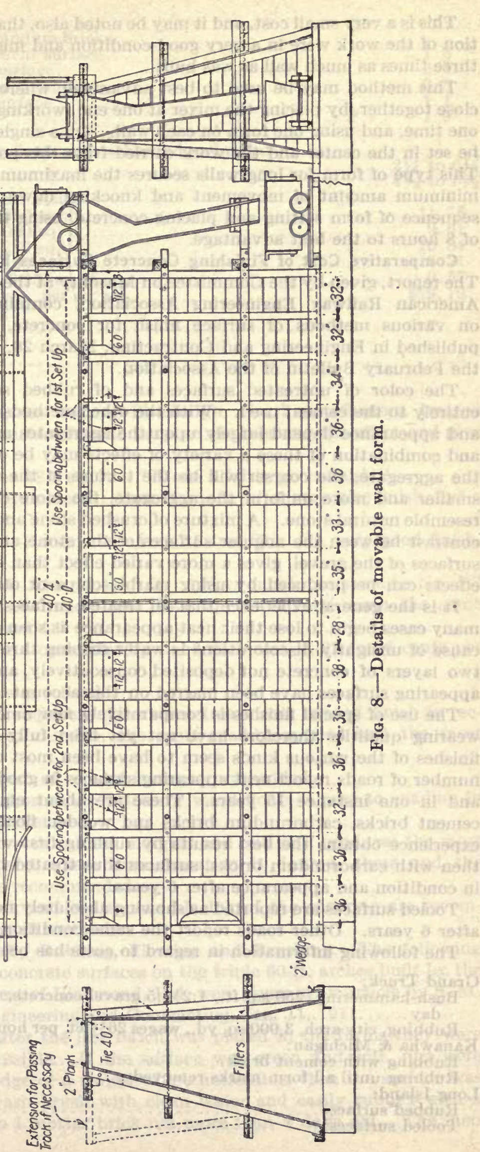

Fig. 8.—Details of movable wall form.

This is a very small cost, and it may be noted also, that the forms on completion of the work were in a very good condition and might have been used for three times as much wall as was built.

This method may be used to best advantage, where walls are parallel and close together, by placing the mixer at one end, working both walls forward at one time, and using one form on each wall. On a single wall the mixer should be set in the center and the work carried from this point in both directions. This type of form for long walls secures the maximum use of forms with the minimum amount of movement and knocking down, and gives the proper sequence of form setting and placing concrete, using the average day's work of 8 hours to the best advantage.

Comparative Cost of Finishing Concrete Surfaces by Various Methods.—The report, given by the Committee on Masonry at the 1917 convention of the American Railway Engineering Association, contained some cost figures on various methods of surface finish for concrete. The following notes published in Engineering and Contracting, March 28, 1917, were taken from the February Bulletin of the Association.

The color of untreated surfaces and of rubbed surfaces is due almost entirely to the cement used. With the other methods of treatment the color and appearance depend largely upon the aggregates and by proper selection and combination of these a variety of effects may be obtained. The coarser the aggregate, the coarser will be the texture of the finished surface. The smaller and more uniform the aggregate, the more closely will the surface resemble natural stone. A mixture of crushed stone and gravel, because of the contrast between the angular surfaces of the stone and the round smoother surfaces of the gravel, gives a more varied effect than either alone. Pleasing effects can be produced by using marble chips or other colored aggregate.

It is the general experience that all treated surfaces darken in time and in many cases begin to lose their neat appearance as soon as finished. A fruitful cause of unsightly discolorations is water seeping through the seam between two layers of concrete not deposited consecutively, and many otherwise fine appearing surfaces have been marred on this account.

The use of special finishes is comparatively new among railroads and their wearing qualities therefore have not yet been fully determined. Rubbed finishes of the various kinds seem to have been most commonly used, and a number of roads report neat appearing surfaces in good condition after 3 to 8 and in one instance 15 years. These are about equally divided between cement bricks, carborundum bricks and wooden floats. One road of large experience obtains the best results by rubbing first with wooden floats and then with carborundum bricks, surfaces thus treated being very satisfactory in condition and appearance after 6 years.

Tooled surfaces are reported as showing absolutely no signs of deterioration after 6 years. Other roads report the same condition after 4 years' service.

The following information in regard to costs has been received:

	Ct. per sq. ft.
Grand Truck:	
Bush-hammering, 250 sq. ft., 1:2½:5 gravel concrete, wages $4 per day	7.2
Rubbing, city arch, 3,900 sq. yd., wages 26½ ct. per hour	5
Kanawha & Michigan:	
Rubbing with cement brick	4
Rubbing until all form marks removed	6
Long Island:	
Rubbed surfaces	1½ to 2
Tooled surfaces	2½ to 3

Michigan Central:	
Rubbing with carborundum bricks:	
1,610 sq. ft. abutment surface	1.6
1,005 sq. ft. pier surface	2.6
4,200 sq. ft. abutment surface	2.8
4,600 sq. ft. pier surface	1.1
Average	1.9
New York Central:	
Rubbing with wooden floats and carborundum bricks:	
Varied from	2¼ to 6⅛
Average	4⅜ to 5½
New York, Chicago & St. Louis:	
Bush-hammering, 1,960 sq. ft	11.75
Bush-hammering, 5,000 sq. ft	9.61
Bush-hammering, 8,280 sq. ft	10.84
Bush-hammering, 3,420 sq. ft	6.21
Rubbing wood floats, 6,250 sq. ft	0.57
Paneled posts, complete, per sq. yd	$19.19
Philadelphia & Reading:	
Bush-hammering	7
Seaboard Air Line:	
Scrubbing	5.5

The Pennsylvania Lines west of Pittsburgh, Northwest System, treated several small areas of surface for the purpose of observing the effect and give the following results:

(1) Tooth-Axed: Area 18.5 sq. ft. "Made a fairly good finish."

(2) Six-Point, Bush-Hammered: Area 16 sq. ft. "A very nice finish, but a little too fine."

(3) Four-Point, Bush-Hammered: Area 15.4 sq. ft. "A very good finish, perhaps the best."

(4) Beam-Hammered: Area 15.4 sq. ft. "Very much the same as No. 1."

(5) Crandled: 10-lb. hammer, area 16.2 sq. ft. "Very much the same appearance at Nos. 1 and 4."

All were done by the stonecutter by hand at a cost of 22 to 26 cents per square foot.

The conclusions were as follows:

1. For all work not requiring decorative treatment, spaded finish is recommended as the most durable, the most readily applied and the most economical.

2. Coating with a wash of cement is not recommended.

3. Rubbing with carborundum bricks or wood floats is next to spading in ease of application and cost.

4. Tooling, alone or with rubbed margins and outlines, produces the most pleasing appearance, and where ornamentation is desired, these and the scrubbing methods are recommended.

5. Careful form work and continuous placing of the concrete are recommended as essential for all methods.

Finishing Concrete by Rubbing, Floating and Brushing.—The following data, on finishing the concrete surfaces on the triple 60-ft. arches built by the Pennsylvania R. R. west of Richmond, Ind. were given in an article by S. M. Klein published in Engineering and Contracting, Jan. 11, 1911.

Forty-eight hours after the last batch was placed in the forms they were removed whenever possible. If the surface was green and soft, fins were scraped off with the edge of a trowel where noticeable, then the surface was wetted with a whitewash brush with clean water and easily rubbed with a 2½ × 2½ × 6-in., 2 to 1 mortar brick not more than 8 days old. The men rubbed the wall with a circular motion which left spots in places. Next day the wall was moistened and floated all over the surface with a wooden float and after that stroked in one direction up and down with a moist, clean whitewash brush. Two men rubbed and finished a section 10 ft. high, 30 ft. long and 3 days old in four hours at 17½ cts. per man per hour.

Where the concrete was a week old and older after forms were removed all fins were removed with a bush hand chisel having five blades. The surface was then wetted with plenty of cold water and rubbed with a 2½ × 2½ × 6-in. 1 to 1 mortar brick not more than 6 days old. One section was rubbed down well, all rod holes were plugged and next day the section was floated down and stroked with a moist, clean whitewash brush. No cement wash of any kind was allowed. Any broken corners had to be carefully repaired by thoroughly cleaning the surface, wetting the patch down well, then if possible driving 20d nails or railroad spikes into the concrete, putting up a form and grouting the broken place. Several patches were thus made and when finished could never be discovered.

The surfaces thus rubbed, floated and brushed bleached out uniformly everywhere, showed neither spots nor blemishes and gave the whole face a beautiful smooth dull finish. One foreman at 40 cts. per hour and 6 laborers at 17½ cts. per hour averaged 25 sq. yds. per man nearly every day rubbing and finishing was done, and they became very efficient at it and took a great deal of pride in their work.

Cost of Waterproofing Concrete Surfaces to Decrease Disintegration by Frost.—J. L. Lytel, project manager of the Strawberry Valley project, Utah, records in the "Reclamation Record" for April, 1915, an interesting experience in waterproofing of concrete surfaces. Engineering and Contracting, April 14, 1915, gives the following abstract of Mr. Lytel's article.

The storage works and tunnel of the Strawberry Valley project are located in the Wasatch Mountains at an elevation of 7,500 ft. There is a wide variation in temperatures in this vicinity and the climate is very severe during the winter months, the lowest temperature on record being 50° below zero. The snow fall ranges from 10 to 24 ft. in depth.

The extreme cold, with alternate thawing and freezing of water in the pores of the exposed faces of the structures, was found to have a very destructive effect on these concrete structures and the waterproofing of the surfaces was decided upon as a preventive against their continued disintegration.

It was decided to treat the vertical surfaces with alum and soap solutions and the horizontal surfaces with paraffine. The alum solution was made by dissolving 2 ounces of alum in 1 gal. of hot water. The soap solution was composed of ¾ lb. of castile soap dissolved in 1 gal. of hot water. The paraffine was boiled to drive off water as the presence of water rendered it hard to apply. Ordinary commercial products were used.

The surface to be treated with paraffine was first thoroughly dried and cleaned of loose concrete, dirt, and other foreign substances. The paraffine was then heated and applied with a paint brush, and was forced into the pores by the heat of a blow torch on the surface. Only one coat of paraffine was applied as the concrete would not absorb more.

The surface to be treated with soap and alum was prepared as above stated. The alum solution was applied at a temperature of 100° F. with a moderately stiff brush and was then worked in with a stiff horse brush. While the surface was still moist from this treatment the hot soap solution was applied in the same manner as the alum solution. One treatment by each solution in the manner described above constituted a coat. If other coats were considered necessary, they were applied in like manner after the preceding coat had been allowed to stand 24 hours or more.

Twelve structures were given this treatment, the surface area covered being approximately 28,000 sq. ft. Four thousand square feet were treated with paraffine, at the rate of 1 lb. for 11¾ sq. ft., and the remainder with soap and alum. It required 1 gal. of alum solution and a ½ gal. of soap solution to cover 50 sq. ft. with two coats. Two coats of alum and soap were applied at an average cost of 76 cts. per 100 sq. ft., and the cost varied from 41 cts. minimum to $1.28 maximum The cost of one coat of paraffine varied from $1.70 to $3.78 per 100 sq. ft., and averaged $2.11. This cost covers everything except general expense. The two men who did this work received $75 and $80 per month. Brushes cost $6.06, Castile soap 12½ cts. per pound, alum 18 cts. per pound, and crude paraffin $4.80 per hundred weight.

The results obtained by this waterproofing are considered very satisfactory. The structures that were repaired and treated have gone through two severe winters and no further disintegration of the concrete on any part has occurred.

CHAPTER VI

DAMS, RESERVOIRS AND STANDPIPES

This chapter besides giving general costs of a large number of well known reservoirs is largely composed of detailed methods and costs of concrete and steel structures. For detailed methods and costs of building earth dams the reader is referred to Gilette's "Earthwork and Its Cost." Further data on the cost of dams is also given in the "Handbook of Cost Data" by Gillette.

Cost of Storage Reservoirs per Million Cu. Ft.—Tables I and II, published in Engineering and Contracting, Sept. 4, 1912, are from a discussion by Seth A. Moulton on power costs and efficiencies contained in the Report of the Maine State Water Storage Commission.

TABLE I.—COST OF AMERICAN STORAGE RESERVOIRS
(From James D. Schuyler)

Name and location	Character*	Cost	Capacity million cu. ft.	Cost per million cu. ft.
Asokan Reservoir, N. Y.	M and E.	$12,669,775	16,030	$ 792
Belle Fourche Dam, S. D.	E.	879,164	9,360	94

Cost per Acre-foot of Large Storage Dams.—Francis L. Sellow, Project Engineer, U. S. Reclamation Service in a discussion in Proceedings, American Society of Civil Engineers, Vol. XXXIX (reprinted in Engineering and Contracting, May 14, 1913) gives the following costs of reservoirs in the United States and foreign countries. (Tables III and IV.)

TABLE III.—RESERVOIRS IN THE UNITED STATES, BUILT BY THE RECLAMATION SERVICE‡

Location	Type of controlling works		Storage, in acre-feet	Cost—Total	Cost—Per acre-foot
Arizona:					
Roosevelt Dam	Masonry	280 ft.	1,284,000	$3,697,000	$2.90
California:					
East Park	Concrete	139 ft.	45,600	239,000	5.25
Idaho:

Cost of Large Concrete Lined Water Works Reservoirs.—The following table is taken from Engineering and Contracting, Dec. 23, 1914.

TABLE V.—COST OF SIX LARGE AMERICAN WATER WORKS RESERVOIRS

Reservoir	Capacity in million gals.	Cost	Cost per million gals
Queen Lane, Philadelphia, Pa.	383	$1,188,000	$3,100
New Roxborough, Philadelphia, Pa.	147	524,000	3,600
Settling Basins, Cincinnati, Ohio	330	1,276,000	3,900
Service Reservoir, Minneapolis, Minn.	93	442,000	4,750
Prospect, Rochester, N. Y.	110	554,000	5,000
Northside, Pittsburgh, Pa.	150	676,000	4,100

Approximate Cost of Reservoirs per 1,000,000 Gal. Water Stored.—Engineering and Contracting, March 14, 1917, publishes the following tabulation from the report of the Water Commissioners of Hartford, Conn., C. M. Saville, Chief Engineer, for the year ending March 1, 1916, which gives comparative figures of size, capacity and cost of various reservoir developments.

TABLE VI.—APPROXIMATE COST OF RESERVOIRS PER 1,000,000 GAL. WATER STORED

Supply	Reservoir	Area flowed, acres	Average depth, feet	Storage, million gallons	Cost per M. G. stored
Hartford	Nepaug	851	34.	9,560	$ 130*
Boston	Wachusett	4,195	46.	63,068	145*
New York	Ashokan	8,180	48.	128,000	155*
Salem and Beverly	Lawrence Station	4,430	7.6	10,900	250†
Hartford	Richards Corner	437	21.	3,000	255†
Salem and Beverly	Topsfield Station	2,480	9.8	7,900	265*
Hartford	Reservoir 4	168	11.1	601	290*
Boston	Reservoir 3	253	14.3	1,180	360*
Boston	Sudbury	1,220	18.2	7,254	395*

* From records. † Estimated cost.

Cu. Yds. of Concrete per Foot of Dam.—Fig. 1, from an article by R. C. Beardsley published in Engineering and Contracting, Feb. 1, 1911, gives the cu. yds. of concrete per foot of dam for four different types of dams and for heads of from 1 to 225 ft.

Estimates of Dams.—The following notes are taken from Smith's "Construction of Masonry Dams" (1915).

Regarding estimates of cost: other things being equal they will carry more weight and conviction in proportion as they show evidence of having been formed after careful analysis; *i.e.*, a reasonable determination of quantities based upon some survey and plan and a subsequent, complete orderly estimate. Thus a mere statement of 100,000 cu. yds. of masonry at $4.50, $450,000, while possibly a very excellent guess is not nearly as valuable and convincing as a plan or profile from which the quantity can be derived, accompanied by a tabulation of all the items entering into the cost, with a sum of $450,000.

The following diagrams may be of some assistance in making up an estimate although they should be used only with some caution and an appreciation of their limits as to accuracy and consequent applicability for the particular estimate. A partial list of existing dams, with dimensions, quantities of masonry, cost and some accompanying pertinent notes, may (aside from its interest) be taken as a very rough indication of what another dam may cost if due regard is given as to whether the particular circumstances of the case are comparable. Such particular circumstances are location, size, accessibility, price and quality of labor, cost of cement, amount of excavation and refill involved, amount expended in beautifying the structure and surroundings, etc.

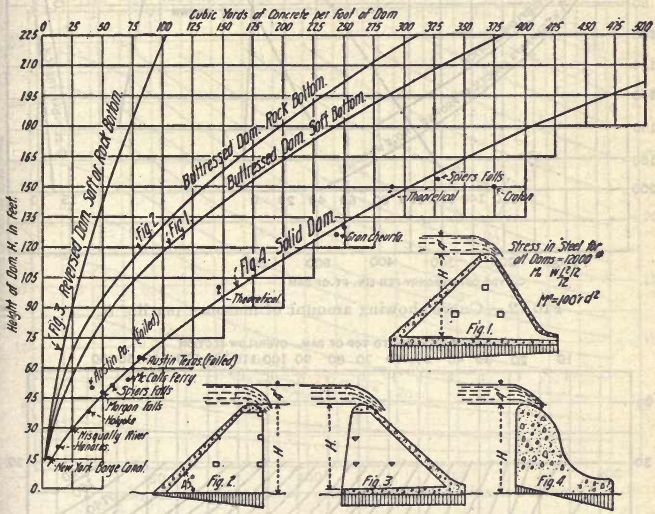

FIG. 1.—Cu. yds. of concrete per foot of dam.

Obviously the length and maximum height as given in the table is only a very crude indication of the amount of masonry involved. For that reason, therefore, it would be much preferable to construct a profile of the dam and from the diagrams (Figs. 2, 3 and 4) arrive at some number of cu. yd. as a basis for comparison. However, such analysis of and comparison with the table can at best furnish only a rough guide toward intelligent guess.

For the purposes of a preliminary estimate, it would be necessary to have a fairly accurate profile across the valley or canyon at the dam-site, together with a fair indication from borings, test pits or otherwise, of the location of the rock surface; also some opinion as to depth to which it will be necessary to go into the rock for a foundation. With such information it should be sufficiently accurate to obtain cu. yd. of excavation and masonry from the diagrams; they are constructed from acceptable masonry sections, and the possible error should be much within that of the then available data. When, however, the project has reached a stage to warrant special studies and designs to meet all

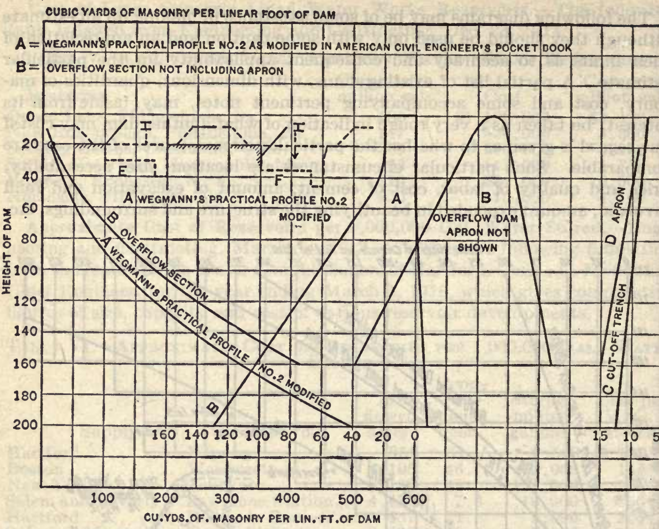

FIG. 2.—Curve showing amount of masonry per lin. ft.

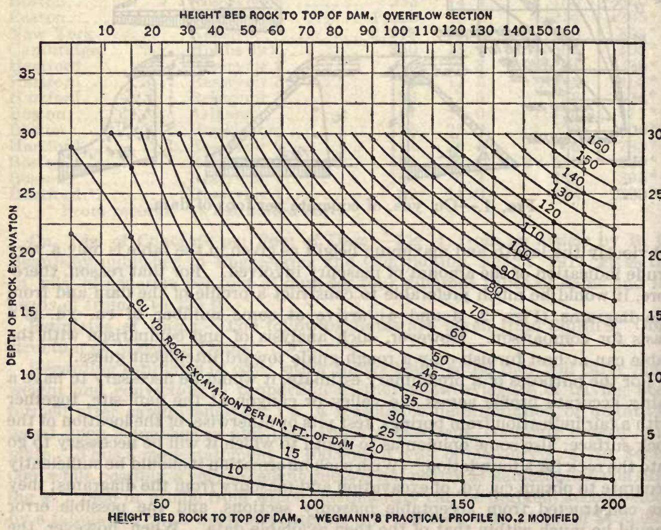

FIG. 3.—Diagram showing cu. yd. of rock excavation.

the particular conditions, much more accurate and detailed data in the way of surveys and borings will be at hand. Such diagrams will then be superseded by sections of the site and the proposed structure.

Diagrams for Preliminary Estimates of Quantities.—For a preliminary estimate of the quantities involved, based upon profiles of earth and rock surfaces across the valley, use accompanying diagrams as follows:

For masonry in a dam without overflow, assume as acceptable, Wegmann's Practical Profile No. 2 as modified on page 616 of the American Civil Engineers Pocket Book. (See section "A" Fig. 2.) For cu. yd. of masonry per lin. ft.

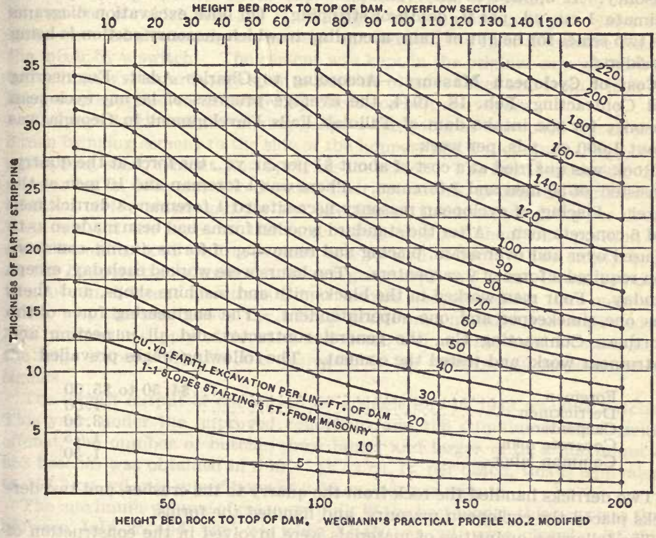

FIG. 4.—Diagram showing cu. yd. of earth excavation.

of dam read curve "A" for neat section to a horizontal base not including masonry in cut off trench.

If the dam is built on surface of rock add for masonry in cut-off trench as per curve "C."

If rock is excavated and masonry slopes can start from the original rock surface, as at "E," read curve "A" for a height above rock surface, and add an amount equal to rock excavation as obtained from diagram Fig. 3.

If masonry slopes must be extended down to a certain elevation below original rock surface, as at "F," read curve "A" for a height of dam above that elevation, and add an amount equal to the rock excavation below that elevation.

For masonry in an overflow dam, proceed precisely as above, reading curve "B" Fig. 2. Then if on account of height of dam, or for another reason, an apron is necessary, add an amount obtained from curve "D."

For rock excavation, read diagram Fig. 3 in which ordinates equal depth of rock which it is assumed necessary to excavate; abscissa represent width of excavation in terms of height of dam, which height should be considered as starting from the elevation where the neat masonry slopes begin. Curves show cu. yd. per lin. ft. and include cut-off trench as per curve "C" Fig. 2. If applied to an overflow dam with an apron, add to rock excavation as thus determined an amount at least equal to curve "D" Fig. 2 masonry in apron.

For Earth Excavation.—Read diagram Fig. 4 similar to rock excavation diagram, observing same rule for height of dam. Curves show cu. yd. per lin. ft. of dam for excavation to 1–1 slopes starting 5 ft. from neat lines of masonry. If applied to an overflow dam with an apron add for tentative estimate 1 cu. yd. per ft. depth of stripping. On both excavation diagrams are two scales for height of dam, according to which masonry section is being considered.

Cost of Cyclopean Masonry.—According to Charles Adsit, Engineering and Contracting, Feb. 18, 1914, the average progress of laying cyclopean masonry for the intake dam of Tallulah Falls Development in Georgia was about 1,000 cu. yds. per week.

Rock was quarried at a cost of about $1 per cu. yd., the force at the quarry, consisted of 50 men and 2 foremen. There was 1 foreman and 10 men at the mixer. Placing of cyclopean masonry necessitated 1 foreman, 3 derrick men and 6 concrete men. After the standard wooden forms had been made so as to be used over and over again, placing and removing of forms during construction required a force of 9 carpenters. Ten hours were worked each day, except Sunday. Four men worked in the blacksmith and machine shops, and there was one timekeeper and one superintendent. The engineering force of the Northern Contracting Co., the general contractor, did all inspection and instrument work, and tested the cement. The following wages prevailed:

Foremen	\$4.50 to \$5.00
Derrickmen	4.00
Carpenters	3.50
Concrete men	1.75
Common labor	1.50

Two derricks handled the rock from the quarry to the crusher, and two derricks placed the cyclopean masonry, and handled the forms.

The following quantities of materials were involved in the construction of the dam: Excavation, 10,600 cu. yds.; Cyclopean masonry, 39,200 cu. yds. The contract price for excavation, including stripping, earth excavation, rock excavation wet or dry, was $1.50 per cubic yard. The contract price, for cyclopean masonry, concrete in the bridge piers, and abutments, was $4.80 per cubic yard. The setting of gates and steel girders, and the reinforced concrete was paid for separately as extra work.

The construction plant consisted of the following equipment:

1 200-HP. Hardie Tynes corliss engine.
1 150-HP. and 2 80-HP. boilers.
1 Allis-Chalmers No. 8 gyratory crusher.
1 Allis-Chalmers No. 5 gyratory crusher.
1 set of 14 × 36-in. sand rolls.
3 American Hoist & Derrick Co. derricks, 115-ft. mast, 100-ft. boom, 15-ton capacity, 30-HP. steam engine.
1 wooden derrick, 65-ft. mast, 70-ft. boom, 18-HP. engine.
18 7 × 2 × 9-ft. steel skips.
3 2½-cu. yd. concrete buckets.
1 2-cu. yd. Austin cube-mixer.
1 Duplex steam pump.

Organization and Output of Gravity Type Mixers Operated at Kensico Dam.—George T. Seabury in Engineering Record, Feb. 13, 1915, gives the following record of the gravity type mixers in use at Kensico Dam.

Three mixers of the Hains-Weaver gravity type, of nominally 2½-yd. capacity, were used in 1914. The average batch, however, had a volume of 52 cu. ft. of fluid concrete. It was the study of the arrangement of these mixers and of their operation that, to a considerable degree, made possible the really remarkable progress attained. Each mixing plant had nearby a large bin for the storage of sand and stone and was also surmounted by a small bin for the same purpose. These bins were connected by belt conveyors, the longest one of which was 340 ft. in length between end pulleys. Sand and stone were fed alternately to the belts and deflected to their respective bins at the mixer by a switch. The cement was kept in the original cars which were brought on a standard-gage spur to the side of each mixer and from which the bags were supplied to the mixer by chutes or belt conveyors.

The organization of the mixing gangs when going at top speed consisted of 6 men bringing cement to the side of the hoppers and 6 more men filling them with stone, sand, cement, and applying the water. The last mentioned 6 men were under an overseer, who directed their operations, giving the word for the addition of the water and for the opening of the measuring hopper doors. Two men cut the tapes on the cement bags and got them into position for quick handling, and two more men were needed to remove the empty bags. At the hoppers below were the three regular men, and when it was required to chute in different directions a fourth man was needed for that operation alone. At the bins above the mixing platform, one man was stationed to look out for the supply of the sand and stone, and another man, located under the large storage bins, fed the aggregate to the conveyor in response to his signals.

The largest output of one mixer for a single day in 1913 was 384 batches. This year, under the improved conditions and the stimulus of the bonuses offered, the number of batches grew larger and larger until a maximum of 653 batches was obtained in 8 hr. At 52 cu. ft. per batch, this is equivalent to 157.2 cu. yd. per mixer-hour or 2.62 cu. yd. per minute.

The maximum volume of masonry built in the best month this year was that between July 25 and Aug. 24, when 84,450 cu. yd. were placed. Of this, 7810 cu. yd. were blocks previously made and placed at night, and 1630 cu. yd. were cyclopean masonry placed in a second shift operated a few nights, and includes a little work done on one Sunday. The remaining 75,010 cu. yd. were placed in the 26½ working days, of 8 hr. each. In this month, therefore, there was placed a daily average of 3125 cu. yd. Considering, however, only the 75,010 cu. yd. of cyclopean and mass concrete placed in the regular 8-hr. day shift, there was an average of 2831 cu. yd. of masonry placed per day, or 353.8 cu. yd. per hour.

Unit Cost of Concrete on Gravity Dam.—The Humpback reservoir is the storage unit in the new Sooke Lake water-supply system for Victoria, B. C. The main dam located at the natural outlet of the reservoir basin has a maximum height of 60 ft. and a total length of 675 ft. The cross-section of the dam is shown in Fig. 5.

Engineering Record, Aug. 15, 1914, gives the following construction costs.

The usual full force employed on the work included 6 foremen, 20 mechanics, 2 blacksmiths and 100 laborers. Concreting began about Sept. 15, 1913, and was continued until about the end of the year. The wages were as follows:

	Per hour
Common labor	$0.34½
Blacksmiths	.45
Carpenters	.53⅛
Foremen	$0.50 to .60

Board and camp charges to all were $1 per day.

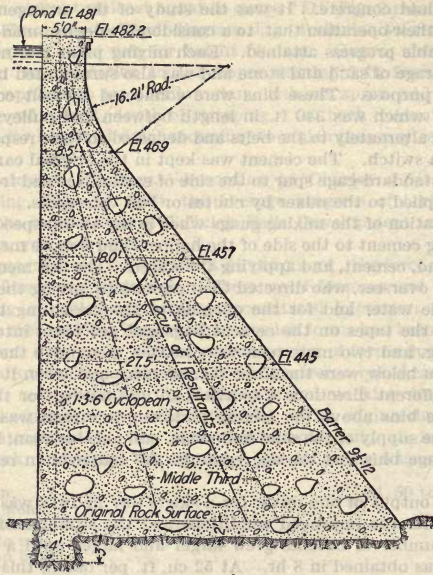

FIG. 5.—Cross-section of dam.

The average cost per yard of all concrete in place was distributed as follows:

Materials	
Cement, 1.01 bbl., at $2.64	$2.664
Sand, 0.285 cu. yd., at $3.13	.892
Gravel, 0.142 cu. yd., at $1.00	.142
Crushed rock, 0.846 cu. yd., at $1.72	1.454
Plums, 0.087 cu. yd. at $1.80	.157
	$5.309
Mixing and Placing	
Labor	$0.747
Supplies	.016
Tools and equipment	.014
Mixer plant	.039
Other plant	.021
	$0.837
Forms	
Total labor	$0.556
Lumber	.096
Plant and supplies	.021
	$0.673
Total cost per cubic yard	**$6.821**

This cost figure, however, includes no charge for rental of plant, which would be cost less salvage divided by 9000.

The usual rate of progress varied from 200 to 250 cu. yd. of concrete placed per nine-hour day, depending on the forms available.

Cost of Las Vegas Arched Masonry Dam.—An arched dam, 250 ft. in radius, of plain concrete, 50 ft. high and only 15.5 ft. wide at the base, was built across the Gallinas River to store 68,000,000 gal. of water for the Agua Pura Company at Las Vegas, New Mexico. Eventually it will be raised to a height of 95 ft. to create a reservoir of 425,000,000 gal. capacity. The structure was completed on Feb. 14, 1911, and in a paper before a meeting of the New England Water-Works Association William T. Barnes, of the staff of Messrs. Metcalf & Eddy, consulting engineers, of Boston, who designed the dam, described in detail the construction methods employed. A summary of his paper is given in Engineering Record, Jan. 4, 1913, from which the following data are taken.

The concrete plant consisted of a ½-cy. yd. Chicago cube mixer. The concrete was delivered to the forms by wheelbarrows. The sand was secured from the bed of the Gallinas River, passed through a ½-in. screen in order to remove occasional gravel, and hauled fully ½ mile up two long and steep hills. The stone was of good quality sandstone, and was crushed locally. In order to supply the stone in sufficient quantity to keep the mixing and placing crews busy throughout the day it was necessary to operate the crushing plant in two shifts of 10 and 12 hours respectively.

When the work was contracted it was expected that the cyclopean form of masonry would be adopted, and with this in view, the contractor erected two small guy derricks, hand-operated, which proved to be entirely inadequate for handling the large stones profitably. Not over 200 cu. yd. of stone were thus utilized, and this amount only in the lower portion of the structure. It is probable, according to Mr. Barnes, that not over 20 per cent of the first thousand yards of concrete was composed of large stones, or not over 8 per cent of the entire structure.

The dam contains 2703 cu. yd. of concrete. The excavation for foundations amounted to 790 cu. yd. of rock and 245 cu. yd. of earth. The cost of the entire work to the contractor was $21,289.89 and to the water company $23,037,93, allowing a contractor's profit of $1748.04. The scale of wages per hour was: Mexican labor, 15 cents; sub-foreman, 17.5 cents; engineer, 25 cents; carpenter, 30 and 20 cents; foreman, 35 cents; double teams, 40 cents.

Cost of the Lost River Multiple-arch Curved Dam.—The following is abstracted from an article by W. W. Patch Engineering News, April 30, 1914. To reclaim farming land being submerged by the rising waters of Tule Lake, which has no visible outlet, a dam was built by the U. S. Reclamation Service to divert a part of the inflowing water, the contract for building the dam being let to Geo. C. Clark, of Everett, Wash, in Dec., 1910.

To save length of diversion channel the dam was placed on indurated volcanic diatomaceous ash instead of on rock. An overflow capable of passing heavy floods being necessary, and this requiring protection against scour below the overflow, a horseshoe-shaped multiple-arch concrete spillway, 289 ft. in length, was adopted, with a low wall or secondary dam thrown between the toes of the horseshoe. The pool so formed was floored with reinforced concrete, covered with plank secured by concrete "toe-holds." The masonry spillway is flanked by paved embankments, held in place at their spillway ends by reinforced-concrete retaining walls, 31 ft. high.

The principal features of the dam are shown in Fig. 6.

The proportions for the concrete used on the work were 1 cement, 2½ sand, and 5 broken basalt rock. The latter was screened into two sizes which afterwards were remixed in nearly equal proportions in order to minimize the percentage of voids. In pier foundations many large rocks were placed in the concrete to save cement. In joining new work to old a mortar coat was applied immediately ahead of the first batch of concrete, but after stripping forms, the exposed surfaces were neither plastered nor coated with cement wash. The arches proved almost absolutely water-tight, even under the maximum head of over 30 ft.

The embankments were constructed in 4-in. layers, wetted and rolled.

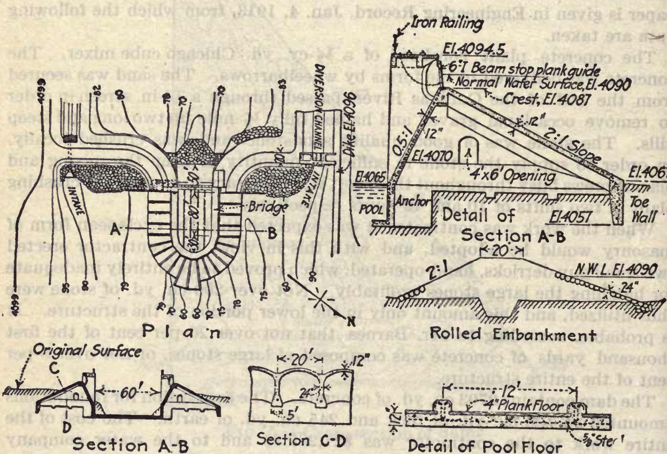

FIG. 6.—Details of dam.

For making concrete of the character required on the dam, sand of proper quality could not be had in the vicinity. Hence, before the contract was let, arrangements were made to ship it in 75 miles by rail and then haul it 8 miles by canal, and 2 miles by wagon to the work. This sand on the job cost $3.75 per cu. yd. During the progress of the work the sand contractor could not supply his material fast enough, and the quality began to deteriorate, so that the United States shipped in quartz sand 300 miles by rail from Marysville, Calif., and delivered it on the siding of the contractor for 10¢. per yd. less than he had been paying for the other sand.

Cost of Work.—The average force on the work comprised 82 men and 36 horses, working for most of the time ten hours per day. Wages were: foremen, $4.38; carpenters, $5; laborers, $2.50; two-horse teams, $6.25. The labor was not efficient as a rule. The accompanying table gives actual, not contract, cost, and includes cost of materials and engineering.

COST OF WORK ON LOST RIVER DAM

Item	Unit	Quantity	Total	Cost per unit
Exc. above Elev. 4067	cu. yd.	9,073	$ 4,743	$ 0.522
Exc. below Elev. 4067	cu. yd.	6,044	10,460	1.73
Embankment	cu. yd.	13,141	8,738	0.665
Rolling, sprinkling and overhaul			305	
Concrete	cu. yd.	5,536	84,510	15.258
Hndlg. reinf. steel	lb.	209,016	7,030	0.033*
Hndlg. structl. steel	lb.	48,254	557	0.012
Stone paving	cu. yd.	1,238	3,386	2.736
Pool flooring	ft.b.m.	25,588	846	33.07
Tool and plank house			2,145	
Five sluice gates and hoists			1,502	
Pump and turbine			1,118	
Stop-plank guides			847	
Stop-planks			330	
Hand rail			282	
Steel rails			342	
Tram car and miscell			786	
Total cost			$127,927	

* Includes cost of steel.

The above includes reasonable allowance for depreciation of the contractor's equipment, which comprised the following:

1—70-hp. Minneapolis traction engine for operating the crushing, screening and mixing plant. This used 4-ft. slabs for fuel.
1—12 × 18-in. Aurora portable crusher, with bucket elevator.
1—rotating 29-ft. screen.
1—1-yd. Ransome concrete mixer.
1—7 × 10-in. double-drum hoisting engine for excavating with drag-bucket.
1—10-hp. gasoline engine with 6-in. centrifugal pump.
1—4-hp. gasoline engine with plunger pump connected.
1—band-saw for form work.
1—bucket elevator for sand hoist.
1—20-in. blower for removing surplus dust from crushed stone and stone dust so that the latter could be added to the sand.
6—9-cu. ft. steel concrete cars with about 600 ft. of 24-in. track.
1—driving team and buckboard.
Blacksmith shop, tools, iron pipe, etc.

All hauling was done with hired teams. In addition to running the plant the traction engine for the last two months of 1911 heated all the water used in making concrete to temperatures of 150° to 204°.

Cost of the East Park Dam, Portland Project, U. S. Recl. Service.—The following data are taken from articles by E. G. Hopson and F. H. Tillinghart appearing respectively in Engineering and Contracting, Oct. 18, 1911, and Engineering Record, June 24, 1911.

Design.—The dam rises to a height of 140 ft. above the foundation rock, and is a solid concrete structure of the gravity type, curved in plan to radius of 275 ft., forming a horizontal arch with abutments in the rock on the sides of the gorge, thus giving it a greatly increased stability. The abutments being somewhat seamy, it was not thought advisable to trust altogether to arch action; hence the combined gravity and arch type. The dam also is located within the so-called earthquake belt. At the top the dam is 10 ft. wide and 249 ft. long, while the maximum thickness at the bottom is 86 ft.

Spillway.—The spillway is located in a saddle in the same ridge about ¼ mile south from the dam, the waste water flowing into a natural tributary to Little Stony Creek and emptying into same at a point about 500 ft. below the dam. Test pits for foundation showed a hard blue shale close to the surface of the ground, conglomerate being encountered only at the north abutment.

The maximum measured flow of Little Stony Creek at the dam site is 8000 sec-ft., but the spillway was designed on the basis of a flow of 10,000 sec.-ft. The distance across the saddle where the spillway is located is only about 300 ft. In order to increase the length of spillway thereby reducing the head, a design consisting of a series of half-circles of arched weirs, butting against piers, was made. The piers are 8 ft. wide and the arches have a radius of 13 ft. 6 in., the whole structure being on a radius of 474 ft. This arrangement gives a total length of 459.9 ft. and after reducing for curvature and incomplete approach there is obtained a total available length of 414 ft., over which the maximum 10,000 sec.-ft. floods should flow 3.7 ft. deep, according to Hazen and Williams' weir formula, as derived from Bazin's. The crest of the spillway is at El. 185, making the high-water elevation in the reservoir 188.7. Small weirs, 2 ft. high and 1 ft. wide, built on a 29-ft. radius and located down stream from the overflow weirs, form a water cushion.

Dikes.—At low points around the reservoir four small earth dikes were constructed ranging in height from 3 to 20 ft. The principal dimensions are 20 ft. width on top, 3 to 1 water slope and 2 to 1 back slope. Rock pitching 1 ft. deep was placed on both slopes.

Costs.—All cement was manufactured at Tolenas, California, cost price f. o. b. cars being $1.55 per barrel. The cost delivered at the nearest railroad station to the work was $2.05 per barrel. Cement and all material brought by rail required hauling over 18 miles of mountain road. The average price of hauling cement, iron work and other materials was 32 cts. per ton mile. The cost of road haul and storage for cement was $1.08 per barrel, so that the net cost delivered at the work was $3.13 per barrel.

In the main dam the total concrete built was 12,202 cu. yds., in which 12,383 barrels of cement were used, or 1.01 bbls. per cubic yard of concrete. The mixture was generally proportioned at 1 volume of cement to 10 of the unmixed aggregates.

In the spillway a richer grade of concrete was used, the total yardage being 1,456, in which were placed 1,758 barrels of cement, or 1.21 bbls. per cubic yard. The mixture was generally proportioned at one of cement to eight of the unmixed aggregates.

The concrete was mixed in standard revolving mixers and handled by cars and track.

The principal item of construction was placing concrete in the dam and spillway as given in Tables VII and VIII.

TABLE VII.—COST OF CONCRETE IN SPILLWAY, 1,456 CU. YDS.

Items	Total cost	Cost per cu. yd.
Cement delivered at R. R. station (1,758 bbls.)	$3,620.99	$ 2,487
Cement—hauling and storing	1,961.25	1.340
Form—Material	373.15	0.260
Form—labor	1,418.50	0.980
Sand and gravel—labor and furnishing	2,438.80	1.670
Mixing and placing	1,388.70	0.960
Finishing	414.40	0.280
Total		$ 7.977
Preparatory expense	$ 161.35	0.111
Interest on investment	1,259.00	0.869
Plant depreciation	318.95	0.218
Miscellaneous and supplies	654.71	0.447
Total		$ 1.635
Superintendence	$1,233.41	0.846
Engineering	913.91	0.628
General administration	1,503.27	1.032
Grand total		$12.118

TABLE VIII.—COST OF CONCRETE IN MAIN DAM, 12,202 CU. YDS.

Items	Total cost	Cost per cu. yd.
Cement delivered at R. R. station (12,382 bbls.)	$25,333.86	$2.076
Cement—hauling and storing	13,394.98	1.097
Forms—Material	2,054.39	0.168
Forms—labor	5,143.45	0.424
Sand and gravel—labor and furnishing	7,074.20	0.580
Mixing and placing concrete	5,304.29	0.434
Finishing	429.60	0.035
Total		$4.814
Preparatory expense	$ 1,817.57	0.149
Interest on investment	4,326.00	0.354
Plant depreciation	3,201.31	0.262
Miscellaneous and supplies	6,700.08	0.550
Total		$1.315
Stream control and unproductive work at quarry	$ 2,611.34	0.213
Superintendence	7,530.02	0.617
Engineering	5,800.14	0.475
General administration	9,540.59	0.782
Grand total		$8.216

Force.—The contractor's average force engaged on this work was 38 men, including 8 teamsters and 20 teams. The engineering and inspection force consisted of 4 men.

The total cost to the United States for the whole work was as follows:

Main dam	$104,358.26
Spillway	15,846.52
Lands for reservoir	86,047.11
Engineering—preliminary and construction	32,076.34
Total	$238,328.23
Cost per acre foot of storage	5.23

Cost of Stony River Hollow Concrete Dam.—G. H. Bayles gives the following data (Engineering News, Jan. 22, 1914) in regard to the construction cost of the dam.

Various rates of wages were paid at the beginning of the work, but these soon settled to the following:

Mechanics, $0.30 to	$0.50 per hour
Carpenters, $0.30 to	0.35 per hour
Helpers	0.25 per hour
Laborers in cutoff trench	0.25 per hour
Other laborers	0.22 per hour

All field costs included, the costs of the parts of the work completed with cableway were as follows:

Cutoff excavation	1,273 cu. yd.	@ $2.93
Earth excavation	3,432 cu. yd.	@ 0.48
Rock excavation	44 cu. yd.	@ 3.43
Crushed stone and sand for 1 cu. yd. of concrete	1 cu. yd.	@ 1.23
Mixing and placing concrete	7,594 cu. yd.	@ 0.72
Forms (not including materials)	7,594 cu. yd.	@ 1.67
Placing steel	366,277 lb.	@ 0.005

The dam as constructed consisted of 56 panels 15 ft. long with buttress supports at each panel point. The maximum height was 51.17 ft. above foundations. A spillway 150 ft. long was provided with elevation 3 ft. below top of the dam. The height of dam at the spillway was 34.75 ft. The width of dam (at foundation line) varied from a minimum of approximately 16 ft. to a maximum of 70 ft.

TABLE IX.—UNIT COSTS OF THE CORBETT DIVERSION DAM, SHOSHONE IRRIGATION PROJECT

Distribution of cost	Excav., class 1, 7865 cu. yd.	Excav., class 2, 2681 cu. yd.	Excav., class 3, 1454 cu. yd.	Puddling, 1712 cu. yd.	Reinforced concrete 4950.59 cu. yd.	Hauling and placing reinforcing steel 319,382 lb.	Hauling and placing cast iron, 39,385 lb.
Interest on investment	$0.044	$0.132	$0.261	$0.042	$0.338	$0.0004	$0.0007
Preparatory expense	.053	.163	.332	.052	.418	.0005	.0009
Plant depreciation	.044	.132	.261	.042	.338	.0004	.0007
Executive	.145	.434	.857	.140	1.122	.0013	.0023
Labor	.948	2.853	5.648	.953	6.632	.0084	.0164
Supplies	.035	.097	.181	...	1.000	....	....
Total contractor's cost	$1.269	$3.811	$7.541	$1.229	$9.848	$0.011	$0.021
U. S. materials	.001	.004	.006	....	4.925	.022	.129
U. S. Engineering	.052	.175	.383	.026	.436	.001	.005
Total actual cost	$1.322	$3.990	$7.930	$1.255	$15.209	$0.034	$0.155

The quantities from which the above figures were derived were made up from the number of batches placed. It was found that it required a little more than the figured yardage to fill the forms, say 5%, and where the concrete came in contact with the earth—the footings and cutoff—as much as 25% more than the neat quantities was required, and the average for footings was a little under 20%.

The dam site is 19 miles distant from the nearest railway station, and all men and material had to be brought in over logging railroads, which materially affected the cost.

Six months after its completion 5 bays or panels of this dam went out due to leakage under the cut-off wall which did not go down to solid rock.

Cost of Corbett Diversion Dam, Shoshone Irrigation Project.—The Corbett Diversion Dam was built by contract during the latter part of 1906, and the forepart of 1907 for the total contract price of $66,750. This dam is located on the Shoshone River about eight miles below Cody, Wyo., and is a part of the irrigation structures pertaining to the Shoshone Project, of the U. S. Reclamation Service.

The following description of the diversion dam and data on its cost are given in the August number of the "Reclamation Record," 1908, and reprinted in Engineering Record, Aug. 22, 1908.

The Corbett Dam is of the reinforced concrete buttressed type, having a deck 30 in. thick on the upper side with a slope of 1 to 1. This deck rests on buttresses two feet thick, spaced 14 ft. on centers. The structure is founded on gravel and shale, and has a reinforced concrete platform two feet thick resting on the foundation and extending from the deck wall downstream to a distance of about 40 ft. Beneath the deck of the dam and this platform are three cut-off walls running lengthwise of the dam and extending down into the shale. The total length of the dam between abutments is 400 ft., and extending at the right abutment of the dam to the bluff is an earth embankment about 450 ft. in length. At the left end of the dam are located the sluiceway and the headworks controlling the entrance to the Corbett Tunnel.

Careful records of cost were kept during the construction of the dam, and the data relating thereto are given in Table IX under the primary heading of distribution of cost and under the secondary heading of the class items of the schedule. Labor conditions were extremely bad during the entire construction period, but the contractor was provided with fairly efficient equipment. Laborers were paid at the rate of $2.50 to $3 per eight-hour day, carpenters at the rate of $3 to $4.50 and teams at the rate of $2.50 per eight-hour day.

There was no suitable sand for concrete in the vicinity of the dam, and it was necessary to establish a crushing plant for manufacturing the same from cobblestones. The crusher and concrete mixer were located at a distance of about 400 ft. from the right abutment of the dam. The concrete was hauled from the mixer to central points on the dam by means of cars of one-half cubic yard capacity drawn by horses. At these central points the concrete was transferred to small hand carts, and thus conveyed to various local points on the dam.

The shore ends of the dam were constructed during ordinary stages of the river without diverting the river from its channel. For the portion of the dam in the channel of the river it was found necessary to construct a temporary dam from the end of the sluiceway wall diagonally across the river, thus diverting the entire low-water flow of the river through the sluiceway.

The total actual cost for all of the items tabulated was $127,277.43.

Cost of Concrete Core Wall, Moline Pool Dam.—J. B. Bassett in "Professional Memoirs" described the methods and costs of construction of the concrete core wall in Moline Pool Dam in the Mississippi River at Moline, Ill. The following is taken from an abstract of that paper published in Engineering and Contracting, July 27, 1910.

The core wall was constructed to make more permanent the loose rock fill dam forming "Moline Pool" which in times of high water acted as a spillway and was therefore subject to disintegration from the top.

The construction details are as follows: A dipper dredge is first employed to dig a trench along the toe of the dam to steepen the slope to its most abrupt angle of repose and to get down through the mud, sand, etc., to the solid rock bottom. Following the dredge a drillboat is employed to drill holes 10 ft. apart along the toe of slope and approximately 3 ft. therefrom. These holes are carefully placed, as the alignment of the wall depends on their proper location. Upright 6 × 8 in. form posts having a 2-in. steel rod, pointed on the lower end, bolted thereto, and allowed to extend about 1½ ft. below the end of the post, are then set, being dropped into the holes by the drillboat crew as fast as the holes are drilled, and left standing. Later the posts are lined up, slanted to a batter of about 1 to 3½, and tied to anchorages in the rock dam by 3 × 6-in. strips bolted to the sides of the posts. The remainder of the form consists of horizontal 6 × 6-in. waling strips spaced by means of sink planks about 3½ ft. between centers, and 2-in. plank sheathing set on end to make as good a contact as possible with the irregular bottom. It will be noted that only the face side of the wall is joined, the rough slope of the dam forming the back side, except near the top, where the section is reduced to a finish to a 2-ft. width of coping.

The concrete plant was erected on a flat barge and consists of a rolling drum mixer and small, stiff-leg derrick with a 40-ft. boom, together with the necessary boilers, hoisting apparatus, etc. This barge is floated alongside the form, with the gravel and cement barges on its other side. A straight sided, bottom-dumping bucket was designed for the work, arranged with two doors joining at the center and held shut by latches that can be tripped at will by latch strings. The concrete is deposited directly in the water with this bucket with very little agitation or loss of cement. For conveying the raw material to the mixer a special arrangement of an automatically dumping skip car was devised. A hinged and counter-weighted track extension allows the car to run out to the center of the gravel barge moored alongside, where it is filled by hand. The car itself is gaged so that the proper quantity may be secured. A small barge containing the cement is moored alongside the gravel barge, the cement being carried a few steps by hand and dumped into the skip car from the containing sacks.

The proportions used average about 1 cement to 6 gravel. For the deeper portions of the wall, the gravel is reduced to about a 1-to-5 mixture to allow for some loss of cement, but the top of the dam is made of proportions of about 1 to 7. The gravel is furnished on United States barges by contract, being pumped direct from the river bed. It is not screened and re-mixed, as is the practice in some localities, since the natural mixture is quite uniform and tests show voids running from 12.5 to 17 per cent. The depth of water in which concrete has been deposited varies from 5.5 to 17 ft. A considerable length of wall was built with the depth at the latter figure. In this case it was found inadvisable to attempt to carry the wall to completed height in one day, due to the excessive pressure on this style of form. It can be readily seen that a continuous contact between the form and the rough rock bottom would not be had. Occasionally, a stone would fall from the dam and, lodging along the line of the form, would prevent the sheathing from reaching to the proper depth, and a hole would be the result. It was found that concrete to a height of 3 or 4 ft. would not run out, but if an attempt was made to carry the section to completion a leak would result, and, once started, it could not be stopped until equilibrium was restored. For this reason the custom was established of building the deeper sections in two layers. Scrap steel rods, etc., in short lengths were stuck into the first layer to assist in bonding.

When the work was started, alternate sections were constructed, the intermediate sections being filled later; but in some cases where the dam behind the wall had quite a strong leakage it was found better to build continuously and push the leak ahead, each day's work being ended at a bulkhead. Later, this practice was followed altogether. Some cement was lost at points opposite the leaks, but not enough to materially weaken the dam. It must be remembered that the upper part of this wall is the vital part, as the dam breaks from disintegration on the crest. For this reason a reinforcing rod of about seven-eighths inch diameter is run longitudinally about 6 ins. below the coping of the wall, tied by 8-ft. rods set vertically near the face of the wall and bent at the top to hook over the longitudinal rod. This is done to hold in place any chunks of concrete which might come loose through shrinkage cracks or from impact of running ice.

The work is being conducted by hired labor, and the wages paid on the concrete outfit are as follows:

One foreman, at $90 per month; 1 derrickman, at $90 per month; 2 firemen, at $40 per month; 1 hoistman on conveyor, at $40 per month; 1 watchman, at $40 per month; 11 laborers, at $1 to $1.25 per day, depending on scarcity of labor. Also, the drillboat crew, of 1 drillrunner, at $60 per month, and 1 fireman, at $40 per month.

Subsistence and sleeping quarters are furnished to all employes in addition to the above wages. Eight hours constitute a day's work, and the usual Saturday half-holidays are allowed at full pay during July, August and September. Full pay is allowed to all employes for all legal holidays. Weather conditions are usually good in the summer season, but about six weeks in the spring and four weeks at the end of the season in November are usually attended by storms and exceedingly high winds.

The cement is taken from the cars and stored in a warehouse and afterwards loaded on the barges by hand. All cement is tested in a laboratory on the office boat.

The dredging and towing expense is also charged for the time put in by the dredge at digging the trench and by the towboat in carrying the various supplies to the work.

A cost statement of the work to date is as shown by the accompanying table:

TABLE X.—COST STATEMENT

13,112.6 cubic yards concrete, 6,301.8 linear feet of wall.

Items	Amount	Cost per cu. yd. of concrete		Cost per lin. ft. of wall
Preliminary expense:				
(plant equipment, warehouse, etc.)	$ 6,530.12		$0.4980	$ 1.037
Quota miscellaneous charges	375.12		.0286	
Superintendence and office:				
Field	5,551.26	$0.4233		
Quota R. I. office charges	2,060.92	.1572		
Total			$0.5805	
Excavation	1,241.56		.0947	
Forms:				
Material	2,752.39	$0.2099		
Labor	2,514.95	.1917		
Drilling	660.67	.0504		
Drilling, coal for	186.53	.0142		
Total			$0.4662	
Materials:				
Cement	17,952.72	$1.3691		8.917
Cement handling	936.02	.0714		
Cement tests	627.39	.0479		
Gravel	7,140.71	.5446		
Reinforcement	290.08	.0221		
Towing	2,889.68	.2204		
Towing, coal for	942.03	.0718		
Total			$2.3473	
Mixing and depositing:				
Labor	7,890.41	$0.6017		
Coal	843.10	.0643		
Total			$0.6660	
Backfilling	766.47		.0585	
Plant repairs	572.92		.0437	
Total	$62,725.05		$4.7835	$9.954
Miscellaneous	283.40		.0216	.045
Plant charge (rental)	4,995.74		.3810	.762
Total, including plant charge	$68,004.19		$5.1861	$10.791

The above statement includes all money spent on the work in plant construction and operation, material, and supplies of all kinds, repairs during season, superintendence, field and main office charges and a plant charge presumed to be equal to its rental charge were it not owned by the United States Government.

Cost of Constructing Small Concrete Dam.—Engineering and Contracting, March 15, 1911, gives the cost of a hollow concrete dam 70 ft. long and 4 ft. high built at East Earl, Pa. by H. L. Bauman using day labor.

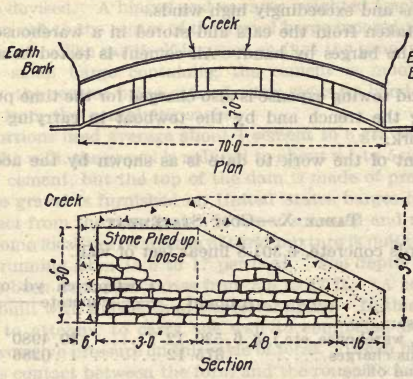

Fig. 7.—Plan and section of concrete dam.

Fig. 7 shows the essential dimensions and it will be noted that the concrete structure is hollow, is divided into compartments by interior cross walls of dry masonry and that the compartments are filled with gravel. The concrete used was a 1:2½:5 mixture plastered with a 1:1 mortar. The amount of concrete is not recorded but estimating from the sketch and from the amount of concrete used it was about 40 cu. yds.

Item	Cost
Hauling gravel (3 men 3 days at $1.75)	$ 15.75
Hauling gravel (2 men and team 1 day at $3.00)	6.00
Hauling gravel (2 men, horse and cart, 3 days at $2.25)	13.50
Screening sand from gravel (1 man 3 days at $1.75)	5.25
Washing gravel (6 men 1 day at $1.75)	10.50
Pump and pumpman (1 day at $5)	5.00
Cofferdam (3 men 4 days at $1.75)	21.00
Cofferdam (2 men, horse and cart, 2 days at $2.25)	9.00
Excavation (6 men 2 days at $1.75)	21.00
2,000 ft. B. M. from lumber at $20 per M	40.00
Delivering lumber	5.00
Settling forms (2 men 2 days at $1.75)	7.00
Placing concrete (7 men 3 days at $1.75)	36.75
2 hp. gasoline mixer engine 3 days	3.00
Removing forms and clearing away (2 men 1 day at $1.75)	3.50
Plastering (4 men 1 day at $1.75)	7.00
Pump 20 hrs. at 40 cts	8.00
Charges on borrowed pump	7.50
10 tons Atlas cement at $8 delivered	80.00
Total	$304.75

A 10-hour day was worked.

Cost of Small Concrete Dam Built by Unskilled Labor.—Fred. J. Wood in Engineering Contracting, March 26, 1913, gives the methods and cost of constructing a small concrete dam at Paris, Maine.

The dam has a total length, on the top, of about 48 ft., of which only 20 ft. are of the full height of 3 ft. The section being so small, a 32-in base, bringing the resultant within proper limits, the dam was made rectangular in section and of that width. No other engineering problems were involved; the foundation was a solid ledge without a sign of a seam, and the location was between two ledge walls which narrowed as they stretched down stream. A man of many years' experience as a contractor's foreman, who had had charge of some concrete construction, composed the whole "expert" force. He was told to build the dam on the lines outlined above and left to his own devices. The dam was built October 2 to 9, 1912, while the river was very low.

First, a diversion dam was built of feed sacks full of sand, placed above the dam site and at a point to turn the river flow through the canal leading to the mill. The canal was cleared of rubbish, all gates opened wide, and the end of the penstock taken off, by all of which means nearly the entire flow was diverted from the new work.

Much difficulty was found in securing laborers and only by offering nearly double wages could a gang of ten men be secured for two days. With the help of one laborer, a handy man with carpenter tools, and a horse, the river had been diverted, the site cleared, and the form built by the night of Oct. 6, and a full gang of ten men reported on the morning of the 7th.

An adjacent pile of old railroad ties was soon transferred into a cob house trestle across the river bed adjoining the form and about a foot above its top. This planked over, formed the mixing platform and the runways. The sand, previously hauled from a bank a mile away, had been dumped on the bank at the west end of the dam, with emery ore (used as aggregate because convenient) immediately behind it. Not enough water ran past the work to provide the amount needed for mixing, so a supply was brought and placed in barrels. Mixing and placing concrete began about 10 o'clock and occupied the rest of the day and about four hours of the next day.

Distribution	Cost	Per cu. yd.
Labor:		
Filling sacks and building diversion dam	$ 14.375	$ 1.65
Cleaning diversion channel	4.50	.52
Clearing site	4.225	.49
Building forms	16.50	1.90
Building mixing platform and runways	6.45	.74
Handling material to the mixing platform	13.60	1.57
Mixing and placing	27.70	3.18
Cleaning up	13.25	1.52
Time lost by rain	2.65	.30
Total for labor	$103.25	$11.87
Material:		
Emery ore (at price quoted for trap rock)	$ 30.00	$ 3.45
Cement, delivered	35.00	4.02
1,500 ft. B.M. boards for forms, delivered	30.00	3.45
10 lbs. 8d. wire nails at 4 cts	.40	.05
20 loads of sand at 5 cts	1.00	.11
Hauling sand, 2½ days at $3	7.50	.86
Total for material	$103.90	$11.94
Total for labor	103.25	11.87
Grand total	$207.15	$23.81

The form was simply built with longitudinal top and bottom stringers, tied across the top at intervals and braced from the outside, with vertical boarding on their inside faces.

Laborers were paid $2.50 per day, one dollar more than the customary rate in that section. The cement a standard brand of Portland was obtained from a local dealer, the sand was also locally secured, and the concrete was mixed in the proportions of 1:2:4.

Life of Equipment Used in Building Dam by the Hydraulic Fill Method.—The following data are taken from an article in Engineering Record, July 11, 1914.

In placing 2,000,000 cu. yd. of material, in a dam 145 ft. in height and 1,700 ft. long, about 95% of the material was moved by water and 5% by Fresnos in building up the dikes.

The material was conveyed a maximum distance of 3,000 ft. with a normal flow of water of 12 sec.-ft. With a normal solid content of water about 10 per cent and with a head of 50 ft. on the pumps, which were 12 × 12 in. centrifugals, operating at 600 r.p.m., the life of the manganese steel runners was about 3 months. The life of the 14 ga. steel distributing pipe with 10 ga. slip joint butts was about 500,000 cu. yd. of material handled. The pipe cost 48.75¢ per ft.

A crew of 6 men for each shift operated 2 pipe systems and deposited 8,000 cu. yd. per 24 hours. Additional men were required for making the dikes and shifting the plant.

Dimensions of Storage Tanks or Reservoirs for Economical Design.—In Engineering News-Record, April 3, 1917, Arthur Jobson gives the following formulæ for obtaining such dimensions that the construction cost of a storage tank or small reservoir will be a minimum. The formulæ were obtained by finding expressions for the cost of the sides and bottom, adding them to get an expression for total cost and equating the first derivative to zero.

The final equations obtained are as follows:

$$R = \sqrt[4]{\frac{V^2 w_1 w_2 c_1}{\pi^2 S c_2}} \qquad (1)$$

and

$$d = \sqrt{\frac{S c_2}{c_1 w_1 w_2}} \qquad (2)$$

in which R is radius in feet; V, capacity in cubic feet; w_1, weight per cubic foot of material in sides; w_2, weight per cubic foot of reservoir contents; c_1, cost per pound of installing sides; c_2, cost per square foot of installing bottom; S, allowable unit stress in pounds per square foot for material in sides, and d, depth in feet.

It is interesting to note in equation 2 that the proper depth for the lowest cost is independent of volume or capacity. For any assumed capacity the depth will be constant for given values of unit stress, costs of installing sides and bottom, unit weight of contents and unit weight of side material Trial computations with equation 1 will show that for the value of R giving the lowest cost the cost of installing the sides and bottom will be approximately equal, as they should be theoretically.

The quantity c_1 is intended to include all expense for labor and material in connection with the cost of installing the sides, and c_2 may not only include the expense for labor and material in laying the bottom, but also the cost of grading and leveling the reservoir site. In the use of these equations, S should be assumed rather small, for two reasons—to allow for efficiency of riveted joints and to proportion properly the thickness of vertical sections of the plate so that the actual net area may approximate the theoretical area used for computing weight and cost. For steel plate with an ultimate strength of 60,000 lb. per square inch, a factor of safety of 4, and a joint efficiency of 70 % the writer found that the value of S to be used was about 1,296,000, or 9000 lb. per square inch.

Sides of Constant Thickness.—If the side-plate thickness is arbitrarily selected without reference to the depth or diameter, the expressions for the most economical dimensions become:

$$R = \sqrt[3]{\frac{tVw_1c_1}{\pi c_2}} \tag{3}$$

and

$$d = \frac{Rc_2}{tw_1c_1} \tag{4}$$

where t is plate thickness in feet.

If the value for R given by equation 3 is substituted in the total-cost formula, it can be shown that the dimensions giving the lowest cost result in making the cost of the sides equal to twice the cost of the bottom, as against these costs being equal where the thickness of the plate is assumed to vary either with the depth or with the diameter of the reservoir.

Cost of Open Concrete Reservoir.—The following unit costs of constructing the 1,300,000 gal. concrete reservoir for Webb City, Mo. are given by E. W. Robinson, in Engineering Record, May 11, 1912. The reservoir was 100 × 200 ft. by 9.5 ft. deep, no roof was provided.

Cost of Concrete Reservoir

	Unit cost	Total
Walls:		
Concrete (634.6 cu. yd.)—		
Materials	$5.053	$ 3,206.62
Mixing and placing	1.217	772.31
Placing steel, labor	0.024	15.23
Forms (634.6 cu. yd.)—		
Making and setting	1.007	639.04
Removing, labor	0.098	62.19
Plastering (980 sq. yd.)—		
Materials	0.170	166.73
Labor	0.145	141.78
Total for walls, 634.6 cu. yd., at $7.885	$7.885	$ 5,003.90
Floor (432.8 cu. yd.):		
Concrete base (323.8 cu. yd.)—		
Materials	2.758	893.13
Labor	1.156	374.43
Finish (109.0 cu. yd.)—		
Materials	5.473	596.52
Labor	1.774	193.37
Asphalting (1972 sq. yd.)—		
Materials	0.431	952.29
Labor	0.052	106.95
Total for floor, 432.8 cu. yd., at	$6.954	$ 3,009.74
General:		
Excavation (3242 cu. yd.)		551.14
Embankment		348.29
Bond and insurance		73.00
Superintendence		700.00
Overhead charges		500.00
Grand total		$10,186.07

Common labor was paid $2, carpenters $3 and $3.50, helpers $2.50 and teams $3.50 per day of 10 hours. The man in charge of placing the steel was paid $2.50, and a few other men received $2.25, $2.50 and $2.75 per day for special reasons. As a whole the labor was fairly efficient, but would have been more so under more competent supervision. The excavation was sub-let to another party at $0.17, which allowed but small profit. The item of superintendence included the time of two members of the contracting firm that was spent upon the job, and one paid superintendent for part of the time. The item of overhead charges, which was partly an estimation and partly taken from statements from the contractors, included traveling and other general expenses, and though excessive was not far from the actual expense incurred.

The aggregate use is what is known as "chats" or "tailings" which is crushed blue and white flint running in size from ⅛ to ¾-in. and is obtained from the various mills of the zinc mines. The mix was 1 part of cement to 2 parts of fine "tailings" to 4 parts of coarse "tailings." Tailings can generally be had for the hauling.

Cost of Covered Concrete Reservoir.—G. Stanley Whitehead gives the following data in Engineering Record, July 1, 1911.

The reservoir, for the town of Brookline, Mass. is circular in form with a capacity of 4,000,000 gals., 180 ft. in diameter and 23.5 ft. deep at the wall. The side walls are of reinforced concrete, 2 ft. thick at the top and 3.5 ft. thick at the bottom, with a batter of ¼ in. per foot on the inside. The bottom slopes toward the center at the rate of 0.5 per cent, with a channel sloping in the opposite direction to drain off the water when emptied. The roof is of mushroom construction, upheld by square reinforced concrete piers, and is covered with 14 in. of cinders and 10 in. of loam; this and the adjoining embankment slopes have been grassed over and treated as a small park.

The reservoir was so located on the hill as to make the cut and fill about equal. After stripping the surface loam the material encountered in the excavation consisted entirely of hardpan, which was hauled largely by carts and dumped between the reservoir wall and retaining wall to form the slopes. The fill thus made was thoroughly rolled with a two-horse grooved roller. After the reservoir wall was closed in, the excavation was removed by the use of a derrick set up just outside the main wall and used later to carry the concrete from the mixing plant.

A concrete retaining wall, 18 in. wide on top, with a batter of ½ in. to the foot on the inside and 1 in. to the foot on the outside, nearly encircles the reservoir. It is of 1:2:4: Portland cement concrete, varying from 2 to 6 ft. in height, and takes the earth embankment graded to a 1½ to 1 slope from the roof of the reservoir. It was built primarily to shorten that portion of the embankment that faces private residences. The foundation is of stone and cinders extending 4.5 ft. below the natural surface of the ground, at the bottom of which is a 6-in. tile pipe, laid to drain the wall and take any possible leakage from the reservoir. No reinforcement was used in the wall; consequently, cracks extending from top to bottom opened up about every 60 ft. after standing through the first winter. This condition, however, was expected, and no effort was made to prevent it, as the wall will be ultimately covered with vines and shrubbery.

The concrete in the main reservoir wall is composed of 1 part Atlas Portland cement, 2 parts sand and 4 parts screened gravel containing stones not larger than 2½ in. The reinforcement consists of 1⅛ and ¾-in. round bars, spaced as shown in the cross section. The bars were held in place by the use of perpendicular steel lattice work supports set 15 ft. apart; the ends of the rods were lapped 40 diameters and wired.

COST OF CONCRETE PER CUBIC YARD

Main Wall	
Labor	$ 2.54
Cement	2.04
Gravel and sand	2.84
Steel	2.26
Lumber	.77
Tools, concrete mixer supplies and miscellaneous	1.00
	$11.45
Credit for sale of material	.34
Total cost per cu. yd	$11.11
Retaining Wall	
Labor	$ 2.54
Cement	2.04
Gravel	2.84
Lumber	.77
Total cost per cu. yd	$ 8.19

Gravel and sand	2.85
Cement	2.54
Steel	1.55
Tools, cars, derrick and miscellaneous	.99
	$12.17
Credit for sale of material	.29
Total cost per cu. yd	$11.88
Waterproofing roof	.99
Plastering bottom and sidewalk	.97

COST OF LABOR AND MATERIALS

Cement	$ 1.62 per bbl.
Sand and gravel	2.10 per cu. yd.
Lumber *	23.00 to $29.00 per M.
Steel	0.015 per lb.
Labor	2.25 per day

* Dimension lumber cost $29.00 per M.

The total cost of the reservoir, including the land purchased and the construction of 1500 ft. of roadway, was $80,212.

Cost of Small Reinforced Concrete Reservoirs.—John W. Ash in Engineering Record, Jan. 25, 1913, gives the following costs of constructing the concrete tanks and reservoir for the waterworks plant, Dalton, Ga.

The main reservoir is 80 ft. in diameter, 21 ft. deep, and has 10-in. walls, with coping floor 6 in. thick. The footing course is 12 in. deep and 2 ft. wide. Concrete was a 1:2:4 mixture. The construction of the main reservoir, which is located on the top of a hill about 300 ft. above the creek level, involved some features a little out of the ordinary. There was no road to the top and to have built one would have required considerable time and money. It was decided, therefore, to put the mixing plant at the foot of the hill and haul the concrete and other materials to the top on a tramway. The tramway ties were poles and stringer pieces and the rails were made of 2 × 4-in. timbers, laid double and well spiked together. The total length of tramway was about 900 ft.

The concrete was carried in two concrete carts; each cart carried one batch. While these were being hauled to the top and returned empty two more would be loaded and ready when the empties returned. At the top the landing platform was nearly on a level with the top of the reservoir walls, but as these walls were carried up in 7-ft. sections, the concrete was dumped down a chute to a platform on a level with the top of the section, where it was rehandled with wheelbarrows. After the work of concreting was well started and each man knew just what he was to do, a round trip could be made very quickly. The best day's run was 74 trips in 8 hours—less than 7 min. to a trip. The average, however, was about 9 min., owing to an occasional derailment or other slight delay. The car made about 800 trips and got away once through some carelessness in letting it get unhooked after landing at the top.

It took about 3 hours to get the track back in shape, rig another car and start running again. This was the only accident and no one was hurt.

Reservoir Costs

	Hauling	Labor	Material	Total
Shanties, tool and cement houses	....	$ 67.00	$ 46.20	$ 113.20

The coagulating basin is 40 ft. inside diameter and 10 ft. deep. The walls are 9 in. thick and bottom is 4 in. thick. The basin has four wooden baffle walls built of 2-in. plank and 4 × 6-in. posts. The concrete was mixed in the proportions of 1:2:4.

Coagulating Basin Costs

	Labor	Material	Total
Excavation, 325 cu. yd	$160.25	$ 34.75	$195.00
Concrete, 56 cu. yd	50.60	214.70	265.30
Steel, 3030 lb	24.20	65.90	90.10
Forms	58.10	52.15	110.25
Baffle-walls	12.30	72.00	84.30
Finishing and waterproofing	23.90	12.30	36.20
Pipe connections, etc	8.60	3.70	12.30
Grand total			$793.45

The clear water well is 40 ft. inside diameter, 12 ft. deep, with 9-in. walls, 6-in. floor and a self-supporting concrete roof having a rise of 4 ft. at the center, where there is a 4-ft. man-hole with screen ventilator. The mixture of concrete used was 1:2:4.

CLEAR WATER WELL COSTS

	Labor	Material	Total
Wet excav., 150 cu. yd	$ 65.00	....	$ 65.00
Concrete, 128 cu. yd	146.40	$484.00	630.40
Forms	115.20	128.00	243.20
Reinforcement, 7880 lb	59.10	213.90	273.00
Pipe conn's, ventilator, etc	13.50	12.25	25.75
Coal, oil, waste, etc	....	21.30	21.30
Finishing walls	16.25	8.70	24.95
Grand total			$1,283.60

Cement cost $1.35 per barrel; sand, $1.05 per ton; stone, $1.43 per ton. Labor was $1.35 and $1.50 per day; carpenters, $2.25 to $3.50 per day. The labor item includes foremen and superintendence.

Cost of Concrete-Lined Oil-Storage Reservoirs.—Bulletin 155 of the U. S. Bureau of Mines prepared by C. P. Bowie gives some detailed costs and specifications for constructing reservoirs of the above type. The following matter is taken from an abstract of this bulletin published in Engineering and Contracting, May 15, 1918.

The reservoirs are commonly circular in plan, and are constructed by making an excavation and building an earthen embankment with the excavated material. The area within the inner crest of the embankment is then covered with a wooden roof and the bottom and sides of the inclosed place lined with concrete.

The dimensions of a typical container are as follows: Inside diameter at top, 488 ft.; inside diameter at bottom, 437 ft. 6 ins.; maximum depth, approximately 25 ft. 11 ins. The slopes of the embankment are: Slope of embankment inside reservoir, 1 to 1; slope of embankment outside reservoir, 2 to 1; slope of embankment top of reservoir, 20 to 1. The width of the embankment on top is 15 ft. The roof is constructed of wood, covered with roofing paper.

The cost of such a reservoir would be 10 to 13 cts. per barrel of capacity, dependent on the situation and other governing conditions. On a basis of 11 cts., the cost would be distributed approximately as follows:

Cost of earthwork, cts	3.5
Cost of roof, cts	3.0
Cost of concrete lining, cts	4.5
Total, cts	11.0

An unlined earthen reservoir with the same type of roof construction would cost 7 to 9½ ct. a barrel, and it is estimated that a concrete lined reservoir with a concrete roof on concrete roof supports and covered with 2 ft. of earth would cost about 30 ct. a barrel.

The following figures for labor costs cover the construction of two 750,000-bbl. reinforced concrete lined reservoirs built at Bakersfield, Cal., during the winter and spring of 1913–14:

Earthwork:	
Excavating for embankment, per yd	$0.22
Lining inner slopes with selected material, per yd	.51
Finishing floor, per sq. ft	.005
Excavating for pier footings, trenches, etc., per yd	.70
Trimming slopes, per sq. ft	.012

Roof:	
Hauling lumber from cars (½ mile), per M	1.19
Framing lumber for roof, per M	1.60
Erecting roof, per M	3.80
Sawing sheathing, per M	1.35
Roofing:	
Laying roofing paper, per square	.12
Hauling roofing gravel from cars (½ mile), per ton	.25
Placing asphalt and gravel coating, per square	.32
Concrete lining:	
Hauling cement from cars (½ mile), per ton	.54
Hauling sand from creek bed (2 miles), per yard	.86
Hauling rock (½ mile from cars), per yd	.50
Laying reinforcing metal on slope, per square	.16
Laying reinforcing metal on floor, per square	.08
Pouring concrete piers, per yd	*4.63
Pouring concrete floor, per yd	*2.51
Pouring concrete slope, per yd	*3.46

* Including cost of rock, at $1.60 per ton. All material except sand and gravel was furnished by the owner at the Southern Pacific R. R. ½ mile distant from the work.

The figures given are based on the following conditions:

Situation of reservoir, ½ mile from railroad.
Formation of soil, light sandy clay.
Excavators used, wheel and "fresno" scrapers.
Hours worked a day, 9.
Wage paid laborers, $2.50 a day.
Wage paid carpenters, $3.50 a day.
Wage paid concrete laborers, $2.75 a day.
Wage paid concrete finishers, $4.50 a day.
Wage paid foremen, $6 a day.

Cost of Small Reinforced Concrete Reservoir.—C. A. Bingham in Engineering and Contracting, April 3, 1912, gives the following costs of constructing a small concrete reservoir at Mt. Holly, Pa. The reservoir was built in 1909 by the Cumberland Clay Co. to impound water for various processes in the refining of clay.

The reservoir is 73 ft. long and 53 ft. wide and 5 ft. inside depth, thus holding 140,000 gals. About 3 ft. of the wall is in cut, which was shale and tough clay; and the remainder is above the natural surface. The walls are 6 ft. total height, and 12 ins. thick at top and 18 ins. at bottom, with an inside heel 12 × 15 ins. Batter is all on the outside. On three sides a fill was made to within 18 ins. of top of wall, but on lower side this would have meant an excessive cost so buttresses were built every 10 ft.

The walls were heavily reinforced both horizontally and vertically with light rails and other steel on hand and at the corners heavy steel bent to right angles was placed on 12-in. centers, the arms running from 3 to 6 ft. into each side wall. Keyed expansion joints were used every 30 ft. The floor was constructed by a well puddled mixture of clay and gravel and given a surfacing of 4 ins. of concrete and cut in blocks.

A heavy wire fence was placed on top of the wall. The outlets to the mills are controlled by valves and the overflow is taken care of by a small spillway. After three years of service the reservoir is as good as the day completed; the only maintenance being an occasional cleaning of the clay sediment on the bottom. It doesn't leak at all and the walls haven't cracked.

The work was performed by the company forces under plans of the writer; and the sand and gravel was procured on the property. The cost data follow:

Excavation:	
1 foreman 7 days at $2	$ 14.00
7 laborers 7 days at $1.25 up	75.25
2 carts 5 days at $3	30.00
Total for 360 cu. yds	$119.25
Cost per cu. yd., excavation, 33 cts.	
Concreting:	
Form work: Carpenter and helper (old lumber used)	$ 22.75
Mixing and placing: Foreman 7 days and 7 laborers 7 days	75.25
Materials:	
186 bbls. cement at $1.35	249.75
192 cu. yds. gravel at $0.40	76.80
Reinforcing	16.00
Total for 144 cu. yds. concrete	$440.55
Cost per cu. yd., concrete, $3.06.	
Clay floor, fence, miscellaneous (not including pipes or valves)	84.40
Total cost	$644.20

The cost of the reservoir complete per 1,000 gals. was $4.60.

Cost of Reinforced Concrete Cisterns at Fort Moultrie, Charleston, S. C.— R. A. Boothe gives the following in Engineering and Contracting, Aug. 9, 1911.

This work consisted of three 30,000-gal. and four 8,000-gal. capacity reinforced concrete cisterns for the War Department at Fort Moultrie, Charleston, S. C.

The large cisterns were 24 ft. in diameter and 10 ft. high inside with a 10-in. drain and 10-in. inlet and overflow. They were built with a 12-in. base 28 ft. 4 ins. in diameter, reinforced in the center with No. 10 expanded metal with 6 × 3-in. mesh. The walls were 8 ins. thick and were reinforced with ⅜-in. twisted vertical rods spaced 12 ins. on centers and ½-in. twisted horizontal rods spaced 2.4 ins. for the first 2 ft.; 3 ins. for the next 1 ft.; 4 ins. for the next 2 ft.; and 6 ins. for the last 4 ft. The roof was a 10-in. slab, reinforced with ½-in. rods spaced 3½ ins. centers both ways.

The small cisterns were 13 ft. in diameter and 10 ft. high inside with an 8-in. drain and overflow and 6-in. inlet. They were built with a 12-in. base, reinforced the same as the large cisterns. The walls were 8 ins. thick with ⅜-in. twisted vertical rods, spaced 12 ins. on centers, and ½-in. horizontal rods, spaced 4 ins. centers for the first 3 ft. and 6 ins. centers for the remaining 7 ft. The roof was a 6-in. slab reinforced with ⅜-in. rods, spaced 4 ins. centers both ways.

Each cistern had an 18 × 24-in. trapdoor in the roof. All concrete was a 1:2:4 mix, using Pom-Pom gravel and ¾-in. crushed granite.

The segments for the wall forms were sawed at the mill out of 2 × 12 in. long leaf yellow pine. They were sawed to the exact outside diameter and the inner parts were trimmed on the job with sharp hatchets to fit the inside diameter. There were six segments in each circle for the small cisterns and twelve in each circle for the large ones. The circles were spaced 2 ft. centers and 1⅛ in. long leaf yellow pine was used for sheeting.

On the first cistern that was built, which was a small one, the walls and top were built together but it was found to be too hard to remove the forms through the small trapdoor, so for the others the forms were built in sections extending from the bottom to the top and one segment wide for the inside form. After the complete inside drum was built the vertical rods were placed and the horizontal rods bent around and fastened to them. Every sixth vertical rod was held in place by a block spacer. The horizontal rods were wired to the vertical rods at every other joint, the ties being staggered.

The outside forms were then placed. These were 2 ft. high and one segment wide and were made so that the next section fitted into the one below. As soon as one section was filled with concrete the next was placed, three carpenters being able to keep up with the concrete gang. All of the segments were fastened together at the joints with cleats and were found to be so rigid that no braces were necessary.

After the walls had set the cleats were knocked off and the sections removed. On the inside one of the joints was left wide as it was found to be necessary to cut out one board before the forms could be removed. The sections were then slid out over the top and 2 × 4-in. uprights were placed on the inside, these carried the 2 × 6-in. cross pieces on which the floor for the top was laid. The cross pieces were spaced 2 ft. centers and the uprights 4 ft. centers while the sheeting was the same as that used for the walls. The top was then concreted and after it had set about six days the forms were removed and passed out through the trapdoor.

All of the concrete was mixed by negroes on boards as the cisterns were too far apart for a central mixing plant and each one was too small to pay for the setting up of a mixer.

The laborers were paid 15 cts. per hour and worked 8 hours. The carpenters were also negroes and received 20 cts. per hour with the exception of the head carpenter who was a white man and received 30 cts. per hour. There were no foremen as the superintendent looked after everything with the assistance of a young man who kept the time and account of supplies and occasionally acted as gang foreman on excavation.

The usual routine was to mix and place the base for a small cistern, then while the carpenters were erecting the wall forms, mix and place the base for a large cistern, then come back and fill the forms on the small one while the carpenters were building forms on the large one.

In placing the walls and top of the small cisterns the concrete was mixed on the ground and passed up in buckets by hand as the nature of the surroundings did not allow the use of runways, but in building the large one runways were built and the concrete wheeled into place. Although passing the concrete up in buckets was slow it was not a great deal more expensive than wheeling. The cost of large cistern was as follows:

Concreting

		Per cu. yd.
Base:		
22 laborers 8 hrs. at 15 cts.	$26.40	$1.10
Superintendent	5.00	0.12½
Total	$31.40	$1.12½
Walls:		
15 laborers 9 hrs. at 15 cts.	$23.15	$1.21
Superintendent	5.00	.25
Total	$28.15	$1.46
Roof:		
19 laborers 7 hrs. at 15 cts.	$20.70	$1.38
Superintendent	25.00	.33½
Total	$25.70	$1.71½

BUILDING FORMS FOR WALLS

1 carpenter 62 hrs. at 30 cts	$18.60
2 carpenters 62 hrs. at 20 cts	24.80
2 laborers 39 hrs. at 15 cts	11.70
	$55.10

This gives a cost of $.04 per sq. ft. Removing same $4.00, or $.009 per sq. ft.

BUILDING FORMS FOR ROOFS

1 carpenter 18 hrs. at 30 cts	$ 5.40
2 carpenters 18 hrs. at 20 cts	7.20
2 laborers 18 hrs. at 15 cts	5.40
	$18.00

This gives a cost of $.0355 per sq. ft. Removing the forms cost $7.75 or $.005 per sq. ft.

PLACING STEEL

		Per ft.	Per lb.
Walls:			
8 laborers 8 hrs. at 15 cts	$ 9.60	$0.0029	$0.0038
Superintendent	8.00	0.0005	0.0007
Total	$11.60	$0.0034	$0.0045
Roof:			
11 laborers 1 hr	$1.65	....	$0.001

The cost of two small cisterns was as follows:

	Base	Walls	Roof
Concrete, per cu. yd	$1.29	$1.51	$1.80
Steel, per lb	.....	0.005	0.001
Forms, per sq. ft	.....	0.037	0.04
Removing same	.....	0.005	0.01

The costs are higher than they should be on this class of work. This was caused by the inexperienced labor and because the work was scattered. Also by the engineer insisting on a number of minor details that were unnecessary but caused additional work.

Cost of Underground Concrete Cisterns.—Cisterns of 75,000 gal. capacity were constructed in San Francisco as auxiliary water supply for fire protection. There were 85 new cisterns, built beneath the surface at street crossings their exact position indicated by a distinctive type of pavement over them. A. J. Cleary gives the detailed costs of a typical cistern in Engineering Record, July 26, 1913.

The cisterns were constructed by contract, but very accurate cost data were kept by the city's bureau of engineering. Following is a typical cost account for constructing the cistern shown in Fig. 8.

DETAIL COSTS OF CONCRETE CISTERN

GENERAL EXPENSE

Labor Cost:	
Superintendent, 219½ hours at 87½ cents	$192.06
Timekeeper, 142½ hours at 31¼ cents; 5 hours at 50 cents	47.03
Watchman, 652 hours at 31¼ cents	203.75
Total	$442.84
Material Cost:	
Telephone	$ 28.50
Office rent and horse	21.00
10 gal. coal oil at 20 cents	2.00
Total	$ 51.50

Removing Pavement

Labor Cost:	
Foreman, 15 hours at 43¾ cents	$ 6.56
Laborers, 220 hours at 25 cents	55.00
Team, 8 hours at 75 cents	6.00
Total	$67.56

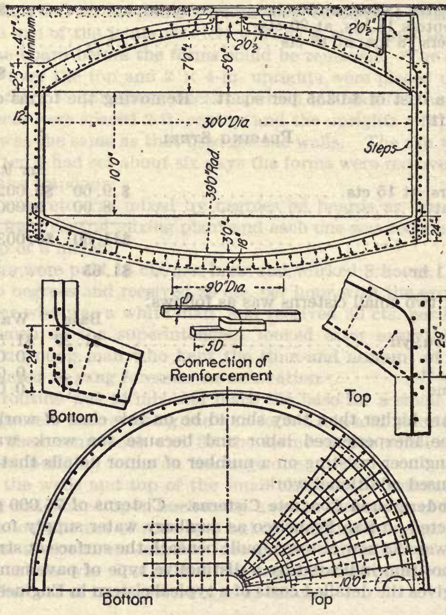

Fig. 8.—Typical reinforced-concrete cistern.

Excavation

Labor Cost:	
Foreman, 169½ hours at 43¾ cents	$ 74.15
Foreman, 46½ hours at 50 cents	23.25
Laborers, 1981 hours at 25 cents	495.25
Team, 317½ hours at 75 cents	238.12
Total	$830.77
Material Cost:	
Motor rent	$ 10.00
Electric power	10.00
Depreciation on equipment	50.00
Total	$ 70.00

Lagging

Labor Cost:	
Foreman, 148 hours at 50 cents	$ 74.00
Foreman, 55 hours at 43¾ cents	24.06
Laborers, 754½ hours at 25 cents	188.62
Laborers, 893¾ hours at 31¼ cents	279.29
Electrician, 77½ hours at 37½ cents	29.06
Total	$595.03
Material Cost:	
4410 ft., 2 × 8 R. P., at 15 cents	$ 66.15
1 keg nails	3.00
Total	$ 69.15

Pumping

Labor Cost:	
Foreman, 11 hours at 50 cents	$ 5. 0
Foreman, 29 hours at 43¾ cents	12.69
Electrician, 88½ hours at 37½ cents	33.19
Laborers, 240 hours at 31¼ cents	75.00
Laborers, 83½ hours at 25 cents	20.87
Total	$147.25
Material Cost:	
7½-hp. motor, 4-in. pump, 105-ft. R. P., at $15 per M	$ 1.60
100-ft. T. & G., at $20 per M	2.00
Motor rent	30.00
Electric power	49.00
Installation fee	10.00
Total	$ 92.60

Bottom Reinforcing Steel

Material Cost:	
Housesmiths, 160 hours at 62½ cents	$100.00
Labor Cost:	
2038 lb. ⅝-in. steel at $0.021	$ 42.80
4566 lb. 1-in. steel at $0.021	95.89
Ties and spreaders	8.00
Total	$146.69

Side Reinforcing Steel

Labor Cost:	
Housesmiths, 72 hours at 62½ cents	$ 45.00
Material Cost:	
1584 lb. ⅝-in. steel at $0.021	$ 33.26
2529 lb. ¾-in. steel at $0.021	53.11
Total	$ 86.37

Dome Reinforcing Steel

Labor Cost:	
Housesmiths, 84 hours at 62½ cents	$ 52.50
Laborer, 8 hours at 31¼ cents	2.50
Total	$ 55.00
Material Cost:	
1623 lb. ¾-in. steel at $0.021	$ 34.09
1829 lb. ⅝-in. steel at $0.021	38.40
3553 lb. 1-in. steel at $0.021	74.61
Ties and spreaders	8.00
Total	$155.10

Bottom Concrete

Labor Cost:	
Concrete foreman, 8 hours at 75 cents	$ 6.00
Concrete laborers, 102 hours at 50 cents	51.00
Foreman, 8 hours at 50 cents	4.00
Laborers, 160 hours at 31¼ cents	50.00
Teams, 8 hours at 75 cents	6.00
Total	$117.00
Material Cost:	
43 yd. rock at $1.40	$ 60.20
54 yd. sand at $1.50	8.10
60¾ bbl. cement at $2.45	148.84
360 lb. Medusa at 14½ cents	52.20
Depreciation on equipment	5.00
Total	$274.34

Side Concrete

Labor Cost:	
Foreman, 18 hours at 50 cents	$ 9.00
Carpenters, 3 hours at 50 cents	1.50
Laborers, 184 hours at 31¼ cents	57.50
Teams, 8 hours at 75 cents	6.00
Total	$ 74.00
Material Cost:	
216 sacks cement at 50 cents	$108.00
300 ft. Medusa at 14½ cents	43.50
33 yd. rock at $1.40	46.20
4½ yd. ocean sand at $1.50	6.38
5 yd. city sand at 50 cents	2.25
Total	$206.33

Dome Concrete

Labor Cost:	
Foreman, 7 hours at 50 cents	$ 3.50
Laborer, 92 hours at 31¼ cents	28.75
Concrete foreman, 8 hours at 75 cents	6.00
Concrete laborers, 94 hours at 50 cents	47.07
Engineer, 9 hours at 37½ cents	3.30
Team, 14 hours at 75 cents	10.52
Total	$ 99.10
Material Cost:	
2 M. H. covers and intake pipe	$ 25.00
270 sacks cement at 60 cents	162.00
6 yd. ocean sand at $1.50	9.00
20 yd. city sand at 50 cents	10.00
50 yd. rock sand at $1.40	70.00
Total	$276.00

Summary of Concrete Cistern Cost

	Labor	Material	Labor and material
General expense	$ 442.84	$ 51.50	$ 494.34
Removing pavement, basalt blocks on 6-in. base	67.56	....	67.56
Excavation (sand)	830.77	70.00	900.77
Lagging (2 × 8 in.)	595.03	69.15	664.18
Pumping	147.25	92.60	239.85
Reinforcing steel	200.00	388.16	588.16
Concrete	317.24	779.62	1096.86
Forms	187.33	59.55	246.88
Backfill (sand)	47.06	....	47.06
Pavement and curb	102.93	75.50	178.43
Catch basin	16.87	14.40	31.27
Sidewalk	5.00	51.10	56.10
Total	$2959.88	$1651.58	$4611.46

UNIT COSTS

Removing pavement	800 sq. ft.	$ 0.084 per sq. ft.
Excavation sand	690 cu. yds.	1.305 per cu. yd.
Lagging (2 × 8 in.)	4,410 ft. b. m.	150.61 per M.
Reinforcing steel	9.79 tons	60.08 per ton
Concrete	146 cu. yd.	7.513 per cu. yd.

Hours of Labor Required on Concrete Cisterns.—The following miscellaneous costs on the construction of the foregoing reinforced concrete cisterns are taken from an article in Engineering and Contracting, March 30, 1910, by Benjamin Brooks who was employed by the city of San Francisco to inspect the work and keep cost data on the erection of the cisterns.

The mixture was 1 of cement to 5 of broken stone, with enough sand to fill the voids, which meant a 1:2½:5 or a 1:3:5 mixture, according to the run of materials and judgment of the engineers. Six pounds of some approved water-proof compound was to be mixed dry with each barrel of cement used in the sides and bottom (but not in the domes), and this necessitated at least one extra man to mix it with a hoe, measure it into boxes and pass it to the man on the mixer platform. On completion of the concrete the bottom received a regular sidewalk finish, and the sides and top a brush over with grout.

Cost of Forms.—Cistern A forms cost as follows:

Man hrs. making per M lumber, 12.4; per sq. ft. surface, .03.
Man hrs. setting per M lumber, 47.4; per sq. ft. surface, .24.
Which at $.62½ per hour is equivalent to:
Making $7.75 per M, or $.02 per sq. ft. surface.
Setting, 29.62 per M, or $.15 per sq. ft. surface.

On cistern B, forms already made for another cistern were used and cost for placing and removing as follows:

	Per sq. ft.
Man hrs. at $.62½ placing 17.25 per M	.069
Man hrs. at $.28 placing 12.25 per M	.049
Man hrs. at $.28 removing 12.75 per. M	.014

which is equal to:

Placing forms	$14.21 per M or $.057 per sq. ft.
Removing forms	3.57 per M or .014 per sq. ft.
Total	$17.78 per M or $.071 per sq ft.

For cistern C, wall forms were already made for another cistern and required only a little patching.

Patching and placing required 44 man hours at 25 cts. plus 73 man hours at 62½ cts., which equals 4½ cts. per sq. ft., including the placing of chutes.

Removing forms and clearing cistern required 61 man hours at 25 cts. and 21 man hours at 62½ cts., which equals 2.8 cts. per sq. ft.

For cistern D, wall forms were already made and required for—

Placing (125 man hrs. at 62½c, 20 man hrs. at 25c) equals $22.46 per M, or 11⁷⁄₁₀c per sq. ft.
Removing (12 man hrs. at 62½c, 37 man hrs. at 25c) equals 1½c per sq. ft.

Cost of Reinforcing Bars per Ton, Cistern A.—To bend and place 1 in., ¾ in. and ⅝ in. twisted square bars required 38 man hours per ton, which at 62½ cts. = $23.75.

Cistern B.—Bending and placing 1 in., ¾ in. and ⅝ in. bars required 52 man hours per ton at 62½ cts. = $32.50 per ton.

Cistern C.—Reinforcing bars required 41⅓ man hours per ton to bend and place, which at 62½ cts. = $25.83.

Cost of Concrete, Cistern A.—Concrete was mixed about 1:2½:5 in a Chicago Improved cube mixer, turning out about 7 cu. yds. per hour with a trained crew, and was wheeled and dumped in concrete "buggies." For the bottom of the cistern the man hours per yard required were:

Chutes and runways	....
Measuring and wheeling materials	0.96
Mixing	.13
Wheeling and chuting concrete	.41
Placing and tamping	.27
Total	1.77

which at 50 cts. per hour = 88½ cts. per cu. yd.

Pumping during excavation, lagging, concreting, etc., cost as follows: 162 man hours (exclusive of night watchman), 0.27 man hours per yard of excavation at 28 cts. = 7½ cts. per cu. yd.

Cistern B.—Concrete handled by same outfit and crew as for Cistern A cost as follows:

For the bottom:	Man hrs per yd.
Wheeling and measuring materials	1.16
Mixing materials	.17
Wheeling and chuting concrete	.45
Placing and tamping concrete	.35
Total counting delays*	2.13
Total actual running	1.80

which at $.50 = $1.06 or $.90 per yd., not counting superintendence.

* Ran out of materials.

For the walls:	Man hrs. per yd.
Wheeling and measuring materials	.82
Mixing concrete	.13
Wheeling and chuting concrete	.37
Placing and tamping	.37
Total	1.66

Which at $.50 per man hour equals $.95 per yd. exclusive of superintendence.

Cistern C.—Concrete for the bottom and sides was mixed in a Smith mixer 2 cu. ft. of cement to the batch and run directly from mixer through portable chutes to the bottom, but wheeled in buggies to the side walls. The crew was untrained and poorly managed. The cost was as follows:

	Man hrs. per cu. yd.
Wheeling and measuring materials	1.55
Mixing materials	.30
Wheeling and chuting concrete	.42
Placing concrete	.60
Installing mixer	.74
Total	3.61

Which at 28c equals $1.01, including foreman.

Plastering bottom required 24.6 man hours at 75 cts., which gave a cost of 2⁶⁄₁₀ cts. per sq. ft.

Brushing the sides required 11 man hours at 25 cts. which gave a cost of ³⁄₁₀ cts. per sq. ft.

Cistern D.—Concrete for the bottom was handled as in Cistern C except that on account of a breakdown 44 cu. yds. were machine mixed and 8 cu. yds. were hand mixed, first the cement and sand dry and wet, then the grout and the rock being turned three times. For the machine mixing the costs were:

	Per cu. yd.
Wheeling and measuring materials, 1.50 man hrs. at 28c	$0.420
Mixing materials, .32 man hrs. at 28c	.089
Chuting and placing concrete, .74 man hrs. at 28c	.207
Building chutes, .55 man hrs. at 62½c	.344
Setting mixer, .34 man hrs. at 45c	.153
Total	$1.213

For the hand mixing the costs were:

	Per cu. yd.
Wheeling and measuring materials, 1.50 man hrs. at 28c	$0.42
Mixing materials, 5.12 man hrs. at 28c	1.43
Placing concrete, 1.25 man hrs. at 28c	.35
Building chutes, 1.38 man hrs. at 45c	.62
Total	$2.82

Concrete for the walls cost as follows:

	Man hrs. per yd.
Wheeling and measuring materials	1.97
Mixing materials	.26
Wheeling and chuting concrete	.65
Placing concrete	.62
Setting mixer	.49
Total	4.00

This gives 4 hrs. × 28 cts. = $1.12 per cu. yd.

Concrete for the dome cost as follows:

	Man hrs. per yd.
Wheeling and measuring materials	1.02
Mixing materials	.23
Wheeling concrete	.47
Placing concrete	.32
Setting mixer*	1.02
Total	3.059

* This item seems very high, but often included carting the mixer back and forth from one cistern to another. It could have been reduced by better management.

This gives 3,069 × 28 cts. = 80.85½ cts. per cu. yd.

Finishing the floor with ½ in. of sidewalk finish required 21 man hours at 75 cts. and 8 man hours at 25 cts. = $17.75, or 2½ cts. per sq. ft.

In the above data, costs of getting materials on the jobs are not considered nor is superintendence except in cases where it is specially mentioned.

Cost of Concrete Reservoirs at Brockton, Mass.—Two 4,000,000 gal. reservoirs were constructed in 1911. Charles R. Felton, in the Water Commissioners Annual Report gave the essential features of the design with some notes on their construction and cost. The following is taken from an abstract of Mr. Felton's report published in Engineering and Contracting, Sept. ?, 1912.

Design.—The reservoirs are of concrete, reinforced with plain round bars, except for a few twisted bars where the sides and bottom join. The concrete is of very rich mixture, to render it impermeable, the bottom courses being 1 cement, 1 sand, and 2 stone, to a height of 10 ft., with a 1:1½:3 mixture above this point; both mixtures containing hydrated lime in the proportion of 5 per cent of the cement by weight. The walls are 30 ins. thick at the bottom and 15 ins. at the coping course, which is 19 inches square.

The floor layer consists of two courses of concrete, 6 ins. thick; the lower one of 1:2:4 concrete, and the upper one of 1:1½:3 concrete, reinforced with ½-in. bars 1 ft. apart in both directions. The horizontal reinforcement consists of plain round bars from 1¼ ins. in diameter at the bottom to ⅝ in. in the coping.

The maximum strain upon the metal, considering the stresses as applied to a cylinder 160 ft. in diameter, are 13,000 lbs. per sq. in., with the reservoir overflowing, or 12,000 lbs. at the proposed high water mark, 18 ins. below the top.

Vertical, square twisted rods, ⅞ in. in diameter and 1 ft. apart were introduced into the foundation and also bent into the floor. These rods were extended to the top of the reservoir, but spaced 2 ft. apart after the first three courses. The bottom was also connected with the foundation by ⅞-in. twisted rods.

Sand and gravel were obtained from a large hill three miles distant from the location, and were very expensive, both on account of the length of haul and the large amount of material handled to get stone, about ⅛ of the total being stone of the required size, viz.: That which would pass a 1⅛-in. screen. The screen was of the revolving type, run by a gasoline engine, and under ordinary conditions would pass about 175 cu. yds. of material in eight hours. The resulting product was excellently graded.

The greatest care was taken to make the concrete impermeable, an entire course being run when once started. These courses were 30 ins. in height, except the bottom one, which was 36 ins. and contained about 110 cu. yds. No departure from this plan was found necessary, the concrete being placed continuously in courses 6 ins. thick, from three and one-half to six hours being consumed on a 30-in. course. After the concrete had partially set, usually in about 7 hours, it was thoroughly scraped with wire brushes and kept wet until the next course was ready, usually covered with wet bagging and carefully swept just before placing.

A steel dam, 4 ins. by ⅜ in., was imbedded 2 ins. deep in the top of each course, and about 1 ft. from the inside of the reservoir. This dam was lapped and bolted with five ¾-in. bolts, and figured in the design for its full tensile value as metal. In addition to the dam a triangular groove about 1.5 in. deep was placed in the top of each course. Before beginning a new course the joint was washed with neat cement grout.

No waterproofing or brushing of the surface was required or allowed, and less than a quart of cement was required to remedy any defects of appearance.

Construction Plant.—The plant consisted of an elevated tank of 5,000 gals. capacity, into which water was pumped by gasoline engine a distance of about 1,300 ft. Two Smith concrete mixers, set at an elevation corresponding substantially in level to the top of the reservoirs and operated by 15-h.p. electric motors. The mixers were fitted with side charging apparatus, and the material elevated to the mixers.

The concrete was placed, usually, at the rate of from 24 to 30 cu. yds. per hour with ordinary wheelbarrows, the greatest care being taken to have the material thoroughly tamped.

Cost.—The labor was all paid at the city rate of $2.50 per day of eight hours; carpenters $4.80 per day; foreman $5.00 per day; masons $0.72 per hour; teams $5.50 per day of eight hours. One of the greatest obstacles in accomplishing work of this character economically is the difficulty of employing all the labor to advantage between pourings, especially when it is necessary to conform to the present drastic eight-hour laws.

The total cost of the reservoirs exclusive of the engineering was almost exactly $80,000, or about one cent per gallon. The cost of the engineering and inspection, not including Mr. Felton's time, was about $2,200.

Labor Costs of Reinforced Concrete Tanks for Storage of Storm Water.—W. G. Cameron, in Engineering and Contracting, Jan. 26, 1916, gives the unit-time data for constructing the temporary storage tanks at Toronto, Ont., shown in Fig. 9.

Design.—The tanks are rectangular in shape, and approximately 104 ft. × 112 ft. On the north side, there is a channel 3.5 ft. deep for the Bloor west sewer, separated from the tanks by a weir. On the east side, there is a section 4 ft. deep, separated from the tanks by a weir, and from the storm water outlet by another weir. Into the north end of this section the storm water from the Keele St. sewer flows. The bottom of this section is graded back towards the north end and a gate valve is provided which can be opened to allow the section to drain into the storm water outlet. The tanks proper are divided into three parts, 17½ ft. deep, by two weirs. These three divisions are graded towards the east side, where they drain into an open 18-in. sludge channel, which runs south along the inner side of the east wall and into the 18-in. tile sewer under the storm water outlet. A gate valve is provided at the end of the sludge channel at the south wall.

Eight rows of columns were used in the tanks for the support of the roof. These columns were 18 in. square in section, 12 ft. apart center to center in the rows and 12-ft. centers between the rows. Two rows of columns were in each tank, and one was used as support for each of the two dividing weirs. The tanks were built of all reinforced 1:2:4 concrete. The walls were 12 ins. wide at the top, while the sides had a batter 1 in 7.6. The width at the bottom varied as the height. There was a footing provided 2 ft. deep and 12 ft. 6 in. wide. The reinforcing for the walls was 1-in. square twisted rods on the outside and 0.30 sq. in. mesh on the inside. The columns were reinforced with 1⅛ sq. in. twisted rods, 2 ft. 6 in. long, as dowels into the footing, one 1⅛ sq. in. rod in each corner, the full height of the column, and ⅜ in. round hoops, spaced vertically 12 in. apart. The roof slab was 6 in. thick, reinforced with 0.5 sq. in. mesh.

The girders and beams for the support of the roof slab were 24 in. × 16 in. and 21 in. × 16 in, respectively. They were reinforced with 1 sq. in. twisted rods and ¾ in. square twisted rods, respectively. The weir walls between the tanks were 8½ ft. high, 9 in. wide at the top, and 18 in. wide at the bottom, reinforced with ¾ sq. in. bars.

Construction.—The ground on which the tanks were built was composed of sand on the surface, which, in small areas, formed pockets. The subsoil was hard, blue clay. Trenches were excavated by hand for the west wall and the western third of the north wall. This part was built first because the ground was low at this side. When these walls were built, and the concrete sufficiently hardened, they were used as a retaining wall for the next material excavated. This material was taken from inside the lines of the future tanks and next the west wall. Enough material was taken out to allow for the erection of a portion of the tanks on the west side. This portion was com-

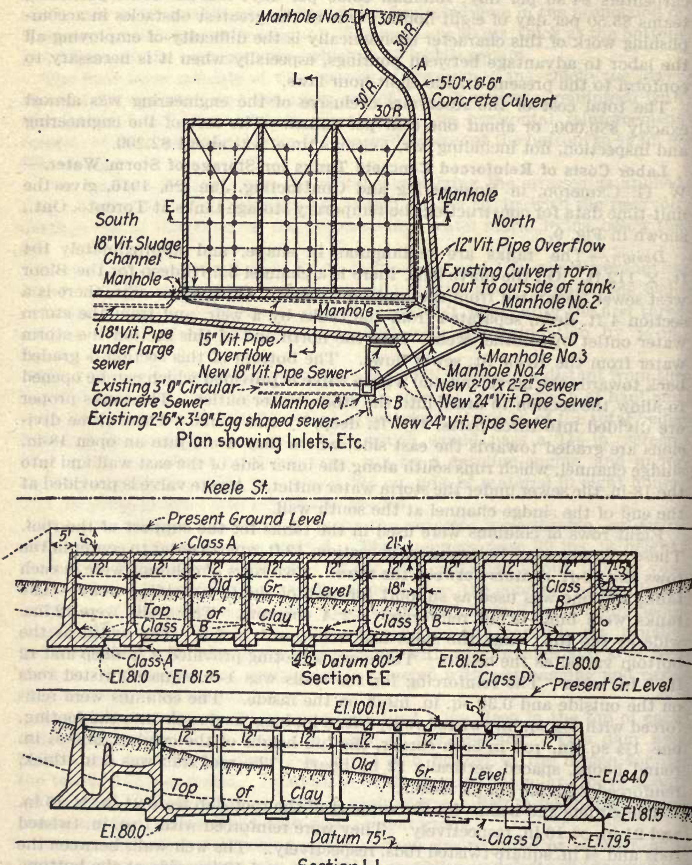

FIG. 9.—Plan and principal sections of reinforced concrete tanks for the temporary storage of storm water, Toronto, Ont.

pleted floor, columns, weirs and roof and allowed to harden. The next material excavated was then deposited on the roof of this finished portion. Thus the excavation and construction proceeded alternately from the west. A clam shell was used for excavating in the body of the tanks, but the clay was so hard that the most of it had to be loosened with picks before it could be gathered up by the clam.

The concrete was all mixed by a drum mixer very conveniently placed at the top of the bank on Keele St. The concrete was dumped into a chute which carried it down the bank to a funnel-shaped box. This box was provided with a slot which slid up and down so that concrete could be taken away in any quantity desired. The concrete was carried in concrete barrows along runways so built that they might easily be taken down and erected quickly again wherever they were required. The forms used for the concrete were all of the panel type. They were built near the work and the same sections used several times. They were made before the work was begun and grouped according to size, so that when they were needed they could easily be found and quickly erected. They were fastened together with bolts.

When the work on the tanks was completed the soil which had been excavated, and soil brought from other work, was spread over the top of the tanks to a depth of 4 ft. The bank on Keele St. was extended and neatly graded, and an easy slope was made from Bloor St. The ground over the tanks and the slopes will probably be sodded and planted, and possibly tennis courts, etc., arranged on it, making in all a very great improvement to this corner of High Park.

Unit Time Data.—The time-costs, in hours' labor on this work, as kept by S. K. Ireland, resident engineer, are as follows:

Excavation.—7,000 cu. yd., 10,472 hours, or 1.496 hours per cubic yard.

Placing Steel.—102 tons, 1,471 hours, or 14.4 hours per ton (85 tons of this were bars and 17 tons mesh).

Building and Erecting Forms.—52,899 sq. ft. took 8,452 hours, or 0.159 hours per square foot.

Removing Forms.—0.0202 hours per square foot.

Mixing and Placing Concrete.—2,522 cu. yds. took 6,394 hours, or 2.53 hours per square yard.

Foreman, 1,658 hours; engineer, 1,098 hours; fireman, 1,133 hours; team, 107 hours; single horse, 451 hours.

Cost of Lining a Reservoir with Gunite.—E. Court Eaton gives the cost of lining a small "balancing reservoir" in Engineering News-Record, July 24, 1919.

The reservoir with a depth of about 9 ft. covered about two acres and was used to store a surplus of water during part of the day and supply the shortage during the balance. Due to the fact that the reservoir was necessarily confined to a certain area close to an old stream bed and the reservoir was excavated in a gravel deposit the seepage amounted to two to three acre-feet per day.

It was decided to line this reservoir with a gunite lining. The total area to be lined was 114,000 sq. ft., and specifications called for a gunite lining 1 in. in thickness, with a mix of one part of cement to 5½ parts of sand; no lime was used in the mixture. The lining was reinforced with galvanized poultry netting, 1½-in. mesh, No. 19-gage wire, placed in the center of the concrete to confine cracks due to expansion to hair cracks, and no expansion joints were used.

This work was let by contract at a price of 10½c. per square foot, including the trimming and preparation of the banks. Work was commenced Jan. 14, 1919, and completed Mar. 19. Because the work had to be done during the winter months the actual number of working days in this time was only 39.

The cement gun used was what is known as the N2 size. It was kept on the upper bank of the canal at a maximum distance of 600 ft. from the compressor, to which it was connected with a 2-in. iron pipe. The compressor was of the portable type, direct-connected to a semi-Diesel type of engine; it was 12 × 12 in. and ran at a speed of 300 r.p.m. A pressure of 42 lb. per square inch was maintained at the compressor, giving about 32 lb. at the gun. A 2-in. rubber hose 200 ft. in length was used from the gun to the nozzle, and the rubber tips in these nozzles lasted nearly one week before requiring replacement. The depreciation on the hose for the period of the job was $200.

In lining the 114,000 sq. ft., 2904 sacks of cement were used, or nearly 39 sq. ft. of lining per sack of cement. The average rate of progress throughout the work was 2900 sq. ft. per working day. The maximum day's run was about 5000 sq. ft., though better average progress would have been made in the dry season, as the principal delays were due to wet sand clogging in the hose and necessitating frequent cleaning out of the machine. A certain amount of moisture is necessary in the sand for this class of work, and the best results were obtained when sufficient water was present so that the sand just failed to hold its shape when squeezed in the hand.

The total quantity of sand used on the work was 600 tons, and the total cost of sand per ton was as follows:

	Per ton
Loading charge at sand pit	$0.30
Freight	.60
Unloading	.12
Hauling to site	1.50
Total	$2.52

The hauling over the wet roads a distance of two miles was the biggest item. The weight of a cubic yard of sand, which was wet, was 2500 pounds.

The cement was $3.45 per barrel delivered at the site, after an allowance of $1 per barrel was made for sacks. The poultry netting delivered at the site cost $1.17 per 100 square feet.

The construction crew employed was as follows:

	Per day
1 Compressor engineer	$ 7.00
1 Nozzleman	5.00
1 Man placing wire	5.00
2 Mixers at $4	8.00
1 Man loadaing gun	4.00
1 Nozzlemn helper	4.00
1 Gun operator	4.00
1 Man cleaning off rebound	4.00
Total payroll	$41.00

One man was kept continuously close to the nozzleman, his duties being to brush back the rebound at the junction of new and old work and to raise the reinforcement by means of a hook to insure its being placed in the center of the lining.

The fuel used consisted of a fuel oil having a gravity of 27 +. Ten drums of this oil of 104-gal. capacity per drum were used. The cost of the oil was $6.55 per drum, delivered to site. The loss by rebound in percentage of the sand used was 8½; this was not wasted, however, as it was collected, screened and used over again with good results, except that only 30 sq. ft. of lining per sack of cement, or 23% less than with new sand, could be gotten when rebound was used, due to the material being coarse and requiring more cement to fill the voids.

Particular attention was paid to the curing, by sprinkling, of the newly completed lining for a period of two days, and up to this time no cracks other than fine hair cracks have developed.

Costs of Grouting Dam Foundations.—Engineering and Contracting, Aug. 19, 1914, publishes the following comparison of the costs of grouting the foundations of the Estacada and Lahontan Dams given by S. H. Rippey in Proc. Am. Soc. of C. E. Vol. XL.

TABLE XI.—COST OF DRILLING AND GROUTING AT ESTACADA AND LAHONTAN DAMS, PER LINEAR FOOT OF COMPLETED WORK

	—Estacada Dam—		Lahontan Dam
Labor and materials	Fisher	Rands	Cole
Labor, drilling	$0.58	$0.59	$0.93
Labor, grouting	0.18	0.18	0.29
Cement	0.12	0.12	0.31
Repairs and supplies	0.17	0.17	0.23
Plant	0.30	.....	.....
Plant depreciation	.....	0.15	0.35
Power	0.05	.....	0.03
Other items	.....	.....	0.94
	$1.40	.....	.....
Salvage on plant, credit	0.17	.....	.....
Direct cost	$1.23	$1.21	.....
Total field cost	.....	.....	$3.08
General plant, etc	0.32	0.45	0.12
Coffers and pumping	.....	0.15	.....
Engineering and superintendence	.....	0.19	0.27
Clerical and office	.....	.....	0.10
Total cost per foot	$1.55	$2.00	$3.57

In regard to the grouting of the Lahontan Dam, D. W. Cole in Engineering News, April 3, 1913, states that:

Drills were worked continuously in 8-hr. shifts, thus employing six crews of two men each for operating the drills, with one daylight crew of two to four men for grouting and testing.

Drillrunners were selected mainly from the men of good mechanical bent available on the job, with one or two importations of experts who had been previously trained. Runners were paid 40c., and helpers 30c. per hr.

Daily bulletins were posted showing output of the several crews and thus a wholesome rivalry was developed.

The maximum depth drilled by one machine in 8 hr. was 19 ft., in rather soft material. The average 8-hr. penetration of a drill was only 6 ft. Omitting the earlier period of work, which was largely experimental, the average performance of each 8-hr. shift was about 7 ft. of hole.

Air pressure of 25 lb. was employed for first batches, as higher pressures sometimes resulted in appearance of air bubbles and even cement color rising from the bed of the river at some distance from the boring; and violent displacement of the formation was not desired.

As the grouting advanced the later batches were driven in at a higher pressure, gradually increasing to 100 lb. per sq. in. at the finish of each hole.

In some of the tighter holes the extreme pressure was required for an hour or more to drive home the grout, but ordinarily the flow of grout was nearly continuous and as fast as the alternating process with the double-cylinder machine could be performed.

Costs of Groined Arch Roof for Minneapolis Reservoir.—W. N. Jones in Engineering Record, April 19, 1913, gives the methods and construction costs of covering with groined arch vaulting the clear water basin of the Minneapolis filter plant. The reservoir is 877.5 ft. long, 413.5 ft. wide and from 21 to 23 ft. deep. Very careful detailed costs were recorded with a view of securing not only the cost of the work but also an index of the efficiency of the labor employed. The following is taken from Mr. Jones article.

Equipment.—The quantity of equipment used has been very small and of the simplest type. No complicated machinery of any kind was employed on the work, and when the site was visited by a prominent engineer of Chicago, he said, "The thing that appeals to me most is the lack of elaborate equipment, such as expensive towers, cable-ways, etc." In fact, about all the machinery used outside of hand tools and a small woodworking shop for use in turning out forms, was a 1¼-cu. yd. concrete mixer, six 1¼-cu. yd. side-dump cars, about 1500 ft. of 24-in. gage track, and a traveling crane designed by the writer for the special use of handling groined arch forms. This crane cost about $500 complete.

For hauling earth, etc., common dump wagons of 1¼-cu. yd. capacity were used. All earth was handled by hand, both in loading and spreading. These wagons were not claimed to be conducive to economy, nor was the handling of the earth by hand, but the prime consideration was the employment of as many citizens and teams as it was possible to employ and still do the work at a reasonable cost.

Construction.—The groined arch concrete vaulting over the reservoir was supported by concrete pedestals and piers spaced 18-ft. centers. Over the roof a 2-ft. covering of earth was deposited. The pedestals were 6.5 ft. square at the base, 3.5 ft. high and each contained 2.85 cu. yd. The pedestal forms cost about $6 each for labor and material and each was used ten times on the average.

The rates paid for labor employed on the work were as follows:

Occupation	Time, days	Rate
Foremen	.....	$4 & $5
Assistant foremen	22⅛	3.00
Timekeepers	3	4.50
Steam engineers	9⅝	4.00
Watchmen	2⅞	2.25
Handy men	190⅝	2.40
Carpenters	24⅜	3.00
Millwrights	3⅜	3.00
Blacksmiths	2⅛	3.00
Concrete men	9⅛	3.25
Water boys	7⅝	1.25
Teams	56⅞	4.72
Single horses	6+	3.00
Laborers	738⅛	2.25

Table XII gives the cost in detail of all the most important items entering into the construction of the groined arch covering of the clear water basin during the season of 1911. The figures for 1910 are omitted, as it was found upon investigation that a number of reports had been lost. Items which were peculiar to this piece of work or were too small to classify are omitted also, as they are of no great consequence in the total cost or desirable for comparisons with similar work elsewhere.

TABLE XII.—CLASSIFIED UNIT COSTS FOR COVERING CLEAR WATER BASIN

Type of work	Quantity	Unit cost	Total cost
Concrete	11,475 cu. yd.	$0.967	$11,080.82
Making groined arch forms	39,595 sq. ft.	0.057	2,243.45
Setting groin forms and braces	348,954 sq. ft.	0.020	6,867.01
Dropping forms	330,541 sq. ft.	0.017	5,761.13
Transporting forms to derrick	298,344 sq. ft.	0.005	1,590.89
Hauling forms from yard	83,841 sq. ft.	0.008	658.34
Building column forms	7,120 sq. ft.	0.017	121.75
Setting and wrecking column forms	102,566 sq. ft.	0.056	5,690.85
Setting and wrecking 4 × 6-in. posts	3,382 units	0.485	1,639.55
Setting and wrecking column supports	810 units	0.747	605.85
Making manhole forms	350 sq. ft.	0.163	57.03
Tearing up forms	492 ft. b.m.	0.602	295.00
Oiling, repairing and notching forms	23,210 sq. ft.	0.034	704.67
Cutting stringers	861 units	0.053	45.60
Earth cover (1,000 to 2,000 ft. haul)	37,024 cu. yd.	0.478	17,714.30
Pointing up rough arches	....	......	176.90

The estimated cost of the work complete was $135,000. While the actual construction cost, including materials, was within $2000 of this amount, the actual costs cannot be exactly determined on account of lumber, etc., being used on the filter plant proper, and no credit being given the clear water basin for it, and also on account of the joint use of machinery, etc.

Cost of Wooden Form Work for Groined Arch Reservoir and Conduits, Pittsburgh Filtration Works.—The following data are from a paper by J. D. Stevenson read before the Society of Western Engineers, published in the Oct., 1910, Proceedings, and reprinted in Engineering and Contracting, Dec. 14, 1910.

Description of Piers.—Fig. 10 shows the form work for a 21.5 ft. circular pier 27 ins. in diameter, being one of 720 piers supporting the roof of the reservoir. The sketch is fully dimensioned. The forms are in three sections each 7 ft. 2 ins. long, each section consists of two semi circular pieces of No.16 galvanized steel, flanged on the vertical edge, the flanges of the two halves being bolted together between two pieces of 2 × 4-in. lumber. The sections are clamped at top, bottom and middle point by a wooden collar made in four pieces and held by bolts.

The pier forms contain 488 ft. of lumber and 688 sq. ft. of metal. The bracing contained 507 ft. of lumber. The cost as compiled by the writer for form work on four piers, 12.68 cu. yds. is given in Table XIII. This is an average from a number of observations taken at random and extending over a period of 8 months.

TABLE XIII.—COST OF FORMS FOR PIERS SUPPORTING GROUND ARCH RESERVOIR ROOF; TOTAL 12.68 CU. YDS. OF CONCRETE IN FOUR PIERS

Item	Total	Per cu. yd.
Stripping, 13 hrs. carpenter at 25 cts	$ 3.25	$0.27
Cleaning, 15 hrs. labor at 15 cts	2.25	0.18
Making:		
15 hrs. carpenter at 30 cts	$ 4.50	.....
15 hrs. labor at 15 cts	2.20	.....
Total	$ 6.75	$0.53
Setting:		
¾ hr. carpenter at 30 cts	$ 0.23	.....
1¼ hr. laborer at 15 cts	0.19	.....
¼ hr. cableway at 50 cts	0.12	.....
Total	$ 0.54	$0.04
Plumbing and bracing, 15 hrs. carp. at 30 cts	4.50	0.35
Grand total	$17.29	$1.37

Barrel Arch.—Fig. 10 shows the design of what was known as the barrel arch form. This form was for that portion of the wall from the springing line of the arch to the center of the first bay. The inside shape was a quarter of a 12 ft. circle and the outside an arc of a 15 ft. circle. These forms caused more trouble than any others on the reservoir. The inside was built in three equal sections, each 9 ft. long and 5 ft. 10 ins. wide on the chord. The ribs, 2 × 12 ins., were placed on 21-in. centers and lagging was 1 × 3 in., southern pine, tongue and grooved and dressed on both sides.

The outside forms were built in three sections, the first section being 3 ft. of the wall form which was left wired to the wall when removing the back wall

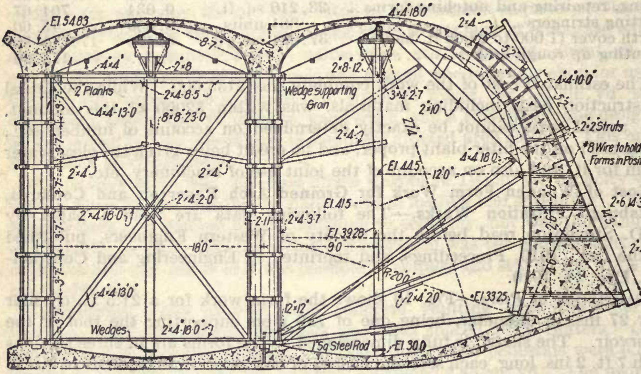

Fig. 10.—Forms for filtered water reservoir showing in elevation piers, walls and groined arch vaulting.

form; this gave a solid base upon which to build. The second was placed before filling and fastened to the inner form by wires and wooden interior struts and held on the outside by an outrigging extending up from the wall. The third was placed after the filling had reached the top of the second form and was wired to the inner form.

The remainder of the arch or a little over one-third of it was screeded, no form being useded on the outside.

Some trouble developed after the third using and was entirely due to the manner of removal. The bracing extending from the top to bottom, shown in Fig. 10, was not removed and the forms were not taken down in three sections, but the entire form was removed at one time. The method of removing was to hitch a set of falls to one of the upper corners to break the bonds and at times twelve men broke the rope before the form left the concrete. It was not uncommon to pull off several ribs in an attempt to break this bond. The result was that this pulling greatly distorted the form. This first showed up in the inability to make a good joint between forms and finally necessitated rebuilding the forms. The trouble could have been eliminated by removing the forms in three pieces rather than in one. The barrel arches on the filters were similar, but one-half the length. On these there was no particular trouble.

The barrel arch in filtered water reservoir contained 0.92⅓ cu. yd. per running foot and the units placed were 36 ft. long or 33¼ cu. yds. The cost of forms is given in Table XIV.

The cost is an average from a number of observations made by the writer. The cost of hauling out is rather high and unusual, the forms, however, were of awkward shape and very large, and had to be hauled on a truck by hand a distance as great as 300 ft. The floor over which they were hauled consisted of inverted groins with piers every 18 ft. The trimming and trueing at 58 cts. a yard is due to the trouble previously explained.

TABLE XIV.—COST OF FORMS FOR BARREL ARCH FILTERED WATER RESERVOIR, PITTSBURG, PA.

	Total	Per cu. yd.
Fabrication at mill:		
240 hrs. at 35 cts.	$84.00*	$0.31
Taking Down:		
1 foreman 2 hrs. at 30 cts.	0.60	
9 laborers 18 hrs. at 20 cts.	3.60	
Total	$ 4.20	$0.13
Hauling Out:		
1 foreman 1½ hrs. at 30 cts.	$ 0.40	
12 laborers 16 hrs. at 20 cts.	3.20	
Total	$ 3.60	$0.11
Cleaning and Repairs:		
1 foreman 5 hrs. at 35 cts.	$ 1.75	
4 carpenters 20 hrs. at 30 cts.	6.00	
2 helpers 10 hrs. at 20 cts.	2.00	
Total	$ 9.75	$0.30
Placing:		
Cableway ⅓ hr. at $2	$ 0.66	
1 foreman ⅓ hr. at 40 cts.	0.13	
3 carpenters 1 hr. at 35 cts.	0.35	
5 laborers 1⅔ hrs. at 15 cts.	0.25	
Total	$ 1.39	$0.04
Trimming and Trueing:		
1 foreman 10 hrs. at 35 cts.	$ 3.50	
4 carpenters 40 hrs. at 30 cts.	12.00	
2 helpers 20 hrs. at 20 cts.	4.00	
Total	$19.50	$0.58
Grand total	$48.94	$1.47

* Used 8 times.

Walls.—The wall forms shown in Fig. 10, are in accordance with the general practice in such work. All forms were made in 9-ft. sections and from top to bottom in one unit. The method for preventing the forms from raising is shown in the illustration and consisted of hooks set in the first layer of concrete and wires tying the forms to these hooks.

The forms were used on an average of 10 times and the only repairs made were a board now and then, where the bar in removing had splintered or broken the forms. The edges of the forms become more or less frayed and this was cared for by a metal strip tacked over the joint. This practice was permissible in this work as the face would not be exposed. In finished surfaces it should never be used, as the metal leaves a surface entirely different from the wood and very readily noticed.

The regular wall in the reservoir contained 2.33½ cu. yds. per running foot and as a rule the wall was built in 36-ft. sections or 84 cu. yds. This amount varied within a yard as the point where the wall ceased and the barrel started was not closely defined. The cost of forms is given in Table XV. This cost is a weighted average as in this work there was a great amount of variance. Often the cable way was used in removing forms and the cost cut down, then again the forms would be in bad shape and require much repairing. As an example, on the

21st wall forms cost	$0.73 per cu. yd.
23rd wall forms cost	.53 per cu. yd.
24th wall forms cost	.55 per cu. yd.
25th wall forms cost	.42 per cu. yd.
26th wall forms cost	.49 per cu. yd.

TABLE XV.—COST OF WALL FORMS, FILTERED WATER RESERVOIR, PITTSBURG, PA.

	Total	Per cu. yd.
Fabrication in Mill:		
110 hrs. carpenters at 35 cts	$38.50*	$0.038
Taking Down:

Total	$29.50	$0.350
† Grand total	$50.20	$0.596

†This does not include cost of material. * Used 12 times.

Groined Arch Forms.—Fig. 10 shows groined arch forms in elevation. Each pier top was molded on forms built in four triangular sections, the joints between sections being on centers of arches and on diagonal lines between piers. The ribs were 2-in. white pine placed on the diagonal line and on 2-ft. centers between the diagonals, the decking was 1-in. southern pine tongue and grooved. The forms were well oiled before filling.

The pier edge of each form rested on a collar bolted to the piers. The piers, having been built 2 ins. higher than the springing line of the arch, prevented any horizontal movement in the form. The four corners were supported by 8 × 8-in. posts and midway between corner posts were placed 4 × 4-in. posts. The proper elevation on the top of arch was first secured by placing wedges between the top of post and form. Later it was found that dumping the concrete disarranged these wedges and their use was discontinued and 0.5-in. boards were used and toenailed. This allowed only an adjustment of 0.5 in. which was considered close enough.

The joint between forms on the top was made by a crown strip which varied from 2 to 4 ins. wide. The corner joints were finished by a 1-in. triangular strip which relieved the rough corner. The forms being square and piers round required a filler in the corners. This filler was first made of plaster paris mixed with excelsior, but was unsatisfactory as the breakage was high and it was impossible to use it a second time. The cost of the fillers in plaster paris was about 27 cts. each. Later wood was used and the work was finished using wood. On Contract 11 the contractor used a metal filler cut from No.

16 gage sheet iron. This filler was used over and over, the first cost being 10 cts. each.

On Contract No. 1, the filters, the total amount of arch centering placed was 2,130,012 sq. ft. There were 240,000 sq. ft. of forms actually made to complete the work, an average of ten times use for each form. The actual cost was $0.0435 per sq. ft. placed; this cost includes plant charges, administration charges, material, etc.

On Contract No. 2, the reservoir, there were placed 243,390 sq. ft. of vaulting forms and there was actually made about 20,000 sq. ft. The cost was $0.096 per sq. ft. placed, or about $3.50 per cu. yd. of concrete placed. This cost is a final cost including everything chargeable to the forms.

For a detailed cost Table XVI was prepared from information gathered by the writer:

Four forms made one pier top or	8.1864 cu. yd.
Lumber in one pier top	1,000 ft.
Lumber in posts and bracing	400 ft.
Lumber in shoring on piers	150 ft.

To the above cost must be added a charge for hauling the forms from the place of removal to the place of setting. This varied greatly and from observations cost 15 man hours per 100 ft. hauled.

Table XVI.—Cost of Vaulting Forms for Filtered Water Reservoir, Pittsburg, Pa.

Making of Groins at Mill:	Total	Per cu. yd.
120 hrs. at $0.35	$42.00*	$0.42
Setting Groins:		
1 foreman ¼ hr. at 35 cts	$ 0.09	
3 carpenters ¾ hr. at 30 cts	0.225	
6 laborers 1½ hr. at 20 cts	0.30	
1 cableway ¼ hr. at $2.00	0.50	
	$ 1.115	$0.14
Setting Corner Posts:		
Cableway 0.1 hr. at $2.00	$ 0.20	
3 carpenters 0.3 hr. at 30 cts	0.09	
	$ 0.29	$0.03
Intermediate posts, 3 carpenters 1½ hr. at 30 cts	$ 0.45	$0.05
Shoring piers, 2 carpenters 3 hrs. at 30 cts	0.90	$0.11
Trimming and trueing, 4 carpenters 3 hrs. at 30 cts	1.20	$0.15
Taking Down Groins:		
1 foreman 1⅓ hrs. at 30 cts	$ 0.40	
5 laborers 6⅔ hrs. at 20 cts	1.35	
5 laborers 6⅔ hrs. at 15 cts	1.00	
Total	$ 2.75	$0.33
Grand total	$10.20	$1.22

* Used 12 times.

Cost of Bending Reinforcing Steel.—In the equalizing chamber the steel required careful bending. There were 27 different shapes. A record kept by the writer on the bending of 10,325 lbs. extending over a period of 10 days showed a cost of: 0.88 man hours per 100 lbs. for blacksmith and of 1.66 man hours per 100 lbs. for helpers. At the prices paid, or 25 cts. per hour for blacksmith and 16 cts. for helper this cost was 48.9 cts. per 100 lbs. In addition to this was chargeable 0.24 man hours per 100 lbs. for the layer out, which work was done by the boss carpenter at a cost of 20 cts. per 100 lbs., the total cost being 68.9 cts. per 100 lbs. In bending the steel a large platform was built and all shapes laid out full size, cleats were nailed at points of curvature and the rods bent to fit.

Conduit.—The construction of conduit forms was governed greatly by the place they were to be installed and the surroundings. A conduit in a trench offers different requirements than conduit in the open. The inner form or barrel is generally first placed. This is held to the proper elevation by piers, or saddles, separately cast, and the tops set to grade. The steel is next placed and then the outer forms.

Care must be exercised to prevent the form floating or rolling and in filling the bottom. The bottom is sometimes cared for by placing grout tubes, or by simply smoothing up after the removal of the forms. In a number of conduits on the reservoir work a board was left off the outside forms just above the invert and through this opening the bottom was successfully filled by tamping. The filling of one side and allowing the concrete to run under and seek its level on the opposite side, thus assuring filling in the bottom, is rather dangerous practice as there is great chance of moving the inside form or barrel.

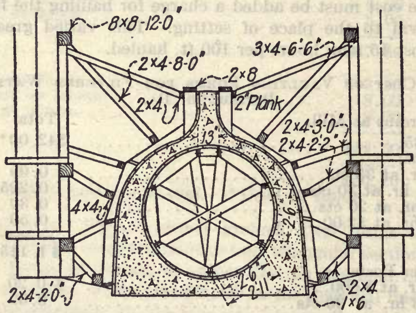

FIG. 11.—Forms and bracing for by-pass conduit.

The by pass conduit, shown in Fig. 11 is 7 ft. in diameter and about 1,200 ft. long, built in 36-ft. sections, contained 48.8 cu. yds. and 3,600 lbs. steel per section, and was built after the roof of the reservoir was in place, the piers and roof being used to brace against. The barrel was placed on concrete saddles and painted with cold water paint. The reinforcement was next placed and then the outside forms. The braces were all fitted and marked and they together with all except the bottom outside form were removed and stored conveniently for easy access. The barrel was held down by braces to the roof and held laterally by braces to stringers placed along the piers. When the concrete reached the level of the top of the bottom form, the second form was placed and so on until the top was reached. After the concrete was placed to a depth level with the top of the barrel it was found that there was no tendency to rise and the braces to the roof were removed.

The forms in this conduit were all bolted together; the inside or barrel form collapses by dropping the top section. The time required to build one section was three days and the time to fill it was seven hours.

The forms including bracing contained 6,350 ft. of lumber. The lagging was 1 in. southern pine and the ribs 2 in. white pine. The cost of a 36-ft. section, including taking down, placing steel, etc., as compiled from a number of observations was:

	Time	Rate	Cost	Times used	Cost per cu. yd.
Building forms at mill..............	489	$0.35	$171.15	10	$0.36
Carpenter work in field—					
Carpenter........................	227¼	.35	....	..	.....
Helpers..........................	19¼	.20	83.39	1	1.70

The forms for the seven foot filtered water conduit shown in Fig. 12 is a good example of form work for a conduit in a trench. In this conduit no outside forms except one on either side of the top was necessary. The sections were 30 ft. in length, contained 22 cu. yds. of concrete and 2,600 lbs. of steel. One foreman, 4 carpenters and 4 helpers took down the back forms, set them up ahead and placed the steel ready for filling at the rate of one section a day. Two sets of forms were used and they were removed the following day as early as 10 o'clock; thus while filling one section another

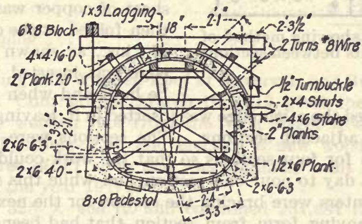

FIG. 12.—Forms and bracing for 7-ft. filtered water conduit.

was being prepared. The cost of setting up the forms and placing steel was $1.15 per cu. yd. and the cost of bending steel 40 cts. per 100 lbs.

The 48-in. conduit was a plain circle inside with perpendicular sides and semicircular top outside. The drain was located in a 21-ft. fill, placed in sections varying from 20 ft. to 50 ft. in length and contained 0.387 cu. yd. of concrete and 35 lbs. steel per lineal foot of conduit. The forms were built in the mill and used six times in the field:

	Per cu. yd.
Lumber..	$0.72
Mill work...	.30
Bending steel...	.26
Carpenter work in field.................................	2.13
Total...	$3.41
Total, cu. ft. of drain.................................	1.59

Cost of Relining a Brick-lined Reservoir with Concrete.—Thomas Fleming, Jr. gives the following data in Engineering and Contracting, April 3, 1912.

The Bellevue reservoir of the Ohio Valley Water Co., which supplies a large suburban territory west of Pittsburg, consists of an earth embankment with a vertical lining of brick masonry 2 ft. thick. The reservoir is 130 ft. in diameter and 20 ft. deep. It rests on solid rock foundation which several years ago was covered with a concrete floor. It has a capacity of 2,000,000 gals.

During the winter season the joints between the bricks opened up enough to allow as much as 400,000 gals. per day to leak out. While the leakage was was not seriously threatening the stability of the reservoir, yet it was a serious proposition financially. The cost of pumping water at this plant against the high head (480 ft.) prevailing, was at that time 3 cts. per 1,000 gals. This cost includes only fuel and labor. It was estimated that the leakage averaged 100,000 gals. per day per annum, which amounted to a financial loss of $3 per day, or $1,095 per year. This capitalized at 8 per cent would represent an investment of $13,688.

Several schemes were proposed to stop this leakage, but it was finally decided to reline the reservoir with an 8-in. concrete lining. This lining was designed to be constructed in sections 29 ft. long horizontally and extending the full vertical height of the reservoir. The sections were connected by a metal expansion joint. This was made of thin sheets of copper of No. 28 gage 12 ins. × 20 ft. The sheet of copper was corrugated and then folded at the center for a width of 4 ins., as shown in Fig. 13. One edge was inserted in the section to be built and when the adjacent section was constructed the other edge was inserted in it, leaving the fold between the faces of the adjacent sections. The sections were built alternately. There were forms for four sections so that the work could progress continuously. It took a day to pour one section and while this section was being poured, the carpenters were bracing the section for the next day's work and laborers were removing form from section that had been poured two days before and were setting this form for work to follow two days later.

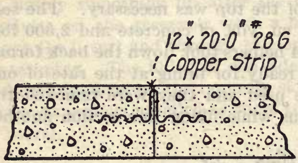

FIG. 13.—Sketch showing method of making copper joints between sections of concrete.

The form for each section was constructed in one piece with vertical struts and horizontal nailing pieces. These nailing pieces were 2 ins. × 12 ins., cut to the arc of the circle and spaced 2 ft. c. to c.; 1-in. sheeting was nailed to these vertically and 2-in. × 10-in. struts also vertical were spaced on the back of the form 5 ft. c. to c. The braces were nailed to these struts. The specifications stated that the contractor must not cut any holes in the concrete floor for supporting or bracing form work. Heavy pieces of timber were therefore laid on the floor of the reservoir entirely across it and braced against the wall on the opposite side. The form braces were then nailed to these timbers. Each section was poured in one day. The concrete was a 1:2:4 mixture and was placed wet and thoroughly spaded. The filling was made slowly so that the concrete in the lower part of the section would attain its initial set before the pressure from above could cause a deformation of forms. Upon the completion of a section it was allowed to stand two days before removing the form. The surface was then gone over with tools, imperfections removed, and a thin coat of liquid cement grout was applied. Upon the completion of the work, the test showed that the reservoir was absolutely water tight. The work had to be completed in 24 days.

The following costs do not include overhead charges, nor do they include 10,000 ft. B. M. of old lumber which was used for form work in addition to the lumber itemized in the list given. The cost of material was much higher than usual, due to the fact that it was necessary to haul it all several miles up a very steep grade where it was necessary to use extra teams for a part of the distance. Prices quoted for hauling were 25 cts. per barrel for cement and $2.10 per 1,000 for brick. There was a total of 201⅔ cu. yds. of concrete used.

Cost of Relining Brick-lined Reservoirs with Concrete

Item		—Per cu. yd. concrete—
260 bbls. cement at $1.25, deliv'd	$ 325.00	.....
123 tons sand at $1.65, delivered	202.95	.....
276 tons gravel at $1.45, delivered	400.20	.....
Total concrete material	$ 928.15	$4.60
4 M. ft. of 1-in. boards at $22	88.00	.....
Tools and lumber	55.00	.....
Nails, oil, supplies and incidentals	18.50	.....
Total form mat'l and incidentals	$ 161.50	$0.80
Foreman, 20 days at $5	100.00	.....
Carpenters at $3.50 per man per day	310.14	.....
Labor at $1.85 per day	297.30	.....
Finishing and cleaning up	54.16	.....
Total for labor	$ 761.60	$3.77
Total cost of lining	$1,851.25	$9.17

Cost of Removing Old Wooden Roof of Reservoir and Building New One.—Engineering and Contracting, March 19, 1919, gives the following costs of removing an old wooden roof from the Villa Street reservoir of the Water Department of Pasadena Cal. and erecting a new wooden covering. The roof covers an area of 3.7 acres and was originally built in 1899. The new roof was built in the year 1917.

The roof was 325 × 495 ft. and contained 251,681 ft. B.M. of lumber. The total cost of removing and salvaging the materials was $781, detailed as follows:

	Total	Cost per M. ft. B.M.	Cost per 100 sq. ft. of roof
Preparing yard for receiving lumber:			
Labor	$ 19	....	....
Auto	4	....	....
Total	$ 23	$0.0917	$0.0143
Removing lumber from reservoir:			
Labor	162	.6484	.1014
Hauling and stacking lumber in yard:			
Labor	139	....	....
Auto	20	....	....
Material	64	....	....
Total	$223	.8883	.1390
Removing 2-in. pipe posts:			
Labor	16	.0632	.0100
Engineering and other supervision:			
Labor	78	....	....
Auto	20	....	....
Total	$ 98	.3889	.0608
Sale and other disposal of materials:			
Labor	119	....	....
Auto	67	....	....
Total	$186	.7407	.1159

Overhead	71	.2821	.0441
Grand total		$3.1033	$0.4855

The value of the materials recovered was:

Broken and split lumber sold as kindling at $2.50 per truck load, 49,663 ft.	$ 82
Serviceable lumber sold at $9 and $10 per M. ft., 119,844 ft.	1,189
Lumber taken into stock, 82,174 ft.	821
Total value of lumber recovered	$2,093
Pipe posts sold (9,373 ft. 2-in. screw pipe)	350
Appraised value of hardware cloth (2,334 sq. ft. at 3 ct.)	70
Total	$2,513

The new roof is the same size as the old one. Its details are as follows: Roofing, 1 in. × 8 in., 1 in. × 10 in., and 1 in. × 12 in. R. W. boards; joists, 2 in. × 8 in. O. P. 16 ft. long spaced 40 ft. c. to c. (west tier 2 in. × 10 in.—20 ft., 4 ft. c. to c.). Girders, 2—2 in. × 12 in. O. P.—18 ft. long spiked together, spaced 15 ft. 9 in. c. to c. Posts, 6 in. × 6 in. R. W. 18 ft. and 20 ft. long with 6 in. × 6 in. × 3 ft. R. W. corbels. Work was begun on Jan. 8, 1918, and was completed March 9, 1918. The detailed costs were as follows:

	Total	Per M. ft. B.M. in roof	Per sq. ft. roof
48 concrete footings on slope:			
Labor, 11⅝ man days at $3.523	$ 41	....	....
Material	6	....	....
Total	$ 47	$ 0.158	$0.0003
Construction of wooden roof:			
Labor, 390⅝ man days at $3.459	$ 1,352	4.500	0.0084
Auto	12	.039	....
Material, 300.4 M. ft.	10.150	33.788	.0631
Total	....	$38.327	$0.0715
Hauling lumber:			
Labor, 44⅜ man days at $2.857	127	0.423	....
Auto	57	.190	....
Total	....	$ 0.613	$0.0011
Other hauling:			
Labor, 1 11-16 man days at $3.342	6	....	....
Auto	3	....	....
Total	$ 9	$ 0.030	$0.0001
Engineering and supervision, 30 man days at $4.952	149	.495	.0009
Disposal of surplus and waste material	25	.083	.0002
Overhead	1,193	3.971	.0074
Grand totals	....	$43.679	$0.0814

Cost of Concrete Wave Protection for Earthen Dams.—The costs of placing concrete linings on the earth dikes of the North Laramie Land Co., Uva, Wyoming is given by W. D'Rohan in Engineering and Contracting, Nov. 27, 1912.

The principal features of the concrete linings are indicated in Figs. 14 and 15.

In the reconstruction of the system, it was necessary to increase the capacity of No. 1 reservoir, by raising the height of the dams. Owing to the scarcity of any suitable material, it was decided to increase the height of the North dyke by means of a parapet wall and as the dyke is exposed to the greatest wind storms, the opportunity of putting a wave break on the top of the wall could not be neglected. The East dyke is of horseshoe form about 2,500 ft. long; 1,300 ft. of it being faced with plain concrete slabs, and the two ends with

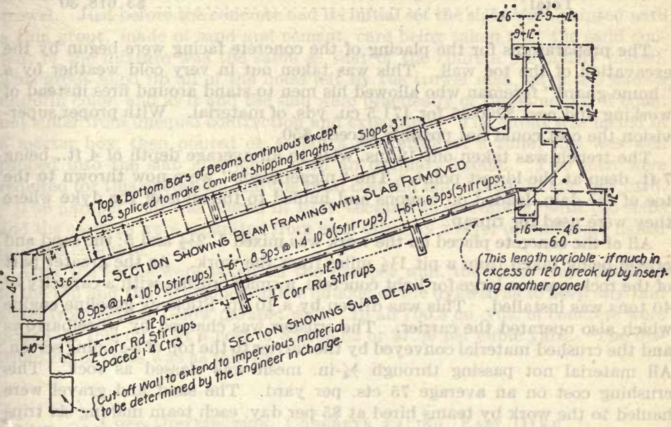

Fig. 14.—Reinforced concrete beam and slab-facing for dams and reservoirs Nos. 1 and 3, North Laramie Land Co.

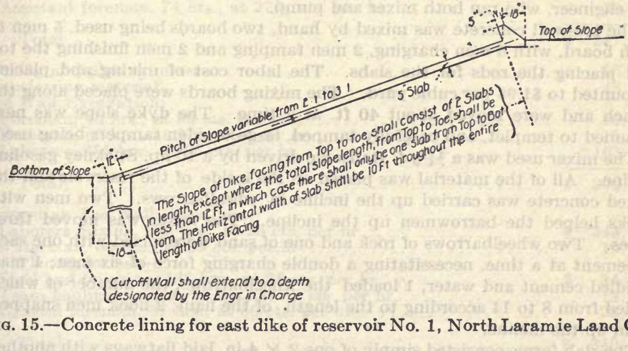

Fig. 15.—Concrete lining for east dike of reservoir No. 1, North Laramie Land Co.

hand laid riprap. This dyke being favorably suitated as regards material, 15,624 cu. yds. of dirt were placed on it. The dyke was first plowed and the fill placed in 3 ft. layers by means of wheelers and scrapers. All of this material was taken from the outside of the dam with an average haul of 300 ft. and cost $3,618.30 or about 23 cts. per yard. The detailed cost of this was as follows.

EARTH WORK, EAST DYKE DAM

Foreman, 360 hrs., at 35 cts. per hr.	$ 126.00
Laborers, 1,020 hrs., at 25 cts. per hr.	255.00
Laborers, 750 hrs., at 30 cts per hr.	225.00
Teams, 4,395 hrs., at 45 cts. per hr.	1,977.75
Teams, 2,178 hrs., at 47½ cts. per hr.	1,034.55
Total	$3,618.30

The preparations for the placing of the concrete facing were begun by the excavation of the toe wall. This was taken out in very cold weather by a "home-guard" foreman who allowed his men to stand around fires instead of working and cost $200.25 for 171.5 cu. yds. of material. With proper supervision the cost could not possibly exceed $50.

The trench was taken out 18 ins. wide to an average depth of 4 ft., being 7 ft. deep at the lowest point. The "niggerheads" were now thrown to the toe of the dam, loaded on wagons and hauled to the ends of the dyke where they were used for riprap.

All of the concrete placed on the work was mixed 1, 2½ and 5; the sand and gravel being taken from a pit 1½ miles from the work. As the greater part of the rock was too large for light concrete, a small crusher with a capacity of 40 tons was installed. This was driven by a 10 hp. Stickney gasoline engine which also operated the carrier. The crusher was charged by wheelbarrows and the crushed material conveyed by the carrier to the top of a sloping screen. All material not passing through ¼-in. mesh was classed as rock. This crushing cost on an average 75 cts. per yard. The sand and gravel were hauled to the work by teams hired at $5 per day, each team making six trips and hauling 10 cu. yds. The water for mixing was pumped by a 3 hp. Stickney gasoline engine through ¾-in. pipe, the delivery at 1,500 ft. with 10-ft. lift being 30 gals. per hour, necessitating storage in barrels and overtime for the engineer, who ran both mixer and pump.

The toe-wall concrete was mixed by hand, two boards being used, 5 men to each board, with 6 men charging, 2 men tamping and 2 men finishing the top and placing the rods for the slabs. The labor cost of mixing and placing amounted to $1.98 per cubic yard. The mixing boards were placed along the trench and were moved about 40 ft. at a time. The dyke slope was next trimmed to templet, and carefully tamped, large wooden tampers being used.

The mixer used was a ¼-yd. Ransome driven by a 10 hp. Stickney gasoline engine. All of the material was placed on the inside of the reservoir and the mixed concrete was carried up the incline in wheelbarrows. Two men with hooks helped the barrowmen up the incline. The mixer was moved three times. Two wheelbarrows of rock and one of sand were mixed with one sack of cement at a time, necessitating a double charging force of six men; 1 man handled cement and water, 1 loaded the wheelbarrows, the number of which varied from 8 to 14 according to the length of the haul; 2 hook men snapped them up the incline.

The slab forms consisted simply of one 2 × 4-in. laid flatways with another one on edge nailed to it and held in place by stakes. For the ends of the slabs the top 2 × 4-in. had holes bored in it for the tie rods; 1 carpenter and 1 helper attended to the moving and placing of the forms, rods and rubberoid. The concrete was run into the slabs by means of troughs made of galvanized sheet iron. These chutes were 7 ft. long in a light frame and as they weighed only 75 lbs. were very easily moved.

Two slabs were placed at a time, the placing gang consisting of 1 man cleaning the wheelbarrows and chutes, 2 men placing the concrete, 2 men on straight edge, and one man troweling. In placing the concrete the men were careful to turn their shovels upside down with every shovelful. In this way, rich mortar that usually sticks to the shovel was on top, making it possible for the trowel man to put a good finish on the slab, using an ordinary 9-in. plasterer's trowel. Just before the concrete had its initial set the slabs were painted with a thin grout, made of sand and cement, care being taken that the sand content of the mixture was the same as that of the conrete previously placed. This grout filled up all of the holes left by the trowel man, gave the slabs a uniform color, and as it and the slab were practically of the same mix it could not suffer from unequal contraction and expansion. The grout was mixed in a mortar box, then poured on a slab a bucketfull at a time; this was well rubbed into the slab and joints with an ordinary broom. Two men were required for this operation, and the total cost did not exceed 10 cts. per yard.

The parapet wall was placed in 10 ft. sections to correspond with the slabs and the sections were separated from each other by a layer of rubberoid nailed into the concrete.

After the forms were taken off the parapet wall, the latter was backfilled to the top and the dirt sloped to the outside of the dyke so as to keep any rain water from getting below parapet wall. In all 790.8 cu. yds. of concrete were placed on this dyke at a cost of $5,983.62 or $7.56 per cubic yard. The distribution of costs was as follows:

COST DISTRIBUTION, CONCRETE FACING, EAST DYKE

Excavation and Leveling:		
Laborers, 910 hrs., at 25 cts. per hr.	$	227.50
Assistant foreman, 74 hrs., at 27½ cts. per hr.		20.35
Total	$	247.85
Moving and placing mixer		65.00
Transferring material		48.00
Toe Wall Excavation:		
Foreman, 40 hrs., at 50 cts. per hr.		20.00
Foreman, 60 hrs., at 27½ cts. per ar		16.50
Laborers, 655 hrs., at 25 cts. per hr.		163.75
Total	$	200.25
Concreting Toe Wall (hand mix):		
Laborers mixing, 980 hrs., at 25 cts. per hr.	$	245.00
Waterman, 66 hrs., at 35 cts. per hr.		19.80
Placing forms—		
Steel and finishing, 138 hrs., at 25 cts. per hr.	$	34.50
Team hauling cement, 25 hrs., at 50 cts. per hr.		12.50
General foreman, 57 hrs., at 50 cts. per hr.		28.50
Total	$	340.30
Materials Used:		
Cement, 567 sacks, at $2.60 per bbl	$	368.55
Gasoline for pump, 30½ gals., at 25 cts. per gal.		7.60
Steel, 1,246 lbs., at 3 cts. per lb.		37.40
Sand, 63 cu. yds., at $1.25 per cu. yd.		78.75
Gravel, 126 cu. yds., at $1.25 per cu. yd.		157.50
Total	$	649.80

Backfilling	$ 76.15
Placing Slabs and Parapet Wall.	
East Dyke:	
Laborers mixing 3,505 hrs., at 25 cts. per hr	$ 876.25
Waterman, 143 hrs., at 35 cts. per hr	42.90
Carpenters, 289 hrs., at 45 cts. per hr	130.05
Placing steel and finishing, 436 hrs., at 25 cts. per hr	109.00
Team hauling cement, 39 hrs., at 50 cts. per hr	19.50
Mixer feeder, 124 hrs., at 27½ cts. per hr	34.10
General foreman, 133 hrs., at 50 cts. per hr	66.50
Extra waterman, 79 hrs., at25 cts. per hr	19.75
Total	$1,298.05
Material Used, Facing East Dyke:	
Cement, 2,835 sacks, at $2.60 per bbl	$1,843.40
Steel, 3,600 lbs., at 3 cts. per lb	108.00
Gasoline for mixer, 100 gals., at 25 cts. per gal	25.00
Gasoline for pump, 55 gals., at 25 cts. per gal	13.75
Lumber (estimated)	25.00
Sand, 263 cu. yds., at $1.25 per cu. yd	328.75
Gravel, 530 cu. yds., at $1.25 per cu. yd	662.50
Rubberoid	52.00
Total	$3,058.40
790.8 yds. of concrete placed for	$5,983.80

A total of 350.2 yds. of rip-rap placed on the outer ends of the East dyke at a cost of $492.05, which also includes the picking up of the rock. A small trench 18 ins. wide and 15 ins. deep was first dug along the toe of the dyke and from this the rock was laid at right angles to the slope. The gang consisted of 5 men laying rip-rap, with 3 helpers passing rock, 2 teams with 2 helpers picking up and loading rock. The costs distribution was as follows:

Gathering and Placing Rip-Rap, East Dyke.	
Laborers, laying rock, 1,053 hours at 25 cts. per hour	$263.25
Foreman, 83 hours at 27½ cts. per hour	22.80
Team hauling rock, 241 hours at 50 cts. per hour	120.50
Men loading rock, 342 hours at 25 cts. per hour	85.50
350.2 cu. yds. placed for	$492.05

The greater part of the concrete of the North dyke was placed in the fall of 1911, and before the writer was connected with the work. The toe wall was dug to a depth of 5 ft., and all of the concrete placed by means of chutes, the mixer being moved along the top of the dam. In this way 554.8 cu. yds. of concrete were placed at a total cost of $8,478.43, or $15.28 per cubic yard. The writer, however used the stationary mixer and wheeled the concrete, making faster time and much cheaper work, placing 576.1 cu. yds. of concrete at a cost of $5,658.17 for labor and material or $9.82 per cubic yard.

The forms for the parapet wall were built at the bench in 16-ft. sections and were held in place by No. 9 soft wire tied to the reinforcement, the inside form being also braced to loops of wire previously bedded in the beams and allowed to stick out. All of the reinforcing was placed by union structural iron workers. It is not usual to employ union men on such work, but from previous experience with laborers on similar work, the writer is of the opinion that the union men are the cheapest in the end. They understand the work and know how to go about it, and allow the foreman to devote his time to the execution of the work.

The forms being in place the concrete was dumped into mortar boxes and shoveled into the forms, 2 men shoveling and 1 tamping from each box, of which there were three, made 100 cu. yds. as the best day's run. The charging gang always remained the same.

The detailed costs of this work including that previously placed were as follows:

Concreting Face of North Dyke

Work Done Previous to May, 1912

Foreman, 480 hours at 50 cts. per hour	$ 240.00
Teams, 294 hours at 45 cts. per hour	132.30
Laborers, 10,154 hours at 25 cts. per hour	2,538.50
Laborers, 276 hours at 27½ cts. per hour	75.90
Carpenters, 793 hours at 45 cts. per hour	356.85
Carpenters, 190 hours at 50 cts. per hour	95.00
Ironworkers, 819 hours at 50 cts. per hour	409.50
Total	$3,848.05
Material Used:	
Lumber, 1,000 ft. at $31.00 per M	$ 31.00
Cement, 850 bbls. at $2.60 per bbl	2,210.00
Gravel, 550 cu. yds. at $1.25 per yd	687.50
Sand, 278 cu. yds. at $1.25 per yd	347.50
Gasoline, 480 gals. at 25 cts. per gal	120.00
Steel, 40,812.8 lbs. at 2 cts. per lb	1,224.38
Wire (estimated)	10.00
Total	$4,630.38
554.8 cu. yds. for	8,478.43

Work in May, 1912

Laborers mixing, 3,085 hours at 25 cts. per hour	$ 771.25
Waterman, 109 hours at 30 cts. per hour	32.70
Carpenters, 342 hours at 45 cts. per hour	153.90
Carpenter helpers, 234 hours at 25 cts. per hour	58.50
Union steelmen, 392 hours at 50 cts. per hour	196.00
Team on cement, 48 hours at 50 cts. per hour	24.00
Mixer feeder, 100 hours at 27½ cts. per hour	27.50
General foreman, 113 hours at 50 cts. per hour	56.50
Assistant foreman, 11 hours at 30 cts. per hour	3.30
Helpers on steel, 218 hours at 25 cts. per hour	54.50
Total	$1,378.15
Materials Used—	
Cement, 747 bbls. at $2.60 per bbl	$1,942.20
Sand, 280 yds. at $1.25 per yd	350.00
Gravel, 554 yds. at $1.25 per yd	692.50
Lumber, 3,000 ft. B.M. at $31.00 per M	93.00
Steel, ½-in., 38,941 ft. at 2 cts. per ft	778.82
Steel, ¾-in., 8,100 ft. at 4½ cts. per ft	364.50
Gasoline, 136 gals. at 25 cts. per gal	34.00
Wire, nails, etc	25.00
Total	$4,280.02
576.1 yds. placed for	$5,658.17

No. 3 reservoir is a natural depression surrounded by almost level land, with an opening at the south end where the dam is located. The facing of this dam was of the beam and slab type. As the chief engineer was desirous of obtaining a good idea of the actual costs of construction of this design, everyone put his best foot forward. The toe-wall was excavated by a competent foreman to an average depth of 9 ft., the deepest part being 17 ft. and the shallowest 5 ft. It was taken out 2 ft. wide at a cost of 47 cts. per cubic yard; which was some improvement over $1.16 per cubic yard, the cost of excavating the East dyke toe-wall. The beams were dug out for 23.6 cts. per cubic yard. The beam forms were put together in sections, being wired at the bottom and slotted at the top to receive the reinforcement, which was also put together at the bench, a lap of 10 ins. being allowed. For the placing of the toe-wall, the mixer was on the inside of the reservoir in the center, and the concrete wheeled each way a distance of 550 ft. The same organization was used throughout.

This dam is 5½ miles from the gravel pit, and the sand and gravel haul was let to the teamsters as piece work, $1.82 per cubic yard being the price agreed on. The teams made two trips one day and three the next, hauling on an average 1½ cu. yds. to the load. Owing to the heavy roads, two snap teams had to be provided, and this, with the heavier stripping at the pit, brought the sand and gravel price up to $3.05 per cubic yard.

For the beams, slabs and parapet wall, the mixer was placed at each end of the dam, 600 ft. of the dyke being faced from one end and 350 ft. from the other. The beam concrete was run into a mortar box placed in the center of a slab. Two men shoveled this concrete into the surrounding beams, one tamper being used for each shoveler; in this way the concrete was thoroughly spaded and placed around the steel.

The system used in placing the slabs and parapet wall was the same as that for the East and North dykes. The edges of the beams and slabs were rounded with an ordinary side-walk edger, and this wonderfully improved the general appearance of the whole work. The slabs were washed with a sand and cement grout about 1 to 3 being similar to the concrete mix, sand content. The trowel finish on the beams and slabs took 440 hours of labor at 25 cts., or $110, and the grout wash was placed by two laborers who used 80 sacks of cement and spent 200 hours on the work, that is, the total labor and material cost was 10 cu. yds. of sand at $3.05, 80 sacks of cement at $2.70 per bbl., 200 hours labor at 25 cts., making a total of $134.50.

During the progress of this work, the Colorado & Southern R. R. tracks washed out, so that the cement had to be hauled from Wheatland, making an extra cost of haul $70. The itemized costs of facing No. 3 dam are as follows:

Leveling Dyke—	
Laborers, 588 hours at 25 cts. per hour	$ 147.00
Foreman, 48 hours at 35 cts. per hour	16.80
Teams, 10 hours at 50 cts. per hour	5.00
981 cubic yds. moved for	$ 168.80
or 17.5 cts. per yd.	
Filling in Slabs and Tamping Dirt in Place—	
Laborers, 1,151 hours at 25 cts. per hour	$ 287.75
Foreman, 41 hours at 35 cts. per hour	14.35
950 cu. yds. moved for	$ 302.50
or 31.8 cts. per yd.	
Excavating Toe-Wall—	
Laborers, 711 hours at 25 cts. per hour	$ 177.75
Foreman, 95 hours at 35 cts. per hour	28.50
Teams, 15 hours at 50 cts. per hour	7.50
453.1 cu. yds. moved for	$ 213.75
or 47 cts. per yd.	
Beam Excavation—	
Laborers, 440 hours at 25 cts. per hour	$ 110.00
Foreman, 49 hours at 35 cts. per hour	14.70
395 beams 12 ft. long and 2 ft. deep for	$ 124.70

Backfilling Toe-Wall—	
Laborers, 153 hours at 25 cts. per hour	$ 38.25
Foreman, 12 hours at 50 cts. per hour	6.00
	$ 44.25
Concreting Toe-Wall—	
Carpenters, 222 hours at 45 cts. per hour	$ 99.90
Helpers, 122 hours at 25 cts. per hour	30.50
Laborers mixing, 1,810 hours at 25 cts. per hour	452.50
Waterman, 62 hours at 30 cts. per hour	18.60
Steelmen, 40 hours at 50 cts. per hour	20.00
Team on cement, 62 hours at 50 cts. per hour	31.00
Mixer feeder, 62 hours at 27½ cts. per hour	17.05
General foreman, 62 hours at 50 cts. per hour	31.00
Assistant foreman, 30 hours at 30 cts. per hour	9.00
356 yds. of concrete for a labor cost of	$ 709.55
or less than $2.00 per yd.	
Material Used—	
Cement, 1,477 sacks at $2.70 per bbl	$ 996.97
Gasoline for mixer, 61 gals. at 25 cts. per gal	15.25
Gasoline for pump, 32 gals. at 25 cts. per gal	8.00
Sand, 164 yds. at $3.05 per yd	500.20
Gravel, 328 yds. at $3.05 per yd	1,000.40
	$2,520.82
Concreting Face and Parapet Wall, No. 3 Reservoir—	
Carpenters, 1,410 hours at 45 cts. per hour	$ 624.50
Carpenters' helpers, 958 hours at 25 cts. per hour	239.50
Laborers mixing, 5,362 hours at 25 cts. per hour	1,340.50
Waterman, 212 hours at 30 cts. per hour	63.60
Steelmen, 970 hours at 50 cts. per hour	485.00
Steelmen helpers, 112 hours at 25 cts. per hour	28.00
Team on cement, 94 hours at 55 cts. per hour	51.70
Feeder for mixer, 191 hours at 27½ cts. per hour	52.50
General foreman, 171 hours at 50 cts. per hour	85.50
Assistant foreman, 93 hours at 35 cts. per hour	33.25
862 yds. placed for	$3,004.05
or $3.48 per yd.	
Material Used—	
Cement, 4,567 sacks at $2.70 per bbl	$3,082.72
Gasoline for mixer, 184 gals. at 25 cts. per gal	46.00
Gasoline for pump, 110 gals. at 25 cts. per gal	27.50
Gravel, 832 yds. at $3.05 per yd	2,537.60
Sand, 416 yds. at $3.05 per yd	1,268.80
Steel (½-in. 98,105 ft., ¾-in. 3,483 ft.), 71,167 lbs. at 3 cts. per lb	2,135.01
Lumber, 6,000 ft. at $27.00 per M	162.00
Cement haul extra	70.00
	$9,329.63
Moving and Placing Mixer—	
Laborers, 90 hours at 25 cts. per hours	$ 22.50
Teams, 6 hours at 55 cts. per hour	3.30
Carpenters, 12 hours at 45 cts. per hour	5.40
General foreman, 4 hours at 50 cts. per hour	2.00
Assistant foreman, 2 hours at 35 cts. per hour	.70
	$ 33.90

The total cost of placing 1,218 cu. yds. of concrete was $16,451.55, or $13.50 per cubic yard. To mix and place toe-wall cost $2 per yard, the beams cost $4.10, the slabs $3 and head-wall $3.60 per yard.

As the work on No. 1 reservoir progressed, water was gradually let into it, and four days after the completion of the work, when the reservoir was at its full capacity, a terrific windstorm arose from the northeast creating waves

3 ft. high and blowing them almost directly on to the facings of the dams; this storm lasted five hours and in the ensuing two weeks three similar storms came in the same direction. The writer, in company with Mr. Shelburne, engineer for the Land Company, visited the dams. We found them in excellent shape. The East dyke showed no signs of settlement or cracks of any description and very little seepage; the North dyke showed a slight parting along the line of the slabs about two-thirds of the height from the top, and the parapet wall had three small cracks straight across, about ⅛ in. wide at top and disappearing toward the bottom of the wall. These came from settlement and were to be expected. In all probability, several more will develop within the next year. when the cracks can be poured full of grout or repaired in some other manner.

Cost of Concrete Standpipes in Mass.—William S. Johnson in the Journal of the New England Water Works Association June, 1914 gives the following data. The standpipes were constructed "recently" according to the author.

Town	Size, diam. height, ft.	Capacity, gals.	Cost including foundations	Cost per 1,000 gals.
Ashland	40 × 32	300,000	$5,812	$19.35
East Douglass	45 × 18	214,000	4,524	21.15
Leicester, Chester Valley and Rochdale)	40 × 21	197,000	4,976	25.25

Cost of Concrete Water Tower at Victoria, B. C.—A. Kempkey in the Proc. Am. Soc. C. E., Vol. XXXVI, gives in detail the methods and costs of construction of the above tower. The following data are taken from an abstract of Mr. Kempkey's paper published in Engineering and Contracting, March 9, 1910.

The tower, as built, consists of a hollow cylinder of plain concrete, 109 ft. high, and having an inside diameter of 22 ft. The walls are 10 ins. thick for the first 70 ft. and 6 ins. thick for the remaining 39 ft., and are ornamented with six pilasters (70 ft. high, 3 ft. wide, and 7 ins. thick), a 4-ft. belt, then twelve pilasters (12 ft. high, 18 ins. wide, and 7 ins. thick), a cornice, and a parapet wall. A steel tank of the ordinary type is embedded in the upper 40 ft. of this cylinder. To form the bottom of this tank, a plain concrete dome is thrown across the cylinder at a point about 70 ft. from the base, the thrust of this dome being taken up by two steel rings, ½ in. by 14 ins. and ⅜ in. by 18 ins., bedded into the walls of the tower, the latter ring being riveted to the lower course of the tank. The tank is covered with a roof of reinforced concrete, 4 ins. thick, conical in shape, and reinforced with ½-in., twisted steel bars.

The tower is built on out-cropping, solid rock. This rock was roughly stepped, and a concrete sub-base built. This sub-base consists of a hollow ring, with an inside diameter of 20 ft., the walls being 5 ft. thick. It is about 2 ft. high on one side and 7 ft. high on the other, and forms a level base on which the tower is built. The forms for this sub-base consisted of vertical lagging and circumferential ribs. The lagging is of double-dressed, 2 × 3-in. segments, and the ribs are of 2 × 12-in. segments, 6 ft. long, lapping past one another and securely spiked together to form complete or partial circles. These ribs are spaced 2 ft. center to center.

Similar construction was used for form the taper base of the tower proper, except, of course, that the radii of the segments forming the successive ribs decreased with the height of the rib. Tapered lagging was used, being made by double dressing 2 × 6-in. pieces to 1¾ × 5$^{13}/_{16}$ ins. and ripping on a diagonal, thus making two staves, 3 ins. wide at one end and 2¾ ins. wide at the other. This tapered lagging was used again on the 4-ft. belt and cornic forms, the taper being turned alternately up and down.

The interior diameter being uniform up to the bottom of the dome, collapsible forms were used from the beginning. These forms were constructed in six large sections, 6 ft. high, with one small key section with wedge piece to facilitate stripping, as shown in Fig. 16. There were three tiers of these, bolted end to end horizontally and to each other vertically.

Above the taper base and except in the 4-ft. belt and cornice, collapsible forms were used on the outside also. There were six sections.

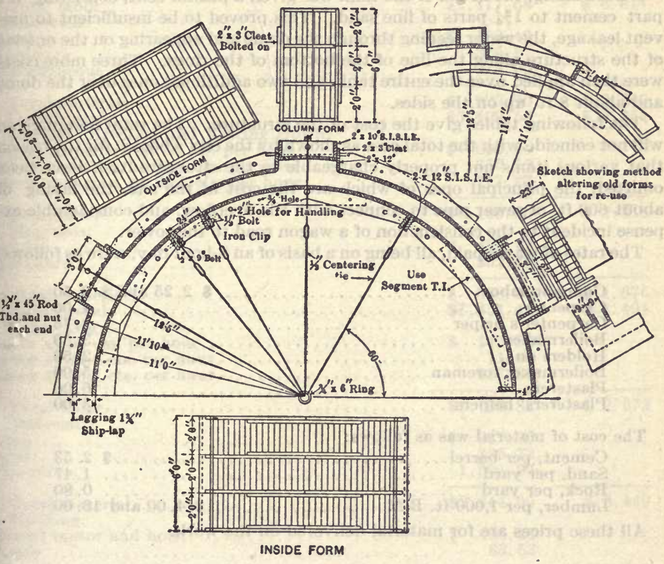

FIG. 16.—Movable forms for shaft of concrete water tower.

The concrete used was as follows: 1:3:6 for the sub-base and taper base; 1:3:5 for the barrel of the tower and tank casing; and 1:2:4 for the dome and roof. The dome was put in at one time, there being no joint, the same being true of the roof.

In order to insure a perfectly round tank, each course was erected against wooden templates accuratedly centered and fastened to the inside scaffold. The tank is the ordinary type of light steel, the lower course being 3/16-in., the next, No. 8 B. W. gage, the next, No. 10 B. W. gage, and the remaining four, No. 12 B. W. gage.

Work on the foundation was started on Aug. 15, 1908, and the tower was not completed until April 1, 1909. Much time was lost waiting for the delivery of the steel, and also owing to a period of very cold weather which caused entire cessation of work for about one month.

The tower as completed presents a striking appearance. In order to obliterate rings due to the successive application of the forms and to cover the efflorescence so common to concrete structures, the outside was given two coats of neat cement wash applied with ordinary kalsomining brushes, and, up to the present time, this seems to have been very effective in accomplishing the desired result. Irregularities due to forms are unnoticeable at a distance of 200 or 300 ft., and the grouting gave a very uniform color. The application of two coats of cement wash cost, for labor, $97.68, and for material, $15.18, or $1.32 per 100 sq. ft., labor being at the rate of $2.25 per 8 hours and cement costing $2.53 per bbl. delivered on the work.

Before filling, the inside of the tank was given a plaster coat, consisting of 1 part cement to 1¾ parts of fine sand. This proved to be insufficient to prevent leakage, the water seeping through the dome and appearing on the outside of the structure along the line of the bottom of the rings. Three more coats were then applied over the entire tank, and two additional ones over the dome and about 8 ft. up on the sides.

The following tables give the cost of the structure. The total herein given will not coincide with the total cost as shown by the city's books, for the reason that various items not properly chargeable to the structure itself have been omitted, the principal ones of which are the cost of the site, the laying of about 600 ft. of sewer pipe to connect with the overflow, and considerable expense incident to the construction of a wagon road to the tower.

The rates of wages paid, all being on a basis of an 8-hour day, were as follows:

Common labor	$ 2.25 and $ 2.50
Carpenter	4.00
Carpenter's helper	2.75
Boilermaker	3.50
Holders on	2.50
Boilermaker foreman	5.00
Plasterers	6.00
Plasterers' helpers	3.00

The cost of material was as follows:

Cement, per barrel	$ 2.53
Sand, per yard	1.47
Rock, per yard	0.80
Lumber, per 1,000 ft. B.M	$14.00 and 16.00

All these prices are for material delivered on the work.

An examination of the cost data, as given, will show that for the most part the unit costs are very high. This is due chiefly to the continued interruption of the work, during its later stages, owing to bad weather, particularly in the case of the erection of the steel tank. The material cost in this case was also exceedingly high. In the case of the concreting, inability to purchase a hoist and motor and the high cost of renting the same, together with the delays mentioned, added greatly to the unit cost. When it is considered that the cost of plastering covers that of four coats over the entire inside of the tank and three more over about one-third of it, it does not appear so high, especially in view of the high rate of wages paid. The cost per yard for concrete alone was $25.126, and this is probably about 25 per cent in excess of the cost of the same class of work executed under more favorable conditions as to location, weather conditions, etc.

The following costs have been rearranged and further analyzed by the editors of Engineering-Contracting from the tables given by the author:

Preliminary work:	Total	Per cu. yd.
Labor, carpenter at 50 cts. per hour	$ 11.00	
Labor, common, at 34.4 cts. per hour	64.94	
Labor, common at 28.1 cts. per hour	249.67	
Total labor	$ 325.61	$ 0.790
Materials	133.62	0.324
Total labor and materials	$ 459.23	$ 1.114
Forms: Building, Shifting, Stripping:		
Labor, carpenter, at 50 cts. per hour	$1,832.99	
Labor, common, at 34.4 cts. per hour	80.85	
Labor, common, at 28.1 cts. per hour	563.84	
Total labor	$2,477.68	$ 6.014
Materials:		
Lumber	$ 583.49	
Hardware	325.51	
Miscellaneous	13.90	
Total material	$ 922.90	$ 2.240
Grand total	$3,400.58	$ 8.254
Scaffold: Erecting and Tearing Down:		
Labor, carpenter, at 50 cts. per hour	$ 693.00	
Labor, common, at 34.4 cts. per hour	350.59	
Labor, common, at 28.1 cts. per hour	117.27	
Total labor	$1,160.86	$ 2.818
Materials:		
Lumber	$ 487.77	
Hardware	202.79	
Total materials	$ 690.56	$ 1.676
Grand total	$1,851.42	$ 4.494
Concreting:		
Labor at 50 cts. per hour	$ 142.00	
Labor at 34.4 cts. per hour	11.00	
Labor at 28.1 cts. per hour	947.81	
Total labor	$1,100.81	$ 2.672
Material:		
Rock	$ 317.30	
Sand	335.72	
Cement	1,591.97	
Total material	$2,244.99	$ 5.449
Hoisting:		
Rental motor and hoist	$ 406.56	
Power	83.53	
Total power	$ 490.09	$ 1.189
Grand total	$3,737.89	$ 9.316
Grand total concrete	$9,449.12	$23.178

These figures do not include apparently any charge for superintendence which with perhaps some other items may account for the difference between the final total and the cost of $25.126 for concrete given by the author of the paper.

The cost of plastering 3,000 sq. ft. was as follows:

Labor:	Total	Per sq. ft.
Plasterers, at 75 cts. per hour	$ 116.50	
Labor at 46⅞ cts. per hour	15.00	
Labor at 37½ cts. per hour	198.52	
Labor at 28.1 cts. per hour	105.66	
Total labor	$ 435.68	$0.1452

	Total	Per sq. ft.
Materials:		
Sand	$ 8.64	
Cement	66.10	
Alum and potash	16.00	
Total material	$ 90.74	$0.0302
Grand total	$ 526.42	$0.1754

The cost of washing 8,560 sq. ft. with cement wash was as follows:

Labor:	Total	Per sq. ft.
Common at 43¾ cts. per hour	$ 50.00	
Common, at 28.1 cts. per hour	47.68	
Total labor	$ 97.68	$0.0114
Material:		
Cement	$ 15.18	$0.0018
Grand total	$ 112.86	$0.0132

The itemized cost of the steel tank, 20,000 lbs., was as follows:

Labor:	Total	Per lb.
Carpenter at 50 cts. per hour	$ 124.24	
Helper at 34.4 cts. per hour	2.75	
Boilermakers	382.57	
Holders on	147.33	
Labor	40.61	
Foreman at 62.5 cts. per hour	186.25	
Total labor	$ 883.75	$0.0441
Materials:		
Tank, rivets, etc	$1,740.69	$0.0875
Grand total	$2,624.44	$0.1316

The various miscellaneous items of cost were as follows:

Windows, Doors, Etc.:	Total
Labor	$ 49.00
Material	47.26
Total	$ 96.26
Equipment, 40% of $461.46	$ 184.58
Ironwork: (Spiral stairway, inlet and overflow pipes, radiator, reinforcing steel, etc.):	
Labor:	
Machinists at 50 cts. per hour	$ 89.50
Helper, at 34.4 cts. per hour	240.16
Labor, at 28.1 cts. per hour	100.79
Total labor	$ 430.45
Material	$ 1,814.71
Grand total	$ 2,245.16
Grand total (tower, and tank complete)	$16,578.29

Construction of Reinforced Concrete Water Tower Using Steel Forms and Movable Staging.—In constructing the 650,000 gal. reinforced concrete standpipe at Westerly, R. I., the contractor used sectional steel forms and special reinforcement as described in Engineering-Contracting, Oct. 5, 1910.

The standpipe is 40 ft. inside diam. with 14-in. walls and is 70 ft. high. The wall reinforcing consists of 12 vertical 1½ pipe columns made in 3-ft. sections, connected by ordinary pipe couplings, spaced equidistant and extending from the bottom of the floor slab to the cornice. These pipe columns have drilled in them ¼-in. holes spaced the proper distance apart for attaching the horizontal reinforcing rods. These rods consist of fifty

1½-in. bars in the first 10 ft. from the base, thirty 1½-in. bars in the second 10 ft., then twenty-five 1½-in., thirty-four 1⅛-in., twenty-five 1⅛-in., fifteen 1⅛-in. and ten 1⅛-in. in each succeeding 10 ft.

The horizontal reinforcing bars are bent around the outside of the pipe columns and attached to them by ¼-in. round clamps. In the first 5 ft. 8 ins. from the bottom, the bars are doubled, being clamped to the inside and outside of the pipe column.

The steel forms are made up of 3 × 3 × ¼-in. angles and ⅜-in. boiler plate. The inside form is 6 ft. high and has a key section in which the plates

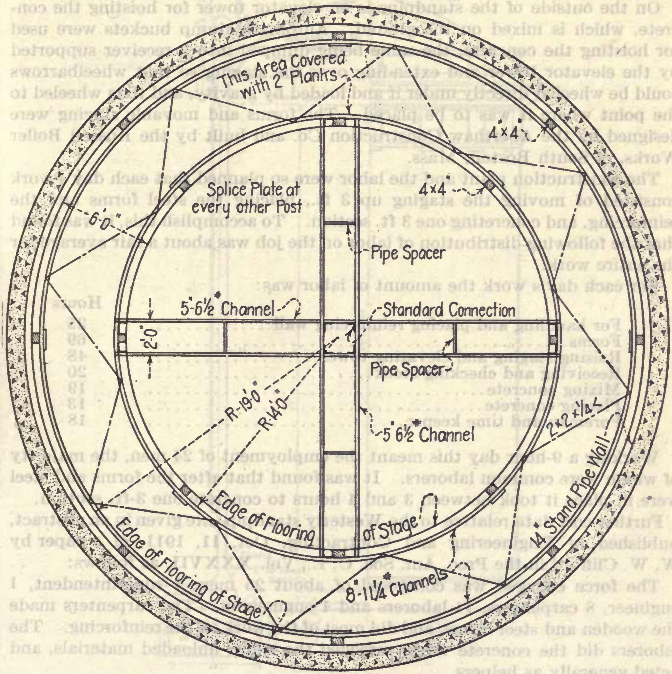

FIG. 17.—Plan showing erection staging.

lap about 6 ins., and on either side of the joint angles are securely riveted to the plates and connected by short turnbuckles, so that the whole form can be sprung in and reduced in diameter so as to make it possible to raise it when necessary. The outside forms are made in seven segments to the circle in sections 3 ft. high. Two complete sections are all that are used, as when one 3-ft. section has been erected and the concrete placed, the next section is placed on top of this, and by the time the concrete is placed in this section the lower form can be removed and placed on top. On the outside forms all the rivets are countersunk, and the face of the angles making joints are machined so as to secure a perfectly smooth fit, thereby securing a practically smooth finished surface.

The movable steel staging is located on the inside of the tower, Fig. 17. It consists of four 5-in. channels in the form of a cross joined at the center with a standard connection. Around these channels are bent two channels in concentric circles of 14 and 19 ft. radius braced with $2 \times 2 \times 1\frac{1}{4}$-in. angles. The floor of this staging is covered with plank, giving a platform 5 ft. wide around the inside of the standpipe. This platform was raised as the work progressed and held in place by 4×4-in. guide posts spaced 45° apart.

On the outside of the standpipe is an elevator tower for hoisting the concrete, which is mixed on the ground. Automatic dump buckets were used for hoisting the concrete, the same being dumped into a receiver supported by the elevator tower and extending over the staging so that wheelbarrows could be wheeled directly under it and loaded by gravity, and then wheeled to the point where it was to be placed. The forms and movable staging were designed by the Aberthaw Construction Co. and built by the Russell Boiler Works, of South Boston, Mass.

The construction plant and the labor were so planned that each day's work consisted of moving the staging up 3 ft., placing the steel forms and the reinforcing, and concreting one 3 ft. section. To accomplish this, it was found that the following distribution of labor on the job was about a fair average for the entire work.

For each day's work the amount of labor was:

	Hours
For handling and placing reinforcing wall	25
Forms	69
Raising staging and elevating tower	48
Receiving and checking stock	20
Mixing concrete	19
Placing concrete	13
Foreman and time keeper	18

Working a 9-hour day this meant the employment of 24 men, the majority of whom were common laborers. It was found that after the forms and steel were in place it took between 3 and 4 hours to concrete one 3-ft. section.

Further cost data relative to the Westerly standpipe are given in an abstract, published in Engineering and Contracting, Oct. 11, 1911, of a paper by W. W. Clifford in the Proc. Am. Soc. C. E., Vol. XXXVII, as follows:

The force engaged was composed of about 25 men: 1 superintendent, 1 engineer, 8 carpenters, 14 laborers and 1 engineman. The carpenters made the wooden and steel forms, and did most of the work on the reinforcing. The laborers did the concrete work, screened the stone, unloaded materials, and acted generally as helpers.

The lower section of the wall and the floor were put in on June 15 in 20 hours of continuous work. Each of the first few sections above the floor took 2 or 3 days. When well started, however, a 3-ft. section was poured in a day. This meant placing the steel and moving up the forms, in which all the men were used, the laborers as helpers, cleaning and greasing the forms, etc., then the stage was raised, usually about noon, and the concrete was poured in the afternoon. It was allowed to set for a few hours while the men were clearing up and getting ready for the next day's work, then in the early evening the concrete foreman and three or four laborers cleaned the top surface. The concrete was finished and ready for the dome 10 weeks after the floor was put in.

The cost of the work is given in Table XVII. In considering these costs note should be taken of the fact that certain parts of the work were done under pressure; namely, those parts for which the whole work waited. Other parts were done in a more leisurely manner, owing to the fact that men cannot work continuously at their maximum speed. For example: In the morning the first thing done was to place the steel, secondly, to raise the forms, and thirdly, to raise the stage. All these had to be done before concreting could begin.

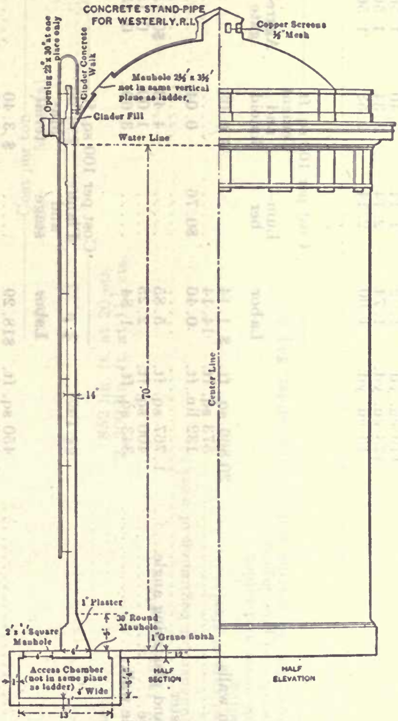

Fig. 18.—Elevation and section of reinforced concrete stand-pipe, Westerly, R. I.

This work was done by the carpenters working at maximum speed, some of the laborers acting as helpers. During this time the other laborers were screening stone, washing down the walls, etc., under no great pressure. Later in the afternoon the laborers were working at top speed on the concrete, while the carpenters were placing the necessary bracing on the staging, and getting ready for the next day's work, all at a less forced speed. Consequently, the labor costs for reinforcement, forms and concrete show up much better than those for staging, screening stone, finishing the wall, etc.

TABLE XVII.—COST OF REINFORCED CONCRETE STAND-PIPE AT WESTERLY, R. I.

Items	Quantities	Labor	Plant and stage	Cement and limoid	Aggregate	Total unit cost	Total cost
		Cost per cubic yard					
Concrete:							
In foundation	337 cu. yd.	$ 0.90	$1.44	$ 1.43	$2.09	$ 5.86	$ 1,975
In floor	119 cu. yd.	1.52	1.44	3.40	1.56	7.92	942
In walls and cornice	423 cu. yd.	1.74	2.14	3.34	1.56	8.78	3,714
In parapet	13 cu. yd.	1.00	2.14	2.53	1.56	7.23	94
In walk around roof							60
		Cost per 100 sq. ft.					
		Labor	Lumber	Cement and limoid	Aggregate		
Finish:							
Rubbing and wash on walls	20,866 sq. ft.	$ 1.14	.....	$ 0.03	.....	$ 1.17	$ 244
Packing on plinth	573 sq. ft.	14.14	.....	.....	.....	14.14	81
Plaster on plinth	132 lin. ft.	0.46	$0.76	0.04	.....	1.26	166
Picking angle for plaster	....	.....	.....	.....	.....	.....	33
Granolithic on floor and plastering angle	1,767 sq. ft.	5.85	.....	4.43	$0.15	10.43	184
Granolithic on cornice	400 sq. ft.	2.25	.....	1.00	0.15	3.40	14
Granolithic on outside walk	343 sq. ft.	1.84	.....	3.60	0.15	5.59	19
		Cost per 100 sq. ft.					
		Labor	Plant and stage	Material			
Forms:							
Foundation	450 sq. ft.	$18.29	.....	$ 3.40	.....	$21.69	$ 98
Plinth	1,249 sq. ft.	12.50	.....	2.20	.....	14.70	184
Walls	16,733 sq. ft.	4.40	$3.36	5.46	.....	13.22	2,212
Walls, triglyphs	1,208 sq. ft.	18.00	3.36	20.24	.....	41.60	502
Floor	247 sq. ft.	5.08	.....	2.20	.....	7.28	18
Cornice	1,163 sq. ft.	38.22	3.36	13.58	.....	55.26	643
Parapet	1,225 sq. ft.	13.63	.....	8.41	.....	22.04	269

	Quantity	Labor (cost per ton)	Stage (cost per ton)	Material (cost per ton)	Total per ton	Amount
Steel Reinforcement:						
Rods	68 tons	$ 9.73	$ 4.50	$39.00	$53.23	$ 3,619
Crosby clips						171
Pipe standards for steel	852 lin. ft. at 20 cts.					169
Hook spacers	2,200 lin. ft. at 1¼ cts.					28
Office and General:						
Telephone, stationery, traveling, etc						$ 200
Board						320
Travel and superintendence (at beginning of work)						56
Watchman and lights						50
Delay (waiting for lost cars of steel)						104
Clearing site and grading						120
Setting pipes, manhole cover and tablet						17
Miscellaneous extra work and pipe laying						196
Material for steel ladder, $90.50; setting and painting ladder, $44.25						135
Guastavino tile dome						1,200
Trap door in dome						9
Weatherproofing (test blocks)						10
Bond (surety)						105
Total						$17,961

The materials were delivered by a granite company, on a side track about 100 ft. from the site of the work, for 35 cts. a ton, the additional costs being for the labor of unloading and carrying the materials to the site of the work. The steel was carried by hand, and the cement in wheelbarrows. The stone and sand were delivered in piles beside the mixer by carts. The following prices were paid for labor:

	Cents per hour
Foreman carpenter	48
Foreman carpenter	43¾ and 45
Carpenter's helper	35
Engineman	35
Labor foreman	50
Laborers	22½ and 25

The following prices were paid for materials:

Cement per bbl. (less 30 cts. for bags returned)	$ 1.52
Sand, per yd., delivered at site	1.15
Stone, per yd., delivered at site	1.07
Limoid, per bag (100 lbs.)	1.00
Plaster of paris, per bbl	2.00
Steel, per ton, plus the freight	38.00

In Table XVII the cost of the stage is divided between concrete, forms, and steel, in the proportions of ¼, ½ and ¼. In the labor costs for the wall steel, about one-third is charged to bending and two-thirds to placing. In the secondary reinforcement, the cost of bending was a negligible quantity.

Cost of 300,000-Gal. Reinforced Concrete Standpipe. — The following data are taken from an article by L. R. Hanson published in Engineering and Contracting, Dec. 13, 1911.

The standpipe was built for the city of Norway on the upper Peninsula of Michigan near the Wisconsin state line. The walls are 12 ins. in thickness, 43 ft. high, and have an internal diameter of 35 ft. The forms were built in sections 5 ft. in length by 3 ft. in height, and two complete inside and outside rings were used. The concrete was a 1:1:2 mixture. The stone, specified as between ⅛ and ¾ in. size, was shipped from a point 300 miles distant and this item materially raised the concrete cost. Sand was obtained near the standpipe site. The cement was mixed with 10 per cent by volume of hydrated lime for waterproofing. Bending and placing the steel cost $5 per ton.

SUMMARY OF COST DATA FOR 300,000 GAL. REINFORCED CONCRETE TANK
(Prices do not include overhead charges or profit)

Walls—1 : 1 : 2 mixture, 235 cu. yds.

	Total cost	Cost per cu. yd.
Forms:		
Material	$ 422.00	$ 1.80
Labor	404.00	1.72
Total	$ 826.00	$ 3.52
Steel:		
Material	$ 906.00	$ 3.86
Labor	118.00	.50
Total	$1,024.00	$ 4.36
Concrete:		
Material	$1,377.00	$ 5.85
Labor	627.00	2.67
Total	$2,004.00	$ 8.52

Plaster:		
Material	$ 77.00	$ 0.33
Labor	265.00	1.12
Total	$ 342.00	$ 1.45
Doors, ladder, drains, etc	$ 237.00	$ 1.00
Removing debris, etc	80.00	.34
Total for floor and circular wall	$4,513.00	$19.22
Roof—1 : 2 : 4 mixture—20 cu. yds.:		
Forms	$ 54.00	$ 2.70
Material	140.00	7.00
Labor	38.00	1.90
Total	$ 232.00	$11.60
Total cost reservoir	$4,745.00	

Wages:	
Common labor, per hr	$0.25
Foreman, per day	8.00
Sand, cu. yds., delivered	1.00
Stone, cu. yd., delivered	2.65
Cement, bbl	1.75
Steel, lb., delivered at tank	0.02

After the entire tank was complete it was given three coats of plaster inside, mixed in the proportions of 1 part cement, 1½ parts sand, ¼ part hydrated lime and hydratite. The first coat of ¼ in. thickness was applied rough, and while still wet was covered with a second coat about ⅛ in. thick which was brought to a wood floated surface; this was next gone over with a brush coat and brought to a very smooth troweled finish. The plaster was applied in circumferential strips 6 ft. in height, and the cost of the three coats per sq. ft. of surface was 7¼ cts.

Upon the completion of the entire tank, it was filled and allowed to stand 48 hrs. and no change in the water level could be detected. For the first week, however, some sweating was noticeable, but in only one place was it of enough consequence to gather and flow, and this evaporated before it was 3 ft. below where it first appeared. No attempt was made to remedy the sweating other than emptying the tank and refilling in two days, but within ten days all discoloration disappeared and no sweating has since been apparent. The tank received a severe winter's test during the past winter when ice over 2 ft. in thickness covered the top and extended around the side walls of the tank as well.

The more successful waterproof construction effected in this tank using a 1:1:2 mixture than in others built under the same supervision and care but of 1:2:4 mixture, seems to justify the additional expense for cement. The plaster is also an effective "waterproofing aid" although how large a part of the good results here obtained, are due to the plaster and the 1:1:2 mixture respectively is a matter of personal opinion. Results secured by plastering other large tanks of 1:2:4 mixture would seem to indicate that the mixture was more important than the plaster face.

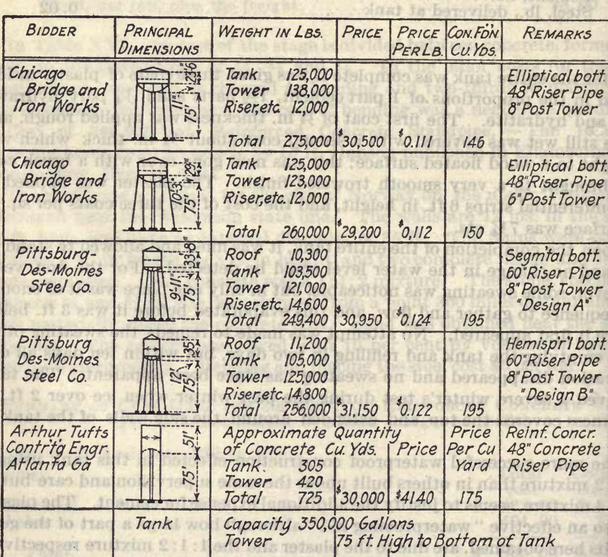
Cost of Steel Standpipes in Mass.—Table XVIII is taken from a paper by William S. Johnson published in the Journal of the New England Water Works Association, June, 1914, and reprinted in Engineering and Contracting, Sept. 30, 1914. According to the author the standpipes were constructed "recently."

TABLE XVIII.—COST OF STEEL STANDPIPES IN MASS.

Town	Size, diam. height, ft.	Capacity, gals.	Cost of foundation	Cost including foundations	Cost per 1,000 gals.
Bedford	20 × 100	235,000	$1,030	$6,640	$28.25
East Brookfield	25 × 50	184,000	300	3,550	19.30
Littleton	35 × 40	288,000	700	4,638	16.10
Marion	20 × 100	235,000	......	5,883*	25.00*
North Chelmsford	22 × 125	355,000	......	9,772	27.50
Oxford	27 × 50	214,000	400	5,060	23.60
Pepperell	45 × 40	476,000	839	6,707	14.10
Plainville	25 × 67	246,000	710	4,979	20.25
So. Hadley (Fire Dist. No. 2)	35 × 60	432,000	......	6,165*	14.30*
Wareham	20 × 100	235,000	......	6,835*	29.10*
West Groton	30 × 40	212,000	613	4,021	18.95
Wrentham	30 × 50	264.000	800	6,000	22.70
Wrentham State School	22 × 50	142,000	368	2,596	18.25

*Without foundation.

Cost and Weight of Steel Water Tank of 350,000 Gal. Capacity.—Fig. 19 from Engineering and Contracting, Oct. 31, 1917, gives a rèsumè of the bids



BIDDER	PRINCIPAL DIMENSIONS	WEIGHT IN LBS.	PRICE	PRICE PER LB.	CON. FDN. CU. YDS.	REMARKS
Chicago Bridge and Iron Works	23'-6" 11' 75'	Tank 125,000 Tower 138,000 Riser, etc. 12,000 Total 275,000	$30,500	$0.111	146	Elliptical bott. 48" Riser Pipe 8" Post Tower

FIG. 19.—Bids received by Akron, O., for elevated steel water tank.

received by the city of Akron, Ohio, Sept. 27, 1917 for constructing, furnishing and erecting an elevated steel water tank of a capacity of 350,000 gal., the tower to be 75 ft. high to bottom of tank.

Cost of Steel Standpipe at Youngstown, Ohio.—N. E. Hawkins in Engineering and Contracting, March 17, 1915, gives the contract price of a steel standpipe constructed in Youngstown, Ohio as follows:

2,400 cu. yds. earth excavation, at 40 cts.	$ 960.00
1,700 cu. yds. granulated slag fill, at 90 cts.	1,530.00
830 cu. yds. concrete, at $6.50	5,395.00
4-in. drain pipe	1.40
Brick valve house complete (10 ft. × 12 ft.)	516.32
Total masonry contract	$ 8,402.72
Standpipe proper	35,960.00
Total	$44,362.72

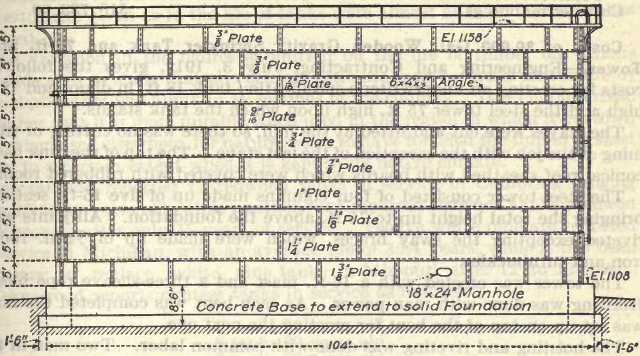

FIG. 20.—Elevation of new steel standpipe at Youngstown, Ohio.

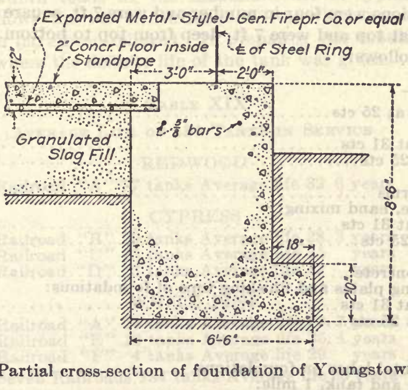

FIG. 21.—Partial cross-section of foundation of Youngstown standpipe.

The tank is 100 ft. in diameter and 50 ft. high and provides a storage of about 2,855,000 gals. making the cost per million gals. about $15,500.00. Figs. 20 and 21 show the principal features of the design.

Cost of 2,500,000 Gal. Steel Standpipe at West Roxbury, Mass.—Engineering and Contracting, Aug. 11, 1915 gives the contract prices to the Metropolitan Water and Sewerage Board of Mass. of the standpipe as follows:

COST OF STANDPIPE, ERECTED IN 1914

Excavation and concrete base 117.5 ft. diam., 2 ft. 8 ins. thick for width of 7 ft. at circumference, 3 ft. thick under 6 columns which support the roof, 12 ins. thick under remainder of tank	$ 6,382.28
Steel reservoir, 100 ft. in diameter, bottom ⅜ ins. thick, sides 44.25 ft. high from ⅞ to ⅜ ins. thick	19,397.00
Grouting under tank bottom 1 : 1 mixture requiring 222 bbls. of cement and 33 cu. yds. of sand	1,053.67
Total	$26,832.95
Cost per million gal	$10,733.00

Costs of 30,000 Gal. Wooden Gravity Sprinkler Tank and 75-ft. Steel Tower.—Engineering and Contracting, July 3, 1912, gives the following costs for erecting an underwriter's specification tank 18 ft. in diam. and 18 ft. high and the steel tower 75 ft. high upon which the tank stands.

The staves were cut and fitted at the mill, so there was no cutting or trimming at the job with the exception of the last stave. The top of the tank had a conical roof sheathed with boards which were covered with rubbered roofing.

The steel tower consisted of four columns made up of five 15-ft. sections, bringing the total height up to 75 ft. above the foundation. All joints were riveted excepting the sway braces, which were made up of ⅞-in. round iron and turnbuckles.

The tower was erected with a 16-ft. mast and a three-sheave rope block. Hoisting was done with man power. As each bent was completed the mast was set up on top of the bent for erecting the next one.

The hoisting and riveting was done with common labor. Two men in the gang were experienced in this work. The others of the gang were picked up locally.

The foundations were four in number and were 7 ft. square at the base and 30 ins. square at top and were 7 ft. deep from top to bottom. The itemized costs were as follows:

Excavation—	
221½ hrs. at 25 cts	$ 55.37
Forms:	
29½ hrs. at 31 cts	$ 9.15
33 hrs. at 25 cts	8.25
Total forms	$ 17.40
Laying concrete, hand mixing:	
19½ hrs. at 31 cts	$ 6.05
91 hrs. at 25 cts	22.75
Total concrete	$ 28.80
Grouting bearing plates and finishing tops of foundations:	
13½ hrs. at 31 cts	$ 4.03
2½ hrs. at 25 cts	0.68
Total	$ 4.71
Grand total labor on foundations	$106.28
Teaming tower and tank, 1 mile:	
Team, 19 hrs. at 60 cts	$ 10.80
Laborers, 37 hrs. at 30 cts	11.10
	$ 21.90
Erecting tower and tank and painting two coats:	
643 hrs. at 30 cts	$182.00
	$204.80
Grand total	$311.08

Superintendence is not included in the above figures. The superintendent spent 198 hours on the job.

Life of Wooden Water Tanks in Railway Service.—The following data published in Engineering and Contracting, Nov. 13, 1918, are given by C. R. Knowles, Superintendent Water Service, Illinois Central R. R., in a paper presented at annual convention of the American Railway Bridge and Building Association. In collecting the information letters of inquiry were sent to 45 railroads and 27 answers were received.

While much valuable information was obtained from the replies, the figures and estimates given as to the life of tanks were almost as many as the replies received.

The variation in the figures submitted on the life of timber on various railroads goes to show that no accurate estimate may be made on the life of tank timber that will apply to all sections of the country. It is characteristic of timber that it is more durable when used in the region in which it is grown than when used elsewhere, for nature seems to have fortified the timber against decay to a certain extent when it is kept in its native climate.

One railroad reported 77 redwood tanks in service in California ranging from 26 to 48 years old, while another road reported redwood tanks renewed in Wisconsin after only 15 years of service. Twelve white pine are reported in service in Michigan, with an average life of 35.4 years, while it has been necessary to replace white pine tanks in Missouri after 12 to 13 years. A Texas road reports cypress tanks in service as follows:

5 tanks 31 years old,
8 tanks 30 years old,
3 tanks 29 years old,

while several eastern roads fix the maximum life of cypress at 25 years.

Table XIX shows the life of 310 tanks, 184 of which are still in service, and 126 of which have been relieved. In preparing this tabulation only figures were used where the definite life of the tank was given.

TABLE XIX

AVERAGE LIFE OF 184 TANKS IN SERVICE

REDWOOD			
Railroad "A"	77 tanks	Average life	32.6 years
CYPRESS			
Railroad "B"	29 tanks	Average life	28.3 years
Railroad "C"	25 tanks	Average life	25 years
Railroad "D"	3 tanks	Average life	32 years
WHITE PINE			
Railroad "A"	24 tanks	Average life	29.7 years
Railroad "E"	12 tanks	Average life	35.4 years
Railroad "F"	4 tanks	Average life	29 years
Seven Railroads	184 tanks	Average life	30 years

AVERAGE LIFE OF 126 TANKS RELIEVED

CYPRESS			
Railroad "B"	24 tanks	Average life	27.3 years
Railroad "G"	16 tanks	Average life	30 years
Railroad "D"	3 tanks	Average life	32 years
	43		29 years

WHITE PINE

Railroad "H"	27 tanks	Average life 27.5	years
Railroad "B"	22 tanks	Average life 25.8	years
Railroad "I"	14 tanks	Average life 23	years
Railroad "F"	4 tanks	Average life 29	years
Railroad "D"	3 tanks	Average life 33	years
Railroad "E"	3 tanks	Average life 38.3	years
Railroad "C"	5 tanks	Average life 27	years
	78	Average life 27	years
YELLOW POPLAR			
Railroad "C"	3 tanks	Average life 30	years
RED CEDAR			
Railroad "C"	1 tank	Average life 28	years
YELLOW PINE			
Railroad "C"	1 tank	Average life 29	years
Eight Railroads	126 tanks	Average life 28	years

It will be noted that the white pine tanks show a higher average life than the cypress tanks in the table of tanks still in service while the opposite is true in the table of tanks relieved. This may be explained by the fact that cypress tanks were not used as extensively as white pine tanks up to 20 years or so ago, and on the roads shown there are probably many white pine tanks which were in use before cypress tanks were constructed, although there is apparently very little difference in the durability of the two woods.

It is interesting to note that a yellow pine tank is shown with a life of 29 years while the life of a yellow pine tank as constructed today would probably not exceed 12 years. This difference in life can probably be explained in the fact that the trees from which the tank mentioned was cut had not been bled of the rosin and preservative oils natural to the wood. It should be explained that the life of 28 years given the red cedar tank did not represent the extreme life of the timber as when the tank was taken down the best of the timber was used in the construction of a smaller tank which is still in use. The original tank was constructed in 1870, which makes the timber in the smaller tank 48 years old.

In the letters received many records were given showing a life of only 10 to 15 years for cypress, white pine and redwood tanks. This was unfair to the timbers mentioned as the short life obtained was undoubtedly due to poor selection of timber, poor construction, the tank not being kept filled with water or some one or more of a number of faults that would cause early decay.

Conditions of Steel Water Tank After 30 Years' Service.—Walter E. Miller gives the following notes in an article published in Engineering News-Record, March 31, 1921.

The water tank with supporting and inclosing masonry tower of the water-works of Madison, Wis., was erected in 1890. Its demolition was completed early in January, 1921. It was removed because (1) the daily consumption of water and the pumping rates had so greatly increased since the tank was erected that the size of the tank became too small to be of material value, and (2), because the tower and tank obstructed an important street. The history of this structure shows how greatly the allowances for depreciation might differ, depending upon whether they include or exclude the functional as well as physical depreciation.

The structure consisted of a steel tank, 12⅓ ft. in diameter by 60 ft. high, supported and enclosed by a cylindrical brick wall above a one-story square structure of stone masonry. The bottom of the tank was 72 ft. and its top was 132 ft. above the street.

The tank rested on a grillage of steel rails laid upon four 16-in. I-beams carried by the heavy brick wall. Above the bottom of the tank the wall had three thicknesses, nominally 8, 6 and 4 in. The lower third of that portion was laid in conact with the tank and had a thickness of the widths of two bricks laid flat. For the middle third of the tank the wall consisted of two rings of brick, one laid flat and one on edge, and was 2 in. from the tank. Around the top third of the tank 4 in. from it was a wall one brick width in thickness.

Examination of the structure before and during its removal revealed but little deterioration; so little as to make it appear that its thirty years of actual service would be but a small part of its possible physical life. The most noticeable and important deterioration was incipient disintegration of the outer brickwork near the level of the bottom of the tank, but this might have been repaired at moderate expense had the continued use of the structure been desired. Notwithstanding the apparent fact that the tank plates had never been cleaned and repainted the greater part of their surfaces was still well preserved and smooth, although in places the paint was gone and rust had formed. In a few places there was a noticeable pitting of the metal, but in no case had this gone far enough to warrant any apprehension as to weakening of the plates.

Data on Life of Iron Water Tank and Cost of 537,000 Gal. Elevated Steel Tank at Princeton, N. J.—The following notes are given in an article by R. W. Becker in Engineering News, Jan. 27, 1916.

In 1883 the firm of Tippett & Wood, of Phillipsburg, N. J., fabricated and erected an elevated water tank at Princeton, N. J., for the Princeton Water Co. The capacity of the tank was 141,000 gal. The growth of the town since has made it inadequate and it was replaced by a 537,000-gal. tank, built by the same firm early in 1915.

Recent inspection of the old materials (iron tank and tower) showed that the tower was exceptionally well preserved. Rust had not caused sufficient deterioration in the tank plates to be perceptible by calibration. The tank received two coats of paint when it was erected and had been painted once every 3 to 4 years since. It had always been filled with water. The only repair required was the replacing of the oak timbers under the tank by 6-in. steel I-beams, 5 yr. ago. The wood was decaying rapidly and appeared unsafe to carry the load much longer after 25 yr. of use.

The old tank and tower were torn down carefully, so as not to injure the plates, by cutting off and backing out the rivets, Each piece as it was cut off was carefully lowered to the ground. As the tank was in such good condition, it was reërected on a concrete foundation at Lawrenceville, N. J., where it is now in service. The tower was reërected at New Brunswick, N. J., where it is supporting a wooden tank of 100,000 gal. capacity. The cost to Tippett & Wood of taking down the old tank and tower was $1,000.

The new tank is 45 ft. in diameter, 30 ft. high from the top to the beginning of the curved bottom, and 58½ ft. high overall. The steel tower supporting the tank is 87½ ft. high from the column foundations to the balcony. The distance from the base of the columns to the peak of the roof is 133 ft.; and from the ground to the top of the finial about 135 ft.

Although the columns are vertical, the tower is very stable on account of the large diameter of the tank. Each column is anchored to a massive concrete pier by four 1½-in. round anchor bolts. The total cost of the structure was about $26,000.

CHAPTER VII

WATER WORKS

This chapter, while touching upon the general subject of waterworks, lays special stress upon the particular phases of construction costs usually allotted to the field of civil engineering. Additional data on pipe costs are given in the chapter on Irrigation and data on operating and construction costs of water treatment plants are given in the following chapter.

For further data the reader is referred to: Gillette's "Handbook of Cost Data" Section VII, Waterworks; Gillette's "Earthwork and Its Cost" and "Handbook of Rock Excavation" for trenching costs and to Gillette and Dana's "Handbook of Mechanical and Electrical Cost Data" for costs of pumps and pumping.

Construction and Operating Costs.—The following matter is abstracted from Hazen's "Clean Water and How to Get It" (1914)

In America water works receipts average about $2.50 per capita for the population supplied, but figures ranging all the way from $2.00 to $4.00 are common, and some figures are outside of this range. These are for publicly owned works. Private companies average to make about the same collections for domestic rates, and in addition they are paid for fire service, so that their total receipts average about $3.00 per capita. Publicly owned works as a rule receive no separate payment for fire protection.

There seems to be no well marked tendency to either higher or lower collections per capita in the larger cities, as compared with the smaller ones. Large cities usually have to go farther for water. Small sources near at hand are not available to them, and it would seem reasonable to suppose that the relative cost would be greater. But it seems that the savings which are made by operating on a larger scale offset this tendency, and on the whole, the expense of securing water is just about the same on an average in proportion to population in small cities and in large ones.

The disposition of the $2.50 per capita collected on an average in America is about as follows: First, in works where the supply is from a gravity source, and no purification is used, about $0.50 per capita annually is used for paying the general expenses of administration, of taking care of services, meters, etc., of making repairs, and of maintaining the works generally. The $2.00 remaining pays 4 per cent interest, and 1 per cent depreciation, or together 5 per cent capital charges on a cost or value of works averaging $40 per capita. The $40 is about equally divided between the distribution system, which includes the pipes in the streets of the city, the services, meters, etc., and the source of supply, which includes all the works for securing the water and bringing it to the city.

Second, in works where the supply is pumped from a river or lake near at hand, with or without purification, about $0.50 is used for the general expenses as above mentioned. Another $0.50 is used for pumping and purification (rather more when the water is purified; less when it is not); and the remaining $1.50 pays 5 per cent capital charges on an average investment of $30 per capita, of which $20 is in the distribution system and $10 in the source of supply.

Gravity sources of supply cost more to secure, but are cheaper to operate.

The above mentioned figures are general approximations, given to show general water works conditions in America at the present time, but wide fluctuations will be found in individual cases.

Some cities are so located that no good, adequate source of supply is near at hand; and where water is brought from long distances and is pumped and purified, it is clear that it cannot be delivered at the cost or sold at the price that is fair for a water drawn from a pure and ample source near at hand.

Then the cost of distribution differs. In a city on level ground where one service or one system of pipes does for all, the cost both of construction and of operation is less than on a hilly site where separate high service districts must be maintained, involving additional pipe systems and additional pumping stations. And a city that is compactly built up, so that it can be served with a pipe system having a mile or less of pipe per thousand of population, can be more cheaply served than a scattered city with long lines of pipe running out where there are but few houses, and where, taking it right through, two or even three miles of pipe are required per thousand of population.

Cities that waste large amounts of water have to pay for it. The cost of the works is greater, and this cost is sure to be represented sooner or later in the assessments.

Matters of these general natures largely explain why some cities can be supplied for less than \$2 per capita while others must collect over \$4 per capita.

The service of water is one of the cheapest. The average American family pays far more for gas, for ice and for milk, than for water. In my own household in New York, taking the cost of Croton water at \$1, the average cost of other household supplies is as follows: Ice \$3, Light \$4, Telephone \$5, Coal \$13, Milk \$15. Taking into account the nature of the water service, which has become absolutely indispensable, the low cost is very remarkable.

Rates Charged for Water Service.—Berlin, Germany, collects twelve marks, equal to about three dollars per annum, for each service, and in addition collects payment for all water recorded by the meters. Milwaukee has similarly collected one dollar per annum for each service, but this is clearly too low a figure. It will not pay for the maintenance of the services and meters.

A better way is to base the payments upon the size of the service. Most of the services of a system are domestic services, that is to say they serve residences. These services are commonly five-eighths of an inch in diameter. The assessment on these may be placed at \$3.00 per annum, let us say. Some takers insist on a larger service because they wish to draw water more rapidly. Many discussions take place because the prospective taker is insistent on a larger service, while the water works superintendent believes the usual size to be sufficient. Why not let the taker have a service as large as he likes and charge him for it in proportion to its size, or, let us say, approximately in proportion to its ability to deliver water?

Starting with a charge of \$3.00 for a five-eighth inch service, and using round figures, the charge for larger services, not including the charge for water would be

For ¾-inch	\$ 5.00 per annum
For 1-inch	10.00 per annum
For 1½-inch	20.00 per annum
For 2-inch	30.00 per annum
For 3-inch	70.00 per annum
For 4-inch	125.00 per annum
For 6-inch	300.00 per annum
For 8-inch	500.00 per annum

This arrangement has the practical advantage of making a substantial charge for a substantial service, and for a service that too often is not adequately paid for, where large pipes lead from the mains into mills, warehouses, etc., for fire purposes only, and from which pipes ordinarily no water is drawn.

These pipes cause more trouble to water departments, and the privileges granted are subject to more gross abuse, than those from any other class of service; and it is right and proper that substantial payments should be made for them.

Such large fire services should always be metered and they should not be allowed to exist on any other condition. This has not been possible until recently, but it can be done now, for a type of meter has been invented which is satisfactory from a water works standpoint, and which does not interfere materially with the value of the pipe for fire service. With this meter the water ordinarily passes through a by-pass on which there is a small meter. But in case of need, that is in case of fire, a valve on the main line opens automatically and the full quantity of water that the pipe will carry flows through it unobstructed for use. Even in this case an approximate idea of the amount of water drawn is registered by some extremely ingenious devices which are only brought into play when the main valve is opened.

The general idea of charging in proportion to the areas of the service pipes has been expressed in the form of minimum rates at Cleveland and other places. I do not know that it has been followed anywhere to its logical conclusion, as above outlined.

Another way to divide the sum to be taxed on services is in proportion to fixture rates. This method is applicable especially in cities which are gradually changing from fixture charges to the meter system. In this case the fixture rates are known for each house. Supposing it is decided to assess one-third of the whole amount to be raised upon fixtures then when a meter was installed on a given service the charge for that service would be one-third of the previous fixture rate, and in addition all water used would be charged for.

For these conditions this system has much to recommend it. But it is a transition system. When all services are metered it is not to be supposed that it will be worth while to continue making fixture rates.

In the case of an excess of revenue being demonstrated, the charge for water could be reduced to six cents or to five cents as the business would stand, or the charge for services might be lowered. Practical experience with the general method would be available to indicate where the cuts could be best and most equitably made.

The use of a sliding scale, that is to say, or making lower rates to large takers, is firmly fixed, and it will be hard to do away with the idea. But the writer believes that such a scale as that suggested contains all the provisions of this kind that are necessary or wise.

In the first place this kind of scale is in reality a sliding one. The small cottage pays, let us say, $3 per year for the service, and in addition uses water charged at $0.10 per 1000 gallons, let us say, amounting to $3 per year in addition. The total payment is $6 per year and the average cost of water to the taker is $0.20 per 1000 gallons.

A larger taker pays, let us say, $12 per year for his service, and uses at the same rate water worth $120 per annum. The whole bill is then $132 and the average cost of water to him is $0.11 per 1000 gallons, against the $0.20 paid by the smaller taker.

The basing figures of course are to be fixed to meet local conditions, and when so fixed they will give all the slide that is desirable. There is no reason why the man in a cottage, who lets his plumbing get out of order and wastes an extravagant quantity of water, should be asked to pay a larger price per thousand gallons for the water wasted by his neglect than is paid by the largest establishment.

Manufacturers are often supplied by cities at special rates which are less than cost. This is most frequently done on special pleas, and is comparable to giving exemption from taxation. The practice is not a wise one and should not be encouraged.

Low rates are also often made to secure customers who would not otherwise use water or who would not use so much. This is most apt to be done in the early days of operation of a system when the capacity of the works built in anticipation of growth is beyond present requirements. Hydraulic elevators and motors are most common and objectionable subjects for such special rates. As long as the capacity of the works is really in excess of the demand, a little financial help is received by the department from such rates; but as soon as the capacity of the plant is approached such rates become a drag and a source of loss. Experience shows that they are not, and cannot possibly be shut off promptly when they cease to be profitable. It is, therefore, better and safer to charge the regular rates for water used for these and all other special purposes, and to take good care that all water so used is paid for. Some revenue will be lost; some elevators and printing presses will be driven by electricity instead of by water power, but electricity is a better way of transmitting power than water under pressure, and in the end all will be better off.

American cities having high service systems make precisely the same charges for water from them as for water from the low service pipes. The man on the top of a hill with high service water pays no more than the man in the valley, though to supply him costs the city usually from two to five cents more per thousand gallons, and where the high service districts are small and isolated the extra cost may greatly exceed these figures. There seems to be no well-founded reason for this equality in charge with clearly defined difference in cost of service.

It would seem rational and wise to charge more for high service water than for low service water, and to establish the differential carefully at so many cents per thousand gallons, to pay as nearly as it can be computed for the additional cost of the high service water; and the differential should be subject to revision from time to time as the conditions of service change. Usually it would be higher at first, with few takers, and less as the quantity sold became greater.

The present method is unfair to those on low ground. They pay their share (usually the largest share) of the excess of supplying water to those located on the hills. And this is the more unfair, as the hill sites are usually more desirable for residences, and those who live on them are well able to pay the added cost which their service entails on the water department.

I have described this meter rate question at some length, because I feel strongly that present methods of charging are in general unfair and unreasonable, and because I believe that the adoption of the general principles here outlined will do a great deal to improve the situation.

The sooner arbitrary and unreasonable methods are abandoned, and more reasonable methods are adopted, the better it will be for both consumers and

21

for water departments, and the easier it will be to supply clean water and to make the financial arrangements for doing it.

The Required Sizes of Filters and Other Parts of Water Works.—The following matter is given in Hazen's "Clean Water and How to Get It" (1914).

One of the most perplexing questions to a beginner is to find the reasons for the apparent discrepancies in the sizes of the different parts of a well designed water works system. If a system is capable of supplying 15,000,000 gallons per day, it would seem at first thought that all parts should be of this capacity and that nothing beyond it would be necessary. But this condition is never realized. The pumps have one capacity, the pipes another, the filters still another, and the plant is declared to be too small while the average consumption of water is below any of the figures given for the capacities of the component parts.

In laying out a system of works there is no matter which calls for more careful study than the most advantageous sizes of these component parts. To some extent these sizes are not capable of calculation, but are matters of judgment. The judgment to be valuable must be based on extended experience, and must take into account all the particular conditions in the case in hand.

Let us take a particular case to illustrate in a general way the method of getting at these sizes.

The city under consideration has a present population of 80,000, we will say. The works now built should be large enough so that no addition will be required for ten years. In some parts it may be worth while to anticipate growths for a longer period. The rate of growth to be anticipated is judged from the past rate of this particular city, and of other cities similarly situated, taking also into account any special conditions likely to make it grow either more or less rapidly than it has done, or than its neighbors. In this case we will say that, all things considered, 25 per cent per decade seems a reasonable allowance. Adding 25 per cent to the present population brings us to a population of 100,000, which must be provided for in the first construction.

The amount of water per capita is next to be considered. This depends somewhat upon the habits of the people as to the use of water for domestic purposes, and for watering lawns and streets; somewhat upon the amount of water sold now or likely to be sold for manufacturing, railway, and trade purposes; and still more upon the amount of water that is wasted by takers and the amount lost by leakage from the pipes.

The present consumption we will say is 100 gallons per capita daily. A greater manufacturing use is to be anticipated, but on the other hand, it is proposed to install more meters upon the services which will reduce the waste. This will offset the increase in actual use per capita, and we will consider 100 gallons per capita daily as the probable consumption ten years hence.

The quantity of water to be provided is thus 100 gallons per capita for a population of 100,000, or 10,000,000 gallons per day.

Ten million gallons per day is the average daily amount for the year. Sometimes the use will be less and sometimes more than the average. There are few cities where the maximum month does not exceed the annual average by 15 per cent. There are some where it is 50 per cent greater. In this case 25 per cent is assumed.

The maximum monthly consumption will thus be 25 per cent above the average, or 12,500,000 gallons per day.

The maximum daily consumption must be taken as 10 per cent more than this figure, or 13,750,000 gallons per day.

During some hours of the day the rate of consumption is far greater than at other hours. The excesss of the maximum hourly rate over the average daily rate is more nearly in proportion to the population supplied than it is to the average amount of supply. In other words, the use of water fluctuates, while the waste does not fluctuate, and where waste is large in proportion the fluctuations expressed in percentage of the whole are less. In this case a rate of 80 gallons per capita is taken as representing the excess of maximum rate of consumption over the average of 100. The maximum rate of use, therefore, will be at the rate of 180 gallons per capita, or 18,000,000 gallons per day.

This does not include the water required for fire service, which must still be added. For ordinary fires which are quickly put out, no very heavy drafts are made. But for the larger fires, which occur at long intervals, a liberal supply must be furnished.

In this case, taking into account the nature of the situation and value of the property, we assume that water to supply 30 standard fire streams should be available. Such streams use 250 gallons of water per minute, or at the rate of 360,000 gallons per day for each fire stream. Thirty streams will require water at the rate of 10,800,000 gallons per day.

If this was added to the maximum rate of use, 18,000,000 gallons per day, it would give the extreme maximum rate to be provided for of 28,800,000 gallons per day.

Actually there is so little probability of the occurrence of the maximum fire at precisely the time of the maximum use of water for other purposes that we can afford to take a few chances on it, and this figure may be cut somewhat. With an average use of 100 gallons per capita, rates exceeding 130 gallons per capita would not occur for more than a small percentage of the time. This would be 13,000,000 gallons per day. Adding our 30 fire streams, or 10,800,000 gallons per day, to this, we have 23,800,000,or say 25,000,000 gallons per day, as the amount which the works must be capable of supplying when there is demand for it in case of a heavy fire.

It is only necessary to prepare to supply water at this highest rate for three or four hours, but the works must be able to supply water at the maximum daily rate of 13,750,000, or say 14,000,000 gallons per day, when required, for a number of days in succession.

We can now take up the sizes required for the different parts of the works.

If an impounding reservoir and its catchment area are sufficient to maintain a constant supply in a dry year equal to the annual average contemplated use, that will suffice. The reservoir will take care of fluctuations in the rate of draft, and no computation need be made of the effect of such fluctuations.

The pipe line leading from the impounding reservoir to the distributing reservoir near the city must have a capacity equal to the maximum daily use of 14,000,000 gallons per day, or 40 per cent above the average annual use.

The hourly fluctuations will be balanced by the distributing reservoir. The storage capacity required to balance the fluctuations of ordinary use will be about 15 per cent of the average daily use or 1,500,000 gallons. In addition to this, enough capacity to maintain the maximum fire draft for four hours should be added. This will require:

$$\tfrac{4}{24}\,(25 - 10) = 2{,}500{,}000 \text{ gallons capacity.}$$

This makes the required capacity of the distributing reservoir 4,000,000 gallons.

It is not usually convenient to so operate a plant as to keep the distributing reservoir always full, and a fire might occur when it was somewhat drawn down. To provide for this a further allowance should be made, bringing the capacity to 5,000,000 gallons, or one-half a day's average supply. And if the fire risk is large, the site suitable, and the financial conditions warrant it, a larger reservoir, up to at least a full day's supply, will be safer and better.

Purification works and pumps, if used, located between the impounding reservoir and the distributing reservoir, must have capacities equal to the maximum day's use, and, in addition, reserve units or capacity must be provided to cover the time lost in cleaning filters and in repairing pumps; and it is customary to have a reserve unit of each kind, so that the supply would not be crippled by having one pumping or filtering unit out of service for some time.

As a general rule, where the distributing reservoir balances hourly fluctuations and provides for fire service requirements, the filters should have a capacity a half greater than the average rate of consumption, and the pumps should have a nominal capacity twice as great as the average rate of pumping.

The average rate of the filters will thus be two-thirds of the maximum rate, and the pumping machinery will operate equal to one-half its nominal capacity when the capacity of the plant is reached. At all other times the ratio of use to capacity will be less.

The pipes from the distributing reservoir to the city, and through it, must have a capacity up to the maximum rate of use of 25,000,000 gallons per day.

If the water is pumped from the reservoir to the city, the pumps must have this capacity with one unit in reserve. This means practically that the pumps for direct service must have a capacity equal to three times the average rate of use. In small works the pumps must be even larger than this in proportion.

It never pays to build filters and purification works to meet the maximum rate of consumption. Even in case of a river supply and direct pumping of the filtered water into the distribution pipes, it pays to provide a pure water reservoir at the filters to balance the hourly fluctuations in rate. This permits the purification plant to work at a constant or nearly constant rate throughout the twenty-four hours, which is advantageous.

The figures used in this illustration are representative, but there are reasons in particular cases why higher or lower values must be used. But in every case there are certain ratios that must be met. With pumps capable of lifting 10,000,000 gallons per day, and filters capable of filtering, and pipes capable of carrying this quantity, it has never been possible, and it never will be possible, to deliver under the required conditions of practical service 10,000,000 gallons of water per day, nor even an approximation to this amount.

This matter, although very simple, is mentioned at length because it is one of the most common matters to be misunderstood, and a perfectly clear understanding of it is essential.

Some most important projects have been seriously defective and incapable of their supposed capacities because of inadequate allowances of this kind.

Waterworks Data for Small Towns and Villages.—Prof. D. D. Ewing gives the following in Engineering and Contracting, April, 14, 1920.

The data for the accompanying statistical graphs and empirical equations were drawn from the descriptions of waterworks plants contained in "Municipal Water Supplies of Illinois," by Edward Bartow, Bulletin of the University of Illinois, Water Survey Series No 5,1907 and "Water Supplies of Kansas," by C. A. Haskins and C. C. Young, Engineering Bulletin No. 5, University of Kansas, 1915.

In Fig. 1 are plotted the relations between water consumption in gallons per capita per day and population for small towns in Indiana, Illinois and Kansas. As is indicated in the figure the points through which the graphs are drawn are averages for a number of communities of about the same size. The water consumption of a town depends on a number of factors, some of the most important being:

Industrial development.
Social characteristics of the people.
Climate.
Character of the water supply.
Sewerage development.
Percentage of metered services.

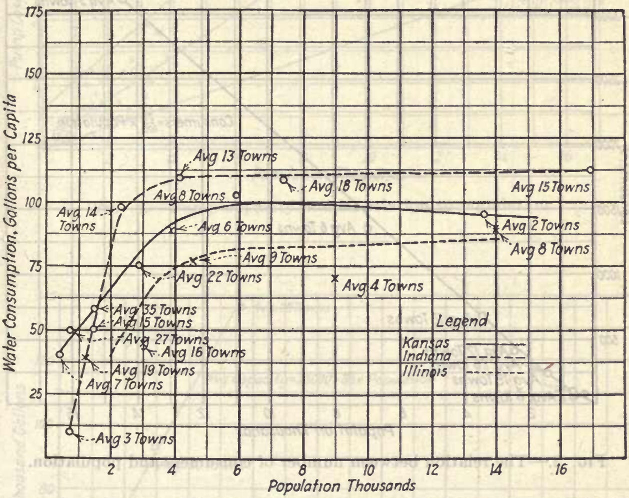

FIG. 1.—The relation between water consumption and population.

As the graphs represent average values it is to be expected that in specific cases there may be wide deviation from the figures indicated by the graphs. For example, in a small country town of the poorer type with nothing in the way of sewer systems and industries the consumption may be as low as 5 gal. per capita per day. On the other hand in a small city containing a number of fairly large water using industries the consumption may reach 500 gal. per capita per day.

A study of the graphs indicates that for ordinary middle west towns of less than 4000 population the average daily water consumption may be expressed by

$$\text{Gallons per capita per day} = \frac{\text{Population}}{40}$$

For towns of more than 4000 population the average consumption is independent of the population and is about 100 gal. per capita per day. In passing it may be stated that reliable water consumption data are very hard to obtain since in only a very few of the plants of the country is the water pumpage metered.

The relation between number of consumers and population for small Kansas communities is shown in Fig. 2. Mathematically the relation is approximately expressed by.

$$\text{Number of consumers} = 21 \times \frac{\text{Population}}{100},$$

or roughly the average number of consumers is one-fifth of the population.

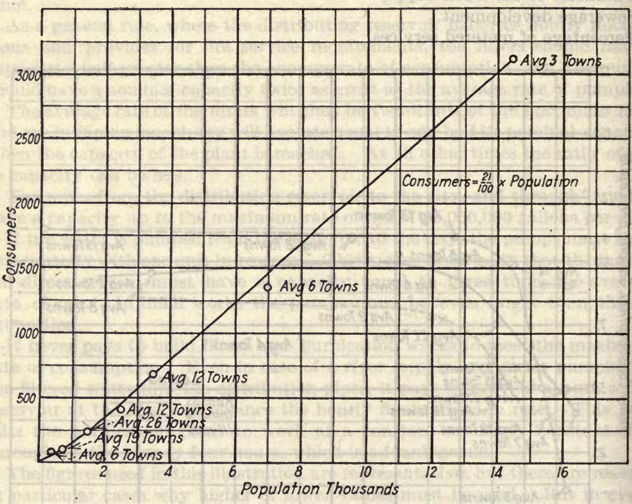

FIG. 2.—The relation between number of consumers and population.

Fig. 3 shows the relation between pump capacity in gallons per minute and population and indicates the method used in determining the relation. The figures plotted are for Kansas towns and the equations of the graphs are:

$$\text{Pump capacity (maximum)} = 600 + 43 \times \frac{\text{Population}}{100}.$$

Pump capacity (average) = 100 + $\frac{1}{8}$ × Population.
Pump capacity (minimum) = $\frac{1}{6}$ × Population.

Similar studies of pump capacity data for Illinois and Indiana plants give the following equations:

Illinois plants:
Pump capacity (maximum) = $\frac{5}{8}$ × Population.
Pump capacity (average) = $\frac{26}{100}$ × Population.
Pump capacity (minimum) = $\frac{1}{8}$ Population.

Indiana plants
Pump capacity (maximum) = $\frac{11}{12}$ × Population.
Pump capacity (average) = $\frac{43}{100}$ × Population.
Pump capacity (minimum) = $\frac{1}{10}$ × Population.

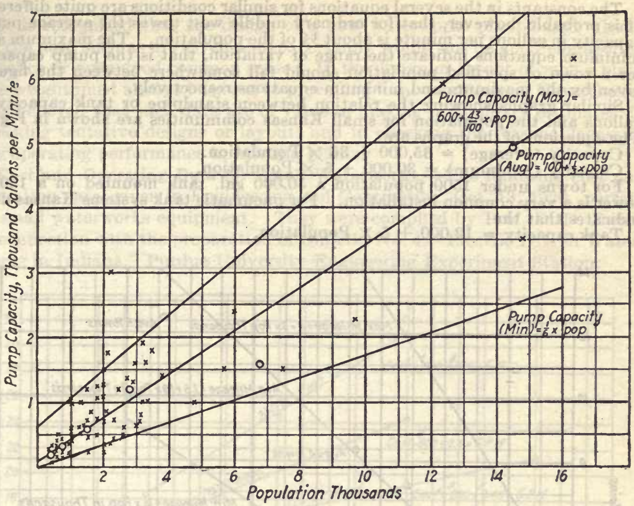

FIG. 3.—Pump capacity and its relation to population.

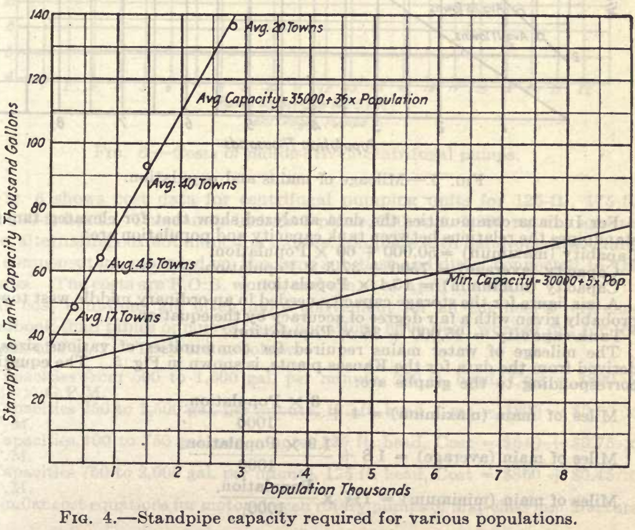

FIG. 4.—Standpipe capacity required for various populations.

The constants in the several equations for similar conditions are quite different. It is probable, however, that for ordinary middle west towns the average pump capacity in gallons per minute is about $\frac{1}{3}$ of the population. The maximum and minimum equations indicate the range of variation, that is the pump capacity for a town of specified population should fall somewhere between the figures given by the maximum and minimum equations respectively.

Similar graphs showing the relation between standpipe or tank capacity in gallons and the population for small Kansas communities are shown in Fig. 4. The equations of the graphs are:

Capacity (average) = 35,000 + 36 × Population.

Capacity (minimum) = 30,000 + 5 × Population.

For towns under 1500 population a 50,000 gal. tank mounted on a 100-ft. tower is a very common installation. For pneumatic tank systems Kansas data indicates that the

Tank capacity = 12,000 + 5 × Population.

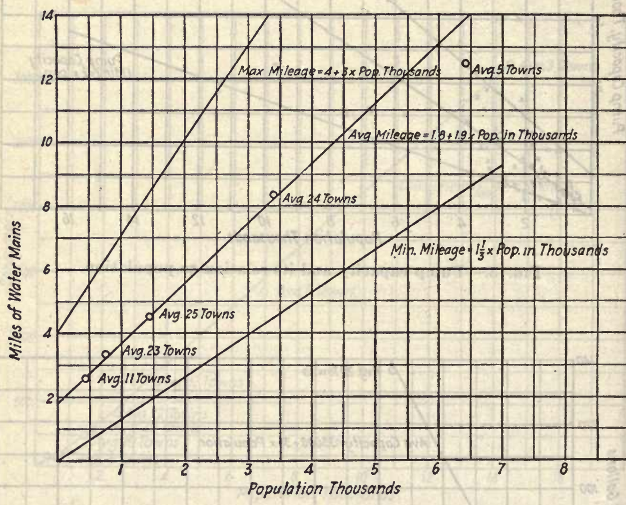

FIG. 5.—Mileage of mains and population.

For Indiana communities the data analyzed show that for elevated tanks or standpipes the relations between tank capacity and population are:

Capabity (maximun) = 50,000 + 60 × Population.

Capacity (average) = 7500 + 37.5 × Population.

Capacity (minimum) = 15.4 × Population.

A fair figure for the storage capacity needed in an ordinary middle west town is probably given with a fair degree of accuracy by the equation.

Tank capacity = 25,000 + 35 × Population.

The mileage of water mains required for communities of various sizes, as derived from the data for the Kansas plants, is shown in Fig. 5. The equations corresponding to the graphs are:

$$\text{Miles of main (maximum)} = 4 + \frac{3 \times \text{Population.}}{1000}$$

$$\text{Miles of main (average)} = 1\ 8 + \frac{1.9 \times \text{Population.}}{1000}$$

$$\text{Miles of main (minimum)} = 1\tfrac{1}{3} \times \frac{\text{Population.}}{1000}$$

It is recognized that the design of a new waterworks plant based wholly on the data such as are given above, certainly would not be good engineering practice or even good common sense. In the design or layout of such a plant due weight must always be given to prevailing local conditions. Nevertheless it is believed that such data are of value in making preliminary estimates, in checking tentative designs or layouts and in checking the reasonableness of the operating performance in existing plants.

Cost and Operating Data for Small Waterworks.—The following cost and operating data, given in Engineering and Contracting, Oct. 13, 1920, pertain to small waterworks equipment. They were compiled by Prof. D. D. Ewing in connection with the preparation of Bulletin No. 4, "Electric Driven Waterworks in Indiana," Purdue University Engineering Experiment Station.

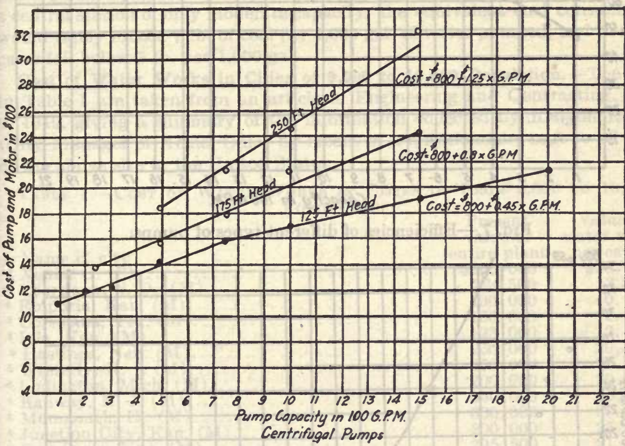

FIG. 6.—Costs of motor-driven centrifugal pumps.

Fig. 6 shows cost data for centrifugal pumping units for 125-ft., 175-ft. and 250-ft head. These units include 3-phase, 220-volt, 1,800 r.p.m., squirrel cage, alternating current induction motors, complete with hand-operated starting compensators, mounted on the same sub-base and direct connected to the pumps. The costs are F.O.B. works, and are as of April 1, 1919.

As cost equations are often more convenient for an engineer's reference handbook than tables or curves, such equations have been worked out for the graphs of Fig. 1. They are as follows:

Capacities from 500 to 1,500 gal. per minute, 250-ft. head, Cost = \$800 + \$1.25 × G.P.M.

Capacities 250 to 1,500 gal. per minute, 175 ft. head, Cost = \$800 + \$0.80 × G.P.M.

Capacities 100 to 750 gal. per minute, 125 ft. head, Cost = \$640 + \$0.75 × G.P.M.

Capacities 750 to 2,000 gal. per minute, 125 ft. head, Cost = \$860 + \$0.45 × G.P.M.

Similar cost equations for motor-driven rotary pumps of first-class manufacture are:

Capacities 100 to 400 gal. per minute, 125 ft. head, Cost = $4.50 × G.P.M.
Capacities 500 to 2,000 gal. per minute, 125 ft. head, Cost = $1,300 + $1.60 G.P.M.

For air pumps with motor-driven compressors the equations are:
Capacities up to 500 gal. per minute, 50-ft. lift, Cost = $500 + $4 × G.P.M.

For motor-driven deep well reciprocating pumping units the equations are:

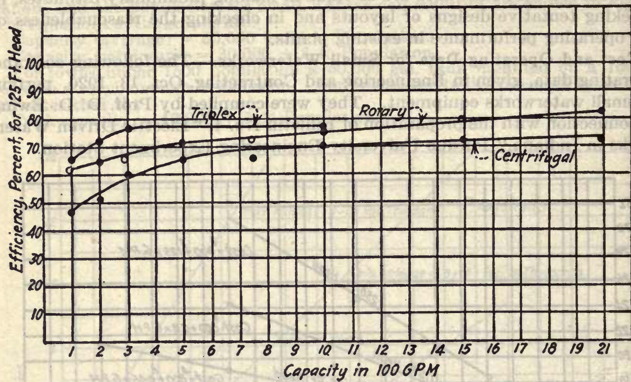

FIG. 7.—Efficiencies of different types of pumps.

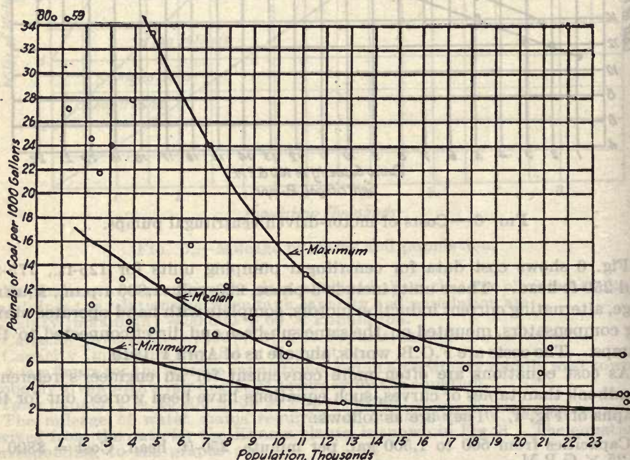

FIG. 8.—Coal consumption in small waterworks plants.

Capacities up to 200 gal. per minute, 50-ft. lift. Cost = $600 + $6 × G.P.M
Capacities up to 200 gal. per minute, 160 ft. head, Cost = $600 + $9 × G.P.M.

For elevated tanks, height to top of tank 100 ft., tank capacities, 25,000 to 200,000 gal., Cost = $3,200 + $45 × capacity in 1,000 gal.

The tank costs are for the tanks erected complete and include everything except freight charges. The weights of these tanks and their towers are given by,

Weight = 14 tons + ¼ × capacity in 1,000 gal.

In Fig. 7 are shown the efficiencies of triplex, rotary and centrifugal pumps. These curves do not represent the efficiencies of just one pump of each of the different types operated under various discharge conditions, but are the efficiencies of lines of pumps of the several types, the efficiency of each pump in a given line being the best operating efficiency of that pump.

Fuel consumption and conservation are matters of prime importance today and in Fig. 8 is shown an analysis of the fuel consumption of a number of small steam operated waterworks plants in Indiana. It will be noted that in the small plants the fuel consumption reaches an almost prohibitive figure. Were these plants operated by electric motors receiving their energy supply from a central station of only moderate capacity, the equivalent coal consumption would rarely exceed 7 lb. of coal per 1,000 gal. of water pumped, and in many cases fall below 5 lb. per 1,000 gal.

Cost of Water Works in Cities of 9,000 to 10,000 Population.—The data in Table I are taken from an article in Engineering and Contracting, April 9, 1919, giving a summary of the information collected by Kenyon Riddle, (City Manager of Xenia, Ohio) by means of a questionnaire sent to all cities of the above size in the United States.

Table I.—Cost of Water Works in Cities of From 9,000 to 10,000 Population

Name of city	Present value of entire plant	Value of water works per capita
[1] Xenia, O. (P)	$260,000	$29.00
[2] Aberdeen, S. D. (M)	224,500	13.50
[4] Emporia, Kan. (M)	400,000	40.00
[2] Corsicana, Tex. (M)	160,000	12.00
[4] Iola, Kan. (M)	123,000	12.30
[5] Hastings, Neb. (M)	250,000	20.00
[5] Westerly, R. I. (M)	350,000	35.00
[6] Ludington, Mich. (M)	200,000	20.00
[4] Rahway, N. J. (M)	350,000	35.00
[8] Monmouth, Ill. (M)	300,000	30.00
[5] Junction City, Kan. (M)	200,000	25.00
[9] Fort Scott, Kan. (M)	295,500	21.00
[8] Kewanee, Ill. (M)	395,000	23.00
[5] Delaware, O. (P)	300,000	33.00
[1] Owosso, Mich. (P)	150,000	19.00
[3] Tyler, Tex. (M)	285,000	19.00
[4] Defiance, O. (M)	150,000	16.60
[4] St. Charles, Mo. (M)	150,000	15.00
[10] Abilene, Kan. (M)	80,000	16.00
[10] Herington, Kan. (M)	90,000	19.00
[5] Albuquerque, N. M. (M)	400,000	22.00
[5] Pomona, Cal. (P)	500,000	31.00
[4] Clarksville, Tenn. (M)	200,000	20.00
[5] Arkansas City, Ak. (M)	200,000	18.00
[4] Chickasha, Okla. (P)	240,000	16.00
[5] Goshen, Ind. (M)	220,000	22.00
[4] Billings, Mont. (M)	500,000	28.00
[6] Ashland, Wis. (P)	480,000	24.00
[8] Barre, Vt. (M)	390,000	39.00
[12] Menominee, Mich. (M)	284,000	28.00
[4] Ottawa, Kan. (M)	130,000	14.40
[11] Adrian, Mich. (P)	150,000	12.50

Source of Supply: [1] Wells and springs. [2] Artesian wells. [3] Reservoir. [4] Rivers. [5] Wells. [6] Lake. [8] Deep wells. [9] River and two deep wells. [10] Springs. [12] Green Bay, Michigan.
(P) Private ownership. (M) Municipal ownership.

Cost Data on Small Water Works Systems.—William Artingstall gives the following data in Municipal and County Engineering, Oct., 1919.

The expenditure incurred for water supply for small cities is dependent on the locality and varies in the per capita cost due to the local conditions peculiar to each city. This variation is due not so much to the cost of the water mains and feeders as it is to the cost of the pumping plant and the difficulty (or ease) with which the necessary amount and kind of water is obtained. For this reason it is customary to let separate contracts covering these two phases of the work and in the majority of cases the cost of the supply is not reported for public information. In Table II the cost of the distribution system is all that is given unless otherwise noted. To this cost must be added an amount per capita of from $15 as a minimum to $40 or $50 as a maximum. In cities where there are no deep wells nor expensive pumps to install, the cost would run in the neighborhood of $15 or $20.

TABLE II.—COST OF SMALL WATER DISTRIBUTION SYSTEMS IN 1919

Town State	Population	Expenditure, per capita
Oneida, S. D	150	$200.00*
St. Clair Beach, Mich	200 approx.	50.00
Ladora, Iowa	260	58.50
Waconda, S. D	326	92.50*
Garber, Okla	382	59.00
Pretty Prairie, Kans	327	97.50
Menno, S. D	621	56.30
Foley, Minn	710	56.30
Hettinger, N. D	766	35.00
Dexter, Ia	767	47.00
Townsend, Mont	759	39.60
Wendell, N. C	759	47.30
Orem, Utah	800	125.00*
Markesan, Wis	892	61.50
Walker, Minn	917	27.80
Fairmount, Neb	921	37.00
Grand Junc. Ia	1,012	40.00
Ferndale, Mich	1,070	79.00*
Spearfish, S. D	1,130	44.00
Spirit Lk., Ia	1,162	45.50
Roundup, Mont	1,513	25.70
Aiken, Neb	1,638	24,00
What Cheer, Ia	1,720	29.00

Note that as the size of the city increases, the cost per capita becomes less due to a greater density of population. *Complete.

Costs of Small Water Works Systems in Massachusetts.—The following data are taken from an article by Harry R. Crohurst published in Engineering and Contracting, May 26, 1915.

TABLE III.—COST PER CAPITA OF SMALL WATER WORKS SYSTEMS

	Population	Total cost of water works	Cost per capita
Ashland	1700	$ 46,034	$27
East Brookfield	2204	23,927	11
Littleton	1229	45,896	37
Medway	2696	100,032	37
Pepperell	2953	105,451	36
Oxford	3361	57,539	17
Wrentham	1743	50,683	29

The system at Ashland was constructed in 1911 and consists of twelve 2½-in. driven wells varying in depth from 25 to 32 ft. with an average depth of 30 ft., a small field stone pumping station 25 × 33 ft. in plan with a red asbestos shingled roof, and a pumping plant consisting of two 17-HP. oil engines and two 7 × 8-in. Smith-Vaile triplex pumps.

The distribution system consists of a covered, reinforced concrete standpipe 40 ft. in diameter and 32 ft. high with a capacity of 300,000 gals., and 6½ miles of cast-iron mains varying from 12 to 6 ins. in diameter. On the system there are 66 gates and 52 hydrants, and the number of services connected at the end of the year 1913 was 250, all of which were metered.

In laying out the system no unusual conditions were encountered, and no large amount of rock was found with the exception of the main leading to the standpipe.

The cost of constructing the system to the end of the year 1913, not including service connections, as given in the 1913 report of the Board of Water Commissioners was as follows:

Bond issue		$ 55 22
Land		1,710.38
Legal expenses		122.65
Office expenses		74.76
Wells		1,266.80
Pumping station		2,122.95
Pumps and engines		4,358.20
Standpipe		5,812.00
Mains:		
Pipe	$15,116.38	....
Gates, hydrants, specials	2,579.32	....
Laying pipe	9,369.86	....
Freight, express and miscellaneous	1,160 62	28,226.18
Engineering		2,285 20
		$46,034 34

During the year 1913 the average daily consumption of water was 20,000 gals., or about 12 gals. per capita, one of the lowest consumption figures in the state.

The cost of operating the works during 1913 was as follows:

Pumping plant	$ 77.95
Service repairs	27.74
Pipe repairs	262.17
Fuel	198.73
Wages	865 00
Office expense	62.91
Interest on bonds	2,000.00
Miscellaneous	27.37
	$3,521.87

From the above consumption and cost of operation the cost of supplying 1,000 gals. of water was 48 cts.

The source of supply of East Brookfield is from the shore of Lake Lashaway, or Furnace Pond, just north of the village. The wells are located on the westerly shore and the water which is taken from a stratum of coarse water-bearing gravel is pumped through 1,325 ft. of 6-in. main to the standpipe from which it is distributed by gravity.

The system installed in the fall of 1908, consists of twelve 2½-in. tubular wells varying in depth from 19 to 24 ft., a small brick pumping station 24 × 30 ft. in plan with a slate roof, and a pumping plant consisting of two 8-HP. oil engines and two 5½ × 8-in. triplex pumps each having a capacity of 100 gals. per minute, The distribution system consists of a covered wrought-iron standpipe 25 ft. in diameter and 50 ft. high with a capacity of 185,000 gals., and about 2.6 miles of cast-iron mains 12 to 6 ins. in diameter. On the system at the time of examination there were 80 services and 32 hydrants.

The cost of constructing this system, not including service connections, was as follows:

Wells		$ 567.72
Pumping station		1,627.70
Pumping plant		3,050.00
Standpipe		3,150.00
Mains:		
Pipe	$8,480.40	....
Hydrant, gates, specials	1,357.60	....
Laying pipe	3,009.90	12,847.90
Engineering and inspection		1,384.07
Bills payable		1,300.00
		$23,927.39

The water works system of Littleton was constructed in 1911 and consists of nine 2½-in. driven wells varying in depth from 17 to 27 ft., a brick pumping station with a slate roof 35 × 25-ft. in plan, and a pumping plant consisting of a 25-HP. oil engine, a 25-HP. motor and a 7½ × 10-in. triplex pump.

The distribution system consists of a covered steel standpipe 40 ft. high and 30 ft. in diameter having a capacity of 275,000 gals., and 5.7 miles of 12 to 6-in. cast-iron mains. On the system are 17 gates, 37 hydrants, and 130 metered services.

The cost of installing the system, not including the cost of service connections, is given in the 1912 report of the Board of Water Commissioners as follows:

Wells		$ 431.31
Pumping station		2,929.00
Pumping plant		3,735.00
Standpipe		3,938.00
Land and right of way		1,575.83
Mains:		
Pipe	$19,036.88	....
Gates and hydrants	1,175.00	....
Express and freight	93.42	....
Laying pipe	8,728.04	....
Setting hydrants	74.00	....
Rock excavation	1,225.00	....
Miscellaneous	954.47	31,286.81
Engineering		2,000.00
		$45,895.95

The cost of operating the Littleton works for the year ending March 1, 1913, was as follows:

Salaries	$ 580.00
Supplies	116.66
Fuel oil	219.77
Expenses	8.15
Freight	39.15
Repairs	25.38
Miscellaneous	42.85
Rent	36.00
	$1,067.96

The water works system of Medway was built in 1911 and 1912 and consists of 30 2½-in. wells varying in depth from 32 to 75 ft., each provided with a 3-ft. strainer point, a pumping station 40 × 20 ft. in plan of terra cotta blocks with cement plastering inside and out and having a wooden truss roof covered with slate, and a pumping plant consisting of two 32-HP. oil engines and two triplex single acting pumps. This plant was tested Sept. 11, 1911, by running both engines together for 11 hours successively. The economy test showed nearly 8,000 gals. pumped to 1 gal. of oil. The cost of oil taken at 6 cts. per gallon at the station shows a fuel cost of ¾ ct. per 1,000 gals. pumped into the standpipe.

The distribution system consists of a steel standpipe 30 ft. in diameter and 80 ft. high with a capacity of 437,000 gals., and 12.35 miles of cast-iron mains 12 to 4 ins. in diameter. On the system there are 87 gates, 111 hydrants and 338 service connections which are only a part of the final number.

The cost of these works up to Feb. 1, 1913, not including service connections, was as follows:

Preliminary examination		$ 2,750.00
Legal bond issue		944.95
Land		1,303.65
Wells and connections		4,650.00
Pumping station		3,632.00
Pumps and engines		7,550.00
Standpipe		8,800.00
Standpipe foundations		2,325.00
Mains:		
Pipe and laying	$52,142.85	
Gates	1,454.00	
Hydrants	3,885.00	
Freight	92.12	
Rock excavation	5,000.00	
River crossing	1,000.00	
Repairs to roads	1,500.00	65,073.97
Engineering		3,002.40
		$100,031.97

The above figures were taken from the engineer's final estimate of the cost of all of the works.

At the present time record of the quantity of water supplied cannot be obtained. The cost of operating the works during 1912 was as follows:

Administration	$ 631.98
General expense	71.17
Interest on bonds	4,325.40
Pumping sation—	
Fuel oil	379.43
Cylinder oil	37.81
Labor	818.90
Coal	56.55
Supplies	94.49
	$6,415.73

The water works system of Pepperell was constructed during the summer of 1910.

The source of supply is from wells located near Gulf Brook just south of the Massachusetts and New Hampshire State line about three miles north of the town.

The works consist of 34 2½-in. wells having an average depth of 25 ft., a brick pumping station 30 × 20 ft. in plan with a slate roof, and a pumping plant consisting of two 25-HP. oil engines and two 8 × 10-in. triplex pumps each having a capacity of 250 gals. per minute.

The distribution system consists of a covered steel standpipe 45 ft. in diameter and 40 ft. high having a capacity of about 475,000 gals., and 16.42 miles of 12 to 6-in. cast-iron mains. On the system are 130 hydrants.

The cost of these works, not including service work, taken from the special 1910 report of the water commissioners, was as follows:

Bond issue		$ 154.35
Wells		2,544.37
Pumping station		2,852.38
Land for station and wells		750.00
Standpipe		6,728.98
Land for standpipe		600.00
Engines and pumps		6,062.52
Mains—		
Pipe and fittings	$49,069.34	
Laying	24,877.13	
Hydrants	3,033.80	
Valves, gates, specials	2,288.69	
Freight	1,099.65	
Inspection of pipe	270.86	
Miscellaneous	1,188.44	81,757.91
Engineering		4,000.00
		$105,450.51

The total consumption of water for the year 1912 was 40,282,000 gals, which is equivalent to an average daily consumption of 110,000 gals. or 37 gals. per capita.

The cost of operating the system for 1912 is given as follows:

Maintenance	$2,728.36
Services	657.84
Piping system	341.15
Meters	65.73
Interest	5,080.00
	$8,873.08

The source of supply of the Oxford Water Works is from driven wells near a small brook flowing into the French River near North Oxford.

The water works system was constructed in 1906 and consists of 8 2½-in. wells varying in depth from 23 to 28 ft., a brick pumping station 25 × 25 ft. in plan and a pumping plant consisting of two oil engines and two triplex pumps.

The distribution system consists of a steel standpipe 27 ft. in diameter and 50 ft. high having a capacity of 220,000 gals., and 9.7 miles of cast-iron mains 10 to 2 ins. in diameter. On the system are 60 hydrants and 405 service connections.

These works are privately owned and the following cost figures are taken from the 1906 report of the company:

Preliminary engineering		$ 250.00
Wells		581.25
Station		1,720.00
Pumping machinery		3,200.00
Standpipe		4,564.95
Foundations		500.00
Mains—		
Pipe	$28,424.60	
Hydrants, valves, specials	5,098.07	
Laying	8,077.87	
Rock excavation	927.95	42,528.49
Land		1,425.00
Engineering		1,769.59
Miscellaneous		1,000.00
		$57,539.28

The cost of operating the Oxford plant for the year 1912 was as follows:

Labor	$ 884.34
Oil and gasoline	710.32
Interest on notes	913.53
Coupons on bonds	1,250.00
Dividends	1,717.50
Salaries	200.00
Repairs	164.27
Miscellaneous	268.07
	$6,108.03

The Wrentham water works were constructed in 1907. The source of supply is from driven wells near the "Trout Ponds," so-called, about a mile south of the village.

The system consists of 9 2½-in. tubular wells having an average depth of 29 ft. The pumping station is a brick structure with a slate roof, 25 × 36 ft. in plan, containing two 25-HP. oil engines and two 8 × 10-in. triplex pumps each having a capacity of 250 gals. per minute.

The distribution system consists of a steel standpipe 30 ft. in diameter and 50 ft. high having a capacity of 265,000 gals., and 5.6 miles of cast-iron mains 10 to 2 ins. in diameter.

The cost of the system, not including service connections was as follows:

Wells		$ 1,048.22
Pumping station above foundation		1,646.97
Engines and pumps		5,933.55
Standpipe above foundation		5,204.63
Foundations (station and standpipe)		1,556.50
Mains—		
Pipe	$21,002.62	
Hydrants	969.68	
Specials	1,215.57	
Laying	9,410.39	
Bridge crossing	195.18	32,793.44
Engineering		2,500.00
		$50,683.31

The above figures are compiled from the 1907 report of the water commissioners.

Reports from 66 Cities on Pumpage, Meterage, Repairs and Renewals, and Depreciation.—Information on certain phases of water works operation, concerning which there is considerable diversity of opinion, has been collected by Engineering and Contracting and published in the issue of May 8, 1918. Table IV contains a summary of the replies to a questionnaire sent to water works superintendents. Of the 66 cities represented in the table, 63 report on pump capacity and output of pumps. The total daily pumping capacity of these cities is 1,500,000,000 gal. and the daily average output averages about 823,000,000 gal. or a ratio a little less than 2 to 1. Excluding Chicago with its daily pump capacity of 923,000,000 gal. and the remaining 62 cities have a daily pump capacity of 583,000,000 gal. and a daily average output of 192,000,000 gal., or a ratio of 3 to 1. Of the 66 cities 57 reported the per capita water consumption. The arithmetical average consumption for 37 cities having more than 69 per cent of their services metered was slightly less than 70 gal. per capita. The average per capita consumption for the 22 cities with less than 56 per cent of their services metered was 133 gal.

Fifty-seven cities reported on maintenance expenses of their water works. The total investment was $133,600,000 or about $30 per capita and the total maintenance expense for the last recorded year was $2,236,000 or about 1.7 per cent. The average depreciation annuity for 34 plants was 2.9 per cent.

TABLE IV

City	Daily capacity of pumping plant, gal.	Average daily output of pumps in 1917, gal.	Population served	Average daily per capita consumption	Per cent of services metered	Average annual expense of repairs and renewals for entire water works	Approximate investment in entire water works	Depreciation annuity per cent of plant maintenance in excess of average expenses, per cent
Akron, Colo	45,670	44,000	1,200	36	75	$ 1,000	$ 32,500	½

[1] Has two units of 6,000,000 gal. each. [2] In 10 hours. [3] Maximum capacity [4] 7.4 per cent of service pipes metered; 23.1 per cent of consumption metered. [5] Thinks plant will depreciate $10,000 per year. [6] For 1917. [7] 1 per cent to 1½ per cent. [8] ½ per cent to 1 per cent. [9] 1 per cent on mains; 4 per cent on stand-pipe, and 5 per cent on buildings and pumps. [10] Depreciation fund 2 per cent to 4 per cent put into renewals. [11] Individual rates of depreciation for different portions of plant and equipment; 1917 depreciation 3.6 per cent. [12] Capacity of reservoirs. [13] Operation and maintenance. [14] 3 per cent or 4 per cent. [15] 3 per cent on mechanical equipment, and 2½ per cent on buildings, etc. [16] Main supply gravity. [17] Depreciation in 1917 was $10,000. [18] For main and renewals.

Per Cent of Water Works Plant Charged to Fire Protection.—Curves based on public utility decisions have been found useful by Chester & Fleming, Consulting Engineers, Pittsburgh, as a guide to show what portion of water charges should be allocated to fire service. The diagrams prepared by the above mentioned firm were reproduced in Engineering and Contracting, May 14, 1919, from which paper the following is taken. Each curve is platted from 24 decisions for plants having a value above $50,000 and gross revenues from $5,000 to $100,000 per year. The decisions from which these curves were prepared are shown in the table, each division's place in the diagram being indicated by its number given in Table V.

The diagrams are self explanatory. For instance, in Fig. 9, there appears at the bottom the gross revenue from plant operation. At the left of the diagram appears the annual revenue from fire protection in dollars, which permits the location on the face of the diagram at its proper point each

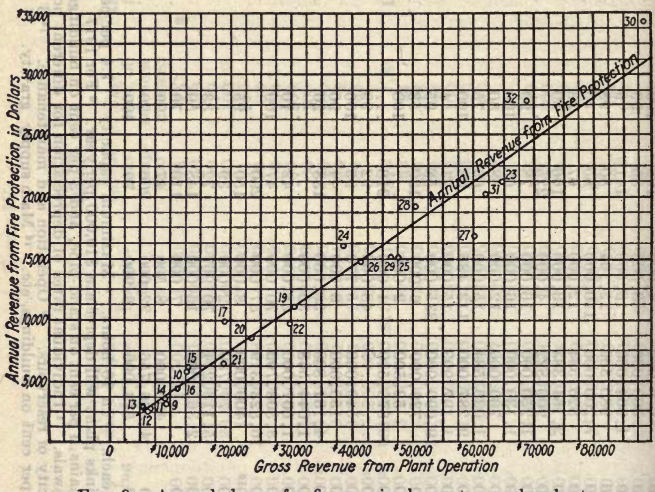

FIG. 9.—Annual charge for fire service by water works plant.

decision and through these decisions the line of average is drawn, and so knowing the gross revenue from plant operation one may readily obtain what the decisions plotted would indicate would be the fair amount of the gross to be derived from the municipality as compensation for fire protection.

Fig. 10 instead of stating the annual revenue from fire protection in dollars, tabulates the percentage of gross revenue.

Fig. 11 deals with the value of the plant as fixed by the Commission in its relation to the revenue from fire protection in dollars.

Fig. 12 deals with the value of the plant as fixed by the Commission with relation to the percentage of the plant chargeable to fire protection.

By plotting the curves which represent the average of the decisions, the average result may be found within the limit of these decisions, and by utiliz-

Cost of Baltimore High-pressure Fire Service System.—The following table giving the construction costs of the Baltimore high-pressure fire service system is taken from an abstract in Engineering and Contracting, April 16, 1913, of a paper by James B. Scott before the American Society of Mechanical Engineers.

TABLE X.—CONSTRUCTION COST OF THE BALTIMORE HIGH-PRESSURE FIRE SERVICE SYSTEM

Portable Equipment.	
2 automobile hose wagons at $5,000	$ 10,000
8,000 ft. 3-in. hose at $1	8,000
30 portable heads and regulators at $385	11,550
Total	$ 29,550
Pipe System	
Material delivered Baltimore	
Hydrants, 226 at $100	$ 22,600
8-in. pipe, 7,137 ft. at $2.35	16,700
10-in. pipe, 28,229 ft. at $3.10	87,700
16-in. pipe, 17,052 ft. at $5.25	89,600
24-in. pipe, 1,275 ft. at $10	12,750
8-in. gate valves, 6 at $100	600
10-in. gate valves, 193 at $130	25,000
16-in. gate valves, 90 at $210	18,900
18-in. gate valves, 2 at $300	600
24-in. gate valves, 3 at $1,000	3,000
Air and relief valves	200
Low pressure gates, 2 30-in.	500
Suction pipe, 400 ft. cast iron, 30-in., at $4	1,600
Steel air chambers, 2 30-in., at $500	1,000
Venturi meter	500
Cast steel specials	17,500
	$ 298,750

Installation	
Laying pipe, including placing valves, fittings, hydrants, etc.	
8-in. pipe, 7,137 ft. at $0.70	$ 4,996
10-in. pipe, 28,229 ft. at 0.75	21,200
16-in. pipe, 17,052 ft. at 1.15	19,600
24-in. pipe, 1,275 ft. at 1.75	2,230
Pump connections in station	6,000
Laying 30-in. c. i. suction	3,400
Tapping 40-in. main	1,500
Concrete valve boxes, 293 at $30	8,790
Excavation, back filling and rubble paving	
41,318 ft. open trench, at $3.84	158,600
12,375 ft. tunnel, at $4.08	50,400
Improved paving, 6,650 sq. yds., at $1.50	10,000
Superintendence, use of tools, etc	50,000
	$ 336,716
	$ 635,466
Pumping Station	
Site and preliminary work	$ 37,730
Building, including machinery foundations and men's quarters	124,800
Harbor intake and screen chamber	10,000
Equipment	
Four 4,000-gal. pumps	$ 82,000
One 1,000-gal. pump	3,500
Auxiliary pumps	4,250
Feedwater heaters and purifiers	4,750
4 boilers and settings, 27,200 sq. ft. heating surface	33,000
16 underfeed stokers, blowers, air piping, etc	18,000
4 steel stacks and supports	8,000
Coal handling apparatus	7,000
Turbo-generators and switchboard	4,500
Electric crane	4,000
Steam and auxiliary water pipping	30,000
	$ 199,000
	$ 371,530
Miscellaneous	
Signal system, cables, etc	$ 1,500
Furnishings for men's quarters	500
Incidentals	5,000
	$ 7,000
Engineering	50,000
Total cost of construction	$1,093,546

The following analysis of operating expenses, for electric pumps and steam pumps, was an additional argument for the use of steam pumps for the Baltimore installation.

Electric Pumps (New York Type)	
Investment	
5 motor driven pumps (rated capacity 3,000 gals. per min.), switchboard, etc	$112,500
Building and pump foundations	84,000
	196,500
Operation	
Maintaining pressure continually 8,760 hr. less 100 hr. = 8,660 hr. at 100 kw	866,000 kw-hr.
Fire service, 100 hr. per annum 3,150 kw. demand	315,000 kw-hr.
	1,181,000 kw-hr.

Service charge, maximum demand = 3,150 kw.		
Central station investment, 3,150 kw. at $75		$236,000
Underground cable (Baltimore conditions)		40,000
Cash requirements		236,000
Underwriting at 90		31,000
Total investment		$307,000
Fixed charges on $307,000		
Interest	at 5 per cent	
Depreciation	at 5 per cent	
Profit	at 5 per cent	
Total	15 per cent	$ 46,000
Underground conduits, duct rental (Baltimore conditions)		1,300
Total service charge		$ 47,300
Operating expenses		
Service charge		$ 43,700
Meter charge, 1,181,000 kw-hr. at 1 ct		11,810
Salaries, station operating force		10,650
Supplies, lubrication and repairs		1,000
		$ 67,160
Fixed charges on $196,500		
Interest at 4 per cent		$ 7,860
Depreciation at 5 per cent		9,825
		$ 17,685
Total annual expense, electrical plant		$ 84,845

Steam Pumps

Investment		
Four 4,000-gal. pumps and auxiliaries		$ 86,000
Boilers and auxiliaries		70,000
Piping, steam and auxiliary water		30,000
		$186,000
Building and machinery foundations		125,000
		$311,000
Operation		
Coal consumption		
Banking fires, 8,760 hr.—		
100 hr. = 8,660 hr. = 360 days at 6 tons per day		2,160 tons
Fire service. 100 hr. per annum at 5 tons coal per hour		500 tons
Total		2,660 tons
Operating expenses		
Coal, 2,660 tons at $3.30		$ 8,778
Salaries, station operating force		13,350
Supplies, lubrication and repairs		2,000
		$ 24,128
Fixed charges on $311,000		
Interest at 4 per cent		$ 12,440
Depreciation at 5 per cent		15,550
		$ 27,990
		$ 52,118

Summary

Total annual expense, electrical plant	$ 84,845
Total annual expense, steam plant	52,118
Total annual saving	$ 32,727

This saving capitalized at 9 per cent represents an investment by the city of $363,630, considerably more than the first cost of the steam plant in the above comparison.

Operating Costs of Water Works Per Million Gals. and Per Capita.—Engineering and Contracting, Jan. 28, 1914, gives the following from a report on an investigation of the municipal water works at Lorain, Ohio, by Philip Burgess.

TABLE XI.—ANNUAL OPERATING COSTS OF 16 WATER WORKS PROPERTIES

City	Dates	Total population	Annual operating cost Per 1,000,000 gals.	Per capita
Ashland, Wis.	1904–09	12,150	$36.23	$1.25
Manitowoc, Wis.	1907	13,400	47.76	1.32
Janesville, Wis.	1909	13,800	49.96	1.30
Beloit, Wis.	1908	14,100	23.35	1.02
Chillicothe, O.	1908–12	14,500	.....	1.00
Marinette, Wis.	1909–10	14,650	26.17	1.09
Private Water Co. in Arkansas	1908–12	15,400	.....	1.57
Elyria, O.	1910–12	15,500	34.88	1.47
Appleton, Wis.	1909	16,700	36.73	1.29
Fond duLac, Wis.	1907	17,800	20.31	0.77
Eau Claire, Wis.	1907	18,650	18.24	0.71
Private Water Co. in Western Pa.	1905–10	22,570	40.45	1.17
Green Bay, Wis.	1907	24,000	48.56	0.90
Battle Cr., Mich.	1908–12	25,270	26.20	0.72
Madison, Wis.	1908–12	25,460	49.70	1.28
Sheboygan, Wis.	1908	25,500	24.74	0.77
Lorain, O.	1900–10	22,070	23.72	1.17
Average of 16 cities above	....	18,090	34.51	1.10

The costs shown include true operating costs exclusive of extraordinary expenses such as are incurred by extensions or replacements.

Cost of Setting 25,000 Water Meters at San Francisco.—The following data are given by George W. Pracy, Ass't. Sup't. Spring Valley Water Co. in Engineering News-Record, May 9, 1918.

During portions of 1916 and 1917 the Spring Valley Water Co., which supplies the city of San Francisco with water, installed 24,993 meters, practically all of ⅝-in. size, with marked effect in reducing water consumption. Careful records of cost were kept.

In 1915 the average daily water consumption of San Francisco was 42,-635, 014 gal., which was in excess of the developed supply and 3,261,229 gal. over that for 1914. As 1915 was the exposition year, with attendant extraordinary water uses, it was confidently expected that 1916 would see a decrease in the use of water. When instead the first four months of that year showed a substantial increase the problem of adding to or restricting waste was squarely put before the company.

On May 1, 1916, water was supplied through 65,000 service connections of which about 22,000, or 34%, were metered. These meters were all on business houses. All dwellings were on a flat-rate basis. The company felt that the metering of these flat-rate services was not only the most economical but also the best way of meeting the situation. Accordingly in May, 1916, an order was placed for 15,000 ⅝-in. meters, with the option of purchasing a second 15,000 at a later date, a total of 30,000 meters being purchased.

For local reasons it was decided to meter only those consumers whose monthly bills were $1.80 or more. This made the work of setting the meters harder and more costly than metering all houses. All meters were set at the curb.

Organization.—The field work was done by two crews. For the first month each crew consisted of a foreman and about 30 men. The crews were later cut down to 12 to 15 men. The two foremen were under the general foreman of the service and meter department. A Ford truck and a Ford wagon delivered the meters, boxes and other material on the ground.

Method of Setting.—The meters were delivered to the meter shop by the manufacturers. There they were taken out and tested. A testing machine of six-meter capacity was used. Each meter was tested for a 10-cu.-ft. flow at the rate of 15 gal. per minute. Meters reading from 99 to 100% correct were set. Those reading under 99 or over 100% were sent to the bench for adjustment. After testing, the meters were piled up ready for delivery to the job.

The meter boxes were delivered f.o.b. cars at San Francisco. Thence they were hauled to the yard, where they were stacked. The other material was delivered at the yard by the various manufacturers.

A large tool box mounted on wheels was kept in the locality at which each crew was working. At this tool box was kept about half a day's material for the crew. This enabled the crews to start work at 8 a.m. and continue till the truck arrived.

The Fords were sent out each morning with the material needed for the day. They also moved the tool boxes along as the work progressed. The material was delivered from the tool boxes to the houses by one man using a wheelbarrow. Meterset orders were written in the main office and given to the general foreman, who routed them and gave them to each gang foreman. The gang foreman in turn had a man who took these orders and went ahead of the crews measuring up and marking out the services that were to be metered. The marking was done by chalk on the sidewalk or curb. This man was followed by the laborers, who excavated down to the service and stopcock. If the meter was to be set in the concrete sidewalk a piece about 2 ft. square was first broken out. In lawns the sod was carefully taken out and set aside. The laborers were followed by the servicemen, who set the meter. The servicemen were then followed by other laborers who set the concrete boxes and filled in. In concrete sidewalks the laborers just filled in, the repaving being done by a contractor. A team followed to clean up and haul away the debris.

For each hole made in a paved sidewalk an order was filled out and sent to the paving contractor. This order specified the location, kind of paving and size of opening.

Each serviceman was provided with a pad on which he wrote the number and location of the meter as it was set, using a new sheet for each. These were collected by the foreman, who checked each one and entered the information on the orders. The servicemen could not make the original entry direct into the meter-set orders, as it was necessary to keep them clean. The orders were then sent to the clerk at the yard, who made out the paving orders. They then went to the main office, where an account was opened for each meter.

The speed of the crews varied from day to day, depending on various conditions. In the old part of the town, which was burnt over in the fire of 1906 and where the service records were not always correct and the services in poor condition, the least headway was made. In the new residence districts the work went along rapidly. The crews as a whole averaged 4¼ meters per man per day, though on some days they set as many as 8 per man. Each serviceman set an average of 15 meters a day. A record was kept of the number set by each man, and if any serviceman could not keep up with the rest of the gang he was dropped. The cost data for the job are given in Tables XII to XV.

TABLE XII.—AVERAGE COST OF INSTALLING 24,993 ⅝-IN. STYLE 2 TRIDENT METERS ON OLD SERVICE CONNECTIONS AT SAN FRANCISCO, CAL. AUG. 1, 1916, TO APRIL 30, 1917*

	Cost — Total	Per meter	Percentage
1. Labor	$ 21,013.84	$ 0.840	7.90
2. Teaming	2,088.89	0.083	0.79
3. Paving	45,488.48	1.820	17.17
4. Permits	8,934.00	0.357	3.37
5. Material	180,750.16	7.232	68.30
6. Tools	1,202.47	0.048	0.45
7. Miscellaneous	970.96	0.039	0.37
8. Supt., warehouse, etc	4,354.37	0.170	1.65
	$264,803.17	$10.589	100.00

1. Labor: Sub-Foreman, $4.25. Fitters, $3.75. Laborers, $2.50. Eight hours. Average crew consisted of sub-foreman, five fitters, ten laborers and one Ford. Set about 63 meters per day. Meters set per man day, 4.25.
2. Teaming: Horse-drawn vehicles, $1,238.89. Ford auto trucks, $850.
3. Paving: Replacing sidewalks and setting plates at 25c. per square foot. This charge applies only to 19,524 meters set in sidewalks and becomes, per meter paved, $2.33.
4. Permits: Permit to open paved sidewalks at 50c. each. Applies to meters set in paved sidewalks only at 50c. each.
5. Materials:

24,993 meters f.o.b. yard at $5.95		$149,238.55
Concrete boxes	.88	5,197.80
Cast-iron plates	.60 and .65	10,677.74
Meter couplings	.16 to .19	8,244.27
Pipe and fittings		7,391.80
Total		$180,750.16

6. Tools: New tools purchased, $1,149.39. Tools repaired, $53.08.
7. General:

Miscellaneous	$346.44
Carfares	63.65
Machine shop	114.60
Stationery	186.40
Repair sewer vents	170.83
Clean carpets	27.22
Replace lawns	61.82
Total	$970.96

8. Superintendence, employees, insurance, foreman, yard office (proportion), warehouse expense (proportion), auto (proportion of assistant superintendent's and foreman's and all of two sub-foreman's autos, $4,354.37).

* A few larger meters are included as well as a small amount of street paving due to having to shut off at main in some cases. These amounts are practically negligible.

TABLE XIII.—DETAILED COST OF SETTING A ⅝-IN. METER

	Paved sidewalks		Unpaved sidewalks
Labor	$ 0.840 (including testing)		$0.840 (including testing)
Teaming	.083		.083
Paving	2.330		
Plate	.625	Box	.880 (including 0.03 handling car to yard)
Permit	.500		
Material*	6.590 (including meter)		6.590 (including meter)
Tools	.048		.048
Miscellaneous	.039		.039
Superintendent, etc†	.170		.170
Total	$11.225		$8.650

* Meter at $5.95 f.o.b., Bryant St. Yard. † Departmental overhead only as far as assistant superintendent.

Approximately 19,524 meters were set in paved sidewalks and 5,473 meters in unpaved sidewalks. In paved sidewalks there occurs a charge for permit to open sidewalk ($0.50), replacing pavement at $0.25 per square foot, amounting in this case to $2.33 per meter paved, and the cost of a cover either concrete or iron varying from $0.60 to $0.65 each, say $0.625. In unpaved sidewalks these costs do not occur, but there is the cost of a concrete meter box ($0.88). In lawn sidewalks the removal and replacement of sod is equivalent to the cost of breaking up concrete walks.

In the following cost segregation only the difference in paving, materials and permits has been taken into consideration.

TABLE XIV.—SEGREGATION OF LABOR COSTS FOR METER SETTING

Hauling concrete boxes and covers from railroad to yard	$27.62
Unloading meters from wagon to warehouse	16.92
Testing meters	542.11
Installation of meters	19,215.74
Replacing lawns and gardens	28.42
Miscellaneous yard work	118.62
Services of clerks	562.09
Repairs to sewers broken in setting meters	238.92
Cleaning out sewers	44.68
Locating services with wireless pipe finder	105.40
Rearranging services	79.74
Machine shop	33.58
Total	$21,013.84

TABLE XV.—CLASSIFIED RATES OF PAY AND TIME FOR LABOR USED IN SETTING METERS

	Rate	Days	Hours	Amount
Foreman	$4.25	447	..	$ 1,899.75
Fitters	3.75	1,732	..	6,495.00
Helpers	2.75	230	.	632.50
	3.00	220	3	661.12
Laborers	2.50	2,347	6	5,869.37
	2.75	1,198	4	3,295.88
Teamsters	3.00	56	2	168.92
	2.75	63	4	174.63
	4.00	2	3	9.50
Miscellaneous	3.50	2	1	7.44
	3.25	.....	4	1.63
Total		6,299	3	$19,215.74

Cost of Outdoor Meter Installations at Terre Haute, Ind.—The Terre Haute, Ind., Water Co., for outdoor meter installations, has been using recently a pit made of two 2½-ft. 20-in. vitrified sewer pipes with a slot in the bottom of the lower one to fit over service pipes laid some years ago before the present rules concerning the depth of the services were in force. These pipes are provided with a Clark cover and coupling yoke. The cover is 6 in. high, making the total depth of the installation 5½ ft. The average cost in 1918 of an installation of this type including service pipe from the main to the curb was $42.27, according to a paper by Dow R. Gwinn, president of the company, in the January, 1920, Journal of the American Materials Association and abstracted in Engineering and Contracting, Feb. 11, 1920. The itemized cost of the installation as given by Mr. Gwinn is as follows:

Corporation cock, ⅝ in	$1.09
Curb cock, ⅝ in	1.66
Brass tail piece, ¾ in	.38
Extra strong lead service pipe, 3 lb. per foot, 17.1 ft., ⅝ in	3.72
Service box with 2½ in. shaft	1.50
Labor, 10.9 hours at 35 ct	3.82
Labor, 2.2 hours at 40 ct	.88
Drayage $	1.25
City permits	.87
Overhead on tools and equipment	1.30
Total for services	$16.47
Empire meter, ⅝ in	$12.00
Tile, 2	3.70
Clark cast iron cover	2.75
Meter yoke	1.50
Pipe and fittings	.93
Cement	.37
Labor, 5 hours at 35 ct	1.75
Labor, 2 hours at 40 ct	.80
Drayage	2.00
Total for meter and installation	$25.80

Number of Meters Read Per Man Per Day.—The following data are taken from Engineering and Contracting, July 9, 1919.

Judging from a recent tabulation given in the Municipal Journal, there is a wide range of effectiveness of meter readers, even where conditions seem to warrant no such variation. Thus in Los Angeles, with 100,000 "outside" meters, 50 per hour is said to be the average; whereas in Washington, D. C., with 61,000 "outside" meters, 22 per hour is given as the average. The ratio is almost 2½ to 1. Even greater differences exist in other cities as to the number of "inside" meters read per hour.

The number of meters read per hour obviously depends not only upon the efficiency of the men, but upon other conditions such as: (1) The distance from the office to the place where meter reading begins. (2) The distance apart of meters. (3) Whether the meters are inside or outside the building. (4) Whether the readers walk or ride.

The following are typical examples selected from the above mentioned tabulation:

Cities Having Outside Meters

	Number of meters	Average number read per man-hour
Alhambra, Calif	2,100	29
Los Angeles, Calif	99,600	50
San Diego, Calif	15,169	41
Pasadena, Calif	12,547	38
Whittier, Calif	1,951	20
Washington, D. C	61,107	22
Atlanta, Ga	33,000	30
Augusta, Ga	7,500	20
Gadsden, Ala	2,030	60
Lewiston, Ida	1,200	38
Atlantic City, N. J	7,398	40
Oklahoma City, Okla	13,000	28
Portlant, Ore	17,588	30
Memphis, Tenn	19,734	30
Knoxville, Tenn	13,908	67

Average for these 15 cities, 36.

Cities Having Inside Meters

	Number of meters	Average number read per man-hour
Hartford, Conn.	15,451	12
Middleton, Conn.	2,300	11
Concord, N. H.	2,576	20
Elmira, N. Y.	10,032	18
Syracuse, N. Y.	28,133	20
Solvay, N. Y.	990	*15–†20
Worcester, Mass.	20,715	14
Grand Rapids, Mich.	24,530	8
Duluth, Mich.	12,144	15
Minneapolis, Minn.	60,930	10
Akron, O.	26,000	28
Cincinnati, O.	55,000	20
Dayton, O.	30,438	23
Meadville, Pa.	3,376	31
Wilkinsburg, Pa.	15,686	25

Average of these 15 cities, 18.
*Residence. † Business.

Comparing the averages in these two tables, it would appear that twice as many outside meters can be read daily as inside meters.

Cost of Meter Reading at Terre Haute, Ind.—In Engineering and Contracting April 11, 1917, Jay A. Craven describes the methods employed in meter reading at Terre Haute, Ind.

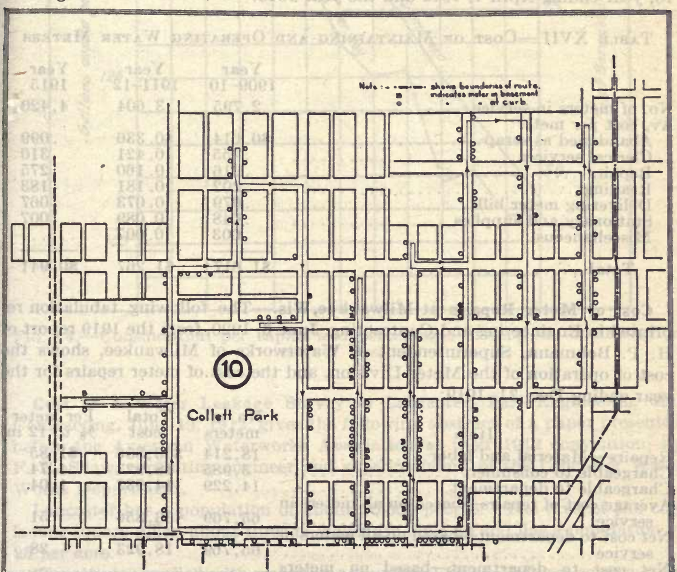

Fig. 13.—Section of large routing map, showing typical route.

A brief outline of the method is as follows. The city is divided into routes with about 200 meters (to be read) on each route. Individual cards for each meter are arranged in proper order in a loose leaf book for each route. At the time the meters are read, a spirit of competition is aroused by having a blackboard record kept showing each reader and the time for completing each book taken out. This record is also transferred to a more permanent form.

The following table is made up of data given by Mr. Craven.

TABLE XVI.—A SUMMARY OF METER READING RECORDS

Month	Total hrs.	Number meters read	Not read	Read per hr.	Cost per meter in cents
Sept	288.25	6,617	297	23	1.7
Oct	254.25	6,805	235	27	1.1
Nov	243.00	6,676	220	27	1.1
Dec.*	347.10	6,703	258	19	3.7*
Jan	291.45	6,672	235	23	1.6
Feb	243.60	6,660	289	27	1.3

* Time shown only represents the time the book was out, and on most of the books, a man accompanied the reader to sweep snow and assist in locating the meters. The cost for this month was exceptionally large.

The best record made was an average of 54 per hour for 4 hours.

Cost of Maintaining and Operating Water Meters.—Table XVII gives the annual cost per meter for the meter system at Reading, Pa. for the years 1909-10, year ending April 1, 1912 and the year 1915.

TABLE XVII.—COST OF MAINTAINING AND OPERATING WATER METERS

	Year 1909–10	Year 1911–12	Year 1915
No. of meters in service	2,795	3,604	4,420
Av. cost per meter:			
Abandoned as scrap	$0.614	$0.336	.099
Clerical services	.455	0.421	.310
Repairs	.216	0.160	.275
Reading	.202	0.181	.183
Delivering meter bills	.079	0.073	.067
Stationary and supplies	.048	0.089	.007
Miscellaneous	.003	0.007	......
Total	$1.617	$1.267	$0.941

Cost of Meter Repairs at Milwaukee, Wis.—The following tabulation reprinted in Engineering and Contracting, June 6, 1920, from the 1919 report of H. P. Bohmann, Superintendent of Waterworks of Milwaukee, shows the cost of operation of the Meter Division, and the cost of meter repairs for the year ending Dec. 31, 1919:

Item	No. of meters	Total cost	Per meter ⅝ to 12 in.
Repairs—Material and labor	18,214	$33,856	$1.85
Chargeable to consumer	3,985	18,923	4.74
Chargeable to department	14,229	14,932	1.04
Average cost of repairs—based on all meters in service	65,769	33,856	.51

Effect of Meters on Consumption of Water.—The effect of meters upon the consumption of water is too well know to need further comment. This effect is graphically illustrated in Fig. 14 which shows the daily number of gallons used per capita in the city of Boston and the percentage of unmetered taps for each year, 1904 to 1916 inclusive. The figure is taken from a paper by Samuel E. Killam, Sup't. of Pipe Lines and Reservoirs of the Metropolitan Water works presented at the 1917 convention of the New England Water Works Ass'n.

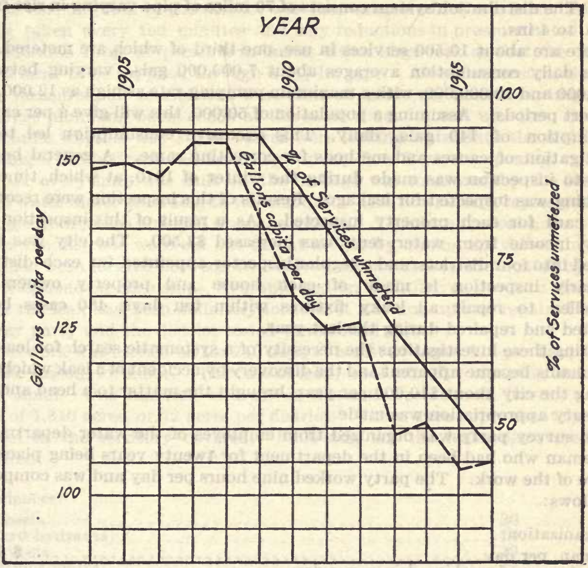

FIG. 14.—Consumption per capita and percentages of services unmetered in city of Boston.

Cost of A Water Leakage Survey at Lancaster, Pa.—Engineering and Contracting, June 19, 1912, gives the following abstract of a paper presented before the American Waterworks Association at their 1912 convention, by F. H. Shaw, consulting engineer and superintendent of the Lancaster Water Works Department.

Lancaster has a population of about 50,000 people. The area of the city is four square miles, about three of which are built up and has a population of 25 per acre.

The city is supplied with water by a municipal plant, the first construction dating back to 1836. The water taken from the Conestoga Creek, a tributary of the Susquehanna River, is filtered and pumped into the city against a head of 250 ft., the supply being measured by a Venturi meter located between the filter plant and the pumping station. The distribution system is connected with the pumping station by two force mains, one 30 in. and one 36 in., each being about one mile in length.

The distribution system is divided into high and low service districts. The low service district contains about 0.4 of a square mile and is supplied from the old reservoir constructed in 1836 and in 1850, which has a capacity of 6,000,000 gals. These reservoirs are filled at night by pumping through the 36-in. main.

The high service district is supplied through the 30-in. main by direct pumping. The water passes through a standpipe having a capacity of 400,000 gals. The distribution system consists of 70 miles of pipe varying in size from 24 ins. to 4 ins.

There are about 10,500 services in use, one-third of which are metered.

The daily consumption averages about 7,000,000 gals., varying between 5,000,000 and 10,000,000, with a maximum pumping rate as high as 12,000,000 for short periods. Assuming a population of 50,000, this will give a per capita consumption of 140 gals. daily. This excessive consumption led to an investigation of causes and methods for correcting same. A general house-house-to inspection was made during the winter of 1910, at which time all plumbing was inspected for leakage. Results of this inspection were recorded on a card for each property inspected. As a result of this inspection the yearly income from water rents was increased $3,500. The city was then divided into four districts, and a regular inspector appointed for each district. A yearly inspection is made of each house and property owners are compelled to repair all leaky fixtures within ten days, 480 cases being reported and repaired during the last year.

During these investigations the necessity of a systematic search for leakage from mains became apparent and the discovery by accident of a leak which was costing the city about $10,000 per year, brought the matter to a head and the necessary appropriation was made.

The survey party was organized from employes of the water department, a foreman who had been in the department for twenty years being placed in charge of the work. The party worked nine hours per day and was composed as follows:

Organization:	
Foreman, per day	$ 3.00
Single team and working driver, per day	2.50
Three laborers, at $1.80 per day	5.40
Total cost per day	$10.90

Outfit:
One 4-in. meter with 2½-in. connections on truck.
One ⅝ in. meter.
One pressure gauge.
Two 25-ft. lengths 2½-in. fire hose.
250 ft. 2½-in. galvanized pipe.
One small tool box.
Picks, shovels, wrenches, caulking tools, lead, wool, etc.

The first step in preparing this work was an inspection of all valves and repairs to same, placing them in working order and replacing some which could not be operated. This work was done by the men in the distribution department in advance of the survey. The survey was started on March 6th, 1911, and stopped for the winter on December 13th. The method of procedure was as follows:

The 4-in. meter was mounted on a small 4-wheeled truck and the connections bushed down to 2½ ins., with a 2½-in. valve at inlet and outlet. The large meter was by-passed by a ⅝-in. meter for use on small flows. A pressure gauge was attached to the outlet end of the large meter. The districts tested had an average area of 12 acres, containing about 80 houses. The district to be tested was shut off from the remainder of the system by closing all valves on street mains. The meter was then connected with a hydrant outside the district by means of a 25-ft. length of fire hose. The 2½-in. pipe line was laid from the meter to a hydrant inside the district, being connected with it by another short length of hose.

The consumption of the district was then measured for one hour, readings being taken every ten minutes and any reductions in pressure noted. Any considerable drop in pressure indicates either large leak or that the district is too large to be supplied through a 2½-in. pipe. After the consumption had been measured, all connections were shut off inside the houses, an inspection of house plumbing being made at the same time. A test was then made to determine whether any street valves were leaking water into the district by opening a fire hydrant and watching for any flow from the opening.

After everything was shut off the leakage was measured by the large or small water meter according to the amount. This flow, if any, represented the leakage from mains and also from the service. To locate the leaks, the streets inside the districts were cut out one at a time by closing the valves until the leak had been located between two valves, after which it was located by using the telephone on curb stops, hydrants and on drills driven down to the main. After the leak had been definitely located, it was dug up and repaired by the survey party and the district tested until found tight.

The work was carried on for 240 days at a cost of about $11 per day, $2,640 for the season, for labor. The cost of lead, wool, etc., for repairing leaks was very small. One hundred and eleven districts were tested, having a total area of 1,310 acres, or 12 acres per district. There were approximately 9,000 houses in the territory covered. Following are the leaks discovered and repaired:

Residences:		
Closets	20	
Yard hydrants	10	
Faucets	19	
Service mains	17	
		66
Street valves	12	
Fire hydrants	35	
Street mains	29	76
Total		142 leaks

The leaks varied from 1 to 19 cu. ft. per minute. The largest leak found was a 3-in. elbow split wide open and running at the rate of 205,200 gals. per day. This line had been by-passed around the meter outside the building and was supplying four buildings. In this case the survey not only stopped the leak, but detected the illegal use of water. This leak amounted to 75,000,000 gals. per year, the actual cost of furnishing which was $2,812.50, or $172.50 more than the cost of the entire survey.

The total mileage of mains inspected was 40.8, varying in size from 4 ins. to 24 ins. The total leakage record was 118 cu. ft. per minute, or 1,271,000 gals. per day. Using $37.50 per 1,000,000 gals. as the actual cost of furnishing water exclusive of interest, the total leakage was costing the city about $17,000 per year.

About one-quarter of the system remains to be tested, also the 20-in. supply main which runs directly across the city. One mile of 36-in. force main laid in 1888, was tested by closing the valves at both ends, and supplying it from the other force main through a smaller meter. Leakage was found amountting to $2,000 per year.

A comparison of the consumption before and after the survey shows a decrease of 10,000,000 gals. per month during March and April, an equal consumption from May to September, a decrease of 8,000,000 gals. per month during October and November, a decrease of 24,000,000 gals. during December and an increase of 20,000,000 gals. during January, February and March. While the present consumption is about equal to that before the survey began, the consumption for 1911 is slightly less than for 1910.

Mr. Shaw considers the decrease of 24,000,000 gals. per month shown in December a fair indication of the results of the survey, as abnormal conditions existed before and after this time, which had a tendency to increase the consumption.

As an investment he believes a survey of this kind, which not only locates but repairs leaks, is a good one and well worth following up until one is assured that the distribution system is reasonably tight.

Cost of Concrete Siphon on the Los Angeles Aqueduct.—D. L. Reaburn, Engineer Saugus Division, Los Angeles Aqueduct gives the following data in an article in Engineering and Contracting, July 3, 1912.

Whitney Siphon, about 28 miles north of Los Angeles, has a slant length of 955 ft. and a maximum head of 70 ft. The pipe is 10 ft. interior diameter, with a uniform thickness of 9 ins. The reinforcement consisted of round rods. The circumferential rods were spaced 4 ins. apart, and varied from ⅝ in. to ¾ in. in diameter. A working strength of 15,000 lbs. per square inch was used, and the rods were designed to carry the total stress, regardless of the strength of the concrete. The longitudinal rods were ¾ in. in diameter and they were spaced about 2 ft. c. to c.

The trench was excavated with teams and trimmed to shape by hand. It had a bottom width of 14 ft. with slopes of about 1 on 1. Care was taken to have most of the dirt placed on one side of the trench. This was leveled off for about 30 ft. from the edge of the trench, so as to give sufficient elevation to the mixer for delivery of the mixed concrete by gravity, to provide room for gravel and cement storage near by, and also to allow the mixer to be moved along as the work progressed.

After the trench was excavated to line and grade the first operation in the construction of the siphon was setting the concrete blocks to support the inner forms. These blocks, which were 4 ins. thick, 10 ins. wide and about 12 ins. high, had been made a few weeks previous to allow ample time for hardening. The tops were cast to fit the curve of the inner forms. They were spaced 6 ft. apart in two parallel rows, so that each pair supported a 6 ft. length of the inner forms. They were set in mortar a few days before the forms were placed on them. This arrangement not only insured correct alignment and grade, but permitted the concrete to be readily poured and thoroughly spaded. The concrete blocks became a part of the concrete shell of the siphon.

The next step was the setting of the inner forms, which were of wood and not very satisfactory, as it was difficult to maintain them in a circular shape after they were once moved. Each 6 ft. length of forms was made up of eight sections, three below the horizontal diameter and five above it, braced and bolted in such a way that they could be collapsed for moving ahead (See Fig. 15). Each section was made of four ribs cut to the proper curve, on which the 2 in. lagging was nailed. The lagging was dressed on the outer side. The arrangement of the cross braces which held the sections in place permitted the dismantled sections to be moved ahead through those already erected, by means of a platform car on a track which rested on the cross ribs of the bottom section. The car was pulled back and forth with a rope.

In conjunction with the setting of the inner forms the reinforcement rods were placed on them, having been previously bent to the required circle with a small bending machine, and properly spaced, wired and blocked away from the forms. After the inner forms were assembled, circular ribs were placed to support the outside lagging. These were spaced 4 ft. apart and braced against the side of the trench. The outside lagging was 2 × 6 × 4 ins. The concrete work was commenced near the middle and carried first toward one end and later toward the other. There were 120 lin. ft. of inner forms used. They were set up by a crew of 8 men.

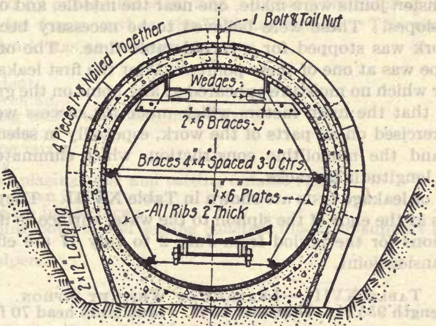

FIG. 15.—Section showing forms used in constructing Whitney Siphon.

When everything was in readiness one of the regular tunnel concrete crews of 26 men and a foreman was detailed to the work. From 36 to 40 men were required to keep the work going continuously. The concrete was delivered on top of the forms through a chute, and flowed to the bottom over them. The outside lagging was placed about 2 ft. high at the start, to allow room for inspection and spading on the bottom. As the concrete rose in the forms, more lagging was placed. The bottom of the trench was filled for the whole length of the day's run and the complete pipe was finished the same day, whether it was 30 ft. or 50 ft. A rough connection was made by means of a sand bag bulkhead, and particular pains were taken to ensure a good bond at this point. About three days were required to complete the 120 ft. of pipe. About noon of the second day the work of taking down the inner forms and moving them ahead was begun, without interfering with the progress of the concreting. In about 24 hours the outer forms were removed and the pipe was immediately backfilled and thoroughly flooded for about a week. When the foot of the steep slope was reached the mixer was moved to the top of the slope and the work continued in the same way until the top was reached. At each end of the siphon a manhole 30 × 36 ins. was constructed.

Electrical energy was used for light and power and water was supplied under pressure from a large tank on the adjacent hill. Sand and gravel were obtained from the adjacent creek without screening. All stone larger than 3 ins. was rejected. The mix was 1:4 or 1 bbl. of cement to 16 cu. ft. of concrete. About 20 per cent of water was used, which insured a very wet mix.

No serious difficulties were encountered in carrying out the work. As the work was done during flood season, Whitney Creek carried considerable water and the excavation was a little more costly owing to the construction of the necessary protecting dams to prevent flooding the trench. At the lowest point, where the creek crosses the siphon, the top was paved with cobble while the concrete was soft, as a precaution against scour in flood season.

At the lowest point on the siphon a special cast iron pipe with a flange moulded to fit the inner side of the pipe was placed. This connected through a 10 in. valve in the blow off chamber to the blow off pipe which consisted of second-hand 12 in. vent pipe embedded in concrete. The inside of the pipe was finished with two coats of neat cement wash put on with a brush.

Three expansion joints were made, one near the middle, and one at the foot of the steep slopes. These were believed to be necessary because at these points the work was stopped for a considerable time. The only noticeable leak in the pipe was at one of these points. After the first leakage test it was repaired, after which no moisture appeared at any point on the ground surface. It is believed that the main factors which made for success were the painstaking care exercised on all parts of the work, especially in selecting the sand and gravel, and the monolithic construction, which eliminated the danger of developing longitudinal cracks.

The results of leakage tests are shown in Table XVIII. They are based on measurements at the ends of the siphon to the water surface as it was lowered. The observations for the period from July 2 to July 17 are effected by the defective expansion joint.

TABLE XVIII.—LEAKAGE OF WHITNEY SIPHON.
(Length 955 ft. Diameter 10 ft. Maximum head 70 ft.)

Period.	1910.	Leakage, gals. per day
16 days	July 2—July 17	4,146
32 days	Sept. 30—Nov. 1	165
10 days	Nov. 1—Nov. 11	135
20 days	Nov. 11—Dec. 1	132
44 days	Dec. 1—Jan. 13	356

Remark.—The leakage shown for the last period indicates that someone had tampered with the blowoff. This is borne out by the fact that the padlock on the cover of the blowoff chamber was found broken.

TABLE XIX.—COST OF WHITNEY SIPHON.

Item	Per lin. ft.
Excavation	$ 5.47
Concrete lining	8.33
Steel in place	3.82
Backfill	2.63
Engineering	0.13
Anchorage proportion	0.14
Blowoff proportion	1.28
Average cost per lin. ft. completed section	21.80
Average labor cost mixing and placing per lin. ft	2.14
Average labor cost placing steel per lin. ft	0.83
Average cost per ft. for forms	1.20

(As there are about 0.78 cu. yd. of concrete per lineal foot of this siphon any of the above items multiplied by this sum gives cost per cubic yard of concrete.)

South Antelope Siphon.—The Antelope Valley Siphon is about four miles long with a maximum head of 200 ft. It is a composite structure, composed of 3,446 ft. of 10 ft. reinforced concrete siphon on the south end and 2,734 ft. on the north end, while the middle portion is of steel. The maximum head on the concrete pipe is about 75 ft. The ground slope is very uniform and level transversely, making an ideal condition for construction.

The excavation for the pipe was taken out to a depth of 8 or 9 ft. with a model No. 20 Marion steam shovel. About two-thirds of the dirt was placed on one side and the remaining one-third on the side from which concreting was carried on.

Construction on the south end was commenced July 7, 1911, at the conduit end and completed Sept. 2, 1911.

The average progress was 44 ft. per day. After the first week a rate of 40 ft. was maintained for about 20 days, after which a uniform rate of 49 ft. per day was made until completion.

The inner forms were of wood built up in sections about 20 ins. wide and 4 ft. long, supported by collapsible steel ribs. These were much more satisfactory than the wooden forms used on the Whitney siphon. The working force on the concrete work was as follows:

1 superintendent.
1 concrete foreman.
6 men charging mixer with wheelbarrows.
1 man on cement.
1 man running mixer.
5 men placing.
6 bending and placing steel and setting outside ribs.
4 men taking down inside forms.
4 men setting up inside forms.
1 man trimming bottom and setting concrete blocks to support inner forms.
2 plasters.
2 plasters' helpers.

32 men, total.

The average rate of pay for this force was about $2.75 per day, or a labor cost of $2 per lineal foot on the basis of 44 ft. progress for mixing and placing, moving and setting forms and finishing.

Rock for a large part of the work was hauled 7½ miles from a plant in the hills and the average haul for sand was 1½ miles. Cement and steel was hauled by teams from Lancaster on the Southern Pacific R. R., a distance of 36 miles. Monolith Tufa cement manufactured by the city of Los Angeles, was used in the ratio of 7 sacks per cubic yard of concrete. The details of cost for the 3,446 ft. of pipe are as follows:

	Per lin. ft.	Per cu. yd.
Excavation	$ 0.94	.....
Sand and gravel	0.606	$0.45
Rock	3.07	2.32
Cement	5.80	4.37
Mixing and placing	0.91	0.69
Moving forms	0.62	0.47
Plastering	0.26	.....
Steel in place	4.30	.....
Backfill	0.39	.....
Engineering (instrument work)	0.04	.....
Superintendence	0.26	.....
Total per lin. ft.	$17.20	.....

The above does not include the cost of forms, which will be distributed at the completion of all work on which they are used. It will approximate $1 per ft.

Cost of Reclamation Service Concrete Siphons.—The following data are taken from Engineering and Contracting, March 15, 1916.

No record is had of the number of siphons constructed by the Reclamation Service. Including those of small size it is large. The siphons of major size are few, however, and those selected as examples represent construction practice adequately.

Belle Fourche Siphons.—There was built three siphons on this project: One 8 ft. in diameter and 477 ft. long; one 6 ft. in diameter and 395 ft. long, and one 5 ft. in diameter and 3,565 ft. long. Fig. 16 shows a section of the 8-ft. siphon the sections for the smaller siphons were similar. A 1:2:4 machine-mixed concrete was used; sand being screened to pass a ¼-in. screen and stone being

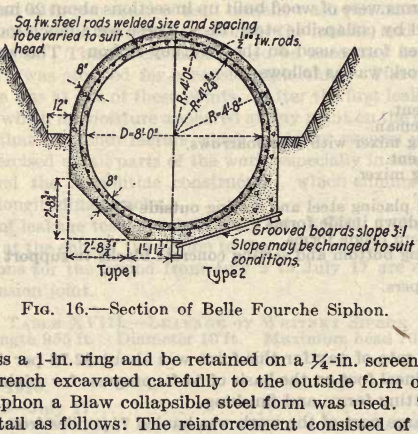

Fig. 16.—Section of Belle Fourche Siphon.

screened to pass a 1-in. ring and be retained on a ¼-in. screen. All siphons were built in trench excavated carefully to the outside form of the siphons. For the 5-ft. siphon a Blaw collapsible steel form was used. This siphon is recorded in detail as follows: The reinforcement consisted of 304,956 lb. of twisted steel bars; cost per pound Belle Fourche 2.4 ct., plus cost for hauling and storing of ½ ct. per pound. Cement at Belle Fourche cost $2.15 and $2.43 per barrel; hauling and storing cost, $1.28 per cubic yard of concrete. Cement hauled 16 miles; gravel hauled 1 mile. Wages per 8-hour day averaged $2.44 one foreman at $2.25 and one at $100 per month. Weather conditions favorable. Costs of concrete work alone were:

Item:	Per cu. yd.
Preparatory expenses	$0.30
Plant depreciation	0.43
Administration	1.03
Engineering	0.29
Superintendence	0.42
Inspection	0.06
Camp maintenance	0.32
Water work	0.28
Blacksmith and carpenter shop	0.26
Total general	$3.39

Item:	Per cu. yd.
Crushing and screening	$1.40
Hauling gravel and sand	0.50
Building (including lumber) wood forms	0.84
Hauling lumber for forms	0.18
Erecting steel forms	0.47
Miscellaneous	0.32
Cleaning reinforcement	0.08
Bending and welding	0.30
Mixing concrete	0.53
Placing concrete	0.42
Finishing and watering	0.22
Total labor	$5.26
Cement	$3.67
Steel	3.26
Hauling and storing cement	1.28
Hauling and placing steel	0.73
Miscellaneous	0.30
Total	$ 9.24
Rent of steel centering	0.86
Miscellaneous supplies	0.17
Total concrete	$18.92

The distribution of labor and materials costs it will be noted is not precise and totals for these items are therefore slightly in error; final total is accurate. The total cost of the concrete work proper was $41,929; the total cost of the siphon, including excavation, filling equipment, etc., was $59,310. Costs recorded in 1908; reported by U. S. Reclamation Service.

Sun River Siphon.—This work was a reinforced concrete siphon 1,568 ft. long, inside diameter 5 ft. 3½ in., with concrete piers and intake built for Sun River project U. S. Reclamation Service. Concrete, 613 cu. yd. in siphon and 272 cu. yd. in piers and intake, 1-2-4 mixtures. Wages were per eight-hour day for laborers, $2.24 to $2.74, two foremen at $125 per month, one carpenter foreman at $5.50 per day and carpenters at $3.50 per day. Cement cost $5.60 per barrel and reinforcing steel 4.12 ct. per pound, delivered. Work done by day labor; weather favorable. Sand and gravel hauled 2 miles; cement and reinforcing steel hauled 27 miles. Forms collapsible steel; progress 18 lin. ft. per day. Costs covering concrete work only were:

Item:	Per cu. yd.	Per cu. yd.
Amount of concrete, cu. yd	Pipe, 613	Piers, etc., 272
Engineering	$ 2.09	$1.57
Superintendence	1.26	0.95
Preparatory expenses	0.38	0.67
Administration	3.47	2.61
Camp maintenance	0.96	1.09
Total general	$8.16	$6.89
Hauling sand and gravel	2.91	2.85
Handling cement and steel	0.27	0.30
Hauling, wood, water and miscellaneous	0.26	0.40
Pumping	....	1.85
Making forms	1.85	2.03

Building trestle	0.25	.....
Total labor	$11.69	$10.50

Item:	Per cu. yd.	Per cu. yd.
Lumber	1.41	1.59
Steel	4.10	4.06
Cement	6.35	4.90
Total materials	$11.86	$10.55
Steel forms and supplies	0.81	.....
Installing and removing plant	0.28	0.21
Depreciation	0.47	0.52
Miscellaneous	1.32	1.49
Corral expenses	0.40	0.45
Total supplies	$ 3.28	$ 2.67
Total concrete	$34.99	$32.16

There were 1,254 ft. of tile underdrain which cost 81 ct. per lineal foot, and charges for excavation, backfilling rip-rap, survey and design, depreciation of buildings aggregating about $7,000, making the total cost of the siphon $23.49 per lineal foot. Costs recorded in 1907–8; reported by U. S. Reclamation Service.

Salt River Siphons.—Two twin-tube siphons were constructed, one under Pinto Creek 2,130 ft. long under 35 ft. head and one at Cottonwood Canyon 250 ft. long under a head of 76 ft. A cross-section of one of the Pinto Creek tubes is shown by Fig. 17. The concrete was a 1:2½:4 mixture, mixed wet by hand. The novel feature of the work was the use of a traveling form.

The forms consisted of an outside form constructed as shown by Fig. 17, by inserting 2½-in. × 5½-ft. lagging strips in the metal ribs. The inside form was designed to permit continuous work by moving the form ahead as the concreting progressed. It consisted as shown by Fig. 17, of an invert form on which an arch form was carried on rollers. The invert form was pulled along by cable from a horse power whim set ahead, being steered, aligned and kept to grade by being slid on a light wooden track. It had the form of a long half cylinder, with its forward end beveled off to form a scoop-like snout. The arch center consisted of semi-circular rings 2 ft. long, set one at a time as the work required. Each ring, when set, was flange-bolted to the one behind, and each was hinged at three points on the circumference to make it collapsible. In operation, the invert form was intended to be pulled ahead and the arch rings to be placed one after another in practically a continuous process. So that the arch rings might continue supported after the invert form was drawn out from under them, invert plates similar to the arch plates were inserted one after another in place of the shell of the invert form. The plan provided very nicely for continuous work, but continuous work was found impracticable for all but about 2,500 ft. of the 6,000 ft. of conduit built. The reason for this seems to have been at least in a great measure, the slow setting cement made at the cement works established by the Government, at Roosevelt. In building the first 300 ft. of conduit, a commercial cement was used and a progress of 120 lin. ft. of pipe per 24 hours was easily made. This work was done in June. Later, but still in warm weather, using the Government cement and 70 ft. of arch plates, not more than 70 ft. of pipe could be completed in 24 hours; if the plates were taken down sooner, patches of concrete fell out or peeled off with them. As the weather grew colder, this difficulty increased, until finally, the idea of continuous work was abandoned and for some 3,500 ft. of conduit only one 8-hour shift per day was worked. In December and January the plates had to remain in place three days, so that the progress was only 24 ft. per day; in warm weather this rate was increased to 40 ft. per day.

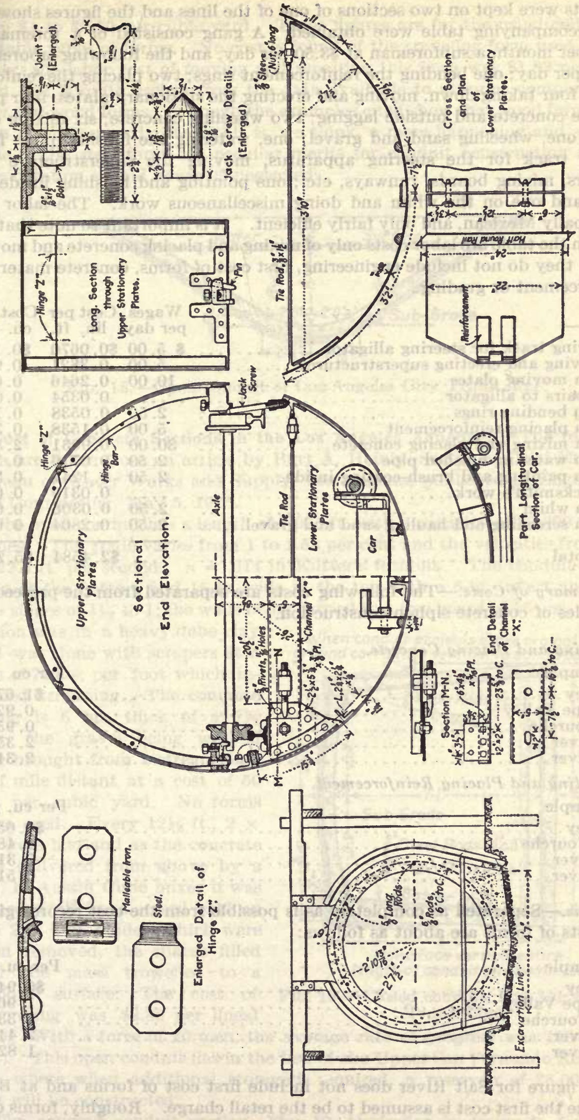

FIG. 17—Section of and detail of traveling form for Salt River Siphon.

Costs were kept on two sections of one of the lines and the figures shown in the accompanying table were obtained. A gang consisted of a foreman at $175 per month, a subforeman at $3.50 per day, and the following laborers at $2.50 per day; one bending the reinforcement rings; two placing the reinforcement; four taking down, moving and erecting the stationary plates; four placing the concrete and outside lagging; two wheeling concrete; six mixing concrete; one, wheeling sand and gravel; one, watering the finished pipe; four, laying track for the steering apparatus, moving the superstructure and hangers, mixing boards, runways, etc.; one pointing and finishing inside the pipe; and one on the whim and doing miscellaneous work. The labor was principally Mexican, and only fairly efficient. It is important to note that the costs in the table are labor costs only of mixing and placing concrete and moving forms; they do not include engineering, first cost of forms, concrete materials, reinforcement or grading.

	Wages per day	Cost per lin. ft.	Cost per cu. yd.
4 men—			
Laying track for steering alligator	$ 5.00	$0.0670	$0.16
Moving and erecting superstructure	5.00	0.3821	0.93
4 men moving plates	10.00	0.2646	0.65
Repairs to alligator	......	0.0354	0.08
1 man bending rings	2.50	0.0538	0.13
2 men placing reinforcement	5.00	0.1538	0.38
12 men mixing and placing concrete	30.00	0.9631	2.34
1 man watering finished pipe	2.50	0.0716	0.17
1 man painting and brush-coating inside	2.50	0.1241	0.31
Blacksmith's work	....	0.0319	0.08
1 man whim	2.50	0.0306	0.07
1 man screening and hauling sand and gravel	2.50	0.2804	0.68
Total	....	$2.4584	$5.98

Summary of Costs.—The following costs are separated from the preceeding examples of concrete siphon construction.

Mixing and Placing Concrete.

Example	Per cu. yd.
Whitney	$1.67
Antelope Valley	0.92
Bell Fourche	0.95
Sun River	2.35
Salt River	2.34

Bending and Placing Reinforcement.

Example	Per cu. yd.
Whitney	$0.65
Belle Fourche	1.48
Sun River	0.31
Salt River	0.51

Forms.—Separated as completely as is possible from the cost records given the costs of forms are about as follows:

Example	Per cu. yd.
Whitney	$0.94
Antelope Valley	1.96
Belle Fourche	1.33
Sun River	2.44
Salt River	1.82

The figure for Salt River does not include first cost of forms and at Belle Fourche the first cost is assumed to be the retail charge. Roughly, forms cost from $1 to $2.50 per cubic yard. These figures are for the usual collapsible portable types of forms. No cost is found of the traveling form used at Salt River; the labor cost of moving and repairing this form was $1.82 per cubic yard. It is quite useless from the data available to attempt comparison of steel and wood forms. Though the examples cited show that wood forms have been most frequently used, this is, we think, a mere happening and signifies little. The steel form has peculiar merits for conduit construction and its consideration should never be neglected.

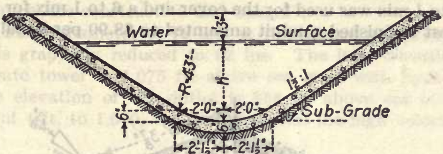

Fig. 18.—Open conduit of Los Angeles City Trunk Line.

Cost of Concrete Sections in the Los Angeles Aqueduct.—The following data are taken from an article by Burt A. Heinly, Secty. to Chief Engineer, Bureau of Water Works and Supply, Los Angeles, published in Engineering and Contracting, May 5, 1915.

The open conduit has a length of 7,975 ft. with a capacity of 20,000 miner's inches. The grade varies from 1 to 2.58 per cent and the velocities from 15.6 to 22.3 ft. per second. $n = .014$ in Kutter's formula. The conduit is 4 ft. wide at the bottom and 15 ft. wide at the top with a 6-in. invert and with side slopes of 1½ to 1; the walls being carried to a free board of 15 ins. Excavation was in a heavy dobe clay and was done with scrapers at a cost of 70 cts. per foot which included trimming. The concrete lining is 6 ins. thick of a 5½ mix, the gravel being washed and brought from a stream one-half mile distant at a cost of 50 cts. per cubic yard. No forms were used. Every 12½ ft., 2 × 6's were laid and as the concrete was delivered from above by a No. 11 Austin Cube mixer it was screeded off by a screed held on the 2 × 6-in. guides, which were then removed, the spaces filled and the mass trowelled to a smooth surface. The cost of concreting was $2.80 per lineal foot. With a force of 20 men, the average rate of progress was 150 ft. per day. This open conduit lies in the bed of the Upper San Fernando Reservoir site, where when additional storage is required, a reservoir of 23,000 acre-feet will be constructed.

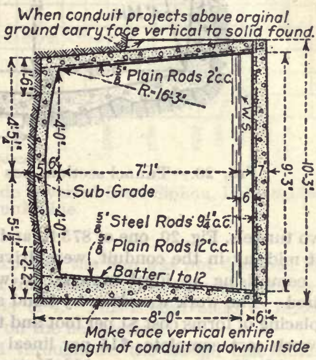

Fig. 19.—Closed conduit, Los Angeles City Trunk Line.

The covered conduit section, Fig. 19, is similar in design to Aqueduct covered conduit sections but is smaller. The depth is 8 ft. 1 in. and the width 8 ft. at the bottom to 9 ft. 3 ins. at the top, with a batter of 1 to 12. On the reservoir side of the conduit, the outer face of the lining was made vertical. Side walls are of a minimum thickness of 6 ins., the bottom 9 ins. and the cover from 6 ins. at the sides to 7 ins. at the center. Reinforcement of sidewalls on the hill side is of ⅝-in. plain rods spaced 2 ft. center to center, and on the reservoir side, ⅝-in. rods spaced 1 ft. center to center. The cover is reinforced by ⅝-in. square twisted rods, placed 9 ins. center to center, and is designed to carry a load of 300 lbs. to the square foot with a factor of safety of 4. A 5½ to 1 mix was used for the cover and a 6 to 1 mix for side and bottom. The cost of finished conduit amounted to $8.90 per lineal foot.

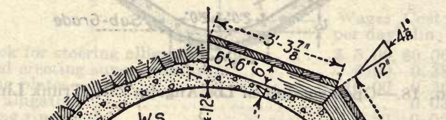

FIG. 20.—Tunnel section, Los Angeles City Trunk Line.

Two tunnels, Fig. 20, one of 875 ft. and the other of 700 ft. which are located about midway in the conduit, were driven through an indurated gravel and clay, comprising an ideal material in which practically no timbering was required. The work was done by hand at a cost of $7.50 per foot. Making and placing of forms cost $1 per foot and the concreting $6.50 per foot, making this work cost complete, $15 per lineal foot. The tunnels have a slope of .0009, with V = to 5.8, n = .014 Kutter's formula. The sidewalls are on a batter.

Construction Quantities.—Per linear foot of tunnel normal section: Excavation, (timbered) 3.10 cu. yds., (untimbered) 2.73 cu. yds.; concrete, (timbered) 0.83 cu. yds., (untimbered) 0.69 cu. yds.; timbers, 15 B. M.; spreaders, 5 B. M.; shoulder braces, 7 B. M.; lagging, 48 B. M.

The regular rate for day labor on this work was $2.50 per 8 hour day.

Cost of the San Fernando Inverted Steel Siphon, Los Angeles Aqueduct.—The following data are taken from an article in Engineering and Contracting, May 5, 1915, by Burt A. Heinly.

The San Fernando Inverted Steel Siphon carries the aqueduct across the San Fernando Valley a total distance of 63,327 ft. under a maximum working head of 260 ft. to the crest of the Santa Monica mountain range which hems the valley on the south. This siphon, a profile of which is shown in Fig. 21, comprises the most difficult and expensive part of the City Trunk Line. It required 8,260 tons of steel for its fabrication and is a noteworthy example of pipe line construction and design.

From an inside diameter of 72 ins. at the inlet, the siphon, as diversions are made, is gradually reduced to 62 ins. The inlet elevation at the San Fernando gate tower is 1,075 ft. above sea level with hydraulic grade at 1,134. The elevation of the outlet is 854 ft. above sea level. With the steep slope of 4 ft. to 1,000, the siphon carries the high velocity of 8 ft. per

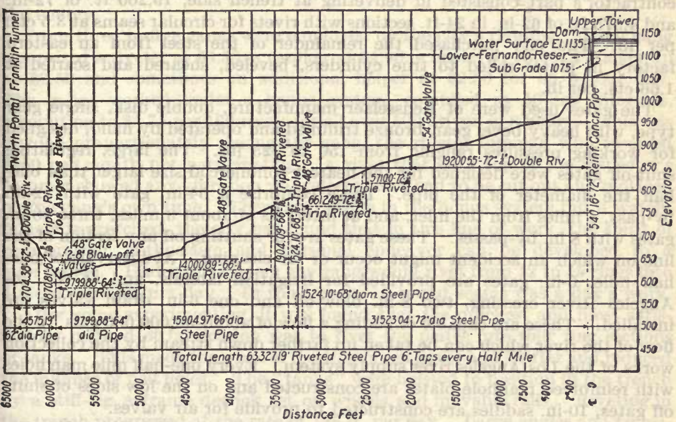

FIG. 21.—Profile of the San Fernando Inverted Steel Siphon, Los Angeles City Trunk Line.

second. On account of the high expense, the line was not designed for full static pressure but is constructed for full pressure up to the maximum hydraulic grade line with a maximum safety of 4. This is equivalent to 15,000 lbs. per square inch maximum pressure on the net section.

Single sheet construction is used throughout, the design and fabrication following the methods employed on the 21 steel siphons of the Los Angeles Aqueduct. The line was designed and built of lap joints of alternate inside and outside sections, the plates being 69 ins. long. All rivets were cone headed: ⅝-in. rivets were used on the ¼-in. and 5/16-in. plates with 11/16-in. open holes; and ¾-in. rivets for the ⅜-in. plate with 13/16-in. open holes. Riveting followed the Hartford Boiler Standard specifications with the efficiency of the joints having a maximum of 72 per cent.

The steel for both plates and rivets was all made by the basic, open hearth process, the quantities, diameters, riveting, etc., being as follows:

Length, ft.	Diameter, ins.	Thickness, ins.	Longitudinal riveting
19,200.55	72	1/4	Double
5,710.00	72	1/4	Triple
6,612.49	72	5/16	Triple
1,524.10	68	5/16	Triple
1,904.09	66	5/16	Triple
14,000.89	66	3/8	Triple
9,799.88	64	3/8	Triple
1,870.81	62	5/16	Triple
2,704.38	62	1/4	Double
63,327.19			

As the time was an important element, the work was divided so that a local contracting firm did part of the work, and the city the remainder. The contractor's part consisted in delivering at trench side, 19,200 ft. of 72-in. and 4,575 ft. of 62-in. in 24-ft. sections with rivets for circular seams at 3.5 cts. per lb. The city purchased the remainder of the steel from an eastern factory in plates rolled to true cylinders, beveled, sheared and scarfed at 1.66 cts. per lb.

The gates used were of Rensselaer manufacture, double disk, single gear type, with heavy bevel gear, bronze trimmed and operated by hand, designed for working pressures ranging from 150 to 225 lbs. The large, regulating shut-off gates were designed for the nearest commercial size larger than one-half the diameter of the pipe. These comprise a 54-in. gate with 12-in. by-pass, 4 miles from the inlet, and at intervals of about 3 miles, three 48-in. gates with 8 in. by-passes. These gates are for shutting off any section of the line on which an accident might occur or for cleaning. At intervals of one-half mile, 6-in. gates are provided for irrigation laterals, and at the Los Angeles River crossing, two 8-in. blow-off and one 6-in. drain valves are installed. These are capable of adding a flow of about 50,000,000 gals. to the flow of the river which can be taken up farther down stream by the collection works of the Los Angeles river supply system. Every one-half mile man holes with reinforced manhole plates are constructed and on the low sides of shut-off gates, 10-in. saddles are constructed to provide for air valves.

The work of construction, as is the rule of the Los Angeles Water Department, was accomplished by its own laboring force under the direction of its own engineers.

The excavation was done with two Model 40 Marion steam shovels of 3/4-cu. yd. and 1 1/4 cu. yd. capacity. Each was equipped for this particular kind of work with an extra long boom 25 ft. in length. The aim was to have the top of the pipe a minimum of 3 ft. below the surface of the ground. This made the depth of ditch range close to 9 ft., the width being as narrow as the shovel could dig, or from 10 to 11 ft. Excavation was in an ideal formation of sandy loam that stood without cribbing excepting in a few instances. Shovel crews in an eight hour day accomplished from 85 to 190 lineal feet, the average cost of trenching ranging from 25 to 30 cts. per foot. Shovel runners were paid $150 per month; cranemen, $115; firemen, $75 per month, and pit-men $2.50 per day. The shovels worked 6 days per week, the crews over-hauling the shovel on the seventh without allowance for overtime. Back-filling was with Fresnos at the rate of 150 ft. per day for each gang, teamsters being paid $2.50 per day. The cost of this item averaged 18 cts. per running foot.

As stated, the contractor was required to deliver the pipe in 24 ft. sections at the side of the trench. He found it cheaper to rivet into single sections in his shop, then rivet four sections into a tank, or 24 ft. length of pipe, on the ground, air being sold to him for this purpose by the city. With the city it was necessary to unload the nested, unriveted plates and do all the work of riveting, both circular and longitudinal at the side of the trench. For this purpose the equipment comprised three compressor stations situated at points near the inlet, middle and outlet of the siphon with air lines of 2-in. and 4-in. inside diameter standard screw pipe. The longest delivery was one of 26,000 ft., through 4-in. pipe. Air compressors used were one Clayton 2-stage tandem of a capacity of 200 cu. ft. of free air per minute under 100 lbs. pressure, driven by a 75 hp. Westinghouse motor, and two 2-stage Ingersoll Rand No. 10 Imperials, each of a capacity of 700 cu. ft. of air per minute under 100 lbs. pressure driven by 100 hp. General Electric motors. Transmission lines of the Southern California Edison Co. in the vicinity were tapped to supply the energy.

From three to five gangs were employed on the city's riveting. Each gang comprised a riveter at $3.50, a caulker at $4.00. a heater at $3.00, a bucker-up at $2.50 and sometimes an additional helper at $2.50 for an 8-hour day. The gangs worked under a bonus system, compiled at 10-day intervals, amounting to $1.75 per 100 rivets for all over 500 driven in 8 hours. This was divided proportionately among the gang, the riveter foreman who received $150 per month not participating. A rivet that on a tap of the inspector's hammer showed any vibration was rejected and had to be cut out and replaced on the gang's own time. There are defects in the bonus system but if watchfulness is exercised, the city has found that in this line of work, the spirit of co-operation, enthusiasm and personal endeavor can be developed to a high degree. Under this system one gang would rivet from 12 to 15 rings into 4-piece sections in a day. In the trench, 10 round seams was a day's work.

After some experimenting, it was found that the quickest and most satisfactory method of fabrication was to rivet the plates into four ring sections or tanks. This made the work of riveting much easier and swifter and reduced the number of bell holes. The "tanks" were hoisted to position in the trench by a stiff-leg A-frame derrick set on wheels and movable rails. Riveting in the trench progressed at the rate of 125 ft. per day. Large angles and transitions were shop made but on small bends, no special construction was required, the plates being simply cut and beveled. On curves where the radius was equal to or larger than a 6° railroad curve, it was found that the situation could be handled by a little reaming of the rivet holes. The pipe was all laid with the longitudinal seams uppermost, as it has been found by experience that most of the leaks occur where the three thicknesses of steel come together and they are thus made easy of access for recaulking.

In painting, coal gas and water gas tars were used. A coating of the latter which is much thinner than coal tar and of high penetrating qualities was first applied and then on succeeding days, two coats of coal tar both inside and out. No heating was required in the summer months but was necessary with the approach of autumn and winter temperatures. Painting was done at trenchside with brushes. After the pipe was laid, another coat was applied to all round seams and to any abrasions. Comparison of expense with patented preparations is to be noted from the fact that coal tar cost 11 cts. per gallon and gas tar 10 cts. per gallon laid down on the ground in carload lots.

The department after having had three years of tests of these materials on the exposed aqueduct siphons finds them an effective substitute for the higher priced coatings.

The transitions at both ends of the siphon consist of blocks of heavily reinforced concrete, covering the pipe to a depth of 2 ft. on all sides for a lineal distance of 8 ft. which serve as anchorages to hold the pipe in place.

Cost of Steel Section of Antelope Valley Siphon, Los Angeles Aqueduct.—The followig data are from an article by William W. Hurlbut published in Engineering Record, July 19, 1913.

The steel, or middle portion of the Antelope Valley siphon, was furnished by the Riter-Conley Manufacturing Company, rolled and punched at a cost of $1.50 per hundredweight f.o.b. factory at Leedsdale, Pa., or $2.30 per hundredweight laid down at Mojave, Cal., the distributing point for this work. The plate was shipped nested in order to obtain the minimum rate for carload lots. The plate is of the lap-joint type, the inside rings being 10 ft. in diameter.

Table XX gives lengths and weights and safe heads of each thickness of metal.

TABLE XX.—STEEL-PLATE DATA

Thickness	Safe head, feet	Length feet,	Weight, pounds
¼-in. double-riveted	100	2,690	938,810
¼-in. triple-riveted	144	4,559	1,609,440
5/16-in	180	3,698	1,626,920
⅜-in	210	4,650	2,648,970
Total		15,597	6,648,970

Table XXI gives the schedule for siphon work for a typical riveting crew of four men.

The world's record for field-driven rivets was made on the erection of this pipe, one man driving 1650 ⅝-in. rivets in one eight-hour shift.

TABLE XXI.—BONUS RATE FOR RIVETING CREW

Mechanic, Each per shift	Size of rivet, in.	Wages, per day	Base rate, per shift	Crew bonus, cents per rivet	Per cent of bonus per man per shift
Riveter	⅝ ¾	$3.50	500 400	1½ 1¾	30
Heater	⅝ ¾	3.00	500 400	1½ 1¾	30
Bucker	⅝ ¾	2.75	500 400	1½ 1¾	20
Sticker	⅝ ¾	2.50	500 400	1½ 1¾	20

The compressor plant was located in the center or 1½ miles from each end of the pipe. The plant consisted of four 40-hp. Aurora gas engines, all belted to a line shaft, the line shaft in turn being belted directly to an Ingersoll-Rand air compressor. Two lines of 4-in. O. D. casing delivered air at a pressure of 110 lb. Erection of this siphon commenced in the middle and was worked both ways from this point. All rivets were cone-headed and of full-diameter shank; ⅝-in. rivets were used on the ¼ and 5/16-in. plate and ¾-in. rivets on the ⅜-in. plate.

Table XXII gives direct field charges of costs for the steel pipe.

TABLE XXII.—FIELD COSTS FOR STEEL PIPE

Description	Length, feet	Unit cost	Cost per cwt.
Trench excavation	15,597	$ 0.33	.....
Anchorages, proportion	15,597	.48	.....
Steel pipe:			
Cost rolled and punched at Mojave	15,597	9.84	$2.30
Loading and hauling	15,597	1.46	.34
Placing	15,597	.52	.12
Riveting	15,597	1.19	.28
Calking	15,597	.24	.06
Painting	15,597	.15	.04
Equipment	15,597	.87	.21
Superintendence	15,597	.11	.03
Engineering	15,597	.04	.01
Backfill	15,597	.19	.....
Bell hole, proportion	15,597	.11	.....
Dismantling camp, proportion	15,597	.01	.....
Manholes, proportion	15,597	.01	.....
Blow-off valves, proportion	15,597	.03	.....
Total		$15.58	$3.39

To the cost shown in the table should be added 10 per cent for overhead charges. The average cost of driving 645,957 rivets was 2.9 cents per rivet, and the average cost per pound of erecting was 3.39 cents.

The erection of steel commenced in April and was completed in September, 1912. The greatest progress was made during the month of August, when 5940 ft. were erected.

Weight and other miscellaneous data of steel pipe are given as follows in Moritz's "Working Data for Irrigation Engineers" (1915).

Fig. 22 gives the thickness of steel pipe for three different efficiencies of joint, single riveted at 55 per cent, best double riveted at 72 per cent, and lock-bar pipe at 90 per cent. The lock-bar joint is capable of developing 100 per cent efficiency; but, due to occasional defects in material or workmanship on the lock-bars, an efficiency of 90 per cent is recommended for calculating the thickness. The thickness given in the diagram is the net thickness of steel required to withstand the given pressure at a unit stress in the steel of 16,000 lbs. per sq. in. It is customary to allow a slight excess of thickness to take care of weakening by corrosion.

The following table (from "American Civil Engineers' Pocket Book") gives the greatest allowable depth of earth cover over steel pipe in feet. If a pipe is to be subjected to a greater pressure of earth than indicated in the table, the thickness must be increased or the pipe shell reinforced with angle irons or other suitable shapes.

DIAMETER OF PIPE

Thickness	30 ins.	36 ins.	42 ins.	48 ins.	54 ins.	60 ins.	72 ins.
3/16	5	..	..	..	..	..	..
1/4	8	5	4	3	..	..	..
5/16	12	9	6	5	4	3	2
3/8	18	12	9	7	6	4	3
7/16	25	17	12	9	8	6	4
1/2	..	22	16	12	10	8	6
5/8	..	..	..	..	15	12	9

Example of Use of Diagram (Fig. 22).—Given a 72-in. steel pipe for a power plant static head of 200 ft.; an allowance of 50 per cent is to be made for water-ram and 10 per cent for corrosion, making the total head (200 × 1.60) = 320 ft.

Enter the diagram at a head of 320 ft., thence horizontally to the line for 72-in. pipe, then vertically down and read thickness slightly more than $\frac{9}{16}$-in. for single-riveted joint, slightly less than $\frac{7}{16}$-in. for double-riveted joint, and slightly more than $\frac{11}{32}$-in. for the lock-bar. Single riveting is seldom used

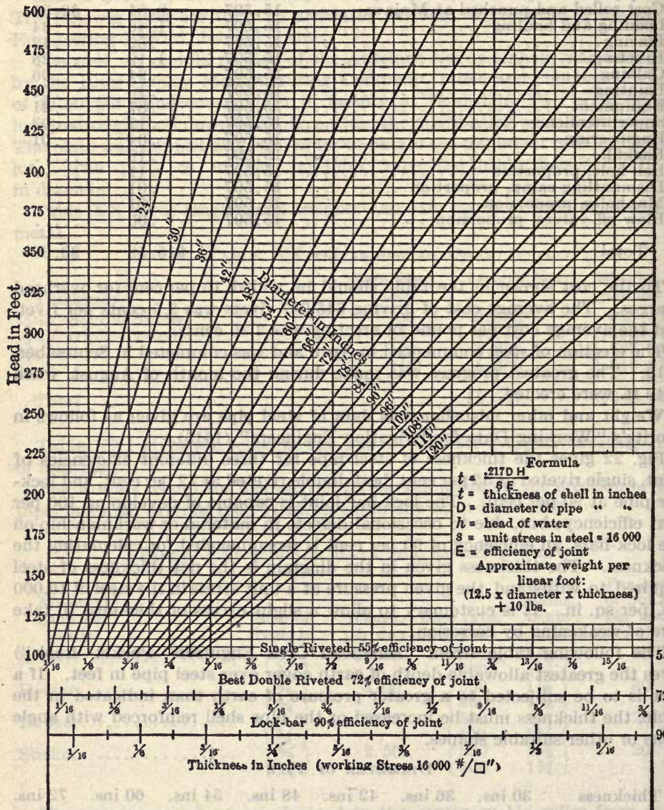

Fig. 22.—Thickness and weight of steel pipe.

for any but unimportant and temporary structures. Carrying the above example further, we note from the foregoing table that the $\frac{7}{16}$-in. shell will withstand a back-fill of 4 ft., and the $\frac{11}{32}$-in. shell will withstand between 2 and 3 ft. The approximate weight of the pipe is given by the formula in the diagram.

Maintenance of Steel Pipe Line, 350 Miles Long.—The following data are taken from an abstract in Engineering Record, Oct. 21, 1916, of the 1914–15 Annual Report of P. V. O'Brien, engineer for the Goldfields areas of the Water Supply, Sewerage and Drainage Department of Western Australia.

The pipe line and pumping project, was completed in 1902. After having been in service a few years the pipe showed signs of serious corrosion. The steel of this conduit was manufactured in Australia from material supplied from England. The thickness of the plates is ¼ in. for all pipes under pressure up to 390 ft. head and 5/16 in. thick for pressures above that amount. The material employed was open-hearth basic steel. When completed and tested the pipes were heated to 300 deg. Fahr. and immersed in a mixture of coal tar and Trinidad Asphalt. Over the outside coating sand was sprinkled to make the material resistant to the sun's heat.

Maintenance Costs.—Mr. O'Brien presents the following figures on the cost of maintenance since the pipe line was completed in 1902:

TABLE XXIII.—COST OF MAINTENANCE OF 30-INCH STEEL MAIN 351½ MILES LONG

Year	Cost	Year	Cost
1902–3 } 1903–4 }	$83,500	1909–10	83,000
1904–5	37,600	1910–11	61,200
1905–6	38,000	1911–12	83,000
1906–7	68,700	1912–13	111,000
1907–8	96,600	1913–14	192,600
1908–9	74,500	1914–15	248,000

The corrosion on the exterior of the pipes took three distinct forms—rusting, pitting and scaling. It appears that the greatest deterioration has occurred where the pipe has been buried in the ground, while sections lying above the surface show comparatively slight damage.

TABLE XXIV.—HOLES DUE TO EXTERNAL CORROSION

Financial year	No. of holes	Financial year	No. of holes
1904–5	2	1910–11	131
1905–6	27	1911–12	124
1906–7	54	1912–13	774
1907–8	55	1913–14	966
1908–9	91	1914–15	2,078
1909–10	177		

The great increase in the number of holes in 1914–15 is partly accounted for by the large amount of work done in scraping the pipe preparatory to recoating. In this way many holes appeared that ordinarily would not have been noticed for several years later.

The method adopted for dealing with external corrosion consists of uncovering the pipes wherever they are found to be badly pitted and continuing the opening up in both directions till they are found to be in good condition. In this way all those parts of the main in the vicinity of places where corrosion is known to be bad have been opened up, and in addition, other portions which were likely to be similarly bad have been opened up during the past year. The length opened up and left open for the financial year 1914–15 was 36½ miles, making a total of 80 miles uncovered at the close of the year. Judging by the condition of the pipes that have been opened up during the past year, it is anticipated that the work of dealing with the external corrosion of the pipes can be satisfactorily dealt with for some years in the same manner as hitherto, and at no greater cost. Although almost the whole of the coating on the pipes where they are underground is more or less perished, and has been so for many years, the condition of the steel plates is, apart from the pitting and scaling already referred to. almost uniformly good.

Life of Cast Iron Water Pipe.—The following data are taken from an article in Engineering and Contracting, Dec. 15, 1915 which gives the substance of replies to a questionaire conducted by Thomas H. Hooper, Sup't of Water Works, Winnipeg, Manitoba.

Baltimore.—Cast iron pipe was laid in Baltimore as early as 1805. The old pipe has been found in good condition. Electrolysis has been found the worst enemy of cast iron pipe. Reported by Robert L. Clemmitt, Acting Water Engineer.

Boston.—The oldest cast iron pipe was laid in 1848. The condition of this pipe depends upon the soil in which it was laid. Have taken out pipe in practically perfect condition, as far as condition of iron goes, after 60 years use. In other cases, in bad ground, or where electrolysis exists, pipe has been destroyed in half that time. Reported by F. A. McInnes, Div. Eng., Pub. Works Dep't.

Chicago.—The first cast iron pipe was laid in 1852. Some of the oldest pipe has been found in excellent condition when examined. Very little deterioration has been observed unless pipe has been attacked by cinders or slag filling or electrolysis. These cases are comparatively rare. Reported by John Ericson, City Engineer.

Hamilton, Ont.—The first pipe was laid in 1859 which on examination is shown to be in good condition. The only deterioration has been from electrolysis. Reported by Thomas Towers, Sup't. of Water Works.

Minneapolis.—The earliest records of cast iron pipe are about 1874. Old pipe when exposed appears to have suffered no depreciation. A piece of 12-in. pipe, 32 years in service, cut out to pass under a 48-in. pipe, looked like new. The coating even had its original lustre. Reported by J. A. Jensen, Sup't of Water Works.

Montreal.—First cast iron pipe was laid in 1852–4. In replacing 4 and 6-in. pipes, which had been in use over 55 years, with pipes of larger diameter, to meet increased demands due to growth of city, it was found that the cast iron was in good condition and the outside appearance almost perfect. In places, the area was much reduced by tubercules of rust or calcareous deposit and silty matter. On the whole, with the nature of Montreal soil, and leaving out the particular cases where electrolysis (due to electric tramways) may effect condition, it is safe to say that the cast iron pipes last as long as their usefullness will warrant. Reported by T. W. Lesage, Eng.—Sup't. of Water Works.

New York City.—Cast iron pipe was introduced in 1815. In 1915, in connection with an investigation of a break on a 30-in. main some of the old pipe was examined. It was found that the material was in good condition and showed hardly any depreciation. It was estimated that this main was made of, what is known as, Scotch iron and was laid about 1830. Reported by Merrit H. Smith, Chief Eng. Bureau of Water.

Philadelphia.—The first cast iron pipe was laid in 1817. Pipes recently taken up, laid in 1817 and 1827, were removed for obsolescence rather than because it could no longer perform its service. Of course tubercles and incrustations were found on the interior but the iron showed no evidence of deterioration. Reported by Carlton E. Davis, Chief of Bureau of Water.

Rochester.—The first pipe was laid in 1872. The pipe examined at frequent intervals has been found to be practically in as good condition as at time of laying. Reported by B. C. Little, Sup't of Water Works.

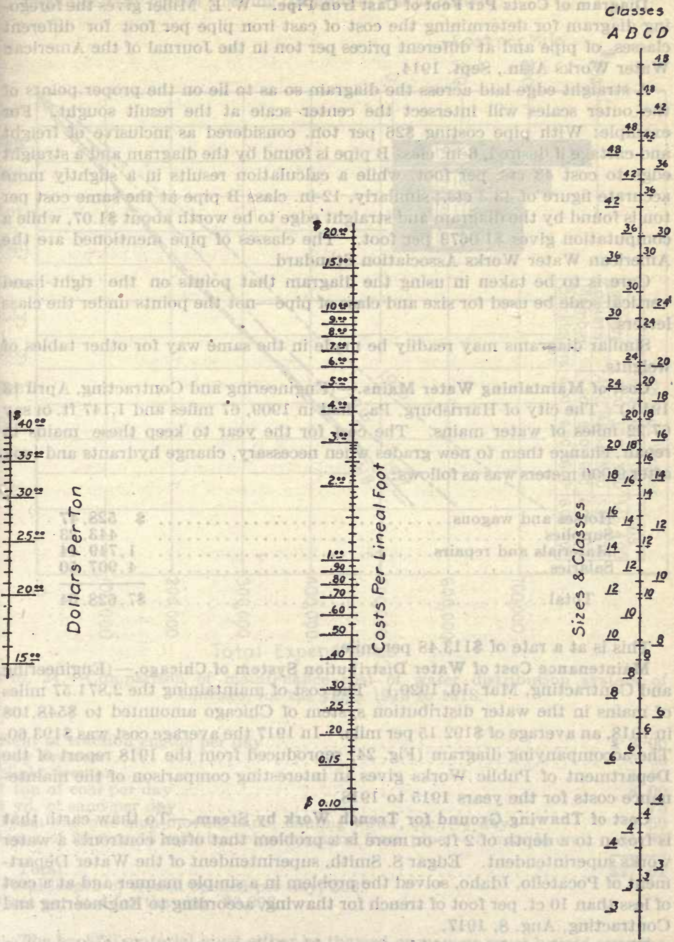

FIG. 23.—Diagram for determining cost of cast iron pipe per foot from price per ton and class of pipe.

St. Louis.—Physical condition of pipe in ground over 60 years in almost every instance has been found good. Reported by Francis T. Cutts, Asst. Water Commissioner.

Toronto.—Cast iron pipe laid in 1854 is still in use and upon examination shows little depreciation except where electrolysis has taken place. Reported by R. C. Harris Commissioner of Works.

Diagram of Costs Per Foot of Cast Iron Pipe.—W. E. Miller gives the foregoing diagram for determining the cost of cast iron pipe per foot for different classes of pipe and at different prices per ton in the Journal of the American Water Works Assn., Sept. 1914.

A straight edge laid across the diagram so as to lie on the proper points of the outer scales will intersect the center scale at the result sought. For example: With pipe costing $26 per ton, considered as inclusive of freight and cartage if desired, 6-in. class B pipe is found by the diagram and a straight edge to cost 43 cts. per foot, while a calculation results in a slightly more accurate figure of 43.3 cts.; similarly, 12-in. class B pipe at the same cost per ton is found by the diagram and straight edge to be worth about $1.07, while a computation gives $1.0673 per foot. The classes of pipe mentioned are the American Water Works Association Standard.

Care is to be taken in using the diagram that points on the right-hand vertical scale be used for size and class of pipe—not the points under the class letters.

Similar diagrams may readily be made in the same way for other tables of weights.

Cost of Maintaining Water Mains.—(Engineering and Contracting, April 13 1910.) The city of Harrisburg, Pa., had in 1909, 67 miles and 1,147 ft. or say 67.22 miles of water mains. The cost for the year to keep these mains in repair, change them to new grades when necessary, change hydrants and look after 9,000 meters was as follows:

Horses and wagons	$ 528.47
Supplies	443.23
Materials and repairs	1,749.44
Salaries	4,907.50
Total	$7,628.64

This is at a rate of $113.48 per mile.

Maintenance Cost of Water Distribution System of Chicago.—(Engineering and Contracting, Mar. 10, 1920.) The cost of maintaining the 2,871.57 miles of mains in the water distribution system of Chicago amounted to $548,108 in 1918, an average of $192.15 per mile. In 1917 the average cost was $193.60. The accompanying diagram (Fig. 24) reproduced from the 1918 report of the Department of Public Works gives an interesting comparison of the maintenance costs for the years 1915 to 1918.

Cost of Thawing Ground for Trench Work by Steam.—To thaw earth that is frozen to a depth of 2 ft. or more is a problem that often confronts a water works superintendent. Edgar S. Smith, superintendent of the Water Department of Pocatello, Idaho, solved the problem in a simple manner and at a cost of less than 10 ct. per foot of trench for thawing, according to Engineering and Contracting, Aug. 8, 1917.

The ground was frozen 4½ ft. deep and in 24 hrs. was completely thawed to a depth of 2½ ft. The remaining 2 ft. were softened sufficiently to be easily picked. The method of thawing consisted in laying a double line of 1½-in. pipe over the trench and covering it with 6-in. of fine sand. Steam was fed into the pipe from a traction engine boiler, and a block 300 ft. long was thawed at one setting of the engine. It took about 2 hrs. to shift to the next block, haul the sand and cover up the pipe, using 2 men and 2 teams.

The total daily cost of thawing the ground was as follows:

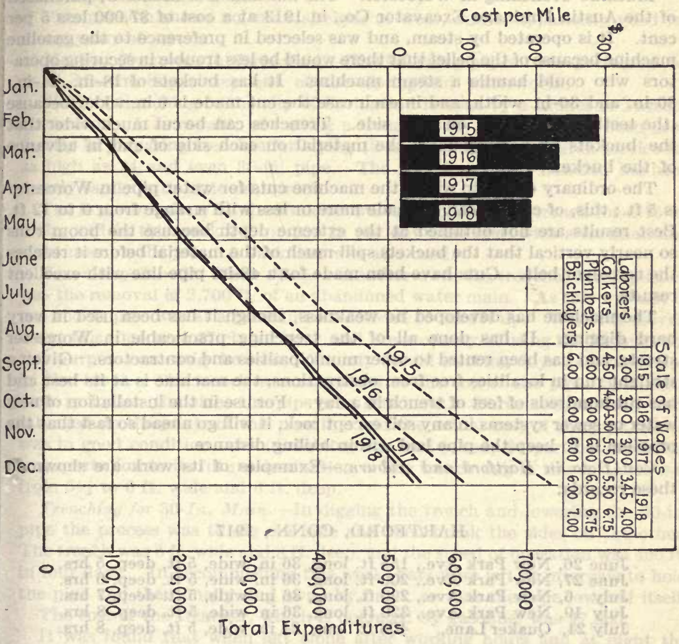

FIG. 24.—Comparison of maintenance cost of water distribution system of Chicago, for the years 1915 to 1918.

Rent of traction engine per day	$ 3.00
Day fireman	5.00
Night fireman	4.50
1 ton of coal per day	8.00
1 yd. of sand per day	.75
Team and one man moving sand, hauling water, etc., ½ day	4.50
Gang of 20 men 15 minutes removing sand from pipe = 5 man hours	1.87
Total	$27.62

Total length of trench opened per day, 300.
Cost per foot for thawing, $0.092.

The backfill material must either be thawed or manure must be laid over the water pipe before back-filling with frozen earth.

Experience with Trenching Machines in Massachusetts.—At the annual (1920) convention of the New England Waterworks Association a general discussion about the use of trenching machines for excavating waterworks trenches brought out some valuable information. George W. Batchelder, Water Commissioner of Worcester, opened the discussion with a paper, the substance of which, as given in Engineering and Contracting, Nov. 10, 1920, follows:

Machine Trenching in Worcester.—The machine is a Model O, purchased of the Austin Drainage Excavator Co., in 1913 at a cost of $7,000 less 5 per cent. It is operated by steam, and was selected in preference to the gasoline machine because of the belief that there would be less trouble in securing operators who could handle a steam machine. It has buckets of 18-in., 24-in., 30-in. and 36-in. width, and in each case the cut made is 6 in. wider because the teeth project 3 in. on each side. Trenches can be cut much wider that the buckets by barring down the material on each side of and in advance of the buckets.

The ordinary depth to which the machine cuts for water pipe in Worcester is 5 ft.; this, of course, can be made more or less with a range from 0 to 12 ft. Best results are not obtained at the extreme depth because the boom runs so nearly vertical that the buckets spill much of the material before it reaches the conveyor belt. Cuts have been made for a 48-in. pipe line with excellent results.

The machine has developed no weakness, though it has been used in very hard digging. It has done all of the trenching practicable in Worcester streets, and has been rented to other municipalities and contractors. Given a straight run in localities free from obstructions, the machine is at its best and has cut hundreds of feet of trench in a day. For use in the installation of new water or sewer systems in any soil except rock, it will go ahead so fast that the problem is to keep the pipe laid within hailing distance.

Cost Data in Hartford and Auburn.—Examples of its work are shown in these records:

HARTFORD, CONN., 1917

June 26,	New Park Ave.,	155 ft. long,	36 in. wide,	5 ft. deep,	5 hrs.
June 27,	New Park Ave.,	200 ft. long,	36 in. wide,	5 ft. deep,	6 hrs.
July 6,	New Park Ave.,	220 ft. long,	36 in. wide,	5 ft. deep,	7 hrs.
July 19,	New Park Ave.,	320 ft. long,	36 in. wide,	5 ft. deep,	8 hrs.
July 24,	Quaker Lane,	408 ft. long,	24 in. wide,	5 ft. deep,	8 hrs.

AUBURN, MASS., 1920

Aug.—					
18, Very coarse gravel	410 ft. long,	24 in. wide,	5 ft. deep,	8	hrs.
19, Loam, hard pan & gravel	250 ft. long,	24 in. wide,	5 ft. deep,	5	hrs.
20, Hard pan, clay & sand	380 ft. long,	24 in. wide,	5 ft. deep,	6½	hrs.
21, Sand & fine gravel	165 ft. long,	24 in. wide,	5 ft. deep,	3	hrs.
23, Filled land, very rocky	384 ft. long,	24 in. wide,	5 ft. deep,	6½	hrs.
24, Coarse gravel & sand	438 ft. long,	24 in. wide,	5 ft. deep,	8	hrs.
25, Very rocky and wet	445 ft. long,	24 in. wide,	5 ft. deep,	8½	hrs.
26, Fine gravel & hard pan	295 ft. long,	24 in. wide,	5 ft. deep,	5½	hrs.
27, Gravel, clay & hard pan	472 ft. long,	24 in. wide,	5 ft. deep,	8	hrs.
28, Filled land, rocky	180 ft. long,	24 in. wide,	5 ft. deep,	3½	hrs.

This total excavation amounts to 34,190 cu. yd. The costs of this work are:

Operator, $88; fireman, $66; freight, $38; coal, $48; oil, etc., $20; repairs and depreciation, ex. labor, $50. Total, $330.

Cost per cu. yd., excl. rental	9.65 cts.
Cost per cu. yd., including rental price	17.2 cts.
Cost per cu. yd., hand labor (estimated)	63.0 cts.

In addition to the work done in Worcester the machine has brought in a revenue for rentals of $9,011, not including the job now going on at Auburn Mass. The total cost of replacements and repair parts since the machine was purchased has been $3,864.

The machine shows no unusual signs of wear, and is apparently good for many years of service.

Machine Trenching in Springfield.—The following paper was presented by A. L. Martin, Superintendent of the Springfield waterworks.

Work of trenching in the city of Springfield is done by a Model 24 Parsons Excavator. It is capable of cutting a trench 26 in. wide, and has been used mostly in preparing trenches for laying 12-in. pipe, but has been in service for as high as 24 and even 30-in. pipe. The soil that it has handled has been mostly sandy with little or no rock.

The first work done by the trencher was the digging of a trench for a 16-in. main, and in this work 300 or 500 ft. per day were laid, with a foreman and eight men on the job. A backfiller was also used.

Excavating Over Old Water Main.—Another work the trencher accomplished was the removal of 2,700 ft. of an abandoned water main. As this was not in use and as pipe was at a premium we decided to take it up. Wages of shovelers at this time were 67 ct. per hour, and the economy of using the trencher for this purpose can easily be seen. Twenty actual working days were consumed in the labor. The trench was excavated to the top of the pipe, then, with men to loosen the side, the pipe was lifted out. Three tons of lead were salvaged on the joints of this pipe line and the actual cost of the pipe, which was in good condition, was (deducting the lead saved) $1 per foot including transportation to its future destination. The trench dug in this instance was from 5½ to 6 ft. wide and 6 ft. deep.

Trenching for 30-In. Main.—In digging the trench and lowering the 30-in. pipe the process was to dig one side and then break the sides on the other. The trench was 6 ft. wide and 8 ft. deep, and the speed of operation was 400 ft. in four days. In accomplishing this work, bars were left at intervals to hold the pipe and then finally dug away by hand, so that the pipe lowered itself.

The cost of the trencher, which is operated by gasoline, was $7,800.

It was found that when left alone after working hours and at night the trencher was apt to be tampered with by curious persons or mischievous boys. A watchman would cost $35 per week. A cage, placed entirely around the machine and made of strong steel wire, much like that used in the cages around the cashier's offices in banks, fulfilled the object it was devised for and cost about $400.

The operator of the trencher is paid 80 ct. per hour, and the assistant 70 ct.

Cost of Machine Trenching for Water Mains at Erie, Pa.—By using a trenching machine the Water Department of Erie, Pa., has overcome difficuities incident to the labor shortage and at the same time has effected a large saving in excavating for water main extensions. A report on the work of the machine, prepared by E. W. Humphreys, Superintendent of Waterworks, and abstracted in Engineering and Contracting, May 8, 1918, shows that it has dug trenches 5½ and 6 ft. deep at a cost as low as 0.9 ct. per lineal foot. This particular trench was dug in hard clay. The figure covers the wages of operator and helper and the cost of gasoline, oils and grease. In laying 10,000 ft. of 6 in. main in 1917 the cost of hand digging alone was 19 ct. per lineal foot, with common labor at 27½ ct. per hour. The hand dug trench was in clay with shale at the bottom.

The accompanying tabulation shows work done by the machine at various times from May 1, 1917, to Jan. 3, 1918:

	—Trench—				Cost per lin. ft. of trench
	Le. ft.	De. ft.	Wi. ft.	Kind of material excavated	
Rankine Ave., N.	1,000	5½	2	Running sand and gravel	$0.065
Rankine Ave., S.	800	5½	2	Hard shale	.036
22d W. Cranberry	665	6	2	Hard clay	.010
28th W. of Sigsbee	652	6	2	Clay loam	.010
Cherry N. of 30th	360	5½	2	Clay and gravel	.012
5th W. Raspberry	400	5½	2	Sandy	.014
27th W. Cascade	420	5½	2	Hard clay	.009
Old French Road	230	6	2	Hard clay	.009

The costs given in Table XXV are the actual operative costs, exclusive of overhead, depreciation and repairs, and pay of watchman. The costs in detail for each of these jobs follow:

TABLE XXV

	Per lin. ft. trench
Rankine Ave., N. (1,000 lin. ft. trench)	
Operator, 62 hr. at 32½ ct.	$0.0200
Helpers, 115 hr. at 30 ct.	.0345
Gasoline, 39 gal. at 24⅓ ct.	.0090
Oils, 4 qt. at 9½ ct.	.0004
Grease, 2 lb. at 7½ ct.	.0001
Total (1,000 lin. ft.)	$0.0640
Ranking Ave. S. (800 lin. ft. trench)	
Operator, 26 hr. at 35 ct.	$0.0114
Helper, 38 hr. at 28 ct.	.0130
Gasoline, 35 gal. at 25 ct.	.0109
Oils, 4 qt. at 11½ ct.	.0006
Grease, 1 lb. at 9 ct.	.0001
Total (800 lin. ft.)	$0.0360
22nd W. of Cranberry (665 lin. ft. trench)	
Operator, 4 hr. at 35 ct.	$0.002
Helper, 4 hr. at 32½ ct.	.002
Gasoline, 15 gal. at 25 ct.	.006
Oils, 3 qt. at 11⅓ ct.	......
Grease, 1 lb. at 9 ct.	
Total (665 lin. ft.)	$0.010
28th W. of Sigsbee (652 lin. ft. trench)	
Operator, 3 hr. at 35 ct.	$0.002
Helper, 3 hr. at 27 ct.	.002
Gasoline, 12 gal. at 25 ct.	.005
Oils, 4 qt. at 11½ ct.; grease, 1 lb. at 9 ct.	.001
Total (652 lin. ft.)	$0.010
Cherry N. of Cranberry (360 lin. ft. trench)	
Operator, 2 hr. at 35 ct.	$0.002
Helper, 2 hr. at 27½ ct.	.002
Gasoline, 10 gal. at 25 ct.	.007
Oils, 3 qt. at 11⅓ ct.; grease, 1 lb. at 5 ct.	.001
Total (360 lin. ft.)	$0.012
5th W. of Raspberry (400 lin. ft. trench)	
Operator, 3 hr. at 45 ct.	$0.003
Helper, 3 hr. at 33 ct.	.002
Gasoline, 12 gal. at 27 ct.	.008
Oils, 1 gal. at 10 ct.; grease, 1 lb. at 5 ct.	.001
Total (400 lin. ft.)	$0.0014

27th W. of Cascade (420 lin. ft. trench)	Per lin. ft. trench
Operator, 2 hr. at 45 ct	$0.002
Helper, 2 hr. at 35 ct	.002
Gasoline, 8 gal. at 25 ct	.005
Oils, 1 qt. at 10 ct	....
Grease, 1 lb. at 5 ct	....
Total (420 lin. ft.)	$0.009
Old French Road (230 lin. ft. of trench)	
Operator, 1 hr. at 45 ct	$0.002
Helper, 1 hr. at 35 ct	.002
Gasoline, 4 gal. at 25 ct	.005
Oils, 1 qt. at 10 ct	....
Total (230 lin. ft.)	$0.009

The figures on the last six jobs represent the actual time the machine was engaged in trenching. On the old French Road work 230 lin. ft. of trench was excavated in one hour, while in the 27th St. work 210 ft. of trench was dug in one hour. A summary of the operating costs on the six jobs shows the following:

6 jobs trenching (2,727 lin. ft.)	Per lin. ft. trench
Operator, 15 hr. at 39 ct	$0.0021
Helper, 15 hr. at 31½ ct	.0017
Gasoline, 61 gal. at 25.1 ct	.0060
Oils, 13 qt. at 11 ct	.0005
Grease, 5 lb. at 6½ ct	.0001
Total (2,727 lin. ft.)	$0.0104

The trenching machine, a Pawling & Harnischfeger, was purchased by the Water Department early in 1917 at a cost of $5,650 f. o. b. Erie.

Cost of Excavating and Backfilling Trench by Machines.—Engineering News-Record, May 24, 1917, gives the following. The excavating was done by a municipally owned Austin excavator which will dig a trench 72 in. wide and cost $10,000.

The cost of operating this excavator 66 working days for a 54-in. force main, at an average depth of 11 ft., was $3665, divided as follows: Repairs, $808; coal and oil, $549; labor, $2308. The volume of material excavated, based on daily reports, was 39,200 cu. yd., or by computation on approximate sections, 43,700 cu. yd. The cost per cubic yard, based on the daily reports, was 9.3 cents.

Labor was paid as follows: Foreman, $4.50; timekeeper (one-fourth of his time, as he was on four jobs), $1; engineer, $4; watchman, $3; fireman, $2.75; laborers, $2.50; team, $5. The cost of repairs was thus divided: Labor, $358; repair parts, $352; repair work at local shop, $98.

Cost of Backfilling by Steam Shovel.—Backfilling was done by means of a small steam shovel. The job was in the outskirts of the city, and the excess dirt was easily disposed of. Cost figures are not available, but on another job in a built-up part of the city the backfilling of a 48-in. main 9520 ft. long cost $1146, or 4.8 cents per cu. yd. The cross-section averaged 75.3 sq. ft gross, or 62.8 net, for backfill, after deducting 12.5 sq. ft. for the 48-in. pipe. There were 22,143 cu. yd. in the trench and 1590 cu. yd. in bell holes, making a total backfill of 23,733 cu. yd. against a total excavation of 29,757 cu. yd.

The cost of the backfilling, plus the hauling away of excess material (6024 cu. yd.) and the refilling of the street surface, was $6302, or a unit cost of 21.2 cents. The cost of removing excess material and refinishing the street surface was $0.839 per cu. yd., a high cost due to long haul.

The steam shovel engineer was paid $6 a day. Other daily wages, all for 8 hours, were: Foreman, $2.75; watchman, $3; assistant foreman, for hauling material away, $3; teams, $5; and two pitmen, $2.50 each.

Saving Effected by Using Excavating and Pipe Laying Machinery.—The following data are taken from Engineering and Contracting, Feb. 12, 1919.

Trenching and backfilling machines were first employed by the Detroit Water Department in 1916, and in 1917, and their value was so fully demonstrated that more equipment was purchased.

In his report for the year ending June 30, 1918, Geo. H. Fenkell, General Manager of the Water Department, gives the following table showing the saving effected by the use of machines:

	All hand labor			Dug and backfilled by machine			
Size—Ins.	Feet laid	Total labor cost	Cost per ft.	Feet laid	Total labor cost	Cost per ft.	Saving by machine per ft.
6	59,238	$35,095	$0.59	60,407	$21,118	$0.35	$0.24
8	33,161	19,108	.58	31,007	12,550	.40	.18
12	4,628	5,159	1.11	5,863	2,845	.49	.62
16	797	1,291	1.62	13,011	12,852	.99	.63

On the 42-in. and 48-in. pipe lines a material saving was effected by the use of mechanical appliances to replace hand labor. The following are some of the most striking instances, the figures being based upon the prevailing scale of wages:

Labor per foot in laying 42-in. and 48-in. pipe will average $8.70 by hand, and $3.50 by machinery; caulking averages $1.32 per joint by hand and $0.49 using pneumatic hammers; handling and lowering each pipe by hand labor averages $6.70 and $1.88 using the steam crane. Backfilling ditches on small lines costs about 9 ct. per lineal foot by hand and 3½ ct. per foot by machine.

A Scraper for Backfilling Trenches.—S. Leonard Cyphers gives the following data in Engineering and Contracting, July 23, 1913.

The "Go-Devil" as it was called by the originator, was used on the 154-mile oil pipe line near Los Angeles to minimize the cost of back-filling the ditch. This ingenius device was designed and first used by James R. Kelly, Superintendent for Mahoney Brothers, Contractors, San Francisco, on the construction of the 8-in. oil pipe line built by the General Petroleum Co. from Shale in the Midway oil fields of California to San Pedro on the coast. It was found to be such a success and money saver that it was adopted by other contractors in similar work.

The appliance illustrated was made of a share taken from a Little Western Road Grader and a handle was attached in the manner shown. Chains were attached to each end of the share by means of hooks designed to shorten or lengthen the chains when it became necessary to reverse the action of the blade on return work upon the ditch. It is drawn by four head of stock attached as shown. The stock are hitched in pairs, one pair being driven on the dirt to be turned into the ditch, the other pair on the opposite side of the ditch and pulling at an angle of 20° to 30° away from the center line of the ditch.

The labor required consisted of a teamster and one other man whose duty it was to guide the share by means of the handle. In operation the share runs at an angle of 20° to 40° to the center line of the ditch, so that in effect its action is similar to a plow in throwing a furrow.

From data kept by the writer, covering a period of several months, and from such sections of the previously mentioned line where the use of this "Go-Devil" was practicable the following facts appear:

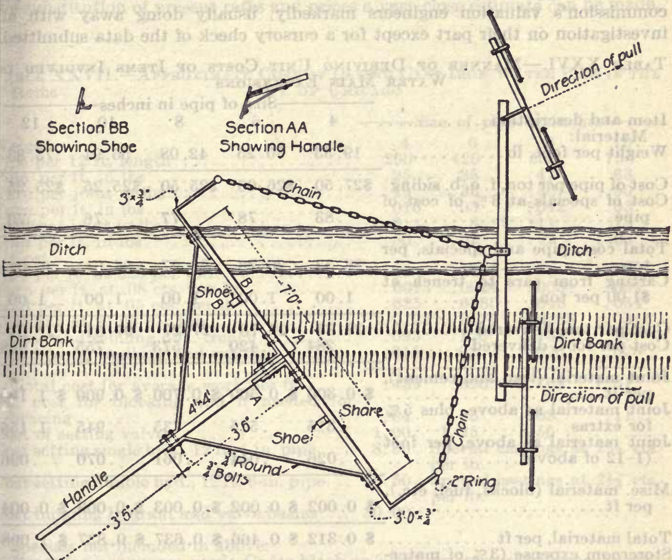

FIG. 25.—Scraper for backfilling trench.

By means of this device, two men and four head of stock were able to fill approximately 5,000 ft. of ditch, 3 ft. deep and 1½ ft. wide in a day of nine hours at a cost as follows:

4 head of stock	$10.00
1 teamster	4.00
1 laborer	3.50
Total	$17.50

This shows a cost of about 0.2 ct. per cubic yard. These figures were taken where runs were at least one mile long. Under different circumstances, the figures would necessarily vary.

The difficulty encountered in the use of the Go-Devil has usually been because of an attempt to move too much dirt at one time, and also because of inability to properly handle the stock. Four to six rounds are necessary to fill and crown a 3 or 4 ft. ditch. Upon the completion of this number, the ditch should be rounded up as well as can be done by hand.

Table for Estimating Water-Main Extension Costs.—Allen F. Brewer gives the following data in Engineering News-Record, May 9, 1918.

Table XXVI shows how an itemized calculation for unit costs of water mains may be prepared. The figures quoted have been assumed arbitrarily, merely to serve as an example.

Such a tabular estimate is of much value where affirmative action is required of a State Public Utility Commission before the company may legally charge for water supplied by any new extension. It will lessen the work of the commission's valuation engineers markedly, usually doing away with all investigation on their part except for a cursory check of the data submitted.

TABLE XXVI.—MANNER OF DERIVING UNIT COSTS OF ITEMS INVOLVED IN WATER MAIN EXTENSIONS

Item and description	Size of pipe in inches 4	6	8	10	12
Material:					
Weight per foot, lb.	19.33	30.25	42.08	55.91	73.83
Cost of pipe per ton, f. o. b. siding	$27.50	$26.00	$25.50	$25.25	$25.25
Cost of specials at 3% of cost of pipe	.83	.78	.77	.76	.76
Total cost, pipe and specials, per ton	28.33	26.78	26.27	26.01	26.01
Carting from cars to trench at $1.00 per ton	1.00	1.00	1.00	1.00	1.00
Cost per ton, delivered	29.33	27.78	27.27	27.01	27.01
Cost per foot, delivered	.284	.420	.573	.755	.998
Joint material (lead and cement), per jt.	$ 0.300	$ 0.500	$ 0.700	$ 0.900	$ 1.100
Joint material as above, plus 5% for extras	.315	.525	.735	.945	1.155
Joint material as above, per foot (1–12 of above)	.026	.044	.061	.070	.096
Misc. material (blocks, fuel, etc.), per ft.	$ 0.002	$ 0.002	$ 0.003	$ 0.003	$ 0.004
Total material, per ft.	$ 0.312	$ 0.466	$ 0.637	$ 0.837	$ 1.098
Storeroom expense (3% of material cost)	.009	.014	.019	.025	.033
Total material cost	$ 0.321	$ 0.480	$ 0.656	$ 0.862	$ 1.131
Labor:					
Average width of trench, ft.	1.5	1.66	1.75	1.83	2.0
Total depth of trench, ft.	3.42	3.57	3.75	3.91	4.08
Contents of trench per foot, cu. ft.	5.13	5.95	6.57	7.17	8.16
Contents of trench per foot, cu. yd.	.19	.22	.243	.265	.303
Trenching and backfilling (at 60c. per yd.), per ft.	.114	.132	.146	.159	.182
Laying, calking, setting valves, etc.	.023	.027	.030	.035	.040
Total, labor laying pipe	$ 0.137	$ 0.159	$ 0.176	$ 0.194	$ 0.222
Tools, carting, lost time, overhead, etc. (10% of above)	$ 0.014	$ 0.016	$ 0.018	$ 0.019	$ 0.022
Total labor cost	$ 0.151	$ 0.175	$ 0.194	$ 0.213	$ 0.244
Total labor and material costs, per ft.	$ 0.472	$ 0.655	$ 0.850	$ 1.075	$ 1.375

Cost of Laying Cast Iron Water Pipe in the City of Chicago.—Table XXVII, published in Engineering and Contracting, Oct. 11, 1911, is a result of the compilation of the cost of laying cast iron water pipe in the city of Chicago for a period of 10 years. The costs were compiled in the City Engineer's office from careful records of contract work. The table has since been used as a check on later work and has been found to be very close. The rates of wages for all men, and the prices of all kinds of material are given so that by the substitution of present rates and prices a very close estimate can be made.

TABLE XXVII.—APPROXIMATE COST OF LAYING CAST IRON WATER PIPE IN THE CITY OF CHICAGO

Items	Size of pipe in inches 4	6	8	10
Weight				
Pipe per 12 ft. length	290	420	555	756
Pipe per ft. in lbs	25	35	47	63
Yarn per joint in lbs	.19	.36	.50	.50
Yarn per ft. in lbs	.016	.03	.042	.05
Lead per joint in lbs	6	8	11	13
Lead per ft. in lbs	.50	.67	.92	1.08
Cost				
Pipe per ft. at $23 per ton	.29	.4025	.54	.73
Yarn per ft. at .08 cts. per lb	.0013	.0024	.0034	.004
Lead per ft. at .05 cts. per lb	.025	.0335	.046	.054
Teaming at $1.00 per ton	.0125	.0175	.0235	.0315
Excav. and refilling 6-ft. trench	.095	.120	.130	.16
Pipe laying, caulking and cutting	.015	.02	.025	.028
Total cost for average work per ft	.439	.596	.768	1.01
Ad. cost for blocking and if needed for bracing	.04	.05	.08	.11
Cost of setting valves	1.00	1.25	1.50	......
Cost setting single hyd., 12 ft. 4-in. pipe	8.50	Special castings at 2½ cts. per lb.		
Cost setting double hyd., 12 ft. 6-in. pipe	13.50	Special castings at 2½ cts. per lb.		
Cost building hydrant and valve basins	30.00	......	......	......

Specials not included in above.

Repaving per square yard: Cedar block on plank or on crushed stone, 50 cts.; brick on concrete, $2.00; macadam, 9 ins. deep, 40 cts.; 12 ins. deep, 50 cts.; granite block, $1.50; asphalt, $3.00.

Rock requiring blasting will cost an average of $3.00 per cu. yd.

Items	12	14	16	18	24	30	36	42	48
Pipe per 12 ft. length	1,000	1,224	1,500	1,824	3,000	4,230	5,400	7,944	9,350
Pipe per ft. in lbs	83	102	125	152	250	352	450	662	780
Yarn per joint in lbs	.75	.84	1.00	1.10	1.50	1.80	2.16	2.50	3.00
Yarn per ft. in lbs	.063	.07	.083	.092	.125	.150	.180	.21	.250
Lead per joint in lbs	16	20	24	28	38	60	80	126	144
Lead per ft. in lbs	1.33	1.67	2.00	2.34	3.17	5.00	6.70	10.50	12
Pipe per ft. at $23 per ton	955	1.17	1.4375	1.75	2.875	4.05	5.175	7.61	8.97
Yarn per ft. at .08 cts. per lb	.005	.0056	.0066	.00736	.010	.012	.0144	.017	.02
Lead per ft. at .05 cts. per lb	.067	.0835	.10	.117	.160	.250	.335	.525	.60
Teaming at $1.00 per ton	.0415	.051	.0625	.067	.125	.176	.225	.331	.39
Excav. and refilling 6-ft. trench	.200	.21	.220	.24	.30	.40	.45	.48	.50
Pipe laying, caulking and cutting	.03	.045	.07	.09	.20	.25	.30	.40	.50
Total cost for average work per ft	1.30	1.565	1.90	2.28	3.67	5.14	6.50	9.36	10.98
Ad. cost for blocking and if needed for bracing	.12	.13	.15	.20	.25	.30	.40	.45	.50
Cost of setting valves	2.20	......	3.00	......	4.40	6.15	8.40	.....	12 00

The costs (Table XXVII) are based on the following rates for labor and material.

8 hrs. = day's work.
Foreman, $3.75 per day.
Caulker, $2.50 per day.
Timekeeper, $2.75 per day.
Laborer, $2.25 per day.
Watchman, $2.00 per day.
Mason, $4.00 per day.
Helper, $2.50 per day.
Brick, $6.50 per M.
Timber, $16 per M.
Cement, $2.25 per bbl.
Sand, $1.25 per cu. yd.
Hydrant covers, $6.75 ea.
Valve covers, $7.50 ea.
Bottoms, $1.50 ea.
4-in. valves, $14.00 ea.
6-in. valves, $18.00 ea.
8-in. valves, $ 35.00 ea.
Hydrants, ea. Dbl., $38.00; Sgl. $26.00

Cost of Water Mains at Los Angeles.—Table XXVIII from the last annual report of Thos. Brooks, Assistant Superintendent and published in Engineering and Contracting, March 12, 1919, shows the cost of laying 4-in. and 6-in. cast iron pipe in 6 months' periods from July 1, 1911, to July 1, 1918:

TABLE XXVIII

Year	Av. cost of pipe per ton	Av. cost of labor per foot	Average per foot	Total cost per ton
	4-inch			
1911	$32.70	$0.0967	$0.519	$51.90
1912	33.88	.0995	.548	51.46
1912	35.05	.1189	.607	56.05
1913	36.22	.1144	.603	55.62
1913	32.42	.107	.553	51.10
1914	32.42	.109	.544	50.27
1914	33.13	.122	.647	59.77
1915	30.17	.145	.620	57.18
1915	28.85	.145	.626	57.68
1916	31.96	.145	.660	60.83
1916	38.40	.161	.741	68.33
1917	43.66	.174	.807	74.42
1917	55.60	.175	.93	85.52
1918	75.17	.173	1.14	105.51
	6-inch			
1911	31.60	.133	.775	48.98
1912	33.71	.127	.782	49.43
1912	33.04	.163	.859	51.56
1913	33.93	.1595	.855	51.42
1913	31.24	.164	.822	49.34
1914	31.24	.170	.836	50.18
1914	31.20	.149	.833	50.05
1915	28.60	.160	.799	48.01
1915	31.09	.171	.878	52.71
1916	33.72	.171	.941	56.54
1916	34.65	.182	.977	58.71
1917	40.11	.212	1.07	64.23
1917	41.43	.221	1.11	66.71
1918	44.92	.242	1.26	75.23

It will be noted from the table that the increased labor cost, as might be expected, keeps pace with the increasing cost of material. The day wage has been raised from $2.25 to $2.50 to $2.75 and $3, but while wages have been increased, the efficiency shows a decrease of possibly one-third from old standards. Foremen with gangs of less than half the normal number, and many small instead of long straight-away jobs also show their effect on unit costs which in the last year reached the maximum.

Owing to the war conditions the tonnage of cast iron pipe laid in the fiscal year 1917–18 by the Construction Department was the smallest of any year in the history of the Department. Only 1,435 tons were laid as against 4,036 tons for the year preceding and 6,420 tons for the year 1915–16. Of this tonnage, approximately two-thirds was in 4 and 6-in. sizes. The tonnage represents a footage of 75,799 ft., or 14.36 miles, laid at a total expenditure of $103,464. In 1915–16 the average cost of cast iron pipe laid, including resurfacing costs was $50.93; in 1916–17 this had increased to $60.60 per ton and for the year ending July 1, 1918, the charges had mounted to $72.10 per ton.

Cost of Laying Water Mains at Hartford, Conn.—During the 1919 season the Water Commissioners of Hartford, Conn., laid 37,400 ft. of 4-in. to 4.2-in. main pipe. Of this, 3,234 ft. were renewals and 34, 166 ft. were extensions. The force employed consisted of two foremen and a total average gang of 42 men. The following table given in Engineering and Contracting, Dec. 8, 1920, is from the report of the Commissioners for the year ending March 1, 1920, and shows the average costs of main pipe work in 1919, and a comparison with previous years:

		Cost per linear foot						
		1919						
Size, inches	Length laid 1919, feet	Labor	Mat'l incl. transportation	Total	1918 Total	1917 Total	1916 Total	1915 Total
4	411	$0.74	$1.06	$1.80	$....	$1.20	$0.81	$....
6	3,560	0.88	1.72	2.60	2.43	.....	1.46	1.26
8	10,160	0.92	2.20	3.12	3.45	2.41	1.66	1.62
10	3,773	1.31	3.22	4.53	*4.72	3.00	2.15	1.93
12	539	1.72	3.71	5.43	4.15	4.12	2.82	2.43
16	547	1.38	8.17	†9.55	6.17	4.92	4.58	.....

* Includes some macadam. † Two special bridge crossings.

Labor....................	$ 3.55 for eight hours
Pipe....................	60.00 per ton
Specials....................	110.00 per ton
Lead....................	0.09 per pound

No overhead charges.

Only a small amount of pipe laying was done during 1918 by the Water Department of Hartford, Conn., due to lack of building and absence of requests for extensions. The cost of this work was very much in excess of any previous figures of the department, due to high wages, excessive cost of materials and difficulty in obtaining proper labor. The following table given in Engineering and Contracting, May 12, 1920, is from the report of Caleb Mills Saville, Manager and Chief Engineer of the Department, and shows the average figures for costs in 1918.

		Cost per lin. ft.		
Size, in.	Length laid 1918, ft.	Labor	Material including cartage	Total, 1918
6	1,736	0.83	1.31	2.14
8	5,431	1.45	2.14	3.59
10	3,561	1.37	3.56	4.93
12	336	1.11	3.04	4.15
16	570	1.29	4.88	6.17

The 1918 costs are based on the following: Unskilled labor, average $3.50 for 8 hours; pipe, $60 per ton; specials, $110 per ton; lead, 9 ct. per pound; no overhead charges.

The following table shows relative costs before the war and during 1918.

	1918	1915	Increase pct.
Labor, average of 45 permanent employes, per 8-hour day	$ 4.30	$ 3.00	44
Cast iron pipe per ton	65.00	23.00	183
Lead per 100 lbs	7.15	3.95	82
Meters (¾ in.)	18.00	12.00	50
Valves, 6 in	20.00	10.00	
Valves, 8 in	31.40	15.75	100
Valves, 10 in	49.00	22.50	
Hydrants 2-way	49.90	25.06	
Hydrants 2-way steamer	54.75	33.40	100
Hydrants 4-way	66.10	33.10	

Cost of Laying 16 miles of 20-in. Cast Iron Water Pipe.—M. V. Moulton in Engineering and Contracting, Oct. 26, 1910, gives the cost of laying the 20-in. supply main for the city of Cheyenne, as follows:

LABOR COST OF LAYING 83,328½ FT. OF 20-IN. CAST IRON WATER MAIN

Item	Total	Per lin. ft. cts.
192¼ dys. No. 0 excavator at $10	$ 1,922.50	*5.24
146 dys. No. 1 excavator at $16	2,336.00	†5.84
2,910 dys. E. & C. bell holes at $2.50	7,275.00	8.73
949.8 dys. laying pipe at $2.50	2,374.50	2.84
199 dys. yarning at $3.50	696.50	0.79
190 dys. lead heating at $2.75	522.50	0.68
174½ dys. pouring at $2.75	479.87	0.58
219 dys. caulking at $3.50	766.50	0.92
237½ dys. helper at $2.50	593.75	0.71
116 dys. testing at $3	348.00	0.42
304½ dys. refilling at $7.50	2,284.00	2.74
453 dys. foreman at $4	1,812.00	2.18
410 dys. teams and teamsters at $5	2,005.00	2.40
147 dys. blacksmith, at $4	588.00	0.70
Pumpmen	119.00	‡99.2
Total	$24,123.12	

* Figured on 36,700 lin. ft. † Figured on 39,600 lin. ft. ‡ Figured on 1,200 lin. ft.

EXTRA WORK IN LAYING 83,328½ FT. OF 20-IN. CAST IRON WATER MAIN

Item	Total
Rock excavation near intake	$ 48.00
Rock excavation west of Round Top	877.80
Cutting off 176 pipe	70.40
Extra fill near intake	162.30
Extra depth of trench	698.59
Diverting creek	38.85
Replacing broken pipe	330.00
Hauling pipe	131.43
Total	$2,357.32

Adding these two totals gives $24,123.12 + 2,357.32 = $26,480.44, which divided by 83, 328.5 lin. ft. gives a cost of 31.8 cts. per lin. ft. The contract price was 39 cts. per lin. ft.

The wages paid did not always correspond to the scale adopted therein, but in most cases the average wages paid will be about the same as those given. An exception is the cost of teams for backfilling, the actual cost of teams for refilling during May and June being $9.50 for a team and two men. Final estimate, including all previous estimates and extras allowed Messrs. Bash and Gray, was $35,246,62, making the actual cost to the City of Cheyenne a little more than $.42 per lin. ft. The average weight of the 20-in. pipe was 1,631 lbs., and the cost of the pipe delivered on the line, including hauling, transportation and cost of material, was $29.70 per ton, or $2.02 per lin. ft., making the total cost of the line when completed $2.44 per lin. ft.

So far as possible, the trench excavation was done by a No. 0 and a No. 1 Municipal Trenching Machines. The former was driven by a 4-cylinder gasoline engine and was capable of digging a trench 28-ins. wide and 7 ft. deep. The No. 1 was a steam driven machine capable of digging a trench 28-ins. wide and 10-ft. deep.

This machine-dug trench had to be widened and deepened at the bell points to allow free access for yarning and calking, considerable hand grading and straightening of the trench had to be done also before the pipe could be properly laid. All this was hand work and is included in cost data under hand grading and bell holes.

The pipes were lowered and entered by means of a derrick, formed by two A-shaped forms connected by a beam, each end equipped with a rope windlass and two single blocks; one man at each windlass lowered a pipe and the pipe last laid was driven home with the pipe that was still swinging from the derrick. This derrick was pulled ahead by a pony. From 15 to 20 pipes an hour could thus be placed by a gang of 7 men, though the average daily progress did not equal this rate.

The calking was done with a pneumatic hammer, a small gasoline compressor, maintaining a pressure of not less than 65 lbs. per sq. in., supplied the hammer. This compressor was mounted on an ordinary wagon truck.

The pipe was tested in sections of variable length, the maximum pressure being 150 lbs. per sq. in.

Cost of Constructing Two 18-in. Cast Iron Water Mains by Day Labor for the Fort William, Ontario, Water Supply.—The following data, published in Engineering and Contracting, May 18, 1910, are from a paper by H. Sydney Hancock, Jr., presented to the Canadian Soc. of Civil Engs.

Supply Main to Reservoir.—The line, which was 10,200 ft. in length, was located to avoid solid rock as far as possible; 8,400 ft. was in a marly clay with occasional boulders, 6,000 ft. in muskeg and 1,200 ft. in solid rock. The grade line was kept at a minimum depth of 4 ft. 6 ins. to insure at least 3 ft. of cover. In the muskeg sections clay, on which the pipe was laid was found at a depth of about 4 ft.

One 18-in. gate valve was placed near the middle of the line and a second close to the reservoir. A check valve was also placed 50 ft. back from the reservoir and two 18-in. valves in the two bye pass lines leading from the supply main parallel to the east wall and past the reservoir to the two 18-in. pressure mains. A cluster of three 1-in. Brook's air valves at every summit and a 6-in., off 18-in., blow off at every depression, a drainage ditch on a 5-10ths grade being executed at each. Manholes of dry rubble were built over each air valve cluster and over the gate valves. The pipes were of standard specification, the limits of weight being from 1,800 to 1,950 lbs. per 12-ft. lengths.

The entire work was done by day labor. Wages paid were as follows:

Superintendent, per mo	$150.00
Sub-foreman, per hr	.40
Blacksmith, per hr	.35
Calkers, per hr	.30
Laborers, per hr	.25

The cost of the work was as follows:

Item	Total	Per lin. ft.
Cleaning and grubbing	$ 460	$0.045
Trenching and backfilling rock, labor	1,698	......
Materials	193	......
Total	$ 1,891	$0.186
Earth, labor	4,504	......
Tools and materials	725	......
Total	$ 5,229	$0.512
Pipelaying, labor	1,065	0.105
Lead, yarn, tools	1,632	0.160
Total	$ 2,697	$0.265
Cast Iron Pipe:		
760,858 tons at $40	$30,691	......
13,812 sleeves, specials at 3 cts	414	......
Total	$31,105	......
Less credits	183	......
Net total	$30,922	$3,030
Hauling pipe	2,130	0.209
Manholes, labor	162	......
Materials	54	......
Total	$ 216	$0.021
Valves	652	0.064
Grand total	$44,198	$4,332

Pressure Main From Reservoir.—This line was 12,520 ft. long, including bye-passes. Six inch, off 18-in., "blow-offs" were placed every half mile, as well as at depressions. Three clusters of three 1-in. Crispin automatic air valves were placed about 4,000 ft. apart.

The pipe used was 18-in. diameter cast-iron pipe of standard specification, from 1,900 lbs. to 2,000 lbs. for all heads over 200 ft., and 1,800 lbs. to 1,900 lbs. for all heads less than 200 ft., excepting across the property of the Grand Trunk Pacific Ry., where no pipe of less than 2,050 lbs. was used. The line was cut into three sections by two 18-in. geared gate valves.

As there was greater possibility of the territory through which this line passed becoming inhabited, the minimum depth for the invert of the pipe was fixed at 6 ft., but in deference to the wishes of the Grand Trunk Pacific Railway Co. the grade line across their property averaged a depth of 12 ft. A 12-in., off 18 ins., cross was placed for the future water requirements of the Grand Trunk Ry.

It was decided that the sand and swamp portions of the line could be laid more economically during the winter, as at that season the movement of the sub-soil water is more sluggish and the depth of frozen ground obviated the use of sheet piling. These advantages were considered to more than compensate for the cost of shoveling snow and the difficulty of excavating frozen ground.

Seven thousand feet of pipe were laid south from the river in February and March at an average rate of 372 ft. per day. The upper section of the pipe was laid during May and June.

No unusual features developed during the progress of the work, the cost of which was as follows:

	Per lin. ft.	Total
Clearing right of way	$0.008	$ 103.50
Excavating trench labor	0.423	5,294.10
Tools	0.028	356.25
Backfilling and tamping	0.104	1,297.34
Total		$ 7,051.19
Cast iron pipe (18-in.)	$3.060	$38,310.87
Inspection at foundry	0.021	267.63
Pig lead	0.147	1,832.90
Yarn	0.003	37.45
Specials	0.041	541.56
Hauling material	0.048	607.20
Total		$41,570.61
Skidding and laying pipe, labor	$0.258	$ 3,228.02
Tools, lumber, plant	0.043	537.19
Accident	0.004	52.00
Total		$ 3,817.21
Culverts and road repairs	$0.021	$ 262.81
6 gate valves	0.080	1,007.00
8 blow off valves	0.015	186.43
9 air valves	0.012	151.08
Total		$ 1,344.51
Manholes, fountain, head walls, etc	$0.057	$ 702.76
Engineering and supt	0.090	1,131.20
Total cost of pipe line	$4.463	$55,880.29
Repairs and alterations at river crossing		$ 1,015.40
Total cost, Section IV		$56,895.69

In the above work common labor was paid 22½ to 25 cts. per hour, calkers 30 cts. per hour and a superintending foreman $150 per month. Cast-iron pipe cost $36.75 per ton at the local foundry, and specials $65 per ton. Pig lead cost $3.80 per 100 lbs., and yarn 8½ cts. per lb. Nearly half a mile of the line was inaccessible to teams, and as a consequence the cost of skidding and handling pipe was high.

Cost of Laying 10,137 Ft. of 12-in. Water Pipe by Day Labor at Tuscaloosa, Ala.—The following data were published in Engineering and Contracting, July 6, 1910.

The work consisted in laying 10,187 ft. of 12-in. pipe and erecting thereon two hydrants with 92 ft. of 4-in. pipe. Prior to starting the work all the pipe had been placed along the line of trench. For laying the pipe five Mueller tripod derricks and equalizers were set and 10 lengths or 120 ft. of pipe were connected, calked and handled at once. The trench was 3 ft. deep. With an average gang of 40½ men and two teams the work was accomplished in 19 working days and 23 days total time. The average length of pipe laid per 10-hour day was 533.5 ft.; the maximum day's work was 1,059 ft. of pipe laid. After completion the pipe was tested to 125 lbs. hydrostatic pressure and only two leaks developed. These were at joints whose pipe had been laid one length at a time in crossing another pipe line and where the ground was too rough to permit lining up 10 lengths at once. There were no leaks in any of the joints caulked on the surface.

The wages paid, working a 10-hour day, were: Laborers, $1.25; yarners and calkers, $1.50 and $2; foreman, $2, and team and driver, $3.50 The cost of the work was as follows:

Labor	$1,051.69
950 lbs. oakum at 3½ cts	33.25
15,864 lbs. lead at 5.15 cts	817.00
1,800 lbs. coal at $2 per ton	1.80
15 gals. coal oil at 17 cts	2.55
Lanterns, nails, etc	11.95
Total	$1,918.24

This gives a cost of 18.9 cts. per lin. ft. of pipe laid. A bid received for the work asked 30 cts. per lin. ft. for laying the 12-in. pipe, 10 cts. per lin. ft. for laying the 4-in. pipe, and $3 each for setting the hydrants or a total of $3,056.30.

Cost of Laying 12-in. Pipe in Deep Trench with Quicksand Bottom.—L. R. Howson, who was Resident Engineer in charge of the construction of the gravity water supply for Norway, Mich. gives the following data, in an article describing this work, in Engineering and Contracting, Dec. 13, 1911.

The system as planned comprises a 12-in. cast iron pipe connection between the lakes, an inlet in Forest Lake, a concrete screening chamber on the shore of Forest Lake, a 12-in. cast iron gravity pipe line 23,000 ft. in length, a reinforced concrete reservoir and connections with the present distribution system and pumping station.

No exceptional difficulties were encountered until the "deep cut" section of 4,000 ft. nearest the lake was reached. This section had an average cut of about 14 ft. with a maximum of 21 ft., and the amount of water in the ditch varied from 4 to 9 ft. in depth when the pumps were closed down. The original contractor removed the top 6 ft. of material with teams and slip scrapers, then started his sheathing and hand excavation. For the first few hundred feet the water was taken care of by two diaphragm pumps, the ditch being dammed with sod behind each bell to prevent flow from behind. Progress became continually slower, and it was apparent that power pumps and other methods must be used and the contractor defaulted.

The National Surety Co. as bondsmen, sublet the contract to a Chicago contracting firm, who started on the deep cut after numerous delays. They tried two No. 2 Nye vacuum pumps to handle the water, but as the entire trench was in a sand carrying a great deal of water, the vacuum pumps on open suction cared for only a short length of ditch, and progress was still very slow. An Emerson vacuum pump with well points was next tried. Four manifolds of well points each 20 ft. long and carrying 16 1¼-in. points 36 ins. in length were purchased, and in this way 80 ft. of ditch could be opened and pipe laid at one pump setting.

Contractor No. 2 also handled his top material differently, using a 30-ton steam shovel with 30-ft. boom and 1-yd. dipper. Owing to the quicksand bottom, the necessity for tight sheathing and the presence of large boulders, this proved to be an impracticable way of removal. This contractor too became discouraged after laying only 500 ft. in three months of experimenting and also defaulted.

The city of Norway was in great need of water at this time (July, 1910), and decided to complete the work under the supervision of the engineers by force account. The steam shovel was dismantled and the top material removed by scraper as before, at a considerable reduction in cost due to the excessive amount removed by the steam shovel to cut out its running benches. The Emerson pump and well points were now operated day and night, and in this way effectually lowered the ground water level below the grade. Lead wool had been used in the joints, but when the trench was dried by continuous pumping the poured joint was again adopted. Sixteen foot planks were used for sheathing, and three or four sets of 4-in. × 8-in. stringers were required. In some places the bank was so heavy that braces were necessary at 3-ft. intervals and 6 ft. was standard. Bell holes were kept dry with diaphragm pumps where necessary.

Progress and Cost.—Proceeding in this way, an average of 50 ft. per day was laid at a cost of $2.57 per ft. Deducting salvage in pumping machinery and planks purchased, the net cost was a trifle under $2.50 per lin. ft. Common labor was paid at the rate of 25 cts. per hour.

After the city assumed charge of the work, there were no accidents or delays of any kind. Previous to this, one man had been killed and four "bottom men" buried in a quicksand "cave-in" for 14 hours before they could be removed. The ditch besides having depth, quicksand and water, paralleled a railroad track but 25 ft. off center, and the jar from passing trains added new difficulties to those already present. The last 500 ft. of pipe was laid along the edge of the lake some 10 ft. from the water, and from 6 to 7 ft. below the water level, but due to the impervious character of the deposit in the lake bed, the difficulty of handling the water was less than was found in caring for the ground flow further removed from the lake.

Cost of Laying 10,693 Lin. Ft. of 8-in. Water Main at Tuscaloosa, Ala.—C. E. Abbott gives the following data in Engineering and Contracting, Nov. 16, 1910.

On July 22, 1910, work was started at Tuscaloosa, Ala., of laying an 8-in. main to the A. G. S. depot, a distance of 10,693 ft., inserting 10 valves and locating thereon 23 fire hydrants and 7 specials for future extensions, using 60 ft. of 6-in. pipe and 312 ft. of 4-in. pipe. Prior to starting this work all pipe, fittings, valves and hydrants had been distributed along the route. This main was laid to replace a 4-in. and 3-in. main along the main thoroughfare to the cemetery and the A. G. S. depot.

The streets had been graveled and rolled with a 5-ton roller, making the first 6 ins. of very hard picking. The trench was 3 ft. deep from the surface of the ground the entire distance, except 420 ft., which was 5 ft.

The main was tested to 125 lbs. hydrostatic pressure without a single leak.

The work was done by day labor under the personal supervision of the writer at the following cost.

Labor	$ 986.43
11,275 lbs. lead at $4.85	546.84
760 lbs. oakum at 3½ cts	26.60
1,000 lbs. coal at $2 per ton	1.00
Nails, etc	.60
Oil	2.55
8-in. plug wood	1.50
Total	$1,565.52

This gives a cost of 14.2 cts. per lin. ft.

In laying this pipe, 120 ft. were laid at a time, using tripod derricks, equalizers, tongs, etc.

The time required to complete this extension was 15 days, of 10 hours each; average number of men each day, 44 4–5; greatest number of feet of pipe laid in one day, 994; average number feet per day, 737 2–3; price paid labor, 12½ cts. per hour, yarners and calkers 15 and 20 cts. per hour.

Cost of Laying 1924-Ft. of 4-in. Water Pipe Extensions.—The following table is prepared from data given by Clark A. Bryan in Engineering and Contracting, July 2, 1913.

TABLE XXIX.—LABOR COST OF LAYING 1924-FT. OF 4-IN. PIPE

Item	Total hours	Hours per foot of pipe	Rate per hour	Cost per foot of pipe, etc.
Foreman	170.5	0.0886	$0.30	2.68
Plowing	11.5	0.0060	0.525	.31
Excavation	678.0	0.3530	0.175	6.18
Pipe laying	122.5	0.0635	0.175	1.11
Pouring and caulking joints	249.0	0.1295	0.22	2.85
Backfilling and tamping	254.5	0.1326	0.175	2.32
Cleaning up	36.0	0.0187	0.175	0.33
Hauling	45.0	0.0234	0.35	0.82
Total				16.60

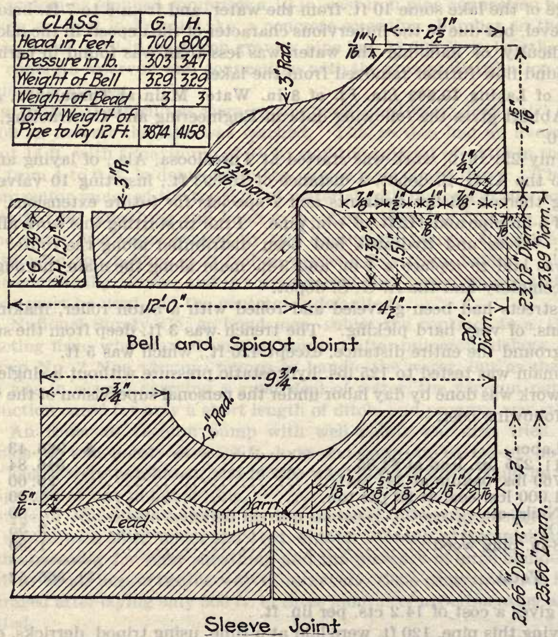

FIG. 26.—Types of pipe joint used in solid ground and soft ground.

The work consisted in laying five 4-in. extensions to the water system of Ridgely, Md. A 4-in. hydrant was installed at the end of each line by 4 × 4-in. tees and no valves were used. The pipe was laid at an average depth of 4-ft. 2-ins. in easily excavated, sand, loam and clay. To break up the first 2-ft. of the excavation a new ground plow attached to a traction engine was used with success on 1414-ft. of the trench. The work was done by force account Mr. Bryan being the Resident Engineer in Charge of Construction.

Of the five different connections, the maximum cost was 18.8 cts. per ft. for labor and the minimum cost was 14.4 cts. per ft.

Construction Cost of San Francisco's High-Pressure Fire Mains.—The following data are taken from an article in Engineering News, Feb. 18, 1915.

In the construction of the high-pressure system of San Francisco, after numerous tests, the types of pipe joints shown in Fig. 26 were finally approved. The bell and spigot joint was used in solid ground and the sleeve joint, which allows a greater displacement of the pipe without leakage, was used in soft ground and in places most susceptible to earthquake action.

The fire mains were constructed under contract, the following table gives the cost of labor, as estimated by the engineers in charge of construction.

TABLE XXX.—COST OF LABOR, AS ESTIMATED BY ENGINEERS IN CHARGE OF CONSTRUCTION

1. TRENCH WORK:

Removing pavements having concrete base, $0.06 per sq. ft.

Removing pavements without concrete base: not counted separately, as cost was found to be practically equal to that of an equal volume of ordinary digging.

Excavating and backfilling trenches and removing surplus excavated material.

Nature of ground	Labor cost per cu. yd. Congested district	Average conditions
Sand, about one-half lagged	$1.10	$0.95
Sandy clay	1.25	1.10
Hard clay	1.40	1.25
Soft rock (shale, red chert)	....	1.40
Hard rock (gadding, some blasting)	$4.00	$6.00

2. LAYING PIPE (Not including setting valves and hydrants):

Kind and size of pipe	Cost of labor, per foot: Hauling	Laying	Calking	Testing	Total
Congested district:					
Bell and spigot pipe: 8-in. (hydrant connection; all joints bolted)	$0.05	$0.17	$0.25	$0.02	$0.49
10-in.	0.06	0.16	0.11	0.02	0.35
12-in.	0.07	0.17	0.11	0.02	0.37
14-in.	0.09	0.26	0.12	0.02	0.49
16-in.	0.11	0.19	0.16	0.02	0.48
18-in.	0.12	0.25	0.14	0.02	0.53
Spigot pipe, sleeve joints:					
10-in.	0.07	0.13	0.14	0.02	0.36
12 in.	0.08	0.13	0.17	0.02	0.40
14-in.	0.10	0.13	0.20	0.02	0.45
16-in.	0.12	0.23	0.21	0.02	0.58
18-in.	0.14	0.15	0.24	0.02	0.55
Average conditions:					
Bell and spigot pipe: 8-in. (hydrant connections; all joints bolted)	$0.03	$0.29	$0.12	$0.01	$0.45
12-in.	0.05	0.06	0.07	0.01	0.19
14-in.	0.07	0.09	0.08	0.02	0.26
16-in.	0.08	0.10	0.12	0.02	0.32
18-in.	0.10	0.19	0.14	0.04	0.47
Spigot pipe, sleeve joints:					
12-in.	0.06	0.11	0.14	0.02	0.33
16-in.	0.09	0.06	0.15	0.03	0.33

Note: Cost of calking, per joint, was as follows:

	Congested district	Average conditions
8-in. joints	$0.90	$0.90
10-in. joints	0.85	....
12-in. joints	1.00	0.78
14-in. joints	1.10	0.90
16-in. joints	1.25	1.23
18-in. joints	1.40	1.44

3. Setting Gate Valves and Hydrants:

8-in. gate valves, each	$ 4.50
10-in. gate valves, each	4.50
12-in. gate valves, each	6.00
14-in. gate valves, each	7.50
16-in. gate valves, each	10.00
Hydrants, each	5.00

4. Miscellaneous Items:

Setting manhole castings	$ 7.00	per ton
Bolting joints of pipe lines	$24.00	per ton
Concrete valve vaults—labor only	$ 9.60	per cu. yd.
Setting reinforcing steel in valve vaults	$14.00	per ton
Laying creosoted wooden telephone duct	$ 0.036	per duct-foot

5. Wage Schedule, per day of eight hours:

Superintendent	$ 6.00 up
Foreman	$ 4.00 to $5.00
Straw boss	$ 3.50 to $4.00
Calker and yarner	$ 4.00
Leadman	$ 3.00 to $3.50
Laborer, watchman	$ 3.00
Team and driver, 4-horse	$10.00
Team and driver, 2-horse	$ 6.00
Team and driver, 1-horse	$ 4.50

Note: The above figures include only the wages of foremen, mechanics and laborers immediately engaged upon the work. Add 10% for general superintendent, timekeepers, watchmen, service wagon, and depreciation and repair of tools. The total cost of construction to the contractor will be obtained by adding the cost of all materials used, and the overhead expense, including office expense, liability insurance, etc.

The excellence of the workmanship on San Francisco's high-pressure pipe system is illustrated by a comparison with New York's fire system. The latter comprises 105 miles of mains, which are maintained under a pressure of 30 lb. per sq. in., and from which the leakage is approximately 850 gal. per minute or 1,200,00 per day. The San Francisco system contains 71.81 miles in which an average pressure of 200 lb. per sq. in. is maintained and the leakage is only 152,000 gal. per day, equivalent to a leakage of only 59,000 gal. per day under a pressure of 30 lb. per sq. in. Since the length of pipe in the San Francisco system is only 71.81 miles, and that in the New York system 105 miles, this 59,000 gal. per day in 71.81 miles of pipe is equivalent to 86,000 gal. per day in 105 miles of pipe, or the leakage per mile in San Francisco's system is only 7.2% of the leakage in the New York system.

Perhaps the principal reason for the tightness of the system were the tests which were made before the work was accepted, as follows:

Class of pipe	Use of head of	Test pressure, lb. per sq. in.
G & H	600 to 760 ft.	450
F	500 to 600 ft.	400
E	400 to 500 ft.	350
D	300 to 400 ft.	300
C	200 to 300 ft.	250
B	100 to 200 ft.	200
A	0 to 100 ft.	150

After several blocks of pipe were laid and calked, the trench between the joints was backfilled, and the bells left exposed. The pipe was then tested, the test pressure varying with the class of pipe.

Pipe to be tested was filled with water and the specified pressure applied by means of a double-cylinder force pump. This pressure was maintained for 20 minutes. If during that period the additional water introduced to keep the pressure constant exceeded 0.0055 gal. per lineal foot of pipe joint under test, the contractor was forced to recalk all joints that gave any evidence of leakage.

Cost of Making an 18-in. Tap on a 24-in. Water Main, Without Interrupting Service, at Columbia, South Carolina.—F. C. Wyse, gives the following matter in Engineering and Contracting, July 4, 1913.

The pipe on which the tap was made is 24 ins. in internal diameter and 25.80 ins. externally, and carries a pressure of about 20 lbs. per sq. in. The excavation was in earth bearing a large quantity of spring water and no record of cost of excavation was kept for the reason that the work was prosecuted intermittently and only at favorable times. A pump was necessary all the time, and the entire hole was close sheeted in order to preclude any accident to the machine by sliding mud. The excavation, however, was no larger than would have been necessary for the cutting in of a tee, and practicaliy the same amount of sheeting would have been used, therefore in making a comparison of costs it would be accurate to place the cost of excavation the same in both cases.

A 24-in. by 18-in. clamped sleeve, internal diameter 26¾ ins., and weighing 1,400 lbs., was adjusted on the pipe with lead wedges. Mud rolls were then placed at each end and in the neck of the sleeve and the lead was poured in the usual manner. This gave a sheet of lead approximately ½ in. thick between the sleeve and the pipe to be tapped. The ends were calked first then the lead in the neck, and the neck lead very carefully trimmed in order not to come in contact with the steel cutter. Onto the neck of the sleeve an 18-in. flanged valve weighing 1,600 lbs. was bolted, and to the valve the tapping machine, weighing 1,000 lbs., was bolted. A derrick supported the weight of the machine. The cutter was then started through the open valve and the cut was completed in 4½ hours, the cutter being turned by hand ratchets. After the cut was made the shaft was withdrawn, the valve closed, and machine removed.

The plug cut out remained tightly in the cutters, the center tapered drill helping in this. The plug was a clean cut, there being no break in the metal other than about 1/16 in. thickness of the inside shell. There were no leaks other than through the stuffing box of the machine which amounted to nothing.

The cost of the work was as follows:

Sleeve and valve	$210.00
Freight on sleeve, valve and machine coming, and machine returning	32.42
350 lbs. lead at 5 cts	17.50
Drayage on material with department truck	1.50
Labor placing sleeve, valve and machine (5 hours)	4.80
Labor operating and removing machine (4½ hours)	5.55
Total cost without excavation	$271.77

The work was done by the water department forces, the men being paid as follows:

Foreman, $2.75; calkers, $1.50; and helpers, $1.25 per day of 10 hours. More men were used in operating the machine than in placing the sleeve, hence the higher cost for a shorter time.

Relative Efficiency and Speed in Making Poured Joints and Lead Wool Joints also of Hand and Pneumatic Hammer Caulking.—The following data are taken from an abstract, of a paper before the Annual Convention of the American Society of Municipal Improvements by Andrew F. Macallum, City Engineer of Hamilton, Ontario, published in Engineering and Contracting, Oct. 20, 1915.

It was found that with the pneumatic hammers between four and five poured lead joints could be caulked to every one in which lead wool was used. This difference was due, generally, to the hammers becoming wedged in driving in the lead wool. It was also found that the compression in the caulking went deeper in the poured than in the wool joint, thus giving greater density.

Several alternate joints were caulked by the pneumatic hammers and by hand and this section was gradually put under pressure. It was found that every joint caulked by hand commenced to leak slightly at 110 lbs. pressure but that the pneumatic caulked joints remained tight.

To compare the relative speed of hand and pneumatic caulking, tests were made with the results shown in the following:

Size pipe, ins.	Class	Depth of lead joint, ins.	Weight of lead used, lbs.	Depth of yarn, ins.	No. of hand caulkers	No. of joints per day	No. of machine caulkers	No. of joints per day
36	C.	3½	121	1	2	4	2	12
30	C.	3	90	1	2	6	2	15

From the above it will be seen that on the 36-in. pipe the machine men caulked three times as many joints as the hand men and 2½ times as many on the 30-in. pipe.

Cost of Cement Joints for Cast Iron Mains.—In 1912 the city of Long Beach, Cal., began the use of cement joints with its cast iron water pipe. At the present time the city has 60 miles of mains, ranging from 4 in. to 24 in. in diameter, laid with joints of this type. All these pipes are under pressures ranging from 40 to 80 lb. per square inch and are giving perfect satisfaction. In a paper presented April 18, 1917 before the American Society of Civil Engineers Clark H. Shaw, Hydraulic Engineer Long Beach Water Department describes Long Beach's method of making these joints. The following, abstract from Mr. Shaw's paper, is taken from Engineering and Contracting, Dec. 12, 1917.

In making the cement joint the pipe is placed and spaced in the usual manner. A thin backing of the best dry jute is used instead of oakum, as the jute is free from oils and grease (which should be avoided). A Portland cement, conforming to the specifications advocated by the American Society for Testing Materials, is used. The dry cement is placed on a piece of canvas (usually a cement sack ripped open) and moistened just so that when thoroughly mixed by hand it will be of such a consistency that when gripped tight it will hold the form of the hand and when dropped 12 in. it will crumble.

The canvas containing the cement is placed under the bell and the cement is tamped into place by hand with a caulking iron until the bell is about half full. It is then caulked with heavy blows until the cement is thoroughly packed in the back of the socket. This process is continued until the bell is packed solid out to the face. A small bead of neat cement in a plastic condition is then put on, using the caulking iron as a trowel. As soon as the initial set of the cement in the bead has taken place the joint is covered with earth to protect it from the air and sun. In backfilling, the excavated material is always settled with water, which helps to cure the exposed portion of the joint.

In Mr. Shaw's opinion, the bead is essential, as the cement packed in the bell is so dry that without protection it would absorb moisture from the water used in settling the trench. It is believed that, should the joint develop seepage when the pressure is put on in the main, the cement, being dry, would expand and aid materially in keeping the joint tight.

Experiments on cement joints constructed without the bead showed that, 24 hours after completion, they absorbed water readily. In cases where seepage has developed and has subsequently closed, it is assumed that the dry cement absorbed the moisture from the inside, expanded, and filled the seepage pores.

About 20 per cent of the cement is wasted by falling off the canvas or being thrown out by the caulker. If any dust or earth from the trench falls on the canvas or in the cement, it is immediately taken out, together with enough cement to make sure that the remainder is clean. In mixing the cement with water, care is taken that there shall be no lumps in the material, no matter how small. If any cement is left on the canvas when a joint is completed, it is used on the next joint, provided the work is continuous, otherwise new batches are made. Special blunt caulking tools are used.

The joint is allowed to stand 48 hours before the pressure is turned on and the main is put into regular service. Cement joints have been used with satisfactory results, however, 12 hours after completion, but this is not considered safe practice.

At San Diego, Cal., a pressure test was made by caulking a 6-in. cast-iron tee, one side of the tee being filled with a plug and each of the two ends filled with short lengths of cast-iron pipe with plugs caulked in the ends. As the pieces of pipe caulked in the tee were scrap ends cut from other pipes, they had no bead on the joint end, and, notwithstanding the fact that the joint was made with smooth pipe, it took a pressure of more than 300 lb. per square inch to force the pipe out. The test was made about 48 hours after the joint was made.

In another test, made at Winnipeg, Man., three lengths of 6-in. pipe were laid with four cement joints, on Jan. 13, 1916. After 6 days, pressure was put on the pipe, in increments of 25 lb., and the joints were found to show no leakage or moisture, up to 125 lb. At 150 lb. one joint showed moisture on the surface of the cement.

On Jan. 24 another test was made, and at one joint moisture appeared at 175 lb. On Jan. 31 this joint showed moisture with 200 lb., and also on March 15, with a pressure of 225 lb. This joint was the weakest of the four. The pressure was kept on the pipe about one-half hour in each case.

The cement joint can be taken apart in a very simple and economical way The pipe is uncovered about one-half, or a little below the center. At the joint where the original bell-hole was dug, the trench is usually made wider on the sides (but not deeper under the pipe, in order to permit the caulker to work at the joint. The upper half of the joint is cleaned out with a cape-chisel; then, with tripod and blocks, the free end of the pipe is raised until the lower half of the joint breaks free from the bell. The pipe seldom has to be pulled out of the bell, as it nearly always works itself out as the free end is lowered. If portions of the cement stick to the spigot end of the pipe, or fail to be entirely crushed in the bell, it is a very simple matter to clean out the bell with a cape-chisel, or knock the cement from the spigot with a hammer.

On occasions, after a joint has been cemented tight in the line, it is necessary, to cut it out entirely (such as for laying a valve on its side; turning a tee or Y in another direction; adjusting a tee to conform to or meet a grade; avoiding a sewer connection or any other unforeseen obstacle). Table XXXI has been compiled from records of the actual time spent in doing such work.

At Long Beach unit costs have been kept on all construction, covering nearly the entire 60 miles of cast-iron water mains. Table XXXII has been carefully compiled from these unit costs, and presents data concerning cement joints.

TABLE XXXI.—TIME REQUIRED FOR ONE MAN TO DIG OUT A COMPLETE CEMENT JOINT, WITHOUT REMOVING FITTING OR GATES FROM THE LINE

Size	Time
4-in	18 min.
6-in	22 min.
8-in	26 min.
10-in	30 min.
12-in	38 min.
14-in	48 min.
16-in	60 min.

TABLE XXXII.—DATA RELATIVE TO CEMENT JOINTS

Size of pipe	Rings of jute per joint	Jute per joint in pounds (approximate)	Number of joints per 94-lb. sack of cement*	Number of joints per 8-hour day (one caulker)
4-in	2	0.14	24	50
6-in	2	0.19	18	42
8-in	2	0.24	14	34
10-in	3	0.43	11	28
12-in	3	0.51	8	24
14-in	3	0.58	7	20
16-in	3	0.66	6	17
18-in	3	0.73	5	14
20-in	3	0.80	4	11
24-in	3	0.95	3	7

*Including the 20 per cent of cement wasted or left over.

Cost of Repairing Fire Hydrants by Welding.—Engineering and Contracting, Aug. 13, 1919, gives the following:

In a discussion of damages to fire hydrants by motor vehicles at the (1919) convention of the American Water Works Association, Wm. W. Brush, Deputy Chief Engineer Department of Water Supply, Gas and Electricity of New York City, states that during the past two years an average of about 400 hydrants were damaged yearly by motor trucks, requiring an annual expenditure of about $12,000 for repairs. Repairs are made by welding by the oxyacetlene process. The hydrant is taken to the city shop and the broken section ground away to a bevel of about 45°, and then new metal is fused in at the break. If the portion of the hydrant thus treated is to be exposed above the ground it is finished off after the welding process is completed. If it is to be below the ground the rough surface is not finished off.

Mr. Brush gives the following costs on this work: The cost of replacing a broken hydrant when the old hydrant is salvaged and repaired, is as follows: welding standpipe of hydrant, $10; assembling hydrant, one mechanic $5 per day, ½ day, $2.50; total cost of repairing salvaged broken hydrant, $12.50. The cost of removing and resetting the hydrant where it has to be taken up about 3 ft. below the surface of the ground is as follows:

1 caulker, one day	$ 5.00
2 laborers at $3.25 per day each	6.50
1 Ford car, one day	3.00
Relaying 16 ft. of sidewalk at 30c per foot	4.80
Contingency	.70
Total	$20.00

The greater part of that $20 would be eliminated in the case of a hydrant that has a flange at the level of the sidewalk.

In the same discussion F. W. Cappeten, City Engineer of Minneapolis, Minn., stated that in his city 43 hydrants had been broken by motor vehicles in 16 months. The average expense per hydrant was as follows:

Excavation, removal and resetting	$14.40
Shop work and assembling	3.84
Welding (done by private concerns)	10.47
Cartage	2.50
Total	$31.21

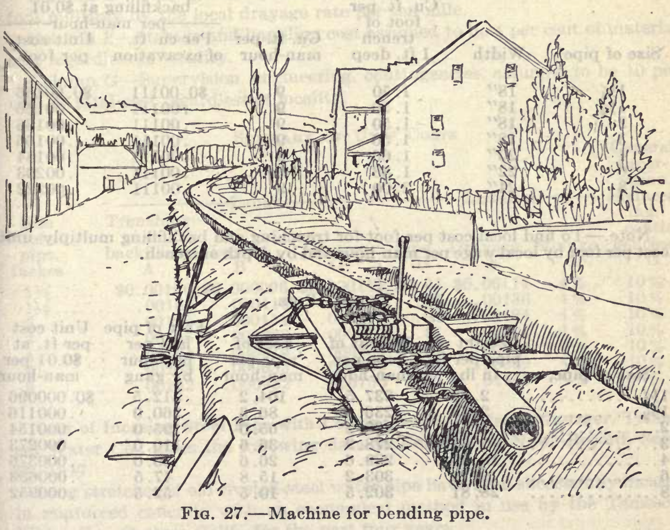

Fig. 27.—Machine for bending pipe.

Cost of Pipe-bending with a Machine (Engineering and Contracting, June 10, 1917).—A labor-saving device is used by the Philadelphia Suburban Gas & Electric Co., Chester, Pa., for the cold bending of 8-in. pipe. The machine is described by Charles Wilde, Engineer of Mains, in a paper presented to the October, 1916 meeting of the American Gas Institute. The arrangement consists of a 10-in. I-beam, 10 ft. long, braced with 1¼-in. tie rod; two ¾-in. chains 8 ft. long one at each end of the beam and an ordinary 20-ton screw jack and block. To operate, all that is necessary is to link the chains around the pipe and I-beam by means of a slip link, place the jack and pipe block in position between the pipe and the beam, and then by the force of the jack make the bend. If the bend required is only a slight one, it may be made without any shift of the machine. If it is a bend of any considerable extent, the machine should be shifted one way or the other, bending the pipe a few degrees until the required bend is made.

With this machine four men can make a bend in an 8-in. pipe, depending, of course, upon the radius and degree of the bend required, in from ½ to 2½ hours. To make the same bend—when possible to be made—in the old way would require about 25 men, who would never lose less than half an hour from their regular work, and would often require twice this time.

Unit Costs of Laying Standard Screwed Steel Pipe.—The following tabulations are taken from data compiled by George Wehrle, Supt. of the Gas Dept. of the Denver Gas and Electric Light Co. and were published in Engineering and Contracting, Jan. 8, 1919.

TRENCHING AND BACKFILLING

Size of pipe	Width	Cu. ft. per foot of trench 1 ft. deep	Cu. ft. per man-hour	Cost of excavating and backfilling at $0.01 per man-hour: Per cu. ft. of excavation	Unit cost per foot
1¼	18″	1.50	9	$0.00111	$0.00166
1½	18″	1.50	9	.00111	.00166
2	18″	1.50	9	.00111	.00166
3	18″	1.50	9	.00111	.00166
4	20″	1.66	9	.00111	.00184
6	22″	1.83	9	.00111	.00203
8	24″	2.00	9	.00111	.00222

Note.—To find local cost per foot for trenching and backfilling multiply unit cost per foot by local wage per man-hour and by depth of trench.

LAYING PIPE

Size of pipe,	Weight of pipe per ft. in lb.	Weight of pipe per man-hour	Feet of pipe per man-hour	Feet of pipe laid per per hour by gang	Unit cost per ft. at $0.01 per man-hour
1¼............	2.28	237.5	104.2	312.5	$0.000096
1½............	2.73	236.4	86.6	260.0	.000116
2..............	3.68	238.2	65.0	195.0	.000154
3..............	7.62	278.9	36.6	110.0	.000273
4..............	10.89	289.6	26.6	80.0	.000376
6..............	19.19	303.2	15.8	47.5	.000633
8..............	28.81	302.5	10.5	52.5	.000952

Note.—Laying pipe covers, reversing of couplings and handling of the pipe from the curb line to the trench and lowering into same. The weight of pipe per man-hour is not constant due to the reversing of a variable number of couplings per unit weight of different size pipes. To find the local cost per foot multiply unit cost by local pipemen hourly wage.

The number of men engaged in laying pipe is taken as 1 foreman and 2 pipemen for all sizes with the exception of the 8-in. pipe when 4 pipemen are used.

JOINTING

Size of pipe	Number of men	Joints per hour per gang	Ft. of pipe per hour per gang	Unit cost per ft. at $0.01 per man-hr.
1¼	2	9	180	$0.000111
1½	2	8	160	.000125
2	2	6	120	.000166
3	2	4	80	.000250
4	2	3	60	.000333
6	2	2	40	.000500
8	3	2	40	.000750

Note.—Jointing pipe covers the work of entering and screwing up pipe in the trench. The number of joints per man-hour varies as the diameter of the pipe. To find local cost per foot multiply unit cost per foot by local wage scale per hour.

Explanation of Summary Table for Standard Screwed Steel Pipe.—Column A—Cost per foot for trenching and backfilling a trench 1 ft. deep at a labor cost of 1 ct. per hour. For local costs per foot multiply by depth of trench in feet and by labor wage rate per hour.

Column B—Cost per foot for laying pipe at a 1 ct. per hour wage scale. For local costs per foot multiply by local wage rate in cents per hour.

Column C—Cost per foot for jointing pipe at a 1 ct. per hour wage scale. For local cost per foot multiply by local wage scale in cents per foot.

Column D—Cost per foot of pipe at 1 ct. Substitute local cost per foot.

Column E—Drayage cost per foot at $1 per ton-mile. For local cost per foot multiply by the local drayage rate per ton-mile.

Column F—Storage and handling cost assumed to be 4 per cent of material cost regardless of locality.

Column G—Supervision, engineering, contingencies, assumed to be 10 per cent of total cost regardless of locality.

SUMMARY OF UNIT COSTS

Size of pipe, inches	Labor			Material			General supervision, engineering, contingencies
	Trenching and backfilling A	Laying B	Jointing C	Pipe D	Drayage E	Storage F	G
1¼	$0.00166	$0.000096	$0.000111	$0.01	$0.00114	4%	10%
1½	.00166	.000116	.000125	.01	.00136	4%	10%
2	.00166	.000154	.000166	.01	.00184	4%	10%
3	.00166	.000273	.000250	.01	.00381	4%	10%
4	.00184	.000376	.000333	.01	.00544	4%	10%
6	.00203	.000633	.000500	.01	.00959	4%	10%
8	.00222	.000952	.000750	.01	.01440	4%	10%

Cost of Incasing Steel Pipe with Concrete.—H. R. Case, Manager, Temescal Water Co., gives the following data in Engineering News-Record, Sept. 20, 1917.

Long stretches of old riveted-steel water pipe have been successfully incased in reinforced concrete with an economical method in use by the Temescal Water Co., Corona, Calif., for the past four years.

The details were worked out for use in covering 10,000 ft. of 24-in. riveted-steel pipe line used as inverted siphons working up to 80 ft. head. This line was laid 30 years ago and is beginning to give way near the ends of the siphons, and where light weight steel was used on account of low heads. Possibly

95% of the iron is still in the pipe, but it has rusted badly and pitted particularly at the seams, so that it has been necessary to make repairs during the irrigation season. The system not only protects the outside of the pipe and prolongs its life by the jacket of reinforced concrete, but eventually utilizes all the iron in the old pipe, and when it has disappeared leaves a reinforced-concrete pipe without joints, sufficiently strong to carry the pressure.

Figure 28 shows the details of the wood form used in covering the 24-in. pipe. The forms are constructed of Oregon pine and lined with No. 26 black iron, which saves not only the forms but much material, making a smooth outside surface to the finished pipe. Forms for 24-in. and larger pipe are made in 8-ft. lengths, while the smaller sizes are made up in 12-ft. lengths.

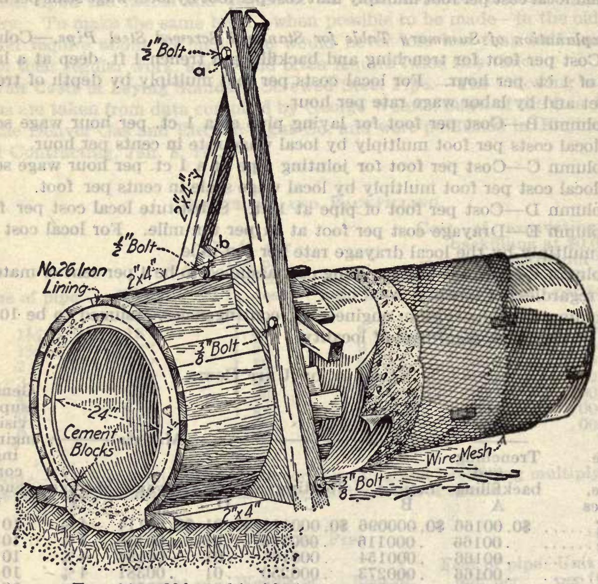

FIG. 28.—Old steel inside form for new concrete pipe.

After the steel pipe is uncovered it is thoroughly scraped and cleaned with steel brushes. The ground under the pipe is then shaped to the required depth, the pipe being supported on wood blocks until the forms are set. Bedplates of 2 × 4s are then spaced with a template, similar to the end section of the form, on each side of the pipe to support the forms when in place. The wire-mesh reinforcement cut to 50- or 75-ft. lengths is then wound spirally around the pipe and supported where the edges unite by small cement-mortar blocks made in the form of truncated pyramids, 1½ in. high, 2 in. square at the base and ¾ in. at the apex, which is placed next to the pipe. A man with a hand mold will make 2,500 or 3,000 of the small blocks in nine hours. The edges of the mesh rest on the base of the little pyramids, thus keeping the wire mesh spaced a uniform distance from the steel pipe or forms. As the blocks are placed, the edges of the wire mesh are tied together with No. 24 soft stovepipe wire.

The forms are then placed on the 2 × 4s and held rigid by the two ½-in. bolts as shown. The wood blocks supporting the pipe are removed, and the pipe is held in place by a strand of wire and a turnbuckle clamp until the form is filled to a point where the concrete will support the pipe. The concrete is a 1:2½:1 mixture of cement, sand and crushed rock or screened gravel of ¾-in. maximum size. It is mixed by hand and poured rather wet, being worked to place with a light rod and by tapping the forms with a hammer. In laying the pipe up hill the top openings, as the forms are filled, are closed with covers clamped to place until the concrete sets slightly, when the covers are removed and the surface is well trowled and smoothed. The next morning the forms are removed, and the pipe is painted with neat cement. The pipe is then covered with soil and kept wet for two weeks.

Progress and Cost.—Twelve men will easily build and backfill 140 ft. of 18-in. pipe, 100 ft. of 24-in. or 80 ft. of 30-in. pipe in a day of nine hours.

The company is replacing 30-in. steel pipe under 40-ft. head, placed on bridges, with concrete siphons of the same size, at a cost of $2.50 per ft., including the ditching. Covering 24-in. pipe including the digging costs $1.70 per ft., and 18-in. pipe $1.40 per ft. Cement is $2.30 per barrel and labor from $2.25 to $2.50 per day.

Cost of Wood Stave Pipe at Seattle, Wash.—The following data, taken from Engineering and Contracting, Feb. 13, 1918, show the cost of wood stave pipe in place at Seattle, Wash. The work was done in 1914 by the municipal water works of Seattle. The figures cover the cost of 42-in. and 54-in. pipe and are based on lumber at $31.25 per M ft. B. M. in place, steel bands at 4½ ct. per pound in place and common labor at $2 to $2.25 per day:

COST OF 42-IN. PRESSURE PIPE IN PLACE PER LINEAL FOOT WITH 3 ⅝-IN. BANDS PER FOOT

	Per lin. ft.
27 ft. B. M. of fir staves at $31.25 per M	$0.844
3 ⅝-in. bands 40½ lb. at 4½ ct	1.822
3 mal. iron shoes, 5.64 lb., at $0.0515	0.290
48 cu. ft. ex. back fill per lin. ft. at 31 ct. per yd	0.551
Total	$3.507

COST OF 54-IN. PRESSURE PIPE IN PLACE PER LIN. FT. WITH 3 ⅝-IN. BANDS PER FOOT

33 ft. B. M. fir staves at $31.25 per M	$1.03
3 ⅝-in. bands 52½ lbs	2.36
3 mal. iron shoes, 5.64 lb., at $0.0515	0.29
63 cu. ft. excavation at $0.31 cu. yd	0.72
Total	$4.40

42 in.	—25 ft. B. M. per ft	25 to 27 staves
44 in.	—26 ft. B. M. per ft	26 staves
54 in.	—33 ft. B. M. per ft	33 staves
*51½ in.	—40 ft. B. M. per ft	32 staves
60 in.	—46¼ ft. B. M. per ft	37 staves
48 in.	—30 ft. B. M. per ft	30 staves

The staves for this 51½ in. pipe are thicker than for the other sizes.

Forty eight-inch Wood Stave Pipe Line Across Marsh Land, Atlantic City, N. J.—George L. Watson, Engineer for the contractor describes in detail the methods employed and the difficulties encountered in carrying on the construction of the 48-in. wood stave pipe line supplying Atlantic City, in the Sept., 1912 number of the Journal of the American Society of Engineering Contractors. The following data are taken from an abstract of Mr. Watson's paper published in Engineering and Contracting, Oct. 30, 1912.

The work consisted of constructing 25,500 lin. ft. of 48-in. continuous wood stave pipe with three submarine "thorough-fare" crossings. The contract price for which was approximately $225,000.

The marsh, across which the pipe runs, is flooded at high tide and at times the work was completely stopped because of the water that covered the meadows. The surface of the marsh was so soft that it was necessary to float the pipe on a 2 × 12-in. plank cradle. This consisted of a 2 × 12-in. plank on each side of the bottom of the 2½-ft. ditch, in which the pipe was constructed, with the cross-pieces of the same size every 4 ft. Manholes were constructed at intervals of 1.000 ft. To protect the pipe line across the meadows from wave and ice action it was necessary to construct fenders on each side of the pipe embankment.

Construction of the Pipe.—The actual construction of the pipe was subdivided into sections. The excavation gang consisted of a Parsons Trenching machine and six men, and this outfit was about 1,000 ft. ahead of the finishing gang. This machine crept along and excavated a trench 5 ft. wide and 2 ft. deep, and at the rate of 500 ft. of ditch per day. However, there were so many delays not due to any defect in the machine, that it was not found expedient to continue to use this machine for more than 2½ miles of the work.

Following this machine was a gang of about 20 men and a foreman, who had to maintain the trench the proper width. This was necessary because the banks continually pushed toward each other into the trench, and, therefore, this gang was generally only about 500 ft. ahead of the men who were placing the cradles or foundation for the pipe. It was necessary to keep the ditch about 8 ft. wide to allow the men to do all the work properly and to cinch the bands.

The foundation gang consisted of six men and a foreman, and their duty was to build the timber foundation upon which the pipe was laid.

Then came the pumping gang, which consisted of six men, one engine man or pump man, and one foreman, and whose duty was to keep the ditch dry ahead of the pipe layers. Their outfit consisted of a larry upon which was mounted a 10 h.p. Olds gas engine, belt-connected to a 6-in. centrifugal pump, sod spades and other necessary tools. They divided the trench into sections by means of bulkheads, and kept dry only the sections in which the men were working, while other men threw up low dikes around the excavation to hold back tides as long as possible. It cost about 2 cts. per linear foot to build these dikes.

The pipe-laying gang consisted of 13 men and a foreman, and they were divided up so that in laying the pipe each man had only one portion of the work to perform. Two men were located on the bank as peddlers to handle the material of which the pipe was assembled, one man was located inside the pipe with mallet and chisel to set the staves and round them out, and two men placed at the end of the advanced pipe to assist in setting the staves. Along each side of the ditch three men would set the forms, and shape the section, while two men at the head of the section were employed to drive the staves home and band them up.

To assemble the pipe a form consisting of a piece of 3-in. pipe bent to a radius of 26½ ins. and reaching half-way up to the circumference was laid about 2 ft. back of the end of the advancing staves. This form was generally laid flat upon one of the foundation cross-pieces; then five or six staves were set at the bottom and tapped into position; and immediately thereafter the form was raised to an upright position, thus shaping the bottom of the pipe. The inside form, which consisted of a piece of 2-in. gas-pipe bent to a radius of 24-in., was next placed inside the lower portion of the pipe. It was set on the inside of the pipe directly over the outside form and the additional staves were then placed under the direction of the foreman at the head of the pipe who calls out whether he wants a long or a short stave. As soon as the circle was completed a band was slipped on at the head of the pipe and loosely cinched; one of the side staves was then marked with a pair of calipers and every sixth mark crossed as a guide to the "banders" who followed.

About ten bands were slipped on a section, which was then "rounded out," rolled and "driven home," after which the gang proceeded to lay the next section.

The pipe gangs averaged about 150 lin. ft. of pipe per day, while the best day's work of any one gang was 680 ft. Under ordinary conditions 400 ft. was a fair day's work, but the construction was much delayed because the men could not stand in the ditch without a platform or they would sink in the mud up to their waists, which, together with the large amount of water that had to be pumped was the cause of the slow progress made.

The tides also proved troublesome, especially when the wind was contrary, and at times the work was completely stopped because of the water that covered the meadows. Another thing that was a constant source of delay was the effect of the weather on the staves. The specifications called for 29 staves to complete the circle. During good and dry weather there was no difficulty in inserting the required number, but the slightest change in the weather affected the lumber, and if the air was damp or if it rained it was impossible to use all the staves. In that case, unless the work was to be stopped entirely, 28 staves and one strip cut out of a full stave had to be used.

Following the pipe layers came the band gang, which consisted of a foreman and 20 laborers, with four "band men." The latter were paired, one of each pair on opposite sides of the pipe. They slipped the bands on the pipe at the marks made by the pipe layers and tightened the nuts so as to merely hold the shoes in position.

The cinching gang, which came next, consisted of from 30 to 40 men and two foremen. This gang had to tighten the nuts on the bands to almost their final position by using a brace wrench. At the extreme end of this gang were four "spacers," who hammered the bands to their ultimate position and gave the nuts their final tightening. After them came the painters, who applied on the bands the remaining coat of rust preventive, as demanded by the specifications.

Finally, the gang which completed the embankment over the pipe varied from 10 to 40 men, depending upon the tides and conditions that influenced the building of the pipe.

Cost Data

The following are cost data for various operations of the pipe line work.

Pipe Line Materials

Staves, $47.17 f. o. b. cars job.
Bands, $2.20 per 100 lbs. f. o. b. cars job.
Saddles, $3.50 per 100 lbs. f. o. b. cars job.
Clips, $3.50 per 100 lbs. f. o. b. cars job.

Staves

Unloading from cars and hauling to job, 2 miles	$ 1.00
Sorting into sections and unloading	5.00
Loading on larries (teams $5.00 per day, 10 hrs.)	2.10
Delivering in sections along R. O. W	1.05
Per cent of cost of track and laying 30-lb. rails	0.15
Supervision	2.30
Total labor cost along ditch	$ 11.60
Cost lumber	47.17
Cost per M. ft. B. M	$ 58.77

Bands

Unloading from cars at Atlantic City, giving second coating of asphaltum as called for by Specs. reloading and shipping to Absecon, N. J., per 100 lbs	$ 0.10
Unloading from cars and haul to job	.035
Rehandling in yard	.015
Third coating in troughs. (Laborers at $2.00 per 10 hrs.)	.20
Loading on cars	.02
Delivering along R. O. W	.22
Per cent of cost of track laying	.005
Supervision	.015
Labor cost per 100 lbs	$ 0.610
Band cost per 100 lbs	2.20
Total cost per 100 lbs	$ 2.810

Saddles

Unloading from cars at Atlantic City, giving second coating of asphaltum, reloading and shipping to Absecon, N. J	$ 0.05
Unloading from cars and hauling to job	.035
Rehandling in yard	.015
Third coating in trough	.10
Delivery along R. O. W	.22
Loading on cars	.01
Per cent of cost of track laying	.005
Supervision	.015
Labor cost per 100 lbs	$ 0.45
Saddle cost per 100 lbs	3.50
Total cost per 100 lbs	$ 3.950

Clips

Cost per 100 lbs. in kegs delivered along the line of work	$ 3.68

Trenching

Cutting trench 2½ ft. deep, 6 ft. wide by Parsons trenching machine, trench filled with water, machine carried on heavy 4 × 12-in. planks 12 ft. long laid crosswise of trench, with 4 × 6-in. planks 24 ft. long laid on top for traction wheels to rest on, coal ($5.00 per ton) carried to machine by men in 50-lb. sacks across marsh, water rolled in barrels across marsh one-half mile to machine—cost per lineal foot	$ 0.20
Trenching by hand, cutting ditch to 8-ft. width, trimming bottom and sides, men in ditch standing on movable platform which was dragged along with them. All spoil thrown one side only	.09
Backfilling pipe, using material excavated from trench and placing same over pipe, per linear foot	.09

Cost of Building Pipe

Actual cost of building pipe in meadow exclusive of foundation or repainting or surplus enbankment, not called for by original specifications

29 ft. B. M. at .05877	$ 1.704
80 lbs. bands at .0281	2.248
10 lbs. saddles at .0395	.395
Total material per linear foot of pipe	$ 4.397
Machine trenching	.20
Hand trenching	.09
Pumping	.10
Laying pipe	.13
Banding	.11
Cinching	.42
Spacing	.103
Painting	.05
Backfilling	.09
General supervision	.14
Tools	.10
General expense	.22
Total cost per linear foot	$ 6.150

Actual cost of building pipe in Boulevard, trench 8 ft. wide, 7 ft. deep, running sand, water 18 ins. below surface, close sheeting, no allowance made for sheeting lumber, which was afterward used in fenders.

Total cost materials	$ 4.397
Excavation at .31	.63
Sheeting 16 sq. ft. at .023	.368
Pumping	.16
Laying pipe	.22
Banding	.13
Cinching	.48
Spacing	.12
Painting	.055
Backfilling	.15
Removing sheeting	.24
General supervision	.14
Tools	.10
General expense	.22
Total cost per linear foot	$ 7.410

Actual cost of building pipe along side of Meadow Boulevard Road, extra was paid for removal of sloping shoulder, trench 8 ft. wide, 3 ft. deep, in moist sand.

Total cost, materials	$ 4.397
Excavation	.07
Laying pipe	.09
Banding	.07
Cinching	.383
Spacing	.09
Painting	$ .04
Backfilling	.08
General supervision	.14
Tools	.10
General expense	.22
Total cost per linear foot	$ 5.680

Actual costs of building pipe on trestle over thoroughfare crossings 3 hrs. per tide.

Total cost, materials	$ 4.397
Temporary working platforms	.20
Additional cost, lighters and scows	.10
Laying pipe	.13
Banding	.10
Cinching	.40
Spacing	.10
Painting	.053
Blocking and temporary wedges	.12
General supervision	.14
Tools	.10
General expense	.22
Total cost per linear foot	$ 6.060

Embankment

Cost of constructing an embankment 18 ins. thick on top and 2 ft. thick on sides over pipe, to a width of 6 ft. at the top, 12 ft. at meadow level, all material taken from meadow, 16 ft. from center of pipe, trench to be cut even and graded, to act as drain for water in pipe trench.

1 foreman at $4.00	$ 4.00
1 sub-foreman at $2.50	2.50
15 laborers at $1.75	26.25
1 waterboy at $1.00	1.00
Per cent of cost of tools for sharpening	1.00
150 ft. per day	$ 34.75
Cost per linear foot	.231

Timber Foundation—Extra Work

Timber per 1,000 ft. f. o. b. Atlantic City	$ 26.50
Hauling to job, 6 miles, one trip per day	5.00
Unloading to cars and pushing along line	10.00
Unloading from cars, sawing and assembling along ditch	1.50
Placing in position and spiking	5.00
Supervision	2.00
Cost per M	$ 50.00
Cost per foot of pipe	.45

Erection of Laborers' Quarters, etc.

Cost based on 25,500 linear feet of pipe, for building and erecting one bunk house of 150 men capacity, one house of 100 capacity, one mess house, one store house, etc.

One storehouse and one foremen's quarters, no lumber taken into account, as the houses were torn down and the lumber used in the pipe foundation when a change of base was made.

Cost per foot of pipe	$ 0.18

Fender Construction

The operation costs per day of the pile driving crew were as follows: This crew was paid 12 hours for a day's work, but worked only 8 hours, 4 hours on each rising tide.

1 foreman at .80	$ 9.60
1 engineman at .30	3.60
1 topman at .225	2.70
2 deck hands at .20	4.80
2 set men at .20	4.80
1 boatman at .20	2.40
Labor per day	$ 27.90
Coal	2.00
Scow rental	8.00
Total cost per day	$ 37.90
8 piles for 2 tides, cost per pile	4.74
Cost per foot of pile driven	.157

This cost is high, but it must be borne in mind that the tide rose and fell so quickly that only 4 piles could be driven in one tide, while with deep water 25 piles could and have been placed under like conditions.

Fenders

One 30-foot pile every 5 feet.

Stringers, two 2-in. by 12-in. lower, two 2-in. by 12-in. upper notched in piles, and bolted with 1-in. by 8-in. bolts with O. G. washers. Uprights 2-in. by 12-in. —6 feet long, 2 bolts, one in upper and one in lower stringer, 4 O. G. ¾-in. washers. Fenders painted with bituminous paint.

Based on 10 linear feet of fender:

60 feet of creosoted piling at .28	$ 16.80
Hauling piling	2.00
Driving piling	9.42
120 feet B. M. uprights, $36.00 on job	4.32
80 feet B. M. stringers, $36.00 on job	2.88
Placing lumber and bolts, including boring holes	47.00
Painting	1.00
Bolts and nuts	4.80
Supervision	5.00
Cost per 10 linear feet of completed fender	$ 93.22
Cost per linear foot	9.32

Bottom stringers and bolts below low water 2 hours work per day, all timber floated out in position, bored and bolted and placed by men in small row boats; no scows or lighters to be had.

Scale of Wages

Pipe layers, $2.00 per 10-hour day.
Cinchers, $2.00 per 10-hour day.
Banders, $2.25 per 10-hour day.
Spacers, $2.25 per 10-hour day.
Painters, $1.75 per 10-hour day.
Laborers, $1.75 per 10-hour day.
Superintendent and engineer, $11.66 per day—$350.00 per month.
General foreman, $5.00 per day.
Gang foremen, $4.00 to $3.00 per day.
Excavation foremen, $3.50 per day.
Pump men, $3.50 per 10 hours.
Watchmen, $2.00 per 10 hours.

Wages paid were high, as all work was in water always at least 18 ins. deep, boots' average life 4 weeks with good care, cost $5.50 per pair wholesale. Hard to keep men at work, 600 to 700 on payroll—200 to 300 working.

Cost of Driving Piles for Manholes.

Four 30-foot piles for each manhole. Manholes 1,000 feet center to center. Cost includes building pile driver, assembly of plant, driving piles, moving driver, dismantling and returning to store yard and completion.

Lumber for machine, except skids	$ 90.00
Delivery at Absecon Camp	20.00
Hauling engine from Atlantic City to Absecon	15.00
Bolts, lines, bars, rollers, nippers, tools, etc.	80.00
Labor assembling driver—	
Foreman carpenter at $5.00; 3 laborers at $2.00, 4 days	44.00
Total cost plant	$249.00
Dismantling engine and haul to yard	10.00
Dismantling leads and skids and haul to yard	22.00
	$281.00
Less credit for skids, rope and tools charged to another branch on completion of driving	56.00
Total charge against the work for plant	$225.00

It must be remembered the machine started at Absecon end and worked toward Atlantic City; all piles were delivered at Absecon with exception of 12, which were delivered on "Old Turnpike Road;" therefore machine had to carry with it 40 piles. As each manhole required 4 piles, each move meant 4 piles less to drag forward, but you can see the handicap the work was done under having no base of supplies. This crew started out before track was laid or shanties built and water sometimes 2 feet deep on meadows, so that machine had to be blocked up or fire would be put out.

Pile Driving Crew

1 foreman at $4.00	$ 4.00
1 engineman at $3.50	3.50
1 top man at $2.25	2.25
4 laborers at $2.00	8.00
2 hours of superintendent's time at $1.16	2.32
2 hours of timekeeper's time at .30	.60
Coal, delivered within 2 miles of work and carried in 50-lb. sacks across marsh by men, per day—Coal cost delivered $5.00 per ton	4.10
Water rolled in barrels ½ mile across marsh	1.05
Oil, waste, etc	.09
Rental charge on engine and boiler	2.00
Total cost per day	$ 27.91
Number of days worked	16
Total cost of labor	$446.56
Total cost of plant	225.00
Entire cost of work	$671.56
52 30-ft. piles driven in place:	
4 piles, each 1,000 feet, cost per pile	$ 12.915
Cost per linear foot of pile	.43

Manhole Gang

1 foreman at $3.50	$ 3.50
6 skilled laborers at $2.00	12.00
1 hour timekeeper at $3.00	.30
1 hour superintendent at $11.66	1.16
Per cent of waterboy	.09
Cost per day	$ 17.05
Time required to set manhole complete, 2 days	2
Labor cost to set	$ 34.10
Per cent of plant cost	1.30
Unloading and hauling material	5.00
Cost each	$ 40.40

Cost of constructing manholes on meadow upon piles driven by pile driving crew. Weight of completed manhole, 4½ tons. Composed of 1 Tee (4,000 lbs.), 2 Bells and Flange Pins (4,200 lbs.), 88 1½-in. by 7¼-in. Tobin Bronze Bolts and Crex Nuts, 2½-in. Seamless Tubular Lead Gaskets, 1 Manhole Plate and Bolts. Base of supplies, average 1½ miles. Plant used to set manhole—1 tripod, 1 5-ton chain hoist, 1 2-ton chain hoist, six 10-in. × 10-in. × 30-ft. timbers, 8-in. × 8-in. blocking, chains, tackle, wrenches with 3-ft. handles, spades, cross-cut saws, diagraphm pump, 1 timber cart, wheels, 48-in. with 10-in. tread (iron), coup hooks, etc., rollers.

Manholes

Unloading from cars at Absecon and hauling to end of track at Absecon Camp, $1.00 per ton by contract	$ 5.00
Loading on cars and transporting to end of track	2.10
Unloading on cribs	.80
Excavating around piles 8 ft. by 8 ft. by 3 ft. 6 ins. water level at surface requiring constant pumping	3.30
Cutting off 4 piles and capping	.60
Skidding casting over hole and cribbing	6.20
Bolting on 2 bell pieces, including gaskets	12.00
Lowering into position and adjusting	3.10
Supervision	6.00
Percentage of plant cost less credit	1.30
Total labor cost each for setting	$ 40.40
Total labor cost each for piles	51.66
Total labor cost for foundation and setting	$ 92.06
Cost of 4 piles delivered	16.00
Cost of 2 caps delivered	2.04
Final cost, including piles, foundation and labor	$110.10

Cost of building intersection at Sta. 78 + 0 composed of two 48 × 42-in. reducers, two 42-in. gate valves, one 42 × 42 × 42-in. T., one 42-in. blank flange, 200 Tobin bronze bolts, five lead gaskets, etc. Nearest supply depot, 3 miles. Intersection located within 300 ft. of W. J. & S. R. R. main line; made arrangements with railroad to load all material on flat car at Atlantic City ; haul to job at night and railroad to unload all material on ground by railroad derrick.

Unloading from cars at Atlantic City at contractor's plant; by derrick of all material for intersection	$ 8.70
Loading on flat cars at contractor's plant at Atlantic City of all material and tools for intersection	12.30
Hauling to job by railroad and unloading on ground, railroad derrick used	25.00
Excavation 8 × 8 × 3 ft. 6 ins. water level at surface requiring constant pumping	18.23
Cutting off 12 piles and capping	1.97
Laying boards for track to skid castings	2.00
Skidding over in position over caps of all castings	62.10
Bolting up, including gaskets and blocking	42.00
Removing blocking and lowering into position	18.30
Supervision	18.00
Percentage of plant cost less credit	2.60
Total labor cost for setting	$211.20
Total labor cost for piles	154.98
Total labor cost for foundation and setting	$366.18
Cost 12 piles delivered	48.00
Cost caps—10-in. by 10-in.—delivered	19.82
Final cost, including piles, foundations and labor	$434.00

Curves for Estimating the Labor Cost of "Continuous Stave Pipe."— The following data are taken from an article in Engineering and Contracting, Feb. 17, 1915, by Andrew Swickard, Hydraulic Engineer.

The total cost of a "continuous stave pipe" is made up of numerous items and is about as follows:

Staves—
- Cost of rough lumber: (Factory price f. o. b. cars)
  - Yarding
  - Handling to mill
  - Milling
  - Interest and insurance
- Transportation:
  - Railway or boat.
  - Wagon or auto truck to convenient points.
  - Distribution along the line.
- Construction:
  - Assembling the staves, including tongues, with only enough bands on to hold them together.

Bands—
- Factory cost of rods:
  - Freight charges.
  - Wagon haul.
  - Distribution along pipe line.
  - Bending to proper form.
  - Painting.
- Factory cost of shoes:
  - Freight.
  - Haul.
  - Distribution
  - Painting.
  - Assembling on pipe, spacing and backclinching.

Tongues—
- Factory cost of band iron:
  - Freight.
  - Hauling.
  - Cutting into proper lengths.
  - Painting and distribution.

The cost of transportation is incidental to the distance and other physical conditions attending any given project. The same applies to the distribution of the material along the pipe line. If the topography is such that wagons can be drawn along in the immediate vicinity of the pipe line, the task is easy but if the line is along the side of a steep canyon and the material must be hoisted from below or let down from above by means of an aerial tramway, or other similar means, the cost becomes comparatively high.

After the staves have been distributed along the line at convenient points, in piles averaging about 300 ft. apart and each pile containing enough staves to fill in the intervening gaps, the material must be sorted and laid ahead of the construction party in piles containing the number of staves necessary to complete the ring of the pipe. This phase of the distribution is a part of the cost

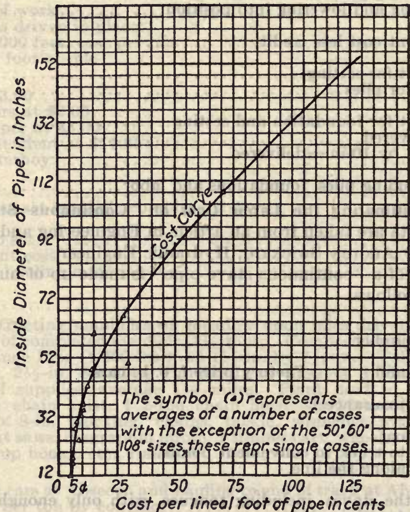

FIG. 29.—Labor cost curve for continuous wooden stave pipe.

Curve gives labor cost of assembling the staves, inserting the metal tongues, putting on 5 or 6 bands per 10 ft., driving the staves end-wise, and sorting and distributing the staves from piles about 100 ft. apart.

of assembling the staves in the pipe. The cost of assembling the staves with only enough bands put on to hold them together varies with local conditions. The cost curve shown in Fig. 29 is an average of actual costs for sizes of pipe below 9 ft. in diameter; above 9 ft. the curve is merely extended. This curve is based on 9 hours labor at $2.50 per day, one foreman at $3 per day, and part of a general foreman's time, say ¼ of $6 or $1.50 per day.

The cost of assembling the staves of a 66-in. pipe as represented in Fig. 29 is 28 cts. In an actual case where the average length of pile set up per day was 64 lin. ft. the detailed cost was as follows:

	Per day
Part of superintendent's time	$ 3.00
Foreman	3.00
Four assistant builders	10.00
One distributor of material	2.50
Water boy	.50
	64)$19.00
	29.7*

*Cts. per foot of pipe.

The crew putting on and placing the bands would follow the assembling gang, and following these would be the back-cinchers. When the spacing of

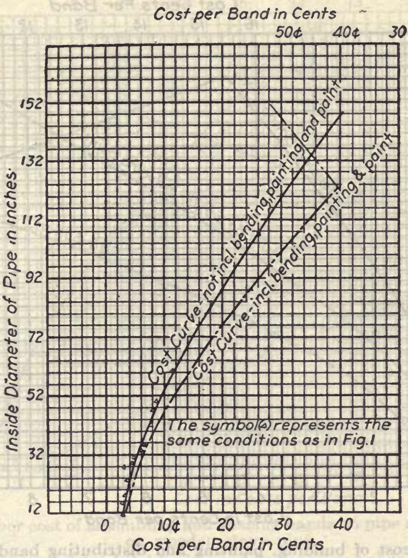

FIG. 30.—Labor cost curves for fitting on bands on continuous wooden stave pipe.

The solid line represents the cost of distributing, putting on, spacing and cinching. The dotted line includes bending, painting and paint in addition to the other items.

the bands averages about 3 ins., two men ordinarily can put on and space the bands as fast as the pipe can be assembled. The size of the pipe and whether the band is in one or two parts will influence the progress made. Because of the same influence the number of the back-cinching crew will vary from 4 to 8 men in order to keep up with the assembling of the pipe. Fig. 30 represents the cost per band in place on the pipe, painted and back-cinched or finally tightened.

A band passes through a number of stages of preparation before it is finally disposed of on the pipe; it must be bent to the proper form, dipped in paint, distributed, assembled and spaced on the pipe, hammered to a proper seating on the wood, and finally cinched. The dotted line in Fig. 30 represents the cost of putting a band through this process, and Figs. 31 and 32 represent the cost of each of the separate steps.

The bending and the painting of the rods is usually done immediately along the pipe line, it being more convenient to deliver the bands straight than bent. Also it is desirable to keep the handling of the bands, after they are painted, at a minimum.

The bending or shaping of the bands requires one man at a bending table. The table is a substantial structure as high as a man's waist, with a raised

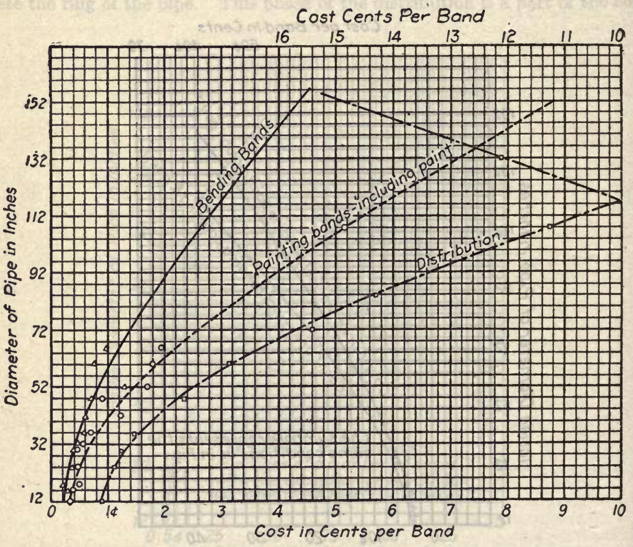

FIG. 31.—Labor cost of building, painting and distributing bands for wooden stave pipe.

Cost of painting includes paint. Distributing cost covers carrying band from dipping tank, located at about 300 ft. intervals along the pipe line. The symbols along the bending and painting curves are average cost, those along the distribution curve are the result of computations from relative information. The painting cost includes that of the rods, shoes and tongues.

circle or half circle on the top, around which the band is bent. A full circle is used when the rod is in one piece and the half circle when the rod is in two pieces.

The quantity and the character of the paint used will affect the cost of the painting; the quality only as far as the price is concerned, but the character will influence the thickness of the coat and waste. The use of a paint that dries rapidly and thickens quickly in the dipping vat, and therefore requires frequent additions of a thinner, will result in considerable waste, especially on the dripping board; the paint that drips from the bands will become too thick to run back into the vat.

The distribution of the bands after being painted should have considerable attention in order to keep the cost at a minimum. They are best placed when left in bundles alongside the line, out of the way of the stave assembling crew but so that the band assemblers have merely to reach for them. The number of bands distributed over, say, every 50 ft. should be determined by the band spacing over the given distance.

The cost of back-cinching, which consists of hammering the bands to a proper bearing on the staves and cinching them down tight, is the most varia-

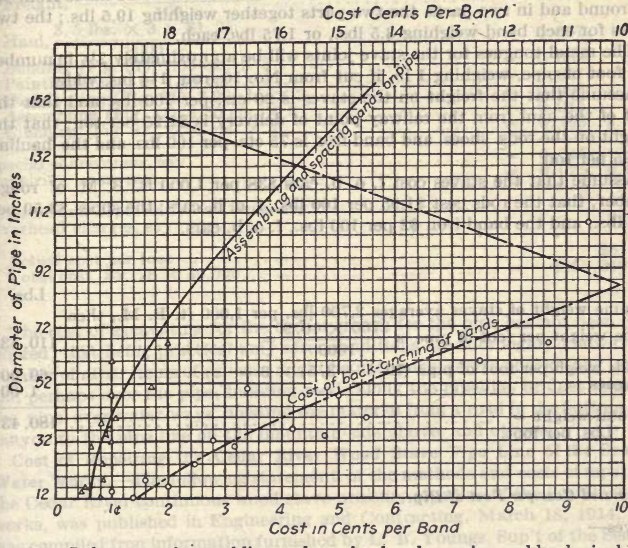

FIG. 32.—Labor cost of assembling and spacing bands on pipe and back-cinching on wooden stave pipe.

Black-cinching consists of tightening and hammering bands to a proper bearing in the wood. The symbols represent average costs; the variation in the cost of back-cinching is much greater than for any other item of cost because all classes of labor are employed on this part of the work.

ble of any item of cost connected with the actual construction of the pipe. It is a thoughtless sort of job and men, good, bad, and indifferent, are usually put at this task; the resulting cost in a way corresponds with the men.

The cost diagrams give average costs for building "continuous stave" pipe. The cost will be affected by: the quantity of pipe to be installed, the character of the season as affected by the locality, the physical character of the country over which the pipe is located, and the kind of labor that is available. A pipe built on a bench cut into a rugged mountain side, where nearly every section of pipe set up will have to be curved, would run up in cost. The assembling of the staves under such condition might exceed the cost given by the curve by 50 per cent. The cost of the items connected with the banding of the pipe would not vary nearly as much as the stave work under such conditions.

Example of Use of Unit Costs.—As an example of the use of the cost of the various items, we will apply them to an assumed case, as follows:

The pipe to be 60 ins. inside diameter; staves 2½ ins. thick, milled from 3 × 6-in. stock, 36 staves to complete the ring, requiring 54 ft. B. M. of rough lumber per foot of pipe, the actual material in the finished staves being 75.7 per cent of that in the rough material or 40.9 ft. B. M.

The total length of the pipe being, say, 30,000 lin. ft., requiring a total of 90,000 bands, or an average of 3 bands per foot; the rods to be made from ⅝-in. round and in two parts, the two parts together weighing 19.5 lbs.; the two shoes for each band weighing 3.5 lbs., or 1.75 lbs. each.

The metal tongues for the stave joints will be approximately 2½ in number per foot of pipe, weighing 1 lb. if cut from No. 10 iron, 1½ ins. wide.

Assume that the freight on the staves is 20 cts. per 100 lbs. and that the cost of the haul from the railway point of delivery is $1.25 per ton; that the freight on the rods, shoes, and band iron is 75 cts. per 100 lbs. and the hauling $1.25 per ton.

Assume that the staves cost f. o. b. cars $38 per 1,000 ft. B. M. of rough lumber; that the rods cost $1.95 per 100 lbs., f. o. b. cars; the shoes $3.50 per 100 lbs., and the band iron $2 per 100 lbs., f. o. b. cars.

	Lbs.
Assume weight of staves averages 2,700 lbs. per 1,000 ft. B. M., then the weight per foot of pipe is $\frac{2700 \times 40.9}{1000}$ =	110.43
Bands weigh per foot of pipe (19.5 + 3.5) × 3 =	69.00
Tongues	1.00
Total weight =	180.43*

*Lbs. per foot.

Estimated Cost per Foot of Pipe.

Staves—		
Material, $\frac{\$38.00 \times 54}{1000}$ =	$2.052	
Waste, ½ of 1% =	0.010	
Freight, $\frac{2700 \times 40.9 \times \$0.20}{1000 \times 100}$ =	0.221	
Hauling, $\frac{2700 \times 40.9 \times \$1.25}{1000 \times 2000}$ =	0.069	
Assembling (from Fig. 29) =	0.230	$2.582
Tongues—		
Material, 1 lb. × $0.02 =	0.020	
Waste, 1½% =	0.003	
Freight, $\frac{1 \text{ lb.} \times \$0.75}{100}$ =	0.008	
Haul, $\frac{1 \text{ lb.} \times \$1.25}{2000}$ =	0.001	
Cutting into clips =	0.002	0.034

Bands—		
Rods, $\frac{19.5 \text{ lbs.} \times 3 \times \$1.95}{100}$ =	1.141	
Waste, ½ of 1% =	0.006	
Freight, $\frac{19.5 \text{ lbs.} \times 3 \times \$0.75}{100}$ =	0.439	
Haul, $\frac{19.5 \text{ lbs.} \times 3 \times \$1.25}{2000}$ =	0.037	
Shoes, $\frac{3.5 \text{ lbs.} \times 3 \times \$3.50}{100}$ =	0.315	
Waste, 1% =	0.003	
Freight, $\frac{3.5 \text{ lbs.} \times 3 \times \$0.75}{100}$ =	0.079	
Haul, $\frac{3.5 \text{ lbs.} \times 3 \times \$1.25}{2000}$ =	0.007	
Bending (Fig. 31), 1.05 cts. × 3 =	0.032	
Painting (Fig. 31), 1.90 cts. × 3 =	0.057	
Distributing (Fig. 31), 3.20 cts. × 3 =	0.096	
Assembling (Fig. 32), 1.50 cts. × 3 =	0.045	
Cinching (Fig. 32), 6.50 cts. × 3 =	0.195	2.452
Special connections, say =	0.045	
Repairing leaks, say =	0.025	0.070
Interest and depreciation on tools, say		0.015
Overhead charges, say		0.025
Actual cost per foot		$5.178
Total cost, $5.178 × 30,000 =		$155,340.00

The cost of excavating for the bed or trench for the pipe has not been considered; that being practical only after conditions are thoroughly known. A number of other items of expense might be necessary, such as backfilling under and perhaps over the pipe, building roads along the pipeline, bridges to carry the pipe over water-ways, hoisting the material from a road in the bottom of a canyon to the pipe line on the mountain-side above, and others.

Cost of Repairing the Cedar River Wood Stave Pipe Line of the Seattle Water Works.—The following statement, of the methods and costs of repairing the Cedar River continuous wood stave pressure pipe line of the Seattle water works, was published in Engineering and Contracting, March 18, 1914, and was compiled fron information furnished by L. B. Youngs, Sup't of the Seattle Water Department.

Cedar River Water Supply Pipe Line No. 1 was put in commission in Jan., 1901. The pipe is mainly 42 ins. inside diameter, though some parts are 44 ins. It is built of 6-in. staves made from the native Douglas firs. These staves are cut from 2-in. × 6-in. scantling dressed outside and inside to true circumferential, and on the edges to radial lines.

After 13 years the steel bands do not seem to be seriously corroded. The staves, however, or more accurately speaking, individual staves here and there, began to show evidence of serious decay as early as seven years after installation. Other staves right alongside of them have remained practically sound. It has been necessary, therefore, to renew certain staves, rather than to renew the pipe as a whole. At some places, where the pressure is light and where the covering is of loose gravel which readily admits the air and changes of temperature, sections from a few hundred to a few thousand feet have been fully replaced, after a use of 12 years, with new pipe, using, of course, the old steel bands.

The method of repair is simple. It consists of uncovering the pipe, loosening the bands, taking out the decayed stave, inserting the new stave in its place, and cinching the pipe up again.

After the staves have been planed to form in the mill they are 1⅝ ins. thick. These staves will hold water very often until in some places they are decayed until there is only a shell ¼ in. thick. Of course this is where the pressure is comparatively light, and the backfilling compact. Sapwood naturally decays rapidly and the department specifies that not more than one-fourth of the thickness of the stave, and then only on the inside, shall be sap.

Following is a detailed statement of the actual cost of replacing 1,600 lin. ft. of 44-in. pipe in 1913. Common labor was $2.75 per day.

The work was done by day labor under departmental direction.

TABLE XXXIII.—COST OF REBUILDING 1,600 FT. OF 44-IN. WOOD STAVE PIPE AT SEATTLE, WASH., IN 1913

Item	Amt.	Cost	Cost per lin. ft.
Cost of Labor:			
Excavation—			
130 days labor	$ 357.50	....	....
28¼ days team	141.25	$ 498.75	$0.31
Wrecking pipe—			
30 days labor	82.50	82.50	0.05
Painting staves—			
17 days labor	46.75	46.75	0.03
Erecting pipe—			
72 days labor	198.00	198.00	0.12
Cinching pipe—			
58 days labor	159.50	159.50	0.10
Tamping pipe—			
78 days labor	214.50	....	.....
26 days team	130.00	344.50	0.22
Total cost of labor, 1,600 ft. pipe	$1,330.00		
Total cost of labor, 1 ft. pipe	$0.83		

Cost of Material:

Item	Amt.	Cost	Cost per lin. ft.
42,551 ft. stave lumber at $31.25 per M	$1,329.72	$1,329.72	$0.83
Hauling staves—			
6 days labor	16.50	....	.....
13¾ days team	68.75	85.25	0.05
155 gals. C. A. wood preserver at 65 cts.	100.75	100.75	0.06
Total cost of material, 1,600 ft. pipe (exclusive of iron bands and shoes)	$1,515.72		
Total cost of material perlin. ft. of pipe			$0.95
Total cost of labor per line ft. of pipe			.83
Total cost of pipe rebuilding per lin. ft.			$1.78

The painting mentioned under labor is an experiment. The department officials cannot say just what its effect will be.

Life of Service Pipes.—The following data, from the Preliminary Report of Committee on Service Pipes submitted at the Portland, Me. Convention of the New England Water Works Association, are given in Engineering and Contracting, Dec. 11, 1916. The figures given are the averages of replies received from a large number of questionnaires sent out by the committee.

	Years before trouble begins	Life of pipe (years)
Plain iron or steel	12	16
Galvanized	15	20
Lead	10	35
Lead lined	10	23
Cement lined	14	28

Methods and Costs of Thawing Water Mains and Services.—Data on the 1917–18 experiences of 96 cities with frozen water mains and services are included in the report of a special committee of the New England Water Works Association. The methods employed by these cities in thawing are summarized by Engineering and Contracting, Jan. 18, 1919, in the following table:

	Mains, No. cities	Services, No. cities
Electricity	36	31
Steam	8	8
Hot water	4	11
Electricity, hot water	5	24
Electricity, steam	5	6
Electricity, hot water, steam	2	10

One city reported that the blow torch was employed in thawing services; another city employed fire.

The cost of thawing with electricity per job varied from $20 to $1. A summary of the costs is as follows:

No. cities	Reported cost	No. cities	Reported cost
3	$20	10	$10
1	18	3	$8 to $10
3	$15 to $16	21	$5 to $8
3	12	6	$3 to $5
2	11	5	Less than $3

The cost of thawing with steam ranged from $4.50 to $75, the later figure being reported by Stamford, Conn. One city reported a cost of $5, one a cost of $17.70, one $20, one $9.41, one $7.63, one $4.50, one $7.50, one $6.50, one $16.50, and one $14.

The reported cost of thawing with hot water ranged from $2 to $20. Four cities reported the cost as being $2. One a cost of $2.67; three a cost of $3; five a cost of $4 to $5; three a cost of $5 to $6; one a cost of $11.20; one $14, one $17 and one $20. One city reported the cost as being 5 cts. per foot of pipe thawed.

Three cities reported on the cost of thawing by fire. In one case the cost was $11.16, in another $10.96 and in the third $10 to $30.

Cost of Water Main Cleaning in Kansas City, Mo.—The following data are taken from an article by Charles S. Foreman in Engineering News-Record, June 16, 1921.

Mr. Foreman believes that the following essential facts based upon his experiences will help to answer some of the questions which are usually asked:

(1) Cleaning can be so arranged that a main need not be out of service longer than twelve hours for cleaning. (2) The cleaning process is not injurious to the mains. (3) An increase in carrying capacity of from 60 to 85 per cent was obtained in large mains and the carrying capacity of such mains was restored to that of new pipe. (4) The saving in coal costs alone, derived from

cleaning, will pay the entire cost of cleaning within from one to three years. (5) Laying of additional mains to obtain increased capacity can be postponed until the consumption demands are equal to the maximum capacity of the old main on the basis of new pipe. (6) When taking as credits such items as coal saving and postponement of obligatory laying of new mains the entire cost of cleaning is saved within from six months to a year.

The contractor's price for cleaning ranged from 26c. per foot for 16-in. pipe to 45c. per foot for 36-in. pipe and the total cost, including all expenses for operating valves, cutting and repairing pipe and for all necessary sleeves and material was $22,046 for 43,837 lin. ft. of pipe cleaned, or 50.3c. per lineal foot for all sizes. The total cost of cleaning the various sizes including pavement repairs and operation of valves, etc., was as follows:

Length, ft.	Size, in.	Total cost	Cost per lineal foot, cents
7,202	16	$2,472.52	34.3
7,280	20	$3,056.80	41.9
3,371	24	$1,813.56	53.5
8,984	30	$5,604.93	62.3
17,000	36	$9,098.28	53.5

The table on the following page shows the length of time in service, the annual operating cost for coal before and after cleaning of the various sizes cleaned, the investment required and the annual interest thereon to obtain the increased capacity by laying new mains, and the total annual saving all being based on 5,000 ft. of each size and on the normal flow through the pipe at time tests were made.

Cost of Cleaning Water Mains of Louisville, Ky.—The following notes are taken from an article by F. Osborne Redford published in Engineering and Contracting, Sept. 6, 1911.

Cost of Cleaning Four-inch Mains in Louisville.—The cost of cleaning 4-in mains for the Louisville Water Company is given below. These costs are fo the work done from June 2 to June 12 inclusive, 1909. These dates are selected because at that time the most troublesome section of the city mains where being cleaned. During these eleven days 7,937 ft. of 4-in. mains were cleaned at a contract price for all labor and material of 7 cts. per ft. The total cost to the city was, therefore, $555.59.

Actual Cost.—The actual cost of labor and material used in this job was as follows:

42 4-in. sleeves	$ 55.88
63 ft. 4-in. pipe	18.26
Yarn	0.60
Lead	12.00
Cement	8.00
Sand	0.65
Labor	162.99
Teams	32.00
Overhead charges	44.69
Total actual cost	$335.07
Actual cost per ft., 4¼ cts.	

It should be noted that the mud and incrustation encountered on this section of 4-in. pipe nearly closed the main. The deposit in this section of the city was mostly a yellow mud from the Ohio, with just a very thin scale of incrustation at the bottom of the main. The capacity of this main was increased 550 per cent by cleaning.

Service years	41	42	28	33	33
Size, inches	16	20	24	30	36
M. G. D. normal flow	2.4	3.4	5.0	12.0	16.0
Loss of head per 5,000 ft.:					
Uncleaned	24.00	23.50	12.60	23.50	15.25
Cleaned	7.50	5.60	5.25	9.00	6.00
Annual coal cost to operate line:					
Uncleaned	$462.53	$641.60	$505.90	$2,264.46	$3,740.52
Cleaned	$144.53	$152.89	$210.79	$867.24	$1,471.68
Annual coal saving	$318.00	$488.71	$295.11	$1,397.22	$2,268.84
Size required to obtain increase in capacity if not cleaned, inches	12	16	16	24	30
Estimated cost	5,000 ft.	$27,200	$33,100	$70,000	$73,500*
Interest on expenditure 5 per cent	$1,360	$1,655	$1,655	$3,500	$3,675
Total annual saving	$1,778.00	$2,143.71	$1,950.11	$4,897.22	$9,618.84
Total cost of cleaning	$1,715	$2,095	$2,675	$3,115	$2,675

Annual cost for fuel to pump one million gallons 1 foot high at Quindaro = $0.042.
Annual cost for fuel to pump one million gallons 1 foot high at Turkey Creek = $0.022.
*No pavement or rock. Surface supply Missouri River water.

Cost of Cleaning Six-inch Water Mains in Louisville.—The contract price for cleaning the 6-in. main on 9,183 ft. of main, for labor and material, was 8 cts. per foot. The total contract price was $734.64.

Actual Cost.—The actual cost for labor and material was as follows:

33 6-in. sleeves	$ 55.77
9 ft. of 6-in. pipe	3.30
Lead	11.72
Yarn	0.39
Cement	4.60
Sand	0.60
Labor	131.69
Teaming	24.00
Overhead charges	28.00
Total actual cost	$260.07
Actual cost per ft., 2.83 cts.	

The writer also cleaned water mains in Middletown, Pa., for the Middletown Sawtara Consolidated Water Co., and found the cost of the work there about the same as in Louisville.

Cleaning Large Mains.—The machine used for cleaning larger size pipe such as 8-in. and over is of similar design, with a double plunger in the rear so as to propel the machine with water power, thereby doing away with the cable used with the smaller type of machine.

The writer knew of one case in the East where about five miles of 20-in. main was cleaned at a contract price of 60 cts. per ft. This price was exhorbitant. As a matter of fact the entire five miles of pipe were cleaned in about two weeks at a total cost not exceeding $1,500. It has been the writer's observation that such exorbitant prices have kept many water companies from cleaning their mains by contract. It is the judgment of the writer that water companies would save a great deal of money by cleaning their own mains.

Prices per Linear Foot for Cleaning Water Pipe.—The following data are taken from an abstract, of a paper by Caleb M. Saville, Chief Engineer of the Board of Water Commissioners of Hartford, Conn. before the New England Water Works Association, published in Engineering and Contracting, Feb. 18, 1914.

The city of Hartford, Conn. is supplied with water by gravity, there being three mains connecting Reservoir No. 1 with the city as follows: two 20-in. mains and one 30-in. main. The south 20-in. main originally laid in 1867 had been largely relaid. The north 20-in. main was laid in 1875 and was therefore 37 years old when cleaned. The 30-in. main was laid in 1896 and was 16 years old when cleaned.

The supply of water was inadequate through these pipes and there was considered the advisability of constructing a new connecting main or of cleaning the existing mains.

If a new supply pipe was laid it would be at least 36 ins. in diameter and about 33,000 ft. long. At a minimum price of $8.25 per linear foot, this line would cost about $270,000, the interests on which at 5 per cent simple interest would be $13,500 per year, and at compound interest the charge would be $74,500 in five years.

The preliminary estimate for cleaning three miles of 30-in. and six miles of 20-in. pipe was $15,300, a little more than the interest for one year on the amount necessary to lay a new 36-in. main. If, therefore, the construction of the 36-in. main could be put off for five years without detriment to the service, the saving to the city was estimated to be about $60,000.

The list prices quoted by the National Water Main Cleaning Co., of New York, for doing work in the distribution system were:

LIST PRICES PER LINEAR FOOT OF WATER PIPE FOR MECHANICAL CLEANING

Diam. of pipe	Cost per ft., cts.
6-in	16
8-in	17
10-in	18
12-in	22
16-in	26
20-in	30
24-in	40
30-in	65
36-in	80

These list prices were stated to be for average conditions for lengths of five miles or more only for purposes of preliminary estimate, and were submitted with the reservation that local conditions might cause considerable variation either way. In Hartford a price of 28 cts. per linear foot for 20-in. pipe was given for a 3-mile contract, with a further reduction if a greater length was cleaned. The conditions were exceedingly favorable for a large part of the way on account of few consumers on the line, advantageous location of gate valves and blow-offs for cutting out sections of proper length and also because of a parallel main with cross-connections which gave ample water for operating the machine without interference with the city supply.

A contract was entered into Sept. 4, 1912, with the National Water Main Cleaning Co. to clean, on trial, 3 miles of 20-in. pipe, and if satisfactory results were obtained the cleaning process might be continued through several miles additional of 20-in. and three miles of 30-in. pipe.

Work was begun Sept. 6 and suspended on Oct. 24 on account of scarcity of water in the reservoirs. The results were very satisfactory and during this period, 49 days, a total of 33,093 lin. ft. was cleaned. On this section there were 154 service pipes which were shut off during cleaning and only four were at all interfered with by the cleaning operations. Three of these were extension meters located at the street line with no curb cocks, and it was necessary to remove the meter and clean out the dirt. The other service affected was plugged, but was easily relieved by a force pump.

The usual force employed on this work was a superintendent, a foreman, a calker, 14 laborers and a double team for carting pipe, materials and supplies.

Under average conditions 3,000 lin. ft. was found to be the maximum effective length for cleaning. The contractor stated that 5,000 ft. had been successfully cleaned by him elsewhere, although in some places it had been possible to go only 1,500 ft. at a time, using water to drive the machine. If the machine is drawn through by a cable, the length of section is from 500 to 1,200 ft. It is stated that the machine can be operated by water under heads of as low as 10 or 12 lbs. The least available head on the Hartford lines was somewhat greater than this.

Relative Merits and Costs of Dug and Driven Wells.—The following data, given in Engineering and Contracting, July 14, 1915, are taken from a paper before the Boston Society of Civil Engineers by William S. Johnson, Consulting Engineer and published in the Journal of the Society for May, 1915.

As to the relative merits of driven wells, dug wells or filter galleries, there is no question but that dug well is the most satisfactory, provided the conditions are favorable and if the expense is not too large. Where water is obtained from some neighboring water source and the depth of porous material is small, a filter gallery parallel to the shore of the surface source may be desirable. Where the water-bearing soil is at some considerable depth it is almost invariably much cheaper to obtain water by means of tubular wells.

Table XXXIV.—Cost of Dug Wells

Place	Year built	Depth in ft.	Diameter in ft.	Cost
Bedford	1909	21.0	20.0	$ 3,981
Avon	1895	22.0	20.0	3,317
Canton	1889	29.0	40.0	8,555
Cohasset	1909	33.67	25.0	3,500
Greenfield	1913	31.0	40.0	7,850
Henniker, N. H.	1914	25.15	20.0	2,141
Manchester	1892	29.0	32.0	10,476
Marblehead	1912	31.0	25.0	6,100
Middleborough	....	22.0	26.0	4,964
Waltham	....	18.0	40.5	8,940
West Warren	1913	18.0	20.0	3,800
Winchendon	1911	35.0	40.0	7,815

Between these two extremes the best method to adopt must be determined by local considerations. One of the advantages of the dug well is that there is a large body of water in store from which to draw while the pumps are being run, and when this is exhausted the well has the time until the pumps are next operated to recover. This means that pumps of larger capacity can be used than with the driven well plant. Furthermore, under these conditions the average suction is likely to be less, as in the case of driven wells the ground water level at the wells goes down quickly when the pumps are started.

Perhaps the chief advantage, however, of the large well is the avoidance of troubles from sand and air which are likely to occur in any driven well plant.

Construction of Wells.—The construction of tubular wells and the method of making connections with the suction pipe are of the greatest importance, as the leakage of a small quantity of air will cause endless trouble; and it is also desirable that it should be possible to cut out any particular well from the system.

Table XXXV.—Cost of Tubular Wells

Place	No. and size	Depth, in ft.	Cost of wells	Cost per well	Cost, including suction to pump-station
Ashland	12–2½ in.	25–32	$1,267	$105.00	$1,460
East Brookfield	9–2½ in.	20.7 av.	604	67.20	......
East Douglas	9–2½ in.	....	......	....	629
Duxbury	22–2½ in.	27.8 av.	......	....	3,324
Littleton	10–2½ in.	22 av.	......	....	2,000
Merrimac	18–2½ in.	35 av.	......	....	3,100
North Chelmsford	20–2½ in.	30 av.	2,800	140.00	......
Oxford	15–2½ in.	24–28	......	....	800
Pepperell	34–2½ in.	19–28	2,704	79.50	3,200
Plainville	11–2½ in.	25–50	4,500	....	......
Uxbridge	16–2½ in.	26–35	1,800	112.50	......
Wrentham	9–2½ in.	29 av.	1,048	116.50	......
State School	6–2½ in.	....	680	113.20	......
Fairhaven	30–2½ in.	22½ av.	2,040	68.00	5,645
Wareham	12–2½ in.	39 av.	1,160	97.00	......

The usual size of driven wells in New England is 2½ ins. The adoption of this size is simply the result of experience, as it is found that this is about as large a pipe as can well be driven under ordinary conditions, and it is, of course desirable to have the pipe as large as is feasible. For the well, an extra heavy wrought-iron pipe should be used, as in the process of driving the pipe receives very hard treatment and it requires a heavy pipe to stand the strain. The pipes are driven with open ends except in the case of very fine sand, when strainers have to be resorted to. The bottom length of pipe is perforated with a large number of small holes about ¼ in. in diameter for a distance of perhaps 2 ft. from the end of the pipe.

The two methods of driving the pipes most commonly in vogue are the use of a tripod carrying a pulley block over which the rope carrying the driving weight passes to men standing on the ground, and the use of a platform, clamped to the well casing above the ground, upon which the men stand and lift the driving weight by hand. The use of the tripod is the simpler, but the platform has the advantage of carrying the weight of the men upon the pipe, which assists materially in sending the pipe down with each blow. It would seem that the raising weight by a rope would be much easier for the men than to stoop and lift the weight as is necessary with the platform. Men, however, incline toward the platform method.

After the pipe is driven and washed out, it is cut off at the level at which the suction is to be placed. A long-turn T is put on and then the pipe is continued up to somewhat above the surface of the ground, the object of the extension to the surface being to provide access to the well for cleaning out, as sand is likely to work into the pipe. The well is then connected to the suction with 2½-in. pipe and a lead gooseneck, each connection being provided with a gate so that it can be shut off in case it gives trouble. The object of the piece of lead is to give flexibility to the connection and prevent danger of leakage.

Cost of Water Supply Wells in Iowa.—The following table is arranged from data published in Engineering and Contracting, Jan. 27, 1915 given by Prof. John H. Dunlap in University Extension Bulletin No. 8 of the State University of Iowa.

TABLE XXXVI.—COST OF WATER SUPPLY WELLS IN IOWA

Place	Date of constr.	No. of wells	Depth, ft.	Diameter ins. Top	Diameter ins. Bottom	Total ft. cased	Water* stratum	Total cost with casing	Cost per foot

Note—

1. Drilled 24 ins. in diameter and filled with concrete outside 20-in. casing to cut off surface water.
2. The 10-in. casing is 374 ft. long, and extends to the surface inside the 12-in., which is 304-ft. long.
3. Double cased with 70 ft. of 12-in. casing and then 120 ft. of 10-in. inside.

*Gvl. = Gravel, R. S. = River Sand, Ss. = Sandstone, Ls. = Limestone.

CHAPTER VIII

WATER-TREATMENT PLANTS

The subject of water purification and treatment is a growing one and its importance becomes greater with increasing population and the consequent danger of contamination of public water supply. In this chapter are included not only, general data on the cost of constructing and operating water-treatment plants but also detailed costs of specific operations.

Further cost data on this subject will be found in Gillettes' "Handbook of Cost Data." For costs of pumps and pumping the reader is referred to Gillette and Dana's "Handbook of Mechanical and Electrical Cost Data."

Hypochlorite and Liquid-chlorine Costs.—The following data published in Engineering News-Record, May 3, 1917, are taken from a paper by Philip Burgess, before the Indiana Sanitary and Water-Supply Association in Feb. 1917.

Hypochlorite and liquid chlorine at Indiana water-treatment plants in 1916 averaged 8.5 lb. of hypochlorite and 1.8 lb. of liquid chlorine per 1,000,000 gal. of water treated. The average costs were 5.3 and 16c. per lb. respectively. Thus liquid chlorine cost only 60% as much for material as hypochlorite.

Cost of Liquid Chlorine Treatment of Water.—Engineering and Contracting, April 10, 1918, publishes the following cost data on the operation of liquid chlorine plants given in a recent technical paper of the New York State Department of Health prepared by C. M. Baker, assistant engineer, Division of Sanitary Engineering. The figures show the approximate cost of apparatus, maintenance and operation of the plants at Hudson Falls, N. Y., and Westfield, N. Y. The costs of chlorine treatment at these two plants was as follows:

HUDSON FALLS

Apparatus—		
Chlorinator	$400.00	
Apparatus for testing B. coli	25.00	
Incubator	10.00	
Total	$435.00	
Yearly cost, interest at 5 per cent		$ 21.75
Operation—		
Chlorine, 100 lb. at 9½ ct	$ 9.50	
Freight	1.05	
Trucking	.50	
Total	$ 11.05	
Yearly cost based on treating 600,000 gal. per day with .3 parts per million of chlorine		60.44
Maintenance per year		15.00
Total yearly cost		$ 97.19
Cost per 1,000,000 gal. water treated		0.44

WESTFIELD

Plant—		
Apparatus	$450.00	
Building	125.00	
Stove	10.00	
Total	$585.00	
Yearly cost, interest at 5 per cent		$ 29.25
Operation—		
Chlorine, 100 lb., at 17½ ct.	$ 17.50	
Freight	.65	
Cartage	1.25	
Total cost of chlorine per 100 lb	$ 19.40	
Yearly cost of chlorine based on treating 1,000,000 gal. per day with .3 parts per million of chlorine		177.00
Attendant per year		100.00
Oil for heater		20.00
Maintenance per year, estimated		20.00
Total yearly cost		$346.25
Cost per 1,000,000 gal. water treated		0.95

At Hudson Falls the plant is located in the pumping station and is attended by the engineer, thus eliminating the cost of the building, heating and attendance, while at Westfield the plant is 2 miles in the country and a new separate building had to be constructed to house the apparatus. The other item of difference in cost is chlorine. With the cost of chlorine the same at Hudson Falls as at Westfield, viz., 17½ ct. per pound, the total cost per 1,000,000 gal. of water treated would be $0.64 instead of $0.44.

Cost of Electrolytic Chlorine.—The following matter is taken from an abstract published in Engineering News—Record, May 24, 1917, of a paper before the American Water Works Association by F. H. Pitcher and James O. Meadows, respectively chief engineer and filter superintendent of the Montreal Water and Power Co.

The electrolytic-cell installation has been in service since only the first part of 1917, but during that time many interesting data have been secured.

The chlorine-cell installation includes a salt-storage bin having a capacity of 40 tons of salt, the brine saturating and purifying equipment, two 15-hp. motor generator sets, four chlorine cells, and the silver ejectors and distributing lines for applying the chlorine water to the water to be treated.

The brine saturating and purifying equipment consists of three vertical galvanized-iron saturators, 27 in. in diameter by 6½ ft. in height, provided with a spray system at the bottom and an outlet 6 in. from the top and two concrete reaction tanks having a capacity of 82 cu. ft. each. These tanks are built with sloping bottoms and have a pipe grid for air agitation. Two sand filters are provided for filtering the purified brine, which passes from the filters to the two concrete storage tanks, having a capacity of 276 cu. ft. each.

The distributing lines for applying the chlorine water to the water to be treated are 1-in. chemical hose lines. The chlorine gas is ejected into the water by means of a silver ejector, which maintains a 4-in. vacuum on the chlorine cells and takes the gas from the chlorine main through the ejector to distributing lines.

The electrolytic cell is of the Allen-Moore type. It is a standard 600-amp. cell and is 7 ft. long by 20⅜ in. wide. Each cell is provided with Acheson graphite anode plates and pure wrought-iron perforated cathode plates. The Allen-Moore cell is of the unsubmerged diaphragm type and uses asbestos paper for the diaphragm material. Unlike several other types of electrolytic chloroine, cells the cell box of the Allen-Moore cell is made of concrete, properly protected at the surface to withstand the chemicals.

The cells are connected in series and are provided with short-circuit switches or cutouts. The voltage carried on each cell is approximately 3.3 volts, and each cell is capable of producing 32 lb. of chlorine per 24 hours.

Cost of Chlorine Production

The annual cost of production is estimated as follows:

Salt at $8 per ton	$ 500
Power at $30 per horsepower	450
Interest at 6% on $5,000	300
Depreciation at 15%	750
Labor and superintendence	500
	$2,500

Three chlorine cells furnish the requisite amount of chlorine for sterilization. yielding 90 lb. of chlorine gas per 24 hours, or 32,850 lb. per year, making the cost of chlorine produced 7.6c. per pound.

Comparison with Present Hypochlorite Cost

The annual cost of sterilization previous to the installation of the chlorine cells was as follows:

Chloride of lime at 3.75c. per lb	$4,105
Interest at 6%	150
Depreciation at 5%	125
Labor and superintendence	500
Total	$4,880

As the amount of chloride of lime required was 300 lb. per day, or 100 lb. of available chlorine, the cost per pound was 13.4c. or 5.8c. per lb. more than chlorine produced by the electrolytic cells.

With normal market conditions the annual cost of the two forms of treatment would be approximately the same, if one did not consider the general depreciation that chloride of lime causes about a water-purification plant.

The three cells required to supply the chlorine consumed for sterilization are operated with a current load of 500 amp. and 13 volts. The electrolytic cells require very little attention and up to date have given excellent satisfaction.

Advantages of Metal and Rubber Tubing for Conveying Alum and Hypochlorite Solutions.—Charles W. Saxe, Chemist in Charge of the Newport, R. I. Water Filtration Plant, gives the following notes in Engineering and Contracting, March 19, 1913.

The conveying of "Alum" solution to the point of application in mechanical filter plants is attended with trouble from the pipes rapidly clogging up and thus hindering the flow.

At the Newport, Rhode Island, water works prior to August, 1912, the solution was fed through a 1¼-in. lead pipe by gravity a distance of 120 ft. It was very difficult to clean out the deposit and also to make the lead flange joints tight again. Inch and a quarter 2-ply chemical rubber hose was substituted in August and so far, 6 months, has needed no cleaning. When this is desired the two lengths are taken apart and are laid out on a flat surface. The hose is lightly rolled with a short piece of board and is then flushed out. The 3,000 grain per gallon "Alum" solution appears to have no effect on the rubber.

Hypochlorite of lime of ½ per cent strength is best carried in galvanized iron pipe. A thin crust forms inside at first but it does not increase rapidly. The 2 per cent "Soda" solution is being carried in galvanized iron pipe also.

Operating Costs of Ultra-Violet Sterilization Plants.—The following statement as to the operating costs of ultra-violet ray water sterilization plants is quoted, by Engineering and Contracting, Nov. 25, 1914, from a paper before the American Water Works Association by Dr. Max von Recklinghausen of New York City:

Operating costs will vary with the size and the running hours of the plant, and the coefficient of safety for the ultra-violet ray treatment. According to the quality of the water I expect in large plants which run 24 hours that the current consumption will vary between 30 and 125 kw. hours per 1,000,000 gals., allowing for a large safety coefficient. The labor charges are negligible as the apparatus only needs an occasional cleaning and starting of lamps. Apart from this the lamps have to be repumped and repaired from time to time. When the water is of variable physical quality, one will have so to establish the plant that all the lamps will be running during the period of least transparent water and only some of them during the period of best transparency.

Copper Sulphate Treatment for Algae.—The following matter is given in Whipple's "The Microscopy of Drinking Water" (1914).

In 1904 Dr. George T. Moore and Karl F. Kellerman, of the Bureau of Plant Industry, U. S. Department of Agriculture published a report stating the results of successful experiments made by them in the eradication of algæ and other microscopic organisms from reservoirs by the use of copper sulphate. This report immediately attracted wide attention and the method was tried in many places. Nearly ten years' experience has shown its advantageous use in many situations and has likewise developed some of its shortcomings.

Copper sulphate had been used as a fungicide long before Moore proved its worth for destroying algæ. Many experiments had been made by Miquel, Devaux, and many others, which showed that very minute doses of poisonous substances were able to destroy the unicellular microscopic organisms, but Moore deserves full credit for the use of copper sulphate in water-supplies. The first practical test on a working scale was made by him at the water-cress beds in Ben, Va., in 1901, where a troublesome growth of Spirogyra was eliminated.

Effect of Copper on the Human System.—The first question that was naturally raised when the copper treatment was mentioned was its possible effect on the human system. Moore had collected extensive data to show the extent to which copper salts were used in medicine and the wide distribution of copper in nature, its presence in vegetables and even in natural waters themselves. Clark showed that some natural waters in Massachusetts contained small amounts of copper. Experience with the use of copper in many water-supplies has fully demonstrated the innocuous character of this treatment if properly carried out. It is not a matter, however, that should be left to the ordinary laborer. It needs intelligent and continual supervision.

Method of Applying Copper Sulphate.—The method of application is extremely simple. Ordinary commercial crystals of blue-vitriol are used. The required quantity of these crystals is placed in a coarse, bag, gunny-sack, perforated bucket, or wire basket, attached to a rope and drawn back and forth in the water at the stern of a rowboat. Or an outrigger may be arranged so as to drag two or more bags at the same time. thus cutting a wider swath. By rowing slowly along about 100 lbs. can be thus dissolved in an hour. By using several boats quite a large reservoir can be covered in a working day. For a very large reservoir a motor launch may be used. In making the trips the parallel paths of the boats should be about 20 ft. apart. Care must be taken not to row too slowly, as too great a concentration may be obtained near the bags, and if fish should swim into this overdosed water they might be poisoned.

It is generally preferable to carry out the treatment on a day when the wind is blowing, so that the circulation of the water may more readily distribute the chemical. Advantage may be taken also of vertical convection currents. If the algæ to be killed are near the surface the application should be made early in the day when the surface-water is warming and tending to become stratified; but if the algæ are well scattered through the water it is better to make the application toward night. It will often be found best to row against the wind. It has been found difficult to treat a frozen reservoir with copper sulphate, as the chemical does not diffuse readily, but precipitates at the bottom near the point of application. The solution of copper sulphate is heavier than water.

Quantity of Copper Sulphate Required.—It is of great importance that just the right quantity of copper sulphate be used. If too little is applied the algæ will not be destroyed; if too much is used, there is danger that fish may be killed and there is also the money waste.

In deciding upon the quantity to be used several factors need to be considered, such as the kind of algæ present, the amount of organic matter in the water, the hardness, the presence or absence of carbonic acid, the temperature, the kind of fish present, and of course the quantity of water to be treated. It is hazardous for one not familiar with the various matters involved to attempt to treat a water-supply with copper, as the effect of overdosing may produce disastrous results in the destruction of fish and other animal organisms. Of particular necessity is it to know what organisms are present that need to be killed. For this a microscopical examination is essential. Fortunately this is an easy matter for a water-works superintendent to determine.

Quantity Required to Eradicate Different Organisms.—Organisms differ considerably in their susceptibility to copper sulphate. Some of the blue-green algæ are destroyed by the application of only one part of copper sulphate in ten million parts of water, while other organisms require more than ten times as much as this, and some twenty times as much. One of the organisms most easily killed is Uroglena which can be eradicated by using as little as one part of copper sulphate in twenty million parts of water.

It is probable that the stage of growth of the organisms is also a determining factor and that the presence or absence of carbonic acid is important. Different observers have brought in different figures for the quantities that have proved efficacious with the same organisms. It is impossible to state any very definite figures for the quantities required, but the following figures chiefly given by Kellerman, one of the originators of the method, are believed to be as reliable as any.

TABLE I.—QUANTITY OF COPPER SULPHATE REQUIRED FOR DIFFERENT ORGANISMS

Organisms	Parts per million	Pounds per million gallons of water
Diatomaceæ:		
Asterionella	0.10	0.8
Fragilaria	0.25	2.1
Melosira	0.30	2.5
Synedra	1.00	8.3
Navicula	0.07	0.6
Chlorophyceæ:		
Cladophora	1.00	8.3
Conferva	1.00	8.3
Hydrodictyon	0.10	0.8
Scenedesmus	0.30	2.5
Spirogyra	0.20	1.7
Ulothrix	0.20	1.7
Volvox	0.25	2.1
Zygnema	0.70	5.8
Microspora	0.40	3.3
Draparnaldia	0.30	2.5
Raphidium	0.30	2.5
Coelastrum	0.30	2.5
Cyanophyceæ:		
Anabæna	0.10	0.8
Clathrocystis	0.10	0.8
Coelosphærium	0.30	2.5
Oscillaria	0.20	1.7
Microcystis	0.20	1.7
Aphanizomenon	0.10	1.2
Protozoa:		
Euglena	0.50	4.2
Uroglena	0.05	0.4
Peidinium	2.00	16.6
Glenodinium	0.50	4.2
Chlamydomonas	0.50	4.2
Cryptomonas	0.50	4.2
Mallomonas	0.50	4.2
Dinobryon	0.30	2.5
Synubra	0.10	0.8
Schizomycetes:		
Beggiatoa	5.00	41.5
Cladothrix	0.20	1.7
Crenothrix	0.30	2.5
Leptomitus	0.40	3.3

The figures given may be assumed to apply at a temperature of 15° C. or 59° F. Moore and Kellerman state that these should be increased or decreased by about 2.5 per cent for each centigrade degree below or above 15° C.

They also state, though with less assurance, that an increase of 2 per cent should be made for each ten parts of organic matter per million and an increase of 0.5 to 5 per cent for each ten parts per million of alkalinity. A 5 per cent increase should be made if the amount of carbonic acid is small.

Calculating the Volume of Water to be Treated.—Usually the quantity of water to be treated is not known exactly, but has to be estimated. The following data will assist in making this estimate.

The problem is first to find the number of million gallons of water in the reservoir. When this has been found, the total quantity of copper sulphate required is ascertained by multiplying this by the figure in the last column of the preceding table corresponding to the organism that is to be killed. This must then be increased or decreased slightly to take account of the other factors above mentioned.

One million gallons of water represents a depth of about 3 ft. over one acre. Hence the number of acres of water surface, multiplied by the average depth of the water divided by 3 gives approximately the number of million gallons of water in the reservoir. In an ordinary reservoir the average depth may be taken as about one-third of the maximum depth.

If the reservoir to be treated is so deep that the lower strata are stagnant the calculation should be made to include only the water above and within the transition zone.

Safe Limit for Treating Water to Prevent Killing Fish.—Kellerman recommends that in order to prevent killing certain fish the following limits should be set to the amount of copper sulphate applied to water.

It will be seen that some of the amounts required for algæ destruction are critically near the amounts that will kill fish. This explains the need of cautious application of this remedy.

Fish	Parts per million	Pounds per million gallons (approximate)
Trout	0.14	1.2
Carp	0.30	2.5
Suckers	0.30	2.5
Catfish	0.40	3.5
Pickerel	0.40	3.5
Goldfish	0.50	4.0
Perch	0.75	6.0
Sunfish	1.20	10.0
Black bass	2.10	17.0

Copper Sulphate as a Disinfectant.—Copper sulphate will destroy bacteria if a sufficient quantity is used. The amount required is considerably greater than that needed to destroy algæ. For killing bacteria copper sulphate is less efficient than hypochlorites or liquid chlorine.

Hypochlorite Treatment for Algæ.—Algæ may be killed by the use of hypochlorite, but just as this substance is better than copper sulphate for bacterial disinfection so the copper treatment is generally better than hypochlorites for the destruction of algæ.

Comparative Costs of Coagulation.—The following matter is given in Stein's "Water Purification Plants" (1915).

Fig. 1 shows the costs of treatment of water by several methods with various amounts of coagulant, and also the cost of removing various amounts of acids. The cost of chemicals includes freight, unloading and cartage, deterioration, and the rehandling in charging the chemical tanks. The costs per hundred pounds used were: aluminum sulphate, \$1.10; ferrous sulphate, \$0.70; lime, \$0.35; soda ash, \$1.00. For large-sized plants these values could be reduced. From these curves it is evident that the iron and lime treatment is cheapest, followed by alum and natural alkalinity, alum and lime (sufficient to produce no CO_2), alum and soda ash, while alum and soda ash (no CO_2) is most expensive. It is also evident that by increasing the amount of lime used with the iron, the cost of this process may rise above that of alum and lime. The iron-lime treatment is slightly more effective for high turbidities, a fact not brought out by these curves. For acid removal, lime is by far the cheapest reagent.

Economic Size of Sand Filter Beds (Engineering and Contracting, Aug. 19, 1914).—The proper size of beds is a question of economical construction.

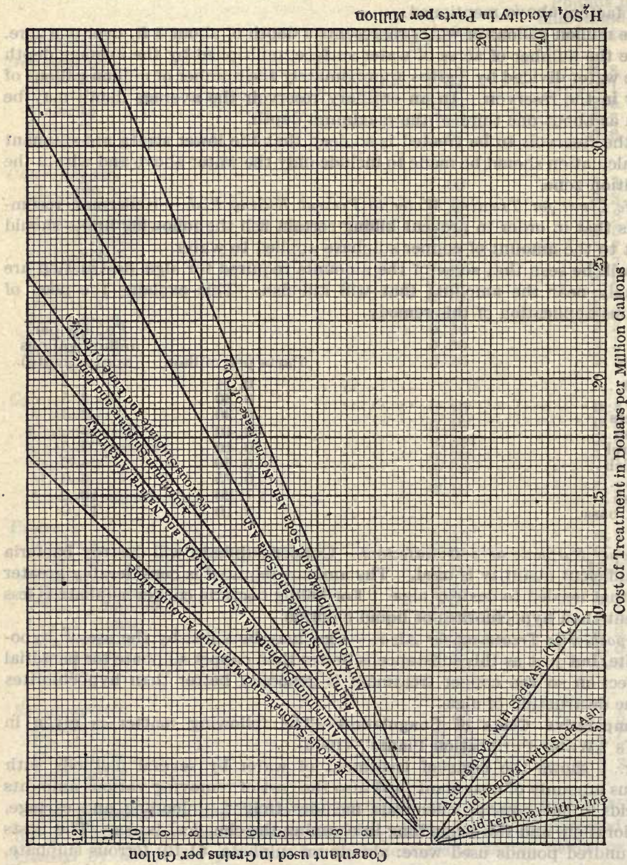

FIG. 1.—Cost of coagulation by various methods.

The larger the beds the less the cost per acre. Covered beds, which are generally used, vary in size from 0.4 to 0.8 acres.

The following calculation from an article on the purification of public water supplies, by C. H. R. Fuller, published in the Aug. 1914 issue of Applied Science, is of assistance in determining the economical number and size of beds. The cost of a filter may be estimated as made up of two items, (1) a portion proportional to the area, which would include cost of bottom, filling small drains, covers, and end walls, assuming basins rectangular and placed side by side, and (2) a portion nearly independent of the size, such as cost of piping, valves, valve chamber, division walls, etc.

Let c = Cost of first portion per acre,
and C = the cost of the latter portion per filter.
If q = area of one filter
n = number of filters
A = Total net area required.

Then, assuming one filter in reserve

$$n = \frac{A}{q} + 1 \tag{1}$$

The total cost is

$$K = Cn + c\,n\,q \tag{2}$$

$$= C\left(\frac{A}{q} + 1\right) + cq\left(\frac{A}{q} + 1\right)$$

$$= \frac{CA}{q} + C + cA + cq \tag{3}$$

We then have $\dfrac{dK}{dq} = -\dfrac{CA}{q^2} + c$

When for a minimum cost

$$q^2 = \frac{C}{c}A. \tag{4}$$

i. e. the economical area of one filter is proportional to $\sqrt{A}$ and to $\sqrt{\frac{C}{c}}$.

The larger the value of "c," the smaller is "q." The values of $\frac{\text{"}C\text{"}}{c}$ will hardly be larger than 1/9 or less than 1/16, giving a value of "q" = $\frac{1}{4}\sqrt{A}$ to $\frac{1}{3}\sqrt{A}$. Thus, when A = 9 acres, the capacity q = ¾ to 1 acre giving 9 to 12 beds. Where A = 1 acre, the capacity would be ¼ go ⅓ acre giving 3 to 4 beds. Larger beds than 1 acre are undesirable on account of increased difficulty of operation.

Filter beds are usually rectangular and arranged side by side. It is usual to place them in two rows with a space between for sand washing, regulating houses, etc The economical proportions of the beds is given by the following formula:

$$\frac{b}{a} = \frac{n+1}{2n}$$

where b = width, a = length, and n = number of beds in a row.

Cost per Million Gals. of Constructing and Operating Slow and Rapid Sand Water Filtration Plants.—Engineering and Contracting, June 17, 1914, publishes the following data given in a paper by George A. Johnson before the 1914 convention of the American Water Works Association.

Relative Cost of Slow Sand And Rapid Sand Filtration.—In discussing the cost of building water filtration works of the slow sand and rapid sand types, respectively, consideration will be given only to those items referring to the filter plant proper. Cost of land, pumping machinery outside connecting piping, intakes, etc., in fact everything outside the filtration plant proper, will not be considered.

For slow sand filter costs the items will include the necessary filter buildings and filters with all appurtenances, all inside piping, sand handling apparatus preliminary sedimentation basins, preliminary filters and appurtenances and clear water reservoirs.

For rapid sand filter costs the items will include the filter buildings and filters with all appurtenances, all inside piping, filter washing apparatus coagulating and clear water basins. Thus a fairly good idea may be had of the relative cost of building purification plants of the two types.

TABLE II.—COST OF CONSTRUCTION OF SLOW SAND AND RAPID SAND WATER FILTRATION PLANTS

City	Present daily filtering capacity, gals.	Approximate cost per 1,000,000 gals. daily capacity
Slow sand:		
Albany, N. Y	20,000,000	$20,000*
Pittsburgh, Pa	200,000,000	26,000*
Philadelphia, Pa.:		
Torresdale	250,000,000	37,700*
Upper Roxborough	28,000,000	29,800
Lower. Roxborough	17,000,000	26,300*
Belmont	60,000,000	45,200*
Washington, D. C	100,000,000	30,000†
Rapid sand:		
Cincinnati, Ohio	112,000,000	11,400‡
Columbus, Ohio	30,000,000	13,000§
Dallas, Texas	15,000,000	13,000
Harrisburg, Pa	16,000,000	10,300
Little Falls, N. J	32,000,000	15,000
Lorain, Ohio	6,000,000	14,000
New Milford, N. J	24,000,000	11,000
Watertown, N. Y	8,000,000	11,250
Weighted averages { Slow sand	....	$32,600
Weighted averages { Rapid sand	....	12,100

* Cost of preliminary filters included. † Cost of Dalecarlia Reservoir not included. Cost of McMillan Park Reservoir included, and also cost of remodeling Georgetown Reservoir, as well as cost of coagulating basin. ‡ Cost of large plain sedimentation basin not included. § Cost of softening works not included.

TABLE III.—COST OF OPERATION AND MAINTENANCE OF SLOW SAND AND RAPID SAND FILTRATION PLANTS

Year	City	Average volume of water filtered daily, gals.	Cost of operation and maintenance per 1,000,000 gals. of water filtered
Slow sand:			
1911	Albany, N. Y	20,000,000	$2.50
1912	Pittsburgh, Pa	100,000,000	3.41
1911	Philadelphia, Pa '	9,000,000	5.62
1911	Philadelphia, Pa.†	13,000,000	3.59
1911	Philadelphia, Pa.‡	38,000,000	3.88
1911	Philadelphia, Pa.§	202,000,000	1.91
1912	Washington, D. C	62,000,000	4.01
Rapid sand:			
1912	Cincinnati, Ohio	50,000,000	4.12
1911	Harrisburg, Pa	9,000,000	3.93
1912	Little Falls, N. J	30,000,000	3.20
1912	Louisville, Ky	25,000,000	3.48
1912	New Orleans, La	16,000,000	6.32
Weighted average { Slow sand		....	$2.86
Weighted average { Rapid sand		....	4.04

* Lower Roxborough; † Upper Roxborough; ‡ Belmont; § Torresdale.

John H. Gregory, who has been personally connected with 7 out of the 15 plants mentioned above, gives the following data in a discussion of the paper prepared by Mr. Johnson, which was delivered before the same convention.

Cost of Construction.—It is exceedingly difficult to compare satisfactorily the costs of construction of different plants, even where the fullest information regarding the same is available. Those who are not well posted as to the history of some of the plants cited in the table may possibly be misled as to the cost of building both slow and rapid sand filters if they accept the figures of the author without full knowledge of local conditions.

One of the features which very materially affects the cost of such works is the total reservoir capacity provided, that is, the combined capacity of the settling basins and of the clear water reservoirs. To illustrate: The rapid sand filter plant at Little Falls, N. J., which, in the author's table is the most expensive one cited, and which cost $15,000 per 1,000,000 gals. daily capacity, has a coagulating basin capacity of 1.3 hours and a filtered water reservoir capacity of 2.6 hours, or 3.9 hours total reservoir capacity. At Columbus, Ohio, the rapid sand filter plant there, which the author states cost $13,000 per 1,000,000 gals. daily capacity, the next to the highest in cost cited, has a settling basin capacity of 12 hours and a filtered water reservoir capacity of 8 hours, making a total reservoir capacity of 20 hours, or five times as much reservoir capacity as that of the Little Falls plant. If the reservoir capacity of the Little Falls plant had been approximately that of the Columbus plant the cost of construction of the Little Falls plant would have been materially increased over that given by the author. Again, the New Orleans rapid sand filter plant might be cited, which has 35.2 hours total reservoir capacity, or practically nine times as much reservoir capacity as that of the Little Falls plant. Other factors which affect the cost of construction are the character of the raw water, the rate of filtration, the character of the construction of the works, etc.

In his reference to the Albany slow sand filter plant the author gives its capacity as 20,000,000 gals. daily. The Albany plant as originally built before the pre-filters were added had a capacity of 15,000,000 gals. daily. The addition of the pre-filters increased the capacity of the plant very materially so that at the present time the capacity is probably in the neighborhood of 28,000,000 gals. daily. If the capacity is taken at 28,000,000 instead of 20,000,000 gals. daily the cost of the plant would be about $14,300 instead of $20,000 per 1,000,000 gals. daily capacity as given by the author.

The Philadelphia slow sand filter plants were expensive plants to build. They differ in one way from many of the other filters of the same type that have been built in that underneath the filter floors and carried up all around the sides of the filter is a layer of puddle. This item alone materially increased the cost of construction. The Lower Roxborough and Upper Roxborough plants were built on high ground in an isolated section several miles from the nearest railroad, and the cost of delivering materials to such plants was higher than would ordinarily be the case.

In the cost of the Lower Roxborough plant the author did not include the cost of the Lower Roxborough Reservoir which was built many years before, and which supplies settled water to the filter plant. Again, a similar condition exists at the Upper Roxborough filter plant with regard to the settling basin. The New Roxdorough Reservoir was built some ten years earlier than the filter plant, and the author has not included its cost in the cost of the filter plant. Strictly speaking, the costs of the reservoirs should be included in the costs of these two plants so that the figures would be comparable with the costs of the other slow sand filters cited.

The Philadelphia plants were built during a period of very high prices, and to use the costs of construction of these plants to indicate the reasonable cost of slow sand filters may be very misleading except to those who are familiar with the early history of these works and who are aware that the costs were high and that the plants could be duplicated at less cost.

The largest slow sand filter plant under construction in America at the present time is at Montreal, and, when completed next year, will have a capacity of 60,000,000 U. S. gals. daily capacity. The total cost of the plant, on the basis of the lump sum contract prices, including the low lift pumping station, will be about $22,600 per 1,000,000 gals. daily capacity. Deducting the low lift pumping station the cost will probably be about $21,000 per 1,000,000 gals. daily capacity.

It would have been interesting if the author had cited the cost of the slow sand filter plant which was completed at Toronto about two years ago. This plant has a capacity of 48,000,000 U. S. gals. daily, assuming one-sixth of the filter area to be held in reserve, and based on a rate of filtration of 6,000,000 U. S. gals. per acre daily, the rate for which the plant was designed. The cost of the plant, omitting the low lift pumping station, was only about $12,700 per 1,000,000 gals. daily capacity.

In considering the weighted average cost of slow sand filters given by the author, namely, $32,600 per 1,000,000 gals. daily capacity, it may be well to bear in mind that the Montreal plant will cost only about $21,000, that the Albany plant cost about $14,300 and the Toronto plant only $12,700 per 1,000,000 gals. daily capacity.

In referring to the cost of rapid sand filter plants the author cites the Columbus plant as costing $13,000 per 1,000,000 gals. daily capacity. This plant was designed and built under the speaker's direction and is a water-softening as well as a rapid sand filter plant. The speaker is not informed as to what items the author included in arriving at the cost of the Columbus plant, but in the speaker's judgment the Columbus plant, considered as a rapid sand filter plant alone, cost nearer $15,000 than $13,000 per 1,000,000 gals. daily capacity, the figure given by the author.

Another rapid sand filter plant which the author might have cited is that at Toledo, Ohio. Part of the plant was built for a capacity of 60,000,000 gals. daily, although the present capacity of the works is considerably less. Including only such items as are chargeable to the filter plant proper the works cost about $14,500 per 1,000,000 gals. daily capacity.

Another rapid sand filter plant which might have been cited is that at Grand Rapids, Mich. The plant was completed inside of the last two years and has a capacity of 20,000,000 gals. daily. The cost of the plant, as given to the speaker by the Grand Rapids officials last year, including such items as are chargeable to the filter plant proper, was $16,300 per 1,000,000 gals. daily capacity.

In December, 1912, the city of New York received bids for a rapid sand filter plant to be located at Jerome Park Reservoir and having a capacity of 320,000,000 gals. daily. Taking the lowest bid received and adding to it the cost of the buildings and other necessary work, the Jerome Park filter plant, which would have been the largest rapid sand filter plant in the world, would have cost $18,400 per 1,000,000 gals. daily capacity. When the plant is built, the actual cost will probably be in the neighborhood of $20,000 per 1,000,000 gals. daily capacity, as much of the excavation for the plant has already been completed.

The author gives the cost of the Cincinnati rapid sand filter plant, which has a daily capacity of 112,000,000 gals., as $11,400 per 1,000,000 gals. daily capacity, and states that the cost of the large, plain sedimentation basins is not included. At Cincinnati there are two large settling basins to which the raw water from the Ohio River is pumped. The water is first settled in these two basins, and is then delivered to the coagulating basins at the filter plant. There is no question in the speaker's mind but that the settling basins are part of the filter plant at Cincinnati, but just how much of the cost of the same should be chargeable to the filter plant may be a question. Mr. J. W. Ellms, the superintendent in charge of the filters at Cincinnati, in a paper printed in the Journal of the Association of Engineering Societies in January, 1912, states:

The settling reservoirs, which have a capacity of 330,000,000 gals. of available water, are in part a portion of the water purification plant, although they also serve the purpose of storage basins and were designed for such a use quite as much as they were for sedimentation purposes.

The two settling basins cost $1,521,000, or about $13,600 per 1,000,000 gals. daily capacity of filter plant. Adding this cost to that of the filter plant would give a total cost of $25,000 per 1,000,000 gals. daily capacity. As the settling basins serve as storage reservoirs also it may be reasonable to charge the filter plant with perhaps only half their cost. On this assumption the cost of the settling reservoirs chargeable to the filter plant would be $6,800 per 1,000,000 gals. daily capacity, thus making the total cost of the filter plant $18,200 per 1,000,000 gals. daily capacity.

Still another plant which the author might have cited, and among the best in the country, is that at New Orleans, which has a capacity of 40,000,000 gals. daily. Including only such items as are chargeable to the filter plant proper the cost of the New Orleans plant was about $30,200 per 1,000,000 gals. daily capacity.

The weighted average cost of the Columbus, Toledo, Grand Rapids, Cincinnati and New Orleans rapid sand filter plants is $18,600 per 1,000,000 gals. daily capacity, while the author gives a weighted average cost for rapid sand filters as $12,100. In other words, the weighted average cost of the five plants just cited, all of which are in operation and which are among the best in the country, is over 50 per cent higher than the weighted average cost given by the author.

The speaker has but little further to say on the subject of costs except that, in his judgment, the weighted average costs as given by the author are too high for slow sand filters and are too low for rapid sand filters. Similarly the fixed charges on the costs of construction would respectively be too high for slow sand and too low for rapid sand filters.

The speaker is not presenting any brief for slow sand filters. The rapid sand filter is more flexible than the slow sand filter and in the majority of cases in the United States is better adapted to the purification of water than is the slow sand filter. The slow sand filter has done and is still doing good work in this country, and the present status of water purification is, to a large extent, due to the introduction of the slow sand filter.

Relative Cost of Mechanical and Slow Sand Filtration.—The following data are arranged from a report to the Commissioner of Works of Toronto, Ont. by Allen Hazen, Consulting Engineer, as published in Engineering and Contracting, Jan. 15, 1913.

	Mechanical filters	Slow sand filters
Head required for filter operation	10 ft.	5 ft.
Settling and coagulating basin	Required	Not required
Average cost per mil. gals. storage	$12,000[1]	
Average cost per mil. gals. daily output	1,500	
Filters:		
Average cost American conditions	$25 per sq. ft.[2]	
Probable cost in Toronto	$30 per sq. ft.	$70,000 per acre[3]
Estimated cost per mil. gals. daily capacity	$11,500	$14,000
Pure water and reservoir piping	Assumed the same for both types of filters	
Cost of construction (exclusive of piping) per mil. imperial gals. daily capacity[4]	$15,000	$14,000
Cost of operation per mil. imperial gals.		
Additional cost of pumping account of greater lift	$.30	
Sulphate of alumina, 172 lbs. per mil. gals. @ $25 per ton	$2.15	
Other costs of operation, including superintendence, labor, laboratory expenses, repairs, renewals, heat, light, drainage, oil waste and pumping wash water	$2.35	
Total operating cost per mil. imp. gals	$4.80	$1.83[5]
Relative efficiency	No appreciable difference[6]	

Notes.—(1) The settling and coagulating basin should be of concrete and covered similiar in general design to the filters but with its flow line 5 ft. higher, and with the bottom sloped to drains to facilitate cleaning out the sludge produced by the action of the chemical on the water. The average depth of the basins would be about 15 ft.—Baffles and other appliances would be required.

2. The filter tanks would be of concrete and about 8 ft. deep similiar in design to those in use at Cincinnati, Columbus, New Orleans and many other places. Mr. Hazen usually allows 430 sq. ft. of net filter area for each million Imperial gals. daily capacity. In the case of Toronto the lake water is usually clear and of very constant composition, as compared with river waters. He assumes 385 sq. ft. of net filter area sufficient.

3. The actual cost of the existing sand filters was $57,000 per acre, including all contingencies. Including 10 per cent for engineering makes the total $62,700 a very low cost. Mr. Hazen assumes that the filters may cost 10 per cent more or $70,000 per acre.

Each acre of net filter surface has a nominal capacity of 5,000,000 Imperial gals. per day.

4. Adding the costs of coagulating basin and mechanical filters we have $13,000 per 1,000,000 gals. daily capacity. Add to this 15 per cent for engineering and contingencies; the total probable cost is $14,950, or say $15,000 per 1,000,000 Imperial gals. daily capacity.

5. *Cost of Operation of Sand Filters.*—The cost of operating sand filters, including superintendence, laboratory expenses, and the cost of pumping wash water, but excluding the cost of the main pumping, was estimated at $1.83 per 1,000,000 Imperial gals., in a communication to Mr. Rust, the former City Engineer, dated Nov. 20, 1908. The records of operation for the present year indicated a cost a third less than this, but it must be remembered

that in subsequent years it may be necessary to handle more sand than in the first period, when everything is clean, and Mr. Hazen therefore deems it wise to use the same figure that he used four years ago.

6. *Relative Cost of Operation.*—The estimated costs of operation, excluding pumping, per 1,000,000 Imperial gals., are as follows:

Mechanical filters	$4.80
Sand filters	1.83

Mechanical filters cost 2½ times as much to operate. This is mainly due to the cost of the chemicals required with them.

Relative Efficiency of Sand and Mechanical Filters.—Lake Ontario water lends itself admirably to the sand filter treatment and excluding the effect of hypochlorite, better and more reliable bacterial or hygienic results will be obtained by sand filters than can be obtained by mechanical filters.

From a physical standpoint there is no appreciable difference; either kind of filters will yield water free of color and turbidity and otherwise satisfactory.

With the systematic use of hypochlorite in the effluents, Mr. Hazen considers that any difference that there might otherwise be in favor of sand filters is eliminated. The hypochlorite treatment conscientiously used can be depended upon to correct any falling off in efficiency that there may be with filters of either system, and he considers that the results will be satisfactory from a hygienic standpoint in either case.

From the standpoint of certain mechanical uses to which the water may be put, and especially with reference to boiler feed water, the sand filters have a certain advantage. The hardness in Lake Ontario water is in the form of carbonate or temporary hardness. This is the least objectionable form of hardness. The use of chemicals in the water changes a certain part of the carbonate hardness to sulphate or permanent hardness, and this is more injurious than the carbonate hardness, especially in boilers. If there were other and sufficient reasons for using chemical treatment, it would be recommended, notwithstanding this condition. In the absence of such reasons, it must be recognized that whatever change grows out of the chemical treatment tends to make the water less desirable and is to be avoided as far as may be.

Cost of Water Purification Plants in Illinois.—The following data given in Engineering and Contracting, Feb. 11, 1914, are taken from a paper before the Western Society of Engineers by Edward Bartow and Paul Hansen, Director and Engineer, respectively of the Illinois State Water Survey and published in the journal of the society, December, 1913.

Table IV.—Data on Some Water Purification Plants in Illinois

City	Waukegan	Mt. Carmel	Rock Island	Quincy	Decatur
Population	18,000	8,000	26,000	37,000	35,000
Source of supply	L. Michigan	Wabash	Miss. R.	Miss. R	Sangamon R.
Ownership	M	P	M	P	M

Chemicals used	H	A-H	A-H	A-L-I-H	A-H
Cost of plant per M. G. D.	$300	$6,700	$10,800	$11,100	$15,400

Legend: A—Alum. L—Lime. I—Iron. H—Hypo. M—Municipal. P—Private.

Cost of Water Purification and Pumping Plant at Bridgeton, N. J.—The following data are given by Henry Ryon in an article published in Engineering and Contracting, March 4, 1914.

The 3,000,000 gal. water filtration and pumping plant at Bridgeton, N. J., a city of approximately 15,000 inhabitants, was placed in regular operation on Nov. 1, 1913. As shown in Fig. 2, the purification plant consists of concrete coagulating basin, rapid sand filters, clear water basin, necessary chemical storage and mixing facilities and piping and the pumping plant consists of pumping station, coal bunker, pumps and boilers and chimney.

The 30-in. intake was built of vitrified tile pipe and cost $3.70 per lineal ft. complete. The maximum cut on the total length of 8,500 ft. was 14 ft.

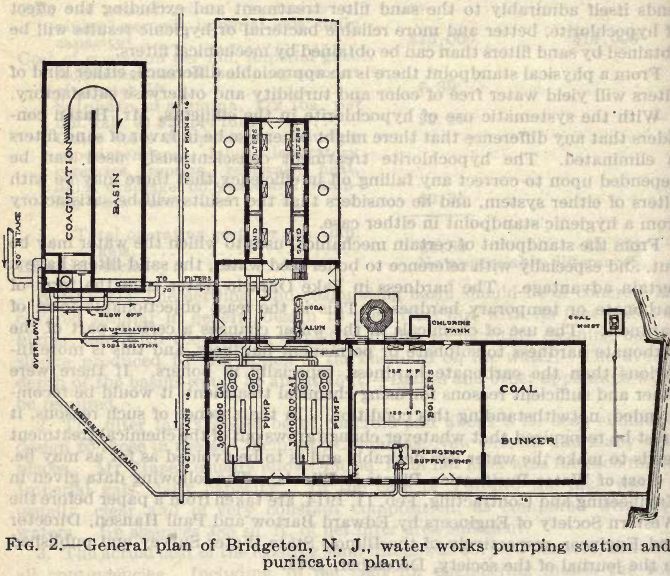

FIG. 2.—General plan of Bridgeton, N. J., water works pumping station and purification plant.

The coagulation basin has a capacity of 150,000 gals. or about an hour's flow. The filters, each 12 ft. by 14 ft. 6 ins., are arranged in two rows of three each on opposite sides of the operating floor and pipe gallery. They are operated at the rate of 500,000 gals. per day (120,000,000 gals. per acre per day). The clear water basin is located beneath the filters and has a capacity of 200,000 gals. This basin extends far enough beyond the end of the filter house to allow four additional filter units to be built on its roof at some future time.

The cost of the filter plant was as follows:

Coagulation basin	$ 5,820
Filters	17,960
Clear water basin	13,256

Making the cost of filter plant proper $37,000 or $12,300 per million gals. capacity.

The pumping plant consists of two cross compound pumping engines of the crank and fly wheel type with capacities of 5,000,000 and 3,000,000 gals. per day respectively. The larger pump had been in service at the old pumping station for several years. The steam for the pumps is supplied by two 125 h.p. water tube boilers and as with the pumps, only one boiler is used at a time, the other being held in reserve.

Under working conditions (average total head about 205 ft.) 430 gals. of water are pumped per pound of coal. This includes the coal burned to furnish steam for the blower and other small engines at the plant.

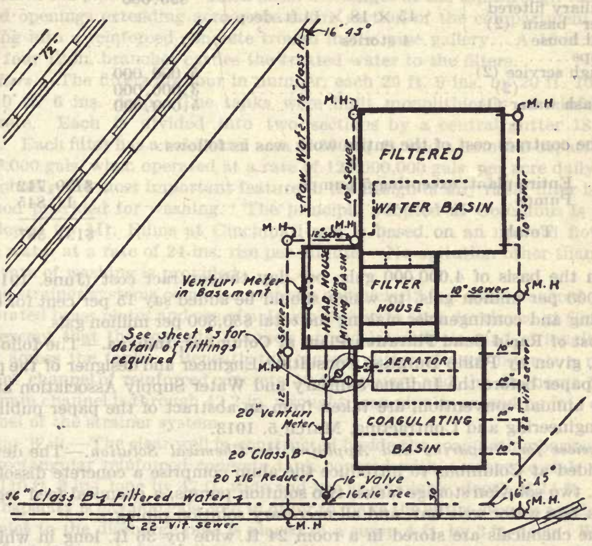

FIG. 3.—Layout of water filtration plant of Whiting, Ind.

The cost of the pumping station and equipment was as follows:

Pumping station	$30,003
Coal bunker	3,919
Pumps and boiler	21,934
Chimney	3,020

A total of $58,876 for the plant or about $19,600 per million gals. capacity including duplicate machinery.

During the period the complete plant has been in operation the cost per million gals. of water supplied has been $31.40. This figure includes interest and sinking fund and maintenance of the distribution mains.

Cost of Rapid Sand Filtration Plant of Whiting, Ind.—Renville S. Rankin describes the filter plant of Whiting, Ind., in Engineering and Contracting, Sept. 10, 1919, from which article the following is taken.

Fig. 3 shows the general layout of the plant, the capacity of which, based upon the filters is 4,000,000 gal. per 24 hours.

The dimensions, capacity and operating period on the basis of 4,000,000 gals. per day are as follows:

Item and number of units	Dimensions, ft.	Capacity, gals.	Capacity, hours
Aerator (1)	30 × 48 (in plan)	...	...
Mixing basin (1)	33 × 12 × 5 ft. deep	...	...
Coagulating basins (2)	40 × 81 × 16 ft. deep	700,000	4.2
Filters (6)	12 × 19.5	666,000 (each)	...
Filtered water storage basin (1)	94 × 91 × 14 ft. deep	890,000	5.3
Auxiliary filtered water basin (2)	45 × 18 × 11 ft. deep		...
Head house	4 stories	...	...
Pumps	...	...	...
High service (2)	...	5,000,000	...
(2)	...	3,000,000	...
Wash water (1)	...	5,000,000	...

The contract cost of the entire work was as follows:

Entire plant, excepting 5 pumps	$179,742
Pumps	11,845
Total	$191,587

On the basis of 4,000,000 gals. per day the contract cost (June, 1919) is $47,900 per million gals. to which should be added say 15 per cent for engineering and contingencies making the total $50,300 per million gals.

Cost of Rapid Sand Filtration Plant at Columbus, Indiana.—The following data, given by Philip Burgess, Consulting Engineer and designer of the plant in a paper before the Indiana Sanitary and Water Supply Association at the 1913 annual convention, are taken from an abstract of the paper published in Engineering and Contracting, March 5, 1913.

Devices for Preparing and Applying the Chemical Solution.—The devices provided at Columbus to introduce the alum comprise a concrete dissolving tank, two solution storage tanks, two solution pumps, a chemical feed regulator, a raw water weir box, and all necessary solution piping.

The chemicals are stored in a room 24 ft. wide by 36 ft. long in which is placed also the mixing tank. Beneath the latter are constructed two reinforced concrete solution storage tanks, each 5 ft. 6 ins. by 6 ft. 4 ins. by 8 ft. deep, containing 2,080 gals. The solution pumps have a capacity of 10 gals. per minute and lift the solution from the tanks into the chemical regulator, located in the pipe gallery near the raw water weir box. An overflow carries the excess of solution back to the storage tanks.

Coagulating Basins.—The coagulating basins are two in number, each 106 ft. 8 ins. long, 78 ft. 6 ins. wide, with an average available depth of 15 ft. 4 ins. The basins are built of reinforced concrete and are uncovered. The total capacity of the two basins is 955,000 gals., equivalent to 5.7 hours' treatment on the basis of 4,000,000 gals. daily capacity.

Each basin is divided longitudinally by a reinforced concrete baffle into two equal compartments so that the length of flow through each basin is 213 ft. Consequently, the maximum velocity of flow through the basin is 0.6 ft. per minute.

The basins are designed to operate semicontinuously and there is provided a sludge disposal system in each of the first compartments to provide for the removal of sludge without emptying the basins. Each sludge disposal system is divided into two sections and comprises 6 lines of 4-in. double strength soil pipe drilled with ⅝-in. holes 30 ins. apart. Each of the four sections discharges through an 8-in. pipe controlled by an 8-in. quick-opening valve, located in the pipe gallery of the filter house.

For the further removal of sludge and for the complete emptying of the basins, there are provided four 8-in. inlets into a 12-in. main drain.

The inlet to each basin is a 16-in. cast iron pipe leading from the raw water weir box to the center of the first compartment and controlled by a gate valve located in the pipe gallery. Each basin discharges at the top through 15 4-in. round openings extending across the entire section of the compartment and leading into a reinforced concrete trough in the pipe gallery. A 16-in. pipe with four 12-in. branches carries the treated water to the filters.

Filters.—The filters are four in number, each 29 ft. 9 ins. by 20 ft. 10 ins. by 10 ft. 6 ins. deep. The tanks were built monolithically of reinforced concrete. Each is divided into two sections by a central gutter 18 ins. wide. Each filter has a total sand area of 350 sq. ft. and a nominal capacity of 1,035,000 gals. when operated at a rate of 125,000,000 gals. per acre daily.

Probably the most important feature in the design of any rapid filter is the method provided for washing. The principal adopted at Columbus is that developed by Mr. Ellms at Cincinnati and is based on an upward flow of wash water at a rate of 24 ins. rise per minute. No agitation other than the high rate of washing is provided.

The strainer systems comprise concrete channels 12 ins. apart covered with perforated brass plates and are of a design similar to that developed at Cincinnati except that the concrete channels extend laterally insetad of longitudinally across the tanks. Beneath the central gutter of each filter is a main effluent channel of reinforced concrete 18 ins. square and the discharge from this main channel is through 42 2-in. wrought iron nipples extending into each channel of the strainer system.

Clear Well.—The clear well is constructed beside the coagulating basins and is a rectangular reinforced concrete tank covered with a concrete slab roof. It is 110 ft. 3 ins. long by 47 ft. wide and has an available depth of 14 ft. Its total capacity is 534,000 gals. and in order to make the entire storage available, the inlet to the discharge pipe is placed in a sump 4 ft. by 3 ft. deep. When the plant is operated at full capacity the period of storage available in the clear well is 3.5 hours, and the elevation of high water in the clear well is such that there is a minimum available head of 9 ft. on the filters.

Filtered water is conveyed from the clear well to the present pumping station through a 20-in. cast iron suction line, approximately 470 ft. long, constructed at large expense, because the trench is for a considerable distance over 20 ft. deep.

In order to furnish the required quantity of wash water, there is provided a 60,000-gal. steel tank and tower supplied by a 2-in. connection to a 4-in main of the distribution system. The bottom of the tank is 18.4 ft. above the gutters in the filters. The tank is of the so-called "railroad" type with an elliptical bottom and a 4-in. riser pipe. In order to maintain a constant depth of water in the tank and to prevent its overflow, an automatic altitude-controlling valve is provided in the 2-in. supply line.

Cost of Construction of Purification Plant.—The contract for the filter plant was awarded in July, 1912. In the following table are shown the costs of the several items comprising the work:

1. Coagulating basins, filters, pipe gallery, chemical laboratory, and office building, filter building together with all necessary inside pipes, valves, etc.	$38,454
2. Clear well, complete	6,600
3. All outside cast iron and tile pipe lines, including raw water force main, high service suction, main wash water line, and all drains.	7,700
4. 60,000 gal. steel tank and tower furnished and erected by the Chicago Bridge & Iron Works	2,150
5. Raw water pump house, including foundations and erection of the raw water pumps and changes in present suction lines	2,713
Total contract price	$57,617

The raw water pumps each of which has a capacity of 4,000,000 gals. daily against a maximum lift of 55 ft., are a centrifugal motor-driven pump with a

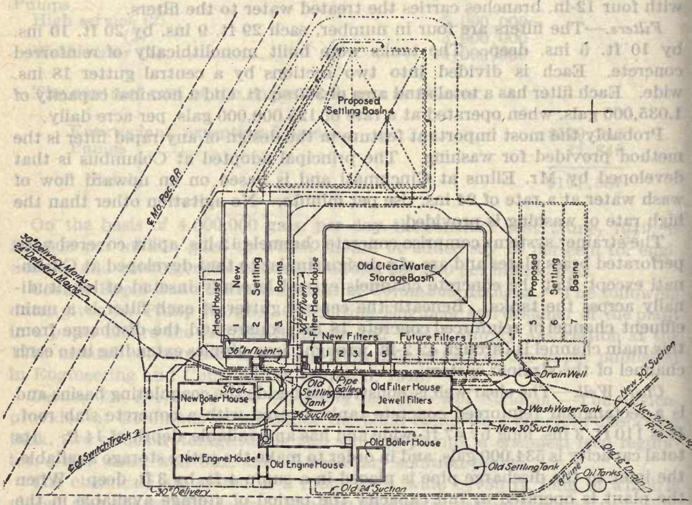

FIG. 4.—Quindaro station of Kansas City, Kan., Water Works.

guaranteed combined efficiency of 65.5 per cent and cost $940, and a centrifugal steam turbine-driven pump with a guaranteed duty of 36,500,000 ft.-lbs. when operated non-condensing, and of 64,600,000 ft.-lbs. when operating condensing, and cost $1,228.

Cost of New Plant for the Purification of the Water Supply Kansas City, Kansas.—Engineering Record, Jan. 27, 1912, gives the following cost of constructing the new 6,000,000 gal. rapid sand water purification plant of Kansas City. The work was done by contract in connection with the relhabilitating of the waterworks system purchased by the city from the Metropolitan Water Co.

Fig. 4 shows the general layout of the entire station and includes both the original plant and the additions, the costs of which follow.

Without going into the details the costs of the new pumping station and pumping station equipment were as follows:

Pumping Station

Pump house basement 60 × 120 ft. (21 ft. deep)	$ 25,922.83
Boiler house foundation, 50 × 108 ft.	6,035.00
Stack foundation	977.00
Pump house and boiler house	48,748.17
Chimney	5,089.00
Steel supports to floor	1,855.43
Tile floor	2,241.13
Grading about station	1,667.36
	$ 92,535.92

Pumping Station Equipment

Snow steam pump, 12,000,000 gals. daily	$ 38,595.00
Strait pumping engine, 15,000,000 gals. daily	18,600.00
Turbo generators, two at 70 kw. each	5,943.84
Turbo generator condensers	800.00
Boilers, two at 600 hp. each	27,007.00
Snow pump foundation	1,334.02
Strait pump and turbo generator foundations	1,923.60
Boiler foundations	719.40
Switchboard and electric wiring	3,937.79
Steam piping	4,793.19
Miscellaneous labor in and about the pump house and in installing steam pipes and small water pipes	3,355.40
Miscellaneous material, piping, fittings and similar materials	2,117.70
	$109,126.94

Inadequate settling facilities provided for the old filters (5,000,000 gals. rated capacity) by the two steel tanks 50-ft. in diameter and 25-ft. high necessitated building the new settling basins large enough to give preliminary treatment for both the old and new filters.

Settling Basins.—Each basin is 200 ft. long, 30 ft. wide and 25 ft. deep at the middle and 23 ft. deep at the ends, constructed of reinforced concrete. The basins have a combined storage capacity of 3,000,000 gals. and an estimated operating capacity of 12,000,000 gals. per twenty-four hours. They were designed to operate in series but may also be operated in parallel or separately if condition of raw water makes such operation desirable.

Filters.—The filters are of reinforced-concrete construction throughout, consisting of five tanks 32 ft. long, 12 ft. deep and 20 ft. 3 in. wide out to out measurements, each tank containing a sand area of 480 sq. ft. and possessing a moderate daily filtering capacity of 1,250,000 gals. or 6,250,000 gals. in the aggregate.

The cast-iron filter connections have been provided of such a size that additional units can be added to an ultimate capacity of 20,000,000 gals. per day.

No air is used, but the wash water is applied at the rate of 30 in. vertical rise per minute for an average of about 5 minutes until the water begins to run clear over the weir edges. With the Missouri River water and a high rate wash, the end point is very sharply defined.

Immediately under the filters is a clear-water basin 13 ft. in depth with a heavily reinforced-concrete 15-in. roof supported by reinforced-concrete columns which in turn rest upon an 18-in. floor slab extending entirely under the clear-water basin and pipe gallery. It is heavily reinforced with steel rods to distribute the pressures uniformly over the ground. The filters rest directly upon the roof of the clear-water basin and its supporting columns and beams. In addition to the 240,000-gal. storage under the filters there is about 70,000-gal. storage under the settling basin head house.

An elevated steel wash-water tank, holding 60,000 gals., built by the Chicago

Bridge & Iron Company, is supplied by an 8-in. motor-driven centrifugal pump. Running at 1700 r.p.m., this pump has a rated discharge of 1500 gal. per minute. The pump discharge pipe is connected into one end of the wash-water line in the pipe gallery. The other end discharges into the wash-water tank. The high water line is 43 ft. above the gutter weirs in the filters.

Cost of the settling basins per 1,000,000 gals. of storage capacity is about $24,000 or about $6,000 per 1,000,000 gal. of estimated operating capacity. In the item "Valves and sluice gates" are included many valves for the "Outside pipe lines" and other improvements, but "Outside pipe lines" include material for the settling basins so the two items tend to offset each other. On the basis of a 6,000,000-gal. plant, the filters, filter house, electrical equipment and drain well cost $14,620 per 1,000,000 gals.

Settling Basin

Concrete work	$51,500.00
Valves and sluice gates	10,000,00
Head house	5,760.00
Booster pumps and pipe connections	3,376.28
Miscellaneous work	1,211.52
	$71,847.80

Mechanical Filters and Drain Well

Material for filters	$21,981.51
Labor on filters	30,521.80
Filter house and drain well house	5,570.00
Floats and gages	222.45
Strainers and screens	2,588.00
Lead for pipe laying	459.58
Pipe and specials	9,080.30
Controllers	2,000.00
Wash-water tank	3,400.00
Valves	4,298.00
Labor on drain well and wash-water tank foundations	1,706.60
Booster pumps	2,784.25
Electric wiring, filter house and settling basin	3,115.00
	$87,727.49

Work was commenced in the fall of 1910 and the filter constructed complete in the latter part of July, 1911. The concrete work was continued throughout the winter months, provision having been made for the heating of all sand and water.

Cost of Water Purification Plant of Great Falls, Mont.—The plant, described, at length, in Engineering and Contracting, Jan. 9, 1918, from which the following is taken, consists of a mixing chamber, settling basins and mechanical filters. The capacity of the plant is 12,000,000 gals. per day and the cost was approximately $225,000, or $18,750 per million gals. per day of capacity, including the entire water purification and softening plant, the low service pumping station, real estate, engineering and supervision.

Operating at rate of 12,000,000 gals. per day the time of treatment is as follows:

Mixing chamber	1,660 ft. travel	36 minutes
Settling basins	465 ft. travel	8 hours

The thorough mixing and long period for settling result in an exceptionally clear water before it reaches the filters and allows of a saving in chemicals which within a short time will pay for the increased cost. Other savings due to the use of the large mixing chamber are, no lime is required for precipitation of the sediment in the water and since the water is exceptionally clean when it passes onto the sand beds less frequent washings are required to keep the filters in condition.

The filters are arranged in eight units of 1,500,000 gals. capacity each. The entire plant is housed in a reinforced concrete structure with brick walls above floor level. All of the chemicals are fed by dry feed machines which are regulated to feed the chemicals in proportion to the water pumped.

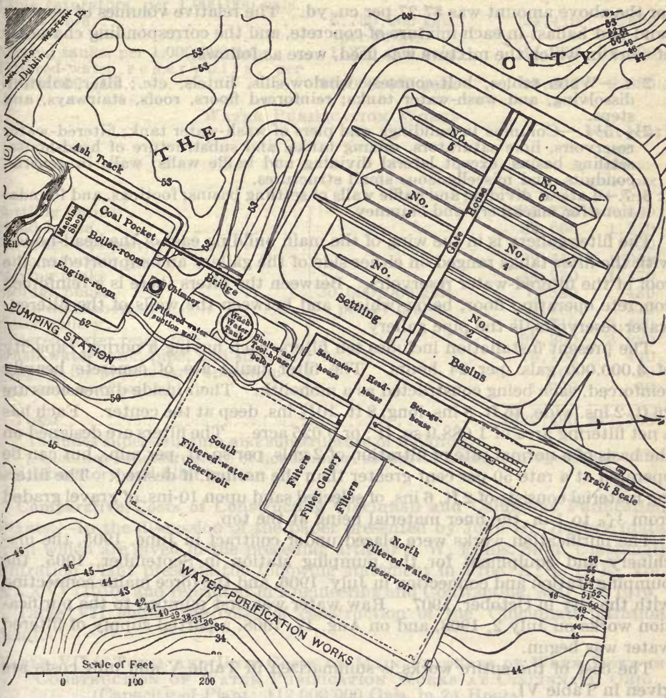

FIG. 5.—General plan of water purification works at Columbus, Ohio.

Some Costs of the Water Purification Works at Columbus, Ohio.—The following data are given in Engineering and Contracting, Feb. 9, 1910, and are from a paper by John H. Gregory in Proc. Am. Soc. of C. E., Vol. XXXVI, 1910.

The pumping station and purification works are designed for extension to an ultimate net normal capacity of 40,000,000 gals. per 24 hours. At present the pumping station has a net normal capacity of 20,000,000 gals. per 24 hours, but the building is of sufficient size for equipment having the ultimate net normal capacity. The purification works at present have a net normal capacity of 30,000,000 gals. per 24 hours, but have been arranged so that extensions may readily be made.

Fig. 5 is a general plan of the works. All building walls are of brick covered with red pressed brick; floors, stairways, etc., are of reinforced concrete. Roof trusses are steel, the covering being of slate laid on 3-in. hollow terra cotta block.

In the construction of the work, concrete, both plain and reinforced, was used extensively, the total quantity in the pumping station, purification works and adjacent structures amounting to 39,560 cu. yds. The average price paid for the above amount was $7.27 per cu. yd. The relative volumes of cement, sand and ballast in each mixture of concrete, and the corresponding character of work in which the mixture was used, were as follows:

1: 2: 4.—Water-tables, belt-courses, window-sills, lintels, etc.; filter, solution dissolving, and wash-water tanks; reinforced floors, roofs, stairways, and steps.

1: 2½: 5½.—Columns in buildings and piers of wash-water tank; filtered-water reservoirs, lime saturators, mixing tanks, and substructure of head-house; settling basins, except lateral dividing and baffle walls; walls in general, conduits, and miscellaneous small structures.

1: 3: 7.—Lateral dividing and baffle walls of settling basins; footings, and foundations for machinery and chimney.

The filter gallery is in the wing of the main building east of the head-house, with the filter tanks ranged on either side of the gallery and supported on the roof of the filtered-water reservoirs. Between the filters there is a reinforced concrete operating floor, below which, and between the walls of the filtered-water reservoirs, is the pipe gallery.

The present installation includes ten filters, each having a normal capacity of 3,000,000 gals. per 24 hours. The filter tanks are of concrete heavily reinforced, each being constructed as a monolith. Their inside dimensions are 26 ft. 2 ins. wide, 46 ft. 8 ins. long, 8 ft. 10½ ins. deep at the center. Each has a net filtering area of 1,088.9 sq. ft., or 0.025 acre. The filters are designed on the basis of a normal rate of filtration of 2 gals. per sq. ft. per min., but can be operated at a rate 50 per cent greater than the normal, if desired. The filtering material consists of 2 ft. 6 ins. of selected sand upon 10-ins. of gravel graded from 1/16 to 1-in. the finer material being at the top.

The purification works were placed under contract in June, 1905, the machinery and equipment for the pumping station in September, 1905, the pumping station and connection in July, 1906, and the force mains connecting with the city in October, 1907. Raw water was first pumped to the purification works on July 2, 1908, and on Aug. 17, 1908, a partial supply of filtered water was begun.

The cost of the entire works is summarized in Table V and unit costs are given in Table VI.

TABLE V.—SUMMARY OF COST

Land	$ 48,410
Work, exclusive of pumping station and water purification works	76,490
Pumping station	399,240
Water purification works	532,480
Total cost of works, exclusive of connections to city and exclusive of engineering	$1,056,620
Connections to city	181,000
Total cost exclusive of engineering	$1,237,620
Engineering*	95,950
Total cost	$1,333,570

* The cost of engineering work, was $95,950, divided as follows: Pay roll, $84,340; supplies, $6,120; expenses, $5,490, amounting to 7.75 per cent of the cost.

TABLE VI.—UNIT COST OF MAIN FEATURES OF WORK

Work	Capacity	Total cost	Unit cost
* Pumping station building, per cu. ft.	1,273,300 cu. ft.	$128,490	$ 0.101
† Main buildings, water purification works, per cu. ft.	534,000 cu. ft.	49,070	0.092
Settling basins, per 1,000,000 gals.	15,000,000 gals.	168,770	11,250
Lime saturators, per 1,000,000 gals. per 24 hrs.	6,750,000 gals. per 24 hrs.	24,410	3,620
Mixing tanks, per 1,000,000 gals.	1,270,000 gals.	44,230	34,800
Filtered-water reservoirs, per 1,000,000 gals.	10,000,000 gals.	98,300	9,830

WATER PURIFICATION WORKS

	Capacity	Total cost	Unit cost per million gals. per 24 hrs.
Settling basins	30,000,000 gals. per 24 hrs.	$168,770	$ 5,630
Head-house		39,660	1,320
Air-wash equipment		3,470	120
Lime-saturator house		32,550	1,080
Mixing tanks		44,230	1,470
Storage house		12,880	430
Office and laboratory		15,280	510
Filter gallery		102,710	3,420
Filtered-water reservoirs		98,300	3,280
Wash-water tank, pipe, and shelter		13,150	440
Supplies for preliminary operation		460	20
Expenses unclassified		1,020	30
Total		$532,480	$17,750

* Includes superstructure and substructure of building.
† Includes superstructure of head-house, saturator house, storage house, office and laboratory and filter gallery.

Comparative Costs of Constructing Cincinnati and Columbus Purification Plants.—In the discussion of the paper presented by John H. Gregory (data from which are given in the preceding article) J. W. Ellms, Supt. Cincinnati Filtration Plant presents the following statement in Proc. A. S. C. E., Vol. XXXVI (1910) and reprinted in Engineering and Contracting, Mar. 30, 1910.

Table VII shows the costs of construction of the Cincinnati filtration plant.

TABLE VII.—TOTAL AND UNIT COSTS OF MAIN FEATURES OF WORK DONE IN CONSTRUCTION OF WATER PURIFICATION WORKS AT CINCINNATI, OHIO (Capacity of Plant: 112,000,000 Gals. in 24 Hours)

Work	Total cost	Cost per million gallons of capacity for 24 hours
Preparation of grounds	$ 33,359.67	$ 297.85
Pipe lines between settling reservoirs and head-house	55,354.77	494.24
Head and chemical house	144,989,85	1,267.77
Coagulation basins, gate houses and pipe lines	304,913.05	2,722.44
Filters, filter house, piping, sand and gravel	592,112.30	5,286.71
Piping, valves and gate-house between filters and clear-water reservoir	29,701.91	265.20
Clear-water reservoir	121,362.39	1,083.59
Total	$1,278,793.94	$11,417.80

At Columbus, the unit costs per million gallons of capacity in 24 hours appear to be considerably greater for the settling basins and mixing tanks combined, than for the coagulation basins at Cincinnati. The figures for the Columbus tanks and basins are $7,100 per million gallons of capacity, as compared with $2,722 at Cincinnati. In a general way, these parts of the two plants correspond; but at Columbus more elaborate baffling of tanks and basins, more divisions of the flow of the raw and treated waters, and more places for the primary and secondary applications of chemical solutions were needed and provided for, than were required at Cincinnati. The greater combined unit costs of the headhouse, lime-saturator house, storage-house, wash-water tank, offices and laboratories at Columbus, than for the corresponding head-house, chemical-house, wash-water tank, offices, and laboratories at Cincinnati, are similarly explained by the necessity for designing a plant for softening, as well as for clarifying and purifying the water. The combined unit costs for the items noted above for the Columbus plant amount to $3,784, as compared with $1,268 for the Cincinnati plant.

The filters and piping in the Cincinnati plant cost more per million gallons of capacity than did those at Columbus. The figures for Columbus, which include the air-washing equipment, are $3,540, as compared with $5,287 for Cincinnati. However, the filtered-water reservoir at Columbus cost more than that at Cincinnati. The figures for the Columbus plant are $3,280 per million gallons, and for the Cincinnati plant, $1,084. At the latter plant, the clear-water reservoir is a separate uncovered reservoir, while at Columbus, it is directly under the filter tanks, which latter form a protecting roof. Virtually, no great difference in costs exists, if the cost of the filters, piping, and clear-water reservoir of each plant be combined and then compared.

The cost per million gallons of capacity for the whole purification plant at Columbus is stated to be $17,750, which amount does not include engineering; the corresponding figure for the Cincinnati plant, as shown above, is $11,418, and this also excludes the cost of engineering. The difference of more than $6,000 per million gallons capacity is doubtless due to the additional requirement demanded by the local conditions at Columbus, that is, for the softening of a very hard water, and one which is at times subject to rapid fluctuations in its physical characteristics.

Costs of Slow Sand Water Filtration Plant at Toronto, Ont.—The following data are taken from an abstract published in Engineering and Contracting, Nov. 19, 1913, of a paper by Francis F. Longley before the Canadian Society of Civil Engineers.

The filtration plant with a daily capacity of 40,000,000 Imp. gals., consists of the pumping station and equipment, 12 filters, each 117 ft. by 312 ft. arranged symmetrically on either side of the regulating equipment, sand bins, etc., and a pure water reservoir 312 ft. square with a capacity of 7,575,000 Imp. gals.

The filters are built of concrete with inverted groined arch floor and groined arch roof. The rate of filtration assumed in the design of the plant was 6,000,000 U. S. gals. per acre per day which with the relatively clear water of Lake Ontario is justified by experience as being fair, although much higher than that ordinarily used.

Most of the filter and reservoir excavation was made by means of slip scrapers and wheel scrapers and moved direct to the spoil banks. A considerable part, however, was dumped from the scrapers through a trap into cars, and these cars were hauled across the site and dumped for fill on top of the finished filter masonry. The fill on top of the filters was finished with 6 ins. of clay, the slopes sodded, and the tops and other unsodded portions grass seeded.

Sand and gravel were obtained in large part on or near the site, the work being on an island only a few hundred feet from Lake Ontario.

The equipment for cleaning the filters and recovering and replacing the sand consists in general of the following parts: A piping system to carry water under pressure into the filters and to the sand washers, and to carry the slush of sand and water in the ejecting and washing processes from the filters to the washers and from the washers to the sand bins; centrifugal pumps in duplicate in the pumping station for supplying water for this purpose; movable ejectors of suitable design for ejecting the dirty sand from the filters; the sand washers in the court; the sand bins for the storage of clean sand, and the appliances for replacing sand in the filters.

The sand storage bins are four circular tanks of reinforced concrete, the bottom of each being in the shape of an inverted cone. Each of these tanks has a diameter of 34 ft., a depth of 16½ ft. above the base of the cone and a capacity of about 600 cu. yds. The conical bottoms of the bins were placed first and included complete arrangements of piping and perforated brass plates and screens for the prompt draining of the water from the sand.

Cost of the Works.—Soon after July 1, 1912, an analysis of all expenditures on this work was made from the figures given in the accountant's books. For all work still to be done at that date, as accurate an estimate as possible was made of the cost, and the approximate total cost of the work made up on that basis.

ANALYSIS OF COST OF TORONTO FILTRATION PLANT

Filters and Appurtenances—		
Drainage during construction		$ 18,628.00
Excavation, 90,367 cu. yds. at 21 cts		18,977.07
Excavation, 2,897 cu. yds. at 63 cts		1,825.11
General fill, 75,517 cu. yds. at 22 cts		16,613.74
Clay fill, 10,185 cu. yds. at $1.50		15,277.50
Sodding, 4,920 sq. yds. at 25 cts		1,230.00
Concrete—		
Floors and walls, 17,641.4 cu. yds. at $6.35	$112,030.75	
Piers, vaulting, 13,209.4 cu. yds. at $8.80	116,247.12	
C. I. manholes and covers in place	9,865.00	
Steel reinforcing	2,722.24	
Filter roof drainage	836.00	
Filter masonry complete		241,701.11
Concrete pipe system		21,942.28
72-in. Venturi meter, main supply		2,133.84
Filter gravel, 11,436 cu. yds. at $1.50		17,154.00
Filter sand, 56,707 cu. yds. at $1.10		62,377.70
4 sand storage bins		9,363.36
7 sand washers		2,268.05
Sand washer pipe system		16,609.41
Sand ejectors, hose, etc		566.41
Cast iron pipe lines		19,600.18
Filter meters, gages, etc		6,750.63
Exterior drainage system, vitrified pipe		2,555.29
Surface drainage system		500.00
Electric duct system in court		1,398.96
Electric lighting, outside		300.00
Electric lighting, in filters		700.00
Tile underdrains in filters		6,090.00
Concrete sidewalks		1,250.00
2 regulator houses, complete		8,564.82
7 entrance houses, complete		7,670.39

Office and laboratory building		12,420.66
Office and laboratory equipment		3,063.85
Castings for additional 72-in. Venturi meter		385.00
Manhole extensions on 6 ft. steel pipe		563.25
Items properly chargeable to maintenance prior to Jan. 1, 1912		10,251.31
Miscellaneous		17,175.58
Total cost of 12 filters		$545,907.50
Pure Water Reservoir—		
Drainage during construction		4,000.00
Excavation, 21,500 cu. yds. at 21 cts		4,515.00
Fill, 17,000 cu. yds. at 22 cts		3,740.00
Fill, 8,323 cu. yds. at 30 cts		2,496.90
Clay fill, 2,346 cu. yds. at $1.50		3,519.00
Sodding, 1,062 cu. yds. at 25 cts		265.50
Entrance houses		1,261.90
Concrete—		
Floors and walls, 4,040.8 cu. yds. at $6.23	$ 25,650.00	
Piers and vaulting, 2,832.5 cu. yds. at $8.80	24,920.00	
Cast iron manholes, in place	617.60	
Steel reinforcing	46.36	
Outlet to 72-in. steel pipe	815.63	
Reservoir masonry complete		52,049.59
Miscellaneous		774.11
Total cost of pure water reservoir		$ 72.622.00
Pumping Station—		
Building, including structure		$ 24,625.12
Machinery—		
3 screw pumps (8 ft. lift)	$ 9,946.90	
48-in. steam pump (tandem compound Corliss)	9,290.32	
2 sand washer pumps (8-in. centrifugal)	5,234.00	
1 drainage pump (12-in. centrifugal)	1,675.00	
2 boilers (100 hp fire tube)	2,911.69	
Priming pump, complete	595.00	
Crane	1,110.00	
2 Venturi meter registers	894.00	
Total machinery		31,656.91
Coal bin (52 × 39 × 10 ft. deep)		3,402.93
Chimney		1,687.28
Gate valves and sluice gates		4,932.11
Cast iron pipes and specials		2,729.96
Steam piping, electric conduit work, Island supply and miscellaneous		17,148.57
Checker plates, in place		500.00
Coal during construction		4,237.82
		$ 90,920.70
Engineering and Inspection—		
General plans, specifications and supervision		$ 29,650.00
Construction, office force		26,810.00
Inspection		15,609.00
		$ 72,069.00
Summary—		
12 filters, complete		$545,907.50
Pure water reservoir, complete		72,622.00
Pumping station and equipment		90,920.70
Engineering and inspection		72,069.00
Total cost of work		$781,519.20

Approximately $14,500 of the above amount is fairly chargeable to improvements in the Island Supply, for which no special funds were provided.

Approximately $10,250 is fairly chargeable to maintenance, prior to Jan. 1, 1912, during which time there was no special fund for that purpose.

Percentage for engineering and inspection	10.2
Cost per acre for filters	$58,000
Cost per 1,000,000 gals. for reservoir	9,700

The total expenditures and outstanding accounts, as shown by the accountant's books about Dec. 1, 1912, amounted to approximately $783,400. Practically all construction work was at that time completed, and it is apparent, therefore, that the analysis given above was reasonably complete and accurate, and show satisfactorily the relative costs of the different parts of the work.

Construction and Operating Costs of Filters of the Pressure Type at New Canaan, Conn.—The following matter taken from an abstract, of a paper by Kenneth W. Leighton before the 1914 annual meeting of the Connecticut Society of Civil Engineers, was published in Engineering and Contracting, Aug. 5, 1914.

Excavation for the foundation of the building was started May 13, 1913, and water was turned through the filters on July 1, 1913. The filter plant was located so that the line of the old 12-in. supply main came about 2 ft. inside of the east wall of the building. About 80 ft. of this old supply main had to be taken up in order to insert the Venturi meter and branches for the filters. As this 12-in. main forms the only supply for the town, a temporary 6-in. pipe was tapped in below the filter plant and run to a notch cut in the concrete spillway of the dam.

The filter plant proper consists of four filters, each capable of filtering 250,000 gals. in 24 hours. This amount is based on 2 gals. per minute per square foot of horizontal filtering area. This arrangement provides sufficient filtered water for washing one filter while the other three are in use, and also allows for future growth in consumption. The consumption for short periods has run as high as 600,000 gals. per 24 hours.

The filters are of the Continental Jewell type and consist of steel tanks 10 ft. in diameter and about 7 ft. high with convex tops and bottoms. Just above the convex portion of the bottom are placed a series of bronze strainers, about 200 in number. The slits in these strainers are so small that the sand or gravel cannot get through them. The bottom of the tank is concreted in up to the strainers. Above the strainers is a 9-in. layer of gravel 1/8 to 3/4 in. in size. Above the gravel is a 30-in. layer of sand. From the top of the sand to the top of the tank there is just room for a man to get in and move around uncomfortably. A section of one unit is shown in Fig. 6.

Before the water reaches the filters some of it is forced by a back pressure valve through either one of two tanks, each containing about 100 lbs. of alum. A certain amount of the alum is dissolved and carried back into the supply main. The alum unites with a portion of the alkali in the water, forming a flaky precipitate of aluminum hydroxide which serves to entangle small particles and coloring matter and to make a coating on top of the sand. One grain of alum per gallon will use up about eight parts of alkalinity per million, so that if the water is deficient in alkalinity some alkali, such as sodium carbonate, would have to be added.

In seven months there has been used 4 1/3 tons of alum, and 47,596,000 gals. of water have been filtered, making 1 4/10 grains of alum per gallon of water. It is very likely that this can be reduced somewhat before long.

The water, on entering at the top of the filter unit, is deflected by a baffle plate, thus spreading it evenly over the top of the bed. In going through the filters, there is a loss in pressure of from 2 to 4 lbs. When it reaches the latter figure it is time to wash. The filters are washed at least once a day, even if the loss in pressure does not reach 4 lbs. The filters are of the sectional wash type and only one-third of a unit is washed at a time. This gives greater pressure and tends to keep the water from burrowing through the filtering material. The washing is done by reversing the flow of water. The washing of a unit takes about 15 minutes, unless the bed is exceptionally dirty.

When the reservoir is low the filters are washed by using the 10,000-gal. clear water tank and the pump. The pump is a 5-in. suction, 5-in. discharge, Kingsford centrifugal pump coupled to a 10-h.p Westinghouse induction motor. The clear water tank holds enough to wash approximately two filter units. The water used for washing is about 5 per cent of the total water consumed during 24 hours. After passing through the filters, the water is measured by a Venturi meter, which records the rate of flow every 10 minutes and the total amount in gallons.

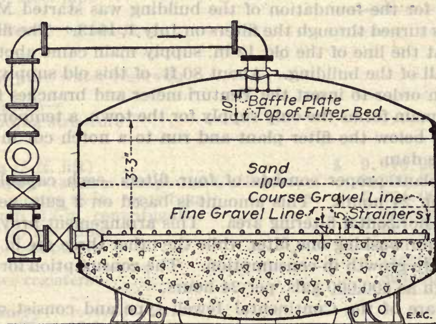

Fig. 6.—Section of filter unit, pressure filters, New Canaan, Conn.

The building is heated by an ordinary round station stove with about a 20-in. fire pot, and will burn about 5 tons of coal during the winter.

The efficiency of the plant is indicated by the comparative analyses of the raw water in past years and of the filtered water at the present. An examination of the raw water analyses made at monthly intervals from December, 1911, to June, 1913, shows that the color ranged from 28 to 96 parts per million, the turbidity from 1 p. p. m. to 60 p. p. m. and the alkalinity from 7 p. p. m. to 25 p. p. m. During the same period the odor has been characterized as grassy, faint, faint peaty, or distinct peaty, and the color of the sediment has been termed slight brown, slight gray or dark brown. The last analysis of the filtered water by the State Board of Health is as follows: Color, 0; turbidity, 0; nitrates, 0; free ammonia, 0; odor, 0; sediment, 0; chlorine, only 0.1 above normal; hardness, 32.68 (less than 60 is considered soft water); bacteria; 175 per c.c., no suspicious ones.

Construction and Operation Cost Data.—The following tabulation gives the approximate cost of the filter plant, the estimated cost of operating for a month, and the cost per 1,000,000 gals. of water:

Cost of filter plant:	
Building	$ 6,000.00
Filters	12,500.00
Venturi-meter	600.00
Miscellaneous	1,900.00
	$21,000.00
Cost of operating per month:	
Attendants' salary	$ 65.00
Power (minimum charge)	10.00
Light	.50
Telephone	4.50
Compensation insurance	1.00
Coal	3.30
Alum	27.00
Miscellaneous	2.00
Depreciation:	
Machinery, 10 per cent	125.00
Building, 2 per cent	10.00
Interest on investment at 6 per cent	105.00
	$ 353.30

Amount of water filtered per month equals 7,000,000 gals.
Cost per 1,000,000 gals. of water filtered, $50.43.

It should be noted that more water could be filtered, if the occasion demanded, without increasing the present cost materially.

Labor Costs of Constructing Filtration Plant at Minneapolis, Minn.—In Engineering and Contracting, June 11, 1913, June 25, 1913 and Nov. 5, 1913, W. N. Jones gives in great detail the design and methods and costs of constructing the 39,000,000 gal. mechanical water filtration plant at Minneapolis, from which the following matter is abstracted.

Hering and Fuller were commissioned to draw up the plans and specifications for the work in March, 1910 and after careful study of the old works, which consisted of a first-class pumping station, three miles of 50-in. steel force mains, and two settling or service reservoirs of a capacity of 47,000,000 gals. each, it was decided to use the old reservoirs as a part of the new plant.

The new plant contemplated the covering of one of the old reservoirs with a groined arch roof to be used as a clear water basin, the raising of the embankments of the other reservoir 10 ft., in order to maintain the elevation of the water in the clear water basin at the old level and provide a working head for the operation of the filters, also a mixing chamber, two coagulation basins, a headhouse, 12 mechanical filter units, with an auxiliary clear water basin underneath, and wash water tank of 135,000 gals. capacity.

The old reservoirs, which were built in 1896, were rectangular in shape, each 877 ft. 6 ins. long by 413 ft. 6 ins. wide, c. to c. of curbing, with a 1 on 2 slope inside.

Fig. 7 gives the general layout of the plant and shows the principal dimensions of the units.

The building of the filter plant was the largest single piece of work ever attempted by the City of Minneapolis under the "day labor system" and employed the greatest variety of labor, both skilled and unskilled of any job under the jurisdiction of the Engineering Department. All the labor had to be trained in filter work, as none had ever worked on a like job before. The conditions under which the work was done were far from being the best. More or less patronage was attempted by some of the aldermen, causing some friction between them and the constructing department. This patronage became less as the work progressed, as it was soon recognized that unless a man did his work well there was no place at the filter plant for him, no matter who his friends might be.

Rainy weather and the extreme cold of the winters delayed the work materially, as it was almost impossible to work to advantage in either. A large amount of work, however, was done at times when it would have meant a saving in the cost had one waited for more favorable weather. Especially was this true of the earth and concrete work, some of which was done under very trying conditions.

The amount of constructing machinery used on the job was very meager, amounting to almost a famine in this line. It caused many things to be

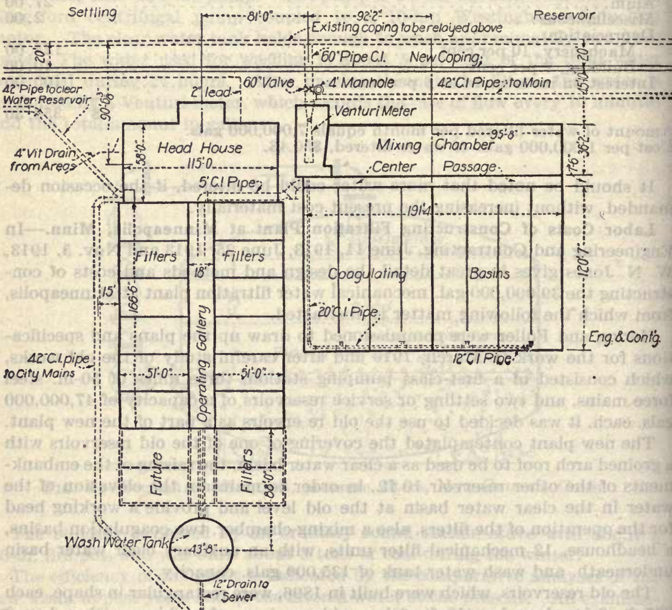

FIG. 7.—General layout plan of Minneapolis water filtration plant.

handled by hand that really required machinery for its economical handling, thus increasing the cost unnecessarily.

The quality of the work turned out by the force account system has been very good. Every man was warned not to place, knowingly, a defective piece of material of any kind in his work, and whenever he discovered anything that did not appear first class to report it to his superiors. Quality was always placed first, and quantity turned out next. It is safe to say that the quality of the work is much better than it would have been had the job been done by contract, and there is no reason to believe that the cost or the time of completion would have been any less.

WAGES PAID ON CONSTRUCTION WORK AT THE MINNEAPOLIS FILTER PLANT

Occupation	1911. Per mo.	1912. Per mo.
Assistant superintendent	$125.00	$125.00
Chauffeur	65.00	65.00
	Per day	Per day
Foreman	$ 5.00	$ 4.50
Assistant foreman	3.50	3.75
Sub-foreman	3.00	3.00
Timekeeper	4.50	4.50
Clerk	3.00	3.00
Rodman	2.75	....
Brick foreman	....	7.00
Bricklayers	5.20	5.20
Structural steel foreman	....	5.50
Structural steel workers	....	4.50
Steamfitters' foreman	5.00	5.00
Steamfitters	4.50	4.50
Plumbers	....	4.50
Roofers	....	4.00
Plasterers	....	5.60

Calkers	....	3.15
Single horse	3.00	....
Teams	4.72	5.00
Laborers	2.25	2.40

The following are labor costs for work done on this filtration for 1911 and 1912.

LABOR COST DATA ON SETTLING BASIN IN 1912

Earthwork.—Excavation: 321 cu. yds. of earth were excavated from trenches by hand at an average cost of 78.4 cts. per cu. yd. This cost includes the sheeting and staging. Of the 321 cu. yds. excavated 236 cu. yds. was dry work, shoveled three times, 40 cu. yds. was wet clay handled four times, and 45 cu. yds. was wet clay handled twice, at average costs of 80 cts., $1, and 40 cts. per cu. yd., respectively. Backfill: 747 cu. yds. were backfilled by hand and scraper at an average cost of 34.7 cts. per cu. yd. The ground was wet and partly frozen. This figure includes the hauling of 93 cu. yds. 900 ft. Fill: The fill of 10,773 cu. yds. was well sprinkled and rolled in layers of 6 ins. with a 14-ton roller. Average cost, 49.8 cts. per cu. yd.

Puddle Wall.—The 1,529 cu. yds. of puddle were tamped by hand in 1½ to 2-in. layers at an average cost of 75.7 cts. per cu. yd. The water needed was pumped by hand.

Recovery of Crushed Stone and Screening Gravel.—All crushed stone was screened by hand to remove dirt. In all 77 cu. yds. of stone and gravel were screened at an average cost of $1.67 per cu. yd.

Hauling Crushed Stone and Gravel.—The crushed stone was handled by hand and hauled in common dump wagons. 172 cu. yds. were hauled an average of 330 ft. at an average cost of 39.9 cts.

Concrete.—Concrete was laid in slabs 13.5 ft. by 10 ft. by 6 ins. on 2 to 1 slope. 142 cu. yds. were laid at an average cost of $2.12 per cu. yd., including the 1:2 cement finish and the setting and removing of screeds.

Laying Crushed Stone.—Crushed stone shoveled down slopes and spread by hand. 1,134 cu. yds. were placed at an average cost of 35.2 cts. per cu. yd.

Laying Tracks.—745 ft. of 24-in. gage track in 16-ft. lengths at an average cost of 3.3 cts. per ft.

Laying Sandstone.—The sandstone blocks were 12 by 14 ins. in section and from 2 to 6 ft. long. They were laid on edge. In all 11,690 sq. ft. were laid at an average cost of 4.9 cts. per sq. ft.

Hauling Sandstone.—11,795 sq. ft. of sandstone was loaded by hand and hauled on a stone jigger at an average cost of 4.4 cts. per sq. ft.

Pouring Asphalt Joints.—805 lin. ft. of asphalt joints were heated and poured at an average cost of 7.1 cts. per ft.

Coping Stone.—Hoisting: The coping stone were hoisted 12 ft. by an old pipe laying derrick operated by hand power. 10,548 sq. ft. of this stone was hoisted at an average cost of 2.8 cts. per sq. ft. The coping stones are 4 × 12 ins. in section and from 4 to 8 ft. long. Hauling: The stone was loaded by hand and hauled a distance of 750 ft. on a stone jigger. The average cost for 2,750 sq. ft. so hauled was 4 cts. per sq. ft. Setting: the average cost for setting 11,792 ft. of coping stone was 5 cts. per sq. ft.

Fencing.—Hauling: 2,207 lin. ft. of fencing was hauled 650 ft. on common dump wagons, which were not suitable for the purpose, at an average cost of 3 cts. per lin. ft. Placing: 2,534 lin. ft. of fencing was placed at an average cost of 16.3 cts. per lin. ft. This includes drilling five ⅝-in. × 3-in. holes in the sandstone coping for every 12 ft. length of fence, placing all bolts, etc. Painting: 2,324 ft. of fencing was painted at an average cost of 5.5 cts. per lin. ft. This is for one coat and includes cleaning off all rust. Fence consists of 3-in. pipe rail and 4-in. by 4-in. ornamental posts 12 feet apart. Bolted lug midway of each section.

Crossover Pipe.—Setting: 14.85 tons of 42-in. cast iron water pipe was set at an average cost of $4.49 per ton. This includes some sheeting and the use of a pipe derrick. Cutting: The 42-in. cast iron pipe was cut in two at three sections outside the trench, by two men using cold chisels at an average cost of $1.50 per cut. The pipe was cut at two sections after the main was in place, in soft ground, at an average cost of $11.50 per cut. Calking: 12 joints in the 42-in. cast iron water pipe were calked by the calkers of the water department at an average cost, including yarning, melting lead, pouring, etc., of $2.41 per joint. This pipe inclines 22½ degrees from the vertical.

Making Bolts.—136 bolts ⅝ × 4½ ins. were made at an average cost of 5 cts. each. 660 bolts ½ × 5 ins. were made at an average cost of 4.3 cts. each. These figures include welding on heads or upsetting, and threading bolts and nuts.

LABOR COST DATA ON CLEAR WATER BASIN IN 1911

Ground and Segmental Arch Forms.—Building: 25,964 sq. ft. of these forms were built at an average cost of 5.2 cts. per sq. ft., including oiling. Transporting: 367,832 sq. ft. of these forms were transported a distance averaging between 200 and 300 ft. at an average cost of 0.6 cts. per sq. ft.

This cost includes hoisting 289,100 sq. ft. of the forms through a height of 22 ft. Setting: 346,731 sq. ft. of these forms were set at an average cost of 1.9 cts. per sq. ft. This includes all bracing, repairs and reoiling. Wrecking: 334,214 sq. ft. of these forms were wrecked an average cost of 1.7 cts. per sq. ft. This includes the wrecking of all braces. In all the foregoing square feet of formwork refers only to the portion exposed to concrete.

Supporting Posts.—Building: 108 supporting posts for the arch forms were built at an average cost of 18 cts. each. This includes the cost of transporting the posts. Setting: 3,524 posts were set at an average cost of 46.7 cts. each. This includes wrecking the posts and hauling them. The cost of wrecking only on 174 posts averaged 2.9 cts. each.

Column Forms.—Building: 3,330 sq. ft. of forms were built at an average cost of 1.3 cts. per sq. ft. Transporting: 17,200 ft. B. M. of these forms was transported about 800 ft. at an average cost of 95 cts. per 1,000 ft. B. M. Setting: 123,243 sq. ft. of these forms were set at an average cost of 3 cts. per sq. ft., including transporting to place and reoiling. Placing Clamps: 16,029 clamps were placed at an average cost of 5.7 cts. each. Wrecking: 112,478 ft. B. M. of these forms were wrecked at an average cost of $10.24 per 1,000 ft. B. M. This includes removal of clamps.

Making Clamps.—4,807 clamps were made at an average cost of 1.2 cts. each.

Tearing Up Forms.—101,930 ft. B. M. of forms were torn up at an average cost of $1.87 per 1,000 ft. B. M.

Sawing Wedges.—1,880 wedges were sawed at an average cost of 1 ct. each.

Recovery of Lumber.—128,200 ft. B. M. of lumber was recovered from the torn down forms at an average cost of $4.10 per 1,000 ft. B. M. This work was the pulling of old nails, removing concrete from the boards, etc.

42-in. Conduit Forms.—Making: 111 sq. ft. of collapsible forms were built at a cost of 17.8 cts. per sq. ft. Setting: 7,779 sq. ft. of 42-in. conduit forms were set at an average price of 2½ cts. per sq. ft. This included oiling and bracing.

Setting Forms for Pedestals.—726 pedestal forms were set at an average cost of 68½ cts. These forms were dropped onto the pedestals and squared up for holding up the column forms.

Concreting.—Conduit: 158 cu. yds. of concrete were placed in the 42-in. conduit at an average cost of $1.58 per cu. yd. This included placing the reinforcing bars. Columns and Groined Arches: 10,933 cu. yds. of concrete were placed at an average cost of 94 cts. per cu. yd. The average haul was 650 ft.

Holes for Pedestals.—Backfilling: 269 cu. yds. were backfilled at an average cost of 59 cts. per cu. yd. Sealing Up: 64 cu. yds. of concrete were used in sealing up holes for pedestals at an average cost of $3.22 per cu. yd. This concrete floor was 6 ins. thick and the cost given covers the 1:2 cement mortar finishing coat.

Tearing Up Old Revetment.—1,589 cu. yds. of the old revetment wall were torn up and hauled away at an average cost of 51 cts. per cu. yd.

Filling on Top of Basin.—36,949 cu. yds. were filled at an average cost of 48.5 cts. per cu. yd. The average haul was 1,200 ft. Common dump wagons were used. All earth was shoveled by hand.

Transporting Lumber.—170,590 ft. B. M. of old form lumber was transported 1,000 ft. at an average cost of $4 per 1,000 ft. B. M.

The total classified costs of this work on the clear water basin are given in Chap. VI. Dams, Reservoirs and Standpipes.

COST DATA ON FILTERS IN 1911

Excavation.—1,454 cu. yds. were excavated and hauled between 300 and 350 ft. with scrapers at an average cost of 26 cts. per cu. yd. 600 cu. yds. were shoveled into dump wagons and hauled 450 ft. at an average cost of 38.7 cts. per cu. yd. 265 cu. yds. were excavated by pick and shovel for the 36-in. drain at an average cost of 69 cts. per cu. yd.

Mixing and Placing Concrete.—This includes all track, trestle and runway building, moving, and wrecking same. Track 24-in. gage, 16-ft. sections. Runways 10 ft. × 16 ft. of 2-in. material. Inverted Arches: 855 cu. yds. of concrete mixed and placed at average cost of $1.21 per cu. yd. Foundation Walls: 445 cu. yds. concrete, average cost of $1.42 per cu. yd. Columns and Groined Arches: 1,423 cu. yds. of concrete, average cost of 47 cts. per cu. yd. Filter Boxes: 1,312 cu. yds. of concrete, average cost of $1.47 per cu. yd. Sewer and Lateral Gutters: 30 cu. yds. of concrete in the sewer cost on an average $1.39 per cu. yd. 55 cu. yds. of concrete in the lateral gutters cost an average of $2.39 per cu. yd.

Making and Setting Forms.—Areas given below are for contact with concrete. Costs given include all necessary supports, braces, scaffolds, etc. Inverted Groined Arches: 6,110 sq. ft. of forms at average cost of 3.7 cts. per sq. ft. Foundation Walls: 26,793 sq. ft. of forms at average cost of 4.2 cts. per sq. ft. Column Forms: 4,628 sq. ft. of column forms at average cost of 3⅓ cts. per sq. ft. 30 clamps were made and placed at an average cost of $1.19 each. and 458 column collars were made and set at an average cost of 12 cts. each, Groined and Barrel Arches: 40,355 sq. ft. of forms at an average cost of 3.6 cts. per sq. ft. Groined Arch Supports: The total cost of the groined arch supports was $151.94. Among other items 94 posts were set at 22 cts. each, 360 struts at 2 cts. each, and 118 intermediate posts at 13 cts. each. Filter Boxes: 75,174 sq. ft. of forms were set at an average cost of 5.9 cts. per sq. ft. Lateral Gutters: 3,328 sq. ft. of forms were oiled at 0.3 cts. per sq. ft. 2,113 sq. ft. of forms were built and set for 7.4 cts. per sq. ft., average. Sewer: 2,449 sq. ft. of sewer forms were built and set at an average cost of 8.8 cts. per sq. ft.

Backfill.—495 cu. yds. of backfill was hand-tamped at an average cost of 81 cts. per cu. yd. This was clay placed under all cast iron pipes.

Bending Steel.—7,063 lbs. of reinforcing steel were bent at an average cost of 0.63 cts. per lb.

Setting Steel.—129,295 lbs. of reinforcing steel was set at an average cost of 0.72 ct. per lb. This steel was tied at all intersections with No. 16 wire. The cost given includes transporting the steel 350 ft. at approximately 0.1 ct. per lb.

Transporting Pipe and Specials.—216.7 tons of cast iron pipe and specials were rolled about 200 ft. by hand at an average cost of 90.4 cts. per ton.

Setting Pipe and Specials.—130 tons of pipe and specials were set at an average cost of $8.25 per ton. This includes the erection of derricks, scaffolds, etc., necessary for setting the material.

Setting Pipe Hangers.—144 short pipe hangers were set at average cost of 8½ cts. each. 46 long pipe hangers were set at 98½ cts. each.

Wrecking Groined Arches and Conduit Forms.—21,586 sq. ft. of these forms were wrecked at an average cost of 1.4 cts. per sq. ft. This includes wrecking of scaffolds, braces, supports, etc., also hoisting out the groined arch form sections.

Wrecking Wall Forms.—63,905 sq. ft. of wall forms were wrecked at an average cost of 1½ cts. per sq. ft. This includes wrecking braces, supports, scaffolds, etc.

Transporting Form Lumber.—73,290 ft. B. M. were transported in common dump wagons, unsuited to purpose, at a cost of $4.14 per 1,000 ft. B. M.

Cutting Pipes.—Two men cut the pipe with cold chisels. 16 pieces of 18-in. pipe were cut at an average cost of 50 cts. per cut. 3 pieces of 20-in. pipe were cut at average cost of 60 cts. each. 3 pieces of 24-in. pipe were cut at average cost of 75 cts. each.

Setting I-Beams.—12.35 tons of I-beams were set at an average cost of $7 per ton. This includes the use of derricks, etc. 48 plates were set under the I-beams at an average cost of 82 cts. each.

Calking Joints.—This includes yarning, heating lead, pouring, etc.:

27 18-in. joints were calked at average cost of	$1.01
35 18-in. joints were calked at average cost of	90 cts.
90 20-in. joints were calked at average cost of	1.12
15 20-in. joints were calked at average cost of	1.00
10 24-in. joints were calked at average cost of	1.46
21 24-in. joints were calked at average cost of	1.19

Making Pipe Hangers.—120 1-in. × 18-in. pipe hangers were made at an average cost of 27 cts. each. One end of each hanger was upset to 1¼ in.

LABOR COST DATA ON FILTERS AND FILTER HOUSE IN 1912

Earthwork.—Excavation: 2,409 cu. yds. of clay was excavated with pick and shovel at average cost of 65.2 cts. per cu. yd. Some of this clay was handled three times. The cost includes a small amount of sheeting. Fill: 6,494 cu. yds. of fill was made at an average cost of 44½ cts. per cu. yd. Sandy soil was used and was tamped by hand under pipes. The average haul of material was 800 ft.

Making and Setting Forms.—Ridge Blocks and Lateral Gutters: 60,110 sq. ft. of these forms were made and set at average cost of 1.7 cts. per sq. ft. These were collapsible forms bolted together. Cost includes oiling and cleaning after collapsing. Beams and Columns: 23,893 sq. ft. of these forms were built and set at average cost of 9.7 cts. per sq. ft. This includes clamping column and beveling all beams. Cost includes all supports, etc. Roof and Floor Slabs: 24,539 sq. ft. of these forms were set at an average cost of 7.1 cts. per sq. ft. These areas indicate only surface of form in contact with concrete. This cost includes all bracing, supports and wiring.

Wrecking Forms.—102, 747 sq. ft. of forms were wrecked at an average cost of 1.2 cts. per sq. ft. This includes wrecking bracing and supports.

Reinforcing Steel.—Transporting: 86,481 lbs. of reinforcing steel was transported an average distance of 350 ft. at 0.2 ct. per lb. Bending: 23,481 lbs. of steel were bent at an average cost of 0.4 ct. per lb. Setting: 12,992 lbs. of reinforcing steel were set at an average cost of 0.4 ct. per lb. This includes wiring with No. 16 annealed wire at all intersections.

Electrical Work.—3,369 lin. ft. of ½ to 1-in. conduit was placed at a cost of 5.9 cts. per ft. 13,110 ft. of insullated wire was placed at 0.7 ct. per ft. 11 switch boxes were set at 25 cts. each. 10 arc lights were set at $1.50 each, and 8 arc lights were set at $1.00 each.

Concreting.—Lateral Gutters: 86 cu. yds. of concrete were placed at average cost of $6.10 per cu. yd. This includes firing of salamanders in each filter box for 72 hours continuously. Floors, Roof, etc.: 608 cu. yds. of concrete were placed at average cost of $1.50 per cu. yd. Ridge Blocks: 325 cu.

yds. of concrete were placed at average cost of $2.86 per cu. yd. This includes placing screen bolts and all reinforcing steel in each block.

Placing Lateral Gutter Weirs.—5,800 lin. ft. of concrete were placed at an average cost of 7.3 cts. per ft.

Ridge Blocks.—Transporting: 314.52 cu. yds. of ridge blocks were transported an average distance of 300 ft. and were hoisted from 20 to 23 ft. at an average cost of $1.39 per cu. yd. Setting: 305 cu. yds. of ridge blocks were set at an average cost of $6.97 per cu. yd. This includes all drilling for anchor rods, cutting and placing rods, grouting in rods, and chipping concrete.

Setting Strainer Plates.—3,736 strainer plates were set at an average cost of 32.8 cts. each. This includes cementing up, bolting, chipping concrete where necessary, etc., complete.

Laying Screen.—15,292 sq. ft. of screen was placed at an average cost of 6.2 cts. per sq. ft. This includes sewing with No. 20 wire, placing washers and bolting down.

Gravel.—Screening: 368.85 cu. yds. of gravel was screened at an average cost of $4.02 per cu. yd. Hauling: 265 cu. yds. of gravel was hauled at an average cost of $1.04 per cu. yd. Placing: 242 cu. yds. of gravel were placed at an average cost of $3.62 per cu. yd. This includes placing in wheelbarrows, hoisting 20 to 23 ft. and wheeling to place.

Filter Sand.—Hauling: 948 cu. yds. of filter sand was hauled 1½ miles at an average cost of 67 cts. per cu. yd. This includes loading from cars and wagons. Placing: 563 cu. yds. of sand was placed at an average cost of 54½ cts. per cu. yd.

Laying Brick.—221,700 brick were laid at an average cost of $12.50 per 1,000. This includes cost of mixing and coloring mortar, and all scaffold work.

Setting Terra Cotta.—14 terra cotta sills were set at an average cost of $2.14 each. Five were set at $1.20 each. 377 lin. ft. of terra cotta was set at an average cost of 14 cts. per ft.

Roofing.—82¾ squares of roofing were placed at an average cost of $3.54 per 100 ft. square. This includes placing tarred felt and shingles.

Setting Window Sashes and Frames.—171 frames and sashes were set at an average cost of 73 cts. each. This includes setting the necessary hardware.

Transporting Pipe, Valves, Specials and Machinery.—418 tons were transported through distances ranging from 150 ft. to 350 ft. at an average cost of $1.56 per ton. This includes loading, hauling, unloading, picking loose from frozen ground, etc.

Setting Pipe and Specials.—476 tons were set at an average cost of $2.00 per ton. This includes scaffolds, derricks, belting, etc.

Pipe Hangers and Supports—

Making:

No. of hangers	Size of hangers	Av. cost per hanger
31	¾ in. × 7 ft.	$1.24
7	⅞ in. × 29 ft.	2.26
12	⅞ in. × 23 ft. 3 ins.	2.15
31	⅞ in. × 18 ft. 6 ins.	1.38
17	¾ in. × 6 ft. 4 ins.	1.26
12	¾ in. × 6 ft.	0.37
18	1¼ ins. × 18 ins.	0.81
11	1¼ ins. × 7 ft. 9 ins.	0.85

Placing:

No. of hangers	Size of hangers	Av. cost per hanger
24	¾ in. × 7 ft.	$0.59
31	⅞ in. × 18 ft. 6 ins.	0.75
14	¾ in. × 21 ft. 6 ins.	1.17
3	¾ in. × 6 ft. 4 ins.	0.75
24	¾ in. × 6 ft.	1.20
18	1¼ ins. × 18 ins.	0.50
11	1¼ ins. × 7 ft. 9 ins.	0.14

Setting Hydraulic Gates:

Size, ins.	No. gates	Av. cost setting
12	14	$1.56
20	12	5.30
30	1	8.25
24	12	1.56

These costs include scaffolds, derricks, gaskets, etc.

Making Bolts:

Diam., ins.	No. bolts	Cost per bolt
½	147	1.7 cts.
⅞	553	8.3 cts.
1	688	9.6 cts.
¾	106	8.4 cts.
⅝	50	3.4 cts.

Ladder Rungs.—42 ¾-in. ladder rungs were made at an average cost of 33 cts. each. Sixty-four rungs were set at an average cost, including grouting, of 18 cts. each.

Transporting Lumber.—141,676 ft. B. M. of lumber was carried about 250 ft. at an average cost of $2.32 per 1,000 ft. B. M.

Cleaning Walls.—20,070 sq. ft. of brick wall was scraped free of cement and mortar and washed with a dilute solution of hydrochloric acid at an average cost of 2.1 cts. per sq. ft.

Drilling Holes in Concrete.—The following data shows the cost of drilling holes in concrete by hand:

Size of holes, ins.	No. of holes	Av. cost per hole
1⅜×9	3	$1.48
1¼×6	25	0.14
1⅛×8	8	0.63
1⅛×9	10	0.24
1⅜×9	18	0.15
1 ×4	30	0.09
⅝×2½	761	0.07

Painting.—27,500 sq. ft. of painting was done, one coat, at an average cost of 1 ct. per sq. ft.

Setting Small Pipe.—The following data relates to steam and vacuum pipe: 850 ft. of 1½-in. and 2-in. pipe was set at an average cost of 19 cts. per ft.

Setting Gate Stands.—Two stands for 36-in. × 48-in. sluice gates were set at an average cost of $2.87 each.

Placing Window Operating Device.—391 ft. of window operating rods were placed at an average cost of 28 cts. per ft. This includes setting all gears, brackets, chains, etc., complete.

Finish Coat on Roof.—A 1:2 cement coat from ¼ to ¾-in. thick was placed on the cinder concrete roof. 9,736 sq. ft. were placed at average cost of 3.7 cts. per sq. ft.

LABOR COST DATA ON HEAD HOUSE IN 1911

Excavation.—2,304 cu. yds. of material were excavated at an average unit cost of 50½ cts. Of this amount, 350 cu. yds. were hauled 750 ft. in dump wagons and 900 cu. yds. were of soft and sticky material excavated by hand tools.

Backfill.—125 cu. yds. of material were backfilled, at an average unit cost of 63 cts. per cu. yd. This material was tamped by hand.

Building Forms.—The following cost data on form building are stated in cents per sq. ft. The area considered is that portion which is exposed to the concrete only. The cost includes all bracing, supports, scaffolds, etc., complete.

Wall Forms.—41,620 sq. ft. of wall forms were built at an average unit cost of 6.9 cts. per sq. ft.

Beam and Column Forms.—29,039 sq. ft. of beam and column forms were built at an average cost of 3.9 cts. per sq. ft.

Stair Forms.—1,687 sq. ft. of stair forms were built at an average cost of 13.9 cts. per sq. ft.

Floor Forms.—7,629 sq. ft. of floor forms were built at an average cost of 5.9 cts. per sq. ft.

Wrecking Forms.—The area of forms wrecked is stated in terms of square feet, exposed to concrete only. The cost includes the removal of all bracing, supports, etc.

Wrecking Wall Forms.—34, 972 sq. ft. of wall forms were wrecked at an average unit cost of 0.86 ct. per sq. ft.

Wrecking Beam Column and Stringer Forms.—24,450 sq. ft. of these forms were wrecked at an average unit cost of 0.45 ct. per sq. ft.

Wrecking Floor Forms.—8,150 sq. ft. of floor forms were wrecked at an average unit cost of 0.81 ct. per sq. ft.

Transporting Lumber.—10,400 ft. B. M. of lumber was transported at an average unit cost of $3.72 per 1,000 ft. B. M. For this purpose ordinary dump wagons were used, and were not well suited to the purpose. The haul ranged from 300 to 500 ft.

Cleaning Lumber.—33,086 ft. B. M. of lumber was cleaned at an average unit cost of $6.38 per 1,000 ft. This includes cleaning off concrete and pulling out old nails.

Building Beam Supports.—663 sq. ft. of beam supports were built at an average unit cost of 14.6 cts. per sq. ft.

Bending Steel and Making Steel Column Reinforcement.—56,753 lbs. of steel were handled for this purpose at an average unit cost of $6.08 per 1,000 lbs. This includes the wiring together of the column reinforcement with No. 16 gage wire.

Setting Steel.—120,412 lbs. of steel were set at an average unit cost of $7.44 per 1,000 lbs. This includes wiring with No. 16 gage wire at all intersections of reinforcing material.

Concreting Floors, Columns and Bins.—1,575 cu. yds. of concrete were placed at an average unit cost of $1.43 per cu. yd. This includes the cost of raising elevator, etc.

Concreting Walls.—531 cu. yds. of concrete were placed at an average cost of $1.29 per cu. yd. This inicudes raising the elevator, etc.

Finishing Floors.—5,734 sq. ft. of floor were finished at an average unit cost of 1.45 cts. per sq. ft.

Preparatory Work for Concreting.—425 lin. ft. of track and trestle were erected at an average unit cost of 13.5 cts. per ft.

Setting Sluice Gates.—Four 36 × 48-in. sluice gates were set at an average cost of $21.45 per gate. One 42-in. sluice gate was set at a cost of $13.15.

Placing Cast Iron Pipe and Specials.—6.2 tons of 42-in. cast iron pipe and specials were placed at an average unit cost of $6.91 per ton. This includes a haul of 200 ft.

3.15 tons of 12 and 42-in. cast iron pipe and specials were placed at an average unit cost of $9.54 per ton. One ton of 12-in. pipe was placed at a cost of $2. The foregoing figures include the erection of derricks, scaffolds, etc.

Calking Joints.—Two joints in the 42-in. pipe lines were calked at an average cost of $2 per joint. This includes yarning, heating lead, etc.

Electrical Conduit.—500 ft. of 1-in. electrical conduit were placed at an average cost of 3.1 cts. per ft.; 100 ft. of 1¼-in. electrical conduit were placed at an average cost of 2½ cts. per ft.; 450 ft. of 1 to 2-in. electric conduit were placed at an average cost of 5 cts. per ft. These figures include transporting the conduit materials.

Manholes.—Three 24-in. manholes were placed on the hypo tanks at an average cost of $1.69 each.

Making Column Clamps, Blocks and Wedges.—75 column clamps were made at an average cost of 30 cts. each.

150 blocks and wedges were made at 1.6 cts. each.

Pipe Supports and Hangers, etc.—20 1-in. by 5-in. by 15-in. pipe supports and hangers were placed at an average cost of 42 cts. each.

60 trolley hangers were placed at an average cost of 20 cts. each. These figures include grouting in.

LABOR COST DATA ON HEAD HOUSE IN 1912

Making Fill.—2,020 cu. yds. of fill were made at an average unit cost of 48.7 cts. per cu. yd. This includes an average haul of 1,500 ft.

Building Forms.—Wall and Foundation Forms.—24, 965 sq. ft. of wall and foundation forms were built at an average unit cost of 5½ cts. per sq. ft. This includes only the surface in contact with concrete. Cost of erecting scaffolding and bracing is included.

Floor and Roof Forms.—20, 433 sq. ft. of floor and roof forms were built at an average unit cost of 8.7 cts. per sq. ft.

Building Tank Forms.—1,335 sq. ft. of tank forms were built at an average unit cost of 8.4 cts. per sq. ft.

Wrecking Forms.—46,294 sq. ft. of forms were wrecked at an average cost of 2.1 cts. per sq. ft. This includes wrecking scaffolds and bracing.

Transporting Lumber.—21,996 ft. B. M. of lumber was transported an average distance of 300 ft. at an average unit cost of $5.60 per 1,000 ft. B. M.

Cleaning Lumber.—6,000 ft. B. M. lumber was cleaned at an average unit cost of $8.80 per 1,000 ft. B. M. This included pulling out old nails and scraping off concrete which adhered to boards.

Reinforcing Steel—Bending.—5,369 lbs. of reinforcing steel were bent at an average cost of $3.26 per 1,000 lbs.; 34,540 were transported at $1.84 per 1,000 lbs.; 35,868 lbs. were set at $6.07 per 1,000 lbs. This includes the cost of wiring with No. 16 gauge wire at every intersection of reinforcing rods.

Structural Steel—Transporting.—21.09 tons of structural steel were transported a distance of 1,600 ft. at an average unit cost of $9.35 per ton.

Setting.—21.86 tons of structural steel were set at an average unit cost of $12 per ton. This includes all wall plates, bolts and rivets.

Concrete—Roof and Thin Walls.—431 cu. yds. of concrete were placed in the roof and thin walls at an average unit cost of $2.08 per cu. yd.

Foundation and Heavy Walls.—148.35 cu. yds. of concrete were placed in foundation and heavy walls at an average unit cost of $1.27 per cu. yd. The foregoing costs on concreting include the erection of runways, scaffolds, etc.

Finishing Floors, Roofs, etc.—17,158 sq. ft. were finished at an average unit cost of 4 cts. per sq. ft. This is for placing a 1:2 cement plaster from ½ in. to 1½ ins. thick.

Placing Expanded Metal Lath and Rib-Truss for Ceiling and Partitions.—7.568 sq. ft. of this material were placed at an average unit cost of 8.3 cts. per sq. ft. This includes all iron studs and part of the ceiling supports, etc.

Plastering.—31,711 sq. ft. of plastering were figured as a single coat and the average unit cost was 3.13 cts. per sq. ft.

Laying Brick.—158,800 brick were laid at an average unit cost of $14.60 per M. This includes all scaffolding. The brick was laid in Flemish bond. Three kinds of mortar were used.

Washing Walls.—8,800 sq. ft. of walls were washed at an average unit cost of 2.3 cts. per sq. ft. A dilute solution of hydrochloric acid was used for this purpose. The cost given includes the cost of erecting and removing the necessary scaffolding.

Windows and Doors.—18 window sills were set in the brick work after it was finished at an average unit cost of $3.26 each.

Copper Work.—Valley, Deck and Flashing.—4,044 sq. ft. of valley and deck copper work were placed at an average unit cost of 2.7 cts. per sq. ft.; 1,323 lin. ft. of flashing were laid at an average unit cost of 7.2 cts. per ft., 1,152 ft. of flashing were soldered only at a cost of 3.3 cts. per ft.

Ridge Roll, etc.—1,483 lin. ft. were placed at an average unit cost of 7 cts. per ft. In the copper work all the copper was cut and formed on the job.

Roofing.—80.75 squares of roofing were placed at an average cost of $4.24 per square. This roofing consisted of asbestos shingles each 16 × 16 ins., placed on a 1:2:4 cinder concrete roof with a layer of tarred felt between.

Electric Work—Conduit, ½-in. to 2-in.—2,435 lin. ft. of conduit were placed at an average unit cost of 5 cts. per ft. This includes the placing of all fittings.

Wiring.—13,190 lin. ft. of electric wiring were placed at an average unit cost of 1.1 cts. per ft. All the wires were well covered.

Cast Iron Pipe and Specials—Transporting.—102.57 tons of cast iron pipe and specials were transported at an average unit cost of $2.87 per ton.

Setting—61.94 tons of cast iron pipe and specials were set at an average unit cost of $3.50 per ton. The foregoing costs include the transporting and setting of scaffolds, derricks and all other necessary equipment.

Calking Joints.—Seven 42-in. joints were calked at an average cost of $1.91 each.

24 6-in. joints were calked at an average cost of 49 cts. each.

31 4-in. joints were calked at an average cost of 56 cts. each. Figures for calking include yarning, pouring, melting lead, erection of scaffolds, etc.

Setting Radiators.—6,942 sq. ft. of radiators were set at an average unit cost of 3.1 cts per sq. ft.

2-in. Lead Pipe.—233 wiped joints were made at an average cost of 60 cts. each. This includes heating, soldering, etc.

Setting.—1,019 lin. ft. of 2-in. lead pipe were set at an average unit cost of 0.5 ct. per ft. All this pipe weighed 7½ lbs. per ft. The cost given includes straightening pipe and placing all valves and fittings.

Small Pipe and Fittings.—The following costs relate to the small pipe and fittings which were installed in the heating, plumbing and vacuum cleaner systems. All valves and fittings, etc., were figured as straight pipe. The costs include all cutting, threading, transporting, etc. The cost of the necessary scaffolding is also included. All the work was done by hand, and some of it was very difficult.

Size of pipe, ins.	Amount placed, ft.	Aver. cost per ft., cts.
¼ to ⅜	127	9.2
½	1,147	6.7
¾	1,804	12.4
1	1,351	13.1
1¼	509	16.5
1½	1,657	24.4
2	1,251	25.7
2½	552	35.9
3	587	43.4
3½	209	37.7
4	422	50.4
4½	132	59.4
5	58	40.0
6	39	49.0

Soil Pipe.—The soil pipe was all placed by plumbers, working most of the time upon scaffolds. Everything connected with the installation of the soil pipe is included in the following costs: 122 ft. of 2-in. soil pipe were placed at an average unit cost of 16.9 cts. per ft.; 87 ft. of 3-in. pipe at 22.5 cts. per ft. and 307 ft. of 4-in. soil pipe at 53.0 cts. per ft.

Making Pipe Hangers.—A total of 532 pipe hangers were made at an average cost of 29 cts. each. These hangers were made of round iron, and the cost includes upsetting, threading, etc. The ¾ × 16-in. hangers were most expensive at 65 cts. each, and the ⅜ × 50-in. hangers cost for labor only 8 cts. each.

Setting Hangers.—445 hangers were set at an average cost of 44½ cts. each. This includes drilling, etc.

Transporting Castings, Machinery, etc.—52 tons of these materials were transported a distance ranging from 50 to 500 ft. at an average unit cost of $2.12 per ton. This includes all necessary loading and unloading.

Placing Miscellaneous Castings.—5,600 lbs. of miscellaneous castings were placed at an average cost of 1 ct. per pound. This includes necessary derricks, scaffolds, etc.

Painting.—42,176 sq. ft. of painting was done, figured as a single coat at 1.2 cts. per sq. ft.

Hand Rails.—360 lin. ft. of hand rails were placed at 29.1 cts. per ft. including all fittings.

Steel Ladders.—These ladders are about 6 ft. long and are of ⅜ × 3-in. iron and ¾-in. round rungs. Four of these were made at $3.71 each, and they were set at 44 cts. each.

Setting Laboratory Tables.—16 laboratory tables, each of oak 38 ins. high and 36 ins. wide; with tops 3 ins. thick, were set at an average cost of $3.65 each.

Excavation.—126 cu. yds. of red clay were excavated at an average cost of 53 cts. per cu. yd.

Calked Soil Pipe Joints.—Following are costs of calking joints in 2, 3 and 4-in. soil pipe, as made by plumbers:

Size, ins.	Av. cost per joint, cts.
2	42
3	48
4	48

Plumbing Fixtures.—A sum of $60 was spent for setting 23 plumbing fixtures, such as wash basins, urinals, showers, sinks, water closets and towel racks.

Setting Small Gates.—66 small gate valves, ranging in diameter from 3 ins. to 10 ins. were set at an average cost of 64 cts. per gate. This includes all gaskets, bolting up and fitting.

Making Bolts.—605 bolts were made at an average cost of 7 cts. each. These bolts were from ½ to 1½ ins. in diameter. The greatest length was 15 ins. The cost given includes cutting steel, welding on heads, threading of bolts and nuts, complete.

LABOR COST DATA ON COAGULATION BASIN IN 1911

Excavation.—605 cu. yds. of material were excavated in trench by pick and shovel at an average unit cost of 60.3 cts. per cu. yd.

Backfill.—350 cu. yds. were backfilled and hard tamped under 60-in. pipe at an average unit cost of 70 cts. per cu. yd.

375 cu. yds. were backfilled at 55 cts.

Setting Forms.—2,025 sq. ft. of forms were set at an average unit cost of 5.8 cts. per sq. ft. The area given is that exposed to concrete only. The cost given includes all bracing.

Setting Screeds.—7,433 lin. ft. of screeds were set at an average unit cost of 1.5 cts. per ft.

Making Forms.—610 sq. ft. of forms were made at an average unit cost of 5.8 cts. per sq. ft. The area given is that exposed to concrete only. All bracing is included. These forms were used about seven times.

Setting Steel.—38,333 lbs. of steel were set at an average unit cost of $4.25 per 1,000 lbs. This figure includes the hauling of the steel.

Placing Concrete.—1,087 cu. yds. of concrete were placed at an average unit cost of $1.16 per cu. yd. This includes the setting of expansion plates, and giving to the concrete a float finish.

Laying Cast Iron Pipe and Specials.—25.72 tons of cast iron pipe and specials were laid at an average cost of $9.65 per ton. Of this amount, 10.6 tons was 12-in. pipe and the balance 60-in. pipe. The cost of making one cut on 60-in. pipe is included.

Setting 60-in. Gate Valve.—A 60-in. gate valve weighing 6 tons was set at a lump sum of $188.50

Building Manholes.—2.6 M. of brick were placed in manholes at an average cost of $7.10 per M. The manholes were round, and the cost given includes the placing of 9 ladder rungs.

Driving Sheeting.—300 sq. ft. of sheeting were driven at an average unit cost of 2.7 cts. per sq. ft. This sheeting was 2 × 10-in. stuff.

LABOR COST DATA ON COAGULATION BASIN IN 1912

Excavation.—883½ cu. yds. of red clay were excavated by pick and shovel in trench at an average unit cost of 84 cts. per cu. yd.; this includes all necessary sheeting.

Fill.—14,580 cu. yds. of fill were made at an average unit cost of 48.8 cts. The fill was not rolled. A 24-in. puddle wall was hand-tamped in layers ranging in thickness from ½ to 2 ins., and the cost is averaged in the foregoing. The cost of puddling was 54 cts. per cu. yd.

Building Forms—Heavy Walls.—50,578 sq. ft. of forms were built at an average cost of 7.1 cts. per sq. ft. The area exposed to concrete only is figured on all form work. The cost includes all scaffolds, braces, supports, etc.

Thin Wall Forms.—28,566 sq. ft. of forms were built at an average cost of 12.8 cts. per sq. ft.

Floor Column and Beam Forms.—45,240 sq. ft. of beam forms were built at an average unit cost of 9.7 cts. per sq. ft.

Wrecking Forms.—121,702 sq. ft. of forms were wrecked at an average unit cost of 1½ cts. per sq. ft.

Transporting Lumber.—164,563 ft. B. M. of lumber was transported at an average unit cost of $3.52 per 1,000 ft. B. M. The average haul was 1,000 ft. A common dump wagon was used and was not well suited to the purpose.

Reinforcing Steel—Transporting.—192,029 lbs. of steel were transported an average distance of 1,500 ft. at an average unit cost of 80 cts. per 1,000 lbs.

Bending.—106,787 lbs. of steel were bent at an average unit cost of $1.15 per 1,000 lbs.

Setting.—234,295 lbs. of reinforcing steel were set at an average unit cost of $4.25 per 1,000 lbs. This includes wiring together of all steel at intersections with No. 16 gage wire.

Structural Steel—Transporting.—9.61 tons were transported an average distance of 1,500 ft. in common dump wagons at an average cost unit cost of 98 cts. per ton.

Setting.—9.61 tons were set at an average unit cost $12.13 per ton. This includes all hoisting, bolting up, riveting wall plates, etc.

Concreting—Heavy Walls.—1,198 cu. yds. of concrete were placed at an average unit cost of $1.11 per cu. yd. This does not include the necessary track trestle and runways.

Concrete Floors, Roof and Thin Walls.—1,413.5 cu. yds. of concrete were placed at an average unit cost of 97 cts. per cu. yd.

Track and Trestle.—1,711 lin. ft. of track and trestle were placed at an average unit cost of 7.6 cts. per ft. All this work was 24-in. gage in 16-ft. sections. The runways were 5 × 16 ft., of 7-in. material.

Finishing Roof and Floors.—5,818 sq. ft. of 1:2 cement finishing coat ranging in thickness from ½ to 1½ ins. were placed at an average cost of 6.1 cts. per sq. ft.

Transporting—Castings, etc.—141 tons of castings were transported a distance averaging 500 ft. at an average unit cost of $2.22 per ton. This includes loading and unloading by hand.

Setting Pipe and Specials.—103 tons of pipe and specials were set at an average cost of $3.54 per ton. This includes the erection of a derrick and all necessary scaffolds.

Setting Gate Stands.—21 gate stands were set at an average cost of $3.85 each. This includes bolting down on a bed of 1:2 cement mortar.

Setting Stems.—Stems for 48-in. gates were set at an average cost of $2.50 each.

Setting Sluice Gates.—25 sluice gates were set at an average cost of $6.80 each. These gates are from 42 × 42 ins. to 48 × 60 ins. The cost given includes cutting all necessary gaskets, bolting up, hoisting, derrick, scaffolds, etc.

Small Piping.—1,030 ft. of small piping ranging from ½ to 3 ins. in diameter were placed at an average cost of 7½ cts. per lin. ft. This includes all cutting, threading, fittings, valves, etc., complete.

2-in. Lead Pipe.—1,091 ft. of lead pipe were placed at an average cost of 18 cts. per ft. This includes straightening pipe, putting in fittings and valves, etc. The pipe weighs 7.5 lbs. per ft. 96 wiped joints were made at average cost of 60 cts. per joint.

Electric Wire.—900 ft. of No. 14 insulated electric wire were placed at an average cost of 0.9 ct. per ft.

Laying Brick.—84.5 M of brick were laid at an average cost of $17.90 per M. This includes the work done on electric conduit, window sills, all necessary scaffolds, etc. The brick was laid Flemish bond.

Setting Window Frames.—92 window frames were set at an average cost of $1.17 each.

Washing Walls.—5,030 sq. ft. of walls were washed at an average cost of 2. 6 cts. per sq. ft. A dilute solution of hydrochloric acid was used. The cost given includes all necessary scaffolding.

Painting.—22,925 sq. ft. was painted at an average cost of 1 ct. per sq. ft. The painting was figured as a single coat only, and the cost includes all necessary scaffolds.

Roofing.—85.5 squares of roofing were placed at an average cost of $3.30 per 100 sq. ft. The roofing consisted of asbestos shingles laid on 1:2:4 cinder concrete with a layer of tarred felt between the concrete and shingles. The cost includes all necessary staging.

Copper Work.—235 sq. ft. of copper work was placed at 10 cts. per sq. ft. 266 lin. ft. of copper was placed at 12 cts. per lin. ft.

Baffles.—19,852 ft. B. M. of baffles were placed at an average unit cost of $4.98 per 1,000 ft. The baffles were made of 1 × 6-in. D. & M. fencing.

Wooden Gates.—27 wooden gates were set at an average cost of $2.30 each. These gates were all of 1 × 6-in.M. & D. lumber. Each 24 × 36-in. with a 2 × 4-in. stem. The gates slide in guides. 53 wooden guides were made at an average unit cost of 0.33 cts. each.

Ladder Rungs—Making.—156 ladder rungs were made of ¾-in. round steel at an average unit cost of 11 cts. each.

Placing.—131 ladder rungs were placed at an average unit cost of 18.4 cts. each, which includes grouting in.

Placing Pipe Hangers.—124 pipe hangers were placed at an average unit cost of 27 cts. each. This includes grouting in when necessary.

220 pipe hangers of various sizes were made at an average cost of 23.5 cts.

Making Bolts.—1,173 bolts ranging in diameter from ½ in. to 1½ ins. and in length from 3½ ins. to 35 ins. were made at an average cost of 24 cts. each. This includes welding on heads, cutting steel and threading nuts and bolts. About one-third of the bolts were upset for 6 ins. of their length to 50 per cent excess diameter.

Drilling Concrete.—1,569 holes were drilled in 1:2:4 concrete from 30 to 90 days old at an average cost of 11 cts. per hole. These holes ranged in diameter from ⅜ ins. to 1 in. and in depth from 3 ins. to 8½ ins.

Wood Conduits.—840 lin. ft. of 6 × 6-in. wood conduit were placed at an average cost of 38 cts. per ft. This was . a conduit of 2-in. lumber around outside of 2-in. lead pipe, It was filled with sawdust.

LABOR COST DATA ON WASH WATER TANK IN 1912

Earth Work—Excavation.—694 cu. yds. of very hard clay were excavated with pick and shovel and wheeled in barrows at an average unit cost of 63.4 cts. per cu. yd.

Backfill.—187 cu. yds. of clay were backfilled at an average unit cost of 21.9 cts. per cu. yd. This clay was sprinkled and tamped by hand in 2-in. layers.

Fill.—6,399 cu. yds. of fill were made at an average cost of 44½ cts. per cu. yd. This includes a haul of 1,000 ft.

Puddle.—82 cu. yds. of puddle were placed at an average cost of $2.79 per cu. yd. This material was sprinkled and tamped by hand in layers ranging in thickness from 1½ to 2 ins.

Form Work—Transporting Lumber.—11,819 ft. B. M. was transported an average distance of 300 ft. at a cost of $3.54 per 1,000 ft. B. M.

Walls and Foundation.—14,271 sq. ft. of forms were placed at an average cost of 6.6 cts. per sq. ft. These forms were made of 2-in. lumber. The cost given includes all bracing. Only the area exposed to concrete is given.

Column, Beam and Floor Beams.—10,602 sq. ft. of these forms were built at an average cost of 9 cts. per sq. ft.; 2-in. lumber was used, and the cost includes braces and clamps.

Wrecking.—23,991 sq. ft. of forms were wrecked at an average cost of 1.7 cts. per sq. ft. This is for the area exposed to concrete, and includes the removal of all clamps, braces, etc.

Reinforcing Steel—Hauling.—57,093 lbs. were hauled an average distance of 500 ft. at an average cost of 85 cts. per 1,000 lbs.

Bending.—34,332 lbs. of reinforcing steel were bent at an average unit cost of $1.40 per 1,000 lbs.

Setting.—57,093 lbs of steel were set at an average cost of $4.55 per 1,000 lbs. This includes the wiring of all interesections of reinforcing rods with No. 16 gage wire.

Structural Steel—Hauling.—4.74 tons of structural steel were hauled a distance of 800 ft. at an average cost of 50 cts. per ton.

Setting.—4.74 tons of structural steel were set at an average cost of $9.32 per ton. This includes hoisting, riveting and bolting up.

Concreting.—636 cu. yds. of concrete were placed at an average unit cost of 95 cts. per cu. yd. This includes placing runways, hoisting, etc.

Finishing.—4,043 sq. ft. of 1:2 cement finish coat were placed at an average cost of 3½ cts. per sq. ft.

Brick.—71.2 M of brick were placed at an average cost of $19.40 per M. This includes the erection of scaffolds, hoisting, etc. Round tower bricks were used and were laid in Flemish bond.

Washing Walls.—21 sq. ft. of walls were washed at an average cost of 1.2 cts. per sq. ft. This includes the necessary scaffolding.

Roofing.—19 squares of roofing were placed at an average cost of $6.50 per square. This includes all scaffolding, Since this was a conical roof, the shingles at the last were very small. They were placed on a 1:2:4 cinder concrete.

Painting.—1,250 sq. ft. of painting figured as a single coat was done at an average cost of 1⅓ cts. per sq. ft.

Cast Iron Pipe and Specials—Cutting.—Cast iron pipe was cut with cold chisels, two men working on a cut. Three cuts were made of 12-in. pipe at 28 cts. each. Two cuts of 12-in. pipe were made under water at 93 cts. each. One 24-in. pipe was cut at 70 cts.

Calking.—15 joints in 12-in. pipe were calked at 57 cts. each. One 24-in. joint was calked at $1.90. These figures include yarning, pouring, heating lead, etc.

Laying.—8.81 tons of cast-iron pipe and specials were laid at an average cost of $2.92 per ton. This includes erection of necessary derricks and scaffolds, etc.

Ladder Rungs.—10 ladder rungs of ¾-in. round steel were made at 10 cts. each and set, including drilling holes, grouting, etc., at 26 cts. each.

Cutting Shingles.—3,140 shingles were cut to fit conical roof at $28.80 per 1,000.

COST DATA OF HAULING MISCELLANEOUS, ETC., IN 1914

Hauling—Cement.—24,590 barrels of cement were hauled a distance of 1½ miles at an average unit cost of 10¼ cts. per barrel. 70 bags to a load were hauled over roads which were very bad at times.

Sand.—7,538 cu. yds. of sand were hauled a distance ranging from 300 to 3,000 ft. at an average unit cost of 46½ cts. per cu. yd. 1¼ cu. yds. made a load. The cost given includes all snatch team work.

Steel.—438 tons of steel were hauled a distance of 1½ miles at an average unit cost of $1.35 per mile. This cost includes loading and handling by hand. Some of the steel was in very long sections, and all of it was badly mixed in the cars.

Cast Iron Pipe and Specials.—1,195 tons of cast iron pipe and specials were hauled a distance of 1½ miles at an average unit cost of $1.34 per ton. All pipe was unloaded by hand, no derrick being used.

Miscellaneous Castings and Machinery.—191 tons of miscellaneous castings and machinery were hauled a distance ranging from 1½ to 5 miles, the greater portion of it being 1½ miles, at an average unit cost of $1.67 per ton. All of this material was handled by hand.

Lumber for Forms.—239,500 ft. B. M. of lumber was hauled a distance ranging from 1,500 to 3,000 ft. at an average cost of $1.61 per 1,000 ft. B. M. This material was handled by hand and was hauled in wagons not well suited to the purpose.

Edgings and Waste Material.—93 loads of this class were hauled a distance ranging from 900 to 1,500 ft. at an average unit cost of 86½ cts. per load. All work was done by hand, and the material was all in small pieces.

Recovery of Lumber.—30,500 ft. B. M. of lumber was recovered at an average unit cost of $1 per 1,000 ft. B. M. This includes the pulling out of old nails.

LABOR COST OF HAULING AND MISCELLANEOUS WORK IN 1912

Hauling.—All hauling includes loading, unloading, handling, etc. Common dump board wagons were used in all cases.

Cement.—8,776 bbls. of cement were hauled a distance ranging from 1$\frac{1}{10}$ to 2½ miles at an average cost of 11.6 cts per barrel.

Sand.—3,137 cu. yds. of sand were hauled a distance of 1,200 ft. at an average unit cost of 31 cts. per cu. yd.; 49 cu. yds. of sand were hauled a distance of 20,000 ft. at an average unit cost of $2.15 per cu. yd. The latter sand was frozen to the ground and had to be picked loose.

Cast Iron Pipe and Specials.—552 tons of cast iron pipe and specials were hauled a distance of 3½ miles at an average cost of $1.16 per ton.

Miscellaneous Castings and Machinery.—142 tons of miscellaneous castings and machinery were hauled a distance ranging from 1½ to 4 miles at an average unit cost of $1.65 per ton.

Lumber.—82,000 ft. B. M. of lumber was hauled a distance ranging from 300 to 600 ft. at an average unit cost of 80 cts. per 1,000 ft. B. M.

Waste Material.—2,104 loads of waste material were hauled a distance of 1,200 ft. at an average cost of 60 cts. per load.

Recovery of Lumber.—158,900 ft. B. M. of lumber was recovered at an average unit cost of $3.73 per 1,000 ft. B. M. This included the pulling out of nails and the cleaning off of concrete.

Costs of Concrete Construction in the Water Filtration Plant at Niles, Ohio.—The following data are given by R. A. Boothe in an article published in Engineering and Contracting, Oct. 23, 1912.

Concrete Mixing.—The concrete plant consisted of a half-yard Ransome mixer with a batch hopper. The sand and gravel were shoveled off the cars onto stock piles at a cost of 8 cts. per ton and hauled from there to the mixer in barrows, the average haul being 50 ft. The cement was unloaded directly from the cars into the cement house at a cost of 2 cts. per bbl. and wheeled from there to the mixer.

The usual force employed on the mixer was 2 men wheeling sand, 4 wheeling gravel, 1 wheeling cement, 1 man on the mixer, and an engineer. The engineer and the man on the mixer received 25 cts. per hour and all others 20 cts. This made a total cost per hour of $1.20 and the usual capacity was 9 cu. yds. per hour, making a cost of 13½ cts. per cubic yard for mixing. The capacity has been as high as 12 cu. yds per hour, being controlled by the rate at which the concrete was taken away from the mixer, so the above costs cannot be taken as the capacity of the plant or the cheapest possible costs.

Concrete Floors.—All of the floors were in two layers, the bottom one being 8 ins. thick and the upper one 4 ins. thick, the upper one being laid after the walls were up.

The bottom floor was laid in alternate strips 8 ft. wide and 16 ft. and 30 ft. long, all joints being broken. The lower floor for the entire plant was laid before any of the walls were started, 2 × 6-in. keys being placed for all walls. This floor was made of a 1:2½:5 mix, using river sand and gravel. The pedestals for all of the columns were built with the floor.

For the floors the concrete was dropped from the mixer down a chute into barrows and wheeled into place.

Cost of labor on forms for screen boards and runs on lower layer of floor:

Item		Cost Per sq. yd.	Cost Per cu. yd.
3 carpenters, 67 hrs. at 25 cts.	$50.25	$0.038	$0.172
1 foreman, 53 hrs. at 50 cts	26.50	02	.09
Totals	$76.75	$0.058	$0.262

Cost of labor on concreting lower layer of floors:

Item	Cost	Per cu. yd.
14 men, 47 hrs. at 20 cts	$105.60	
4 men, 41 hrs. at 25 cts	41.00	$0.591
1 superintendent, 41 hrs. at 50 cts	20.50	.07
Water boy, 41 hrs. at 10 cts	4.10	.014
2 finishers, 50 hrs. at 20 cts	20.00	
1 finisher, 38 hrs. at 25 cts	9.50	.101
Totals	$226.70	$0.776

Or $0.173 per square yard.

Labor Cost of Forms, Placing Reinforcement and Concrete Coagulating Basins. —As soon as the floors were laid the walls of the basins were started. In building these one end and half of each side were built together, then the other end and the balance of the sides, and last the dividing wall and baffles. All were built in 5-ft. lifts. The outside walls are 16 ins. thick at the top and 20 ins. thick at the bottom, the latter being on the inside. On top they have an overhang of 26 ins., which with the wall gives a 42-in. walk, 6 ins. thick. The dividing wall is of the same construction while the baffles are 6 ins. thick with an 18-in. walk on top. The walls are all tied together by five 18 × 12-in. beams which extend across both basins.

For reinforcing, the outside walls have ⅞-in. rods 5 ins. on centers for outside verticals, and ½-in. rods 8 ins. on centers for the inside verticals, with ½-in. rods 9 ins. on centers for the horizontals on both sides. The dividing wall has ⅞-in. rods 5 ins. on centers for verticals on both sides and ½-in. rods 9 ins. on centers for the horizontals. The baffle walls are reinforced with expanded metal weighing 0.6 lb. per foot. The ⅞-in. rods in the walls are made long enough to be bent over to reinforce the walks. In addition the walks have three ⅞-in. rods along their edges. All rods are corrugated.

The average inside dimensions of each basin are 97 ft. × 34 ft. 8 ins. and 20 ft. 3 ins. deep with a high water mark 18 ins. below the top.

For the wall forms sheets 10 ft. wide and the full height of the wall were built of ⅞-in. tongue and grooved stuff on 2 × 6-in. studding spaced 18 ins. centers. These were used for the outside forms and were placed and braced in position, then the steel was placed. For this spikes were driven in the forms for every fifth vertical rod and the head allowed to extend out 2 ins. These rods were wired to the spikes, then a horizontal rod at the top and another at the bottom were wired to these, then the rest of the vertical rods were placed and wired to the horizontals, and then the rest of the horizontals were placed. For the inside reinforcing wooden spacers were used instead of spikes. These were fastened to the outside forms and were removed before the concrete was placed. On the inside the horizontal rods were carried up with each lift as they would have interfered with the dumping of the concrete if they had been placed any higher.

After the steel was placed the inside sheets were placed. These were 4 ft. high and 16 ft. long. Wooden spacers were used between the forms and two strings of 4 × 4-in. waling were placed on each side. No. 10 wire was carried through the forms around the waling and twisted on the inside. On top of the 4-ft. sheet a false sheet 1 ft. high was used. It was used so that the 4-ft. sheet could be removed and placed on top for the next lift, the wiring in the false sheet holding it solidly in place.

The runways were built with 4 × 4-in. uprights placed about 6 ft. from the forms. These were the full height of the wall and were X-braced together. Ledgers were spiked across from the forms to the uprights and the runway plank placed on these. These were raised for every new lift. The runway ran around the inside of the basins and back to the mixer; this gave a continuous circuit for the wheelers. The concrete was dropped from the mixer down a chute into the barrows until the height of the mixer was reached and then it was wheeled direct. In building the outside walls keyways and 2-ft. stubs of steel were placed for the dividing and baffle walls,. As each lift was built it was stepped back 2 ft. from the end of the preceding one so that there would not be a continuous vertical joint the height of the wall. When the concrete reached the height of the outlet box a section was left out and this was built with the boxes.

Cost of labor on forms for coagulating basins

Building sheets:

Item.	Cost
11 men, 6 hrs. at 20 cts	$13.20
5 men, 30 hrs. at 25 cts	37.50
2 men, 18 hrs. at 35 cts	12.60
Superintendent 27 hrs. at 50 cts	13.50
Water boy 20 hrs. at 10 cts	2.00
Total cost	$78.80

Or $0.014 per sq. ft. of form surface; or $0.195 per cu. yd. of concrete.

Cost of labor on erecting forms and runs and wrecking same:

Item.	Cost
5 men, 168 hrs. at 20 cts	$168.00
7 men, 190 hrs. at 25 cts	332.50
2 men, 190 hrs. at 35 cts	133.50
Foreman, 160 hrs. at 50 cts	80.00
Water boy, 100 hrs. at 10 cts	10.00
Total cost	$726.50

Cost, $1.802 per cu. yd.
Cost, $0.052 per sq. ft. of concrete surface.

Cost of placing 58,100 lbs. of steel for basins:

Item.	Cost
4 men, 54 hrs. at 20 cts	$ 43.20
7 men, 50 hrs. at 25 cts	87.50
2 men, 42 hrs. at 35 cts	28.40
Superintendent, 33 hrs. at 50 cts	16.50
Water boy, 33 hrs. at 10 cts	3.30
Total cost	$178.90

Cost, $0.0031 per lb., or $6.20 per ton.

Cost of labor on concreting walls of basins:

Item.	Cost	Cost per cu. yd.
19 men, 44 hrs. at 20 cts	$167.20	$0.490 (both rows)
4 men, 44 hrs. at 25 cts	44.00	
Superintendent, 44 hrs. at 50 cts	22.00	055
Water boy, 44 hrs. at 10 cts	4.40	.011
Totals	$237.60	$0.546

Cost of labor on forms for outlet boxes:

Item.	Cost
2 carpenters, 70 hrs. at 35 cts	$ 49.00
2 carpenters, 70 hrs. at 30 cts	42.00
4 carpenters, 70 hrs. at 25 cts	70.00
1 foreman, 70 hrs. at 50 cts	35.00
	$196.00
Less cost of walls included	34.00
Total	$162.00

Cost per cu. yd., $10.80.

Labor Cost of Forms and Concreting Clear Well.—The inside dimensions of the clear well are 26 ft. 4 ins. × 72 ft. 8 ins. and it is 11 ft. deep. The method of construction here was almost the same as that used on the basins except that the walls were built the full height instead of in 5-ft. lifts. For the forms the large sheets that had been used on the basins were cut down and used for both sides, all of the walls being poured at one operation.

Cost of labor on clear well forms:

Item.	Cost
3 men 22 hrs. at 20 cts	$13.20
8 men, 47 hrs. at 25 cts	94.00
2 men, 48 hrs. at 35 cts	33.60
Foreman, 46 hrs. at 50 cts	23.00
Water boy, 20 hrs. at 10 cts	2.00
Total	$165.80

Cost per cu. yd., $1.842.
Cost per sq. ft. of concrete surface, $0.05.

Cost of labor for concreting clear well:

Item.	Cost
20 men, 12 hrs. at 20 cts	$ 48.00
4 men, 12 hrs. at 25 cts	12.00
Superintendent, 12 hrs. at 50 cts	6.00
Water boy, 12 hrs. at 10 cts	1.20
Total	$ 67.20

Cost per cu. yd., $0.747.

Labor Cost of Column Forms.—Fourteen columns, 14 × 14-ins. and 11-ft. long support the roof of the clear well. The column side forms were built in one piece and were held together with 2 × 4-in. clamps and wedges.

Cost of labor on forms for 14 columns:

Item.	Cost
2 men, 22 hrs. at 25 cts	$11.00
2 men, 25 hrs. at 35 cts	17.50
Total	$28.50

Cost per column, $2.04.
Cost per cu. yd., $4.07.

Labor Cost of Forms and Concreting Filters.—Each filter was built complete including floors and walls and walks, and all poured at one pouring. The filter blocks and troughs were placed after the forms were removed. In building the forms all of the sides were built in sheets, the old sheets used on the pump room and clear well walls being used and cut down. The outside and sheets inside the channels were placed first. These rested on the concrete. Then the steel was placed and next the inside sheets were placed. The latter were set on 4-in. concrete blocks so as to form the floor. The walks were built on 2 × 4-in. brackets built out from the sheets and covered with ⅞-in. tongue and groove flooring. Rebate boxes were placed for the cross troughs. When the concrete was placed the floors were placed first with a mixture that was dry enough to tamp and show water on the surface. Then the walls were poured and as the inside forms were 4 ins. off of the bottom the concrete ran through and bonded with the floor. The walls were poured very wet and were well worked. It was found that in places the concrete would boil out under the inside forms but this was left until the next day and then chipped off before it was too hard; at this time the floors were also trimmed up to a level grade as they were always rough and uneven. The forms were braced across the filters and also had walings and wires in them.

Building 12 forms for filter blocks cost $42.50, or $3.54 each.

Labor cost of forms for four filters:

Item	Cost
Superintendent, 170 hrs. at 50 cts	$ 85.00
2 carpenters, 170 hrs. at 35 cts	119.00
3 carpenters, 170 hrs. at 30 cts	153.00
3 carpenters, 190 hrs. at 25 cts	143.50
2 men, 100 hrs. at 20 cts	40.00
Total	$540.50

Cost per filter, $135.12.
Cost per cu. yd., $5.00.

Cost of labor on concreting filters:

Item	Cost
Superintendent, 4½ hrs. at 50 cts	$ 2.25
3 men, 4½ hrs. at 25 cts	3.38
18 men, 4½ hrs. at 20 cts	16.20
Finisher, 5 hrs. at 30 cts	1.50
Water boy, 4½ hrs. at 10 cts	.45
Total cost	$ 23.78

Cost per cu. yd., $0.88.

The costs of forms given in this article include runways and wrecking. The work was done by contract started May 17, 1911 and the plant started operating Jan. 5, 1912.

Cost of Rebuilding Filter Beds at Cincinnati Filtration Plant.—The filter plant of the city of Cincinnati, O., as placed in operation in 1907, had a strainer system consisting of perforated plates covering concrete channels located at the bottom of trough-like depressions running lengthwise of the filter. The depressions were filled with gravel and to prevent its displacement during washing, wire cloth screens were bolted to the tops of the troughs. These retained the gravel effectively and prevented the passage of sand into the filters. It was found, however, that the screens corroded in the water at Cincinnati, and consequently they were removed, and the necessity for their use avoided by increasing the depth of gravel above the strainers to 14 in. The methods employed in reconstructing these filter beds are described by J. W. Ellms, Superintendent of Filtration, in the 1916 annual report of the Cincinnati Water Works Department, from which the matter following was abstracted by Engineering and Contracting in the issue of Oct. 10, 1917.

Following the experimental work that was undertaken to determine the best plan to pursue in rebuilding the beds after removing the brass wire cloth, one filter, No. 19, was rebuilt and put in service on Dec. 25, 1913. This filter was operated continuously in order to observe its action with the increased depth of the gravel bed (14 in.) that had been substituted for the 7½-in. gravel bed used with the wire cloth screen. The satisfactory results obtained with this filter after operating it for nearly a year, confirmed the conclusions derived from the experiments, and plans were made to rebuild the remaining beds of the plant.

As the handling of the sand by throwing it up to a platform made of plank laid over the top of an adjoining filter, had proven expensive, a centrifugal pump was installed in the middle gallery of the filter house on the motor gallery floor. The pump was capable of throwing 180 gal. of water a minute and would produce a pressure at the pump of 100 lb. per square inch. A sand ejector was purchased and was used to transfer the sand from one bed to another during the reconstruction work. This outfit proved satisfactory, and saved a great deal of the expense of manual labor that would have otherwise been necessary in handling the sand.

Late in the fall of 1914, Filter No. 2 was reconstructed before the sand handling apparatus was installed. The cost of rebuilding this filter, the same as in the case of Filter No. 19, which was rebuilt during the previous year, was much in excess of the cost of reconstructing the remaining 26 filters of the plant.

On Dec. 16, 1914, active work was commenced on the remaining 26 filters and they were completed on March 9, 1916. The laborers doing this work were the men from the reservoir force, and they carried on all the other work of the plant in conjunction with this work of rebuilding the filter beds. In consequence, they were not employed continuously on the reconstruction work, but gave it as much attention as they were able, in order to complete it as soon as possible.

Substantial screens were built to be used in grading the gravel. These screens were necessary, not only to separate the various sizes of new gravel needed for increasing the depth of the bed, but also to regrade the original gravel removed from the filter tanks. The grading and regrading of the gravel proved, if anything, more expensive than any other part of the work, since handling and rehandling the gravel was unavoidable.

The gravel layers placed in the bed were graded as follows:

Size of separation	Depth of layer, in.
Passed a 2-in. and retained on a 1-in. screen	2
Passed a 1-in. and retained on a ¾-in. screen	2
Passed a ¾-in. and retained on a ½-in. screen	3
Passed a ½-in. and retained on a ¼-in. screen	4
Passed a ¼-in. screen	3

Thirty inches of sand were placed directly on top of the finest gravel layer. No new sand was used, except about 6 or 7 cu. yd. in the last filter rebuilt. The sand now has an effective size of 0.38 m.m. and a uniformity coefficient of 1.35.

The sand received no cleaning other than what it may have obtained in being transferred from one bed to another. The handling of the sand was so arranged, that the removal of sand from one bed was the operation that transferred it to a reconstructed bed. Two handlings of the sand were thus avoided.

In order not to disturb the gravel, the sand shoveled into the ejector was discharged into a galvanized iron pocket swung between the wash troughs and above the newly laid gravel bed. The velocity of the escaping water was thus reduced, and no disturbance of the gravel resulted. A systematic method for cleaning the filtered water channels under the brass strainer plates was followed. Plates over the riser pipes were removed, and at the ends of the tank. Caps on the manifold headers under the filters were removed. Any sand that may have gotten down into the effluent piping was flushed back with the wash water out of the open ends of the manifolds. Hose streams were used to wash out the channels under the plates, and any sand in them was washed down the riser pipes and out of the ends of the headers.

Every hole in the strainer plates of each filter was opened up by pushing a sharp piece of steel into it. Any incrustation or lodged sand particles were thus removed. Many hook bolts were replaced that had been broken, either in the course of operation of the filter, or from having been originally strained too hard in placing them in the first place. Any plate that was improperly grouted was repaired, and the plates that had to be removed were carefully cemented back in place.

As the increased depth of the gravel has brought the sand surface nearer the edge of the wash troughs, the wash water valve has had to be reset, so as to give a velocity of wash water of less than 2 ft. per minute. The velocity of wash water is now about 18 in. per minute.

The estimated cost of reconstructing the filter beds was $8,500. Obviously there was not very much exact information on which to base an estimate. The handling of the gravel proved to be the most expensive part of the work. Gravel also cost an average of $1.62 per ton instead of the $1.39 per ton used in the estimate. The actual cost, as nearly as it is possible to get at it, appears to have been $9,502,76. This gives a total cost per filter of $339.38. which is equivalent to a cost of 24.2 ct. per square foot of filter area. There is a credit against the above cost for 150 tons of gravel left over and having a value of $1.62 per ton, or a total of $243. From the sale of old brass wire cloth, there was a saving of the scrap value of 38,125.5 lb., having an estimated value of $3,304.60. Adding these two items together makes a total credit of $3,547.60, which if deducted from $9,502.76, leaves a net cost to the city of $5,955.16 for this reconstruction work. This is equivalent to $205.54 per filter, or 15.2 ct. per square foot of filter area.

The cost of the various items was as follows:

Operation	Quantity	Hours	Costs
Removing old gravel		3,936	$ 996.75
Screening old gravel		3,890	985.25
Removing strainer plates over risers		645	163.12
Cleaning out holes in strainer plates		1,631	458.32
Flushing out filtered water channels		571	144.62
Replacing strainer plates		1,778	450.15
Replacing gravel		3,910	990.25
Transferring sand with ejector		1,218	308.22
Pump and sand ejector operated		304.3	48.77
Screening new gravel		2,885	724.85
Unloading new gravel from cars		192	48.77
Loading and unloading gravel from team		1,416	355.80
Hauling with team		307	153.50
Labor of machinst on header caps		69	34.50
Labor of machinst's helper		82	21.57
Common labor on header caps		665	169.30
Foreman's time (65 per cent)			650.00
Bags used up in hauling gravel	2,000		100.08
Reconstruction of Filters Nos. 2 and 19			819.37
Gravel purchased (tons)	1,159		1,879.57
Total cost of reconstructing 28 filters			$9,502.76

Common labor cost $2 per 8-hour day until Feb. 1, 1916, after which it was $2.25 per day. The machinist was paid 50 ct. per hour and the machinist's helper $2.25 per day. The team cost 50 ct. per hour. The water used was valued at $7 per 1,000,000 gal. The cost of power was placed at $0.086 per hour; or using 180 gal. per minute for sand ejecting, the cost for power and water was 16c per hour.

Cost of Treating Filter Water With Copper Sulphate.—The following matter is taken from an abstract, published in Engineering Record, July 26, 1913, of a paper presented before the American Waterworks Association at

Minneapolis by Frederick H. Stover, Bacteriologist and Chemist, Lousville Water Company.

The chief functions of water filters being the removal of bacteria and suspended matter the natural inference would be that the operation of the plant would be easiest at the times when these substances are present in least amount. Many filter superintendents, however, find that such is not always the case and that warm weather and clear water bring troubles peculiarly their own. The usual symptoms of these troubles are marked shortening in the length of the filter runs and the prevalence about the filter beds of a pronounced odor, varying from "grassy" to "fishy" in nature. Microscopical examination of the water at such times usually reveals the presence of numerous minute forms of the type generally classified by waterworks men as "micro-organisms," which, in the waters of the Ohio River, are principally diatoms, with a few algae and miscellaneous forms present.

The water of the Ohio River, when of a turbidity below 30 parts per million, almost invariably causes decreases in the length of the filter runs. If such turbidities are accompanied by micro-organism and much amorphous matter, still greater decreases follow. Filter runs may be greatly increased by the judicious use of copper sulphate, although after-growths of bacteria sometimes follow its application and must be guarded against.

With the copper sulphate ($CuSO_4$) applications markedly favorable results have been secured in all but one instance, and even in this case the results cannot be said to have been negative, as the runs were kept at 6 hours and above under conditions when much lower ones might have been expected, and probably would have occurred had not the copper been used. The minimum length of runs reached at this time was 5 hours, which occurred 9 days after this dosing.

Within 24 hours after the application of the copper there was in each instance a noticeable increase in the length of the filter runs and that these lengthened runs continued for periods varying from 8 to 19 days in length.

The copper was applied in the second sedimentation basin and in the coagulant basin by dragging bags of it from a boat.

The decreases in the length of the filter runs of course cause correspondingly large increases in the amounts of wash water used. During the year 1912 the average amount of wash water used at Louisville was 2.05 per cent—the lowest average for any one month being 1.44 per cent. During the periods of shortened filter runs, however, the amounts will vary from 6 to 10.7 per cent.

Small doses of hypochlorite of lime do not affect these micro-organisms in such a way as to increase the length of the filter runs. The determination of the time of filtration of samples of water through small laboratory filters will in some instances enable the operator to select the water from that point of his system which will give the longest filter runs.

AMOUNT AND COST OF COPPER SULPHATE TREATMENT

Date	—$CuSO_4$ Pounds	used— P.p.m.	Effects lasted (days)	Total cost	Cost per mil. gal. Dosed	Cost per mil. gal. Treated	*Value wash water saved
Aug. 20, 1910..	650	1.3	19	$31.20	$0.50	$0.065	......
May 27, 1911..	735	1.3	10	36.00	0.52	0.104	$149.76
June 15, 1911..	1000	1.7	9	49.00	0.70	0.217	228.50
June 10, 1912..	625	1.2	9	30.60	0.49	0.132	......

*At $30 per million gallons.

Operating Costs of Filtration Plants.—The following data are taken from Stein's "Water Purification Plants" (1915).

Perhaps the largest single factor affecting the cost of operation of filtration plants is the amount of coagulant used. This varies with the quality of the raw water, and increases greatly when the water is softened. The labor cost increases with the size of plant from the smallest to plants of perhaps 10,000,000 gallons capacity, after which the cost per million gallons decreases. Against the cost of filtering should be charged the cost of pumping the water against the head lost in filtration, which is generally from 10 to 15 feet. The following are typical examples of the cost of filtration in plants of various sizes:

Example No. 1. *Cost of Coagulation and Sedimentation at St. Louis, Mo.*—The treatment consists of coagulation with lime and iron sulphate, followed by sedimentation in large basins. The source of supply is the Mississippi River below the mouth of the Missouri, consequently a very high turbidity prevails much of the time. The average amounts of chemicals used in 1911 were 5.77 grains per gallon of lime and 2.70 grains per gallon of iron sulphate.

Cost of Purification per Million Gallons (1910–1911)

Lime	$1.967
Sulphate of iron	1.969
Unloading	0.094
Operating and maintenance (labor)	0.378
Repairs	0.030
Water, coal, oil, etc	0.047
Light and power	0.098
Water analyses (chemist's)	0.172
Total	$4.755

The average daily pumpage was about 86,000,000 gallons.

Example No. 2. *Cost of Filtration at Harrisburg, Penna.*—This is a standard type mechanical filtration plant. The pumpage for 1911 averaged 8,205,684 gallons per day. The average amount of coagulant used was 0.7 grain per gallon.

Cost of Purification per Million Gallons (1910–1911)

Coagulant	$1.22
Fuel (low service)	0.86
Supplies	0.28
Materials and repairs	0.36
Oil and waste	0.07
Laboratory	0.43
Labor	2.77
Total	$5.99

Example No. 3. *Cost of Filtration at a Typical Small Plant.*—Daily pumpage, 2,000,000 gallons. Water slightly acid at times, requiring the use of soda ash. Average amounts of coagulant used 0.7 grain per gallon of alum, 0.5 grain per gallon of soda ash.

Cost of Purification per Million Gallons

Alum	$1.25
Soda ash	.86
Fuel (low service)*	.73
Supplies, oil, and waste	.42
Repairs	.07
Labor	2.00
Total	$5.33

* Cost of pumping the additional head lost in the filtration plant.

Example No. 4. Cost of Purification in a Large Softening Plant.—Daily pumpage, 50,000,000 gallons; lime used, 8 grains per gallon; iron sulphate, 1 grain per gallon. Plant is equipped with conveyors, automatic scales, and other labor-saving devices.

Cost of Purification per Million Gallons

Lime	$2.71
Iron sulphate	0.72
Labor	0.69
Material, supplies, and repairs	0.56
Laboratory	0.12
Low-service pumpage*	0.40
	$5.20

*Cost of pumping the additional head lost in the filtration plant.

Cost of Water Purification at Cincinnati, O.—(Engineering and Contracting Jan. 14, 1920). The average cost of operating and maintaining the filter plant of Cincinnati, O., for the 10-year period 1908–17 has been $3.96 per 1,000,000 gal. of filtered water delivered for consumption. This total consists of $1.66 for coagulating chemicals, 36 ct. for maintenance and $1.94 for other operating costs, principally labor charges. The following table, from the 1917–18 report of the Water Department summarizes the cost since the plant was started:

Operating Costs per Million Gallons

Year	Operation: Coagulating chemicals	Operation: All other operating costs	Maintenance	Total
1908	$1.72	$2.47	$0.05	$4.24
1909	1.89	2.28	.09	4.26
1910	1.93	1.98	.28	4.19
1911	1.86	1.91	.35	4.12
1912	1.78	1.68	.38	3.84
1913	1.67	1.77	.48	3.92
1914	1.21	1.78	.39	3.38
1915	1.43	1.86	.76	4.05
1916	1.27	1.80	.38	3.45
1917	1.86	1.85	.40	4.11
1918	2.12	2.37	.67	5.16

The increase in maintenance in 1915 was largely due to cost of reconstructing the filter beds which item amounted to $0.34 per 1,000,000 gals. Another unusual item in that year was the cost of repairing roofs which amounted to $0.07 per 1,000,000 gals.

The average period of service has been between 22 to 23 hours. The time required for washing a filter has been from 3.75 to 4.50 minutes. The amount of wash water amounts to from 1 to 2.75 per cent and averages about 1.75 per cent of the total water filtered.

Cost of Operation and Comparative Cost of Chemicals for Columbus, O., Purification Works.—The total expense for operating and maintenance of the water softening and purification works of the city of Columbus, O., for 1916 was $199,299, of which $24,902 was for labor and supervision, $168,346 for chemicals and $6,051 for general supplies. The cost of purification per 1,000,000 gal. delivered to consumers was $27.75. The quantities and costs of chemicals used at the works during the 9 years, 1909 to 1917, inclusive, as given in Engineering and Contracting, June 12, 1918, have been as follows:

	Lime		Soda ash		Alum		Bleach	
Year	Tons	Cost per ton	Tons	Cost per ton	Tons	Cost per ton	Tons	Cost per ton
1909..........	2,467	$5.75	1,402	$17.50	624	$19.00	..	......
1910..........	3,081	5.80	2,164	17.50	423	18.00	..	......
1911..........	3,860	5.42	1,776	17.50	590	17.50	..	......
1912..........	3,296	5.27	1,583	15.20	895	17.15	22	$27.80
1913..........	3,629	5.17	2,895	12.88	711	17.10	17	27.80
1914..........	4,650	5.27	3,540	13.30	880	16.75	14	29.20
1915..........	3,970	5.17	2,383	15.14	69	*16.60	22	34.80
					805	†7.27		
1916..........	4,550	5.17	1,975	62.00	823	†20.18	19	85.00
1917..........	4,206	7.03	1,833	60.00	943	†10.69	24	70.00

* Crystal alum purchased in open market. † Cost of materials.

Cost of Operation of Filter Plant of Erie, Pa.—The following data are taken from Engineering and Contracting, July 11, 1917. The rapid sand filtration plant of Erie, Pa., filtered 6,881,170,000 gal. of water in 1916. Compared with 1915 this is an increase of 1,066,600,000 gal. or 18.34 per cent. At times, especially during the months of July and August, the plant was operated as high as 35 per cent above its normal capacity. While operating above normal capacity no decrease was noted in the high efficiency obtained while operating at normal rates. It required 304, 631 lb. of aluminum sulphate to treat all the water filtered; expressed in grains per gallon is equal to .31. This is an increase of 50 per cent over the amount required per gallon in 1915. The increased turbidity of the water treated made the increase in coagulant necessary. Total hypochlorite of calcium used 27,138 lb. or 3.9 lb. per 1,000,000 gal. treated. In washing the filters, 129,100,000 gal. of filtered water were used. This is 1.88 per centof the total filtered. The cost of operation and maintenance for 1916 was $13,868; cost per 1,000,000 gal. filtered $2.02. Cost of operation and maintenance is divided as follows:

		Per cent
Labor and supervision..............................	$ 6,539.20	47.1
Alum..	4,658.89	33.6
Hypo..	1,045.71	7.6
Wash water..	1,050.40	7.6
Maintenance of plant and laboratories..............	573.77	4.1
	$13,867.97*	100.0

* Does not include low duty pumping, light, heat or pressure water.

Cost of Filtering Water at Grand Rapids.—(Engineering and Contracting, Aug. 14, 1918).

The cost of filtering water at Grand Rapids, Mich., increased from $14.87 per 1,000,000 gal. for the year 1916–17 to $18.84 in 1917-18, according to the annual report of Walter A. Sperry, chief chemist of the filter plant. Comparative figures on the operating costs for the last four years are given in the report, as follows:

	1917–18	1916–17	1915–16	1914–15
Wages............................	$ 4.86	$ 4.26	$ 4.48	$ 3.57
Chemicals........................	10.06	7.37	5.10	4.76
Power............................	2.23	2.26	2.17	2.14
House water......................	.20	......	......	......
Supplies and repairs.............	1.49	.98	1.11	.86
Total............................	$18.84	$14.87	$12.86	$11.33

The Grand Rapids plant was put in operation November, 1912. The method of treatment is lime softening followed by mechanical filtration.

According to Engineering News-Record, Aug. 30, 1917, the amount of wash water for this plant has averaged about 2% of the total amount of water treated.

Eleven Years' Operating Results of Filter Plant.—The filtration plant of Harrisburg, Pa., has been in continuous operation since its completion in October, 1905. The following table, published in Engineering and Contracting, Sept. 12, 1917, shows the average turbidity, coagulants, length of runs and percentage of wash water during this period:

Year	Turbidity parts per million	Sulphate of alumina grs. per gal.	Calcium hypo-chlorite grs. per gal.	Length of runs hrs. min.	Wash water pct.
1906	101	.95	....	18–20	2.0
1907	76	1.05	....	12–20	2.6
1908	52	1.09	....	13–29	2.6
1909	42	.84	.025	14–22	2.4
1910	19	.61	.063	18–40	2.2
1911	32	.95	.070	23–07	2.3
1912	59	.77	.067	21–54	2.3
1913	56	.79	.069	17–26	2.9
1914	33	.53	.056	20–17	2.9
1915	85	.69	.064	17–41	3.2
1916	60	.66	.045	16–39	3.6
Average	56	.81	.057	16–11	2.6

The method of operating was as follows: The water is pumped to the settling basin, capacity 4,000,000 gal., flows by gravity to the secondary or coagulation basins, capacity 334,000 gal. and then flows by gravity to the 12 filters which are of the American gravity type. The filtered water is pumped to the storage reservoir, which has a capacity of 26,000,000 gal.

Cost of Water Purification at St. Louis, Mo.—(Engineering and Contracting, Sept. 8, 1920).

During the fiscal year ending April 1, 1920, 39,642 million gallons of water were pumped into the basins. To this amount of water were added 1,387 tons of sulphate of iron and 14,753 tons of lime, or an average of 0.49 grains per gallon of the former chemical and 5 21 grains per gallon of the latter. To the 39,092 millions of gallons filtered were added 2,388 tons of sulphate of alumina and 120,187 lb. of chlorine, or an average of 0.86 grains per gallon of the sulphate and 3.07 lb. per million gallons of the chlorine. The sulphate of alumina was added before, and the chlorine after, filtration. The average cost per million for lime was $3.89; for sulphate of iron, $0.67; for sulphate of alumina, $1.92 and for chlorine, $0.29. These costs are for chemicals alone and do not include the cost of handling or application. A comparison of the costs of the various parts of the purification work done during the past five years, based on the quantity of water delivered to consumers, is shown in the following table:

Table VIII.—Cost per Million Gallons, Based on Consumption

Old Plant	1915–1916	Nov., 1915 to April, 1916	1916–1917	1917–1918	1918–1919	1919–1920
Lime	$ 1.70	$1.61	$ 1.89	$ 2.94	$ 3.72	$ 3.89
Iron	1.42	.64	.61	.57	.82	.67
Unloading	.08	.07	.08	.09	.12	.12
Operating, maintenance and repairs	.47	.51	.38	.41	.60	.59
Water, coal, oil, etc	.03	.04	.03	.05	.08	.05
Light and power	.07	.07	.04	.10	.12	.11
Chemical work	.43	.49	.38	.34	.30	.31

[3] Switching and demurrage	......	....	....	....	......	.02
Total	$ 6.42	$6.08	$ 5.58	$ 7.43	$ 9.10	$10.11
Total consumption for year in million gals	32,583	13,138	35,633	38,090	36,840	38,004
Cost of Chemicals						
Lime, per ton, average 2 contracts	$ 3.65	.....	$ 4.49	$ 6.86	$ 8.75	$10.03
Sulphate of iron, per ton, average	10.00	.....	12.50	12.84	16.84	18.48
Sulphate of alumina, per ton, average	......	.....	21.00	22.25	27.60	30.49
Chlorine, per pound	.08	.....	.13⅜	.13⅜	.12⅝	.09¼

[1] Water used in basin cleaning—Omitted prior to 1916.
[2] Water used in filter plant operation—Omitted prior to 1916.
[3] Switching and demurrage in years 1915 to 1918, inclusive, are included in operating, maintenance, repairs, etc.

The complete purification system was not in use until October, 1915. The heading, November, 1915-April, 1916, is included to show the costs of purification after the system was completed. The figures are included for the year of 1915–1916. Under the head of lime, iron, sulphate of alumina and chlorine are included all charges connected with the switching of these materials from the interchange tracks at Bissell's Point and Humboldt avenue to the Chain of Rocks. The sulphate of iron, in the form of sugar sulphate, was furnished at $14.16 per ton after Aug. 1, 1919. The price of $23.50 was in effect prior to that date, but none was brought under that contract after April 1, 1919. Liquid chlorine cost 10.75 ct. per pound until Aug. 1 and at 5 ct. per pound after that date. The prices given are f. o. b. Niagara Falls, the prices delivered being 11.78 ct. and 6.40 ct. per pound. Sulphate of alumina was purchased under the same specifications as last year. Basic sulphate of alumina containing not less than 17 per cent of available water soluble alumina, Al_2O_3, was required. The sulphate was supplied from April 1st to Sept. 15th at a price of $34.50 per ton, from Dec. 15th to Jan. 1st at $30 per ton and after that date at $28.50 per ton. A few cars furnished during September cost $23 per ton. From Oct. 1st to Dec. 15th the sulphate of alumina was supplied at $30.90 a ton. Lime was purchased under a specification requiring a lime containing 85 per cent CaO with a bonus or penalty of 1½ per cent of the contract price for each per cent of CaO above or below the required 85 per cent. All lime was sampled as it came from the crusher after unloading and these samples, together with the samples obtained from the daily supply hopper, were analyzed in the laboratory. Lime was supplied at a price of $9.30 a ton from April 1st to Sept. 1st at $10.30 a ton, from Sept. 1st to Feb. 1st and at $11.30 a ton after that date. The above notes are taken from the report of August V. Graf, Chief Chemist, Filter Plant, as embodied in the 1920 annual report of Edward E. Wall, Water Commissioner, St. Louis.

Cost of Filtering Water at Providence, R. I.—The unit costs of filtering and pumping water at the Pettaconsett slow sand filters of Providence, R. I., are given by Engineering and Contracting, Oct. 10, 1917, as follows:

Year	Pumping on to filter beds	For cleaning beds	Total cost per mil. gals. to filter water	Pumping water to Sockanosset reservoir
1907	$3.28	$4.20	$7.48	$5.63
1908	3.48	2.03	5.51	5.03
1909	3.23	2.05	5.28	5.14
1910	3.20	1.78	4.98	4.74
1911	2.98	1.59	4.57	4.95
1912	2.72	1.56	4.28	5.05
1913	3.00	1.59	4.59	4.98
1914	3.15	1.71	4.86	4.78
1915	3.07	1.66	4.73	5.67
1916	2.79	2.13	4.92	5.40

With the exception of 1907, when open filter beds were used, the figures are for operating covered beds. In 1916 the plant consisted of 10 filters each of which was in service for from 7,969.5 to 8,216.0 hours; 8,101.9 being the average number of hours in service.

The beds required from 15 to 19 scrapings during year, the average being 17.3. The lengths of run in days varied from 2.3 minimum to 59.3 maximum, the average being 19.5. The average quantity of water filtered between scrapings varied from 35,890,000 to 47,080,000 gals., the average being 40,020,000 gals. The average quantity of water filtered per day varied from 2,010,000 to 2,070,000 gals., the average being 2,045,000.

Cost of Operating the Purification Plant of Wilmington, Del.—Engineering and Contracting, Oct. 11, 1916, gives the following:

The purification plant of Wilmington, Del., consists of preliminary filters, sedimentation basins and final filter. The water flows by gravity to the preliminary filters, of which there are 10, each 14½ × 100 ft., the medium being gravel, coke and sponge, through which the water passes upward. After the water has passed these filters, it is possible to treat it with liquid chlorine. The water then flows by gravity to the pumps, from whence it is delivered to the settling reservoir. The settling reservoir has a capacity of 35,000,000 gal., 91½ per cent of which is available. From the settling reservoir the water flows by gravity to the final filters. The final filters are regular English slow sand units. There are six of these units, each 364 × 40 ft. The water after passing these filters is treated with liquid chlorine before entering the mains. The water flows by gravity to the consumers.

The following figures on the operation of the plant are taken from the annual report of Edgar M. Hoopes, Jr., Chief Engineer of the Water Department, for the fiscal year ending June 30, 1915.

The total quantity of water delivered to the slow sand filters was 3,518,990,000 gal. (36-in. Venturi meter registration) of which 8,400,000 gal. or 0.24 per cent was consumed in washing the sand beds. The remainder of 3,510,590,000 gal. is the net amount delivered to consumers. The total quantity of water delivered from the preliminary filters was 3,551,373,390 gal., or about 40,000,000 gal. more than was actually distributed. This amount represents the difference in water stored at Porter Reservoir at the beginning and end of the year as well as leakage in the forcing main between the pumping station and reservoir.

At the slow sand, or final filters, the average rate of filtration was 4,900,000 gal. per acre per day, and the time of beds out of service for washing or raking 13.78 per cent. The average time out of service for each bed was 2.3 per cent.

The total number of gallons of water treated with liquid chlorine was 2,859,410,000 or about 84.2 per cent of the amount actually distributed to consumers. The actual time during which this treatment was applied was 308 days or 84.2 per cent of the year. For this purpose 3,842.5 lb. of chlorine were consumed—equivalent to 1.343 lb. of gas per million gallons of water treated. The total quantity of water used for absorbing this gas prior to treatment was 347,089 gal., or 1 lb. of chlorine to 750 lb. of water. A subdivision of operating expenses is given in the following table—interest on plant investment or depreciation not being included.

	Total	Per 1,000,000 gal.
Slow Sand Filtration (3,510,590,000 Gal.)		
Salaries	$1,578	$0.449
Labor	349	.099
Supplies	582	.163
Light and power	620	.176
Repairs and renewals to equipment	297	.084
Miscellaneous	535	.152
Total	$3,961	$1.123
Preliminary Filtration (3,551,373,390 gal.)		
Salaries	$1,293	$0.364
Labor	11	.003
Supplies	101	.028
Repairs and renewals to equipment	31	.008
Light and power	166	.046
Miscellaneous	60	.016
Total	$1,661	$0.465
Laboratory (3,551,373,390 gal.)		
Salaries	$1,516	$0.426
Labor	299	.084
Supplies	143	.040
Repairs and renewals to equipment	6	.002
Miscellaneous	313	.088
Total	$2,277	$0.640

Cost of Philadelphia Water-Filter Operations.—The following data are taken from Engineering News, March 25, 1915.

TABLE IX.—OPERATING DATA OF SLOW SAND FILTERS AT PHILADELPHIA, 1914

Item	Name of plant: Torresdale	Queen Lane	Belmont	Upper Roxborough	Lower Roxborough
Cost per mil. gals	$ 2.23	$ 2.65	$ 3.62	$ 3.02	$ 5.10
Rate per acre per day:					
Av. entire area	3.668	3.054	2.977	2.287	3.478
Max. area in service	4.761	4.224	4.159	3.615	5.531
Av. no. of cleanings per filter	4.60	1.86	7.12	6.00	10.6
Av. days in service between cleanings	73.04	201.33	48.43	58.36	33.44
Av. no. rakings between cleanings	2.00	1.68	0.37	0.19	0.09

Operating Costs of Water Softening and Purification Plant at McKeesport, Pa.—The following data are taken from an abstract published in Engineering and Contracting, May 11, 1910, of a paper by Alexander Potter read at the annual convention of the American Water Works Association, April, 1910.

The water treated is of a variable character which condition requires the greatest care and watchfulness on the part of the employees of the plant.

The variable character of the water is indicated by the fact that the water has jumped from a hardness of 110 at 4 o'clock in the morning to a hardness of 510 four or five hours later, and from an acidity of 30 up to an acidity of 210 during the same period.

The McKeesport plant was fully described by the author in a paper read before the Engineer's Society of Pennsylvania, and appears fully illustrated in their Journal for April, 1909. Novel features of the plant which might be mentioned, and which a year and a half of operation have given a sufficient test, are as follows:

The method of cleaning the settling tanks without emptying them or interfering in any way with the continuous operation of the plant. Carriers are built under the floor of the settling tanks. The carriers in each of the four tanks are divided into four zones. Small circular holes ⅞-in. in diameter, spaced 4 ft. apart, connect the bottom of the tanks with the carriers. The outlet end of each set of carriers is controlled by a valve. In cleaning the basins, the valve controlling each zone is kept open until the precipitated solids are removed, and the water runs free from sludge. The amount of water used in cleaning the settling tanks and baffling tank is approximately 1,700 gals. per day for each degree of hardness in the water.

Another novel feature in the plant is the economic use of wash water. The entire machinery is operated by a water motor on the top floor of the softening building. The waste water from the motor enters the wash water basin for the filters. This water, charged against the plant as power, should not be charged as wash water, thus effecting a substantial saving. The amount of wash water shown in the annexed table is, however, the actual amount of water used in washing the filters, and amounts to 0.72 per cent of the total amount pumped.

The character of the McKeesport water is so unusual that tables of cost of operation are apt to be misleading to other municipalities, because the persons seeking data of cost and practicability of water softening are apt to be swayed adversely in their opinions by applying to their own cases the costs of producing a softened water at other places, as for instance at McKeesport, without taking into consideration the possible differences in conditions between the water to be dealt with at different places.

The only fair way to analyze the cost of any particular plant is to weight cost thereof against the benefits to be derived therefrom. Bearing this in mind, we have on the one hand to consider, (*a*) first cost of plant; (*b*) cost of operation. As against this we must also consider, (*c*) the improvement in the water; (*d*) the decrease in operating expenses of the plant; (*e*) decrease in wear and tear upon the plant; (*f*) decrease in plumbing bills paid directly by private citizens; (*g*) the decrease in the cost of soap; (*h*) lengthening the wear of linens, flannels, and other fabrics; and (*i*) increase in the length of life or boilers.

Taking the case of McKeesport, the annual interest on the cost of construction is approximately $10,000.

The cost of operation for one year is $30,700.

The total cost of producing 4,000,000 gallons of softened filtered water a day is $40,700 per annum.

Against this we have the following saving.

Since the softening plant has been installed, the Water Department has dispensed with a number of its employes engaged on repaving curb connections whose wages, according to the president of the board of water commissioners, amounted to $15,000.

The private consumers expended annually in maintaining their plumbing fixtures over $35,000.

Since the softening plant has been installed, only 72 per cent of the water previously required is now pumped, thus making a reduction in the coal consumption of $6,090 per annum.

The reduction in repairs of plant amounts to $3,000 a year.

From the best evidence obtainable, the saving in soap and soap compounds alone amounts to over $10,000 a year, and the saving in the wear and tear in washing of fabrics of all kinds can be set down at $20,000 a year.

Summarizing these, we have, on the one hand, an added cost of treating the water of $40,700; and, on the other a saving, as enumerated above, of $89,090.

This balance sheet shows that the introduction of the water softening plant for the city of McKeesport, instead of being an added burden to the people, has proved to be a saving of $48,390 per annum.

As a side light upon the saving effected in the McKeesport plant, it may be stated that, before the water softening plant was put into commission, about 156 plumbers were at work in the city. Out of this number, only 46 were left, four months after the plant was put in operation.

The average amount of chemicals used and cost of treating the water from Feb., 1909 to March, 1910 was as follows:

Average time between washings of filters	152 hours
Per cent of total amount of water pumped, used as wash water.	0.72
Amount of chemicals per million gals.*	
Lime	750 lbs.
Soda ash	1,046 lbs.
Coagulant	76 lbs.†
Hypochlorite of lime	4 lbs.
Cost of treatment per million gals.	
Chemicals	$13.36
Labor	8.05
Average amount of filtered water pumped per day	3,928,000 gals.

*The average cost of chemicals (during the period) at the McKeesport plant was:

	Per ton of 2,000 lbs.
Lime	$ 8.30
Soda ash	18.00
Sulphate of iron	11.00
Alum	12.50
Hypochlorite of lime	42.00

†No coagulant has been used since the application of the hypochlorite of lime. A remarkable condition exists with the water at McKeesport, where with 450,000 bacteria and 1,500 turbidity in the raw water, no coagulant was used, and yet a clear water was secured from the filters.

Cleaning Sand in Filters of Wilmington, Delaware.—The cleanings required by the filters at Wilmington Delaware, are accomplished by a Blaisdell Washing Machine. A description of the machine and method of operation was given by Edgar M. Hoopes, Jr. and James M. Ciard in a paper before the 1914 annual meeting of the American Water Works Association.

The machine is operated by electric motors and covers a strip 20 ft. wide. It is mounted on a traveling crane which runs the length of the beds on rails supported on the party walls between the beds. The beds, being but 40 ft. wide, are cleaned in two runs.

It has been found that the time lost by beds being out of service on account of cleanings ranges from 7.5 to 10 per cent, while with the old method of hand scraping, ejecting and restoring from 15 to 25 per cent of time is lost.

Costs of Washing Filter Sand, Using a Nichols Separator.—The following costs, of washing all the sand in four of the slow sand filter beds of the Albany, N. Y., water purification plant, are published in Engineering and Contracting, Oct. 12, 1910, as given in the report for 1909 of H. J. Deutschbein, Supt. Bureau of Water. The beds had been in operation continuously for ten years, and the sand had become more or less segregated and had secured a gradual accumulation of pure clay and other particles which were not retained on the surface. More or less compacting of the sand had also occurred. The work of washing was begun with a box washer, but this, for various reasons, proved so slow and expensive that two Nichols separators were purchased for $1,550 and substituted for the earlier method. The filters cleaned were Nos. 1, 3, 6 and 7, and the Nichols washers were used for all but a portion of the washing on No. 7.

Filter No. 7.—Commenced cleaning June 1, 1909. Finished cleaning July 31, 1909. Cleaned and replaced by box sand washer, 2,808 cu. yds. Cost of labor, $1,147.28. Cost per cubic yard, 40.9 cts.

Cleaned and replaced by Nichols sand separators, 1,558 cubic yds. Cost of labor, $352.30. Cost per cubic yard, 22.6 cts.

Filter No. 3.—Commenced cleaning Aug. 5, 1909. Finished cleaning Aug. 19, 1909. Cleaned entirely by Nichols separators.

Worked 24 hours a day in three 8-hour shifts. Cleaned and replaced 3,213 cu. yds. Labor cost, $723.10. Cost per cubic yard, 22.5 cts.

Filter No. 6.—Commenced cleaning Aug. 14, 1909. Finished cleaning Sept. 8, 1909. Cleaned entirely by Nichols separators. Worked 24 hours a day in three 8-hour shifts. Cleaned and replaced 3,230 cu. yds. Labor cost, $696.74. Cost per cubic yard, 21.57 cts.

Filter No. 1.—Commenced cleanings Sept. 10, 1909. Finished cleaning Sept. 25, 1909. Cleaned entirely by Nichols separators. Worked 24 hours a day in three 8-hour shifts. Cleaned and replaced 3,325 cu. yds. Labor cost, $711.40. Cost per cubic yard, 21.39 cts.

The following is a record of 24 hours' work in Filter No. 3; water pressure 65 lbs. per sq. in.; water used, 47,080 cu. ft., or 1,744 cu. yds., which for a total of 225 cu. yds. of sand washed was a rate of say 7¾ cu. yds. of water per cubic yard of sand. The amount of sand lost was 3 cu. yds., or 1.33 per cent. The cost was as follows:

24 hrs. foreman at 31¼ cts.	$ 7.50
192 hrs. labor at 22½ cts.	43.20
Total	$50.70

This gives for 225 cu. yds. a cost of 22.53 cts. per cu. yd.

Time Studies in Connection With the Cleaning of Filter Sand at Philadelphia.—The following matter is taken from an abstract in Engineering and Contracting, Dec. 23, 1914, of a paper before the American Society of Mechanical Engineers by Sanford E. Thompson.

Philadelphia has five large filtration plants consisting of covered reservoirs operated by slow sand filtration. The water pumped into the reservoir from the Schuylkill and the Delaware Rivers, after passing through the pre-filters, percolates through about 4 ft. of sand and gravel and is thus purified. The impurities are caught largely in the upper few inches of sand, so that if this upper portion is washed the filtration area is practically renewed. Several methods of cleaning filter sands are in use, all of them involving considerable manual labor. Further details of the methods followed in the case under observation are referred to below.

Results.—The object of the plan has been to lay out the work of each gang of men so as to increase the effectiveness of the plant and provide a definite task to be accomplished in a day. The results of the plan which is being put into operation are as follows:

Rotation of cleaning the filters is planned in advance by well-defined rule.

A definite area of sand to clean is assigned to each gang, this area depending upon the depth of cleaning necessary.

This setting of tasks has increased output of each gang 15 per cent and this should be further increased to at least 25 per cent.

Accurate records are kept, showing the time consumed by each gang.

Cost accounts, as well as pay-roll, are made up from the time tickets furnished to the men.

Gang leaders are required to pay closer attention to their duties.

Improved apparatus and machinery are under consideration.

Methods of determining depths of sand to clean are being standardized.

Obstacles.—The greatest obstacle encountered has been the city ordinance fixing the rate of pay of unskilled laborers on a level wage per day regardless of the quality of the workman or the amount of work he is able to accomplish. While in city government strict regulation is necessary, a plan such as is followed in Chicago, where the employes in each department are definitely graded, with different wages for each grade, provides a means for rewarding a man according to his ability and giving a city good value for money expended. The Philadelphia ordinances prevent the payment of a bonus and thus make it difficult to encourage the men to accomplish the tasks assigned them.

Method of Cleaning.—In the filtration plant first handled by the new method there are 65 filters, employing about 128 men for cleaning. Each filter is about 140 ft. wide by 250 ft. long, and is built with groined arch bottom and roof, having columns about 16 ft. on centers.

The Nichols method of washing is used in this plant. In this method the dirty sand from the surface of the bed to a depth specified is shoveled to an ejector, furnishing water under about 85 to 100 lbs. pressure, which forces it through a large hose into the separator, which is a cylindrical iron tank provided with a concentric baffle about 6 or 8 ins. from the outside shell. The water and sand swirl around this, the clean sand settling in the conical bottom and passing out through a 2-in. hose below. The dirty water passes under the baffle and out of the top of the tank, whence it passes out of the bed through a hose and pipe to sewer.

From the separator the sand is returned by the hose to the bed, where it is properly distributed and leveled. Sometimes, according to conditions, the dirty sand is shoveled direct to the hopper of the ejector, and in other cases is scraped and piled from the first and one-half the third bay into the second line of bays; from the other half of the third and one-half the fifth line of bays into the fourth line of bays; and so on, to include the ninth bay. This scraping and piling is done usually as an independent operation by old men unfit for harder work.

Four washing gangs are required for each filter bed, the outside gangs having 2½ bays each and the inside gangs having 2 bays to clean. In each gang there are 3 shovelers to a hopper, 2 men shoveling at a time while one rests. Each man shovels 40 minutes and then rests 20 minutes. The fourth man takes care of the hose from the separator distributing the clean sand to the bed. A fifth man, recently introduced, working with 2 gangs,

Unit Times.—Time studies were made by the aid of the stop watch on the labor operations in the beds, such as shoveling dirty sand to hopper, cleaning up around hopper, moving hopper, moving separator, and moving track. These times for individual operations were then converted for direct use into the time per cubic yard for 1 in. of depth.

Studies were also made on the rate of delivery of sand from separator and the effect of opening and closing the separator on the rate of shoveling. Different methods of handling the ejectors were also included in the investigation.

The object of the time studies was to find the time of each individual operation, so that unnecessary operations could be eliminated and the unit times of the necessary operations could be combined to apply to all conditions. Over-all time records are of no use whatever, because, for example, with each change in depth of shoveling, the number of moves of the hopper and of the separator vary.

The unit times for the individual operations were determined by the taking of a large number of time studies in such a way as to eliminate all unnecessary delays, but with a sufficient allowance for resting and delays which were unavoidable. The unit times obtained are given in Table X.

TABLE X.—UNIT TIMES FOR VARIOUS OPERATIONS IN CLEANING FILTER SAND

Operation	Unit time per operation, min.	Time per cu. yd. per 1-in. depth, min.
Moving hopper	0.20	0.34
Moving separator	0.50	0.45
Moving hopper hose	0.25	0.11
Moving track	0.83	0.44
Waiting for hopper to empty	0.42	0.38
Moving pressure hose	1.80	0.36
Additional necessary rest	. . .	0.12
Shoveling to hopper	. . .	6.32

The time given in each case is that for the gang, since it was necessary on this work to set a task for the entire gang instead of starting the individual men, as it is always best to do when possible. The time of shoveling into the hopper is in each case based on the rate of output that the ejectors will take care of. It was found that one man, instead of two, could very nearly produce the required output, but this would have lengthened the time of cleaning so as to be inadvisable. For example, with one man shoveling, the shoveling time per cubic yard is 8.8 minutes with a 1-in. depth, and 6.75 minutes per cubic yard when the depth is 18 ins. These studies indicate therefore that further change is necessary in the method of operation so as to increase the output of the ejector and separator in order to obtain the full value of the labor of the gang.

In addition to the time studies on the work of the laborers in the filters, time studies were also made on the clerical work, such as making out tickets, operating bulletin board, extending time on tickets, entering time on various records, and checking up the payroll in order to distribute the work equally among the force employed to carry it on.

Setting Tasks.—Having determined the unit times and established the system of routing and giving out of tickets, the area of surface that should be shoveled by each gang was figured and the point to which they were supposed to go in a days' work was marked with a flag. In order to fix this, it is necessary to determine in advance by test holes the depth which should be cleaned, figuring the area from the volume at the required depth. Curves have been plotted, giving areas or rather distances to clean for the outside and inside gangs for various depths. These distances are converted into pier locations, so many feet in front or back of pier number so and so. The actual point reached each day is reported at the office and the mark for the following day calculated therefrom.

On the first two days, after everything was ready, no instructions were given the gang leader or the men as to how much they were expected to do. The total area shoveled by each gang, however, was noted, and compared with the area they should have accomplished. Every gang shoveled less than the figured area, the amount running from 10½ per cent less to 31½ per cent less. After this second day's work we concentrated on E-1 gang, since it is always necessary in order to avoid friction to work with a single man or a single gang, and laid out in advance the amount this gang should accomplish in a day by setting a flag at the point which marked the end of the day's work. As a result, they readily accomplished the task and reached the mark. The task setting was then extended to other gangs.

One rather interesting point came up in connection with the handling of the work at first. The men in the outside bays had to shovel about 7 per cent more sand than those in the inside bays because the areas were wider; never-the less, all gangs had been accustomed to keep abreast, the men who had the narrower width to handle slowing up to accommodate their speed to the outside men. When the men began working by the task, the operation was somewhat similar, except in the other direction, until the men realized the difference. The inside men, because of the narrower width, were given the longer area to cover and gaged their speed to accomplish their task. The outside men, although shoveling a greater width kept abreast with them without special trouble, thus exceeding their task.

Accomplishments.—The rates were set on the basis of a fair day's work which should be accomplished with a first-class foreman and with no incentive to the laborers. Because of this absence of incentive the work actually done averages considerably less than the actual tasks.

To compare the amount of work accomplished before and after setting tasks the records were averaged of 27 cleanings taken at random from a period of 1½ years previous to the introduction of the new methods. These showed an average rate of 6.3 cu. yds. shoveled per day per gang. An average of 55 cleanings after task work was started gave 7.2 cu. yds. per day, an increase of nearly 15 per cent. This increase, however, was less than half of what it should have been, the figured rate being 8.4 cu. yds. per day. Although the 15 per cent increase was well worth accomplishing, our tests showed positively that the larger increase of over 30 per cent should readily be accomplished with first-class supervision. One plan considered as a partial incentive is a record card for each man showing his output and thus indicating his relative rank as a workman. The rank of a man would influence the laying off if work is slack or, on the other hand, if a man is required for a higher position, this ranking would be taken into account. If it had been possible to pay an actual money bonus, the task would have been set still higher and the output would have been increased about 50 per cent.

As the work on the filter management was getting under way, circumstances called the men in charge to other locations in the city temporarily. Going back to the job and making further studies, it was found that time had been lost: (*a*) by not throttling down the separator so as to make it run continuously and thus deliver its full output; (*b*) by unnecessary throttling of the hopper and cleaning up ahead before moving hopper to next portion of pile; (*c*) by not keeping spray open to fullest capacity. It was noticed whenever the gang was watched closely that they accomplished their task without any difficulty.

Apparatus.—The studies, as is always the case where thorough investigations are made, indicated a number of changes advisable in the apparatus and methods of handling it. It was found that the line of piping for the water used under pressure were poorly arranged, so as to require in certain cases long lengths of hose and a consequent deduction in pressure which largely increased labor costs. In other cases certain pipe lines had to be moved from bed to bed during the operation of cleaning. The studies have shown that a mechanical washing device probably can be devised which will greatly reduce the cost of cleaning.

Even with the present apparatus the method of handling the separators, and ejectors can be considerably improved and the cost of this quickly made up by labor saved.

The design of the hoppers and separators, as already stated, could be improved so that they would handle just the right amount of material that a gang can readily shovel. The present output is limited by the design of the hopper and ejector.

Cost of Cleaning Settling Tanks by Perforated Underdrains.—The following matter is taken from an abstract of a paper by Alexander Potter presented at the 23rd Annual Convention of the American Society of Municipal Improvements and published in Engineering and Contracting, Oct. 11, 1916.

Muskogee Settling Basin.—The Muskogee settling basin is constructed of reinforced concrete. It is 212 ft. square and 19.5 ft. deep. When filled to a

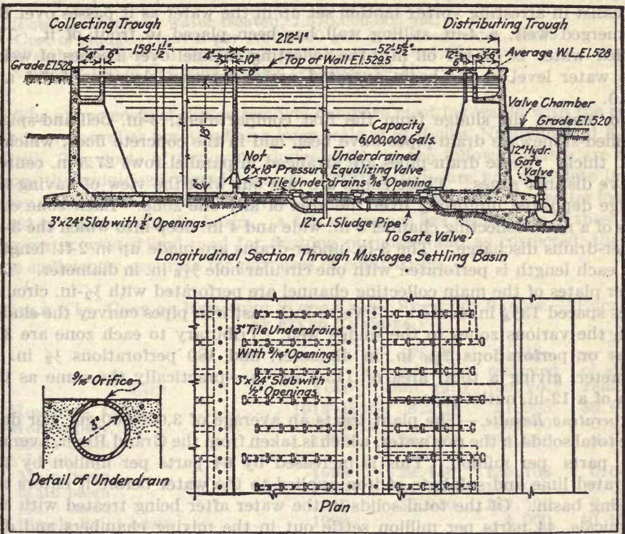

FIG. 8.—Longitudinal section through Muskogee settling basin. Detail of drain and plan.

depth of 18 ft. its capacity is 6,000,000 gal. A reinforced concrete curtain wall, 6 in. thick, supported by buttresses at intervals of 12 ft., divides the basin into two compartments. The first and smaller of these compartments, 52.5 ft. wide and 212 ft. long (about one-quarter of the basin), has its bottom perforated and underdrained for sludge removal. To underdrain the larger compartment was not considered advisable, first, because of the expense and, second, based upon the experience in other plants where the writer adopted this method, it was not considered necessary because of the relatively small quantity of suspended matter which experience indicated would settle out in this compartment. Three and a half years' continuous operation shows it to average about 1.3 per cent as opposed to 98.7 per cent removed over the area with the perforated bottom.

Fig. 8 is a section of the Muskogee settling basin taken parallel to the direction of flow. The raw water, treated with sulphate of iron and hydrated lime at the average rate of 1 and 2½ grains per gal., respectively, enters the settling basin at the left through the distributing trough. From the distributing trough the water is admitted to the first compartment of the basin through 32 8-in. circular openings. A vertical concrete baffle wall, 4 in. thick, constructed directly in front of these openings, tends to arrest all eddy and vortex motion and at the same time deflects the incoming water downward.

The partially settled water passes from the first to the second compartment over a submerged weir formed by the curtain wall. The crest of this submerged weir is about 6 in. below the average water level maintained in the tank. To assist in arresting vortex motion set up in the water as it passes over the submerged weir, a 4-in. stilling wall has been placed in front of it. The settled water is drawn off into the collecting channel over a series of weirs. The water level in the basin operated varies between elevation 527.5 and 528.0.

To remove the sludge from the first compartment, 3-in. bell-and-spigot vitrified-stoneware drain-pipes have been laid in the concrete floor, which is 9 in. thick. These drain-pipes are arranged in parallel rows 27.5-in. centers in five distinct zones. These zones are laid out with the view of having the sludge deposited uniformly over the area of any one zone. Each zone consists of a main collecting channel 8 in. wide and 4 in. deep into which the 3-in. under-drains discharge. The 3-in. under-drains are made up in 2-ft. lengths and each length is perforated with one circular hole 9/16 in. in diameter. The cover plates of the main collecting channel are perforated with ½-in. circular holes spaced 13¾ in. centers Twelve-inch cast iron pipes convey the sludge from the various zones to the sludge well. Tributary to each zone are 315 holes or perforations 9/16 in. in diameter, and 180 perforations ½ in. in diameter, giving a total area of 113.4 sq. in.—practically the same as the area of a 12-in. outlet pipe.

Operating Results.—The plant treats an average of 3,000,000 gal. per day. The total solids in the raw water, which is taken from the Grand River, average 451 parts per million. This is increased by 64 parts per million by the hydrated lime and sulphate of iron applied to the water before it enters the settling basin. Of the total solids in the water after being treated with the chemicals, 44 parts per million settle out in the mixing chambers and distributing troughs, 307 parts per million in the first compartment, i. e., the first quarter of the settling basin, and only about 4 parts per million in the second compartment.

The following table gives the most important facts relative to the operation of the sludge removal system at Muskogee.

Average total weight of dry solids removed daily by underdrains in the form of sludge, lbs	7,690
Average water content of sludge as discharged through blow-off valves, per cent	98.7
Total quantity of sludge water discharged at one operation, gal	70,000
Ratio of blow-off water to total water treated, per cent	2.33
Effective hydrostatic head for sludge removal, feet	20.5
Average velocity through underdrain perforations, feet per sec	20.4
Loss of hydrostatic head through perforations, 26.3% of total head, feet	5.4
Hydrostatic losses in underdrain system, 21% of total head, feet	4.3
Velocity head lost at discharge, 52.7% of total head, feet	10.8

Cost of Sludge Removal.—The total cost of constructing the sludge removal system for the Muskogee settling basin over and above the cost of constructing a plain tank of similar shape and size, and including all piping, valves, sludge chamber, etc., was \$3,570. This is at the rate of 32.5 ct. per square foot of bottom underdrained. The average annual cost of operating and maintaining the sludge removal system, including all fixed charges, amounts to \$523, and is made up as follows:

Interest and depreciation, 8% on \$3,570	\$286
Value of the blow-off water lost, 25,500,000 gallons raised 70 feet at \$6 per million (including fixed charges)	153
4,260 lb. ferrous sulphate lost with blow-off water at 1.15 ct. per lb.	53
9,370 lb. hydrated lime lost with blow-off water at 0.005 ct. per lb.	47
Attendance and supplies	34
Total annual cost	\$573

Total quantity of water treated, 1,970,000,000 gal.
Cost of sludge removal per 1,000,000 gal. of treated water, \$0.29.
Weight of dry solid matter removed in one year, 1,404 tons.
Cost per ton of dry solid matter removed, \$0.41.

The above costs of sludge removal compare most favorably with the cost of sludge removal as practiced on a large scale at St. Louis, Nashville and Kansas City. The costs of removing sludge given in the following table are taken from the municipal records, which, unfortunately, are not complete in that they only give the cost of labor, making no charge whatever for water lost and used in flushing out the basin. A fair allowance has been made in these costs for water wasted and used for flushing purposes, and as corrected, the data are sufficiently accurate for purposes of comparison.

Table XI.—Cost of Removing Sludge from Settling Basins.—(Exclusive of Fixed Charges.)

City	Year	Water treated (mil. gal.)	Sludge removed (cu. yd.)	Cost per cu. yd. of sludge removed
*Muskogee, Okla	1913–1916	3,210	21,903	\$0.0469
*McKeesport, Pa	1908–1913	8,890	96,000	0.0325
Main basin	1907	28,048	114,256	0.043
St. Louis, Mo.:				
Main basin	1908	29,156	135,108	0.048
Main basin	1909	34,201	129,035	0.051
Main basin	1910	33,910	182,500	0.045
Bissels Point basin	1908	......	4,000	†0.133
Baden storage reservoir	1908	......	700	†0.213
Nashville, Tenn	1908	......	4,500	†0.359

*Settling basins have underdrainage systems.
†Labor costs only.

At St. Louis it appeared to have been the practice of lengthening the period during which a settling basin may be kept in service by opening the mud gate 5 or 6 in. daily for a period of about an hour, or until the effluent is comparatively clear. None of this flushing water has been charged up against the cost of sludge removal. It is estimated that during the year 1910 approximately 193,000,000 gal. of water were used for this purpose in 175 days. Including the cost of pumping and treating this flushing water with chemicals, the cost of sludge removal becomes 29.3 ct., which is about the same as the cost of removing the sludge in Muskogee.

At Muskogee the percentage of sludge water to total water treated is 2.33 per cent, which, in the writer's opinion, can be considerably reduced by careful management. This ratio of sludge water to total water treated compares quite favorably with that of St. Louis, where in 1910, the only year for which accurate data are available, 523,000,000 gal. of water were chargeable against sludge removal. Of this amount, 300,000,000 gal. were lost in emptying the basin, 130,000,000 gal. were used for flushing purposes, and 193,000,000 gal. were wasted through the sludge gate, thus giving a ratio of 1.54 per cent.

The conditions at McKeesport are at times especially trying on the sludge removal apparatus, for there are periods, of short duration, when the precipitation reaches almost 10 per cent by volume of the water treated, and in the treatment 1,000,000 lb. of lime and 1,500,000 lb. of soda ash have been used annually. The cost of removing the precipitated material at the McKeesport plant has averaged about 35 cts.per 1,000,000 gal. of water treated.

The ratio of blow-off water to water treated ranges from 1.4 to 8.9 per cent when the water is bad, and averaged 2.3 per cent for the period that the plant has been in operation.

Costs of Cleaning Settling Basins by Sluicing.—The following data on cleaning one of the settling basins at Louisville, Ky., are taken from an article by G. D. Cain, Jr. in Engineering and Contracting, Dec. 3, 1913.

The two basins at the reservoir measure about 500 ft. square, and actual measurements showed that the amount of mud deposited in the basin which was cleaned was in the neighborhood of 18,000 cu. yds. The cost of removing this mass of material by the company's own forces was $2,700, or 15 cts. a cu. yd., which compares very favorably with the cost of the previous cleaning of the basins.

Of course the mud had not hardened sufficiently in the period of 20 months since the previous cleaning, to make literal excavation necessary, and this rendered it possible for the company to use the sluicing method. Lines of firehose were attached to the company's mains, and streams were directed upon the mud under a pumping pressure of 70 to 80 lbs. per sq. in.

The surface mud readily yielded to this treatment, but as the work went deeper the aid of a force of men armed with scrapers was necessary to expedite the removal of the mud. These scrapers were simple affairs made of 1 in. boards, and were constructed for use by three men at once, a fairly large surface thus being covered by each scraper.

The heavy mixture of mud and water was sluiced in this way into the central surface drain of the basin, which discharges into the sewer outlet provided for drainage purposes, and the entire 18,000 cu. yds. of silt were thus removed in about three weeks of actual working time. It was not possible to rush the work at a much greater speed on account of the danger of clogging the sewer. As it was, no trouble of this sort was experienced.

The following data computed from figures given in the report of Geo. H. Benzenberg, Chief Eng. water works, Cincinnati, O. are published in Engineering and Contracting, April 6, 1910.

The reservoir, known as Reservoir No. 1 of the Cincinnati, O., water works, had been in constant service for over two years. It was taken out of service on March 20, 1909, and allowed to stand for 4 days in order to allow complete sedimentation before drawing the water. The original turbidity of the water was 75 parts per million; after 4 days it was found to be 47 parts for a depth of 30 ft. and 50 parts at a depth of 40 ft. On March 30 the water was drawn off for a depth of 3 ft. during the night and allowed to stand during the day, when the mud was washed off the exposed slopes by hose streams under pressure of flushing pumps in the wier house. The following night the water level was again lowered to stand during the day, when the slopes were washed down. This procedure was repeated every 24 hours until April 9, when the water had become very turbid. The 30-in. drain was then opened, drawing off all the water and such mud as it carried. The deposit of mud remaining on the slopes and bottom was then disintegrated and slid to the drain opening by means of 1½-in. hose streams under heavy pressure. The depth of accumulated mud was found to be from 12 ins. to 36 ins. and the total amount removed was estimated as 30,000 cu. yds. Some 35,494,600 gals. of water were wasted in draining the reservoir and 16,902,600 gals. were used for removing the mud, or about 565 gals. per cubic yard of mud removed. The cost of cleaning was as follows:

16,902,600 gals. water, at $3.28 per mil. gals	$ 55.44
22,032 kw. electric power, at 1.1 ct	242.36
Labor operating pumps	57.94
Labor cleaning reservoir	427.27
Total	$783.01

The cost per cubic yard of mud removed was, for cleaning proper, 2.61 cts. Charging in the 35,494,600 gals. of water lost in draining the reservoir at $3.28 per million gallons we have an additional item of $116.42, or 0.39 ct. per cu. yd., making a total cost of 3 cts. per cu. yd. The cleaning was completed May 1, 1909, and water was turned back into the reservoir on May 8.

The cost of cleaning Reservoir No. 2 of the Cincinnati, O. water works is given in Engineering Record, June 21, 1913, as follows:

The time required to wash out the mud from this reservoir was twenty-eight working days. As nearly as could be estimated, 41,100 cu. yd. of mud were removed. This refers only to the sediment containing less than 50 per cent of water, which was left after draining off the liquid sludge. This volume of mud, together with the semi-liquid sludge, represents the deposit from over 34.5 billions of gallons of water. Besides 61,000,000 gal. of water being wasted in draining, about 21,000,000 gals. were used in cleaning out the reservoir.

The following table shows the costs for cleaning:

Cost of Cleaning Reservoir at Cincinnati, Ohio

	Total cost	Cost per cu. yd. of sediment removed
Labor	$1,100.45	$0.0267
Supplies	440.23	.0107
Power	154.44	.0037
Value of water used in cleaning	62.82	.0015
Value of water wasted in draining	183.13	.0044
Total	$1,941.07	$0.0470
Cost of cleaning per 1,000,000 gal. of water settled		$0.056+

The methods employed were similar to those used in cleaning reservoir No. 1. The increased cost noted is largely due to an increase of some 30 per cent in the rate paid for labor and the difficulty of opening the closed sump openings in this reservoir.

CHAPTER IX

IRRIGATION

In this chapter are included both general and specific cost data and articles dealing with many of the economic problems met with in irrigation.

For further data relating to this subject and included in the volume, see chapter on the following subjects: Excavation; Concrete; Dams, Reservoirs and Standpipes; Water Works; Small Tunnels and Land Drainage. Also refer to the index for other special information.

For costs of Pumping see "Handbook of Mechanical and Electrical Cost Data" by Gillette and Dana. For Methods and costs of excavation see "Earthwork and Its Cost" by Gillette also "Rock Excavation" by Gillette.

Cost of Irrigation Works Per Acre of Land Supplied with Water.—The cost of irrigation works per acre of land irrigated has been tabulated by the U. S. Reclamation Service for some 140 projects of which 87 are Carey act projects, 39 are private projects and 14 are projects of the Service. The data given in Tables I, II and III, are published in Engineering and Contracting, June 4, 1913.

TABLE I.—COST OF PRIVATE IRRIGATION PROJECTS

Name of project or company	Acreage in project	Cost or water right charge per acre
Colorado:		
Amity Canal	80,000	$100[2]
Beaver Land and Irrigation Co	20,000	175[2]
Catlin Canal	25,000	100
Colorado Co-operative Co	5,200	60
Denver Reservoir and Irrigation Co	200,000	45
East Palisade Irrigation District	645	63
Montana:		
Fort Lyon Canal	70,000	100[3]
Grand Valley Canal	40,000	60[4]
Greeley Poudre Irrigation Co	125,000	45
Mesa County Irrigation Project	2,568	73
Orchard Mesa Irrigation District	9,122	119
Otero Irrigation District	20,000	40
Palisade Irrigation District	6,000	41
Paradox Valley Irrigation Co	30,000	45
Pueblo-Rocky Ford Irrigation Co	100,000	150[5]
Redlands Irrigation and Power Co	5,000	100[6]
Routt County Development Co	39,000	45
South Palisade Heights Irrigation District	700	127
Conrad Land and Water Co		40
Great Falls Land and Irrigation Co	36,000	50

[1] Engineers' estimates where project is proposed or incomplete.
[2] Estimated at from $75 to $150 per acre. Includes land.
[3] Estimated at $75 to $150 per acre.
[4] Per miner's inch.
[5] Includes land.
[6] Estimated at from $65 to $150 per acre.

TABLE I.—(*Continued*)

Name of project or company	Acreage in project	Cost or water right charge per acre
Nebraska:		
Belmont Canal and Irrigation District	20,000	25[7]
Tri-state Canal	60,000	42

[10] Estimated at from $20 to $60 per acre.
[11] Estimated at from $50 to $60 per acre.
[12] Estimated at from $75 to $200 per acre.
[13] Estimated at from $100 to $250 per acre.

The figures in Tables I and II obtained from printed reports of state engineers and public data, show that on over 90 modern irrigation systems being built by private or corporate capital, the cost per acre averages nearly $53. This cost does not include the annual cost for operation and maintenance.

Cost of Reporting on an Irrigation Project.—The following is given by Charles Kirby Fox in "Western Engineering," reprinted in Engineering any Contracting, Nov. 5, 1913.

During 1911–12 I was employed to make the surveys and estimates for an irrigation project. Careful records were kept of the time and cost of each item pertaining to the work. All told, the project covers 70,000 acres, of which a part is already irrigated and some of it does not require irrigation. We prepared preliminary plans for irrigating 80 per cent of the unirrigated arable land, or 40,000 acres. As a rule, the land was fairly smooth and for the greater part covered with sagebrush about waist high.

On account of the distances from trade centers, it was necessary in making the designs and estimates to provide for using as much local material as possible and minimize the quantity of materials shipped in from the outside. The approximate estimates follow: Excavation, 8,000,000 cu. yds.; tunneling, 5,800 lin. ft. lumber, 830,000 ft. B. M.; iron and steel, 500 tons; main and diversion canals, total 61 miles; laterals, 144 miles. There will be approximately 2⅔ miles of flume and a little over ½ mile of siphons in the system.

Outside of the engineering crew, local men were used. It was necessary with the greater part of the work to establish camps. These were, as a rule, 10 to 20 miles from the adjacent towns. Chainmen and rodmen were paid $40 to $50; cooks, $60 to $70; level-men, $75 to $85; instrument men, $90 to $110; draftsmen, $75 to $150, and assistant engineers, $100 to $150. All rates given are by the month and include board and expenses. About 10,000 meals were served in camp at a cost of 28 cts. each, segregated as follows:

	Cents
Food	21
Cook	6
Incidentals	1
Total	28

It was necessary to use canned goods almost exclusively. The cost of provisions was very high. The meals were excellent. Horses were hired at a cost usually of about $1 per day, including feed.

Water Shed and Irrigation Survey.—Eighteen stations were set by an assistant engineer and rodman with two horses. To place the stations, triangulate them and plot the work cost $35 per station. Eight and one-half days' time was put in on each station.

Sounding Lake and Contouring Reservoir Site.—In sounding a 3,000-acre lake it was necessary to cut over 1,000 holes through 13 ins. of ice. A party consisting of a transit man, two chainmen, two axmen and two horses were used. In contouring 4,000 acres around the lake the same party was used, except that a recorder and three stadia men were substituted for the chain and axmen. The sounding and contouring cost 6.4 cts. per acre.

The high-water line of the reservoir was run before I arrived. I understand that it cost about $50 per mile for 16 miles of exterior line. This includes ties to the section corners.

Section Lines.—Approximately 200 miles of section lines were re-run. Great difficulty was experienced in finding some of the corners. It is thought that between one-fourth and one-fifth of the time was spent in looking for old corners, and the work was greatly delayed by storms. The party consisted of an instrument man, two chainmen, two flagmen, a teamster, four horses and a cook. The work cost $10 per mile. It might be worth noting that on lines which were re-run, only one corner has been found that the original party did not locate. Some 60 corners were replaced at odd times at a cost of $2.50 per post.

Leveling.—(The section line party was followed by a level party (levelman and rodman), which set bench marks every half mile or mile. They ran 150 miles at a cost of $2.50 per mile.

Contouring.—The entire area under the ditch-line was contoured at a cost of 5 cts. per acre. Five-foot contour intervals were used on the flattest sections and 10 ft. on the steeper parts. It was platted on a scale of 1,000 ft. to the inch. The party consisted of an instrument man, recorder and two to four stadia men. Usually two parties were in the field under my supervision, with a draftsman, cook, one or two teamsters and six horses. After the field work was completed it took almost as much time to reduce and plat the transit stadia notes as it did to do the field work.

Cruising.—First the real estate department had a man cruise the land and plat it on a scale of 6 ins. to the mile. This cost 2 cts. per acre. It was later thought advisable to make a rough cultural and property map of the valley now under cultivation, so as to have an idea of the amount of hay and grain available. Two men on foot could cover about 10,000 acres per day. Office work took about the same time.

Canal Line.—With a view to determining the most economical location of the canal line, we ran a low line 39 miles long and a high line 20 miles long, and made a careful reconnaissance of the remainder. From these studies we determined that the high line would be cheapest. The lines were run by the following party: Chief, draftsman, transit man, stadia man, flagman, axman, level man, rodman, teamster, four horses and a cook. It cost $16 per mile to do this work.

We then started out with practically the same outfit except that two chainmen were added. The distance per shot on the preliminary line was about 400 ft. All the work was on the side hill. When contouring was commenced the party was divided.

On the transit line we set stakes every 100 ft. and took the elevation at each station. We then took, very careful topographic data, usually covering 30 to 40 ft. in vertical elevation by 5 ft. contours, which were platted in the field to a scale of 200 ft. to the inch. We were very careful to note all rock outcrops or other characteristics which would influence the final location of the line. We ran 61 miles of these lines at a cost of $30 per mile for the transit and level line, and $20 per mile for the topography. The cost of the ties to the section corners is included in the cost of the transit and level line.

Paper Location and Estimate.—The office work was done in the winter with a small force, consisting of myself, an assistant engineer, a draftsman or two and a blueprint boy. I had the assistant engineer and a draftsman spend a month to work up a special set of excavation tables especially adapted to side hill canal lines. They gave the balanced cut and fill, the yardage and the center cut for each different side slope. I estimate that by the use of these tables were saved several hundred dollars per mile on the excavation at a cost of less than 1 per cent of the amount saved. The estimate cost $16 per mile, or approximately ⅔ of 1 per cent of the cost of the excavation.

Field Notes and Maps for Filing.—The tracings included six sets (34 sq. ft.) of three maps each, and the field notes required 146 pages of legal size paper. All courses were balanced in connection with the section line survey. The office work cost $500, or about $6.50 per mile of canal and reservoir.

Designs and Estimates for Structures.—It is estimated that the structures, flumes, siphons, outlets, etc., will cost about $100,000. The designs and estimates cost 2 per cent of the estimated cost. Usually several types of structures were sketched out and estimates made for each type. These detailed drawings were made according to what appeared to be the best type, and included a complete estimate of the cost, including quantities, weights, etc. The difference in the cost of several types of structures, all of which appear suitable, is surprising.

It cost a little less than 1 per cent to make the surveys, designs and estimates of the rock fill dam and tunnels. Enough money will be saved on changing the dam site from the location selected by the promoters to pay the entire cost of the work. The laterals were laid out on the contour map and only a few of the larger ones were run out. The designs and estimates for the laterals cost about $2 per mile. The entire report with the specifications, etc., contained about 250 pages and 100 blueprints.

General Expenses.—The stenographic and clerical expenses amounted to approximately $400, the general expenses about $800 and approximately $1,000 was spent on hydrographic work. All told, this survey cost approximately $20,000, or 50 cts. per acre, or 3 to 4 per cent of the estimated cost of the work. About 4,000 man-days were worked at an approximate cost of $5 per man-day.

Cost of Constructing Irrigation Works.—The following matter is taken from Newell and Murphy's "Principles of Irrigation" (1913).

It has come to be an axiom that the cost of irrigation works is generally greater than the original estimate. This is due not so much to lack of care and thoroughness in preparing estimates as to the fact that the work is pioneer in its character, and improvements are suggested or new needs arise so rapidly that works which were planned in one year as adequate for the purpose in mind are found to be unsuited or undesirable by the time construction is well advanced. Many changes must be made, or additional details provided which were not known or not considered necessary in the original scheme. It is, of course, possible that an engineer may plan works and build them exactly as planned and within the original estimates, but this condition is one which with existing irrigation systems does not take place under ordinary circumstances.

The engineer may plan for certain works to meet the then prevailing conceptions, but the owners or financiers usually conclude that it is necessary to add certain extensions or modify details such, for example, as increasing the size of the reservoir, or of the main canal, or adding a pumping plant. Thus, as a result, the works cost more than anticipated, and, comparing the original statements of cost with the actual expenditures made, it is seen that the latter are far in excess of the estimates, but the reasons for this are rarely given.

Men's ideas with reference to limits of practicability or cost of the works have rapidly expanded. The small canals built before 1900 were cheaply executed, the structures were of wood and of temporary character. The location was made with reference to keeping the construction cost to the minimum and much of the work was done by the farmers themselves, no account being taken of what is generally termed the overhead cost including that of planning and organization of the work.

At the same time, the estimates of the area watered were very liberally made. If some water was provided for a farm, it was habitually stated that the entire area say of 160 acres was under irrigation, even though water had only been as a matter of fact applied to a portion of it. The capacity of the canal might not be enough to supply all of the lands which were claimed to be irrigated. For these reasons the cost per acre of irrigation was stated at an extremely low price, less than $15 per acre. Beginning about the year 1900, a cost of $20 per acre for irrigation was considered high, but when it began to be appreciated that the land with a sure water supply would yield a large return on a value of $50 or even $100 per acre, it was recognized that larger investments in construction would be justified. Year by year the limits of assumed feasibility have been increased, so that by 1905, it was assumed that $30 per acre was large, then $40 per acre, and finally by 1910, a cost of reclamation of $60 per acre was not considered prohibitory, for lands especially in the southern part of the country. In fact, when consideration is had of the great value of orchard lands an expenditure of $100 or more per acre to provide water is feasible. In semitropical lands, for example, in the Hawaiian Island, where pumping plants have been erected for raising water for irrigation to a height of 550 ft., an outlay of several hundred dollars per acre is not considered out of the ordinary.

In the northern temperate regions, for example, in Colorado and Montana, for the ordinary field crops an investment of $40 to $60 per acre may be now considered as large but not prohibitory. This may be increased notably for warmer regions with longer crop season, such as those of southern Idaho, and portions of Oregon and Washington. Going south from here to points as in

Arizona and California, where crops grow throughout the greater part of the year, an increase of 50 per cent. in the amount above named may be considered as moderate.

If estimates are based on the crop production of thoroughly irrigated lands it can readily be seen that these give a good income on an investment of from $200 to $500 per acre, so that theoretically, the figures above given could be increased several fold, but as a matter of fact, under existing conditions, it is hardly safe to figure on this basis, although it is possible to look forward to a time when far larger investments than now considered wise will be the rule rather than the exception.

Other Costs.—It must not be assumed that the cost of an irrigation system is simply that of the engineering or construction. There are other costs which may equal or exceed these and neglect of which in the preliminary estimates frequently leads to financial ruin. These are the somewhat vague and intangible expenses of the organization, the so-called overhead charges, especially of commission and interest upon bonds, or upon other securities issued for construction purposes. It is not infrequently the case that after the engineer has carefully estimated all of the construction cost and has allowed 15 per cent. or 20 per cent. for contingencies, the business man must double this to cover the items above noted.

Taking the ordinary conditions of private irrigation systems it may be said that assuming the engineer's estimate of construction at 100 per cent., the other items to be added will be about as follows:

Preliminary examinations, organization and promotion, 10 per cent.

General administrative, 10 per cent. This is after the funds have been raised, the general plans determined upon and construction carried to completion.

Interest on bond issue, 20 to 30 per cent. This is assumed to cover most of the construction cost, and is estimated at 6 per cent. per annum on the period required in the construction of large systems.

We thus have from 40 to 50 per cent. of the construction cost to be added at the time when the works are completed.

Beginning with the time of completion of the works and the beginning of active irrigation from then on is the period of greatest difficulty and stress. Settlement of the lands is usually slow, the farmers must experiment, the markets are to be established, and five, ten or more years may elapse before the land is completely irrigated and the farmers are able to make notable payments. During this time the cost of operation and maintenance has been large and this with the interest on bonds or other securities may amount to 75 per cent. or even 100 per cent of the actual construction cost.

Size and Cost of Organization for Operating Irrigation Systems.—The following data are given in Harding's "Operation and Maintenance of Irrigation Systems."

At the 1911 Operation and Maintenance Conference at Boise, a paper was presented by R. K. Tiffany, then manager of the Sunnyside project, in which a series of organizations for different sized systems were given as shown in Table IV. As stated by Mr. Tiffany the number of employees given would represent about the maximum which would be required. Under favorable conditions the number may be materially reduced and many systems are operated with smaller organizations.

As an instance of effect on the organization of the main canal system of the delivery of water to laterals only or to individuals, a case on the Boise project

TABLE IV.—SIZE OF ORGANIZATION

Position	Size of project—20,000 acres: Number of employees	Monthly salary	50,000 acres: Number of employees	Monthly salary	100,000 acres: Number of employees	Monthly salary
Manager	1	$ 200	1	$ 250	1	$ 300
Chief clerk	1	125	1	150	1	175
Bookkeeper	...	...	1	125	1	125
Stenographers	...	...	1	90	2 @ $90	180
Engineer	1	125	1	150	1	150
Hydrographer	...	...	...	...	1	100
Inspector	...	...	1	100	2 @ $90	180
Water masters	1	125	2	275	3 @ $150	450
Ditch riders	8 @ $90	720	20 @ $90	1,800	40 @ $90	3,600
Telephone lineman	1	75	1	90	1	90
Water-record clerks	...	...	...	...	2 @ $90	180
Total per month	...	$1,370	...	$3,030	...	$5,520
Cost per acre per month	...	6.8 cents	...	6 cents	...	5.5 cents

was cited. On 32,000 acres, of which 21,000 were irrigated, water was delivered to laterals only on about half of the area; one water master, one field clerk, 2 gate tenders and 8 ditch riders handled this area at a cost of 5 cents per acre per month. On another division containing about 33,000 acres of which 15,000 were irrigated, water was delivered to each individual farm at a cost of 12½ cents per month.

The average size of the clerical force for government projects was given as follows at the same conference: up to 15,000 acres, one clerk; 15,000 to 40,000 acres, two clerks; 40,000 to 75,000 acres, three clerks; 75,000 to 120,000 acres, four clerks; 120,000 to 175,000 acres, five clerks; 175,000 to 240,000 acres, six clerks. These do not include the keeping of the strictly operation or water-delivery records It was considered that one man should handle about 2,000 individual accounts in the books. For other forms of organization the clerical force is usually somewhat smaller.

Economic Water Conduit Location.—The following is given in Engineering and Contracting, Jan. 14, 1914.

Every conduit must change at certain points along its length from one type of construction to another, as from pipe line to lined canal, unless it traverses a country of uniform topography. Such changes arise from considerations of economy or safety. A conduit of any considerable length seldom consists wholly of canal section but changes from that type of construction to flumes, siphons, pipe lines, bridge flumes or tunnels, as the location conditions dictate. The points at which such changes are made are determined by economic considerations as well as by ground slope, by the nature of the material encountered in the excavation processes and by the other local conditions. Just as the comparative costs of deep cutting and tunneling are used to indicate when to pass from cut to tunnel in railroad location, so the transition from one type of conduit construction to another is based upon comparative costs.

In making various conduit locations C. E. Hickok, has evolved a diagram which gives the equivalent lengths, from an economic standpoint, of various types of conduits. The diagram and Mr. Hickok's discussion of it are here given as described by him in his paper entitled: A Study of Economic Conduit Location, as published in Vol. XXXIX Proc. Am. Soc. of C. E., pp. 2185–2190. When the locator comes to a point where he must decide whether

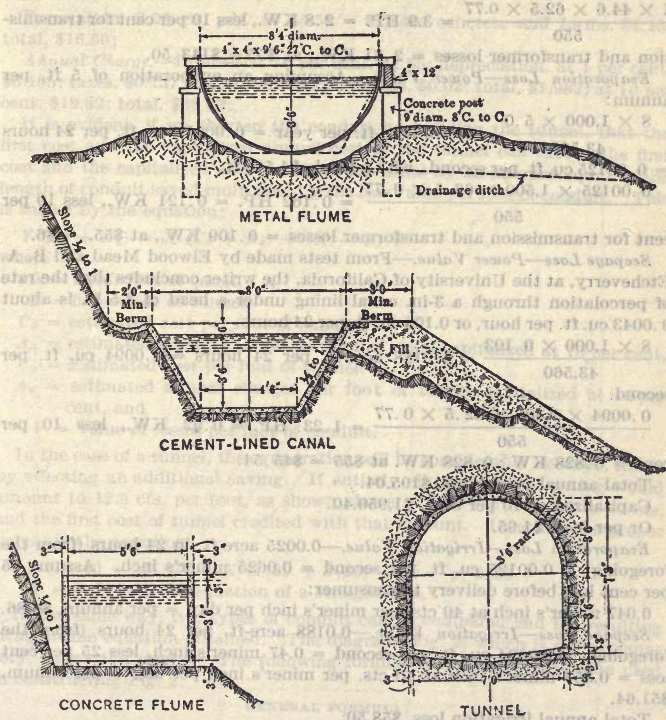

FIG. 1.—Cross-sections of four types of conduits.

to tunnel through a ridge or follow the grade around with a canal, he measures the length of the two possible routes, and, by an inspection of the diagram given herewith, reaches a decision as to the more economical of the two types of conduits. This not only saves time but, with a properly constructed diagram, assures a proper and complete comparison between the two alternatives as to first cost, depreciation, head-loss values, evaporation and seepage loss values, interest, taxes, inspection and repairs.

For purposes of illustration assume a case where the project under consideration is to be used for irrigation and hydro-electric purposes, and where the conduit has a capacity of 44.6 cu. ft. per second and a slope of one-tenth of 1 per cent. Four types of conduit are shown in Fig. 1.

It is obvious that for each foot saved in length of conduit there is a saving in head loss, as well as in evaporation and seepage losses. The value of this saving is ascertained in the following way, taking 1,000 ft. of conduit, for convenience in calculating:

Head Loss.—1,000 ft. of conduit dissipates 1 ft. head. With a discharge of 44.6 cu. ft. per second, and 77 per cent efficiency, the horsepower is:

$$\frac{1 \times 44.6 \times 62.5 \times 0.77}{550} = 3.9 \text{ HP.} = 2.8 \text{ KW.}$$, less 10 per cent for transmission and transformer losses = 2.61 KW., at $55 = $143.50.

Evaporation Loss—Power Value.—Assuming an evaporation of 5 ft. per annum:

$$\frac{8 \times 1{,}000 \times 5.0}{43{,}560} = 0.915 \text{ acre-ft. per year} = 0.0025 \text{ acre-ft. per 24 hours}$$

= 0.00125 cu. ft. per second., with a head of 1,500 ft.

$$\frac{0.00125 \times 1{,}500 \times 62.5 \times 0.77}{550} = 0.162 \text{ HP.} = 0.121 \text{ KW.}$$, less 10 per cent for transmission and transformer losses = 0.109 KW., at $55, = $6.

Seepage Loss—Power Value.—From tests made by Elwood Mead and B. A. Etcheverry, at the University of California, the writer concludes that the rate of percolation through a 3-in. canal lining under a head of 3.5 ft. is about 0.0043 cu. ft. per hour, or 0.103 cu. ft. per 24 hours.

$$\frac{8 \times 1{,}000 \times 0.103}{43{,}560} = 0.0188 \text{ acre-ft. per 24 hours} = 0.0094 \text{ cu. ft. per second.}$$

$$\frac{0.0094 \times 1{,}500 \times 62.5 \times 0.77}{550} = 1.23 \text{ HP.} = 0.92 \text{ KW.}$$, less 10 per cent = 0.828 KW.; 0.828 KW. at $55 = $45.54.

Total annual power loss, $195.04.

Capitalized at 10 per cent, $1,950.40.

Or per foot, $1.95.

Evaporation Loss—Irrigation Value.—0.0025 acre-ft. in 24 hours (from the foregoing) = 0.00125 cu. ft. per second = 0.0625 miner's inch. Assume 25 per cent loss before delivery to consumer:

0.047 miner's inch at 40 cts. per miner's inch per day = per annum, $6.86.

Seepage Loss—Irrigation Value.—0.0188 acre-ft. per 24 hours (from the foregoing) = 0.0094 cu. ft. per second = 0.47 miner's inch, less 25 per cent loss = 0.353 miner's inch at 40 cts. per miner's inch per day = per annum, $51.64.

Total annual irrigation loss, $58.50.

Capitalized at 10 per cent, $585.00.

Or per foot, $0.585.

Summary.—Power loss per foot, $1.95; irrigation loss per foot, 0.585; total loss per foot, $2.535.

The first cost and the annual charges of each type of conduit are next computed. The annual charges are taken as consisting of the following items: Interest, depreciation, taxes, inspection, and repairs. The annual charges of each conduit are capitalized at 10 per cent and added to its first cost, which gives a figure having a real comparative value. For instance, we obtain the comparison between a lined canal and a concrete-lined tunnel as follows:

CONCRETE-LINED CANAL

First Cost—Per Foot.—Excavation, 2 cu. yds. at 36 cts. = \$0.72; concrete, 4.25 cu. ft. at \$10.20 per cu. yd. = \$1.57. Total = \$2.29.

Annual Charge.—Interest at 10 per cent, \$0.23; depreciation, at 2 per cent, \$0.046; taxes, \$0.019; inspection, \$.01; repairs, \$0.02; total, \$0.325; at 10 per cent, \$3.25; total, \$5.54.

CONCRETE-LINED TUNNEL

Excavation, 2.25 cu. yds. at \$5.50 = \$12.40; concrete and forms, \$4.10; total, \$16.50;

Annual Charge.—Interest at 10 per cent, \$1.65; depreciation, at 1 per cent, \$0.165; taxes, \$0.137; inspection, \$0.01; repairs, \$0.02; total, \$1.982; at 10 per cent, \$19.82; total, \$36.32.

It is evident, if we shorten the conduit by building the tunnel, that the first cost and the capitalized annual cost of the tunnel can exceed the first cost and the capitalized annual cost of the canal by an amount equal to the length of conduit saved multiplied by the loss value per foot of conduit. This is shown by the equation:

$$Y\,(C_y + A_y) = X\,(C_x + A_x) + (X - Y)\,V$$

where

X = linear feet of canal,
Y = linear feet of tunnel,
C_x = estimated cost per foot of canal,
A_x = estimated annual charges per foot of canal capitalized at 10 per cent,
C_y = Estimated cost per foot of tunnel.
A_y = estimated annual charges per foot of tunnel capitalized at 10 per cent, and
V = value of losses per foot of conduit.

In the case of a tunnel, the evaporation will be considerably lessened, thereby effecting an additional saving. If entirely eliminated, this saving would amount to 12.8 cts. per foot, as shown above. This was reduced to 10 cts. and the first cost of tunnel credited with that amount. Inserting the proper values in the equation:

$$Y\,(16.40 + 19.82) = X\,(2.29 + 3.25) + (x - y)\,2.53$$

$Y = 0.208\,X$, the equation of a straight line.

In the same way, two types of conduit can be compared and the resulting straight-line equation obtained. The diagram, Fig. 2, which is self-explanatory, shows the results. The following formula and assumptions were used in constructing Fig. 2:

GENERAL FORMULA

$$y(C_y) = xC_x + (x - y)\,V + x\,(A)\,\mathrm{Y} - \mathrm{X}\,(A_y)$$

C_y = Estimated cost per foot of conduit above line.
A_y = Estimated annual expense per foot of conduit above line capitalized at 10 per cent.
C_x = Estimated cost per foot of conduit below line.
A_x = Estimated annual expense per foot of conduit below line capitalized at 10 per cent.
V = Estimated value of one foot of canal for power and irrigation purposes = \$2.53.

Tunnel is credited with 10 cts. per foot for saving in evaporation.

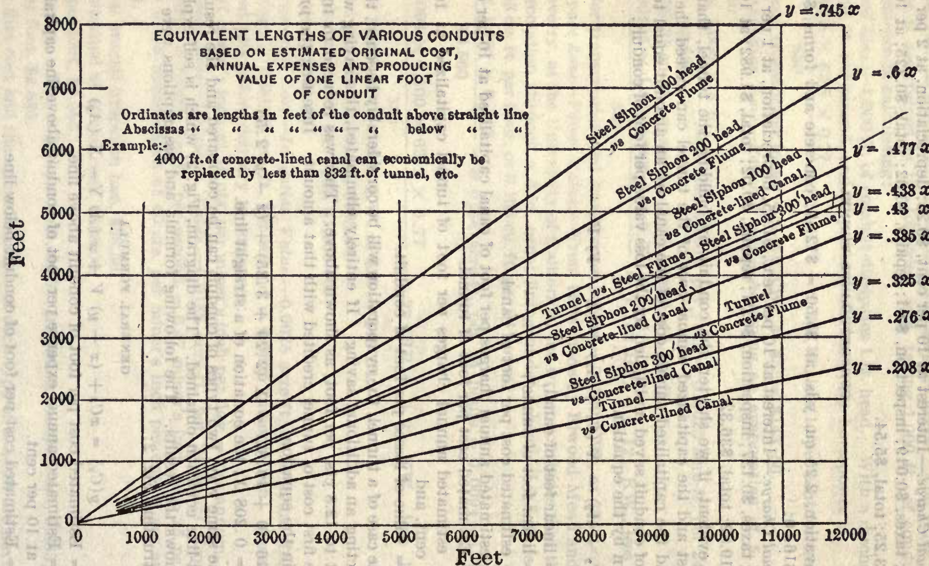

Fig. 2.—Equivalent lengths of various types of conduits all costs considered.

VALUES USED

	Original cost per ft.	Annual expenses per ft.
Tunnel	$16.50	$1.98
Concrete-lined canal	2.30	0.325
Concrete flume	4.28	0.579
48-in. steel siphon, 100-ft. head	5.88	0.961
48-in. steel siphon, 200-ft. head	7.46	1.211
48-in. steel siphon, 300-ft. head	10.64	1.714
Steel flume	5.58	0.887

Steel siphons are credited with $1.10 per ft. for saving in evaporation and seepage.

In the case where a siphon crossing a gulch is compared with a canal or flume passing around the head of the gulch, the cost of the siphon is credited with the saving in evaporation and seepage throughout its length, which in this case amounts to $1.10 per foot.

The writer realizes that such a diagram cannot be relied on entirely in the location of a conduit, for there are local conditions on every piece of work which must be taken into account.

Cost Curves Used for Location of Catskill Aqueduct.—The following notes are abstracted from matter given in White's "Catskill Water Supply of N. Y. City" by J. P. Hogan.

Types of Gravity Aqueducts.—The types of aqueduct construction in order of their relative cost, provided that in embankment or viaduct the elevation of invert above original surface is relatively small, are as follows:

Aqueducts on hydraulic grade	Following natural surface	1. Open channel 2. Cut-and-cover
	Above natural surface	3. Embankment 4. Viaduct
	Below natural surface	5. Grade tunnel
Aqueduct below hydraulic grade	Following or above natural surface	6. Wooden pipe 7. Reinforced concrete pipe (pressure aqueduct) 8. Steel pipe
	Below natural surface	9. Pressure tunnel

On the Catskill Aqueduct, to avoid contamination, open channel is not used. Embankment is used as sparingly as possible, as it is deemed rather unsafe for an aqueduct of this size. Viaduct is not used to any extent, but in a few places the aqueduct was placed on arches and the whole covered with embankment. Wooden pipe is not to be considered for an aqueduct of this size. Reinforced concrete pipe is used to some extent under heads considerably less than 100 ft.

Comparison between Croton and Catskill Aqueducts.—The new Croton Aqueduct was placed entirely in tunnel for the following reasons: greater permanency, decreased likelihood of accident, smaller cost of maintenance, smaller leakage, remote advantage of being less vulnerable in time of war, and decreased cost of real estate. These advantages are very real, but unless there is some special condition which increases the importance of one or more of them, they are outweighed by the smaller linear foot cost of cut-and-cover aqueduct.

The Catskill aqueduct, with twice the capacity of the New Croton aqueduct, cost less than 10 per cent more per linear foot due in great measure to substitution of cut-and-cover for grade tunnel.

Cost Curves.—In deciding upon the type of section to use, and the location for the Catskill Aqueduct, cost curves were prepared for the different sections and estimates of cost were made for alternate lines wherever possible. The combination of section and location that gave the lowest cost was used in determining the final location, depending upon field conditions and the advantages of the shorter line and of eliminating curves.

Fig. 3 shows cost curves used for location of cut-and-cover aqueduct. In preparing these curves unit costs were assumed for different classes of work and applied to quantities determined by planimetering typical sections. Costs were thus computed for every 2-ft. difference in center line elevation; for three different natural conditions, i.e., ground level, slope four on one, and slope three on one; and for five different subsurface conditions, i.e., all earth, all rock and with earth overlying rock, 4, 8 and 12 feet respectively.

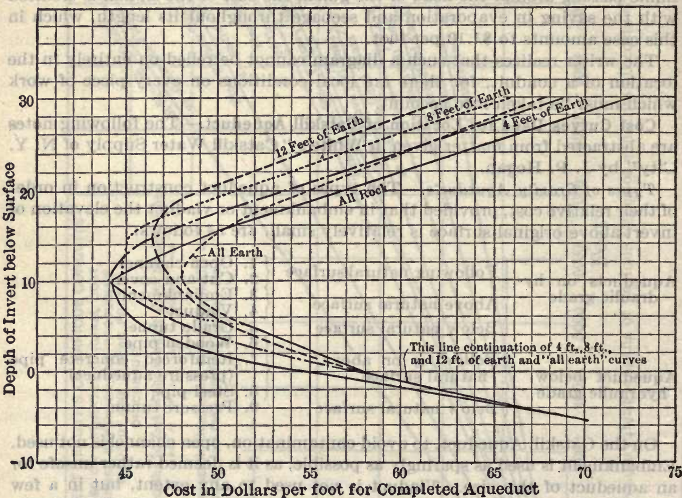

FIG. 3.—Cost curves used for location of cut-and-cover aqueduct.

Similar curves for grade tunnels, for three conditions, i.e. (1) in sound rock, (2) timbered tunnel in rock, and (3) in earth, were used in comparing alternate lines of cut-and-cover and grade tunnel and to indicate approximately the depth of cut at which it would be economical to start tunneling.

In the case of pressure tunnels, a tentative linear foot cost was estimated for each tunnel for comparison with alternate cut-and-cover, grade tunnel and steel-pipe locations.

In preparing curves of this kind the absolute unit prices are not of as much importance as the relative prices. If, for instance the relative price of excavation as compared to concrete is unduly low, the tendency would be to favor the shorter lines. Indeed, the curves in Fig. 3 show too low a cost for the type of aqueduct partly in rock, in some cases the cost being lower than aqueduct in all earth, due to the assumption that narrower cuts would be used through rock, the resulting saving of expensive concrete more than balancing the extra cost of rock excavation. However this assumption did not lead to any notable errors in location, as it was rarely possible to choose the kind of material the cut-and-cover aqueduct was to be constructed in.

The estimated costs for cut-and-cover aqueduct used in preparing the above curves were as follows:

Earth excavation	Cubic yard	$0.30
Rock excavation	Cubic yard	1.50
Refill direct from excavation	Cubic yard	0.30
Refill from borrow	Cubic yard	0.50
Concrete including forms and cement	Cubic yard	7.00
Surface stripping 1 foot deep	Cubic yard	0.60
* Surfacing, smoothing, sodding, and seeding	Cubic yard	Cost of refill plus 0.30
Rubble retaining wall	Cubic yard	2.00
Fencing one foot along aqueduct	Cubic yard	1.00

* Assumed for surface material 1 foot deep.

Unit and Linear Foot Costs of Aqueduct.—It is interesting to compare the original assumption of unit prices and linear costs with the prices for which the contracts were afterwards let. The original assumptions used on location of the Northern Aqueduct Department were as follows:

UNIT COSTS

Cut-and-cover

	Excavation per cu. yd.*	Refill per cu. yd.	Concrete per cu. yd.
Assumed price	$0.50	$0.30	$7.00
Contract price	0.58	0.30	7.30

Grade Tunnel

	Excavation	Refill	Concrete
Assumed price	$5.50	.....	$10.00
Contract price	5.17	.....	9.15

* For earth. A price of $1.50 per cubic yard was assumed for rock. Under the contract there was no classification.

LINEAR FOOT COSTS

Cut-and-cover

	Excav.	Refill.	Concrete	Culverts	Misc.	Total
Assumed price	$10.32	$5.00	$34.48	.....	$1.00	$50.80
Contract price	12.10	5.45	35.19	$1.70	2.90	57.34

All types

	Cut-and-cover	Grade tunnel	Press. tunnel
Assumed price	$50.80	$90.00	$120.00
Contract price	57.34	98.25	141.10

Fig. 4 shows the typical cross-section of cut-and-cover aqueduct in rock trench, showing construction of cover embankment. Rock was usually excavated to a 6 on 1 slope, minimum thickness of concrete along sides 20 ins., but usually thicker owing to disintegrated condition of surface rocks.

Fig. 5 shows the typical cross-section of cut-and-cover aqueduct in loose earth and on foundation embankment and hydraulic elements of aqueduct, side slopes usually 1 on 1, in firm earth 6 on 1, and 20 ins. minimum thickness of side concrete, above concrete slope of 3 on 1 used.

Scarifier Used to Loosen Dirt for Irrigation Ditches.—According to Engineering and Contracting, April 5, 1918, a scarifier has been used successfully in breaking the earth for irrigation ditches on the 70,000-acre properties of the Crocker-Hoffman Land & Water Co. in Colorado. The scarifier pulled by a

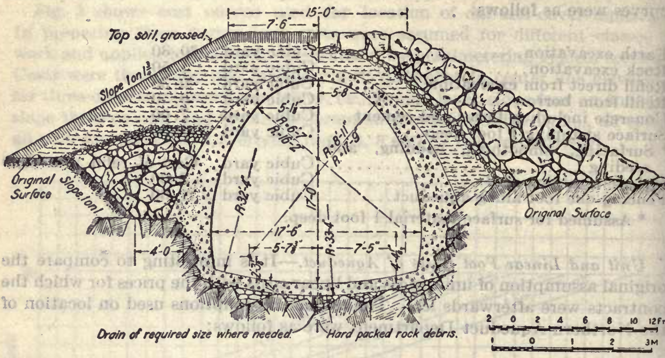

FIG. 4.

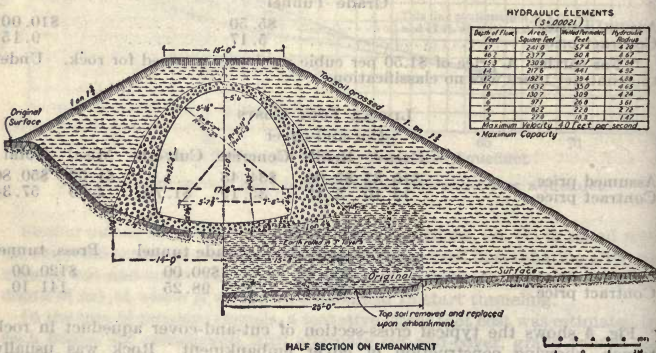
small size Caterpillar tractor loosened the earth and left it in shape to be scooped out by scrapers. Forty 4-mule teams were used to scoop out the dirt loosened by the tractor and scarifier. Prior to the use of this outfit, the dirt had been loosened by plows pulled by mule teams, five 10-mule teams



Depth of Flow, Feet	Area, Square Feet	Wetted Perimeter, Feet	Hydraulic Radius
17	241.0	57.4	4.20
16.2	237.7	50.8	4.67
15.3	230.9	47.1	4.84
14	217.6	44.1	4.92
12	192.6	39.4	4.88
10	163.2	35.0	4.65
8	130.7	30.9	4.24
6	97.1	26.8	3.61
4	62.2	22.8	2.72
2	27.0	18.8	1.47
Maximum Velocity 4.0 Feet per second			

FIG. 5.

being used. Each plow required three men to hold it, in addition to the driver of the teams. The cost of loosening the dirt by the plow method was $125 per day, with wages at $2.25 and mules at $1 per day. Under the new plan the cost was $18 per day—the cost for the tractor and operation.

Cost of Enlargement of the Main Canal Sunnyside Unit—Yakima Project, Washington.—E. A. Moritz and H. W. Elder, in Engineering and Contracting, Sept. 11, 1912, give the following data.

At the time the Reclamation Service purchased the system in 1906 the capacity at the intake of the main canal was about 650 c.f.s. and its designed cross-section was: Bottom width 30 ft., depth of water 6 ft. and side slopes 2:1. For the full supply flow at the intake the section had to be enlarged to a 46-ft. bottom width, 8 ft. depth and 1½:1 side slopes, giving a capacity of 1,076 c.f.s. A corresponding increase in section was required over the full length of 56 miles of the canal.

Methods and Costs of Enlarging the Main Canal.—The excavation of the canal demanded that certain requirements be met which controlled to a large extent the methods to be adopted. The principal controlling factors were the following: (1) A large portion of the work had to be done during the irrigation season which made necessary the use of a floating dredge or some type of excavator which could excavate under water from the banks. (2) The work on the upper half required a reach of about 70 ft. from the center of mass of excavation to the center of mass of waste bank. (3) The quantity to be excavated varied from about 1,200 cu. yds. per station at the upper end to 200 cu. yds. per station at the lower end, requiring, for economical work, that different methods be used for different reaches. (4) It was desirable to deposit most of the material on the lower bank, especially in the upper reaches, and furthermore it was generally impracticable to deposit on the upper side on account of the deep cuts.

After a careful study of available methods a combination was selected which involved the use of a floating dredge for the first 30 miles, a drag line excavator for mile 30 to 48 and team excavation for the remaining 8 miles. The final outcome of this program was that the floating dredge was run to mile 20.69 only as it was found that the drag line machine could do the work from mile 20.69 to 30 more economically. It was also discovered that, on account of the small quantities to be moved, team work was cheaper than drag line works below mile 43.4. Therefore, instead of the program as outlined the following resulted: Floating dredge mile 0 to mile 20.69; drag line excavator mile 20.69 to 43.4; and team work mile 43.4 to mile 56.

The concrete drop structures of which there are about 18 in the first 30 miles of canal had a clearance of only 32 ft. between the abutments, and as the dredge had to pass through these the hull could be only about 30 ft. wide out to out. The machine would nave been much easier to handle if it had had a wider hull. The machine used is a 3½ cu. ft. steam driven, continuous bucket elevator type with an 82 ft. × 30 ft. × 6 ft. 6 in. hull, drawing 5 ft. of water. Steam is furnished by two 80-hp. locomotive type boilers 44 ins. × 18 ft. Main drive and ladder hoist are driven by a 70-hp. 8 × 12-in. double horizontal engine. Winch machinery for spuds and for swinging the dredge are driven by a two cylinder, 20-hp. 6 × 6-in. double horizontal engine. Conveyors are driven by two 18-hp. 7 × 10-in. single cylinder horizontal engines. A No. 1 Hendy hydraulic giant supplied by a two-stage, 6-in. centrifugal pump, belted to an 80-hp. 10 × 12-in. single cylinder, upright engine, is mounted on the bow to remove banks above the water level and beyond the reach of the buckets. Conveyors are 72 ft. long and have seven-ply 32-in. rubber conveyor belting. The machine was furnished by the Bucyrus Co. of Milwaukee, Wis. It was operated from Dec. 1, 1909, to Oct. 1, 1911, and moved 921,000 cu. yds. of material.

The drag line excavator is a Lidgerwood-Crawford 1½ cu. yd. bucket machine with a 60-ft. boom. It is steam driven with a 48 in. × 114 in. vertical boiler and a 9 × 10-in. double cylinder engine. A 6 × 6-in. double cylinder engine is used to turn the machine. The machine was furnished by the Lidgerwood Manufacturing Co. of New York City. It was operated from April 20, 1909, to Sept. 27, 1911, and moved 804,200 cu. yds. of material. About three months of this time was consumed in moving the machine from mile 42.7 to mile 35.5.

Operations of Elevator Dredge.—The elevator dredge was built during the spring and summer of 1909 and began work in November of the same year, but owing to the fact that the machine was largely experimental and the material excavated was very hard, very little progress was made. A great deal of adjusting was necessary and many minor breaks occurred. No fair trial was made before the weather became so cold that little could be accomplished because of heavy ice. No water could be run in the canal because of team excavation which was under way at several points below. Water was held in bays by means of temporary dams built at several points above the team work. Attempts were made to break up the ice by blasting but it would form again so rapidly that almost no permanent good was accomplished. The machine closed down for two weeks during January, and by the time the ice had begun to break up the water had become very low in the bays and after a few days became so full of silt from constant agitation by the machine that it was almost useless as a steam supply.

Much excavation had to be done that, with running water of sufficient depth, would have been unnecessary, for the machine excavated in some cases 4 ft. below grade to keep clear of the bottom. No great amount of fresh water could be run in and the grade was such that sufficient depth to float the machine could not be maintained after the temporary dam at mile 1.30 was removed.

A great deal of difficulty was encountered in disposing of excavated material. So much water was carried over with the earth and gravel that a mud was formed which ran out into the adjoining fields and orchards, covering the original ground to a depth of several feet. Bulkheads were built along the right of way and an attempt made to hold the material. As the slope upon which the material was deposited was very steep, the material would fill to the top of the bulkhead in a short time and then run over into orchards. Higher and stronger bulkheads were built, but this was found to be very expensive. As the extremely wet material could not be held, the water jet which was played into the water buckets to aid in cleaning them, was removed. Then six ¾-in. holes were bored in each bucket to allow the water which picked up with the dirt to escape. This accomplished a great deal toward retaining the material on the right of way, but many bucketsful which in a saturated condition would have been dumped onto the conveyor, stuck in the buckets until they were loosened by the vibrations and released. This usually occurred after the hopper had been passed and the material was then dropped into the canal behind the digging line and had to be left to be excavated by other means later.

With the opening of the irrigation season the machine at once began doing better work. The material up to this time had been chiefly cement gravel, very compact chalky material, or compact wash gravel. Softer material was now encountered, and the weekly output increased from 2,000 to 14,300 cu. yds.

It was found desirable at this time to make some improvement in various parts of the machine. A larger pocket was put in the spud drive to insure greater power in sinking the spud foot. The position of the belt conveyor drive had been a great source of trouble as the drive sprocket was almost under the end of the conveyor drum and caught all the mud and water running off on that side. The sprocket was placed on the end of the shaft outside of the bearing, about 1 ft. from conveyor belt, thus affording a better opportunity for housing.

A great deal of trouble was caused when passing through deep cuts, by lack of dumping space. As built, the conveyor was fixed rigidly parallel to the spud arm. This necessitated depositing all the material excavated from one position into one heap. It was found necessary to have the conveyor swing over a greater arc. This was accomplished by removing the connection between the spud arm and the conveyor ladder and by fixing the conveyor rigidly to the deck forcing it to swing with the boat independently of the spud arm. Thus as the buckets made their swing across the canal, the conveyor covers an arc sufficient to distribute the spoil as desired.

As constructed, the spud sleeve was attached by rivets to the mast, but as this would not permit the raising of the spud arm a pinion hinge was put in with bolts replacing the rivets in the lower part of the plate allowing the spud to be loosened and raised readily.

After about nine months of operation the lower tumbler had become badly worn, and to reinforce it the hollow interior was filled wih cast iron. This added about 4,600 lbs. of weight to the exreme end of the bucket ladder and was probably to a considerable degree the cause of the breaking of the 12-in. I beams of the bucket ladder. After this accident 15-in. I-beams and a lighter tumbler reinforced with manganese steel wearing plates were substituted. The wearing plates had to be removed after six months use. It was found necessary to put similar plates on the upper tumbler but as the wear was not as great these plates did not have to be renewed.

About a week after the ladder was rebuilt with 15-in. I-beams these also broke. The cause of this was not definitely determined but it was probably due principally to a torsional moment. The great bulk of the material excavated was in the left bank and the buckets cut chiefly with the left side causing a twisting motion downward and to the left. This is undoubtedly a condition which should be provided for in the design of a machine for work of this kind.

The hull of the dredge was constructed only 30 ft. wide to permit it to pass numerous drops which had been built before the enlargement of the canal. This hull was too narrow for stability as practically all of the 200 tons of machinery was above the deck. The spuds, of course, served to maintain equilibrium except when raised as was the case when moving. On one occasion when the spuds were raised a man started out upon one of the conveyor ladders, causing the boat to tip. The crew lost control of the boat, which listed so far that water entered the hatches on the deck and caused it to sink. It took 12 days to get the dredge afloat and in working order. On another occasion the dredge was sunk, due to a hole being worn through the side of the bucket well by the returning buckets. This time ten days were lost in raising and repairing the dredge.

The typical sections shown in Fig. 6 show the relative positions of the masses moved by various methods. Much of the material was moved by teams during the last year of operation because it had been found that with the short haul the material not needed on the lower side could be disposed of more economically by team work on the upper side. The original plan had been to wash this material down with the giant and pick it up from the bottom with the buckets and deposit it on the lower side, but it was pulverized by this operation and spread out into the orchards as mud when carried across, which necessitated the abandonment of this process. The fills had to be built by teams ahead of the machine as otherwise much land would have been inundated when the old levee was cut out by the machine.

The statement of costs of the excavation done by the elevator dredge requires some explanation. The labor cost is low. The high cost charged to the item "spoil banks" is due to the fact that much of the material was deposited in the form of mud and ran over valuable farm lands and had to be hauled back when dry unless it had been retained by the expensive bulkheads built along the right of way. Another reason for the high cost of this item is that much of the material was deposited in high mounds which had to be graded down to permit ditch riders to travel over the levee.

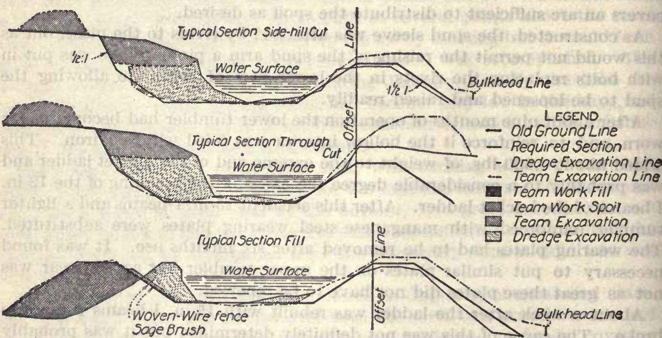


FIG. 6.—Typical sections excavated by elevator dredge.

The high cost of maintenance is due to the fact that much adjusting and many changes had to be made to adapt the machine to local conditions.

TABLE V.—COST DATA—ELEVATOR DREDGE WORK, 920,723 CUBIC YARDS

Item:	Cost	Unit cost
Excavation:		
Labor, dredge	$ 26,960.63	0.029
Labor, spoil banks	31,159.06	0.034
Fuel	33,043.07	0.036
Plant maintenance	52,327.40	0.057
Plant depreciation	41,432.53	0.045
Total	$184,922.69	0.201

Miscellaneous—Maximum excavation per 8-hour shift, 1,429 cu. yds.; maximum excavation for one week, 17,644 cu. yds. (three shifts); average excavation per 8 hour shift, 557.9 cu. yds.; average excavation actual working hour, 128.7 cu. yds.; per cent of lost time, 49; made up as follows: moving, 10 per cent; repairs and miscellaneous, 39 per cent.

Force and wages—An operating force consisted of 8 men and 4 horses.

Wages paid were—Operator, $5.00; engineer, $4.67; spudman, $3.83; fireman, $3.33; oiler, $3.00; deckman, $2.50; man and team, $4.50.

The depreciation item includes the entire cost of the machine charged against the total yardage. Everything except the hull should have considerable salvage value which will go toward reducing the cost.

Fuel had to be hauled about three miles across open country or over roads that were very rough.

One of the most gratifying results of this work is the solid lower bank produced by the saturated material discharged by the dredge and the substantial roadway over it. The trouble from breaks over this reach should be very small and maintenance charges will be correspondingly reduced.

Performance of the Drag Line Excavator.—The reach of the main canal between Miles 20.69 and 43.40 was excavated with a Lidgerwood-Crawford drag line machine. This machine was erected during January and February, 1909, and began operating at Mile 42.67 and worked down-stream to Mile 43.40. An attempt was; made at first to excavate from the lower side but was

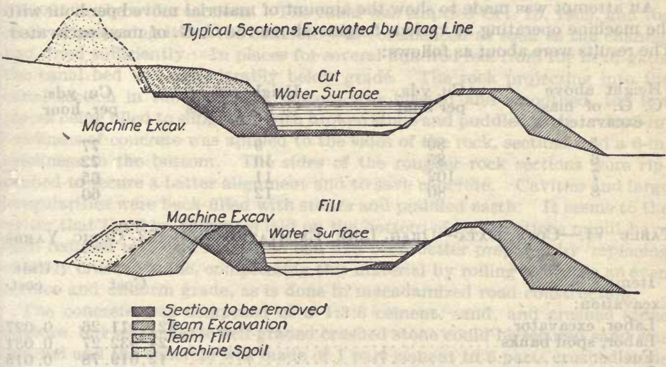

Fig. 7.—Typical sections excavated by drag line excavator.

unsuccessful because of the short boom and inability to sink the bucket into the narrow strip to be taken from the upper side. The machine was then dismantled and hauled to Mile 35.5 where operations were commenced from the upper side of the canal. A road had to be leveled ahead of the machine and all material not needed on the lower side was dumped on the upper side of the canal. The extra amount of road grading, not anticipated in the original schedule, and the additional work that had to be done to strengthen the levee caused the price per cubic yard to run higher than was anticipated.

A complete section, Fig. 7 was excavated from Mile 35.5 to Mile 38.3, but by the time the machine reached this point the demand for water over the lower parts of the project had become so great that it was decided to take out only about two-thirds of the material so as to allow the machine to move faster and increase the capacity over a greater reach of canal. It was found, however, that the machine moved very little faster when removing a two-thirds section, and that the cost per cubic yard was higher, so this plan was abandoned and a complete section was excavated throughout the remainder of the work. A great deal of team work had to be done in connection with the machine excavation. The profile of the upper bank was very irregular and in ravines the old levee had been almost, if not entirely destroyed. A roadway 18 ft. wide had to be built, and, as the grade could not exceed 5 per cent, the hills had to be cut down and the ravines filled up. Where the necessary cut on hills exceeded 5.0 ft., which is the distance from the base of track to bottom of engine car, the cut had to be 23 ft. wide to permit the car to swing and dump. In very deep cuts this placed the machine so far below the level of the natural ground that it was very difficult to dispose of the material because of the lack of dumping space. In some cases the road grading was 30 per cent of the entire excavation in cuts; and as the material was often hauled 200 ft. or more into the fill ahead the cost was high. The team cost was charged against the machine and the total cost distributed into the total yardage.

Much work was done on the spoil banks and in strengthening the levees and was all charged to the machine excavation. All repairs and maintenance costs are included in the item "Plant Maintenance." The item "Plant Depreciation" includes the entire cost of the machine.

An attempt was made to show the amount of material moved per hour with the machine operating at various heights above the C. G. of mass excavated. The results were about as follows:

Height above C. G. of mass excavated	Cu. yds. per hour	Height above C. G. of mass	Cu. yds. per. hour
5	80	9	77
6	85	10	72
7	102	11	65
8	80	12	60

TABLE VI.—COST DATA—DRAG LINE EXCAVATION, 204,183 CUBIC YARDS

Item:	Cost	Unit cost
Excavation:		
Labor, excavator	$21,411.26	0.027
Labor, spoil banks	24,932.27	0.031
Fuel	12,019.78	0.015
Plant maintenance	27,969.81	0.035
Plant depreciation	6,786.97	0.008
Total	$93,120.09	0.116

Force and wages—One crew consisted of 6 men and 2 horses.

Wages paid—Engineer, $4.00; fireman, $2.85; groundman, $2.00; man and team, $4.50.

Miscellaneous—Maximum excavation per 8-hr. shift, 1,170 cu. yds.; maximum excavation for week, 16,000 cu. yds.; average excavation per 8-hour shift, 545.5 cu. yds., average excavation per actual working hour, 93.7 cu. yds.

The excavation was done under water during seven months of the year and during the winter months when there was no water in the canal frost interfered with the work to a considerable extent. Due to the shape of the section the time consumed in lifting and swinging the bucket was probably considerably greater than on most excavation with an equal quantity of material to move.

Team Excavation.—From Mile 43.4 to the end of the canal and at other points where the material was too hard for the excavators to move the excavation was done by hand and teams. The total quantity moved of all classes was 583,400 cu. yds. at an average cost of 37.5 cts. per cubic yard. Most of this work was done by force account and under widely varying conditions.

Much of the material was of such a nature as to make its segregation into the different classes very difficult but approximate classification is as follows: Class 1—earth, 445,000 cu. yds.; Class 3—rock, 41,000 cu. yds.; Class 2—all other material, 97,400 cu. yds. All the work was done during the winter months and much frozen material which otherwise could readily have been plowed had to be blasted.

Cost of Concrete Lining for Irrigation Canals.—In a report by Samuel Fortier, U. S. Dep't of Agriculture, abstracted in Engineering and Contracting, Feb. 10, 1915, the following facts are given.

North Side Twin Falls Land & Water Co., Milner, Idaho.—This company lined 8,400 ft. of its main canal to increase its capacity. The canal is carried for several hundred feet along a rough lava rock cliff and is 60 ft. above low water in the river. The outer bank through this section is a concrete retaining wall. The remainder of the lined section is excavated almost wholly in solid lava. The grade varies from 0.001 in narrow places to 0.0002 and 0.00025 in the wider sections. The canal was emptied Oct. 10, 1909, and the work of preparing it for the concrete was commenced as soon as the channel had dried sufficiently. In places for several hundred feet from the head-gates the canal bed was considerably below grade. The rock projecting into the canal section in the sides and bottom was blasted and smoothed, the low places being filled to subgrade, with broken stone and puddled earth. An 8-in. thickness of concrete was applied to the sides of the rock, sections and a 6-in. thickness to the bottom. The sides of the rougher rock sections were riprapped to secure a better alignment and to save concrete. Cavities and large irregularities were back-filled with stones and puddled earth. It seems to the writer that the 6-in. thickness laid on the bottom of rock sections might have been reduced to 3 or 4 ins. if the bed had been better prepared by replacing of finely crushed stone, compressing this material by rolling to secure an even surface and uniform grade, as is done in macadamized road construction.

The concrete was composed of a 1:3:6 cement, sand, and crushed stone mixture, but whenever a well-graded crushed stone could be secured sand was omitted and the concrete was made of 1 part cement to 6 parts crushed stone from which all particles over 1½ ins. in diameter had geen excluded.

In earth sections the lining of the sides and bottom was 4 ins. thick and had side slopes of 1¾ to 1. Expansion joints of corrugated iron were inserted every 16 to 20 ft. along the sides and bottom except in the bottom of the rock sections. These joints consisted of pieces of corrugated iron cut into strips 4 ins. wide containing 1½ corrugations, these being designed to lock the edges of adjacent sections and to prevent slipping.

The side walls in the rock sections were supposed to have a slope of 1 to 4; but in many places where this would have necessitated the blasting of large amounts of rock, walls were made almost vertical. Heavy, collapsible forms of 2-in. lumber were used in placing concrete for the walls which approached the vertical. The concrete was wheeled directly from the mixers and spread in uniform layers 4 ins. thick over the bottom and on the sides of the easier slopes in earth sections. Concrete placed within forms made of 4 × 4-in. lumber was compacted by tamping and finished by working 24-ft. floats made of 2 × 6-in. timbers back and forth over the upper surface of the forms. Sixty cubic yards of concrete per day were sometimes laid in this way by one gang working under favorable conditions. The sides and slopes were finished with a coat of cement mortar whenever the surface was rough enough to warrant it.

The unusually high cost of this work was largely due to the difficulty of preparing the rock cut for the lining and to the absence of sand and gravel, which made it necessary to crush rock for the concrete. However, a greater factor than either of these was the added expense due to the necessity of prosecuting the work during severe winter weather. To do this the canal was roofed over for a distance of 2,000 ft. and the inclosed space warmed by specially constructed heaters, using sagebrush for fuel. The cost of labor and material was as follows:

Laborers, per day of 10 hrs.	$ 2.50
Drillers, per day of 10 hrs.	2.75–3.00
Engineers (steam), per day	3.00–4.00
Man and team, per day	5.00
Coal per ton, f. o. b. Milner	6.50
Cement per barrel, f. o. b. Milner	2.59–2.89
Cost of crushing rock, per cu. yd	1.10
Cost of labor for placing concrete, per cu. yd	2.75
Complete cost of material, mixing and placing concrete for form work only, per cu. yd	8.50
Same without forms	7.50
Cost of rock excavation (light cuts from 0.4 to 2 feet), per cu. yd.	5.00
Cost of placing riprap 1 foot thick, per cu. yd	2.00
Total cost of preparing 8,400 lin. ft. of canal for concrete	75,000.00
Gross cost of lining 8,400 lin. ft. of canal	200,000.00
Average cost of concrete, per cu. yd	8.00

Main South Side, or New York Canal, United States Reclamation Service, Boise, Idaho.—This canal is designed essentially to carry flood water from a point on the Boise River, nine miles above Boise, to the Deer Flat reservoir, a distance of 36 miles. Seventy thousand acres of land is also watered from the canal before the reservoir is reached. About 6½ miles of the canal was lined to prevent seepage, increase the carrying capacity, and for the safety of sidehill sections where breaks frequently occurred. The canal is an old one, originally built with side slopes of 1½ to 1, but the change and filling up of the section common to old canals necessitated considerable preliminary work in the removal of very gravelly earth and in shaping the sides before the concrete could be laid. The lined section has a grade of 0.00025 to 0.00032 and slopes of 1½ to 1. Forms of 4 × 4-in. lumber were placed upon the slopes and aligned, after which the surface between the forms was smoothed and thoroughly hand compacted. A uniform layer of concrete 4 ins. thick was then applied.

After heavy stripping, a good natural mixture of sand and gravel was secured adjacent to the canal. This was hauled by slip scrapers up a runway and dumped into the mixers, which were placed high enough to permit discharging the concrete directly into one-horse carts. The concrete was a 1:3:6 mixture of Portland cement, sand, and gravel. It was laid in sections measuring 8 × 16 ft. on the slopes and 8 × 16 or 16 × 16 ft. on the bottom. The lining was laid in alternate sections to make room for the workmen, and the upper sections were usually the first completed. As soon as the concrete of the first sections had set, the forms were removed and the intermediate sections filled in. Expansion joints of one thickness of tar paper were used between sections in part of the work.

After being dumped from the cars, the concrete was worked down and later smoothed by drawing long floats made of 2 × 6-in. timbers back and forth across the forms. In order to get a smooth face, the surface was painted with a 1 to 2 finishing coat of cement mortar as soon as the concrete was placed and set. The lining was kept wet by sprinkling for a period of seven days after being laid. It was protected from nightly freezes during the early part of the work by covering with a layer of straw, and during some freezing weather in the latter part of the work some concrete was laid under large tents heated by stoves. Some of the cost items are as follows:

Preparing canal section for lining, per lin. ft., approximately	$2.80
Hauling gravel to mixers, per cu. yd	1.14
Mixing and placing concrete, per cu. yd	2.20
Total cost of concrete, including cement, per cu. yd	7.70
Total cost of concrete in place, per lin. ft.	9.64
Cement per barrel, f. o. b. Boise	2.27–2.50
Common labor, per day	2.50
Man and team, per day	5.00

Northern Pacific Irrigation Co., Kennewick, Wash.—During the winter of 1910–11 this company lined 22,500 ft. of ditches on the "Highlands" at Kennewick to eliminate heavy seepage losses. The soil through which these ditches are built is principally a fine sandy loam overlying gravel at a depth of 18 ins. to 2 ft. One ditch 10,800 ft. long, 3 ft. wide on the bottom, with side slopes of ½ to 1 and a vertical depth of 26 ins., is designed to carry 18 sec.-ft. Another ditch having in part a bottom width of 3½ ft., side slopes of ½ to 1, and a vertical depth of 19½ ins. is designed to carry 14 sec.-ft. This ditch is reduced to a bottom width of 2½ ft., but with the same side slopes and depth as the upper part. The concrete used was a 1:3:4 mixture of cement, sand, and crushed rock.

In preparation for lining, center grade stakes were set and the bottom of the ditch brought to grade. Scantlings 2 × 4 ins. were then placed across the bottom of the ditch at 12-ft. intervals at right angles to the center line and flush with the subgrade. Three forms 12 ft. long were then set in the ditch on the cross strips and centered. Earth was shoveled and tamped behind the forms to secure the desired section. There were 14 men in a crew on this work.

After the earth sections were prepared in this way, 2 × 2-in. screeds were placed at intervals of 5 ft. 8 ins. and upon them forms 6 ft. long were set on every other space. The concrete was mixed with a one-third yard mixer, wheeled to place and dumped on planks laid on top of the forms. It was then shoveled behind the forms and lightly tamped. Strips of sheet iron were inserted behind the forms to protect the slope while the concrete was being put in and also to prevent a too rapid loss of water from the mixture by its contact with the drier earth. These strips were raised as the filling progressed. Two crews of 5 men each placed the concrete behind the forms, 2 men wheeled to each crew, and about 5 men were employed to move forms, etc. About 6 men were in the mixing crew and 2 others plastered rough places in the lining. Water kept in the finished ditch a few hundred feet in the rear of the work was pumped ahead to the mixer with a small gasoline engine.

The engineer stated that in one hour a crew could place about six sections, or 34 lin. ft., of the lining in the ditch having a 3-foot bottom.

Lower Yakima Irrigation Co., Richland, Wash.—The canal of this company parallels the Yakima River for several miles, where the earth sections run mainly through coarse gravel, boulders, or shattered basaltic rock. The remainder of the system is very largely built through sand. In the unlined channel the seepage losses were excessive, and through the sand it was also difficult to maintain the ditch owing to its tendency to fill up both by drifting and on account of the flat side slopes which the sand naturally assumed under the action of water. The lining was intended, therefore, not only to reduce the loss of water, but to increase the carrying capacity of the ditch and render it more stable and easy to maintain. About five miles of the ditch was lined in 1910. The company furnished all materials used and prepared the channel for lining, but the other work was done by contract.

In preparing the ditch, center stakes were set about 1½ ins. above grade, to which the excavating was roughly done with teams and scrapers. At intervals of about 25 ft. along the bottom of the side slopes stakes were set to grade, and from these the top slope stakes were set by the use of a slope triangle. Nails were driven into the grade stakes and chalk lines were stretched on them parallel to the ditch. Trimming to these lines was done then with square-pointed shovels and the slopes and bottom scraped to smooth surfaces with straight edges. The sides and bottom were tamped lightly with wooden tampers and sprinkled before the lining was applied. The section lined has a bottom width of 11½ ft., side slopes of 1½ to 1, and a wetted perimeter of 26½ ft.

The three mixers used were operated on planks in the bottom of the ditch in advance of the work. With each mixer there was a crew of about 25 men and in addition a finishing crew of 5 or 6 men to dress the earth surfaces immediately ahead of the mixer. One rock crusher was also operated, the crushed rock being hauled an average of 2 miles. Most of the sand was procured from pits along the line of the canal and was used without screening. The lining was laid in 8-ft. sections 1¾ ins. thick, with strips of building paper in the joints between the sections. Four hundred feet of lining was considered a good day's work for a crew. A 1:3:4 mixture of concrete was used for most of the lining, but on one section a 1:4 mortar applied 1 in. thick was considered just as good as the thicker lining of concrete, besides being much easier to apply.

The lining in gravel sections leaked considerably the first season, presumably because allowed to dry too rapidly on account of lack of water for keeping it moist after laying. In work that was done the following year this difficulty was obviated by allowing a small amount of water to flow in the ditch soon after lining, using check dams to prevent its interference with construction. Men wearing rubber boots then waded along and with shovels or buckets threw water upon the side slopes at frequent intervals to keep the concrete wet while setting. Where lining had been placed on moistened sand, the results were better than in the sections through gravel, there being no perceptible leakage. Conditions in the gravel portion improved with the first year's use of the lined sections, after which the seepage was considerably lessened. The various items of cost secured are as follows:

Laborers per day of 10 hours, without board	$ 2.50
Man and team per day, without board	4.50
Contract price per sq. ft. for mixing and laying concrete	.025
Cement per barrel*	3.10
Sand per cu. yd., approximately	.50
Total cost of lining, per sq. ft	.065
Total cost of lining	9,064.49

*This does not include an 8-mile haul over heavy roads.

During February and March, 1911, the company placed additional lining, using practically the same methods above described, except that all work was done by force account. The prices for labor and material indicate that the work was done considerably cheaper than in the previous year. Laborers were procured for $2 per day without board and men with teams for $4 per day each. Cement cost $2.95 per barrel delivered at the work.

Belgo-Canadian Fruit Lands, Kelowna, British Columbia.—About 3,000 ft. of this company's main canal, 11 miles long, and about 4 miles of its lateral ditches have been lined with concrete to prevent seepage losses in a porous soil. On the main canal a 3-in. thickness of lining has been used for a finished section having a bottom width of 3.5 ft., depth 3.75 ft., and side slopes of ½ to 1. Lateral linings are 2½ to 3 ins. thick on slopes, with a 3-in. thickness on bottoms which vary in width from 9 ins. to 2 ft.

After excavating the channel to be lined, a drain filled with loose rock or gravel was made beneath the bed. Cross drains from this through the lower bank were placed at 500-ft. intervals. The forms were then set and bolted together. Galvanized-iron plates placed outside the forms were spaced with pieces of lumber, and after the earth was back-filled and tamped behind the plates concrete was poured between them and the forms. The galvanized plates and spacing pieces were withdrawn as the space was filled with concrete, The bottom of the ditch was then floated in and the edges smoothed, using for this purpose the excess concrete which had passed over the forms. The forms were left in place 48 hours.

Curves were made by using special short forms having the outer edge superelevated ½ to 1 in. according to the degree of curvature. In placing the concrete around sharp curves, special galvanized plates were used to close the gap at the outer edge of the forms.

No cost data could be secured on the lining of the main canal. The cost of lining laterals per square foot and exclusive of excavation varied from $0.118 in the larger to $0.142 in the smaller ones. These costs include excavation, back-filling, rock drains and supervision. The work was done late in the fall when protection against frost increased the cost. Cement cost $3.75 per barrel delivered, common labor $2.75 per day, and skilled labor $4 per day.

Tucson Farms Co., Tucson, Ariz.—The water for this project is obtained by pumping from numerous wells. During the winter and spring of 1912–13 a reinforced concrete lining was placed in about 2½ miles of the new main canal for the prevention of seepage losses through a sandy and gravelly soil. The canal has a trapezodial cross section entirely in excavation and as lined is capable of carrying a 2.9-ft. depth of water. The bottom width ranges from 2 to 4¾ ft. and the side slopes are 1 to 1. The greater part of the concrete used in this construction is a 1:4:4 mixture and the lining is 3 ins. thick throughout.

In grading the channel for lining, a framed template was used to get a true section. The reinforcement is made of round steel bars intersecting at right angles and wired together. Four longitudinal bars, 5/16 in. diameter, were placed one on each side of the bottom for the lining floor and one on each side near the top of the side walls. Then at right angles to these, as stated, ¼-in. crossbars were spaced 12 ins. apart. Each crossbar was continuous and extended from the top of the lining on one side through the lining to the top of it on the opposite side of the canal. When it is not possible to obtain the ¼-in. bars, 5/16-in. bars were substituted and spaced 18 ins. apart.

Wooden-framed forms built in 12-ft. sections were then set in position over the steel reinforcement, blocked to place, and the adjoining ends bolted together. Then ⅛-in. steel backing plates, 2 ft. wide and long enough to reach to the bottom of the earth section, were slipped behind the forms and under the reinforcement. Before placing the concrete, wooden spreader-strips, 2 × 3 ins. were set between the wooden forms and the backing plates. Each spreader contained a staple driven almost full length into its side near the bottom, and in setting the spreader the staple loop was slipped over the end of the crossbar and the spreader was then slid into position. In this way the bar was carefully held in position while the concrete was being placed in the forms. A spreader was set beside each crossbar, and as the concrete for the side lining was tamped and puddled into place the spreaders were gradually removed, leaving the crossbars firmly embedded in the concrete. The steel plates likewise were withdrawn as the walls were built up. When the side forms were filled with concrete to within 3 ins. of the top, the longitudinal bars were placed and wired to the crossbars. The remaining concrete was then placed and smoothed with an edging trowel.

Expansion joints were provided by setting 1 × 3-in. wooden strips in the middle of each form in the same manner as the spreaders, except that no staples were used and the joint strips were not removed afterwards. To keep them in position while concrete was being deposited, each one was lightly nailed to the side of the form, aud before the latter was removed the nails were withdrawn. The forms were left intact for a period of 8 hours at least, and they usually remained undisturbed over night during a period of 14 to 20 hours. After their removal any defects in the wall surface were "picked" out and the cavities smoothly plastered with a 1:1½ or 2 cement mortar.

The canal bottom was then carefully cleared of litter, its surface smoothed, and solidly tamped. All reinforcement bars that may have become bent were straightened. The bottom piece of the expansion joint was fitted to the two side pieces and its top carefully laid to grade. The concrete for the floor lining was then tamped and puddled into place, and when it had reached the required thickness the surface was easily brought to grade and smoothed by the use of a straightedge resting on the bottom joint strips as guides. The entire lining was kept wet by continual sprinkling during a period of three to five days. After this was discontinued a wash coat of neat cement mortar was applied to the surface with a brush.

A 1 : 4 : 4 mixture of concrete was used on all the work except for about 1,000 ft. of bottom where there was excessive external water pressure. In this portion of the canal a 1 : 3.2 : 3.2 mixture was used. As a further protection in one very wet and miry place, additional reinforcement was used in the bottom. Extending over a length of about 5,000 ft. of the largest canal section near the Santa Cruz River bed, "weep holes" were formed in the bottom to relieve external water pressure. Two-inch tapering plugs extending entirely through the lining floor were set in the freshly laid concrete and these plugs were later removed as soon as the concrete had set sufficiently to retain its shape. Two rows of these holes were made 2½ ft. apart and spaced 4 ft. longitudinally. During construction a considerable portion of the canal was drained. A line of 8-in. tiling was laid in the bottom and pumps attached thereto were installed at intervals of about 1,000 ft. to withdraw the accumulated water.

The contractor received $12.50 per cubic yard for the finished concrete lining, using slab measurement. This included all costs except the original purchase price of the steel reinforcement. However, no excavation was included and the company paid extra for the wash coat. The contractor rented a rock crusher and delivered the rock. Sand was obtained from the river bed.

All concrete was mixed by hand and transported in wheelbarrows.

The work was performed with gangs of about 30 men, paid for a 9-hour day, as follows:

1 foreman	$4.00
Mixing boss and 2 plasterers	2.50
2 water boys	1.00
25 men	2.00

The gang was used in the following manner: Eight men on mixing board, 2 tampers, 2 men pulling plates and spreaders, 2 men setting forms and putting in expansion joints, 2 men laying steel reinforcement, 14 men transporting and depositing materials and concrete, finishing, screening sand, etc. The forms were usually all moved at one time and the whole force engaged on that work. It required this gang 21 days to place lining in 3,000 ft. of canal in dry excavation having a bottom width of 3 ft. The cost to the contractor was distributed as follows:

Labor, including the building of forms	$1,297.83
1,712 sacks ofment, at $0.81 each	1,386.72
232 cu. yds. of rock, at $1.75 per cu. yd	406.00
232 cu. yds. of sand, at $0.75 per cu. yd	174.00
Lumber in 15 sections of 12-ft. forms, 3,900 ft. B. M., at $30 per M.	117.00
Lumber for expansion joints, 750 ft. B. M., at $30 per M	22.50
Lumber for spreaders, runways, etc., 750 ft. B. M., at $30 per M	22.50
Water purchased from the city of Tucson, 21 days at $2	42.00
Hauling steel reinforcement	10.00
Depreciation of plant, breakage of tools, etc	20.00
Office expenses and expenses of contractor and superintendent, amounting to about $2 per day for this gang, 21 days	42.00
Total	$3,540.55

Computations made on the above basis for 298.9 cu. yds., the cost was $11.845 per cubic yard. However, there were in addition the following costs to the Tucson Farms Co.:

9,300 lbs. of steel, at $0.04	$372.00
One coat of cement wash, 34,500 sq. ft., at $0.0025	86.25
Engineering, about 5 per cent	195.00
Total	$653.50

On this basis the actual cost of the completed lining was $14.03 per cubic yard.

Cost of Lining an Irrigation Canal With Concrete.—In a paper by E. M. Chandler, before the Washington Irrigation Inst., and abstracted in Engineering and Contracting, June 2, 1915, the following data are given.

The canal lined was a used canal of the Burbank Power & Water Co., Burbank, Wash. Construction methods were carefully planned in advance and followed without variation. The canal bed was settled with water for two weeks, the canal being divided into short compartments, and water permitted to run from the upper compartments to the lower for filling.

After canal settlement, line and grade stakes were set every five feet, each stake being a hub with center marked and its top set to the final concrete grade. The pre-determined width of the strips was 5 ft. The pre-determined thickness of concrete of lining was 0.2 ft., the base 6 ft., depth of canal 3 ft. and side slopes 1½ to 1—the carrying capacity being 60 sec. ft.

With the line and grade set once and for all, templates were constructed having the exact thickness of the proposed lining and the exact shape of the finished canals. With the line and grade stakes and a carpenter's level, it was possible for the workmen to trim the sub-grade precisely as it should be. This work was carried on a few hundred feet in advance of the canal lining. Accurate work at this point was very essential to secure uniform thickness of lining.

Sand and gravel, after being run through a 1½-in. rotary screen, was found in natural proportions about one mile from the center of the work. This was hauled by contract at $1.75 per cubic yard measured in the finished lining and placed in piles above the canal 150 ft. apart and 15 ft. back from the slope of the canal, the slope of the ground above the canal not being very great. Experience subsequently proved that the piles of gravel might better have been 200 ft. apart.

Two steam driven concrete batch mixers mounted on trucks and equipped with side loaders were started at the center of the canal to be lined (8,250 ft.) each working away from the other and endeavoring to obtain its end of the lining first. The mixers were moved from pile to pile on plank runways and pushed by the men—the mixers being on the upper side of the canal at all times and passing between the canal and the line of piles of gravel. For each mixer outfit, a movable trough or chute was provided for taking the discharge of the mixer and depositing it in the concrete carts in the bottomof the canal. The lining was laid at two points for each mixer, starting 75 ft. on each side and working toward the mixer. Plank runways in the canal bed were provided and one concrete cart for each laying gang was employed.

The mixture was made on the basis of 1 bbl. of cement to 1 cu. yd. of finished concrete, or about 1 to 7, and made as wet as the side slopes would permit. Two men in each laying gang placed the concrete roughly with square pointed shovels, one man helped dump the concrete carts in the bottom of the five-foot-strip being lined, and between times made ready the next strip and dampened the subgrade, while a fourth man in each laying gang trowelled the rough concrete into the finished shape.

Three men were required for each mixer to supply the raw materials to the machine, one man for fireman and engineer, one man to dump the mixer, and one man to hoe the concrete down the chute. An additional man covered the finished lining with wet burlap strips and kept moving them forward.

The water was hauled 1½ miles on the average by three four-horse teams hauling 400-gal. tanks on wagon trucks. The exact amount of coal required at each setting was pre-determined and left there in advance in sacks. The laying of this 8,250 ft. of concrete lining was completed in 14 working days. As much as 900 ft. in one day were accomplished. The men became very skillful in moving the machines and were able to lose not over 15 minutes time at each moving. The cost of the actual concrete was as follows:

	Per cu. yd.
Sand and gravel	$1.75
Cement delivered	2.65
Water	.25
Coal	.10
Labor mixing concrete	.65
Labor laying concrete	.88
Superintendence	.31
Total per cubic yard	$6.59

In addition to the above, the cost of equipment less its salvage value, was 32 cts. per cubic yard, the cost of trimming the canal bed was 72 cts. per cubic yard and the engineering was 32 cts. per cubic yard. This made a grand total of $7.95 per cubic yard or $1.10 per linear foot of canal.

The cost of cement was $2.25 per barrel f. o. b. Burbank, common labor was paid 25 cts. per hour with a bonus of 2½ cts. for staying until the job was finished, and the finishers and firemen were paid 27½ cts. per hour with a bonus of 2½ cts. under the same conditions. With but few exceptions, we were required to pay the bonus, and it was a good investment, as it overcame the great demoralizer of day labor work of this kind—constant changing of personnel. The incentive to do fast work was created by the two mixer gangs racing for the finish.

Cost of Concrete Lining Irrigation Laterals, Orland Project, U. S. Reclamation Service.—The following is an extract, published in Engineering and Contracting, April 12, 1916, of an article by A. N. Burch, in the "Reclamation Record" for April, 1916.

To February, 1916, there had been lined about 22 miles of laterals on the Orland project, in sections ranging from a few feet in length and requiring less than a cubic yard of concrete to a maximum section of 8,800 ft. The cross sections of the laterals lined have ranged from a bottom width of 2 ft. and vertical depth of 1 ft. to a bottom width of 8 ft. and vertical depth of 4½ ft.

Laterals originally designed for lining were built with 1 : 1 bank slopes; other laterals with 1½ : 1 and 2 : 1 slopes. On the distribution system covering the 6,000 acres recently taken into the project all laterals were designed for lining, where a reduction of cross sections and the elimination of drops would justify this course, as compared with building a larger earth section and installing the necessary drops to reduce the grade.

On the project generally, lining has been placed in all fills; in the small laterals acquired from the old Stony Creek company and located within highway boundaries, for the purpose of increasing their carrying capacity and reducing maintenance; in sections where seepage was excessive; as a protection over storm culverts and on curves; also at forks of laterals where, because of the number of structures, it was difficult to clean with teams.

For the longer stretches of the work a 4-cu. ft. mixer, driven by a 3-hp. gas engine, all mounted on trucks, is used; for the short stretches small hand-mixing crews are employed. The aggregates used are run of bank material obtained from creeks in the vicinity of Orland. The proportions of mix are approximately 1: 3: 5, giving 1 cu. yd. of concrete in place of 1.1 bbl. of cement.

The mixer crew is made up of a foreman, with about 30 men and 2 teams. Nine men are employed at the mixer in wheeling and in placing and finishing, and from 18 to 20 men in trimming the slopes and preparing the bottom for receiving the lining. One team is employed in hauling cement and one in hauling water and miscellaneous work. When it is possible to do so, water is run in the laterals and kept close behind the lining crew, thus reducing the distance of haul to the mixer and simplifying the process of wetting the completed work. No special tools are used in preparing the slopes and bottom for lining, the work being done with mattocks, picks, and square-ended shovels.

The mixer is usually set up at the side of the lateral in the center of a 500-ft. section, making the maximum wheel for concrete 250 ft., which was found to be about the greatest economical distance to which the material could be wheeled. As most of the lining is placed in fills, trenches are cut through the ditch banks to admit of a wheeling plank, which, when placed, lands on a small turning platform, from which an incline leads to the bottom of the lateral, and to additional boards on which the material is wheeled to the placers.

End-dump barrows are used, and the material is dumped into a mud box, from which it is shoveled to the slopes.

The mixing crew is made up of one mixer operator, two shovelers for charging the mixer, three wheelers, and three placers and finishers. Of the latter, No. 1 places the concrete to the required thickness (being guided by a templet), No. 2 compacts the material and finishes it roughly with a square-ended shovel, and No. 3 gives the final finish with a 5 by 18-in. long-handled Arrowsmith trowel, finally cutting the expansion joints with a straight-edge and pointing trowel and smoothing them up with a grooving tool. Before placing the lining the slopes are thoroughly wet by means of a force pump attached to a water wagon, and the finished lining is kept wet from 3 to 5 days, depending on weather conditions. The average daily output of the mixer force is 25 cu. yd., and the maximum 30.3 cu. yd.

For short stretches of lining hand-mixing forces of about 12 men each are employed. From 5 to 7 men are employed in mixing and placing, and about an equal number in preparing the slopes and bottom for receiving the lining. The same equipment and about the same arrangement are used in the operation of these crews as is the case with the mixer, except that the mixing board is placed on timbers which span the lateral, the aggregates are wheeled on to the board, and the concrete shoveled into barrows in the bottom of the ditch, there being no incline over which to wheel the material. These gangs average about 12 cu. yd. per day, and when there has been a full day's run without any long moves have made 15 cu. yd.

There is little difference in the cost of lining whether the material be hand or machine mixed, although the machine turns out a better and more uniform grade of concrete.

From October to June climatic conditions on the Orland project are very favorable for this kind of work, as there are no temperatures low enough to affect the concrete adversely, and moisture conditions are usually such that the lining can be cured properly with little expense for wetting. During the summer months moisture conditions are reversed, and because of the thinness of the lining it is necessary to wet it from two to four times per day until it is properly set. Following are unit costs and related data:

Cost per Square Yard

Cement delivered on work	$0.0957
Gravel delivered on work	.0408
Mixing concrete	.0314
Placing concrete	.0294
Sprinkling and protecting	.0046
Preparing section for lining	.0697
Field superintendence and engineering	.0010
Maintenance of equipment	.0022
Plant arbitrary	.0043
Total labor and material	$0.2791
General expense	.0639
Total cost to United States	$0.3430

Thickness of lining, 1½ inches. Total placed in square yards, 191,400. Total in cubic yards, 7,900. Cost per cubic yard, $8.26. Average haul (round trip), gravel, 5 miles. Average haul (round trip), cement, 6 miles. Foreman, $3.20 per day to $95 per month. Finishers, $3 to $3.20 per day. Laborers, $2.40 to $2.60 per day. Teamsters, with teams, $4.50 to $5 per day. Cement, $2 per barrel. Gravel, $1 per cubic yard. Lumber, $14 to $22 per M. B. M.

Cost of Concrete Lining of Canals and Tunnels of the Natches-Selah Irrigation Works.—Public Works, April 3, 1920, gives the following:

The Natches-Selah Irrigation System in Yakima Valley, Wash., serves about 10,500 acres of orchard land by a conduit carried through a mountainous region in tunnels, flumes and canals. The work includes the reconstruction of about 3 miles of the original water-way and the building of nearly 4 miles of new structures and was executed on the cost-plus-fixed-sum basis.

The flumes and the canal linings were made with concrete mixed with aggregate from a bar in the stream, crushed when necessary, and delivered to the mixers at various plants located at convenient places for the different sections of the work.

Canal Lining.—The canal, some of which is a revision of the old canal, has a regular cross-section so as to conform as nearly as possible with average conditions and made with sloping sides and bottom covered with 3 inches of concrete reinforced by 12 × 12 inch Clinton wire mesh made with No. 12 wire embedded 1½ inches from the surface. Transverse construction joints 5 feet apart longitudinally were scored ½ inch deep to fix contraction cracks.

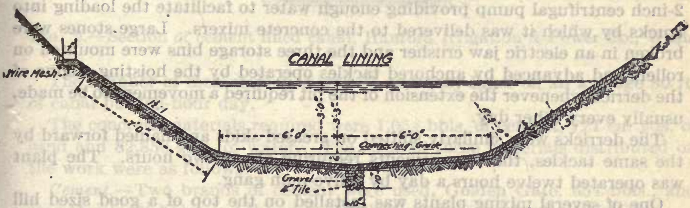

FIG. 8.—Standard cross-section of canal.

In general the canals are in adobe or other soil that retains the moisture and on previous work has caused much trouble with frost. In order to prevent as much as possible temperature cracks the 1:2:4 concrete was placed in cold weather so that any cracks will close by expansion in summer time.

The wire mesh in rolls a little more than 6 feet wide was laid in longitudinal strips, two on the bottom and one on each side, and tied together on the edges with wire projections from the sides of the strips. The concrete was placed in two courses, plastered on the bottom and sides of the canal like mortar with the reinforcement placed on top of the first course and covered by the second course.

Aggregate and cement bags delivered alongside the canal by motor trucks were stored in heaps adjacent to the portable mixers with elevating charging hoppers that were moved at frequent intervals as the work progressed. The mixers discharged through open chutes supported at the lower end on light wooden towers where the discharge was controlled and the concrete delivered to two-wheel carts, pushed by hand over plank runways, dumped as required and shoveled and raked to position.

The cost of preparing the subgrade and building the lining averaged $2.66 per linear foot, equivalent to $0.66 per square yard of surface. The cost of the concrete lining in place including the reinforcement was $5.79 per linear foot, allowing $23.16 per cubic yard for concrete. Laborers received from $4.50 to $6.00 per day and were of inferior quality.

Tunnels.—The tunnels have a horizontal floor, vertical side walls and segmental roofs with 2-foot rise. The uniform width of 7 feet was the most practicable minimum for construction operations and the height of the side walls varied from 4½ to 5 feet, according to grade. Except in timbered sections the concrete lining was generally 6 inches thick with a 4-inch floor over rock bottom.

With one exception, of a tunnel only 1,082 feet long which was through cemented gravel and large boulders, all of the eight tunnels aggregating 8,718 feet in length, were driven through soft dry sand-stone or shale in which the holes for blasting were made with coal augers. The tunnels were driven in full size headings. At one time the double shifts on the double headings of five tunnels required twenty gangs that made an aggregate advance of 140 feet per day. The muck was hauled by mules and the tunnel was lined as soon as possible, because, although the rock stood well when first blasted, a long exposure made it very treacherous.

Concrete Plant.—Concrete was made with sand, gravel and crushed stone all dredged from the river bed with a 1½-yard dragline bucket operated from a 60-foot derrick boom. The sand was washed through the screens by a 2-inch centrifugal pump providing enough water to facilitate the loading into trucks by which it was delivered to the concrete mixers. Large stones were broken in an electric jaw crusher and the three storage bins were mounted on rollers and advanced by anchored tackles operated by the hoisting engine of the derrick whenever the extension of the pit required a movement to be made, usually every other day.

The derricks were similarly shifted on greased skids and hauled forward by the same tackles, these movements requiring about two hours. The plant was operated twelve hours a day by a five-man gang.

One of several mixing plants was installed on the top of a good sized hill that enabled the trucks to dump aggregate directly into the storage bins which delivered by gravity to the two-bag machine that was operated by one man and discharged through an open chute 150 feet long terminating with a spout to the portal one hundred feet vertically below it.

Tunnel Lining.—Two 6 × 2-inch longitudinal strips of concrete were laid on the sides of the tunnel floor to support the wall forms and after the invert between the strips was concreted, the sectional wooden forms that were removed before the wooden arch forms were set, were wedged to position. The 4-foot sections of arch were concreted and rammed in about one-half hour by a four-man gang. The total cost of lining exclusive of engineering, including cost and contractors' compensation, was $103,834 averaging $23 per cubic yard. The total cost of the finished tunnels was $175,307, averaging $20.10 per linear foot. The inefficient labor received $4.50 per day.

Cost of Concrete Lining Irrigation Canal.—An article in Engineering and Contracting, Jan. 1, 1913, by A. T. Petheram, gives the following:

The general dimensions of the canal section are shown in Fig. 9.

The volumes of concrete in lining were 13,502 sq. yds., and 766 cu. yds., the mixture being a 1:6 cement and sand. All mixing was done by hand on 4½ × 10 ft. mixing boards set on the ditch bottom and moved by hand. Sand, water and cement were delivered on the upper side of the canal; the sand was measured in boxes containing 1 cu. ft. and dumped in trough to mixing board. Water was hauled in 650-gal. tanks an average distance of 2¾ miles, and was delivered in barrels to each mixing gang. Each batch was turned over twice dry, water was added and the wetted mixture was turned twice. A mixing gang consisted of 7 men as follows: 4 mixers, 1 top man to deliver sand and water, 1 assistant trowel man, and 1 trowel man, who also acted as foreman. The wages paid for labor were as follows, the rates per hour being for a ten-hour day:

Inspector, per day	$ 5.00
Foreman, per month	125.00
Timekeeper, per month	75.00
Cook, per month	98.00
Carpenter, per hour	35 cts.
Sub-foreman, per hour	27½ cts.
Trowel man, per hour	30 cts.
Team and driver, per hour	50 cts.
Common labor, per hour	22½ cts.

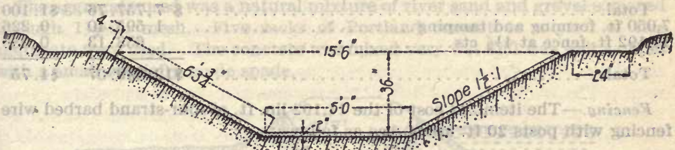

FIG. 9.—Section of cement lined canal, Hanford Irrigation & Power Co., Wash.

The number of men employed was 75 and they lined on an average 80 ft. of canal per ten-hour day.

The concrete materials required were 1,054 bbls. of cement, 771 cu. yds. of sand and 82,850 gals. of water. The costs of these materials distributed on the work were as follows:

Cement.—Two brands of cement were used, Golden Gate, 654 bbls., and Red Devil, 400 bbls., and the costs distributed on the work were as follows:

Item	Golden Gate	Red Devil
Cost, f. o. b. Kennewick	$2.75	$2.60
Drayage at 40 cts. per ton	0.076	0.076
Boat to Hanford at $3 per ton	0.57	0.570
Hauling to job, $1.50 per ton	0.285	0.285
Distribution	0.037	0.037
Total	$3.718	$3.568
Credit, 4 sacks at 10 cts	0.40	0.40
Net cost per barrel	$3.318	$3.168

The total cost for cement distributed on the job was therefore:

654 bbls. at $3.318	$2,170.20
400 bbls. at $3.168	1,267.44
Total	$3,437.64

Water.—The cost of water was the cost of handling 82,850 gals., which was $693.04, or slightly less than 0.85 cts. per gallon.

Sand.—Sand was secured on the company's property and its only cost was for hauling an average distance of 0.85 miles in loads of 1 cu. yd. This cost was $1,079.62. A total of 771 cu. yds. were hauled and 766 cu. yds. were actually used; the corresponding cubic yard costs were $1.40 and $1.41.

Lining.—The cost of lining, including materials as listed above and labor of all kinds, was as follows:

	Total	Per lin. ft.
Excavation		
2,230 cu. yds. earth at 33 cts	$ 735.34	$0.104
400 cu. yds. gravel and loose rock at $1.39	556.71	0.079
660 cu. yds. solid rock at $1.62	1,070.72	0.152
Total	$ 2,362.78	$0.335
Concrete		
1,054 bbls. cement at $3.262	$ 3,437.64	$0.488
771 cu. yds. sand at $1.40	1,079.62	0.153
62,850 gals. water	693.04	0.098
Mixing and placing 766 cu. yds. at $3.33	2,547.46	0.361
Total	$ 7,757.76	$1.100
7,050 ft. forming and tamping	1,595.40	0.226
14,192 ft. fence at 4½ cts	633.13	0.089
Totals	$12,349.07	$1.75

Fencing.—The itemized cost of the 14,192 lin. ft. of four-strand barbed wire fencing with posts 20 ft. apart was as follows:

Barbed wire, 3,168 lbs. at $2.85, f. o. b. Portland	$ 90.29
Freight, Portland to Hanford	21.72
Posts, 705 at 8 cts., f. o. b. Coyote (720 ft. B. M. at $22)	15.84
Timber for braces, 4 × 4 ins. (1,295 ft. B. M. at $23)	29.80
Staples, 210 lbs. at 10 cts	21.00
Miscellaneous material	3.58
Handling and hauling	85.67
Labor (common)	140.29
Surveying and proportionate camp charge	190.26
Total	$633.13
Cost per lin ft. of fence	$00.045
Cost per lin. ft. of canal	0.089

Concrete in Place.—The cost per cubic yard and per square yard of concrete lining in place was from the above costs as follows:

	Total cost	Cost per cu. yd.	Cost per sq. yd.
Cement	$3,437.64	$ 4.49	$0.249
Sand	1,079.62	1.41	0.078
Water	693.04	0.90	0.050
Mixing and placing	$2,547.46	3.33	0.185
Total cost	$7,757.76	$10.13	$0.562

Cost of Concrete Lined Ditch.—The following notes by C. D. Conway are taken from Engineering Record, Dec. 30, 1916.

The irrigation system of the Los Molinos Land Company, in Tehama County, California, comprises 120 miles of ditches with capacities ranging from 5 to 100 sec.-ft. In the main canals and primary laterals, where the water is running constantly during the irrigation season, the seepage losses average less than 1 per cent per mile. In the secondary laterals, in which the water is running only at intervals, the losses are as high as 50 per cent per mile. This excessive loss is owing to the character of the soil through which these laterals pass—a Sacramento silt loam underlain with gravel in which vegetation grows very rapidly and gophers thrive. As the cost of maintenance and the loss of water are very high the company is lining these ditches with concrete. During the spring of 1916, 4,000 ft. was lined.

Instead of reducing the size of the earth ditch, the writer decided to excavate a new ditch within the bank of the existing one, as shown in Fig. 10. Stakes were set at the outside edge of the base. That section was taken out vertically, after which two men with templates trimmed the bottom and sloped the sides. Grade stakes were set every 16 ft. Movable wooden forms in 16-ft. lengths were used.

The concrete was mixed by hand on a board large enough for 1-yd. batches. The platform was built on runners and moved along the ditch for each batch, the gravel being distributed far enough from the ditch to leave room for the board to pass. Water was hauled in a wagon, and the same team moved the mixing board. Six men were employed in mixing and placing the concrete with buckets.

The aggregate used was a natural mixture of river sand and gravel screened through 1½-in. mesh. Five sacks of Portland cement to a yard of this aggregate were used. The concrete was mixed very wet and was well worked with a small specially made spade.

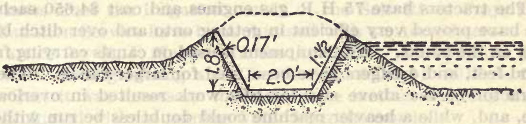

FIG. 10.—Section of new ditch excavated in bank of old one.

Expansion and contraction were provided for by placing ⅜-in. pine boards between forms. These were afterward broken off flush with the concrete. Though the temperature reached 110 deg. Fahr. in the shade at a time when the ditch was dry, no cracks have been noted.

Costs.—The cost per linear foot, including the cost of intake, outlet and a check and takeout every 660 ft., is given in Table VII. While the schedule of wages was low, the laborers were all inexperienced. The average progress was 170 ft. a day with a crew of six laborers and one carpenter, who acted as foreman. Toward the latter part of the job as much as 230 ft. per day was lined.

The itemized cost of concrete, exclusive of excavation, is given in Table VIII.

TABLE VII.—TOTAL COST PER FOOT OF 3050-FOOT DITCH

Excavation	$0.066
Forms (labor)	.021
Lumber	.014
Mixing and placing	.087
Cement	.171
Sand and gravel	.066
Engineering	.004
Superintendence	.010
Miscellaneous	.015
Total	$0.454

TABLE VIII.—COST OF CONCRETE PER YARD, EXCLUDING EXCAVATION

Sand and gravel	$1.45
Cement	3.75
Carpenters	.44
Lumber	.33
Labor	1.90
Equipment and team	.42
Total	$8.29

This ditch has been satisfactory in every respect. In the opinion of the writer this method is much cheaper, where the banks are of sufficient size, than reducing the cross-section of the original ditch. The capacity of the earth section was 10 sec.-ft.; that of the concrete is 9.6 sec.-ft., using 0.15 for the value of n in Kutter's formula and a depth of water of 1.5 ft. The grade of the ditches is 0.08 per cent. Laborers on excavation were paid $2 for a nine-hour day, those handling concrete, $2.25, and carpenters received $3 a day. Lumber cost $20 per thousand and cement $3 per barrel delivered at the job.

The Comparative Cost of Cleaning Irrigation Ditches with a V-machine and by Hand.—C. F. Harvey in the May, 1917 Reclamation Record, abstracted in Engineering and Contracting, May 9, 1917, gives the following:

A V-machine was at first rented for a short time for experimental purposes, and afterwards a similar machine was built on the project at a cost of about $700. The operation of such a machine has continued since May, 1916. At first one caterpillar tractor furnished the power, but now two tractors are used. The tractors have 75 H.P. gas engines and cost $4,650 each. These tractors have proved very efficient in getting onto and over ditch banks and traveling on the banks. This equipment is used on canals carrying from 12 to 50 second-feet, and dredgers have been used for larger canals. The use of a single tractor of the above size for this work resulted in overloading the machine, and, while a heavier machine could doubtless be run without overloading, the experience on the Yuma project has been that two machines of about this horsepower are probably more efficient than one larger machine would be, as the two machines can work to great advantage in getting the V in and out of the ditches and around structures. It is to be noted, by the way, that the number of structures in a ditch greatly affects the mileage cleaned. The life of the V-machines and of tractors on this work will be about five or six years.

The following figures are taken for the month of July, 1916, when the rented V-machine was in use:

Operating 114½ hours.
Repairs, 117½ hours.
Distance cleaned, 11.62 miles.
Distillate used, 715 gal. (one tractor).

Costs (July)

Labor	$552.25
Distillate	75.07
Hauling fuel	10.33
Shop orders	5.06
Oil and waste	8.35
Supplies	18.86
Rent of V machine	175.00
Depreciation	50.00
Total	$894.92
Cost per mile cleaned	77.01

By deducting the $175 rent for the machine the cost of cleaning would be reduced proportionately. The above is for one tractor. By putting on an extra tractor the cost of fuel would be doubled, but it is thought that the mileage of canals cleaned would also be nearly doubled, while the labor cost of repairs would remain about the same. With the benefit of experience and a perfected organization it is expected that the cost can be reduced to $40 per mile. With the old organization for cleaning by shovel and teams the costs would run from $200 to $300 per mile. This was with a foreman at $3 a day and labor at $2 a day, worked in such gangs as could be retained. The organization worked with the machine equipment at present is as follows:

1 foreman at $4.50 per day.	Crew of caterpillar:
Crew of V-machine:	
1 man at $3 per day.	1 operator at $5 per day.
1 man at $2.50 per day.	1 oiler at $2.50 per day.

There are on the Yuma project more than 200 miles of ditches to be cleaned of a size suitable for the economical use of the V-machine. This makes it possible to keep the equipment in operation for 12 months a year. The amount of work to be done is, of course, an important consideration in making the expenditure for the tractors.

Cost of Removing Vegetation from Irrigation Canals.—Excellent results in removing moss from the irrigation canals of the Salt River Project of the U. S. Reclamation Service have been obtained with an Acme harrow, according to an article by A. J. Haltom, in the April, 1917 Reclamation Record, and abstracted in Engineering and Contracting, April 11, 1917 as follows: On this project it was necessary to devise some method whereby the moss could be eliminated without turning water from the canals.

The Acme harrow, or, as called by some, the orchard cultivator, is a machine consisting of long parallel blades attached to an iron frame, with the blades turned to enter the ground and cut the roots horizontally an inch or two beneath the surface. It slices off the top surface of the silt, and after the moss roots are thus cut the moss floats to the top and is then caught by men stationed below on bridges or checks. This machine is drawn by means of a chain to a team on each bank of the canal, and by adjusting the length of the chains the harrow can be run on either slope or in the bottom of the canal. In this manner the moss can be removed without interrupting the flow of water. On part of the canals it was necessary to keep men and teams at work until the end of the season, and on others an occasional cleaning every two or three weeks answered all requirements. The Acme is also useful in stirring up the silt in the bottom of the canal, causing it to be again picked up in suspension, with the result that the silt deposits are considerably decreased. The stirring of the silt with the resultant muddy water tends to retard the growth of the moss farther down the canal, and it also helps to puddle leaky portions of the canal.

The methods employed on the Minidoka Project for the control of moss, weeds and willows in irrigation canals also were described in the above-mentioned issue of the Reclamation Record, from which we quote as follows:

It became necessary to begin the work of removing the moss as early as June 20. At this time the only method which was found successful in clearing the moss from the larger canals was by cutting with the Ziemsen submarine saw. This saw consists of a flexible band of steel with hooked teeth on both edges. It can be obtained in any length, and the weights to hold it to the bottom are adjusted to fit the canal. It is operated at an angle of about 30° with the cross-section of the canal, the crew always working upstream. The rate of progress is from 6 to 12 in. at each double stroke and from ¼ to 1 mile per day can be cut with each saw. The long streamers of moss when cut rise to the surface and float down to the next bridge or check, where they are thrown out by men with pitchforks. At times it has been necessary to have as many as three men to pitch out the moss cut by one crew.

Last season it was necessary to go over many of the canals three times. During the middle of the season the moss grew very rapidly. In one canal a length of 2½ ft. was measured 3 days after cutting. In another place a length of 8 ft. was observed 14 days after cutting. After the 20th of August the trouble began to decrease, partly due, no doubt, to the shorter days and less sunlight, partly to cooler weather, and partly to a slackening demand for water.

Removing the moss by dragging a ½ or ¾ in. chain by teams on each bank was not successful until after about the middle of August, when the moss had ripened enough to break away at the first joint. Prior to that time the chain would drag over the moss without breaking it. A V made out of railroad iron and weighing in all about 600 lb. was dragged up the canal but this method was not successful, as the rails slipped over the moss.

In laterals of about 1 ft. depth it was found that a spring-tooth harrow could be used quite well, but it had to be taken out and cleaned about every 50 ft. The harrow was not successful in the larger canals. In laterals the water was lowered at times so that there was only enough to support the moss and men were put in with brush scythes. This method was found very useful where the farmers on some lateral were having serious trouble in getting water and would get together to co-operate in cleaning it.

Where it can be done, the cheapest and most effective method of cleaning the canal is to shut the water out entirely and let the ditch dry in the sun. Five to seven days' exposure is necessary ordinarily to kill the moss. This method kills the growth, but does not destroy the bulb. On the Minidoka project it has not seemed practical to adopt this method, as it is felt that continuous water service was more important to the farmers than the money saving which would have resulted from a method such as this.

During the 1916 season, 260 miles of cleaning were done. The total cost of this work was $4,200, making the cost per mile a fraction over $16. The average cost per mile of the different methods is about as follows: Sawing, $22; chaining late in the season, $8; cutting with scythes in laterals, $11; spring-tooth harrow in laterals, $9.

Weeds and grass growing along the inner slopes of the canal and laterals decrease the discharge to a considerable extent by retarding the velocity. These are removed by men with brush scythes at a cost of about $12 per mile.

Willows are cut by men with grubbing hoes and brush scythes. Men equipped with grubbing hoes go ahead for cutting out larger willows, and men with scythes follow and cut the remainder. In the past little attention has been given to willows on the Minidoka project, but it is now believed to be advisable to cut them annually. The clearing during the last season was done with the idea of keeping stumps down so that a mowing machine can be used to cut the new growth. The cost on the removing of willows has been about $27 per mile. About 23 miles of banks were cut over.

Costs of Keeping Down Vegetation on Irrigation Canal Banks by Grazing.— The following data, abstracted in Engineering and Contracting, April 14, 1915. are given in a report in Reclamation Record, April, 1915, by A. J. Halton,

A considerable item of expense in irrigation canal maintenance is the cutting of Johnson grass and other vegetation which springs up on the banks. On the Salt River Project of the U. S. Reclamation Service, beginning in 1913, experiments have been conducted in sheep grazing as an aid to ordinary cutting for keeping down the bank vegetation. There follows a comparative statement showing decrease in cost of maintaining canals and laterals before and after introduction of sheep:

	Main canals	Laterals	Header ditches	Total cost
Clearing:				
Before	$1,356.88	$3,275.14	$2,226.53	$6,858.55
After	908.05	1,174.69	659.70	2,742.44
Repairing breaks:				
Before	166.43	211.64	121.87	499.94
After	50.48	....	94.00	144.48
Gopher poisoning:				
Before	39.42	....	96.93	136.35
After	....	....	10.00	10.00
Total:				
Before	$1,562.73	$3,486.78	$2,445.33	$7,494.84
After	958.53	1,174.69	763.70	2,896.92
Decrease, 1914 over 1912	$ 604.20	$2,312.09	$1,681.63	$4,597.92
Mileage	8	22	10	40
Average decrease per mile (after introduction of sheep)	$ 75.525	$ 105.095	$ 168.16	$ 114.95

Note.—Cost of repairing breaks and gopher poisoning are included because this expense has been greatly reduced by the grazing of sheep. The cost of cleaning in 1912 is based on a unit cost per mile.

Cost of Maintaining Ditches in the Imperial Valley, Cal. with a Traveling Clam-Shell Excavator.—J. C. Allison, in Engineering Record, Nov. 16, 1912, gives the following:

The irrigation season in Imperial Valley includes the full 12 months, so the canals are always carrying water. This prevents scraping out the deposits of silt with teams.

Up to 1911, about the only method of keeping the section of the canals large enough to carry the necessary water has been by continuously raising the banks to keep pace with the rising of the bottom, due to the deposition of silt. In the small ditches a V-shaped tool operated by a caterpillar engine has been used to drag the canal, thus crowding part of the silt out on the banks.

Experiments have been made with floating dredges of small capacity but these have been unsuccessful, since they are too cumbersome to transport from one point to another, and the time consumed in pulling the pontoons out around the checks is more than the time actually used in digging the silt between checks.

Design of a Special Dredge.—The time came finally when the limit of raising the canal banks was reached, most of the grade of the canals having been overcome, and it became necessary to obtain a new type of tool. A careful study was made of every available tool, but owing to the peculiar conditions of the work, each one was rejected. It was certain that if an appliance capable of operating a clamshell bucket could be so arranged as to permit moving from one point to another in a quick and easy manner, the silt problem in the main distributing canals could be solved.

With this idea in view, W. H. Holabird, receiver of the California Development Company, arranged with the Stockton Iron Works, of Stockton, Cal., to send an erecting engineer to the valley. With his aid, Mr. Holabird and the writer planned the assembling of an all-steel portable clamshell dredge, which would operate a ½-yd. bucket, and at the same time be light enough and narrow enough to transport over the average Imperial Valley road and over the county bridges spanning the canals.

The machine has a 14 × 22-ft. steel underframe, mounted on wide-tread wheels and carrying an A-frame and 40-ft. steel boom, operating machinery and operator's cabin. The wheels at the working end are 6 ft. in diameter, 24 in. wide and are 10 ft. apart between inside edges. The other wheels are only 3 ft. in diameter and are set close together under the frame, their axle being pivoted to provide for steering from that end. Traction is obtained on the large wheels by chain-drives and gears from the engine. Power for digging and traction is furnished by a 15-hp. Atlas two-cylinder vertical gas engine controlled from the operator's cabin, which is on a platform set in the A-frame. The end of the main boom has a normal elevation of 20 ft. above the wheel base, and has a swinging range of 180 deg. A ½-cu. yd. clamshell bucket is employed.

Owing to the small size of the bucket, the yardage per hour is not very great, and it becomes necessary to operate several machines to keep pace with the work. The unit price per yard, however, is satisfactory. Against this price, that paid in the past presents a marked contrast. In a great many cases the canals were entirely abandoned and a side ditch built to carry the water. The scraper work alone amounted to 15 to 20 cents per cubic yard, exclusive of right of way. Wherever the canals were cleaned with shovels the cost per yard ran as high as 50 and 60 cents.

The only other applicances which are satisfactory for use on the canals in Imperial Valley are the V-shaped drag and an endless-chain machine known as the Ruth dredge. Several of these are now operating. The scope of their work is limited to a very narrow, shallow ditch, since neither will cut more than 1 ft. in depth. The material is deposited only a few feet away from the channel, and in the future it will be necessary to remove this accumulation by some other means, since the banks will become too high for further operation of this nature. The new dredge is capable of discharging the material 35 ft. from the canal, if necessary, where the embankment may be leveled and used as a road.

Cost of Clearing Canals.—Table IX shows the cost of operation of the dredge in the Ash canal for the period between Sept. 18 and Dec. 1.

TABLE IX.—COST OF OPERATION OF DREDGE IN CLEARING CANALS

Item	Operation		Maintenance and betterment

PERFORMANCE OF DREDGE CLEARING CANALS

Total digging time, hours	1066
Cost of digging per hour	$2.43
Total yardage removed, approximate	21,321
Yardage removed per digging hour, approximate	20
Cost per cubic yard, approximate	$0.12

The plant consists of the dredge, a cook wagon, camp and commissary team, and the necessary stock and tools for leveling the road ahead of the machine along the ditch. The whole plant represents a cost of about $7,100 on the ground in this case.

No percentage for depreciation is included in the costs shown, but the actual maintenance work and the material necessary are given, the amount being added to the cost per yard. The maintenance and betterment for this run is considerably above normal, since several small weaknesses were discovered and remedied. Improvements were also made, such as building a pilot house, building moving planks, installing a Bristol lighting plant and providing in general for the comfort of the men in the way of heating applicances for the night shifts.

Two 10-hour shifts were run per day. The digging time shown in the table is the summary of the actual digging hours, and does not include the time spent in repairs, moving, etc. No commissary costs are shown, since each meal is deducted from the man's wages at 25 cents per meal. This amount provides for the cook's wages and the provisions, and accounts for the small credit shown. Of the running supplies necessary, the fuel represents the greatest expense. The engine consumed 0.9 gal. of distillate per hour. This fuel was subject to high customs duty in Mexico.

The labor necessary for operating the machine for the two shifts consists of two levermen at $125 per month each; two enginemen at $85 per month each, and two deck hands at $70 per month each. There was necessary at times an extra deck hand for each shift to aid in placing the moving planks while the machine was in soft material. Several four-horse fresno teams, at $6.50 per day, were sometimes required to level the road along the ditch ahead of the machine. All of this expense is shown under the item of labor.

Cost of Pipes for Farm Irrigation.—The following notes are given in Fortier's "Use of Water in Irrigation" (1915).

The materials composing the pipes most commonly used by irrigators are concrete, clay, wood, and metal. A brief description of each of these kinds follows:

Concrete Pipe.—This kind of pipe is used quite generally in southern California for conveying irrigation water underground without pressure or under low heads not exceeding 10 to 15 feet. C. E. Tait, Irrigation Engineer of the Department of Agriculture, states that "a good pipe for the smaller sizes is made from a 1 to 3 mixture consisting of 5 parts cement, 6 parts sand and 9 parts gravel. A larger proportion of gravel may be used in the larger sizes. A good pipe may also be made of cement, sand and crushed rock, no particle being larger than one-half the thickness of the pipe."

Failures in concrete pipe have been largely due to lean mixtures, the use of sand mixed with earth and improper moulding. A weak unreliable pipe is likely to result when the voids in the sand are not filled with cement, when earthy material is incorporated in the mixture or when the mixture is too dry when moulded. The porosity of concrete pipe is reduced and the carrying capacity is increased by the application to the inner surface of a cement brush coating.

The prices for materials in 1914 in southern California were for cement delivered $3 per barrel, sand and gravel $1 per cubic yard, tampers $3 and mixers $2.25 per day of 9 hours. The quantities of materials used, their respective costs and the cost of the various processes in making pipe, exclusive of overhead charges and profits are given in Table X.

TABLE X.—CONCRETE PIPE

Size of pipe	Lineal feet per barrel of cement	Lineal feet per cu. yd. of gravel	Cost data per lineal foot: Cement	Gravel	Moulding	Coating	Total

36 in.	6–8	8	0.500	0.125	0.200	0.012	0.837

Moulding the Pipe.—Concrete pipe as made in southern California for the farmer's use is moulded in 2-foot lengths with beveled lap joints. Since the price of moulds for pipe between 6 and 12 inches in diameter varies from $50 to $100 per set the tendency is to use the smallest possible number. This effort to economize frequently results in a brittle pipe caused by the use of too dry a mixture, such a mixture requiring less time in the moulds. To obviate this difficulty and increase the output from each set of moulds thin metal cylinders are sometimes introduced in the moulds and allowed to remain for some time around the freshly moulded pipe after its removal from the moulds. In this way a wetter mixture resulting in a stronger pipe can be made.

Vitrified Clay Pipe.—Pipe made of moulded clay, kiln-burned and glazed is extensively used to conduct sewage in the sewer systems of towns and cities. The requirements for this service are quite rigid and the pipe which is rejected by the sewer inspector can frequently be purchased at a low figure. In this way the irrigator who resides within hauling distance of a town or city can usually obtain from the municipality or the clay pipe company a serviceable water pipe for low heads at reasonable prices.

In southern California the rejected sewer pipe is classified into three grades known as Nos. 1, 2, and 3 water pipe. The defects in No. 1 grade are not serious and can be depended on to stand a head of 20 to 30 feet in the smaller sizes and 15 to 20 feet in the larger sizes. The No. 2 grade consists of pipe which is cracked in the main part of the joint or length and withstands less pressure than No. 1. No. 3 grade is used only for drainage, being usually cheaper than the tile. The prices of grades 1 and 2 in 3-foot lengths, f.o.b. cars Los Angeles, are at this writing (1914) as in Table XI.

TABLE XI.—VITRIFIED PIPE

Size	No. 1 grade. Cents per ft.	No. 2 grade. Cents per ft.

22 in.	71 1/2	60 1/2
24 in.	81 1/4	68 3/4

Wood Pipe.—The various kinds of wood pipe used to convey water for irrigation purposes belong to one of two general types. One of these is the continuous stave pipe and the other the machine banded pipe. Since the former is only built in medium and large sizes in which the diameters run from 1 to 12 feet it is not well adapted to the farmer's needs and for that reason will not be considered here.

The factory for making machine-banded pipe in San Francisco, California, uses redwood; those located in Portland, Oregon, Tacoma and Seattle, Washinton, and Vancouver, B. C., use fir. In the States of New York and Pennsylvania the pipes are made of white pine and tamarack while in Louisiana cypress is considered the most suitable wood.

A quarter of a century and less ago, machine-banded pipe consisted wholly of logs turned in a lathe, machine-bored and wrapped with flat steel bands. Staves 8 to 12 feet in length in the eastern factories and up to 20 feet in length in the western factories have since been substituted for bored logs. The staves which vary in thickness from 1 to 1¾ inches are held together by galvanized steel wire spaced far apart or close according as the internal pressure of the water is low or high. In some factories flat bands of steel 14 to 16 gauge are used instead of the round wire. After the pipe is banded and the ends are milled for couplings each section is dipped in a bath of hot asphalt and when withdrawn is rolled in sawdust or shavings.

The joints are made in various ways. A common form for low pressures is that of the mortise and tenon joint. The joint is reinforced when the pressure requires it. Sometimes tenons are made on both ends of each section and the coupling is made by means of collars. In common with other kinds of pipes the joints in wood pipe are the chief source of trouble and expense.

Table XII.—Wooden Pipe

Diameter	Head, feet	Price	Weight, pounds	Diameter	Head	Price	Weight, pounds
2 in.	50	0.087	3.1	10 in.	50	0.268	13.1

	200	0.166	6.3		200	0.532	21.7
	250	0.176	7.0		250	0.618	23.8
	300	0.189	7.3		300	0.660	25.3
6 in.	50	0.163	8.3	14 in.	50	0.445	21.3
	100	0.168	8.9		100	0.550	23.0
	150	0.184	9.1		150	0.629	25.3
	200	0.226	9.6		200	0.745	28.2
	250	0.242	10.0		250	0.834	29.9
	300	0.258	10.4		300	0.916	32.3
8 in.	50	0.203	10.3	16 in.	50	0.547	24.7
	100	0.224	10.5		100	0.639	26.9
	150	0.292	12.8		150	0.734	29.3
	200	0.332	13.7		200	0.871	33.4
	250	0.366	15.6		250	0.987	36.2
	300	0.387	16.2		300	1.132	40.2

According to S. O. Jayne, Irrigation Engineer, U. S. Department of Agriculture, the cost of laying wood pipe exclusive of earthwork, backfilling and haulage varies from 2 cents per lineal foot for pipes 4 to 6 inches in diameter up to 6 cents for pipes 24 inches in diameter.

The prices and weights per lineal foot of machine-banded pipe f.o.b. cars, Seattle, Washington, are given in Table XII.

Metal Pipes.—Space will not permit even a brief description of each kind of metal pipe used by irrigators. Notwithstanding the large variety in the market by far the most common is the steel-riveted pipe. This pipe may be purchased in a large number of sizes ranging from 4 to 30 inches and over in diameter and capable of withstanding heads of 50 to 300 feet. Each joint of pipe is made of a single sheet of steel which is sized, punched, rolled and riveted. A number of these joints are then riveted together making a shipping length about 30 feet. Each length is immersed in a bath of hot asphalt before being stacked up in the shipping yards. For all sizes up to 12 inches designed for ordinary pressures the lengths are simply driven together, the smaller joint of one end telescoping the larger joint of the adjacent length. For high pressures and large sizes the circular seams are single riveted and the seams may be split-calked. For low heads, lighter and less expensive pipe of galvanized iron from 20 to 24 gauge, both coated and uncoated, has during the past few years come into somewhat extensive use throughout certain sections of the Northwest.

The following table gives the list prices of steel-riveted pipe in Los Angeles, California, in 1914, these prices being subject to a discount of about 15 per cent.

TABLE XIII.—STEEL RIVETED PIPE

11 in.	0.43	0.49	0.65
12 in.	0.46	0.55	0.69

Cost of Plain Concrete Pipe for Irrigation Works.—Prof. B. A. Etcheverry gives the following in a report to the Dept. of Agriculture, Province of British Columbia, abstracted in Engineering and Contracting, Sept. 18, 1912.

TABLE XIV.—CEMENT PIPE DATA

Inside diameter of pipe in inches	Thickness of pipe in inches	Number of feet of pipe made with 1 barrel of Cement 1:4 mixture	Number of feet of pipe made with 1 barrel of Cement 1:3 mixture	Men composing one crew	No. of feet made per day
6	1 1/16	95	75	1 mixer, 1 or	400–500
8	1¼	63	50	2 moulders,	350–400
10	1⅜	47	37	1 finisher and	300–400
12	1½	36	28	helper	250–350
14	1⅝	28	22	1 or 2 mixers	225–325
16	1¾	23	18	2 moulders	200–275
18	1⅞	19	15	1 finisher	150–225
20	1⅞	17	14	and	125–175
22	2	15	11¾	helper	100–150
24	2¼	12¼	10½	3 or 4 mixers	100–150
26	2¼	11½	9	2 moulders	90–120
30	2½	9	7	1 finisher and	90–110
36	3	6¼	5	helper	80

Dimensions of Cement Pipes and Rate of Manufacturing.—Tables XIV give the thickness of the pipe, the number of feet made per barrel of cement, the number of men in one crew of pipe makers, and the number of feet of pipe made per day. The number of men stated is the number required for a large production. The number of feet per day is not the maximum which may be obtained but is an average rate for good experienced men. The 1 to 3 mixture requires about 2¼ bbls. of cement per cubic yard of concrete. For the 1 to 4 mixture 1¾ bbls. of cement per cubic yard are required.

TABLE XV.—COST OF MAKING CEMENT PIPES (IN CENTS), PER LINEAL FOOT

Diameter of pipe in inches	Cost for 1:2 mixture, cents	Cost for 1:3 mixture, cents	Cost for 1:4 mixture, cents
6	13	10	7
8	15	12	9
10	20	15	11
12	25	20	15
14	30	25	20
16	36	30	25
18	42	35	30
20	50	43	35
24	68	60	50
26	87	75	63
30	95	85	70
36	130	115	95

Cost of Making Pipe.—The cost given in Table XV is obtained from the above data and for the following prices of labor and material: Portland cement, $3.50 delivered on the ground. Gravel, $1.00 a cubic yard. Labor: Tampers $3.00 a day; mixers and sprinklers, $2.50 a day.

The figures given include all materials and labor and an allowance of about 10 per cent for interest and depreciation on plant, administration and supervision, and should not be exceeded with efficient workers.

CONSTRUCTION AND LAYING OF PIPE LINES

Excavation of Trench.—The pipe should be laid sufficiently deep below the surface to have an earth covering of at least 12 ins. and preferably 18 ins. or even more. The bottom of the trench should be graded on an even grade to avoid short siphons which may produce air chambers in the pipe. The width of the trench should be larger than the outside diameter of the pipe by about 12 ins. to allow the pipe layers sufficient space to work in. The trench width and depth with the cost of excavation are given in Table XVI, based on an 18 in. depth of earth covering. The cost of excavation and backfilling is assumed at 20 cts. a cubic yard.

Laying the Pipe.—The pipes are placed in the trench standing on end with the bell end or grooved end up. To lower the large pipes more easily they may be slid on a chute or skid made of timber. The pipe sections are joined with a mixture of 1 part of cement to 2 of fine sand. The taper end of the pipe which has already been laid, and the bell end of the pipe to which it is to be joined, are brushed clean and well wetted with a fiber brush. About an inch thick of the soil under the bottom of the joint to be made is removed and a trowel full of mortar is spread in its place to form a bed of mortar. The bell end of the pipe which is standing on end is filled with cement mortar and is jammed against the taper end of the previously laid pipe. The mortar which

TABLE XVI.—COST OF EXCAVATION FOR CEMENT PIPE LINES (IN CENTS), PER LINEAL FOOT

Size of pipe	Depth of trench	Width of trench	Excavation in cu. yds. per lineal foot	Cost of excavation in cents at 20 cts. per cu. yd.
6	26	20	.13	2.6
8	28	22	.16	3.2
10	31	25	.20	4.0
12	33	27	.23	4.6
14	35	29	.27	5.4
16	38	32	.32	6.4
18	40	34	.35	7.0
20	42	36	.38	7.6
24	47	41	.50	10.0
26	49	43	.55	11.0
30	54	48	.66	13.2
36	60	54	.83	16.6

is squeezed out on the inside of the joint is wiped with a wet brush to form a smooth joint. To complete the joint a band of mortar from 2 to 3 ins. wide and ¼ to ½ in. thick is formed on the outside of the pipe.

It is always preferable to lay the pipe uphill to avoid the shrinkage at the joints due to the pipe pulling away. It is well to protect the bands from the action of the sun for about 30 minutes before backfilling by using wet burlap or placing a board over them. To raise a pipe and hold it on grade do not use clods but shovel in the dirt and compact it by tamping. The bands should be wetted before backfilling; this must be done carefully by shoveling the earth, free from rocks, around the pipe and tamping it until the pipe is well covered. With loose sandy soil which packs easily, very little tamping is necessary. The pipe should not be used for at least two to three days, especially if under pressure, to give sufficient time for the bands to harden.

In Table XVII is given information regarding the laying and hauling of cement pipe, based on the wages and cost of material given above. Ten per cent has been allowed for supervision, organization, breaking of pipe and miscellaneous.

TABLE XVII.—COST OF LAYING AND HAULING CEMENT PIPE (IN CENTS) PER LINEAL FOOT

Diameter in inches	Weight of pipe in lbs. per ft.	Number of feet laid per bbl. of cement	Number of men in laying crew	Number of feet laid per day	Cost of laying exclusive of trenching and hauling, in cts. per ft.	Cost per ft. of hauling 2 miles
6	20	500	3	600	2.25	.9
8	32	400	3	600	2.50	1.4
10	42	350	3	500	3.00	1.9
12	56	300	3	450	3.50	2.5
14	69	225	3	400	4.00	3.1
16	85	200	3	300	5.00	3.8
18	100	175	4	300	6.25	4.5
20	110	150	4	300	6.60	5.0
24	160	100	6	300	10.0	7.2
26	175	85	6	250	12.0	7.9
30	220	75	6	200	14.0	9.9
36	320	60	7	200	17.0	14.4

The cost data given in the preceding tables are assembled and given in Table XVIII.

TABLE XVIII.—COST OF MAKING, LAYING, TRENCHING AND HAULING CEMENT PIPE (IN CENTS), PER LINEAL FOOT

Diameter of pipe in ins.	Cost of making 1:3 pipe	Cost of making 1:4 pipe	Cost of laying	Cost of trenching	Cost of hauling 2 miles	Total cost 1:3 pipe	Total cost 1:4 pipe
6	10	7	2.25	2.6	.9	15.75	12.75
8	12	9	2.50	3.2	1.4	19.10	16.10
10	15	11	3.00	4.0	1.9	23.90	19.90
12	20	15	3.50	4.6	2.5	30.60	25.60
14	25	20	4.00	5.4	3.1	37.50	32.50
16	30	25	5.00	6.4	3.8	45.20	40.20
18	35	30	6.25	7.0	4.5	52.75	47.75
20	43	35	6.60	7.6	5.0	62.20	54.20
24	60	50	10.0	10.0	7.2	87.20	77.20
26	75	63	12.0	11.0	7.9	105.90	93.90
30	85	70	14.0	13.2	9.9	122.10	107.10
36	115	95	17.0	16.6	14.4	163.00	143.00

These cost values agree quite closely with those given below which are those obtained for about 5 miles of pipe on the irrigation system of the Fruitlands Irrigation & Power Company, near Kamloops. The concrete mixture used was composed of 1 part of cement to 2½ sand and 1½ of stone, which corresponds to a 1 to 3 mixture of cement and pit gravel. Cement cost $3 a barrel, sand 75 cents a cubic yard, crushed rock $2.50 a cubic yard, common labor $2.50 per day, skilled labor $3 to $3.50 per day, and teams $6 per day. The cost given includes all materials, labor, supervision, and depreciation on plant.

TABLE XIX.—COST OF MAKING AND LAYING CONCRETE PIPE ON IRRIGATION SYSTEM OF FRUITLANDS IRRIGATION & POWER CO., NEAR KAMLOOPS

Diameter of pipe, inches	Cost of making, cents	Cost of laying, cents	Total cost, cents
8	11.1	....	....
10	15.7	....	....
12	20	11	31
16	29.5	15.5	45
20	39.5	20.3	59.8
24	54.7	23.3	78

Cost of Manufacturing Concrete Pipe.—The following data were published in Engineering and Contracting, Jan. 14, 1920.

During the past season the Modesto Irrigation District of Stanislaus county, California, constructed several thousand feet of standard concrete pipe. The pipe was hand tamped, reinforced, made in 2 ft. lengths with bell and spigot ends and walls varying in thickness from 1¼ in. for 8 in. to 3 in. for 36-in. pipe. The mix was 1 cement to 3½ sand.

The cost of the pipe was as follows:

Size, in.	Cost per lin. ft.
8	$0.12½
12	.21
16	.36
20	.51
24	.68
30	1.02
36	1.50

The above costs include an allowance of $1,000 for depreciation. Several thousand feet of each size up to and including 24 in. were made. Several hundred feet of the 30-in. and 36-in. pipe also were constructed.

The force consisted of 10 or 12 men at $4 per day each, and a foreman at $5 per day. The cost of materials was:

Cement	$3.25 per bbl.
Sand	1.50 per ton
Rock	1.50 per ton

An 8-hour shift was worked, and an average of 350 ft. of 8 in. or 180 ft. of 24 in. pipe was made per shift.

Costs of Continuous Wood Stave Pipe Lines.—In Engineering and Contracting, July 21, 1915, the following extract from Bulletin 155, U. S. Department of Agriculture, by S. O. Jayne, is given.

Eighteen-inch.—At Astoria, Ore., 7½ miles of 18-in. pipe built in 1895. Staves, fir, 1⅛ ins. thick, milled from 2 × 6-in. lumber. Bands, 7/16 in. diameter upset to ½ in. at threads. Clips No. 12, B. W. G., 1½ ins. wide, treated. Shoes, Allen patent, malleable iron, weight 10 ounces each. Contract prices of steel in bands, 4.8 cts. per pound. Lumber, gross measurement, $35.40 per 1,000 ft. b. m. Average spacing of bands, 5 9/16 ins. Cost of pipe to the city, 90.33 cts. per linear foot, including accessories or 76 cts. excluding them. These figures are not the actual cost of building the pipe, as Mr. Adams says: "It is presumable that the contract prices represent a profit of from 12½ to 15 per cent." The approximate cost of replacing this line with one of the same size and length in 1911 was $75,000, redwood staves 1½ ins. thick being used in the new pipe. The cost given includes engineering expense.

Thirty-inch.—At Denver, Colo., in 1889, a 30-in. pipe 16.4 miles long required 1,869,000 ft. b. m. of Texas pine, which cost $51,399.28, at $27.50 per M., and 271,900 half-inch bands, which cost $54,299.55; erection of pipe by contract, at 5.1 cts. per band, $13,866.03; total, $119,564.86, or $1.36½ per linear foot. Trenching cost 48.3 cts. per foot in addition to foregoing.

At Jerome, Idaho, 1912, 1,529 ft.; 30 ins. diameter; fir staves, 1⅝ ins. thick; bands, ½ in. diameter; pressure, 0 to 47 ft.; average haul, 10 miles; built in trench and buried 2 ft. deep. Cost, including everything except engineering and administration, $2,922, or $1.91 per linear foot.

At Idaho Falls, Idaho, 1905; 800 ft.; 30 ins. diameter; fir, ½ in. bands; maximum head, 34 ft.; supported on wood cradles. Cost, $1.55 per linear foot, including everything.

At Kennewick, Wash., 1908; 9,490 ft.; 30 ins. diameter; head, 0 to 180 ft.; built by contract on prepared foundation for $1.85 per foot. Includes delivery of material at railroad point, but no haul or earthwork.

Thirty-two Inch.—At North Yakima, Wash., 1894; Redwood siphon 940 ft. long; 32 ins. diameter; maximum head, 90 ft.; bands, ½ in. diameter; built by force account for $2,500, equals $2.66 per linear foot. Duplicated by contract, 1903, for same figure.

At Filer, Idaho, 1901; 1,300 ft.; 32 ins. diameter; fir staves, 1⅝ ins. thick, at $40 per thousand feet b. m. on basis of 2 × 6-in. lumber; bands, ½ in. diameter, 57 cts. each; malleable iron shoes, 4 cts. each; tongues, ⅛ × 1½ × 5 7/16 ins., 3 cts.; pressure head, 0 to 40 ft.; work done by force account; wages, $2.50 for 10 hours, and foreman $5; hauling material 8 miles, $75; erecting on top of ground, approximately $250. Cost of staves and steel laid down at

Filer, $1.35 per foot of pipe; haul and erecting, 25 cts.; total approximately, $1.60 per foot.

Thirty-six Inch.—At Jerome, Idaho, 1912; 650 ft.; 36 ins. diameter; head, 0 to 43 ft.; staves, fir, 1⅝ ins. thick; band, ½ in. diameter; built in trench and buried 2 ft. deep; average haul, 4 to 5 miles. Cost, including everything except engineering and administration, $1,596, or $2.46 per foot.

Forty Inch.—At Jerome, Idaho, 1912; 3,113 ft.; 40 ins. diameter; head, 0 to 100 ft.; fir staves, 1⅝ ins. thick; bands, ½ in. diameter; built in trench and buried 2 ft. deep; average haul, 10 miles; cost, $8,933, or $2.87 per foot, including everything except engineering and administration.

Forty-two Inch.—At Jerome, Idaho, 1912; 980 ft.; 42 ins. diameter; head, 0 to 51 ft.; staves, fir, 1⅝ ins. thick; bands, ½ in. diameter; built in trench and buried 2 ft. deep; average haul, 4 to 5 miles; cost, $2,556, or $2.61 per foot, including everything except engineering and administration.

Forty-four Inch.—At Wenatchee, Wash., 1902–3; 9,000 ft.; 44 ins. diameter; maximum head, 235 ft.; bands, ½ in. diameter; fir staves, 1⅝ ins. thick; laid in trench, and on bridge across Wenatchee River; contract price for pipe, $2.20 per linear foot. Excavating and backfilling not included.

At Palisades, Colo., 1909–10; three fir pipes, 44 ins. diameter; 2,850 ft.; 1,055 and 1,150 ft. in length; cost by contract, $3.15, $3.25, and $2.90 per linear foot, respectively. No earthwork included.

Forty-eight Inch.—At Palisades (orchard mesa), Colo., 1909–10; for six pipes 48 ins. in diameter and varying lengths and heads, the unit prices ranged from $2.40 per foot up to $4.75 per foot, the average of the six being $3.52; material, fir.

At Deer Park, Wash. (about 1909), 94,000 ft. of fir pipe; head, 0 to 70 ft., built in trench; contract price, $2.35 per foot, includes delivery of all material at railroad point and erection of pipe, but no haul or earthwork.

Forty-eight Inch.—At Clarkston, Wash., 1906; fir staves, 1⅝ ins. thick, ½-in. bands; built in trench by force account, for light head; cost, $2.25 per foot, no earthwork included. Foreman received $3.50 per day and other men $2.50 for 10 hours.

Fifty-eight Inch.—At Pueblo, Colo., 1907; 2,277.5 ft.; cost by contract, $6.14 per foot, no earthwork included.

Sixty Inch.—At Pueblo, Colo., 1907; on 17 fir pipes the unit price per foot ranged from $4.19 to $6.58, averaging $5.51. The combined length of 17 pipes equals 19,821.5 feet, making the average price per foot on this basis equal $6.27; earthwork not included.

Sixty Inch.—At Nissa, Ore., 1912; 6,700 ft.; average head about 65 ft.; bands, ⅝ in. diameter; staves, fir, 2 × 6 ins.; built on wooden cradles; contract price, $4.25 per foot, included material, erecting, and freight, but no haul or earthwork.

Comparative Annual Cost of Wooden Flumes and Pipes.—Prof. B. A. Etcheverry gives the following in a report to the Dept. of Agriculture, Province of British Columbia, abstracted in Engineering and Contracting, Sept. 4, 1912.

For ordinary conditions it is roughly estimated that a wooden flume system will cost one-half as much as a wooden pipe system. For very rough land requiring a great deal of fluming on high trestles, the comparison in cost would not be so favorable to wooden flume. As far as durability is concerned, the life of a well constructed wooden flume should be between 8 and 12 years. The life of a wooden pipe which is full only part of the time is problematical; it depends somewhat on the kind of wood and on the soil in which it is placed. In Idaho 4 × 4 in. wooden posts used for lot corners, made of the best fir and painted, have been almost completely destroyed in one year. There are a number of instances where wooden pipes have gone to pieces in 4 or 5 years or even less. However, if the pipe is made of good selected material, free from sap wood, the life should be from 10 to 15 years for a wooden pipe empty part of the year. The life of wooden pipe which is kept constantly full and buried to such depth as to prevent freezing would be considerably greater, probably 20 to 30 years, provided the soil in which it is buried does not contain injurious salts. Were it not necessary to prevent the water in the pipe from freezing, it is my opinion that the life of a wooden pipe kept constantly full and under sufficient head for the wood to be saturated would be increased if it was laid above ground not in contact with the soil.

As far as the cost of maintenance is concerned, a wooden flume system requires frequent repairs, tarring and calking, the cost of which would be greater than the maintenance of a pipe system.

It is impossible to represent numerically the above statements with any degree of accuracy because of the varying conditions. Roughly, they may be represented as follows:

Annual Cost of Wooden Flumes and Wooden Pipes Given in Per Cent of First Cost

	Per cent
For wooden flumes, life 8 to 12 years:	
Annual maintenance and repairs distributed over entire life	5
Sinking fund for renewals	9
Interested on capital invested	6
Total	20
For wooden pipes empty part of the time, life 10 to 15 years:	
Maintenance and repairs	2
Sinking fund for renewals	7
Interest on capital invested	6
Total	15
For wooden pipes always full, life 20 to 30 years:	
Maintenance and repairs	1
Sinking fund for renewal	4
Interest on capital invested	6
Total	11

These figures show that the annual cost which must be provided for to maintain and renew a system and pay interest on capital invested is 20 per cent for a wooden flume system, 15 per cent for a pipe system, in use part of the time and 11 per cent for a pipe system always full. These costs are in the ratio of 1.8, 1.3 and 1. Therefore a flume system is more economical than a wooden pipe system, which can be kept full of water only part of the time, when the cost of the wooden pipe system would be in excess of 1.3 times the cost of the flume system. Also the flume system is more economical when the cost of a wooden pipe system which can be kept full of water all the time is 1.8 times the cost of the flume system. As stated above, a wooden pipe system under average conditions will cost about twice as much as a wooden flume system; therefore, if the above cost alone is considered, a wooden flume system is more economical. But there are other relative advantages and disadvantages which should be considered.

The third type of system—that is, the wooden pipe system which can be kept full all the year around without freezing—has the advantage that it can be used for domestic supply. The other two types require a separate domestic system if domestic water is desired. But it is not always possible to combine the two, for often the source of supply from which the irrigation water is obtained may be frozen in the winter or it may be so polluted that it is not safe drinking water and if it must be filtered or treated to purify it, it would be very poor economy to have to purify the irrigation water as well as the domestic water which are carried in the same pipe. If these conditions exist a separate domestic system is preferable.

The Cost of a High Flume Trestle in Idaho.—A. M. Korsmo gives the following in Engineering Record, April 5, 1913.

The flume is a part of the Cottonwood Feeder Canal on the Twin Falls-Oakley irrigation project at Oakley, Idaho. The trestle forms the substruc-

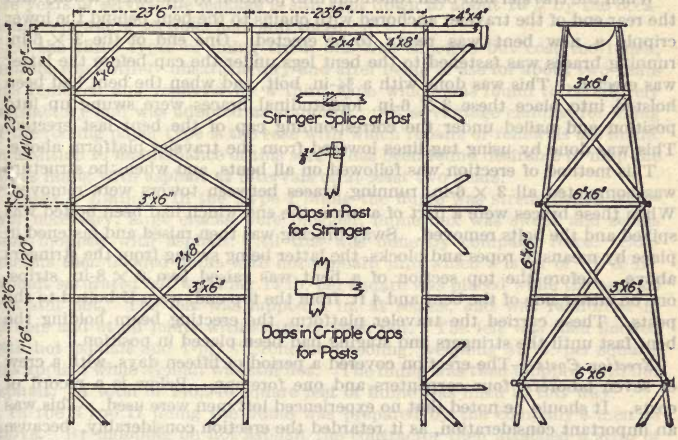

FIG. 11.—Framing details of timber trestle in Idaho.

ture for a corrugated-steel Lennon flume across a deep gulch. The material used in its construction was No. 1 common, rough Oregon fir lumber, which, considering its grade, was of good quality and fully dimensioned. In designing the trestle a batter of 3 in 24 was used on the bent posts, this being considered sufficient on account of the sheltered location of the structure. The gulch is a very winding one and high winds never occur.

Structural Details.—The structure consists of a series of timber bents 23 ft. 6 in. in centers, every pair of bents forming a tower. All posts rest on concrete piers 1 ft. square on top, 18 in. high and built with a batter of 1 to 2. Iron straps, anchored in the pedestals, are fastened to the posts to prevent sliding or overturning.

The trestle is 564 ft. long and has a maximum height of 96 ft. With the bents spaced 23 ft. 6 in. on centers it was considered impracticable to erect one deck at a time on account of the great amount of falsework and staging that would be required by this method. A cantilever erecting beam was then built with the idea of erecting the structure from one end and completing each bent as the work advanced. The framing of the trestle is shown in Fig. 11.

Erection Methods.—The north side of the gulch has a flat slope, the first four bents having no cripples; the erection was begun at that end. All cutting and framing was done below, in the bottom of the gulch, and "snaked up" to place by mule power, where it was assembled and erected.

All the falsework required was a platform 4 ft. below the stringers, running back two bents from the one last erected. It was used to set the traveler on and as a scaffold from which the stringers and kneebraces were placed in position. As the traveler advanced the falsework on the finished section was torn up, the 4 × 4-in. carriers of the flume were placed in position on the stringers and the running planks laid on the carriers.

When the traveler had been rolled out into position by the aid of a dolly and the rear end of the traveler anchored with chains to the bent behind the lower cripple a new bent was ready to be erected. One end of the 3 × 6-in. running braces was fastened to the bent legs under the cap before the latter was erected. This was done with a ⅝-in. bolt, and when the bent had been hoisted into place these 3 × 6-in. longitudinal braces were swung up into position and nailed under the corresponding cap of the bent last erected. This was done by using tag lines lowered from the traveler platform above.

This method of erection was followed on all bents, and when the structure was completed all 3 × 6-in. running braces between towers were removed. When these braces were a part of a tower the end which had been bolted was spiked and the bolts removed. Sway bracing was then raised and fastened in place by means of ropes and blocks, the latter being swung from the stringers above. Before the top section of a bent was raised two 2 × 8-in. strips, one on either side of the bent and 4 ft. from the top end, were U-bolted to the posts. These carried the traveler platform, the erecting beam holding the bent fast until the stringers and staging had been placed in position.

Erection Costs.—The erection covered a period of fifteen days, with a crew of seven laborers, four carpenters and one foreman. Below is a record of costs. It should be noted that no experienced loft men were used. This was an important consideration, as it retarded the erection considerably, because the men were unaccustomed to work high in the air. With an experienced crew the erection would have cost at least $1.75 less per 1000 ft. board measure, this estimate being based on the subsequent erection of another, somewhat smaller, trestle by the same crew that built the high one.

SUMMARY OF COSTS

Total Lumber Used Equals 27.9 *M. Ft. B.M.*

Laborers	775 hours at 25 cents	$193.75
Carpenters	649 hours at 35 cents	227.15
Foremen	148 hours at 45 cents	66.60
Mule	150 hours at 10 cents	15.00
Total		$502.50

Average, $18.00 per 1000 ft., board measure.

Cost of Repairing Leaky Wooden Flume with Roofing Paper Lining.—Engineering News-Record, Jan. 15, 1920, gives the following:

A wooden flume that has now supplied a Southern California irrigation district for over 30 years began to leak badly a few years ago. The leakage increased despite remedial measures, until about 50% of the flow was escaping. The water company was losing revenue and there was danger of crop loss through water shortage, so immediate relief was necessary. On account of the high cost of permanent flume construction and the improbability of earning a return on investment of that sort, effort was made to find some cheap and effective means of reducing leakage in the old flume. Various expedients had been tried before this time. Sections of the flume box had been caulked and battened, or coated with hot asphalt, a layer of burlap applied, and a second coat of asphalt put on over the burlap. None of these expedients, however, reduced the leakage materially.

It was finally decided to try lining the flume with prepared roofing paper. Three methods were worked out and careful records of each were kept. The more effective of these reduced the leakage from 50% to about 3%. After five years of service the leakage is still kept down to about 10% by the occasional renewal of sections here and there.

Of the three types of lining tried, one was effective but cost too much, another was entirely unsatisfactory and after being in use for about two years was removed and replaced by a third type which was found to be entirely satisfactory and was adopted as standard. An advantage claimed for lining of the roofing paper type is the ease with which repairs or renewals are made. In addition to maintenance of this sort it has been found desirable to mop the entire lining with asphalt at intervals of at least two years.

Types of Lining.—In the Type I lining the flume was strengthened wherever necessary, large cracks were plugged, flume box was swept and seams were mopped with asphalt. All this was done by company force. Contractors then flooded flume with hot asphalt, into which a layer of "P & B" asphalt saturated felt weighing 11 lb. per square was placed while the asphalt was still hot. The felt was lapped 3 in. at seams, and was reinforced in corners and at all joints with strips of Irish felt. The felt was then flooded with hot asphalt and 1-ply "Cronolite" roofing, weighing 37 lb. per square, was applied while asphalt was still hot. The lining was then mopped with hot asphalt. A total of 140,940 square feet of flume was lined in this way.

In the Type II lining the flume was prepared by the company's men as above. By mopping on hot asphalt the contractor then attached a strip of water proof felt to the flume box where the roofing paper joints would come. After mopping this felt strip one edge of the roofing sheet was nailed down to it and when the sheet had in turn been mopped the edge of the overlapping sheet was placed and nailed every two inches. Finally, the joint was mopped over the nail heads. The upper edge of the roofing on the sides of the flume was nailed without mopping. Two-ply Trino ready roofing was used in this type on 189,560 sq. ft. of flume. At least 35 lb. of asphalt per square was found to be desirable with this type.

In Type III the flume was prepared for lining by the company's men as already described. The contractor coated both flume and lining with hot asphalt and applied the lining while the asphalt was still hot, thus forming a tight bond between lining and flume box. Laps in the lining at joints were nailed with large flat-headed, roofing nails. A total of 1,051,402 sq. ft. of flume was lined in this way, using 2-ply Flaxine and Argonaut prepared roofing.

Costs.—The cost of preparing the flume for lining, hauling materials, supervision, etc., was $7,838.62, or $0.57 per square. This charge was made against all types of lining. California asphalt was used throughout. The costs were as follows:

TYPE I

Preparing flume, etc., 1,409.4 squares at $0.57	$ 799.67
Lining by contract, 1,409.4 squares at $3.43	4,831.30
1,409.4 squares at $4	$ 5,630.97

TYPE II

Preparing flume, etc., 1,895.6 squares at $0.57	$ 1,075.49
Lining by contract, 1,895.6 squares at $2.47	4,678.07
1,895.6 squares at $3.04	$ 5,763.56

TYPE III

Preparing flume, etc., 10,514 squares at $0.57	$ 5,963.46
Lining by contract, 10,514 squares at $2.43	25,541.44
10,514 squares at $3	$31,504.90
Total: 13,819 squares at $3.10	$42,889.43

Comparison of Wood and Concrete for Use in Irrigation Structures.—The following discussion is given by S. T. Harding, Assistant Professor of Irrigation, University of California, in Engineering and Contracting, April 12, 1916.

The relative economy of wood and concrete structures for use on irrigation systems is a question subject to much debate among irrigation engineers. The following comparisons were made to determine, first, the amount of wood in feet board measure which is the equivalent of one cubic yard of concrete in different types of structures and, secondly, to compare the relative cost for certain assumed conditions. The cost and conditions of use of these two materials will vary so widely in different portions of the West that the choice in any particular case will have to be based on a consideration of these local factors.

The comparisons which are made refer to the types of structures used on distribution systems. The choice of the material to be used in important single structures is often fixed by a consideration of other factors than the relative cost of the material used. The difficulties of replacement and damage from failure generally make the use of the more permanent forms of construction desirable for diversion dams and headgates.

The comparison of wood and concrete for the usual irrigation structures also involves more than considerations of first cost and the life of the structure. In new projects the location of parts of the distribution system, particularly sub-laterals, may need modification or change which involves less loss with the cheaper wooden structures. Also, a wooden structure has some salvage value; a concrete structure if removed is generally a total loss. Experience in operation or general advance in irrigation engineering may enable structures to be designed which may be more suitable than those first used. The methods of applying water to the lands may be modified. The present tendency is toward methods which permit of the handling of larger streams of water on the individual farm. This may require changes in the sub-lateral systems such as larger delivery turnouts and checks.

The financial conditions of the constructing company may be such that the initial expenses must be kept at a mimimum until the project is placed on an operation basis. The interest rate at which funds can be secured in the earlier stages of a project is often much higher than those obtainable later, so that the cheaper wooden structures may be more economical for first construction, to be replaced by concrete. It may be economical where the period of development expected is longer, than the life of the wood structures to construct the canals and structures of only sufficient capacity for this early period and to enlarge the canal at the time of replacement. Concrete structures in the original construction would need to be built to full capacity and thus increase the amount of non-productive investment. This applies to structures in main canals and laterals, such as checks and flumes, more than to individual division or turnout structures.

When originally constructed, the canals may be in undeveloped sections without adequate transportation facilities. Following settlement, this may be overcome so that the relative prices of the two materials may be much different at the time the original wood structures must be replaced. The prices of the two materials has tended to change, wood increasing and cement decreasing, so that concrete may be able to compete with wood in replacements where it would not have been able to do so for the original construction.

These various considerations will fix the choice between these two materials for original construction more often than a strict computation of ultimate economy. After a project has been in operation sufficiently long to establish itself as a going concern, the replacements as needed can be planned with greater attention to the relative cost and service of the two types. This tendency is evident in practice, as on many systems side hill bench flumes have been replaced with retaining wall lined sections, wooden drops with concrete, etc. The comparisons here given will have a larger application in such betterment work than in original construction.

Ratio of Cost of Concrete and Wood in Structures to Total Cost of Structure.—The unit of cost for wood structures generally used is the 1,000 ft. board measure or M.B.M.; that for concrete the cubic yard. These materials form only a part of the total structure, in both cases excavation, backfill, miscellaneous parts such as gates, footwalks, and footings for flumes are required. The proportion of the total cost, which consists either of the wood or concrete, was determined for many structures for which costs were available from various sources. The proportions vary rather widely with different conditions, but the following generalizations, Table XX, were made. The percentages given are for the cost of concrete and wood in place.

TABLE XX.—COST OF CONCRETE AND WOOD IN IRRIGATION STRUCTURES EXPRESSED AS A PERCENTAGE OF THE TOTAL COST OF THE STRUCTURE

Type of structure	Conc. structures: Usual max.	Conc. structures: Usual min.	Conc. structures: Mean	Wood structures: Usual max.	Wood structures: Usual min.	Wood structures: Mean
Turnouts	75	50	65	65	40	50
Checks	85	60	75	75	50	60
Drops	90	60	80	75	50	65
Box culverts	95	60	80	70	50	60
Wood flumes	..	..	..	95	75	85
Buried concrete pipe siphons	85	65	75	..	..	..

Number of Cubic Yards of Concrete Which are Equivalent to 1,000 *Ft. Board Measure.*—Comparisons of the amount of concrete or wood required were made for individual structures. Drawings of either wood or concrete structures were used and the amount of material for an equivalent structure of the other type computed. From these comparisons the number of cubic yards of concrete which were equivalent to one M.B.M. of wood were obtained. The resulting general figures are given in Table XXI.

TABLE XXI.—NUMBER OF CUBIC YARDS OF CONCRETE WHICH ARE EQUIVALENT TO 1,000 FT. B.M., OF WOOD

Kind of structure	Number of comparisons.	Usual min.	Usual max.	Mean
Turnouts	29	9.0	4.5	6.6
Checks	12	8.0	5.5	6.4
Drops	13	7.5	4.5	6.0
Box culverts	23	10.0	5.0	7.6
Flumes	13	5.5	3.5	4.2
Bridge floors up to 20-ft. span	20	7.0	4.0	5.2

As shown in the table, the ratio varies widely. This is largely due to differences in design on different systems. Wood structures are better standardized than concrete, the commercial thicknesses of lumber are used, such as 2-in. plank for the smaller structures and 3-in. plank for the larger ones or those difficult to replace, such as culvert barrels. With concrete, the required thickness of such parts as headwalls for small structures cannot be definitely computed and practice varies with the policy of different forms of organization and climatic conditions. Examples were found of similar structures having over 100 per cent variation in the thickness of similar parts; the inlet floors to turnouts of similar size varied from 4 in. of plain concrete to 8 in. cross reinforced. In the comparisons it was attempted to use wood structures of equivalent heaviness of design to the concrete structure for which the comparison was being made.

If comparisons are made for straight wall construction, such as would be used in small head walls, the ratios in Table XXII will be obtained.

TABLE XXII

Thickness of concrete wall inches	Number of cubic yards of concrete which are equivalent to 1,000 ft. B.M. of wood in straight walls: For 2-in. plank with 4 × 4-in. posts spaced 4 ft.	For 3-in. lumber with 6 × 6-in. posts spaced 3 ft.
3	4.0	2.3
4	5.3	3.1
6	8.0	4.6
8	10.6	6.2
10	13.2	7.7

Three-inch concrete walls have been used in some small structures with separately cast slabs. Four-inch walls have been used in favorable climates, particularly for those parts where forms were not required. A thickness of 6 in. represents the usual minimum where forms are used, especially when reinforcing is needed. Eight and ten-inch walls are used in lalrger structures where more than average strength is required or where generaly heavy types of structures are adopted.

The structures included under turnouts include both lateral headgates and farm turnouts. The ratios for these, as well as for checks and drops, are less variable than for such structures as culverts. In these structures the thickness of the concrete is more often fixed by construction conditions than by any determinate stresses, and the design is as largely the result of experience as of theory. With culverts a wide variation in practice was found; the average ratio was higher than for any other type of structure. This is due most largely to the use of realtive heavy barrels in concrete culverts. Such barrels require forms and the use of thin walls under favorable conditions is prevented where box culverts are used by construction conditions. Separate comparison of the inlets and outlets gave ratios for these similar to those for turnouts, checks and drops; for the barrels of box culverts the ratio averaged about 8.5. Pipe culverts in which the barrel is made of various types of pipe were not included in these comparisons.

The ratios are smallest in those types of structures where the concrete can be designed to withstand definite stresses of compression or as beams. This occurs in bridge floors and in flumes. Concrete flumes have been actually used to only a small extent as yet, due mainly to the difficulties in constructing the trestle members. Standard designs have been prepared for various sizes of flumes of both concrete and wood by the U. S. Reclamation Service, and equivalent sizes of these were compared for both the flume box and for bents 10 ft. high. The average ratio for the flume box was about 4.5 and for the bents 4.0. The cost per cubic yard of concrete in concrete flumes is greater than for other types of structures, and this excess cost may more than balance the smaller amount required.

The standard designs of slab and T-beam highway bridges of the U. S. Bureau of Public Roads were compared with standard designs of wood stringer bridges for the floors only for spans of from 8 to 20 ft. The average ratio for the slab bridges was 6.7, varying from about 5.0 for 8-ft. spans to 7.5 for 16-ft. spans. For T-beam forms of concrete bridges, the ratio varied from 4.3 for 10-ft. spans. to 3. 7 for 20-ft. spans.

The more usual comparison between wood and concrete which will be made in irrigation practice is for the more numerous turnouts, checks, drops and culverts. For flumes the comparison is more often between the wooden flume and other forms of construction, such as siphons or steel flumes. With bridges the choice is often determined by the fact that in many western States the county maintains the bridges after their original construction by the canal company. For the more typical irrigation structures, a ratio of about 6.5 cu. yd. of concrete to 1,000 ft. B. M. can be taken as an average with variations of from about 4.5 to 9.0 under different conditions, methods and policies.

Relative Cost of Wood and Concrete.—The choice between wood and concrete construction depends on the relative total cost. The ratio of the amount of concrete equivalent to 1,000 ft. board measure has been discussed. The relative unit cost also needs to be known, in order to make complete comparisons.

The unit cost of both concrete and wood in irrigation construction varies very widely. This applies both to the material cost and the cost of construction. The price of cement on the work is usually much higher than in the East. Aggregate may be expensive to secure and the haul to scattered structures is usually a considerable item. Also, even water for mixing, particularly on first construction, may have to be hauled considerable distances. Under such conditions the cost per cubic yard of concrete is naturally very variable. Under favorable conditions costs of $10 per cubic yard may be secured. This represents about the minimum for the usual small scattered structures; for larger single structures or linings the cost may be less. Under unfavorable conditions of material, or for thin walls requiring forms, the cost may be as high as $20 or $25 per cubic yard. About $12 to $16 per cubic yard may be taken for such structures, although where the costs vary so widely average costs should be used with caution.

The unit cost of wood in place also varies widely. The material price depends on the nearness to the source of supply and the wagon haul required.

The labor cost of construction varies with the type of structure. For small scattered special structures or for high flumes, it may be as high as $20 per 1,000 ft. B. M.; for standard structures of which large numbers are used, such as individual turnouts where the framing can be done at central points, the cost may be as low as $6 per M. B. M. For usual conditions for structures except high flumes, the labor cost will generally be about $10 or $12 per M. B. M. The material cost varies equally widely. In localities near the sources of supply suitable lumber may be obtained for as low as $15 per M. B. M.; in others it may be as high as $30, averaging perhaps about $20. This gives a cost in place of from as low as about $20 to as high as $50 with an average of $30 to $40. These averages, as in the case of average costs of concrete, have a limited application. They give a ratio of average cost of 1,000 ft. B. M. to that of 1 cu. yd. of concrete of about 2½ to 1. If the average ratio of the quantities required is taken as 6.5 to 1 and cost as 1 to 2½, the ratio of the total cost of the lumber or concrete part of the structure will be 2.6 to 1. The cost of the other parts of structures as previously given is for concrete structures about 25 per cent of the total cost, or one-third of the cost of the concrete, and for wood structures 40 per cent of the total cost, or two-thirds of the cost of the wood in the structure. On this basis the average total cost of concrete structures will be about 100 per cent greater than that of similar wood structures. Where the price of lumber is high and the conditions for concrete are favorable, a condition more often found in parts of California the cost of concrete structures may not be more than 50 per cent greater, and in some particular cases no greater, than equivalent wood structures. In the higher altitudes where lumber is often relatively low in price and the cost of concrete often relatively high, the concrete structures may cost 200 per cent or more in excess of the cost of wood structures.

Maintenance and Depreciation.—Few definite data on the actual cost of manitenance of structures is available. Such costs would be difficult to obtain for smaller structures. In some systems operation and maintenance costs are not kept separate; in others all maintenance is carried in a single account. The life of wood structures has been observed under different conditions. The cost of maintenance is small for the first portion of the life of wood structures and increases in amount until replacement is warranted. The total cost of maintenance during the life of such structures may approach the first cost of the structure. With concrete structures the cost of maintenance should be small. Such maintenance is more often required for the auxiliary parts of structures, such as protection to the adjacent canal and repairs, due to accidents rather than to gradual depreciation. It should be fairly uniform from year to year.

The total life of structures varies with the type and the conditions of use. Concrete has not been in use sufficiently long to give data on its life. There is always a certain probability of failure through injury, such as undercutting, removal due to enlargement of the systems, or replacement with a different type of design.

The life of wood structures depends on the character of their construction and conditions of use. Generally structures set in earth, such as drops and checks, have a shorter life than the boxes of flumes set on well built trestles. Where the operation season is long, so that structures are kept wet practically throughout the year, there may be little difference. Records of wood structures under various conditions indicate that ordinary turnouts, drops and checks can be expected to have a useful life of 6 to 10 years for pine, 8 to 12 years for fir, and 10 to 20 years for redwood. Under favorable conditions redwood structures have considerably exceeded the figures given. For well built trestle flumes, the useful life can be expected to be 8 to 14 years for pine, 10 to 16 years for fir, and 12 to 20 years for redwood. Wood pipe under conditions to which it is suited should have a useful life exceeding these figures.

The cost of replacing structures is usually greater than their first cost. This is due to the fact that the excavation will be more largely hand work and to the cost of tearing out the old structure.

The salvage value of concrete structures is usually negligible; the lumber removed from old structures may have some value for use in forms, etc., being usually greater for flumes than for structures set in the ground.

Comparison of Cost of Wood and Concrete Structures on Investment Basis.— On the basis of the average figures previously developed, comparisons of the cost of wood and concrete structures can be made. This has been limited to drops, checks, turnouts and culverts, as these are the structures occurring in greatest number on irrigation systems and whose design and construction can be most closely organized. A comparison of such structures as high flumes will involve so many local and special considerations that a general comparison would be of little value.

The capitalized cost can be taken as the basis of comparison. Table XXIII has been worked out to show the ratio of first cost at which the capitalized cost will be equal for different conditions.

Interest rates of 6 and 8 per cent were used. Irrigation district bonds generally bear 6 per cent; the terms of sale, however, more often make the rate on the price received 8 per cent or higher. Western mortgage rates vary from 6 to 8 or even 10 per cent; this represents the value of money to stockholders in mutual companies or on systems where improvements are paid for by stock assessments.

Different lengths of life for the structures were assumed. The annual maintenance cost is estimated as a percentage of the first cost, a higher rate being used where the life of the wood structure was relatively short. Maintenance on the concrete was taken as zero. Salvage value was neglected; its amount would probably be less than the error involved in some of the other assumptions.

TABLE XXIII. — RATIO OF TOTAL FIRST COST OF CONCRETE AND WOOD STRUCTURES AT WHICH THE CAPITALIZED COST OF SERVICE BECOMES EQUAL.

Interest rate per cent	Assumed life of concrete structures in years	Assumed life of wood structures in years	Assumed annual cost maintenance in per cent of first cost: Conc.	Wood	Ratio of total first cost of concrete structures to total first cost of wood structures at which capitalized cost becomes equal
6	30	10	0	5	2.6 to 1
6	45	15	0	4	2.2 to 1
6	20	10	0	5	2.1 to 1
6	40	20	0	3	1.8 to 1
6	15	15	0	4	1.4 to 1
8	30	10	0	5	2.25 to 1
8	45	15	0	4	1.9 to 1
8	20	10	0	5	1.95 to 1
8	40	20	0	3	1.6 to 1
8	15	15	0	4	1.3 to 1

Table XXIII shows the ratios of first cost at which the capitalized cost of service becomes equal for these assumed conditions. For useful lives of 30 and 10 years for concrete and wood and interest at 6 per cent and annual maintenance on the wood structure of 5 per cent, a concrete structure costing 2.6 times as much as the wooden one would be equal in capitalized cost. The ratios are higher for the lower rates of interest.

Ratio of Cost of Structures to Total Cost of Canal System.—In comparing the relative economy of different types of structures, the proportion of the total cost of the canal systems which consists of structures must be known, in order that the proportion in which the total construction cost will be increased by different types of structures may be estimated. In some of the Annual Reports of the U. S. Reclamation Service, the total cost of structures and excavation is stated separately for some of the projects. From these and other records Table XXIV was derived.

TABLE XXIV.—USUAL COST OF STRUCTURES ON CANAL SYSTEMS EXPRESSED AS PER CENT OF THE TOTAL COST

	Main canals	Laterals	Whole project
Regular topography:			
Concrete structures	10–20	25–40	20–35
Wood structures	8–15	15–35	10–25
Irregular or steep topography:			
Concrete structures	20–35	40–50	35–45
Wood structures	15–25	25–40	20–35

The use of concrete structures costing twice as much as wood will increase the total cost of the canal system by from 15 to 30 per cent under usual conditions. This applies to the canal system structures only and not to diversion dams or to such conditions as side hill locations requiring bench flumes or lined canals.

Conclusions.—The preceding discussion of the factors involved in a choice between concrete and wood for irrigation structures, both for the factors for numerical limits have been given and also for those not capable of numerical expression but which are of equal or greater importance, makes it evident that no general conclusions can be drawn as to the most economical type of construction. For any particular project where the construction costs can be estimated and the other factors, such as financial conditions of the constructing organization, rate of interest, certainty as to type of structure desired and permanence of its location can be given proper weight, a decision can be made. Under usual conditions concrete will be the preferable material if the capitalized cost of service alone is considered. The other factors are, however, more usually such as to incline the choice toward wood for first construction, except for the larger and more important structures. That the capitalized cost is being given more consideration and that many systems are reaching a condition where replacements and betterments can be made on a more permanent basis is evidenced by the increasing use of concrete in irrigation structures.

Life of Irrigation Structures.—The following notes are taken from Harding's "Operation and Maintenance of Irrigation Systems."

Life of Wood Flumes.—The life of wood flumes depends on the kind of material used, conditions of use and character of construction. As these conditions vary on different systems, the life of wood flumes as reported by different users varies widely. A rigidly built flume having little leakage will outlast one less strongly built. Poor footings which settle and cause leakage will shorten the life of a flume. The thickness of the flume lining also affects length of service. Various protective coatings or even relining the flume box are used to increase the life.

The period of serviceable life which can be expected from flumes for usual conditions will not exceed 20 years for redwood or cedar, 12 to 15 years for fir, and 8 to 10 years for pine. These figures apply to the portions of the flume not in contact with the ground and are as long a life as can be expected under general favorable conditions. Some flumes have been used for periods longer than those given, but the annual cost of repairs in the later years of use or the uncertainty of service will generally make such use undesirable. The life of small flumes is generally less than that of large ones due to the less continuous use of many flumes on sublaterals. Flumes used intermittently on farms will have a shorter life than on laterals operated continuously. Bench flumes or flumes set in contact with or near the ground usually have a shorter life than well-built higher flumes. For unfavorable conditions the life of flumes may not be over one-half that given. Some redwood flumes have been in use for 25 years in California, the relatively long operation season and rains during the remainder of the year keeping them continuously moist. Others have been replaced after fifteen years, the chief difficulty being with the rotting of the butt joints at the end of the lining plank and of the yokes behind them. Well-constructed fir flumes on the Hedge canal in Montana having 3-inch T & G siding were replaced in 12 to 14 years. Small pine flumes have not lasted over 4 or 5 years in some cases.

Life of Wood-stave Pipe.—The life of wood-stave pipe varies more widely than that of wood flumes as it is more dependent upon the conditions of service. Under favorable conditions, the life of wood pipe should exceed that of

Table XXV.—Life of Wood-stave Pipe

Kind of wood	Condition of use	Average life in years
Fir	Uncoated, buried in tight soil	20
Fir	Uncoated, buried in loose soil	4 to 7
Fir	Uncoated in air	12 to 20
Redwood	Uncoated, buried in tight soil, loam or sand and gravel	over 25
Fir	Well-coated, buried in tight soil	25
Fir	Well-coated, buried in loose soil	15 to 20

flumes; under unfavorable conditions, it may be quite short. Wood used in pipes comes into more direct comparison with other materials than does wood used in flumes and the results with its use have been more closely observed. Table XXV prepared by Mr. D. C. Henny and printed in the Reclamation Record of August, 1915, summarizes the data collected from a large number of installations.

The following general conclusions were also given:

"(*a*) Under favorable conditions of complete saturation, fir well-coated may have the same life as redwood uncoated.

"(*b*) Either kind of pipe will have a longer life if well-buried in tight soil than if exposed to the atmosphere. Such life may be very long, 30 years or over, if a high steady pressure is maintained.

"(*c*) Either kind of pipe will have a longer life if exposed to the atmosphere than if buried in open soil, such as sand and gravel and volcanic ash, provided in a hot and dry climate it be shaded from the sun.

"(*d*) Under questionable conditions, such as light pressure or partially filled pipe, fir even if well-coated may have only one-third to one-half the life of redwood.

"(*e*) Under light pressure the use of bastard staves should be avoided.

"(*f*) The use of wooden sleeves in connection with wire-wound pipe is objectionable and has caused endless trouble and expense.

"(*g*) If wooden sleeves are employed they should be provided, at least for sizes from 10 inches up, with individual bands to permit taking up leaks."

These results indicate the importance of the character of the backfill. If porous soils into which air penetrates easily are used, the benefits of covering are lost, with the added disadvantage that inspection cannot be readily made. A covering of heavy soil, 3 to 4 feet in depth, which maintains more constant moisture conditions and excludes air, gives the best results. The pipe should be kept full of water if a long life is to be secured. The upper portions of siphons, which may be only partly filled, have been found to have a shorter life than the parts under greater pressure. The water, when under pressure, maintains a more uniform condition in the staves, a condition also more easily secured if the thickness of the staves is no greater than required for strength. Cuts from the butts of trees, being denser, are considered to have longer life than top cuts. The life of the pipe is usually determined by the life of the staves. Certain chemical conditions in the soil, such as the presence of some alkalis or of acids from decaying vegetation may result in a shorter life for the bands than for the staves. For such locations it is preferable to place the pipe above ground and free from such action.

Wood pipe is often coated, particularly the smaller machine-banded pipe. The coating on these is applied by running the pipe through a bath of warm asphaltum pitch. The pipe is then rolled in sawdust to preserve the outside coating and make handling easier. On large pipes an application of gas tar followed by one or more coats of refined coal tar, is often used. A mixture of asphaltum and tar has also been used. These are applied to the finished pipe before it is put under pressure. It is difficult to secure adherence to wet wood, particularly with oil paints. In general it appears that the use of a coating is preferable for buried pipe in dry porous soil and possibly on all buried pipes, although the added benefit may be small for pipe buried in heavy moist soils free from vegetable matter. Above ground the value of the coating is more uncertain. For the protection of the bands on exposed pipes paints similar to those used on structural steel may be used.

Life of Wood Structures.—The conditions of use for the usual wood structures are not as favorable as for wood flumes or pipes. Parts of the structure may be continuously wet, parts alternately wet and dry and parts continuously dry. The cutoff walls and other substructure may outlast one or more renewals of the superstructure. Heavy well-built structures will have longer life than light ones due to the longer time required to cause the complete decay of the thicker material as well as to the greater resistance to injury offered by the stronger structures.

Under favorable conditions irrigation structures built of redwood or cedar may have a useful life of as high as 20 years; for aveage conditions the average life is about 12 years and in some cases as low as 8 years. It is longest in the larger and heavier structures such as have been used on some of the earlier systems in California. Some of these have actually been in use for over 25 years. It is shortest in regions of high temperature where the wood is both damp and heated at depths of from 1 to 2½ feet below the surface. At lower depths the heat is not sufficient to make decay as rapid; nearer the surface the structure is dryer. Small redwood structures have required replacement after 5 years in such locations. Structures built of fir have a life varying from a usual maximum of 15 years to a usual minimum of 6 years with an expected life under usual conditions of 8 to 10 years. Where pine is used, structures will not generally last over 10 years and may not last over 5 years; under usual conditions a life of 6 to 8 years is to be expected. Structures will usually have a longer life in heavy soils than in those in which the air has greater access such as sands or gravels.

Life of Concrete Structures.—Considered as a material, concrete is practically permanent. There has been some injury from the action of certain forms of alkali but the injuries to concrete structures are much more generally those due to undercutting or other accidents in use rather than to any disintegration of failure of the material similar to the failure of wood structures due to decay. Concrete has not been in use in irrigation sufficiently long to secure data on its rate of depreciation. Depreciation estimates which have been used in valuations have been based on estimated obsolescence or mechanical injury rather than on actual deterioration of the structure. In a few instances resurfacing has been required; such cases have generally been due to lack of care in the original construction rather than to actual abrasion. Structures, such as linings or retaining walls, may fail due to excess pressure behind them; such failures are not due to the material of the structure itself but to faults in drainage or design. Winter operation may cause injury in the opening of frozen gates or in the breaking of side walls.

The examples of injury from the action of alkali while scattered have in some cases been important. There is still need for further knowledge as to the details of such action and the methods of its prevention. Injury is caused by the seepage into the concrete of alkali water, the sulphates, particularly magnesium and sodium sulphate, being the most harmful. With some salts no harmful action may occur. The best remedy is prevention which can be secured most practically by using a dense well-mixed and faced concrete which reduces the absorption of the alkali water to a minimum. The conclusions of the U. S. Bureau of Standards based on the observations of the first year's tests with concrete drain tile exposed to alkali in a number of localities are that tile not leaner than a 1 to 3 mixture are apparently unaffected structurally when exposed for 1 year in operating drains in very concentrated alkali soils. Leaner mixtures are not generally recommended although in some cases tile of 1 to 4 mixture were not affected at the end of 1 year.

To overcome or reduce the effect of low temperatures on concrete, the surfaces have been treated with waterproofing solutions on the Strawberry valley project. This was applied to structures on which surface disintegration had already begun. Vertical surfaces were treated with alum and soap solution and horizontal surfaces with paraffine. The surfaces were thoroughly dried and cleaned before treatment. The alum solution consisted of 2 ounces of alum to 1 gallon of hot water. The soap solution consisted of ¾ pound of castile soap dissolved in 1 gallon of hot water. The alum solution was applied at a temperature of 100°F. and worked in with brushes, the soap solution being similarly applied while the surface was still moist. In some cases additional coats were given. One gallon of alum solution and ½ gallon of soap solution were sufficient to give two coats to 50 square feet. The cost of treating 24,000 square feet varied from $0.41 to $1.28 per 100 square feet and averaged $0.76. Alum costs 18 cents and soap 12½ cents per pound.

For horizontal surfaces, the paraffine was boiled to drive off water, heated and applied with a paint brush. A blow torch was used to force the paraffine into the pores by its heat. The concrete would absorb only one coat of such treatment. On 4,000 square feet treated, 1 pound of paraffine was used for 11¾ square feet of surface. The cost varied from $1.70 to $3.78 per 100 square feet, averaging $2.11. Paraffine cost $4.80 per 100 pounds. The surfaces treated have shown no further disintegration after going through four winters.

Concrete pipe has been used very extensively on a number of systems during the past 10 years. With the present knowledge of its construction and use there should be little difficulty in securing well-made pipe. Such pipe should have a relatively long or indefinite life. In 1907 the Irrigation Co. of Pomona relaid a line of 8-inch concrete pipe of 1 to 4 mixture which had been laid in 1888. Only 7 per cent. of the joints were found to be perfectly sound, the remainder had disintegrated. General maintenance of such pipe lines consists of draining in winter and the sluicing of deposits which may form. It is usual for such pipe lines to operate at higher velocities than the canals so that deposits of silt or sand are not to be expected. Such deposits may occur, however, at the lower rates of discharge which may be used at the beginning and end of the season. Cracks at the joints due to the expansion and contraction of the pipes have caused trouble in some cases where the range of temperature is large or the covering of the pipes porous or thin. A length of life of 30 to 40 years has been used in valuations of concrete pipe lines. These figures are largely arbitrary, however, as direct experience has not extended over the full life of larger concrete pipe. In common with other forms of permanent materials, replacements may be more often needed due to changes in the requirements of use such as changes in location or capacity needed, rather than due to actual deterioration of the material itself.

Life of Steel.—Steel is used in irrigation practice in flumes, in pipes and in gates. The development of steel flumes has occurred within the past 15 years. A steel flume with wood supports is a combination type of structure. The trestles and stringers are similar to those used with wood flumes and should have a useful life similar to that of the same kind of material when used with wood flumes. Such trestles with steel flumes may have a longer life than with wood flumes, if the leakage with the steel flume is less. The useful life of steel flumes has not been determined, as their adoption is guite recent. Many have been built on the systems of the U. S. Reclamation Service. From observations on the Boise project it was reported at the Conference of Operating Engineers in 1914, that "Of the flumes built in 1909 practically all were more or less corroded. Of about 13 flumes built in 1910, the majority were in good condition but one was considerably corroded. Of about 21 flumes built in 1911, two were considerably corroded. Of about 14 flumes built in 1912, two were seriously corroded." It was stated that there was no decided difference between different makes of flumes. The greatest amount of corrosion and rust appeared to be along the joints, on the downstream side. It was recommended that the bands, channels or other parts forming the joints should be galvanized as well as the sheet metal of the flume. In case deterioration appears, painting was recommended. In an article in the Reclamation Record for November, 1916, Mr. F. D. Pyle states that of several kinds of paint tried on the Uncompahgre project only coal tar and coal-tar compound paints had stood one season's use and gave indications of permanence. It was also stated that the indications on that system were that unprotected galvanized-steel flumes will have a life of 10 or or 12 years except under the most trying conditions, *i.e.*, high velocity of water carrying sand and fine gravel, where the life in one particular instance was only four season's use.

The use of steel and iron pipe in irrigation has generally been limited to those conditions of pressure for which other types of pipes were not suited. Their use in irrigation has not been sufficient in length of time or in amount to indicate their probable useful life for such purposes. Data, however, are available from use in mining and power service. Thin steel pipes, such as ⅛ inch in thickness, are used in the smaller sizes for the lighter pressures in some distribution systems, particularly with pumping plants. These should have a useful life of 15 to 25 years. Heavier pipe, ¼ inch thick, should last 25 to 50 years. For pipe of the larger sizes, which can be recoated during the portion of the year when they are not in use, even longer life may be secured.

Due to the thinness of the pipe, protective coatings are relatively more important on steel pipes than on those of other material. The more generally used coatings consist of some of the forms of tar or Asphalt mixtures applied hot, the smaller pipe being dipped and the larger ones treated in the field. The San Fernando siphon of the Los Angeles aqueduct was painted inside and outside with one coat of water-gas tar and two coats of coal tar. One gallon of tar covered about 200 square feet of pipe. The Spring Valley Water Co. has used a mixture of coal tar and natural crude asphaltum, using 1,400 pounds of asphaltum to 50 gallons of coal tar. Some of this coating has been in use nearly 50 years. The Pacific Gas & Electric Co. uses one coat of Dixon's Graphite Paint, inside and outside on unburied pipe, repainting every 2 or 3 years. In some cases steel pipe may be encased in concrete. Where steel pipes are laid in alkali soils special protection may be needed. Pipe 5/16 inch thick has in some cases been corroded entirely through in 3 years where laid in alkali soil in the California oil fields. On the Uncompahgre project in Colorado a 26-inch siphon was built in 1910 in alkali ground for which ingot iron pipe was used. This was in good condition after 4 years use although some rusting had occurred.

Cost of Reinforced Concrete Drops, Canadian Pacific Ry., Irrigation Projects.—Robert S. Stockton gives the following data in Engineering and Contracting, April 14, 1915.

On the Western Section of the Irrigation Block being developed by the Department of Natural Resources of the Canadian Pacific Railway Co., some of the timber structures were built as early as 1905 and have had eight years in the ground. Most of these structures, especially the highway bridges and division gates, are good for a number of years yet, but some of the drops, of which there are a large number, are beginning to develop signs of weakness, and as they must be replaced without stopping the flow of water during the irrigation season, May 1 to Oct. 1, the reconstruction must take place before or after the water season, or during that time by diverting the water around the structure by temporary works.

The policy of the company has been to replace the large timber structures as they approached the end of their life with permanent concrete structures of approved design. The program of betterments for 1913 included the replacement of the large timber holdup drop known as drop No. 2A in the Secondary "A" Canal, Langdon District, S. E. ¼ section 19-23-27. The new 10-ft. drop was designed to be built of reinforced concrete with a central pier and two openings that can be closed with stop plank 5 ft. 9 ins. long. The holdup feature of this drop is required to insure the delivery of water to "B" Distributary in Langdon district, which takes out 3 ft. above canal grade. The drop is designed to discharge 1,000 sec. ft. of water over the crest when the canal carries 8 ft. depth of water. Previous experience indicated the economy of diverting the water and building the drop during favorable weather. The construction crew was moved to the site July 17 to 19 and began the work of excavating the by-pass and building a diverting dam in the canal. The by-pass was completed July 29 and the work of tearing out the old timber drop commenced. The old structure was heavily built, having 2,200 lin. ft. of piling and 54,243 ft. B. M. of lumber incorporated in it. Certain timbers in the old drop proved to be pretty well decayed, particularly above the water line. The piling behind the breast wall was rotted and constituted the weakest spot in the structure.

The excavation disclosed 4 ft. of soil underlaid by a compact boulder clay which proved to be quite impervious, and after the footings and lower concrete floor was in place, there was no pumping required.

The nearest gravel pit was about 15 miles distant and 42 cu. yds, of unscreened material was hauled and used. The pit contains good sand but poor gravel, and when the cost of screening was added and quality considered, it was thought best to ship the larger part of the sand and gravel to Bennett Siding, about two miles from the work. The gravel received from the Calgary Sand & Gravel Co., however, had some oversize that was picked out by hand. The steel shipped to Bennett Siding was mixed up with steel for Strathmore, which necessitated a team haul to straighten out.

A carload of lumber was delivered at Bennett Siding for building the forms, chute, and cement shed, and 1,421 F.B.M. was hauled from Dalroy Watermaster's Headquarters. The carpenters started building forms on August 6 and the cut-off walls were poured on Aug. 27. The last concrete was put in on Sept. 20.

The general mixture was intended to be 1 sack of cement to 2½ cu. ft. of sand and 5 cu. ft. of gravel. For thin walls and copings a mixture of 1-2½-4 was used, and for the lip of the drop 2-2½-5. Since 948 sacks of cement were used, the average was 4.74 sacks per cubic yard of concrete. The concrete was mixed wet enough to spade and was spaded so as to require little patching when the forms were removed. The concrete appears to be of excellent quality. The concrete was mixed with a No. 1 Smith Mixer with steam engine, boiler and side loader mounted on steel trucks.

All labor was paid at prevailing rates, stated at so much per day of 10 hours. Every rate is stated in full and so carried in the time books with board deduction of $5.50 per week. The cost of team feed is taken at 90 cts. per day per team and pro-rated to all work on which team time is charged.

The wages of foreman, barn boss, and for Sunday time of teamsters are pro-rated to all labor items. Two rates of wages were paid, as it has been necessary to make a raise at harvest time to hold the men; even at the increased rate, considerable trouble was experienced, as farmers were then paying about $2.50 per day and board. The wages paid were as follows: Laborers at $2.50 to $2.75 per day of 10 hours; teamsters at $2.10 to $2.35 per day of 10 hours, and including Sundays; carpenters at $3.50, $4 and $5 per day, and foreman at $120 per month.

The detailed cost records follow:

LABOR COST—DROP NO. 2A—LANGDON DISTRICT

Feature	Labor cost	Unit cost	Quantity and unit
Moving camp (16 miles)	$ 68.00	....	
Setting up camp (for 24 men)	19.55	....	
Camp expenses	7.00	....	
Hauling supplies	159.30	....	
Excav. of by-pass (Clayloom)	210.00	$ 0.139	1,507 cu. yds.
Excav. of old drop	1,250.00	0.636	1,967 cu. yds.
Removal of old drop	126.80	2.338	54.243 M. ft. B. M.
Building cement shed	8.96	8.070	1.112 M. ft. B. M.
Building chute in by-pass	34.00	33.660	1.010 M. ft. B. M.
Hauling lumber (2 miles)	46.60	1.987	23.438 M. ft. B. M.
Steel (2 miles)	4.10	0.031	129.96 cwt.
Cement (2 miles)	40.00	0.042	948.00 cwt.
Gravel (2 miles)	162.90	0.975	167 cu. yds.
Sand (2 miles)	72.00	1.060	68 cu. yds.
Sand and gravel (15 mi.)	88.60	2.685	33 cu. yds.
Mixer and pump (21 mi.)	29.30	....	
Pumping water	13.10	....	
Building forms	591.00	0.100	5,929 sq. ft.
Bending and placing steel and wire fabric	110.65	0.851	129.96 cwt.
Mix. and placing concrete	336.10	1.680	200.00 cu. yds.
Removal of forms	51.25	0.009	5,929 sq. ft.
Backfilling by-pass	143.40	0.090	1,600 cu. yds.
Backfilling drop	375.70	0.237	1,588 cu. yds.
Removal of chute	6.88	6.812	1,010 M. ft. B. M.
Repairs to bank	106.88	0.822	130 cu. yds.
Riprap to bank	30.10	1.027	29.3 cu. yds.
Cleaning up, etc	13.72	....	
Total labor cost	$4,105.89	....	Includes team feed.

MATERIAL COST—DROP 2A—LANGDON DISTRICT

Feature	Quantity	Cost	Freight	Total cost	Unit cost
Reinforcing steel	11,921 lbs.	$ 229.72	$ 60.55	$ 290.27	$ 0.024
Wire fabric	1,075 s. f.	22.84	6.73	29.57	0.027
Cement	237 bbls.	482.86	45.75	528.61	2.230
Gravel	167 yds.	183.70	61.30	245.00	1.467
Sand	68 yds.	74.80	25.10	99.90	1.469
Lumber	23,438 ft. B. M.	323.94	54.80	290.13*	12.380
Rope repairs, etc		44.35	......	44.35	....
Total material cost		$1,362.21	$254.23	$1,527.83	......

Total labor cost, including team feed		$4,105.89
Total material cost		1,527.83
Depreciation on concrete mixer, pump, wagons, harness, horses, etc	$302.44	
Depreciation on camp equipment	42.45	
		344.89
Overhead expense of superintendence, engineering, office work, accounting, etc		938.00
		$6,916.61

* Less $88.61 salvage value.

Summary of Feature Costs—Drop No. 2A—Langdon District, 1913

	Cost	Cost per yd. of concrete
Camp and supplies	$ 311.92	$ 1.560
Excavation and backfilling	2,085.98	10.430
Preparatory work	219.04	1.095
Hauling materials	414.20	2.071
Building forms	591.00	2.955
Bending and placing steel	110.65	0.554
Mixing and placing concrete	336.10	1.681
Removal of forms	51.25	0.257
Steel and wire fabric	319.84	1.595
Cement	528.61	2.643
Gravel and sand	344.90	1.725
Lumber	290.13	1.451
Riprap below drop	30.10	0.151
Depreciation	344.89	1.725
Overhead expense	938.00	4.690
	$6,916.61	$34.583
Camp and supplies and preparatory work	$ 530.96	$ 2.655
Excavation and backfilling	2,085.98	10.430
Concrete work	2,986.68	14.932
Riprap below drop	30.10	0.151
Depreciation	344.89	1.725
Overhead expense	938.00	4.690
	$6,916.61	$34.583

Cost of a Reinforced Concrete and Check Delivery Structure for an Irrigation Canal.—H. M. Rouse, in Engineering and Contracting, Sept. 6, 1911, gives the following:

Five small reinforced concrete check and delivery structures were constructed in 1910 by the California Development Co., for one of its new irrigation canals in the Imperial Valley, California. Three of the five gates were under construction at the same time, the common camp being a half mile from the Banyan check and delivery.

All materials were purchased through the company Store Department which made a charge of 10 per cent of cost of materials in store. This charge includes unloading from cars at Calexico, Store Department bookkeeping and miscellaneous labor, and depreciation on tools. The labor rates were as follows:

Foreman, per month	$135.00
Sub-foremen and first carpenters, per day	3.50
Second carpenters, per day	3.00
Carpenter helpers, per day	$2.75 & 2.50
Laborers (white), per day	2.50
Laborers (Mexican), per day	1.50
2-horse team, wagon and driver, per day	4.50
4-horse team, wagon and driver, per day	7.00

The structure contains 66.5 cu. yds. of concrete, and the total cost was $2,124.27, divided as follows:

Development Work.—The development work was little; it comprised building a protection levee, placing a water storage tank and building a mixing board at an aggregate cost of $6.61 or 9.94 cts. per cubic yard of concrete.

Excavation.—The excavation for the concrete work amounted to 180 cu. yds, and was done with shovels. About one-half of the excavation was from trenches 10 ft. deep and 3 ft. wide, maximum dimensions, and the material had to be handled twice. The material was adobe and its excavation cost $160 or 88.8 cts per cubic yard. The charge per cubic yard of concrete in the structure was $2.41. There were 2.71 cu. yds. of excavation per cubic yard of concrete.

Form Construction.—A total of 3,200 ft. B. M., second-hand Oregon pine lumber was used for the forms; 2,400 ft. B. M. 1 × 6-in. boards and 800 ft. B. M. 2 × 4-in. studding. This lumber was valued at $25 per M. ft B. M. by the Store Department. The labor required comprised erecting forms on both sides of 6 and 8-in. walls. The cost of forms for materials and labor was as follows:

Materials:	Cost
3,200 ft. B. M. lumber at $25 per M	$ 80.00
Store department charge of 10%	8.00
Loading	3.00
Hauling	20.00
Total lumber	$111.00
80 lbs. nails at 4 cts	$ 3.20
Store department charge of 10%	0.32
Total nails	$ 3 52
Grand total materials	$114.52
Labor:	
Building and renewing forms	$197.65
Grand total materials and labor	$312.17

Summarizing we have the following cost per cubic yard of concrete for forms:

Item	Per cu. yd.
Materials	$1.72
Labor	2.97
Total	$4.69

The cost of forms per thousand feet, board measure, was as follows:

Item	Per M ft.
Materials	$35.79
Labor	61.80
Total	$97.59

Reinforcement.—The reinforcement used consisted of ⅝-in. round bars and wire. The bars used were of nickel steel and were cut with hacksaw and bent with gas pipe. The cost for materials and labor was as follows:

Materials:	Cost
3,500 ft. ⅝-in. bar at 3.28 cts	$114.80
Store department charge	11.48
Loading	1.50
Hauling	5.25
Total bars	$133.03
Wire at $4.07 per 100 lbs	$ 2.23
Total materials	$135.26
Labor:	
Cutting, bending and placing	$ 27.22
Total reinforcing in place	$162.48

Summarizing we get the following costs per cubic yard of concrete:

Item	Per cu. yd.
Materials	$2.03
Labor	0.41
Total	$2.44

Concrete.—The concrete was a cement, sand and gravel mixture of 1.24 bbls. cement and 1.28 cu. yds. of sand and gravel per cubic yard of concrete in place. The cost of 82½ bbls. of cement on the ground was as follows:

Item	Cost
65 bbls. Calton at $3.80 on cars Calexico	$247.00
17½ bbls. Alsen at $4.98 on cars Calexico	87.15
Store department charge	33.42
Loading	1.50
Hauling	47.00
Total cost on ground	$416.07

This is a cost for cement of $5.04 per barrel on the ground and of $6.26 per cubic yard of concrete in the structure.

There were used 79.07 cu. yds. of gravel and 6 cu. yds of sand at the following cost:

Item	Cost
44.85 cu. yds. Andrade gravel at $2.95	$132.31
30.46 cu. yds. Frink gravel at $3.11	94.80
3.76 cu. yds. Mammoth gravel at $2.91	10.94
6 cu. yds. Whitewater sand at $2.17	13.02
Total on cars at Calexico	$251.07
Store department charge	$ 25.10
Loading	8.00
Hauling	140.00
Total sand and gravel on ground	$424.17

The average cost of sand and gravel on cars at Calexico was $2.95 per cubic yard. Hauling cost $1.65 per cubic yard and the other charges noted brought the cost per cubic yard on the ground up to $4.98. The cost per cubic yard of concrete in the structure was $6.37. The concrete was mixed by hand in ½ cu. yd. batches, wheeled in barrows and rammed in place. The labor cost for mixing and placing was $171.09 or $2.57 per cubic yard of concrete. Summarizing we have the following costs for concrete in place:

Item	Total	Per cu. yd.
Cement	$ 416.07	$ 6.26
Sand and gravel	424.17	6.37
Labor mixing and placing	171.09	2.57
Totals	$1,011.33	$15.20

Backfilling and Puddling.—The cost of backfilling and puddling trench as described above was as follows:

Item	Total
Men	$32.97
Fresno team	2.25
Total	$35.22

This is a charge of 53 cts. per cubic yard of concrete.

Gates and Gate Lifters.—The cost of materials and labor for six gates and lifting apparatus was as follows:

Item	Total	Per gate
410 ft. B. M. redwood at $40	$ 16.40	$ 2.73
82 ft. 2½ × 3-in. angle at 4 cts. lb	20.80	
Bolts	3.43	4.04
6 lifter sets at $20.31	121.86	......
6 c. i. pedestals at $4.34	26.04	......
11 30-in. sections c. i. rack at $1.35	14.85	......
Total	$162.75	$27.12
Grand total material	$203.38	$33.89
Store department charge	20.33	......
Hauling	10.00	......
Total material on ground	$233.71	$38.95
Labor 6 gates at $2.11	12.70	......
Total gates in place	$246.41	$41.07

General Labor.—The charges for general labor was one-third of foreman's time at $135 per month; one-third of time keeper's time at $2.50 per day. The amounts were:

Foreman	$57.35
Timekeeper	16.60
Total	$73.95

Engineering.—Engineering included office work, drafting and paper and field work inspection and staking our structure. The charges were:

Office work	$ 47.30
Field work	68.80
Total	$116.60

This is a cost of $1.74 per cubic yard of concrete.

Recapitulation.—From the above figures we get the following summaries of costs:

Item	Total	Per cu. yd. concrete
Development work	$ 6.61	$ 0.9094
Excavation	160.00	2.4100
Concrete work	1,485.98	22.3400
Backfilling	35.22	0.5300
Gates, etc	246.41	3.7000
General labor	73.95	1.1120
Engineering	116.10	1.7400
Total	$2,124.27	$31.94

Summarized by the items, labor, materials and engineering the cost per cubic yard was as follows:

Item	Per cu. yd.	Pct.
Labor	$10.29	32.22
Materials	19.91	62.32
Engineering	1.74	5.46
Total	$31.94	100.00

Costs of Irrigation Construction on the Rock Creek Conservation Co.'s Project at Rock River, Wyoming.—W. D'Rohan, in Engineering and Contracting, Dec. 27, 1911, gives the following:

All the canals and laterals were taken out by contract to a uniform section of 8 ft. bottom and 1 to 1 slopes, at an average price of 17 cts. per yard, they are all in cut, with an average depth of 4½ ft.

Owing to the wide extent of the project, the long moves over rough roads would soon wreck any machinery, so the management decided that it would be more economical to mix all the concrete by hand, and over 3,000 cu. yds. were mixed and placed in this manner. Gravel was obtained from the creek. and was hauled to the various points by contract at $6.70 per yard. The contractor had to screen it as well. For this, he built a trap 18 ft. high, with a 10-ft. chute, in the bottom of which was placed the screen; the gravel was taken out of the creek bed with wheelers, carried up the inclined run and dumped into the trap from which it ran down the screen into the wagons. Sand was shipped from Laramie at 40 cts. per ton, freight $1, and hauling on the job $1.80 per ton. Ideal cement cost $2.20 per bbl. laid down and was hauled by company teams on the work. Lumber for forms cost $22 per 1,000 ft. and was used four times.

Headgate.—The top slab of the gate over which is a wagon road was reinforced with ½-in. rods spaced 8 ins. apart, while plums were used in the heavier parts of the walls. The mix used throughout was 1:2½:5 for plain concrete, and 1:2:4 for reinforced. The cost of the headgate was distributed as follows, for 111.7 cu. yds. of concrete:

Excavation:	Total	Per cu. yd.
Item		
276 hrs. laborers at 25 cts	$ 69.00	......
15 hrs. teams at 50 cts	7.50	......
50 hrs. foreman at 35 cts	17.50	......
Total excavation	$ 94.00	$ 0.84
Materials:		
133 bbls. cement at $2.20	$ 279.30	......
5,000 ft. lumber at $22 per M	27.50*	......
46 cu. yds. sand at $4.80	220.80	......
60 cu. yds. gravel at $6.70	402.00	......
48 cu. yds. "plums" at $1	48.00	......
160 lbs. steel rods at 2 cts	3.20	......
Water and hauling cement	25.00	......
Total materials	$1,005.80	$ 9.00
Labor:		
540 hrs. mixing and placing at 25 cts	$ 135.00	......
160 hrs. carpenters at 40 cts	64.00	......
90 hrs. helpers at 27.5 cts	24.75	......
80 hrs. foreman at 40 cts	32.00	......
Total labor	$ 255.75	$ 2.29
Grand total	$1,355.55	$12.13

* Lumber used four times.

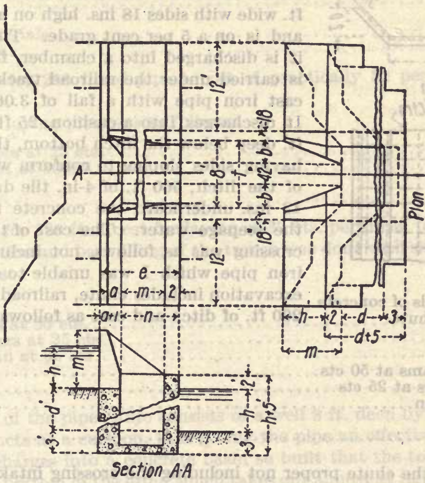

FIG. 12.—Standard concrete drop.

Drops.—All of the drops were of the standard design, shown by Fig. 12. The cost of this drop was as follows for 65.5 cu. yds. of concrete:

	Total	Per cu. yd.
Excavation:		
270 hrs. laborers at 25 cts.	$ 67.50	.....
30 hrs. foreman at 30 cts.	9.00	.....
Total excavation	$ 76.50	$ 1.15
Materials:		
2,500 ft. B.M. lumber at $22 per M.	$ 13.75*	.....
32 cu. yds. sand at $4.80	153.60	.....
317 sacks cement at $2.10 per bbl.	166.42	.....
35 cu. yds. gravel at $6	210.00	.....
25 cu. yds. "plums" at $1	25.00	.....
Total materials	$568.77	$ 8.55

	Total	Per cu. yd.
Labor:		
315 hrs. mixing and placing at 25 cts	$ 78.75	......
58 hrs. carpenters at 40 cts	23.20	......
95 hrs. helpers at 27.5 cts	26.12	......
20 hrs. wiring forms at 25 cts	5.00	......
Hauling cement, water, etc	6.60	......
Total labor	$146.47	$ 2.20
Grand total	$791.74	$11.90

*Lumber used four times.

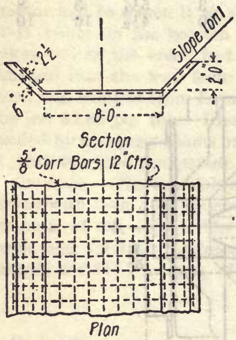

Fig. 13.—Details of concrete lined chute.

Open Chute.—The open chute, shown by Fig. 13, is 297 ft. long. It is built of reinforced concrete 6 ins. thick, the bottom being 8 ft. wide with sides 18 ins. high on a 1 to 1 slope, and is on a 5 per cent grade. The water from it is discharged into a chamber, from which it is carried under the railroad tracks by a 54-in. cast iron pipe with a fall of 3.06 ft. in 60 ft. It discharges into a cushion, 25 ft. long, and 5 ft. deep below the ditch bottom, the upper part having sides sloping to conform with the shape of the ditch; 560 ft. of 4-in. tile drain pipe laid 12 ins. underneath the concrete takes care of the seepage water. The cost of the chute and crossing was as follows, not including the cast iron pipe which I was unable to obtain. The excavation includes chute, railroad crossing and 200 ft. of ditch and cost as follows:

Item:	Total
632 hrs. slip teams at 50 cts	$316.00
735 hrs. laborers at 25 cts	181.25
129 hrs. foreman	38.79
Total	$535.95

The cost of the chute proper not including the crossing intake and outlet, was as follows for 146.6 cu. yds.:

	Total	Per cu. yd.
Materials:		
513 cu. yds. sand at $4.80	$ 246.24	......
77.7 cu. yds. gravel at $6	466.19	......
24.9 cu. yds. "plums" at $1	24.90	......
698 sacks cement at $2.10 per bbl	366.45	......
4,000 ft. B.M. lumber at $22 per M	22.00	......
¾-in. steel rods, 12 ins. on centers, at 2½ cts	279.19	......
Total materials	$1,422.97	$ 9.71
Labor mixing and placing concrete	$ 317.10	$ 2.16
Grand total	$1,740.07	$11.87

The intake and outlet structures, contained 139.3 cu. yds. of concrete which was placed for $10.42 per cubic yard. The chute and railroad crossing were put in according to plans made by the Union Pacific R. R. Co.

Concrete Pipe.—About one mile from the railroad on another hillside, it was decided to put in concrete pipe instead of the open chute; 288 ft. of bell pipe was made. The mix used was 1:2:3 and was reinforced with ordinary barbed wire, 6 rings being used to each pipe. The concrete was placed very wet and allowed to stay overnight in the forms which were painted with crude oil before every setting. The cost of the pipe making and laying was:

Pipe making:	Cost
810 hrs. mixing and placing in forms at 25 cts	$202.50
50 hrs. team hauling water at 50 cts	25.00
158 hrs. foreman oiling and setting forms at 30 cts	47.40
Total	$274.90
Materials:	
220 sacks cement at $2.20 per bbl	$121.00
33 cu. yds. sand at $4.80	158.40
Oil	10.00
Barbed wire	10.50
Total materials	$299.90
Total pipe	$574.80

(This gives for 288 ft. of pipe a cost of practically $2 per lineal foot.—Editors.)

The cost of laying pipe was as follows:

292 hrs. laborers at 25 cts	$73.00
45 hrs. foreman at 30 cts	13.50
Total	$86.50

(This gives for 288 ft. a cost for laying of 30 cts. per lineal foot.—Editors.)

The excavation and backfilling of the trench was done with slip scrapers at a cost as follows:

Item:	Cost
220 hrs. teams at 50 cts	$110.00
160 hrs. laborers at 25 cts	40.00
87 hrs. foreman at 35 cts	26.10
Total	$176.10

The intake of the pipe chute consists of a well 8 ft. deep by 7 ft. wide, the bottom 2 ft. acts as a cushion, thus giving the pipe an effective head of 6 ft. The pipe discharges into a concrete basin so built that the top of the pipe is level with the bottom of the ditch which takes out almost at right angles to the chute. The two structures contain 118.5 yards of concrete and cost $14.10 per yard.

Wooden Drops.—Owing to the difficulty of obtaining sand, it was impossible to complete the concrete structures in time for the irrigation season, so, temporary wooden drops had to be put in. The drops are very effective. The cost of an 8-ft. drop was:

Materials:	Cost
4,000 ft. B.M. lumber at $22 per M	$ 88.00
35 lbs. nails at 5 cts	1.75
Total materials	$ 89.75
Labor:	
42 hrs. carpenters at 40 cts	$ 16.80
90 hrs. labor excavating at 25 cts	22.50
20 hrs. teams at 50 cts	10.00
Total labor	$ 49.30
Grand total	$139.05

Flashboards.—All of the ditches being in cut makes it necessary to place diversion gates in the channel in order to divert a sufficient head into the laterals. For this purpose, large steel overflow gates are provided. Owing to the want of sand however thay could not be placed in time, and temporary flashboards which contain 250 ft. B. M. of lumber and cost $7.75 to build were used.

Siphon Construction.—The intake and the outlet of the siphon ditch which takes out of the Bosler Canal are two massive reinforced concrete structures. The floor of the intake, is 7 ft. thick reinforced top and bottom, with 1 in. corrugated bars spaced 12 ins. apart. The walls are 15 ins. thick reinforced with ½-in. and ¾-in. rods front and back, spaced 12 ins. and are strongly buttressed. The structure contains 394 cu. yds. of concrete, and 26,627 lbs. of steel. The concrete cost $15.88, and forms and placing steel 73½ cts. per cubic yard. The gates are of the Western type, and cost $500, and the whole structure cost $7,249.97.

The outlet of the siphon is a triangular shaped chamber with 200 sq. ft. of floor space; the east and west outlets taking out at the lower corners. The floor is 3 ft. thick, reinforced with ½ in. and ¾ in. rods spaced 10 ins. The outlets are controlled by overflow diversion gates with three openings each 4 × 5 ft. The structure contains 367 cu. yds. of concrete, and 17,727 lbs. of steel and without the gates cost $5,879.07. Forms and steel placing cost 86 cts. per cu. yd. and the concrete $16.01 per cu. yd.

The 54-in. wood pipe inverted siphon is 4,939 ft. long, and is built of Oregon fir. The staves are 1⅝ ins. thick and kiln dried. The shoes are of the Allen patent of cast iron, and the bolts ½ in. thick are of mild steel, and 50,000 lbs. tensile strength. At the intake and the outlet, and also under the track, the wood pipe laps over a 60-in. cast iron pipe, the joint being made by lapping the iron pipe with tarred oakum rope.

All of the pipe forms, and the welding of the bands for the swelled joints were made on the works, the slotting of the staves which is usually done at the factory was also done here. The bands were painted with asphaltum on the pipe. The tarred rope did not make a successful joint as the tar prevented the rope from absorbing water and swelling; so a concrete collar was put around the joint, an open space 2 × 12 ins. being left on the top of the pipe, this was afterwards plugged with oakum. The costs of the pipe were distributed as follows:

Slotting staves:	
970 hrs. laborers at 27½ cts	$ 266.75
260 hrs. foreman at 30 cts	78.00
Total	$ 344.75
Making Pipe Forms, Bells and Sills:	
140 hrs. carpenter at 40 cts	$ 56.00
20 hrs. blacksmith at 25 cts	5.00
Total	$ 61.00
Welding bands:	
50 hrs. blacksmith at 30 cts	$ 15.00
Laying pipe, cinching bands, painting bands:	
7,932 hrs. laborers at 25 cts	$1,983.00
207 hrs. foremen at 30 cts	62.10
541 hrs. foreman at 35 cts	189.35
Total	$2,234.45

Materials used:	
163,000 ft. B.M. lumber at $31	$5,053.00
Bands	3,188.06
Shoes	605.20
Asphaltum	10.00
Splines	196.00
Oakum for iron pipe joints	20.00
Manhole	56.30
Total	$9,128.56
Hauling cost (distance 2 miles):	
Lumber	$ 489.00
Bands	162.75
Shoes	60.00
Splines	4.50
Total	$ 716.25
Back filling of pipe line:	
1,101 hrs. teams at 50 cts	$ 550.50
790 hrs. laborers at 25 cts	197.50
217 hrs. foreman at 35 cts	75.95
Estimated to complete backfilling	150.00
Total	$ 973.95

That is 4,939 ft. of pipe cost $13,473.96, or $2.70 per foot, without the excavation. The pipe was laid under a maximum head of 75 ft., the bands cost roughly about 42 cts. each, the shoes 8 cts. each.

Cost of Spray Irrigation.—The following is an abstract in Engineering and Contracting, March 14, 1917, of a bulletin on Spray Irrigation issued by the U. S. Dept. of Agriculture:

Economic Conditions Justifying Spray Irrigation.—The cost of spray-irrigation systems depends upon the type installed as well as upon conditions peculiar to each form. A portable outfit may cost as little as $50 per acre for the field equipment, while a stationary distribution system may cost as much as $150 per acre. To these figures must be added the cost of a main pipe line leading from the water supply to the fields and usually the cost of developing a water supply and installing a pumping plant. These additional items may being the total outlay per acre up to two or three times the cost of the distribution system, especially on small acreage. Assuming a cost of $250 per acre on a stationary plant for a small acreage, the farmer should be able to increase his annual returns from each acre to cover approximately the following charges:

6 per cent interest on $250	$15.00
5 per cent depreciation on equipment	12.50
2 per cent maintenance and repairs	5.00
Cost of fuel and oil at 4 cts. per 1,000 gal. of water pumped for 6 acre-inches	*6.50
Labor in irrigating, 1 man 6 days at $2	12.00
Total overhead and operating expenses	$51.00

* Cost of pumping estimated for a plant operating at 50 per cent efficiency against a total head of 150 ft., using gasoline as fuel. The amount of water pumped annually is assumed at 6 acre-inches as a typical duty of water in the Atlantic Coast States where spray irrigation is most extensively used. More arid sections require larger amounts.

It will be noted that $51 per acre per year is necessary in returns to cover overhead and operating expense incidental to the spray system. To realize a fair profit from the irrigation plant, the crops must increase in value something more than $51 per acre. In the case of berry, tobacco, and orchard crops the increase must be derived from one main crop and a possible intercrop. On the other hand, the irrigator of truck who follows intensive culture has a chance of dividing the annual increase among three to six crops. The high cost of spray irrigation eliminates its use on many crops which respond readily to irrigation. It is possible, however, to use cheaper methods of distribution on many of these crops which are grown on land having an even surface. A combination of spray irrigation and surface methods on the same farm often can be placed under one pumping plant, as illustrated in Fig. 14, thereby utilizing to the fullest extent the water supply, pumping equipment, and main pipe lines. The typical farm illustrated in Fig. 14 indicates the use of spray irrigation on the more uneven parts where the topography is not adapted to cheaper methods, but where the soil and southern slope are desirable for the growing of early and intensive truck and berry crops that will justify spray irrigation. The main feed pipe is extended to the upper and more even parts of the farm, where cheaper methods of irrigation can be applied to alfalfa, orchard, bush berries, potatoes, and other crops grown in wide rows for horse cultivation.

Truckers in the arid sections seem to favor a combination of spray irrigation and surface irrigation on the same field. The spray is used in the preparation of the seed beds, germinating seeds, and starting newly set plants. Later the crops are irrigated during the maturing and fruiting periods by the surface furrow or check methods. A portable spray equipment often meets these conditions most economically, because it can also be used for the irrigation of hot-bed and cold-frame crops.

Farm Conditions Adapted to Spray Irrigation.—Spray irrigation can be practiced to advantage on both light and heavy soils. By this method it is possible to apply evenly to sandy soils the small quantities of water which such soils will retain, without the loss of water by percolation which might occur with other methods. It is possible also to apply to heavy clay soils the small quantities of water required to soften such soils when they have baked after rains, and to apply water no faster than the soil can absorb it, thus preventing loss by surface run-off.

Lands to be irrigated should be drained as completely as possible of excess moisture. Many tile-drained fields are the most responsive to crops under spray irrigation.

Spray irrigation is practically independent of the topography of the field and can be applied to land too rolling or rough for surface methods. It is, therefore, adaptable to the irrigation of side hills on which soils tend to wash or erode.

Amount of Water Required for Spray Irrigation.—As yet, the available knowledge on the amount of water required for spray irrigation is limited, because of the comparative newness of the methods and the lack of actual records on plants under a time test. In the humid regions amounts not exceeding ¼ in. in depth often are considered a sufficient application to seed beds and young vegetables, while in the case of maturing garden crops and strawberries ½ to 1 in. may be applied. It is probable that truckers in the humid region do not use more than 6 in. in a growing season and in many seasons 4 in. or less will supplement the rainfall sufficiently. More water is required for sandy soils than for clay. A crop like the spray-irrigated citrus groves of

Florida may require as much as 3 in. per irrigation. Truck and citrus growers in the arid regions apply more water than those in the humid region, probably because of a large evaporation loss. In the arid region the truck farmer is inclined to make frequent applications—every 3 or 4 days—rather than to apply the extra amount of water required in large applications which will wet below the reach of the vegetable roots, while the citrus grower applies from 4 to 8 in. each time.

For spray irrigation sufficient water to cover the land to a depth of 1 in. per week for humid regions and 1½ in. per week for arid regions is believed to be a safe estimate for designing purposes. A spray plant should be large enough to supply these amounts of water in a reasonable length of time. This is accomplished generally by installing the system of spray from one-fifth to one-half of the total acreage at one time, depending somewhat upon the type of distribution used and the available water supply.

All spray irrigation plants require power pumping equipment unless pressure can be supplied from an elevated source or municipal waterworks. To generate a spray requires a high-pressure pump producing 25 to 40 lb. pressure on the nozzles in addition to elevating the water to the field.

The Designing of Spray Irrigation Systems.—Every spray irrigation system can be divided into three parts, which must be considered in their proper relation to each other in the design of a plant. First, the distribution-pipe system, which applies the water directly to the crops through some type of nozzle; second, the main feed pipe, which conveys the water from the source to the distributaries; third, the pumping equipment, which lifts the water and develops the pressure, unless the water and pressure are obtained from a gravity or municipal supply.

The distribution system should be laid out to use the minimum amount of large pipe for both distributaries and main feed pipe. The laterals or nozzle lines should run in a direction which will give the least amount of obstruction to the cultivation of the field in the most efficient manner. The field should be laid off in irrigation blocks or units, a unit representing the area to be irrigated at one item. The unit should be of a desirable length for the kind of crops to be irrigated. Where possible, it is advisable to divide the field by the irrigation system into blocks which will make the estimating of acreages easy when arriving at the amount of seed and fertilizer required or determining yields. This is done usually by having a convenient fraction of an acre under each spray line or by having the crop rows a length which will make each rod or yard in width a known fraction of an acre.

To keep the cost of a spray distribution system as low as possible, yet obtain a good uniform pressure and distribution of water, the sizes of pipes must be proportioned properly. Each lateral or nozzle line must be proportioned in size according to the number and capacity of the nozzles used. The main feed pipe must be proportioned to carry the total amount of water to the most distant irrigation unit and then be reduced in size as the water is decreased by each nozzle line within the irrigation unit. The water required to run an irrigation unit determines the capacity of the pumping equipment.

Table XXVI is a bill of materials for the typical farm shown in Fig. 14. Pipe less than 2 in. in diameter can be cut in the field, hence the actual number of feet required is stated for such pipe. "Location" refers to the location in the field. Nozzle lines are assumed to be 630 ft. long on each side of the farm road. Pipe posts are assumed to be set 18 ft. apart, and 9 ft. long, to support nozzle lines 6½ ft. above the surface.

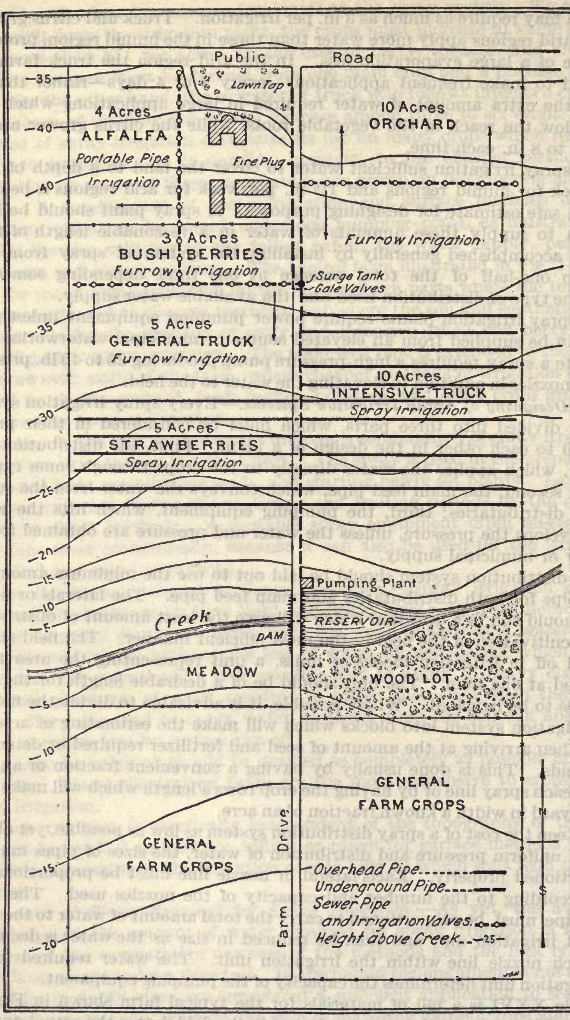

FIG. 14.—Typical 80-acre farm in humid regions, showing development of water supply by reservoir and a combination of spray and surface methods of irrigation operated from one pumping plant.

TABLE XXVI.—BILL OF MATERIALS

Amount	Size, inches	Item	Location
1 run, 410 ft	6	Black guaranteed wrought-iron pipe, cut to exact length, with allowance for 1 tee in each run	Main feed pipe.
12 runs, 50 ft. each	6	do	Do.
1 run, 25 ft	6	do	Do.
20 runs, 30 ft. each	2	Galvanized wrought-steel pipe	Feed end east-and-west nozzle lines.
20 pieces, 7 ft. each	2	do	Nozzle-line risers.
7 pieces, 15 ft. each	2	do	Pipe under road, east-and-west lines.
3,500 ft	1½	do	Do.
3,500 ft	1¼	do	Do.
3,200 ft	1	do	Do.
1,800 ft	¾	do	Far end all nozzle lines.
700 pieces, 9 ft. each	1¼	Galvanized wrought-steel pipe, plain ends	Pipe posts.
7	6 by 2 by 2	Black side outlet cast-iron tees	Main feed pipe.
6	6 by 2	Black cast-iron tees	Do.
7	2	Black malleable 90 ells	Bottom west risers.
20	2	Galvanized malleable 90 ells	Top east-and-west risers.
20	2	Galvanized long nipples	Feed end nozzle lines.
20	2 by 1½	Galvanized reducing sockets	Nozzle lines.
20	1½ by 1¼	do	Do.
20	1¼ by 1	do	Do.
20	1 by ¾	do	Do.
20	2	Standard brass gate valves	Feed end nozzle lines.
20	⅔	do	Far end nozzle lines.
1	6	Standard iron-body gate valve	End of main.
20	2	Trade name, etc., turning unions	Nozzle lines.
3,160	No. —.	Trade name, etc., nozzles	Do.
700	No. —.	Trade name, etc., galvanized hangers	Top of posts.

Note.—Main feed pipe is made 6-in. size full length, as full head of water to be pumped to farther fields for surface irrigation.

Cost of Spray System of Irrigation for Lawn Sprinkling.—According Burt A. Heinly, Engineering News, April 11, 1912, the cost of lawn sprinkling which was practically eating up the annual appropriation for parks, was cut 80 per cent by automatic sprinkling apparatus.

The system is simple in the extreme. It is composed (Fig. 15) of pipes laid in radiator circuits from 12 to 15 in. beneath the ground, which supply stand-pipes to which sprinkler heads placed flush with the ground are attached at intervals of 20 ft. Experiments showed that a circle whose diameter is the diagonal of a 20-ft. square is about the maximum over which water can be distributed from a single sprinkler top. It is obvious that to irrigate any large area simultaneously, the supply main and radiating pipes would have to be of large size, else the resultant release of water from many escapes would so reduce the pressure as to destroy the purpose of the apparatus. The radiator system is therefore separated into circuits or series, each of which is

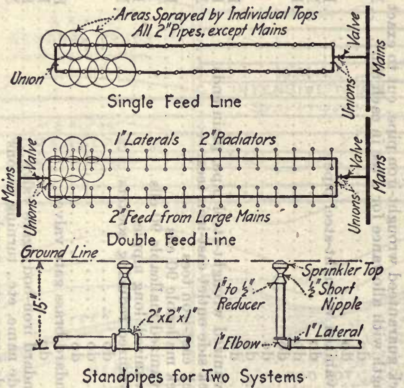

Fig. 15.—Spray irrigation system, Los Angeles, Cal.

controlled by one or two valves, according to whether the circuit is fed from one or two ends. With the application of a volume of water equal to the discharge, the series is set in operation, the sprinkler then providing the necessary distribution in the form of a spray.

The system was devised by Frank Shearer, superintendent of parks, and the installation was made in Central Square, a five acre tract near the heart of the retail shopping district. The park was being entirely remodeled, which included the stripping of the lawn, so that unusual opportunity was offered for the work. Here a single-feed system, controlled by one valve (Fig. 15) was used. The supply main is 4 in. in diameter and the circuit pipes 2 in. in diameter. The water pressure in the city mains is approximately 60 lbs. per sq. in. at this point. Three dozen sprinkler heads were attached to each series, which irrigates approximately 17,000 sq. ft. Eleven series are thus required for sprinkling the 4.3 acres of lawn area. The system cost about $400 per acre, installed, which is nearly double the cost of piping for hose irrigation which includes the purchase of hose.

With this system in use, it requires the time of one man for only two hours to do the day's sprinkling over the entire park. With irrigation by hose sprinkling it took two men the entire day to perform the task. At the rate of $2 per day for eight hours' work this is a net daily saving of $3.50 per day, or $1277.50 per year on this small park, where within 20 months the device will pay for itself.

Selection, Installation and Cost of Small Pumping Plants for Irrigation.—The following discussion is given by B. A. Etchverry, Department of Irrigation, University of California, in Engineering and Contracting Nov. 5, 1913.

The proper selection of a pumping plant depends upon many factors which should be carefully considered by the intending purchaser. These factors are: (1) source of water supply, (2) capacity of plant and period of operation, (3) the kind of pump, (4) the class of engine or driving power. (5) the first cost, (6) the fuel cost, (7) the cost of fixed charges and attendance. These factors are interdependent and should be considered together. Their relative importance will vary with local conditions and for that reason it is not possible to state definite rules which will apply in all cases. A study of the conditions affecting each factor is therefore necessary in each case.

1. *Source of Water Supply.*—The source of water supply may be surface water supply, such as water occurring in rivers, lakes, canals, etc., or may be ground water supply. Where surface water is available, the water will be developed by means of a proper intake, which for the simplest cases will consist simply of the suction pipe of the pump extending into the body of water. Where ground water is available the most common means of development is by wells.

Wells.—The well may be a dug, bored or drilled well. The most common form of well for individual pumping plants in California is a drilled or bored well 10 to 16 ins. in diameter or larger, lined with a casing, which may be one of the three following types:

(1) Standard steel screw casing;

(2) Single galvanized iron casing, No. 12 to No. 16 gauge, with joints riveted together;

(3) Double black steel casing, No. 12 to No. 16 gauge, known as California stovepipe casing, and very generally used in southern California. This casing is made of riveted steel sections 2 ft. long placed with broken joints. The bottom of the casing consists of a starting section 15 to 20 ft. long, made of triple thickness, riveted together, with a steel shoe at the lower end.

The well and casing should extend into the water-bearing gravel sufficiently far to give a perforated area equal to at least five times the cross section area of the well. The perforations are made with an improved cutting tool, and consist of 6 to 8 slits made in each ring or circle; each slit 12 to 18 ins. long and ⅜ to ¼ in. wide. A space of 4 ins. is skipped and another ring of slits staggered with the adjacent ones is made. Slits should not be over 18 ins. long with stovepipe casing.

In southern California, near Chino, the price of drilling deep wells is as follows:

For 10, 12 and 14-in. wells in fine material, $1.25 per foot for first 500 feet.

For 16-in. wells in fine material, $1.50 per foot for first 500 feet.

For depths greater than 500 ft. the price is 50 cts. extra for each additional foot.

The cost per foot of steel stovepipe casing is about as follows:

Diameter, ins.	12 gage	14 gage
10	$1.12	$0.92
12	1.27	0.99
14	1.51	1.12
16	1.80	1.24

2. *Capacity of Plant and Period of Operation.*—The required capacity of the plant will depend on the area irrigated, the duty of water or depth of water required on the land and the period of operation. For ordinary orchard soil a total depth of 12 ins. of water during the irrigation season will be sufficient for young orchards. For a full-bearing deciduous orchard 18 ins., and for a citrous orchard 24 ins. should be ample, while for alfalfa and other forage crops 24 to 36 ins. is plenty. Where the cost of pumping is high, such as for small plants and high lifts, it will usually not be feasible to grow at a profit anything but orchards. To reduce the cost of pumping, no excess water should be used, all losses should be prevented by careful irrigation and thorough cultivation, in which case a young orchard on fairly deep retentive soil may not require more than 6 to 9 ins. of irrigation water and a full-bearing orchard not more than 12 or 15 ins. for deciduous trees and 18 ins. for citrus trees during the irrigation season. To put a depth of 2 ft. of water on one acre, it takes a flow of very nearly 1 cu. ft. per second for 24 hours; this is equivalent to 450 gals. per minute for 24 hours. This relation can be applied to any case to obtain the size of the pump. For example, if it is desired to irrigate a 40-acre orchard 1½ ft. deep, in an irrigation seasons of 120 days, this requires 60 acre feet in 120 days or ½ acre foot per day. This will be obtained by a pump giving ¼ cu. ft. per second, or 110 gals. per minute, when the pump is operated continuously 24 hours a day every day during the irrigation season of four months. For a 10-acre orchard the required capacity based on the same conditions would be one-quarter of the above, or 28 gals. per minute, or 1/10 cu. ft. per second.

The above two examples are based on a pump operating continuously at the rates given above. While continuous operation decreases the required size of plant, it is usually preferable to select a plant of larger capacity and operate it only a part of the time. This is especially desirable for very small orchards, in which case continuous operation gives a stream too small too irrigate with. The other disadvantages of continuous operation are:

(1) Continuous operation requires continuous irrigation and constant attention to operate the pumping plant. For very small tracts a regulating reservoir may be used, but it must be of considerable capacity to be of any service, and it must be lined with concrete to prevent seepage losses of the water, which when pumped is too valuable to lose. Usually it is preferable to purchase a larger plant and do without a reservoir.

(2) Continuous operation gives a small stream which cannot be applied economically.

(3) Continuous operation means that the water cannot be applied to the different parts of the orchard within a short time, so that only a small part of the orchard or farm receives the water when most needed, and the remainder must be either too early or too late.

(4) A small plant is less efficient and requires a proportionately larger fuel consumption than a larger plant, to pump the same quantity of water.

On the other hand, a very short period of operation requires a comparatively large pumping plant, which will greatly increase the first cost of installation the interest on the capital invested, the depreciation and fund necessary to provide for renewal. It also requires a larger source of supply, which may not always be available. For instance, the required flow may exceed the capacity of the well or may so lower the water plane that the cost of pumping will be increased. Also in some localities the power company may offer a low flat rate for continuous use.

Usually it is desirable to operate the pump not over one-half or one-third of the time during the irrigation season and often a shorter period is desirable. This requires a pumping plant two or three times or more the size required for continuous irrigation. The capacity of the pump must be sufficient in all cases to give a large enough stream to irrigate economically; even for the smallest orchards a stream of at least 5 to 10 miner's inches or about 50 to 100 gals. per minute is desirable.

For a full-bearing orchard 18 ins. of irrigation water for deciduous trees and 24 ins. for citrus trees, applied in three to four irrigations of 6 ins. each, at intervals of 30 to 40 days, should be ample in most cases. As stated above where the water has to be pumped to high elevation, the higher cost of the water demands greater care in its use and 12 to 18 ins. total depth of irrigation water would be sufficient.

Table XXVII gives the required pump capacity for various sizes of orchards or farms and for different periods of operation. It is based on a depth of irrigation water of 6 ins. each month, or 18 ins. in three months, which is taken as the irrigation season. The period of operation is given in number of 24-hour days that the pumping plant is operated each month. These days need not be consecutive; for instance, if the operation period is 10 days, instead of applying 6 ins. of water in one irrigation lasting 10 days, the soil may be so porous and gravelly that it will not retain the moisture, in which case it may be preferable to apply 3 ins. at a time in two irrigations during the months, of five days each. The required pump capacity is given in U. S. gallons per minute.

The capacity of pumps for smaller or greater depths of water applied per month can be easily computed by proportion from the values given. For different areas and different periods of operation the capacity may be obtained by interpolation.

TABLE XXVII.—NECESSARY CAPACITY OF PUMPS IN U. S. GALLONS PER MINUTE TO GIVE A 6-INCH DEPTH OF WATER ON THE LAND EACH MONTH WHEN OPERATED THE FOLLOWING NUMBER OF 24-HOUR DAYS EACH MONTH

Area, acres	30 days	20 days	15 days	10 days	5 days	1 day
5	19	28	38	56	113	563
10	37.5	56.25	75	112.5	225	1,125
15	57	85	113	170	340	1,690
20	75	113	150	225	450	2,250
30	113	169	225	338	675	3,375
40	150	225	300	450	900	4,500
60	226	338	450	675	1,350	6,750
80	300	450	600	900	1,800	9,000
120	450	675	900	1,350	2,700	13,500

3. *Kind of Pump.*—The kinds of pump commonly used to raise water for irrigation are: (1) centrifugal pumps, (2) power plunger pumps, (3) deep well pumps, (4) air lift pumps, (5) hydraulic rams. Where the source of water supply is a surface body of water, either a centrifugal pump, a power plunger pump or a hydraulic ram will be used; where the source of water supply is ground water developed by wells, usually either a centrifugal pump, a deep well pump, or an air lift pump will be used and in some cases a power plunger pump. For deep wells usualy the vertical centrifugal pump placed in a pit or an air lift pump is used. Hydraulic rams are used for small quantities of water such as for domestic purposes or for irrigation of small pieces of land. They are economical in operation, but require special conditions such as a nearby stream or canal with sufficient fall in a short distance.

Centrifugal Pumps.—A centrifugal pump consists of a circular casing with the inlet or suction end connected to the center and the outlet or discharge end formed tangent to the perimeter. Inside the casing is the runner or impeller keyed on the shaft and revolving with it. It is formed of curved vanes closely fitting the casing. There are two general types: First the horizontal centrifugal pump, which has a horizontal shaft; second, the vertical centrifugal pump with a vertical shaft. When in operation the impeller by revolving imparts a velocity to the water between the vanes and forces it away from the center of the casing towards the perimeter of rim of the casing through the outlet and up the discharge pipe. This produces a partial vacuum at the center of the impeller, which induces a flow through the suction pipe into the casing. The number of revolutions of the runner or speed of the pump has an exact relation to the head or lift against which the pump is working and for every head there is a speed for which the pump works most efficiently. This speed can be obtained from the pump manufacturers. It is important that the pump be connected to an engine or motor which will give it the proper speed. Over-speeding is preferable to underspeeding, but either reduces the pump efficiency.

Simple centrifugal pumps specially designed and driven at a sufficiently high rate of speed may be used for lifts considerably over 100 ft., but usually the stock pump obtainable from the manufacturers is not suitable for lifts over 75 ft., and for the smaller sizes the total lift should not exceed 50 ft. For higher lifts compound or multi-stage centrifugal pumps are used. These consist of two or more pumps connected in series, the discharge of the first pump or stage is delivered into the suction of the next pump and the operation is repeated, according to the number of stages. Usually 75 ft. to 125 ft. is allowed to each stage. When the required capacity of the pumps is over 100 or 150 gals. per minute and the total lift less than 75 ft. the centrifugal pump is no doubt the best adapted.

Centrifugal pumps are usually denoted by a number which represents the diameter of the discharge in inches. The efficient capacity of each size will vary to some extent with the speed of the pump, which depends on the total lift pumped against. The pumps can, therefore, not be rated accurately. The capacities given in Table XXVIII are worked out from the ratings given by a reliable pump manufacturer and are subject to considerable variations either above or below the values given.

TABLE XXVIII.—CAPACITIES OF CENTRIFUGAL PUMPS

No. of pump or diameter of discharge in ins.	Capacity in U. S. gallons per min.	Capacity in second-feet, or acre-inch per hr.	Number of acres irrigated 6 in. deep each month for operation period during the month of 30 days	20 days	15 days	10 days	5 days	1 day
2	100	0.22	27	18	13	9	4½	0 9/10
2½	150	0.33	40	27	20	13	6½	1 3/10
3	225	0.50	60	40	30	20	10	2
3½	300	0.66	80	53	40	27	13	2⅔
4	400	0.90	110	71	55	36	18	3⅔
5	700	1.60	190	127	95	63	32	6⅓
6	900	2.00	240	160	120	80	40	8
7	1,200	2.70	320	213	160	107	54	10⅔
8	1,600	3.50	430	287	215	143	72	14⅓

To start a centrifugal pump the suction pipe and the pump must be filled with water or primed. This may be done by closing the discharge pipe with a check valve and connecting the suction end of a hand pump to the top of the casing. Where a steam engine is used, a steam ejector may take the place of the hand pump. For small pumps and low lifts a foot valve on the end of the suction pipe may be used and the pump primed by pouring water in the casing or suction pipe. The disadvantage of a foot valve is that if the water is not clear a small stone or twig may lodge itself in the foot valve and prevent priming. This will necessitate that the suction pipe be uncoupled and the obstruction removed.

The pump must be placed as near as possible to the water level to keep the suction lift down. While theoretically the suction lift may be as great as 33 ft. at sea level and about 30 ft. at an elevation of 3000 ft., it is desirable not to exceed 20 ft., and less is preferable. The horizontal centrifugal pump is preferable where the depth from the ground surface to the water plane is not large. But where the depth is large, it is necessary to place the pump in a deep pit, in which case either the vertical centrifugal pump or a deep well pump is generally used. A horizontal shaft centrifugal pump is usually more efficient than a vertical centrifugal, and it eliminates the end thrust of the shaft obtained with the vertical shaft which is difficult to balance properly. During the past few years a new type of vertical centrifugal, commonly named turbine centrifugal pump, has been developed for pumping from deep wells without the necessity of a pit. These pumps are installed inside the casing of bored wells 12 to 30 ins. in diameter.

The plant efficiency can be increased by reducing the friction in the suction and discharge. As few bends as possible should be used and those should be made by using long turn elbows. The suction and discharge pipes should be larger than the intake and outlet openings of the pumps and joined to the pump with an increaser. The diameter of the suction pipe and especially of the discharge pipe should be 1½ times the diameter of the intake, and if the discharge pipe is long it may be economy to make the diameter even larger. Where the source of water supply is a surface body of water, enlarging the lower end of the suction pipe will further decrease the friction. This may be done by a funnel-shaped section whose length is about three times the diameter of the suction pipe and whose large end is about 1½ times the diameter of the pipe. The larger opening at the entrance to the suction pipe will decrease the tendency to suck up sand or gravel. When the water carries weeds, gravel or other material a strainer should be used and the total area of the strainer should be at least twice the area of the suction pipe. The discharge pipe should not carry the water any higher than necessary.

Power Piston or Plunger Pumps.—This type of pump is used where the water is obtained from a surface source or where the water plane is near the surface of the ground and the lift to the point of delivery is large. It consists of one or more cylinders, in each one of which a piston or plunger moving backwards and forwards sucks the water into the cylinder and forces it up the discharge pipe. When the cylinder has only one suction valve and one discharge valve, the motion of the piston in one direction causes suction and the displacement in the opposite direction forces the water through the discharge pipe. With two sets of valves so arranged that there is a discharge for each displacement of the piston, the pump is known as a double acting pump. When the pump has two cylinders, it is known as a duplex pump, with three cylinders it is a triplex pump, and in either case may be either double acting or single acting. The cylinders with the driving gears or pulleys are assembled together and built at a height above the water plane, which must not exceed the suction lift.

The capacity of the pump will depend on the diameter of the cylinder, the length of the stroke of the piston, and the number of strokes or revolutions per minute. The capacities of a few sizes of double acting, single piston pumps, single acting triplex pumps and of double acting duplex pumps are as follows:

CAPACITY OF DOUBLE ACTING, SINGLE PISTON PUMP

Diameter of water cylinder ins.	Length of stroke, ins.	Revolutions or strokes per min.	U. S. gals. per min.
3	5	40	12.4
4	5	40	21.6
5	5	40	34

The sizes of pumps and the capacities vary with the different manufacturers. The values stated above show the approximate range of the different sizes. For small capacities the double acting single piston pump may be used.

Deep Well Pumps.—These pumps are used where the water plane it at large depths below the ground surface. A deep well pump consists of a brass cylinder in which operate two plungers with valves. The lower plunger is connected to a solid rod which fits into a hollow rod to which the upper piston is connected. The plungers are so operated by the driving power that the pump is double acting, one plunger moving up while the other moves downwards, so that there is a continuous discharge. Above the cylinder and connected to it is the vertical discharge or column pipe into which discharges the water passing through the valves in the plunger. The cylinder is about 2 ins. smaller in diameter than the well casing and the delivery pipe about 1 in. less; the cylinder and delivery pipe are both lowered into the well until the plungers are under water. At the surface the driving power and circular motion of the belt of the engine is transmitted to the driving rods by means of gears and levers combined into a power head designed to produce overlapping strokes, so as to eliminate to some extent the pulsations which are further decreased by an air chamber. The sizes range from 6-in. cylinders and

28-in. stroke to 16-in. cylinders and 36-in. stroke. The number of strokes ranges from 16 to 24 per minute, depending on the lift and the size. The maximum lift is 350 ft. The capacity ranges from about 115 gals. per minute to a maximum of 1000 gals. for the largest pump with extra long cylinder.

Air Lift Pumping Plants.—Air lift or compressed air pumping plants consist of one or more air lift pumps. The air compressor with receiver and motive power and the necessary piping to deliver the compressed air from the receiver to the pumps. Each pump consists of: (1) the discharge pipe, which is smaller than the well casing and is placed inside of it, extending below the water surface to a depth equal to 1½ to 2 times the lift measured from the water surface; (2) the air pipe, which is usually inside the discharge pipe, but may, if the well is enough larger than the discharge pipe to so permit, be placed outside and connected at the lower end of the discharge pipe by means standard fittings or special castings; (3) the foot piece, which is a special casting connected to the lower end of the air pipe and so designed to admit the air evenly in small bubbles. There are various designs of patented foot pieces, but there is little difference in their efficiency; (4) the tail piece which forms a slightly enlarged extension of the lower end of the discharge pipe below the foot piece. The air is delivered through the foot piece at pressures varying according to the lift and the ratio of diameters between air pipe and water pipe, and its expansion and displacement produces the lifting power. The relation between the volume of air supplied and the volume of water pumped for different lifts has been found by experiment to be as follows:

Head in feet..........................	10	20	30	50	100
Ratio $\dfrac{\text{Cubic feet of air}}{\text{Cubic feet of water}}$	1.0	1.5	2.0	2.5	3.0

The velocity of water in the discharge pipe, based on the volume of water pumped should not exceed 5 ft. per second in order to keep down friction losses.

The compressor may be direct connected to a steam engine or gasoline engine or may be connected by means of belts, gears, etc., to the driving power which may be a steam engine, a gasoline engine or electric motor. The compressed air passes from the air cylinder to the receiver, which is used to store the air and equalize the pressure. From the receiver the air is conducted through pipes to each well.

The efficiency of the plant when properly installed as calculated from the ratio of actual water horse-power to the indicated horsepower in the cylinder of the engine is generally between 20 and 30 per cent. Air lifts are best adapted for pumping from several wells not farther apart than one-half mile and where the wells are sufficiently deep to allow proper submergence.

Hydraulic Rams.—The hydraulic ram works on the principle that a large volume of water falling through a low head will pump a smaller volume of water through a higher head. The ram consists of the valve box and air vessel, the supply or drive pipe which connects the valve box with the source of supply and the delivery or discharge pipe which connects the air vessel with the point of delivery. The efficiency of the plant is $E = qh/QH$ where q = volume of discharge water, h = discharge head in feet above ram, Q = volume of drive water, H = drive head in feet. For best results the ratio of the length of drive pipe to the length of drive head should not exceed 2.5; but it is practicable to increase this ratio to 25 and use a drive pipe 1000 ft. long. The delivery head may be anything up to about 250 ft. and the drive head anything above 18 ins. The efficiency diminishes as the ratio of delivery to drive head increases. With this ratio as great as 30 to 1 the efficiency will not be over 20 per cent; with a ratio not greater than 4 to 1 the efficiency may be as high as 75 per cent. Rankine gives the following equation to determine the efficiency for varying ratios of drive head to discharge head: $E = 1.12 - .2\sqrt{\frac{h}{H}}$.

Hydraulic rams are usually limited to small quantities of water. A notable example of a large plant for irrigation purposes is one installed at Sunnyside, Wash., for the irrigation of 240 acres of land. The plant was installed by the Columbia Steel Works of Portland, Ore., and consists of eleven 6-in. rams, with a common discharge cylinder emptying into a 10-in. wood stave discharge pipe. The plant is used to irrigate 150 acres under 105 ft. lift and 90 acres under 144 ft. lift. The lifts are measured from rams. The drive head is 38 ft. and the drive water 5 sec. ft. The plant was furnished under guarantee to deliver .75 sec. ft. at higher outlet. The cost of plant is as follows:

Eleven 6-in. rams and 3,212 ft. of wrought iron drive pipe	$3,200
1,900 ft. of 10-in. wood discharge pipe	608
Installation, complete	2,000
Total cost	$5,808

No maintenance except two visits per day to clear weeds out.

An efficiency test gave the following results: $H = 37.6$; $h = 144.1$; $Q = 6.25$; $q = 1.15$

$$E = \frac{1.15 \times 144.1}{6.26 \times 37.6} = .70$$

Adaptability of the Several Types of Pumps for Small Pumping Plants.— Where the source of water supply is a stream or surface body of water, the choice is usually between a power pump and a centrifugal pump and will depend largely on the lift and capacity. Power pumps are best adapted to high heads above 75 ft. and to small or moderate volumes of water, usually under 200 gals. per minute. For these conditions the efficiency of a power pump is usually greater than that of a centrifugal pump. For greater volumes the plunger pumps are comparatively expensive and centrifugal pumps are usually preferable unless the lift is excessive. The centrifugal pump has the advantage that it is simple in construction with no parts to get out of order, and that it is cheaper than a power pump.

Where the source of water supply is ground water with the water table in the well at a depth below the surface not much greater or less than the limit of suction lift, so that a deep pit is not necessary, then the choice is between a centrifugal pump, a power pump and an air lift pump. The selection between the centrifugal and power pump will depend on a consideration of lift and capacity as explained above. Air lift plants have low efficiency, require a depth of well below the water table equal to about twice the lift measured from the water table and are hardly to be considered in connection with separate small pumping plants. They are best adapted to a large number of wells (at least six or preferably more) placed close together.

Where the source of water is ground water developed by deep wells with the water table at a large depth below the surface (50 to 200 ft. or more) the choice is between a vertical centrifugal pump in a pit and a deep well pump which eliminates the pit. Deep well pumps are best adapted where the lift is in excess of 100 or 150 ft. and for wells that do not yield more than about 400 gals. per minute. Their efficiency is greater than that of centrifugal pumps, but the cost of repairs and depreciation is greater.

The selection should be made only after careful consideration of the first cost of the pump and the annual cost of fuel, operation and maintenance. Where the lift is high, the fuel cost will be considerable and it is good economy not to select the cheapest pump obtainable, but one that is guaranteed for its efficiency. On the other hand, if the pump is to be operated only during a very small portion of the season, it would be poor economy to invest a large capital in a high-grade pumping plant to save in fuel cost.

4. *Classes of Engines or Driving Power. Methods of Connection of Pump with Engine.*—The driving power is generally either gasoline engine, steam engine, or electric motor.

Centrifugal pumps are usually either direct connected (except for varying low heads) or connected by means of belt, gears, or chains. Power pumps are connected by belts or gears. Direct connection is preferable when possible; it is more efficient and eliminates the adjustment of belt or chain necessary with belt or chain driven pumps. The connection of these pumps and driving power must be such that the pumps will be given the speed or number of revolutions per minute for which they are designed and for which the highest efficiency is obtained. For this reason direct connection can only be used where the driving power and the pump have the same speed. The speed of centrifugal pumps is usually high; so is that of electric motors; and for this reason they can, if properly designed, be direct connected. This is done usually by means of a flexible coupling. Gasoline and steam engines are generally operated at a much lower speed than centrifugal pumps, and for that reason are not direct connected unless the engine and pump are specially designed. This is done by some manufacturers. Power plunger pumps are operated at a low speed, and for that reason are not direct connected to the driving power. When connected by gears, belts or chains, the driving gear and driven gear, or the driving pulley and driven pulley must be so proportioned that the pump will be given its correct speed. When a plunger pump is built with steam engine in a single machine, with the piston or plunger of the water cylinder on the same driving rod as the piston of the steam cylinder, it is called a direct acting steam pump. The fuel consumption of a steam pump is greater than that of a steam driven power pump and for that reason steam pumps are not considered.

Deep well pumps are usually equipped with gears and levers combined and connected with the driving rods of the pump, forming what is called the pump head, the object of which is to convert and transmit the circular motion of the driving power to the driving rods of the pump. The engine or motor is usually connected to the pump head by belts, but may be connected by means of gears. In some cases steam heads are provided in the place of the pump head.

Capacity of Engine.—The power necessary to life water is indicated in horsepowers. A horse power represents the energy required to lift 33,000 lbs. 1 ft. high in one minute; this is equivalent to 3960 gals. of water per minute raised 1 ft. high. This relation enables one to find the net horsepower required in any case by multiplying the discharge of the pump in gallons per minute by the total lift in feet and dividing by 3960. The result obtained represents the useful water horsepower necessary to lift the water. The horsepower delivered by the engine to the belt or gears when the pump is belted or geared to the engine, or to the pump itself when direct connected is the brake horsepower, and must be greater than the useful water horse power to allow for the loss of energy in the pump and transmisson. The horsepower developed within the engine itself is the indicated horsepower, and must be greater than the brake horsepower to allow for the energy loss in the engine itself. Gasoline engines and motors are rated on brake horsepower, but gasoline engines are frequently over-rated. Steam engines are rated on indicated horsepower.

The combined efficiency of a pumping plant represents the ratio of the useful water horsepower, to the rated horsepower of the engine, and will vary considerably with the type of pump, method of connection of engine with pump and the care taken in operating both pump and engine at the proper speed. In ordinary field practice a good pumping plant, properly installed, should easily reach the efficiency given in Table XXIX:

TABLE XXIX.—EFFICIENCY OF CENTRIFUGAL PUMPING PLANTS AND BRAKE HORSEPOWER PER FOOT OF LIFT

No. centrifugal pump	Discharge, U. S. gals. per min.	Water h.p. per ft. of lift	Efficiency, pct.	Brake h.p. per ft. lift
2	100	.025	30	.081
2½..................	150	.038	35	.11
3..................	225	.057	40	.14
3½	300	.08	45	.18
4..................	400	.10	45	.22
5..................	700	.17	50	.34
6..................	900	.23	50	.46
7..................	1,200	.31	50	.62
8..................	1,600	.41	55	.75

The efficiency of power plunger pumps varies with the size of the pump and with the lift. A greater efficiency is obtained with the higher lifts and with the larger sizes. The efficiencies of properly installed plunger pumps and the horsepower for various lifts are given in Table XXX.

TABLE XXX.—BRAKE HORSEPOWER REQUIRED TO OPERATE PLUNGER PUMPS

Diameter of cylinder ins.	Length of stroke ins.	Capacity in U. S. gals. per min.		—Efficiency and brake hp. for lifts of— 50 ft.	100 ft.	150 ft.	200 ft.	250 ft.
3	4	18	E.	0.30	0.40	0.42	0.45	0.45

			Hp.	5.25	8.0	11.0	14.0	17.0
8	10	270	E.	0.50	0.65	0.70	0.75	0.78
			Hp.	6.75	10.25	14.50	18.25	22.1
9	10	340	E.	0.50	0.65	0.70	0.75	0.78
			Hp.	8.5	13.0	18.0	23.0	28.0

The plant efficiency of deep well pumping plants as ordinarily installed and operated was found from measurements made in a number of pumping plants in southern California to be from 35 to 55 per cent. With proper installation and operation the plant efficiency or ratio between useful water horsepower and brake horsepower should be from 50 to 65 per cent.

The plant efficiency of air lift pumps expressed as the ratio between the useful water horsepower and the indicated horsepower in the engine cylinder was found from test on a number of such plants in southern California to average a little less than 20 per cent.

Type of Engine.—Tables XXIX and XXX will give the size of the engine. The driving power must be either a gasoline engine, steam engine, or electric motor. The methods of connecting the engine with the pump have been already considered. Other factors being equal direct connection is preferable when possible.

For small plants irrigating a few acres, the steam engine, although very reliable, is not so commonly used as the gasoline engine except where coal or oil is very cheap as compared to gasoline. However, for larger areas and where coal or oil is cheap, it may be cheaper than either a gasoline engine or electric motor. For large plants operated continuously it may be economy to install an efficient boiler and a high grade compound condensing, triple expansion, or quadruple expansion, steam engine, in order to decrease the fuel cost. For small plants operated only for short periods during the irrigation season it is much more important to decrease the cost of installation. The interest on the capital invested and the depreciation of the plant are very important items of cost as compared to the fuel cost. For these reasons, unless the acreage is large and the lift very high, the steam plant will consist of a semi-portable locomotive type boiler and an ordinary slide valve steam engine.

5. *First Cost of Plant.*—The first cost of a pumping plant depends on the grade of machinery, the cost of transportation, the expense of installation. Because of these factors accurate estimates of cost cannot be given. However, the approximate cost values given below in Tables XXXI, XXXII and XXXIII will be of value to the land owner who is considering the feasibility of a pumping plant. The values given represent the prices at the factory and do not include transportation and installation.

TABLE XXXI.—APPROXIMATE COST OF SINGLE STAGE CENTRIFUGAL PUMP

No. of pump	Capacity in gals. per min.	Cost
2	100	$ 42
2½	150	51
3	225	57
3½	300	65
4	400	75
5	700	85
6	900	115
7	1,200	145
8	1,600	170

The cost of two step centrifugal pumps of the same sizes will be about four times the values given above.

TABLE XXXII.—APPROXIMATE COST OF TRIPLEX SINGLE ACTING POWER PUMP

Diameter of water cylinder	Length of stroke in ins.	Capacity in gals. per min.	Height of lift, ft.	Cost
4	8	65	75 to 100	$17
5	10	130	100	250
5	12	220	100	340
4	6	48	175	225
5	8	91	175	325
7	8	180	175	450
8	10	270	175	700
8	12	310	175	750

TABLE XXXIII.—APPROXIMATE COST OF ELECTRIC MOTORS GASOLINE ENGINES AND SIMPLE SLIDE VALVE, NON-CONDENSING STEAM ENGINES, WITH LOCOMOTIVE BOILER AND AUXILIARIES

Horsepower	Cost of electric motors, 1,200 rev. per minute	Cost of gasoline engines	Cost of steam engines
2	$ 70	......	......
3	85	......	......
5	110	$ 375	$ 500
10	200	550	625
15	230	700	800
20	320	850	925
25	360	1,000	1,000
30	....	1,200	1,200
40	450	1,600	1,350

Cost of Accessories and Installation.—The costs given in Tables XXXI, XXXII and XXXIII are for the pumps and engines, and do not include the accessories, the foundation, the labor of installation, and the housing. For an electric plant the cost of transformers should be added unless these are supplied by the electric company. The accessories will include the suction and discharge pipes, the valves and fittings, the priming pump, the connection between pump and engine. The suction pipe is usually made of steel; the discharge pipe may be steel or wood banded pipe and should cost delivered as given in table XXXIV.

TABLE XXXIV.—COST OF PIPES SAFE FOR 150 FEET HEAD

Diameter of pipe, inches	Cost per foot of wood banded pipe	Cost per foot of steel pipe
4	$ .20	$ .30
6	.30	.50
8	.40	.80
10	.55	1.10
12	.65	1.35
14	.75	1.60
16	.95	2.00
18	1.10	2.50
20	1.44	3.00

For a rough estimate the total cost of valves, priming pump, all fittings and suction pipe, but not discharge pipe, may be taken as about 10 per cent of the cost of pump and engine for a gasoline or steam plant and 20 per cent for an electric plant. The cost of installation should not exceed 5 per cent. The cost of a building to house the plant will range from about $25 for a small plant to $100 or more for a larger plant. The cost of transportation and hauling will depend on the railway charge and on the distance from the station to point of installation.

6. *Fuel Consumption and Fuel Cost.*—The selection between a steam engine, gasoline engine and an electric motor will depend to some extent on the comparative cost of coal, gasoline and eletrical energy.

A gasoline engine is usually guaranteed for a fuel consumption of ⅛ gal. per rated or brake horsepower per hour. A new engine well adjusted will come up to this efficiency, but an engine that has been operated some time will consume about ⅙ gal. of engine gasoline or distillate per brake horsepower per hour.

The fuel consumption of a steam engine will vary greatly on the type of boiler and engine. A small slide valve non-condensing engine under 25 hp.

will use probably 50 to 60 lbs. of steam per brake horsepower per hour. A locomotive type of boiler should give 5 or 6 lbs. of steam for 1 lb. of coal or about 0.6 lb. of oil. Therefore, a small steam engine under 25 hp. should consume 10 lbs. of coal per brake horsepower per hour or about 6 lbs. of oil. Steam engines of the same type from 30 to 50 hp. will consume from 8 to 5 lbs. of coal per brake horsepower per hour or from 5 to 3 lbs. of oil.

Electrical energy is measured in kilowatts. A killowatt is equal to 1⅓ hp., but because of the loss of energy in the motor, 1 kilowatt will usually give about 1.1 brake horsepower. Based on this figure 1 brake horsepower hour is equal to 9/10 of a kilowatt hour.

The above values show that to produce 1 brake horsepower per hour requires either ⅙ gal. of distillate, about 10 lbs. of coal, or 6 lbs. of oil, or 9/10 of a kilowatt hour. Based on these figures Table XXXV shows the cost of fuel per brake horsepower per hour for several equivalent cost values of fuel. In the table is also given the fuel cost of pumping one acre foot of water through one foot of lift, assuming plant efficiency of 50 per cent and 75 per cent.

TABLE XXXV

Equivalent unit costs of fuel				Fuel cost (in cents)		
Gasoline, cents per gal.	Crude oil per bbl. (335 lbs.)	Coal per ton	Cost of electric, cents per K.W. hour	Per brake hp. per hour	Per acre foot of water lifted 1 foot high 50 per cent efficiency	75 per cent efficiency
6	$ .55	$2.00	....	1.00	2.75	1.83
8	.75	2.66	....	1.33	3.70	2.45
10	.93	3.33	1.85	1.66	4.60	3.05
12	1.12	4.00	2.22	2.00	5.50	3.65
14	1.30	4.66	2.60	2.33	6.40	4.25
16	1.50	5.33	3.00	2.66	7.30	4.90
18	1.67	6.00	3.33	3.00	8.25	5.50
20	1.85	6.66	3.70	3.33	9.15	6.10
22	2.05	7.33	4.10	3.66	10.10	6.70
24	2.25	8.00	4.35	4.00	11.00	7.35
26	2.42	8.66	4.80	4.33	11.80	7.95

7. *Fixed Charges and Attendance. A. Fixed Charges.*—The cost of installation represents a capital which if invested would bring in an income represented by the interest. It is therefore necessary to consider this interest as part of the cost of operation. To this should be added the annual cost of repairs maintenance and renewal. These items of cost represent the fixed charges. After six or eight years a gasoline engine may need to have its cylinder rebored and a new piston provided, the cost of which is about one-fourth the cost of a new engine. With ordinary care the life of a gasoline engine may be taken as 10 years; the life of an electric motor about 15 to 20 years. The fixed charges on the entire plant may be taken as follows:

	Gasoline engine plant	Electric plant	Steam engine plant (small)
Depreciation and renewal	8%	5%	8%
Repairs and maintenance	3	1	2
Interest	6	6	6
	17%	12%	16%

B. Attendance.—An electric motor requires a minimum of attendance, small gasoline plants require frequent inspection, and steam engines require considerable attention and usually cannot be economically used for small plants operated during short periods. The cost of attendance for an electric motor pumping plant should not exceed 5 cts. per hour, for a gasoline engine plant 10 cts. per hour, and for a steam engine plant 30 cts. per hour. While electric motors and gasoline engines are usually operated by the orchardist or irrigator, his time is valuable and a charge should be made for it.

8. *Final Selection of Type of Plant.*—The final selection of a pumping plant should be based on a careful consideration of the factors stated above. The best size of plant, the period of operation, the kind of engine or driving power, can only be correctly determined by a final consideration of a cost of installation and cost of operation. Where electric power is available, the choice is between a steam engine, a gasoline engine and an electric motor. The electric motor requires minimum attendance. It is reliable and its first cost is much less than that of a gasoline or steam engine. For these reasons if electric power is available, an electric motor is preferable and will prove far more economical even should the cost of electrical energy be higher than the fuel cost for a gasoline or steam engine.

The application of the above information and cost data to any particular case is illustrated by the following examples:

A 20-acre orchard is to be irrigated by pumping from a surface body of water requiring no wells. The quantity to be applied is 6 ins. per month, and the total depth in one season 18 ins. The lift is 50 ft. and the discharge pipe 200 ft. long. Engine gasoline or distillate costs 12 cts. per gallon. Assuming the pump is operated one-third of the time or ten 24-hour days each month, this will require a pump capacity of 225 gals. per minute, which is obtained with a No. 3 centrifugal pump and 7 hp. engine. The discharge pipe will be 4 ins. in diameter. The first cost and total cost of operation will be about as follows:

First Cost of Plant

No. 3 centrifugal pump	$ 57
7 hp. gasoline engine	450
Priming pump, suction pipe, fittings, etc	50
Freight charges and hauling	30
Wood banded discharge pipe, 200 ft. of 4-in	40
Installation, 5 per cent of cost	35
Building to house plant	40
Total cost	$702

Total Annual Cost of Operation

Fuel cost of 7 brake hp. engine for 3 periods of 10 days each or 720 hours = 720 × 7 × 0.02	$100
Fixed charges at 17 per cent of first cost	120
Attendance, 720 hours at 10 cts	72
Total cost for 20 acres	$292
Cost per acre, $15.	

Where electric power is obtainable, the first cost of plant and annual cost of operation for same conditions, assuming the unit cost of electric power to be 3 cts. per kilowatt hour, would be:

First cost of plant	$375
Total cost of operation (annual)	215
Cost of operation per acre	11

Tables XXXV and XXXVI show the first costs of gasoline engine pumping plants and the costs of operation for orchards of 20, 40 and 80 acres for lifts of 50 ft. and 150 ft., and for different periods of operation. For the higher lifts single acting triplex pumps are used. The costs given are based on gasoline at 12 cts. a gallon, for a depth of irrigation of 18 ins. for the lower lift and depths of 18 ins. and 12 ins. for the higher lift, it being assumed that by careful use of water, if the soil is retentive, 12 ins. may be sufficient. The discharge pipe is assumed to be 200 ft. long.

TABLE XXXVI.—COST OF PUMPING WITH GASOLINE ENGINES AND CENTRIFUGAL PUMPS FOR 50-FOOT LIFT, GASOLINE 12 CENTS A GALLON

Area in acres	No. of 24-hour days pump is operated monthly	Capacity of pump Gals. per min.	Number of pump	Horsepower of engine	First cost of installation	Annual cost of operating per acre; –18 ins., depth of water applied– Fuel	Fixed charges	Attendance	Total
20	5½	400	4	12	$ 970	$4.80	$8.25	$1.90	$14.95
	10	225	3	7	700	5.10	6.00	3.60	14.70
	20	113	2	5	590	7.00	5.00	7.20	19.20
40	5	900	6	25	1,575	4.50	6.70	.90	12.10
	11	400	4	12	970	4.80	4.10	2.00	10.90
	20	225	3	7	700	5.10	3.00	2.60	11.70
80	10	900	6	25	1,575	4.50	3.35	.90	8.85
	22	400	4	12	970	4.80	2.05	2.00	8.85

TABLE XXXVII.—COST OF PUMPING WITH GASOLINE ENGINES AND SINGLE ACTING TRIPLEX PUMPS FOR 150-FOOT LIFT

Area in acres	No. of 24-hour days pump is operated monthly	Capacity of pump Gallons per minute	Horsepower of engine	First cost of installation	Annual cost of operation per acre for a depth or irrigation, water of: ——18 inches—— Fuel	Fixed charges	Attendance	Total	12 ins. Total
20	8⅓	270	15	$1,850	$ 9.90	$15.75	$3.00	$28.65	$24.35
	12½	180	10	1,375	9.90	11.70	4.50	26.10	21.30
	25	90	6	1,025	10.90	8.70	9.00	28.60	22.00
40	13¼	340	18	2,200	8.70	9.35	2.40	20.45	16.75
	16⅔	270	15	1,850	9.90	7.90	3.00	20.80	16.50
	25	180	10	1,375	9.90	5.85	4.50	20.25	15.45
80	26½	340	18	2,200	8.70	4.70	2.40	15.80	12.10

The capacities of pumps, especially plunger pumps, and the sizes of engines vary with the different makes, and for that reason the sizes given are not always obtainable, but sizes approximating these can be used in place.

The above cost estimates are only approximate. They are based on the conditions stated above and are not applicable to all cases because of the varying conditions which make the installation of nearly every pumping plant a special problem. The estimates are made for gasoline engines and are considerably higher than for electric motors. The first example showed that with an electric plant the cost of pumping was only 73 per cent of the cost with a gasoline plant. The tabulated values show the following interesting results:

(1) The cost per acre of pumping is much larger for a small area than for a large area.

(2) The cost per acre does not vary considerably with the period of operation, and in some cases a plant moderately large operating for a shorter period will cost less per acre than a smaller plant operating a longer period. This is due to the lower fuel cost with the larger and more efficient plant and the decreased cost of attendance for the shorter period of operation which overbalance the larger fixed charges. Even should the resulting cost be smaller for the smaller plant, the inconvenience due to pumping for a long period and the extra labor in irrigation may overbalance the saving in cost.

(3) For the lifts assumed a period of operation equal to about ten 24-hour days during the month of one-third of the time during the irrigation season seems to be preferable with the centrifugal pump. With the higher price triplex plunger pumps a period of operation of one-third to two-thirds of the time is preferable.

Co-operative Pumping.—The lower cost per acre for larger areas shows the advantage to be gained by co-operation between small owners. By uniting and installing a large plant instead of several smaller plants, the cost of installation and operation is very much reduced, and the plant can be given more competent attention, which relieves the orchardist and increases the life of the plant. Where by such co-operation several hundred acres can be brought together, a central steam plant to generate electric power, which is transmitted to the several electric motor pumping plants, is the most economical and best solution.

For separate plants above 20 or 40 hp., gas producer plants connected to gas engines will furnish the cheapest power. These plants are reliable and easily operated. They consist of the producer in which hard coal is placed and through a process of partial combustion, in the presence of air and steam, forms the gas which operates the engine. Gas producers operated on hard or anthracite coal have been in successful operation for a number of years, and those operated on soft or bituminous coal and on oil are coming into use, but are still in the experimental stage. The fuel consumption is very low, usually from 1 to ½ lbs. of coal or ⅙ to 1¼ gals. of crude oil per horsepower for one hour; or ½ to ¾ ct. per horsepower for one hour with hard coal at $10 per ton and about ⅛ ct. with oil at 2 cts. a gallon. This is from 2½ to 6 times less than the fuel cost with gasoline at 12 cts. a gallon. Producer gas plants are much expensive than gasoline engines and for small plants the fuel economy will be overbalanced by the larger interest and depreciation charges. For very large single plants, high duty steam engines will be the most economical form of installation.

Limits of Economical Pumping.—The cases previously worked out for gasoline engine pumping plants show that for small tracts of 20 to 80 acres the cost of lifting sufficient water to give a depth of irrigation water of 18 ins. will range for a lift of 50 ft. from about $8.85 per acre for the larger area to about $15 per acre for the smaller area, and for lifts of 150 ft. the respective costs are about $15 and $25 per acre. These costs may seem high as compared with gravity water, but to obtain an idea of the economy and feasibility of developing water by pumping, comparisons must be made with the value of gravity irrigation water in the same conditions. Except in southern California, up to a few years ago gravity water without pumping has been obtainable. For that reason pumping has not been necessary, and comparatively few pumping plants have been constructed. However, water is becoming more valuable and the steps which many irrigation companies are taking to conserve water and prevent losses of transportation by carrying the water in concrete-lined canals and in pipes constructed at considerable expenses, show that in some localities at least, water has become sufficiently valuable to justify pumping. If a comparison is made with water thus obtained, we find that the cost of construction of a well constructed system may go up to $50 or $60 an acre and even higher. This cost is charged up to the land which is sold to the orchardist and in addition reasonable profit is made on the value of the land. It is probably conservative to assume that land under an irrigation system in localities well developed and where irrigation is necessary, will cost at least $100 an acre more than similar land for which there is no gravity supply. The chief advantage of gravity systems is the low annual cost of operation, usually less than $2 or $3 per acre, although in some cases it may be as much as $5 per acre or more, but if to this be added the interest on the difference in cost between land under the irrigation system and land which is to be supplied by pumping, assumed at $100, the total annual cost may be $10 to $15 an acre. This is about equal to the cost of pumping with gasoline engines to a height of 50 feet and about half as large as for lifts of 150 feet. Where electric power is available or for large pumping plants the cost of pumping would compare very favorably with gravity water, even for higher lifts than those stated above.

Some of the advantages of underground pumped water as compared to water obtained from a gravity irrigation system are:

(1) An underground supply is more reliable and is not likely to be deficient before the end of the irrigation season.

(2) The irrigator is independent and controls his own water supply, and is prepared to irrigate his crops at the best time.

(3) The underground water is free from the seeds of weeds.

A consideration of pumping in some of the well developed irrigated districts is of interest to show its feasibility. In eastern Washington water is being pumped in one case to an elevation of 250 ft. above the source of supply. In the citrus district of southern California lifts above 200 ft. are not unusual, and it is considered profitable to pump 460 ft. In the Pomona district of southern California the cost of pumped water averages $15 per acre for one acre foot when purchased from irrigation companies, while for smaller private plants the cost is often greater. In 1905 the Irrigation Investigations Office of the United States Department of Agriculture made tests on various pumping plants and these show that the cost of pumping at private plants of 10 to 100 hp. with lifts of 100 to 300 ft., varied from $10 to $90 per acre for one acre foot of water.

There is a limit beyond which it is not economically feasible to pump. In the California citrus districts lifts above 400 ft. have been considered profitable. For the orchard lands of the Northwest equally high lifts should be profitable, for the net return per acre from a good apple orchard is usually more than that from a citrus orchard. A citrus orchard 10 years old should average a net profit of $100 to $150 per acre. The net profits from apple orchards 10 to 12 years old in the Yakima Valley are given in bulletins of the United States

Department of Agriculture as $200 to $600 per acre. With profits larger than those obtained from citrus orchards in southern California, what has been considered feasible in pumping there, is at least equally so for apple orchards or other valuable crops when no other more economical source of water supply is available. However, for small pumping plants and small areas it is well not to exceed 200 ft., while the larger plants lifts of 400 ft. may be economically feasible.

First Cost and Cost of Operation of Irrigation Pumping Plants.—The following data, published in Engineering and Contracting, June 2, 1915, are condensed from a paper by H. D. Hanford in the proceedings of the Washington Irrigation Inst.

Plant Costs.—As a basis for the figures, the representative of a well-known manufacturer was asked to give prices, efficiency and other data on both centrifugal and triplex power pumps, ranging in capacity by the hundred gallons, from 100 to 500, inclusive, a minute, and for heads of 25, 50, 100 and 200 ft. Taking these prices as a basis, and adding the cost of motor, fittings, erection and building, we have the following schedule of plant costs:

DIRECT CONNECTED CENTRIFUGAL PUMPS

Capacity, G. P. M.	Head	Size	Cost of plant
100	25	2½-in.	$ 407.00
100	50	2-in.	369.00
100	100	2-in.	479.00
100	200	2-in. 2 S	715.00
200	25	3-in.	550.00
200	50	3-in.	550.00
200	100	2½-in.	600.00
200	200	2½-in. 2 S	875.00
300	25	4-in.	644.00
300	50	3-in.	644.00
300	100	3-in.	715.00
300	200	3-in. 2 S	1,034.00
400	25	5-in.	732.00
400	50	4-in.	698.00
400	100	3-in.	748.00
400	200	4-in. 2 S	1,249.00
500	25	5-in.	787.00
500	50	4-in.	765.00
500	100	4-in.	831.00
500	200	5-in. 2 S	1,524.00

BELT DRIVEN TRIPLEX PUMPS

Capacity G. P. M.	Head	Size	Cost of plant
100	50	5½ × 8-in.	$ 741.00
100	100	5½ × 8-in.	764.00
100	200	5½ × 8-in.	821.00
200	50	7½ × 8-in.	1,216.00
200	100	7½ × 8-in.	1,261.00
200	200	7½ × 8-in.	1,319.00
300	50	8½ × 10-in.	1,437.00
300	100	8½ × 10-in.	1,517.00
300	200	8½ × 10-in.	1,600.00
400	50	10 × 10-in.	1,877.00
400	100	10 × 10-in.	1,979.00
400	200	10 × 10-in.	2,065.00
500	50	10 × 12-in.	2,463.00
500	100	10 × 12-in.	2,510.00
500	200	10 × 12-in.	2,792.00

In comparing the schedule note that in a number of instances the cost of plant for a given head is less than that of the preceding lower head, and that smaller sizes are used,—these are not errors. In centrifugal pumps, the capacity within a certain range is governed by the design of the impeller and the speed, and not by the diameter of the discharge nozzle. Also in the triplex pumps, exactly the same pump is offered for more than one head. The total plant costs are also affected by the cost of motor used, which varies according to the speed, the slow speed motors costing considerably more than those of high speed. The sizes and types of pumps and motor speeds are those selected by a man of large experience in irrigation work; and while better selections might be made in some cases, the list represents probably average practice, and as used here, is a fair basis.

Operating Costs.—In arriving at a basis of operating costs for each year, the following assumptions were made:

(1) That the irrigation season covers the period from May 1st to September 30th, inclusive.

(2) That the pumps would operate 24 hours a day for 26 days each month, or a total of 130 days.

(3) That the pump would operate 624 hours each month.

(4) That the capacity of the several sizes of pumps operating on the above schedule would be as follows for the season:

Size	Acre ft.
100 gallons per minute	57.5
200 gallons per minute	115.0
300 gallons per minute	172.0
400 gallons per minute	230.0
500 gallons per minute	287.5

(5) That power would be paid for on the meter basis, and on the schedule in use in the Yakima Valley.

(6) That interest on investment in plant be figured at 7 per cent.

(7) That depreciation and renewals be figured at 7 per cent.

(8) That cost of supplies be taken at 1 per cent of cost of plant

(9) That insurance be figured at 1 per cent.

The total for the last four items is 16 per cent.

In determining final costs for any particular location, it will be necessary to add the charges upon whatever pipe line is required to deliver the water to the desired point, also the yearly cost of water right, if water is purchased from a ditch. Estimated costs of pumping follow:

Direct Connected Centrifugal Pumps

Capacity, in gals. per min.	Head, in ft.	Cost per acre-foot pumped
100	25	$2.24
100	50	3.00
100	100	4.93
100	200	8.17
200	25	1.68
200	50	2.24
200	100	3.68
200	200	6.59
300	25	1.37
300	50	1.93
300	100	3.16
300	200	5.57
400	25	1.25
400	50	1.74
400	100	2.90
400	200	4.99
500	25	1.11
500	50	1.59
500	100	2.65
500	200	4.82

BELT-DRIVEN TRIPLEX PUMPS

Capacity, in gals. per min.	Head, in ft.	Cost per acre-foot pumped
100	50	$4.08
100	100	4.80
100	200	6.65
200	50	3.47
200	100	4.25
200	200	5.89
300	50	2.83
300	100	3.64
300	200	5.23
400	50	2.76
400	100	3.54
400	200	5.02
500	50	2.77
500	100	3.46
500	200	5.00

By platting these figures on paper, we have, Fig. 16, a diagram from which it is possible to ascertain the approximate cost per acre foot for pumping to any

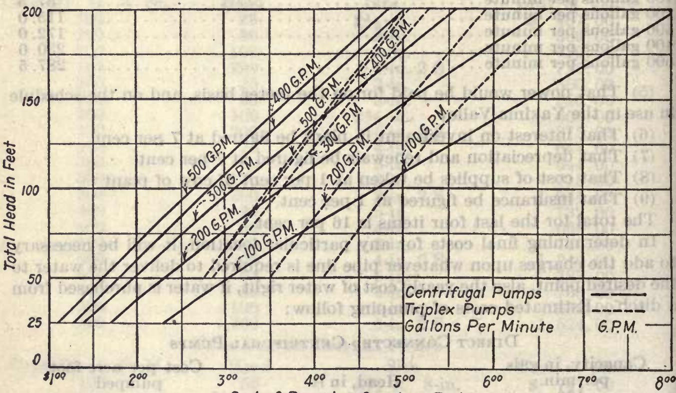

FIG. 16.—Cost per acre-foot of pumping for irrigation.

head between 25 ft. and 200 ft. for the centrifugal pumps of the respective capacities, and for heads between 50 ft. and 200 ft. for the triplex pumps. On the diagram, the centrifugal pumps are represented by full lines, and the triplex pumps by dotted lines. The point at which the full and dotted lines of the same capacity cross, indicates the approximate head at which the types will operate with equal economy. This is 110 ft. for the pumps of 100 G. P. M. capacity, 150 ft. for the 200 G. P. M., and 165 ft. for the 300 G. P. M. Above these heads, the diagram indicates that the triplex pumps will be the more economical. It also shows that for the 400 G. P. M. capacity the types balance at 200 ft. head; and that for the 500 G. P. M., the centrifugal is the more economical pump within the range of head considered.

The figures and diagram clearly show the lower cost per acre foot as the size and capacity are increased. This leads to the suggestion that where conditions are favorable for serving two or more tracts from one point, that it will be economy for the owners to join in building one plant that will give the best results, rather than to construct two or more plants of lower efficiency and higher cost and maintenance.

Over Head Charges for Pumping Plants Used for Irrigation.—In Engineering and Contracting, Aug. 30, 1911, the following is given.

The rate of depreciation of pumping plants varies through an enormous range, being determined largely by the skill and care of the attendant. Many plants are not insured at all. Averaging all conditions, the following appears to be a fair estimate of the rates suitable for use in computing the fixed charges of the various types of plants.

	Per cent
Gasoline engine plants	
Depreciation	12 to 15
Interest	6
Taxes and insurance	1
Average total	20
Motor-driven plants	
Depreciation	7 to 9
Interest	6
Taxes and insurance	1
Average total	15
Steam plants of ordinary type	
Depreciation	9 to 11
Interest	6
Taxes and insurance	1
Average total	17
Highest quality steam plants—average	12

These percentages, determined by the Office of Experiment Stations, Department of Agriculture, are applied to the first cost of the entire pumping station, including the cost of wells.

Cost of Small Earth Reservoirs as an Adjunct to Electrically Operated Irrigation Pumping Plants.—Engineering and Contracting, June 13, 1917, gives the following data:

Earth reservoirs as an adjunct to electrically operated pumping plants are now being used to a considerable extent on small individual irrigation developments in southern California. In the territory served by the Southern Sierras Power Co. some 45 of these storage basins have been constructed within the past two years. The pumping installations in general operate about 700 hours per month and deliver a quantity of water to the storage basins approximately equal to ½ in. of water per acre under cultivation. The reservoir is located upon the highest point of the acreage and the water drawn out through the pipe line as needed.

Three general types of reservoirs have been constructed during the past two years. The least expensive of these is a basin with earthen embankments. This is constructed with a four-horse team and fresno and the bottom is sealed by puddling with clay, adobe or manure. One of these basins, 120 × 120 × 5 ft. inside dimensions, clay sealed and holding 450,000 gal., cost \$125. Another, 150 × 150 × 5 ft., holding 750,000 gal., cost \$147. In each of these the embankments were 14 ft. thick at the base and 3½ ft. at the top.

The cement basins commonly have walls 6 in. thick at the base and 4 in. at the top. They are banked around the exterior with earth. One of these basins, 4 ft. deep and 75 ft. in diameter, with a capacity of 125,000 gal., was constructed at a cost of $380. This basin holds water for the irrigation of 23 acres of alfalfa and 4 acres of garden truck. The pumping installation consists of a 5-hp. motor and a 2-in. horizontal pump. This outfit delivers water at the rate of 140 gal. per minute. The total expense of irrigation in this case is $250 per year.

The third type of earth reservoir is a basin rendered watertight by spraying the bottom and sides with oil or by applying a coat of cement or lime plaster. This plaster lining is from ½ to 1 in. thick and is applied after the soil has been thoroughly tamped. Two-inch mesh chicken wire is spread over the bottom and sides of the basin prior to the application of the plaster. The plastering costs about 6 ct. per square foot.

In sealing the earth reservoir by spraying with oil the best results have been obtained by using heavy crude oil with not less than 90 per cent asphaltum, heating this from 400 to 450° and pumping it on the ground under pressure in the form of a spray, then following this up with sand, which is spread over the oil. This latter feature is very essential, especially on the banks. Best results are obtained with two coatings of oil, in all about ¾ gal. per square yard. The oil costs from $2 to $3 per barrel put on, depending upon the distance to be hauled. It is delivered to the job in motor truck loads, each of about 25 bbl.

The success of construction work of this kind depends upon the thoroughness with which the work is done. The soil should be worked over very carefully and raked with a fine rake, eliminating any large lumps, etc., that might be either in the bottom or on the banks. A second coat of oil has proven very efficient in making the reservoir tight. It must be borne in mind, however, that the oil used should be asphaltum residue of very heavy specific gravity, about the consistency of heavy coal tar. The sifting of the soil and sand on the hot asphaltum keeps it from running until it has an opportunity to cool and thus gives it a better body to keep it in place.

One of these oil-sealed basins, holding 500,000 gal. of water, was constructed in 1916 at a total cost of $350. The sealing required 75 bbl. of oil and cost $160; construction cost $147, and the gates, inlet and discharge pipes cost $33. This basin is operated in conjunction with a direct connected plant consisting of a 25-hp., 400-volt, 3-phase Westinghouse motor and a special 4-in. Bryon Jackson pump. The basin furnished water for 90 acres of alfalfa and 20 acres of grain.

Cost Wells and Well Drilling Equipment.—The following is given in Fortier's "Use of Water in Irrigation" (1915).

According to C. E. Tait, the most common sizes of drilled wells for new plants in southern California at this writing (1914) are 12, 14, 16, and 20 inches in diameter. A few 24- and 26-inch wells are also in use. The increase in size in recent years has been largely due to two causes. The larger circumference of the casing permits more openings to be made and more water to enter from the adjacent gravel. They are also better suited to the use of deep well pumps of the plunger and turbine types in that they permit a long stroke at low speed.

The casing consists of a double thickness of riveted steel sheets 2 feet long. The cost of casing per foot for various diameters and thickness of metal subject to a discount of 30 per cent is as follows:

Diameter, inches	Well casing 16-gauge	14-gauge	12-gauge	10-gauge
7	$0.59	$0.68	....	....
10	0.83	0.99	$1.20	....
12	0.90	1.06	1.37	$1.78
14	1.08	1.20	1.62	1.97
16	1.21	1.33	1.94	2.17
20	....	1.57	2.23	2.64
24	....	....	2.69	3.20

What is known as a starter is a tube about 20 feet long riveted to the bottom of the casing. This consists of a triple thickness of metal for large wells and for wells in bowlders or rock. A steel shoe or ring is in turn riveted to the bottom of the starter. A 3-ply, 12-gauge starter for a 12-inch well costs $1.80 per foot, while a 12 × ¾ inch ring costs $16.

Wells in southern California are drilled by contract. The equipment consists of a California portable rig costing $500 to $600 without the tools. In starting a well a hole is first bored and the starter inserted. A sand bucket is then used to make the excavation unless rock is encountered. The rig is provided with hydraulic jacks which apply a pressure of 100 tons or less to an iron ring which rests on the top of the casing. The cost of drilling in sand or clay exclusive of casing is $1.50 per foot for a 12-inch well. Contractors are usually protected by a provision inserted in the contract to the effect that if bowlders or rock are encountered requiring more than 2 hours to bore through an extra charge will be made.

Strainers, which form so essential a feature of many wells in the rice belt, are not necessary in southern California as there is no quicksand or very fine sand unmixed with coarser material. Water is admitted through long vertical slots in the casing which are cut by a special tool after the casing is in place. The cross sections of the openings thus made are trapezoidal in form, the narrowest side being at the outside to prevent clogging. Four vertical slots about 20 inches long are made in the circumference of each joint of a 12-inch casing opposite and slightly below each water-bearing stratum.

In the rice belt, according to C. G. Haskell, Irrigation Engineer, Department of Agriculture, the hydraulic rotary method for drilling wells is the most common.

CHAPTER X

LAND DRAINAGE

This chapter contains data on the methods and costs of constructing both open and tile drains. Further matter of use in relation to this subject may be found by referring to the index.

The reader is also referred to Gillette's "Handbook of Cost Data" pages 1796–1802 for costs of laying tile drains and for the weights of drain tile which are given on page 1798.

The Elements of Costs of Drainage Systems are given by J. L. Parsons in "Land Drainage" as follows: Cost of materials, cost of labor, cost of delivery of materials, cost of administrating drainage contracts, cost (interest and depreciation) of necessary plant, cost of financing the contract, and probable damage claims and legal expenses. In addition to the probable contract price as thus estimated, the element of engineering and other overhead expenses and right of way or damage claims must be considered by the engineer in arriving at the total estimated cost to the owner.

Probable Damage Claims and Legal Expenses.—During the prosecution of drainage contracts there is considerable danger of stock falling into ditches, with resulting claims for damages by the owners, and some allowance must be made in the contractors estimate for such damages. Also a contractor should avail himself of enough legal advice to insure business methods.

Overhead Expenses.—The overhead expenses incidental to legal drainage organizations, as engineering, legal expenses, publication of notices, etc., if wisely administered, need not exceed 8 to 12 per cent of the total cost for drains costing $5,000 and upward. These expenses equal a larger percentage for the smaller districts, as many of the legal procedures required are as expensive for small drains as for larger ones.

The item of engineering alone, including the preliminary survey, construction superintendence, and assistance in the assessment of benefits and fixing of damages, should not be less than 5 to 10 per cent of the total cost, ranging from approximately 10 per cent for $2,000 districts to 5 per cent for $25,000 districts and upwards.

Types of Equipment Best Adapted to Land Drainage.—Power machinery is now available which will construct outlet drainage ditches of all sizes, and under all conditions of soil and water, more cheaply than can be accomplished by any other method, according to D. L. Yarnell, drainage engineer of the Office of Public Roads and Rural Engineering. In a special bulletin issued recently by the Department of Agriculture, the uses and limitations of the different machines that have been employed in such work are summarized by by Mr. Yarnell, whose conclusions as abstracted in Engineering Record, Feb. 25, 1916, follow.

The floating dipper dredge is more widely used in drainage work than is any other type of excavating machine. For work through wet land no other excavator will equal it in cheapness of construction of ditches having a cross-section of from 100 sq. ft. to 1200 sq. ft. It is by far the most efficient machine to use where many stumps will be encountered. Owing to its limited reach it is not generally applicable to levee construction. Dipper dredges as constructed for drainage work range in capacity from ½ cu. yd. to 4 or 5 cu. yd. The sizes most commonly used vary from 1 to 2 cu. yd. The smallest dredge costs about $5,000; the cost increases rapidly with the capacity of the dipper. The floating dipper dredge should be operated downstream, where practicable, to insure sufficient water at all times.

In general, the clamshell or orange-peel dredge is not well adapted to ditch construction, especially if there be stumps to handle. Certain types of soil, such as the muck of southern Louisiana, can, however, be handled to advantage with this machine. It is also suited to levee building when a long boom is used.

The dragline scraper excavator is constantly increasing in favor for drainage work. It is especially suited to the construction of ditches and levees of large cross-section, where the ground is sufficiently stable to support the machine. The scraper excavator is also suitable for ditch cleaning.

The various forms of so-called dry-land machines find quite extensive use in drainage. The dipper and orange-peel dredges of the dry-land type are suitable for use where sufficient water cannot be had to float a dredge. The templet and the wheel types of excavators are applicable to open land, where the soil is neither too hard nor too wet. The ditches cut by these latter machines are superior in hydraulic efficiency to those of similar section cut by any other type of excavator. The dry-land machines should be operated upstream.

The hydraulic dredge is not suited to ordinary drainage ditch construction. It has been used to some extent in cleaning ditches, and, with the use of slope boards, has in at least one instance made a satisfactory record in levee construction.

Costs of Dredge Excavation of Drainage Ditches.—D. L. Yarnell gives the following in Bulletin No. 300, Office of Public Roads and Rural Engineering, abstracted in Engineering and Contracting, Feb. 2, 1916.

Method of Operating.—With a floating dredge the construction should, where practicable, begin at the upper end of the ditch and proceed downstream. Sometimes it is not feasible to transport the machinery and material to the upper end of the ditch and the dredge must then work upstream. This is undesirable, unless the fall be slight, since in working upstream dams must be built behind the boat to maintain the necessary water level. In working downstream the ditch remains full and the dredge, floating high, can dig a much narrower bottom than if working upstream in shallow water. Moreover, when floating low, the dipper may not properly clear the spoil bank. Again, in working downstream, any material dropping from the dipper into the ditch will be taken out in the next shovelful; whereas if working upstream any material dropped or any silt washed behind the dredge is left to settle in the bottom of the ditch. If work is begun on the natural ground surface a pit must be dug to launch the boat; or if in a stream, it may be necessary to build a temporary dam in the channel to raise the water high enough to float the boat. The depth of water required varies from 2 ft. upward, depending on the size of machine.

The floating dipper dredge moves itself ahead by means of the dipper. The spuds are first loosened from their bearings and the dipper is run ahead of the machine and rested on the natural ground surface in front of the ditch. The spuds are then raised and the engines operating the backing drum are started; the dredge being free, is thus pulled ahead. The spuds are then lowered and excavation continued.

In timbered country the right of way must be cleared. In many cases the timber cut will supply sufficient fuel for the dredge. It is poor policy to fell the trees and leave them on the ground to be removed by the dredge. The stumps should always be shattered with dynamite, as the strain on the machinery is thus rendered much less and the life of the dredge increased.

An engineer, a craneman, a fireman, and a deckhand are required to operate a dipper dredge. The output, loss of time due to breakdowns, and the cost of repairs, depend almost wholly upon their skill and efficiency. The engineer should be an all-around mechanic as well as experienced in dredging.

The amount of fuel consumed depends upon the size and type of boiler used, and upon the burning and heating qualities of the fuel. A very great saving can be effected by covering the boiler with an asbestos coat. Ordinarily, about 25 lb. of coal per horsepower-hour are consumed on dredges. The cost of repairs depends largely upon the operator; a careless operator will cause many unnecessary breakdowns. It is not only the high cost of repairs for machinery but also the time lost which aids in increasing the actual cost of the output. It is a well-established fact that it is not the initial cost of a dredge or of any machine, but the operating and overhead expenses, that reduce the profits.

Cost of Operation.—The cost of dredge work depends upon a number of factors. The locality of the work, the kind of soil, repairs, delays, labor, etc., greatly influence the actual cost of any work. If the water level can naturally be maintained within a foot or so of the surface of the ground, the cost of excavation can be reduced very low with this type of machine. The data given in the following pages were obtained from the actual cost records of the various projects. Unfortunately, the figures are not always strictly comparable, one project with another, owing to variations in the items of cost included. Unless otherwise stated, interest is taken at 6 per cent and depreciation at 35 per cent per annum on the cost of the dredging outfit. Interest and depreciation are, however, charged only for the interval of time upon which the unit cost is based. This is not strictly correct, as a certain amount of time consumed in getting the machine on and off the work should be charged to each project. In most cases it was impossible to ascertain the time that should be charged to moving, building, etc., and therefore the item has been ignored in all cases, for the sake of uniformity. On some projects figures for operation over an extended period were not obtainable. In such cases the unit cost is based upon the daily cost of operation and the average amount of ditch dug per day, no allowance being made for interest and depreciation.

In the construction of a ditch in North Carolina a new 1¼-yard dipper dredge was employed. This dredge had a 5 × 20 × 70-ft. hull and was equipped with 8⅜ × 10-in. double-cylinder hoisting engines; 7 × 7-in. double cylinder, reversible swinging engines; a 50-hp. Scotch marine return-flue boiler; a 1¼-yard dipper, 31-ft. dipper handle, and 45-ft. boom. The spuds were convertible to bank or vertical and were operated by the hoisting engines. The cost of this dredge, erected, was $10,342.19. The dredge was operated continuously, each shift working 11 hours per day. The men were paid at the following rates per month: Superintendent in charge, $110; engineers, $100; cranemen, $60; firemen, $48; deck hands, $36. The men furnished their own subsistence. The ditch was 9½ miles long and ranged from 22 to 30 ft. wide on top and from 8 to 10 ft. deep; it had side slopes of ½ to 1 and a berm 8 ft. wide. The water level was easily maintained near the ground surface. Very little right-of-way clearing was required. In the construction of this ditch the dredge excavated 350,720 cu. yd. of earth. One year was required for the dredge to complete this work. The following cost data were taken from the records of the drainage district which owned and operated the dredge:

Cost of operation, including labor and fuel	$15,889.01
Repairs	1,948.24
Interest and depreciation	4,240.22
Total	$22,077.47
Cost per cubic yard, $0.0629.	

A new dredge of the same size and type as the one just described was used in the excavation of a drainage ditch in the same locality as the foregoing project. The ditch followed an old creek channel for the greater part of its length. The cost of the dredge, erected, was $9,365.34. It was operated in one shift of 11 hours; the actual time of operation was not recorded. The crew and the rates of pay were the same as in the foregoing example. The ditch was 3¾ miles long and ranged in top width from 22 to 26 ft. and in depth from 6 to 10 ft. The side slopes were ½ to 1; the berm was 8 ft. wide. The dredge worked downstream and the water level was easily held near the ground surface. Practically no right-of-way clearing was done. The material excavated was a loam top soil underlain by stiff clay; very little rock was encountered. The cost of the work was considerably affected by the expense ($1,459) of passing three bridges. The total amount excavated in a period of about 10 months was 121,200 cu. yd. The dredge was owned and operated by the drainage district. The following costs were recorded:

Cost of operation, including labor and fuel	$ 5,921.05
Repairs	1,028.73
Incidentals	117.95
Interest and depreciation	3,199.80
Total	$10,267.53
Cost per cubic yard, $0.0847.	

A dipper dredge with a 5½ × 16 × 60-ft. hull, 7 × 8-in. double-cylinder hoisting engines, friction swing, 1-yard dipper, 35-ft. boom, and telescopic bank spuds was used in the construction of about 5 miles of ditch in western North Carolina. No reliable information was available as to the amount of material moved; but the following figures as to the cost of installing the dredge are of interest:

Hull: Labor and material	$1,803.23
Machinery:	
Material	4,800.00
Freight	379.10
Drayage	72.60
Installing	310.60
Extra equipment (forge tools, etc.)	80.00
Lighting equipment (engine and dynamo and wiring)	207.00
Total	$7,652.53

In Colorado, a dipper dredge having a 24 × 75-ft. hull, 1½-yd. dipper, and 50-ft. boom, was used in cleaning out and enlarging about 20 miles of canal. The equipment, complete, including cook and bunk boats, cost $16,500. Two shifts of 11 hours each were run. During the year for which the data are given the dredge was actually in operation but 187 days, or 58 per cent of the total working days. The following crew were paid the given rates per month, including board: Head runner, $120; 1 runner, $110; 2 cranemen at $55; 2 firemen at $45; 2 deckhands at $40; 1 teamster, $40; 1 cook, $50. No right-of-way clearing was required. The water for the boiler was taken from the canal, and as a result considerable trouble was experienced from mud and scale. The cost data below are based on the amount of material moved from inside the grade stakes during the year, amounting to 394,387 cu. yd. It was estimated that an excess of 25 per cent was actually moved. The following was the cost of the work for one year:

Operation:	
Labor operating dredge	$ 6,243.70
Coal, including freight, 1,276.65 tons, at $2.35	3,000.13
Hauling coal, 1,276.65 tons, at 82½ cents	1,053.24
Oil, waste, and miscellaneous supplies	692.80
Cost of controlling water to float dredge	369.24
Repairs, labor, and material	3,894.67
Removing and replacing bridges	837.78
Interest and depreciation	6,765.00
Total	$22,856.56
Cost per cubic yard, $0.058.	
Miscellaneous expenses:	
Engineering and supervision	$ 1,856.10
Building up ditch bank and making road on top	4,721.75
Right of way and legal expenses	190.42
Total	$ 6,768.27

The cost of the dredging outfit was as follows:

Hull:	
Material	$ 1,960.83
Labor, including hauling	1,959.99
Machinery:	
Cost, including freight	9,997.72
Hauling and installing	817.55
Cook and bunk boats:	
Material	663.90
Labor	453.66
Equipment	646.35
Total	$16,500.00

In connection with a drainage project in southwest Louisiana a steam-operated, floating dipper dredge, equipped with a 1-yd. dipper, 40-ft. boom, and convertible power spuds was employed in the excavation of about 10 miles of ditch which varied in width from 18 to 50 ft. and in depth from 4 to 6 ft.; 15-ft. berms were specified. The cost of the dredge on the work is said to have been $10,000. Two shifts of 10 hours each were run, but the actual number of days of operation was not recorded. The crew and monthly rates of pay, including subsistence, were as follows: Two runners, at $100; 2 cranemen, at $60; 2 firemen, at $60; 1 deckhand, $40; 1 cook, $30. The material excavated was a hard, stiff clay. The total amount excavated in about 8 months was 147,000 cu. yd. The average cost, per month, of operation was as follows:

Labor	$ 510
Board	100
Coal	262
Repairs	200
Oil and supplies	50
Interest and depreciation	342
Total	$1,464
Cost per cubic yard, $0.0796.	

On another project in southern Louisiana there was employed a floating dipper dredge with a 5 × 22 × 73-ft. hull; 8 × 10-in. double-cylinder hoisting engine; 6 × 8-in., double-cylinder reversible swinging engines; 1¼-yd. dipper, and 40-ft. boom. The machine was equipped with bank spuds. The cost of the dredge, ready to operate, was $13,000. The ditches averaged about 30 ft. wide and were from 5 to 6 ft. deep. The land was nearly level and the water surface was easily kept within a foot of the ground surface. The material was a top muck underlain by an alluvial mud which was hardly solid enough to hold its shape when dropped from the dipper. There were few submerged logs or stumps. The dredge was operated the year around for two years. No record was kept of the actual time of operation. The average output per shift (12 hours) on a 30-ft. ditch 5 ft. deep was 1,200 cu. yd., at a cost as follows:

Labor (4 men)	$10.50
Fuel, 6 barrels oil, at $1.75	10.50
Repairs, oil, and grease	5.50
Total	$26.50

Cost per cubic yard, exclusive of interest and depreciation, $0.0221.

In the same general locality as the foregoing case, and under the same soil conditions, a 1-yd. dredge which was, except in respect to capacity, equipped similarly to the above-described machine, was operated in the construction of ditches which averaged 30 ft. wide and 5 ft. deep. The cost of the dredge, erected, was $11,000. The average output per 12-hour shift during a 2-years' run was 1,000 cu. yd. The cost per shift was as follows:

Labor (4 men)	$10.00
Fuel, 5 barrels oil, at $1.75	8.75
Repairs, oil, and grease	5.50
Total	$24.25

Cost per cubic yard, exclusive of interest and depreciation, $0.024 2.

In another drainage project in southern Louisiana several ditches, each three miles long, were constructed by a dipper dredge installed on a 5½ × 18 × 70-ft. hull. The power was obtained from a 60-hp. internal-combustion engine. The dredge had a 1¼-yd. dipper, 40-ft. boom, and convertible power spuds. The total cost of the outfit, including house-boats and small towboats, was $12,000. Two shifts of 10 hours each were run for 26 days in each month. The crew were furnished subsistence, and each shift consisted of: One runner, at $125; 1 craneman, at $65; and 1 engine tender, at $40 per month. One cook, at $35, and one general utility man, at $60, were also employed, making a total labor cost of $555 per month. The average dimensions of the ditch were: Top width, 25 ft.; bottom width, 18 ft.; and depth, 8 ft. The ground was nearly level and the water stood about 3 ft. below the ground surface. The excavated material was a stiff, sandy clay. About 3.4 miles of the work consisted in cleaning old channel, which required frequent moving and gave small yardage. The total excavation in five months was about 216,000 cu. yd. The cost was as follows:

Labor and board	$3,555
Fuel and oil	2,300
Repairs	980
Interest and depreciation	2,050
Total	$8,885

Cost per cubic yard, $0.0411.

A steam-operated floating dipper dredge, mounted on a 5 × 15 × 60-ft. hull and equipped with a 1-yd. dipper, 38-ft. boom, and inclined telescopic bank spuds, was used in the excavation of about 10¾ miles of ditch in North Carolina. The cost of the dredge is stated to have been $6,613.82. One shift of 10 hours per day was run. The actual number of days of operation was not recorded. The crew and rates of pay were as follows: One engineer, $125 per month; 1 craneman, $2 per day; 1 fireman, $1.25 per day; 1 watchman, $1.50 per day. The crew furnished their own subsistence. The ditch was about 18 ft. in top width, 12 ft. deep, and had ½ to 1 slopes. It followed an old creek bed for a large part of the distance. The material excavated was a clay, though some rock was also encountered. Based upon the given dimensions of the ditch, the total excavation amounted to 295,000 cu. yd. Eighteen months were required to complete the work. The cost was as follows:

Operation:	
Labor	$ 6,310.94
Fuel	2,210.30
Repairs:	
Labor	1,380.12
Material	1,136.71
Interest and depreciation	4,067.00
Total	$15,105.07
Cost per cubic yard, $0.0512.	
Miscellaneous expenses:	
Engineering	$ 164.83
Clearing right of way	282.70
Rebuilding bridges	104.96
Incidentals	48.77
Administration	618.00
Total	$ 1,219.26

Costs of Dredging Main Canals on a Drainage Project in Louisiana.—Engineering and Contracting, Oct. 25, 1911, gives the following:

The excavation was begun in the latter part of 1909 and was prosecuted almost continuously until the completion in August, 1911. This work was carried on by means of two Marion dipper dredges, one with a ¾ cu. yd. and the other with a 1½ cu. yd. bucket. The large dredge was on the ground when the work was begun and the small one was built afterward at a cost of about $8,500. Two oil barges of about 400 bbls. capacity each were built to carry fuel oil for the dredges from New Orleans. All supplies had to be brought in on barges. One 25-h.p. gasoline tug was used for all towing.

The cost figures for the work which follow were taken from the company's books, with the exception of the charge for plant. This is an arbitrary figure based on an estimate of 25 per cent depreciation of the plant for the two years' work. The plant is taken as worth $20,500 at the beginning of work. The labor charge is taken from the payroll account and includes all labor charged to the contract, such as dredgemen, camp labor, clearing, towing, superintendence, etc. The supplies include all supplies except camp supplies. The repair account includes all repair parts and freight on same, but does not include the labor for making repairs. The general expense account includes all expense not included in other accounts, such as taxes on plant, traveling expenses, railway fares of men, office expenses, etc. No interest is included. The fuel account includes only the oil used for the operation of the dredges.

The rates of wages paid were for common labor $2 per day, engineer $125 per month, craneman $65, fireman $50.

The rates of the monthly men include board in addition. The costs follow:

Total yardage 674,921	Per cu. yd.
Plant (arbitrary)	$0.0076
General	0.0059
Repairs	0.0020
Supplies	0.0138
Fuel	0.0094
Labor	0.0219
Camp	0.0081
Total cost per cu. yd	$0.0687

Costs of Ditch Excavation with Templet Excavators.—Engineering and Contracting, Feb. 9, 1916, gives the following extract from Bulletin No. 300 (Office of Public Roads and Rural Engineering) by D. L. Yarnell.

A single-bucket templet excavator was used in southern Louisiana on the construction of 7,825 ft. of ditch having a 24-ft. bottom width and ranging in depth from 3.5 to 7 ft. The side slopes were 1 to 1, and the width of berm was 15 ft. The total excavation was 43,128 cu. yd. The total cost of this machine on the work was $8,506.22. The soil was a yellow clay with a few spots of gravelly clay, and the top soil was baked very hard. No special difficulties were encountered except that considerable cribbing was necessary to level up the track supporting the excavator when crossing natural water courses; except for these streams the ground was level. Some trouble was also experienced with the traction device, due to the fact that the ditch was larger than that for which the machine was designed. The actual number of working days was 128, 73 days of which were spent in actual digging; 43,128 cu. yds. were dug. The cost of operation per day was as follows: One operator, $3.85; one fireman, $2.28; three deck hands, $6.27; one team and teamster, $5.40. The total cost per day was $17.80. The average daily excavation for the 128 days worked was 337 cu. yds. or 107 lin. ft. of ditch. The total cost of operation for 5 months was $3,500 divided as follows:

Operating, labor	$1,885
Operating, materials	496
Fuel	602
Repairs, labor	294
Repairs, materials	223
Total	$3,500

Interest and depreciation in that time, at 41 per cent per annum, would amount to $1,453, making the total cost $4,953 and the cost per cubic yard $0.1149.

Cost of Operating Wheel Type Excavators in Drainage Ditching.—Engineering and Contracting, Jan. 26, 1916, publishes the following extract from Bulletin No. 300, by D. L. Yarnell, office of Public Roads and Rural Engineering.

Two machines of the wheel type designed to cut a ditch 4 ft. deep, 4 ft. wide at the top, and 2 ft. wide at the bottom, were used on the excavation of some ditches in one of the Gulf States. Each machine was driven by a 28-hp. gasoline engine. The digging wheel was 15 ft. in diameter and the two apron tractors each 5 ft. by 12 ft. The weight of each excavator was about 30 tons. The first cost of the machine was $5,500 and freight to the point of use was $338.36, making the total cost of each machine $5,838.36. The soil was a hard, yellow, sandy clay overlain by a turfy muck, varying in depth up to 2½ ft. The turf was easily cut, but the hard clay caused excessive wearing on the bearings. A large part of the work was done when water was from 2 to 3 ft. deep on the land. The total length of the ditches dug was 165 miles, the average length of ditch being 2,475 ft. The average depth of digging was about 4 ft., with a 4-ft. top and 2-ft. bottom. The average distance dug per shift of 10 hours of actual running time was 2,250 ft.; the maximum distance dug in 10 hours was 6,600 ft. The average yardages per month for the two machines were 13,245 and 13,180 cu. yds., respectively. The average daily outputs on the basis of the actual running time were 1,000 and 1,126 cu. yd., respectively. A part of the time the first machine ran a double shift, which accounts for the higher monthly and less daily average It required 13 months to complete the work, the actual time of operation being about half this. On account of the excessive wearing on the bearings, caused by the heavy sandy clay, it was necessary to make frequent stops for rebuilding the machines, which operation occupied an average of nearly two weeks. The total excavation was 317,162 cu. yd.

The daily operating expense per 10-hour shift for each machine was about as follows:

	Per day
One operator, at $100 per month	$ 4.00
One assistant	2.00
50 gallons gasoline, at 16 cents	8 00
Repairs	6.00
Other charges	12.00
Total	$32.00

The itemized cost for operation for the entire work was as follows:

Labor	$ 5,172.11
Interest, discount, and exchange	202.05
Maintenance and repairs	2,860.08
General expense	273.10
Management expense	1,600.00
Provisions and cooking (cook's wages)	2,245.91
Freight and express	75.74
Towing	458.19
Gasoline	1,792.22
Other oil	281.49
Teams and livery	932.11
Telephone and telegraph	25.29
Motor boat operation	540.96
Interest and depreciation on machinery	5,185.00
Total	$21,644.25

Cost per cubic yard, $0.0682.

	Machine No. 1	Machine No. 2
Machine running	$ 917.97	$1,509.66
Machine repairing	1,431.37	771.96
Machine moving	105.20	88.51
Machine bogged	156.90	190.54
Total	$2,611.44	$2,560.67

The excessive cost of labor given for the machines when bogged was due to the frequent crossings of a wide, muck-filled bayou which ran the entire length of the district. This bayou was about 1,500 ft. wide; the muck ranged from 5 to 15 ft. deep and was very soft. No tree roots, submerged timber, or stumps were encountered. The work covered an area of about 7,000 acres, approximately square, which was traversed by parallel canals every half mile. The ditches cut by the excavators were at right angles to these canals and were spaced 330 ft. apart. It was thus necessary to turn the machine around and run it light 330 ft. for each half mile of ditch cut. The item "moving" is for taking the machine across the canals and for moving from one part of the district to another; it does not refer to the moving between adjacent ditches.

On a project in southern Louisiana a wheel excavator, cutting a ditch 4½ ft. deep with a top width of 4½ ft. and a bottom width of about 20 in., was used. The machine worked on comparatively solid ground. Power was supplied by a 28-hp. gasoline engine. The first cost was $4,000, and freight charges from factory to works were $350. After the machine had been operated for a short time it became apparent that the excavating wheel was far too light and a new wheel was substituted. The soil was a silt loam, firm and uniform but not tenacious. No special difficulties due to soil conditions were encountered in this work. The chief obstacles to rapid progress were at first the weakness of the light excavating wheel, and afterwards the extra-heavy excavating wheel which unbalanced the machine. The tractors were larger than necessary and often broke down when turning on the hard ground. At the time the following cost records terminated, the work had been carried on intermittently for about 18 months; about one-half this time was occupied in repairs. During this time the machines dug 117,000 ft. of ditch 4½ ft. deep, 45,500 ft. 3½ ft. deep, and 9,250 ft. twice over, the machine making two 4½-ft. cuts side by side. The average length of ditch cut per day was 800 ft., while the maximum was 1,950 ft. The daily cost of operation was as follows:

Labor	$ 5.50
Fuel	4.20
Incidentals	.50
Repairs	2.40
Total	$12.60

The average excavation per day was 410 cu. yd., based on the average of 800 ft. of ditch, 4½ ft. deep, 4½ ft. wide at the top, and 20 in. wide at the bottom. The machine excavated 82,330 cu. yd. in 18 months at the following itemized cost:

Gasoline based on 215 actual days' operation (estimated)	$ 903.00
Repairs, actual cost	860.00
Incidentals at 50 cents per day	120.25
Labor of foreman, 18 months, at $75 per month	1,350.00
Other labor, two men, $2.50 per day for 250 days	625.00
Interest and depreciation	2,675.25
Total	$6,533.50
Cost per cubic yard, $0.0793.	

Cost of Straddle Ditch Excavators Work.—D. L. Yarnell gives the following in Bulletin No. 300, office of Public Roads and Rural Engineering, abstracted in Engineering and Contracting, Jan. 19, 1916.

A machine of this type often used has a 30-ft. boom and a 1-yard dipper. The steam power used is obtained through a 2-cylinder, 35-hp. engine and a vertical boiler. The machine rests on a platform which is mounted on two steel beams, each 29 ft. long, that straddle the ditch. It can be mounted on either caterpillar tractors or wheeled trucks. In the latter case, each end of the two beams is supported on a two-wheeled oscillating truck, the wheels being 2 ft. high and 18 in. wide. They run on a wooden track 6 in. thick and 3 ft. wide, which is built in six sections each 20 ft. long. One section of the track on each side is always unoccupied and these are lifted ahead by means of cranes operated by power derived from the engines. This track will support the machine in the softest ground. The excavator will dig 12 ft. deep and 22 ft. wide on firm ground; with an extension to the dipper handle it can dig 18 ft. deep. It will deposit the dirt on either side at a distance of 32 ft. from the center of the ditch. The dipper will swing over a bank 14 ft. high. Where track is used the machine is pulled ahead by a cable from the engine which hooks to the track on both sides; this is done without interrupting the work of excavating. If desired, caterpillar tractors are furnished instead of the wheeled trucks. The front tractors are 4 ft. wide by 11 ft. long, and the rear tractors are 4 ft. wide by 7½ ft. long. This excavator has been known to dig as high as 1,500 cu. yd. in 10 hours in especially favorable material. It has dug through 12 in. of frost. From seven to eight men can set up and take down the machine in from five to eight days.

Another machine of this type has a 38-ft. boom and a 1-yard dipper. Power is supplied by an internal-combustion engine of 25 or 40 hp. which burns kerosene, gasoline, or distillate oil. The machine rests on a platform which is mounted on two steel beams, whose standard span is 32 ft. Extension axles are provided which permit of a maximum increase of 3 ft. in the span. The front axle is mounted on a two-wheeled swiveling truck with cast-steel doubleflange wheels. The rear end is carried by two heavy, wide-faced, doubleflange steel wheels set loosely on the axle. The shipping weight of this size of dredge, including engine, dipper, and machinery, is approximately 38,000 lb.

Perhaps the cheapest straddle-ditch excavator of the dipper type that is in use is a home-made one which has been used to some extent on small ditches in Iowa. The machine is of the revolving type. It is equipped with a ¾-yard dipper and a 28-ft. boom. The power is derived from a 6-hp. gasoline hoisting engine geared to three hoisting drums, one of which hoists the end of the dipper, one hoists the boom, and one pulls the machine ahead. The machinery is mounted on a platform which revolves upon a turntable supported on two wooden beams which straddle the ditch. The beams rest on wooden wheels, the entire span being 22 ft. The dipper handle, instead of moving forward and backward at the boom, is pivoted. The entire machine weighs only about 17,000 lb. and costs about $1,200.

This excavator has dug as high as 400 cu. yd. a day, but averages about 200 cu. yd. It can excavate a ditch with a 20-ft. top and can dig 13 ft. deep, but 6 or 7 ft. is the best working depth. Two men can erect the machine in 2½ days and dismantle it in ½ day; it makes about seven wagon loads. The hoisting apparatus, which is the heaviest part of the machine, weighs 4,100 lb. The excavator is moved ahead by means of a "dead man" and cable, and can be moved across country at a speed of about 1 mile per day. The machine can take out five shovel-loads in two minutes, and has dug through 6 in. of frost. Only two men are required to operate it—one operator and one trackman.

A ditch constructed by this machine in Iowa had an 18-ft. top, 4-ft. bottom and 6½-ft. depth. From 8 to 10 gal. of gasoline, costing 16½ ct. at the works, were used per day. The material, which was a loam underlain by a stiff gravelly subsoil, was excavated at the rate of about 200 cu. yd. in 10 hours. The cost of operation per shift was as follows:

One operator	$4.00
One trackman	2.00
Ten gallons gasoline, at $0.16½	1.65
Total	$7.65

The cost per cubic yard, exclusive of interest and depreciation, was about 3.8 ct. The contract price on 5,000 cu. yd. was 12 ct.

Such a machine as this would be well adapted to digging the small ditches in the South that are almost universally put in by hand at a cost of about 25 ct. per cubic yard. Even in ground covered with stumps, by using plenty of dynamite this type of excavator could be used to advantage in reducing the cost of small ditches.

In general, it may be said that the dry-land dipper dredge, though applicable to certain conditions, has no extensive use in drainage work, as excavation that is suitable to this machine can usually be handled to better advantage by the drag-line scraper excavator.

Drag Line Excavators on Ditch Work.—The following extract, from Bulletin No. 300, office of Public Roads and Rural Engineering on "Excavating Machinery Used in Land Drainage" by D. L. Yarnell, is given Engineering in and Contracting, Feb. 2, 1916.

A drag-line excavator of the rotary type, having a 2-yard scraper bucket and a 60-ft. boom, was used in the construction of drainage ditches in southern Texas. It was built mostly of wood and moved on rollers. Power was derived from an 80-hp. internal-combustion engine, burning oil. The cost of the excavator, ready to operate, was $12,000. It was operated about 10 months in two daily shifts of 10 hours each, a shift consisting of 10 men. The actual working time was not recorded. The ditch ranged from 4 to 22 ft. in bottom width, from 3 to 12 ft. in depth, and had 1 to 1 side slopes. The soil varied from a stiff, heavy clay to a fine sand. The excavation amounted to 230,000 cubic yards; the cost was as follows:

Operating expenses	$22,313.36
Miscellaneous expenses	374.70
Interest and depreciation	4,100.00
Total	$26,788.06
Cost per cubic yard, $0.1164.	

On another drainage project in southern Texas, a 2-yard rotary excavator was used. The machine was of steel throughout, had a 60-ft. boom, and was mounted on caterpillar traction. The crew consisted of a foreman, operator, engineman, oiler, and two laborers. The machine was operated by a 110-hp. internal-combustion engine, with oil as fuel. The total cost of the machine was about $17,500. The cost of erection was $509. During the four months of operation two 10-hour shifts were run. The ditches ranged from 4 to 22 ft. in bottom width and from 3 to 12 ft. in depth, with 1 to 1 side slopes and 8-ft. berms. The material excavated was a stiff, heavy clay. The excavation amounted to 91,400 cu. yd.; the cost was as follows:

Operating expenses	$ 8,873.82
Miscellaneous	371.00
Interest and depreciation	2,391.00
Total	$11,635.82
Cost per cubic yard, $0.1273.	

In the same general locality as the last example a 1½-yard rotary drag-line excavator, operated by a 50-hp. internal-combustion engine and mounted on caterpillar traction, was used in the construction of some ditches in soil ranging from stiff, heavy clay to fine sand. The ditches were of the same dimensions as in the foregoing example. The machine was rebuilt from an old dipper dredge at a cost of about $1,200. It was operated in two daily shifts of 10 hours each. The crew for each shift consisted of from five to six men. During the five months of operation the machine moved 59,014 cu. yd. at an expense, exclusive of interest and depreciation, of $8,921, or $0.1512 per cubic yard.

A rotary drag-line excavator with a 2¼-yard bucket and 65-ft. boom, mounted on skids and rollers, was used in the excavation of 222,500 cu. yd. in South Dakota. The power was obtained from a 50-hp. internal-combustion engine, using gasoline. The cost of the machine, complete, was $10,500. The total time of construction was 148 working days, or approximately six months, of which 23 days were occupied in making repairs. Two shifts of 11 hours each were run. The soil was a loam underlain by clay. The crew and rates per month were as follows: One superintendent, $125; 2 cranemen, at $100; 4 trackmen, at $50; 1 teamster, $45; 1 cook, $40. The operating expenses were as follows:

Gasoline, 15,444 gallons, at $0.124	$ 1,915.05
Labor	3,060.00
Subsistence	561.81
Cables	978.87
Repairs and renewals	845.93
Miscellaneous	2,078.72
Interest and depreciation	2,152.50
Total	$11,592.88

Cost per cubic yard, $0.0521.

The following costs were secured on the operation of a rotary drag-line excavator with an 85-ft. boom, 2-yard bucket, and a 50-hp. engine. The work was done on the New York State Barge Canal. The machine weighed 147 tons and cost $10,000. It excavated earth 90 ft. from center on one side and deposited it 100-ft. from center on the other. It dug a channel 25 ft deep. and deposited the material on waste bank 15 to 25 ft. high. The material was a stiff clay, with few stumps or bowlders. The following is a condensed cost record for five months' work:

Month	Total expense for month	Yards excavated during month	Average cost per yard
April	$1,088.21	5,205	$0.209
May	1,041.53	18,365	.0568
June	1,152.04	25,333	.0455
July	1,317.61	33,055	.0399
August	1,535.36	47,363	.0324

Average cost per yard for 5 months, including all charges, $0.0474.

In May, items of cost were as follows:

Engineer, at $90 per month	$ 90.00
Engineer, at $95 per month	84.04
Fireman, pumpmen, watchmen, etc., at $1.75 per day	363.00
Coal, at $3 per ton	147.00
Repairs, including labor and material	15.82
Interest and depreciation	341.67
Total	$1,041.53

Cost of Drag Line Excavator Operation.—Engineering and Contracting, Feb. 20, 1918, gives the following.

In connection with drainage construction on U. S. Reclamation Projects over 2,000,000 cu. yd. of earth were excavated during 1916 with four Class 9½ Bucyrus electric dragline excavators. The machines were operated by Government employes. Electric power was furnished at a cost of about 0.35 ct. per kilowatt hour from the Reclamation Service power plant.

The drains constructed were all open-channel cuts varying from 7 to 12 ft. in depth, with side slopes of 1½ to 1 and 2 to 1, and with usual base width of from 5 to 10 ft.

The drag-line excavators were operated three 8-hour shifts per day with crews of one operator and one oiler. The material excavated consisted principally of clay, loam, soil, and boulder gravel laid in clay and sand. This latter material constituted about 40 per cent of the total excavation and wore out bucket parts very rapidly. Temporary 3-phase electric transmission lines for operating the excavators were erected at a labor cost of about $85 per mile and torn down at a cost of $20 per mile, the line materials being used repeatedly along successive drains. The following table from the last annual report of the U. S. Reclamation Service shows the cost of excavating with the four drag lines for the 12 months, Jan. 1 to Dec. 31, 1916:

Classification	Total cost	Cost per cu. yd.
Operation	$ 20,529.88	$0.0077
Power	15,661.15	.0059
Repairs	33,650.11	.0126
Moving up	3,943.89	.0015
Cutting side drains	4,984.68	.0019
Finishing (hand labor)	629.37	.0002
Drilling and blasting*	217.34	.0001
Moving to new work	1,923.00	.0007
Sub-total	$ 81,539.42	$0.0306
Project general expense	4,468.96	.0017
Depreciation excavation equipment	31,943.96	.0120
Depreciation temporary power system	29,351.11	.0110
Total cost	$147,302.99	$0.0554
Total yardage	2,660.465	
Total mileage	54.17	
Cost per mile	$ 2,719.27	

*For excavation of 2,385 cu. yd. of rock.

The average digging rate of the four machines was 150 cu. yd. per-hour, or at the rate of two cycles per minute, with 1½ cu. yd. capacity buckets. The following table shows the machine efficiency:

	Total hours	Per cent
Digging	17,732.50	76.9
Repairs	2,729.75	11.8
Moving	1,486.00	6.5
Blasting	64.75	0.3
Side drains and runways	591.75	2.6
Power off	430.25	1.9
Total	23,035.00	100.00

In excavating 2,660,465 cu. yd. the machines worked 2,824 shifts, the average yardage per shifting being 940. The highest run per shift was 1,967 cu. yd.

Cost of Digging Drainage Ditch with Gasoline-driven Dragline.—P. F. Jones gives the following information in Engineering and Contracting, Dec. 17, 1919. A ½ cu. yd. dragline during the past season excavated a drainage ditch for the Modesto Irrigation District of Stanislaus County, California, at cost of 13 ct. per cubic yard. This figure comprises actual running expenses, including labor and material, but not interest or depreciation. The material excavated was 50 per cent sandy loam and 50 per cent clay hard pan. The ditch had a 6-ft. bottom, was 8 ft. deep, with slopes of 1½ to 1. It was approximately 2 miles in length. The crew included one operator at $200 per

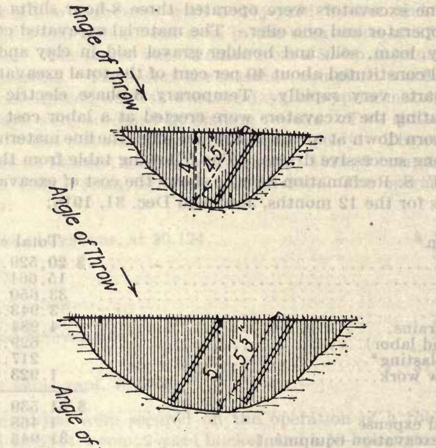

Fig. 1.—Sketches showing arrangement of holes for excavating ditches with dynamite.

month; one oiler at $5 per day and one 2-horse team and driver at $7 per day. The quantity of earth moved per 12-hour shift amounted to approximately 400 cu. yd.

Cost of Excavating Drainage Ditches with Dynamite.—A very considerable amount of farm ditching is being done with dynamite. Instead of digging these ditches by hand or machine, one or more rows of holes are made along the line of the ditch and a small dynamite cartridge is placed in each hole and the cartridges are exploded simultaneously. The result of the explosion is a channel which with very little labor makes a satisfactory drainage ditch.

Dynamiting is confined to the smaller sizes of ditches, say up to 5 ft. deep, but for channels of these sizes in suitable soils some very excellent results are reported.

Fig. 1 shows the arrangement of holes for ditches of several widths. A steel bar driven with a sledge is employed to make the holes. The cartidges are placed at the bottom of the holes and connected up with fuse or wire and then fired in the usual manner. The arrangement and spacing of the holes differ with the soil and had best be determined for each condition by a series of trials. As examples, the following reports of work done at Chadbourne, N. C., for the Brett Engineering Co. are of interest:

"Where the ground was comparatively free from stumps and roots we put down holes 18 ins. apart, 3½ ft. deep, and 100 holes in all. Each hole was pointed 45° and loaded with one stick of Hercules 60 per cent N. G. dynamite 1¼ × 8 ins., the center hole being primed with an extra stick and a double strength exploder. The result was a good ditch 7 ft. wide on top, 3 ft. on the bottom and 3 ft. deep and 150 ft. long. Costs of finishing and trimming according to specifications per running foot were:

Total cost of explosives used	$11.35
Total cost of putting down holes	.50
Total cost of finishing and trimming	4.50
Total cost of 150-ft. ditch	$16.35
Total cost per running foot	.109

"The next ditch was shot at Sollo Swamp, where the ground was heavily matted with roots and stumps. The specifications here called for a ditch 14 ft. wide, 2½ ft. deep. We put a double row of holes, 100 in each row, 18 ins. apart laterally, 4½ ft. apart longitudinally, and 4 ft. deep. Both rows pointed 45° in the same direction. The middle holes primed with an extra stick and a double strength exploder. Along the path of this ditch we counted 35 stumps from 6 ins. to 3 ft. in diameter. The result was a clean ditch 12 to 14 ft. wide, 4 ft. deep and 150 ft. long.

Cost of explosives per running ft	$0.10
Cost of holes per running ft	.0066
Cost of labor per running ft	.03
Total cost per running ft	$0.1366

"The next ditch was shot at Dunn Swamp, where we decided to put down 150 ft. in the muddiest and stickiest kind of ground. We put down a double row of holes 18 ins. apart, 4½ ft. laterally, 4 ft. deep, both rows pointed 45° in the same direction. Each hole loaded with one stick of 60 per cent and the middle hole of each row primed with a double strength exploder. All the holes well tamped. Result was a very clean ditch 14 ft. wide, 3½ to 4 ft. deep and 150 ft. long. The total cost of this ditch was the same as the ditch shot at Sollo Swamp."

According to Engineering and Contracting, March 21, 1917, dynamite was used in blasting open drainage ditches at the experiment station farm of the Montana Agricultural College at Bozeman, Mont. The soil where the ditching was done is very gravelly and contains many large rocks, making digging difficult and expensive.

Two sticks of 60 per cent Hercules dynamite were placed in holes 22 in. apart, this distance being determined by experimenting to be the most desirable for the soil conditions. About 25 holes were usually fired at one shot, the middle hole being used for the primer. A length of 647 ft. was blasted at a cost for labor of $51.25, or $1.31 per rod. The expense of cleaning out the ditch after blasting was 27 cts. per rod, which is included in the above cost. Dynamite, caps and fuse for the job cost $1.05 per rod (dynamite at 22 ct. per pound). The following is a comparison of three lengths of ditch constructed in 1915:

Kind of work	Length of ditch, rods	Total cost per rod
Hand-dug ditch	14.0	$3.35
First length of blasted ditch	17.0	3.10
Second length of blasted ditch	39.2	2.36

Cost of Maintaining Drainage Ditches in the South.—According to Engineering News-Record, Aug. 8, 1918, keeping a land drainage channel clear of growth and debris, cost $15 to $35 per mile on a ditch 8-ft. deep, 14-ft. wide at base and with side slopes of 1½: 1. These costs per mile include: labor, moving camp, food and cook's salary, depreciation on camp equipment and tools, together with all incidental expenses with the exception of Engineering supervision.

The rates of wages were as follows: foreman $3 per day, laborers boarding in camp $1 per day and laborers boarding themselves $1.25 to $1.50 per day.

Costs of Cleaning Drainage Ditches.—Methods employed in cleaning drainage ditches are described by Seth Dean, in the Proceedings of the Iowa State Drainage Association; from which Engineering and Contracting, Oct. 28, 1914, abstracts the following:

In the spring of 1910 the writer cleaned a bed of silt ranging from 6 ins. to 3 ft. in thickness and three-fourths of a mile in length from a channel originally cut 16 ft. wide on the bottom, but at the time in question the stream of water flowing over the silt was about 10 ft. wide and 1 ft. deep, the rate of fall being about 2 ft. per mile. There was considerable sand and some drift in the silt but no growth of weeds or brush. The plant used consisted of a flat-bottomed boat or scow, 7 × 18 ft. in size and 16 ins. deep, made of 1-in. plank. In the bottom of the scow a platform of 2-in. plank was laid to support the machinery, which consisted of a 4-hp. gasoline engine belted to a Myers pump with 3-in. suction and 2½-in. discharge. The pump was equipped with 10 ft. of 3-in. suction hose with strainer on the inlet end, and for discharge had about 15 ft. of 2½-in. fire hose with 1-in. nozzle. The scow when loaded required about 6 ins. depth of water to float. Commencing at the lower end of the silt bed the boat was poled forward or held in place, as required, and a jet of water turned through the nozzle into the silt that readily broke and stirred it up, permitting the water to float it away. The work was done in March and April, when the flowing water was clear and capable of carrying silt in suspension, the distance from the center of the silt bed to the outlet of the ditch was about 10,000 ft., and the current sufficiently strong that little settling of silt occurred. Three highway and one railroad bridge spanned the ditch in the distance cleaned, but the boat readily passed under them. Two men operated the machine and the total amount of silt removed was 2,346 cu. yds. in 33 working days. The cost of the equipment was as follows, viz.:

Cost of scow	$ 45.00
Engine and pump	200.00
15-ft. condemned hose and nozzle	3.00
Belting and fixings	8.60
Freight hauling and setting up	32.00
Two men 33 days at $4	132.00
Gasoline and oil	26.40
Repairs on machinery	1.05
Total	$448.05

After the work was completed the plant was dismantled and the engine and pump shipped to other work which was charged with their cost, thus making the net cost of the plant $248.05 and the cost of cleaning 10.53 cts. per cubic yard.

On one occasion a bed of silt interspersed with logs, brush, cornstalks, etc., was removed, using drags made from the beams and shovels of wornout corn cultivators by bolting the parts together in such manner that they presented the appearance of two anchors placed at right angles. The point of the beam was fitted with a swivel so the implement could revolve. By attaching ropes to the drag, placing a team on each bank and dragging the plow in the channel, the mass was broken up. After pulling out the logs and wire (dynamite being used sometimes to dislodge them) the water floated out the silt. A close measurement of the silt and drift removed from the channel was not made, as the work was done under the day system, but approximately 2,800 cu. yds. were taken out, the cost being the following items:

Four teams with drivers, at $3.50 each for 24 days	$336.00
Two drags with ropes and fixtures	10.00
Dynamite used	5.00
Foreman, 24 days at $2.50	60.00
Total	$411.00

Or about 15 cts. per cubic yard.

In the fall of 1912 we cleaned and deepened what is known as Seaton's ditch, near Missouri Valley. This is a drainage ditch 7,600 ft. long with 6 ft. bottom width, and side slopes 1 to 1. During the rainy season and for a time afterward the ditch carries water but is usually dry during the fall months. The work of cleaning was done by contract at 19 cts. per cu. yd. The contractor bid to do the work with teams, but the ground proved too soft for this method, and a small drag line dredge was purchased and the work successfully carried out with this, which proved to be an excellent machine for the work. The machine was made at Cherokee, Ia., of light timber construction. The framework, 16 ft. wide, is mounted on rollers and designed to work astride the ditch in clean-out work. The power is generated by an 8-hp. gasoline engine, which also serves to move the machine forward or transport it from one job to another along the country roads if the distance is not great. It uses a one-third yard scoop; two men operate it, using about 10 gals. of gasoline per day. About 250 cu. yds. of earth in ten hours was the capacity of the machine on the job in question. The machine is of wood construction and is not very durable, but as most of it is of sizes kept in all lumber yards, defective parts can be easily replaced.

Cost of and Profits from Tile Underdrains.—The following discussion by R. D. Marsden, published in Engineering and Contracting, July 7, 1914, is taken from the Year Book of the Department of Agriculture.

Costs.—The cost of drainage will vary considerably with the location of the work, owing to differences in the cost of tile and of labor: it will vary more with the nature of the soil and the consequent depth and spacing of the drains. Tile of 4-in. inside diameter will cost $16 to $20 per thousand feet at the factory and often $25 per thousand delivered at the railway station. If 4-in. tile cost $25 per thousand, 5-in. will cost about $35, 6-in. about $45, and 8-in. about $80 per thousand feet. Labor will vary from 75 cts. to $1.50 or more per day, but as the cheaper labor is considerably less efficient the cost per rod of drain will be more uniform. As an average cost for trenching, laying, and backfilling over the tile, about 50 cts. per rod for a depth of 3 ft. may be assumed; lower prices may be secured on large contracts that make it economical to use a trenching machine or a large force of experienced workmen. Deeper digging and larger tile require more excavation and involve higher prices. There also will be expense for hauling the tile from the railroad, and for engineering work in planning and laying out the drains. Silt wells, surface inlets, and masonry protection for tile outlets must be provided where needed. The total cost of drainage will ordinarily range from $15 to $45 per acre, the lower price mentioned being reached when the spacing of drains is perhaps 150 ft. and the higher figure when the spacing is about 4 rods or a little less. A very common cost for tile drainage is $25 per acre. The farmer can often do a considerable part of the hauling and other labor with his own teams and regularly employed help, especially where the amount of work is not large, saving no small cash outlay. Of course the foregoing prices do not anticipate the excavation of rock, large stones, or other very hard formation in any considerable quantities, for this will quickly multiply the labor cost.

Open ditches cost from 12 to 20 cts. per cubic yard of dirt removed, the price increasing with the size of the ditch because the material must be moved farther. A ditch 3 ft. deep, 2 ft. in top width, and 1 ft. in bottom width would cost 33 cts. per rod at 12 cts. per cubic yard; a ditch 4 ft. deep, with 3-ft. bottom and 6-ft. top, would cost $1.65 per rod at 15 cts. per cubic yard; and a ditch 4 ft. deep, with 4-ft. bottom and 8-ft. top, would cost $2.95 per rod at 20 cts. per yard. If open ditches of the smallest size were used 150 ft. apart, with a collecting ditch of the medium size, the cost of drainage would hardly be less than $7 per acre. The difference between tile and open drains would then be $8 per acre; the interest on such an investment would be 80 cts. per acre at 10 per cent, or 50 cts. per acre at 6 per cent. This amount would not nearly pay for the labor of keeping the ditches clear of weeds, dirt, and other obstructions, not to mention the increase in labor occasioned by having the field cut into small parts. The advantage of using tile becomes greater as the distance between drains is reduced, not only because of the labor of cultivation, but also because of the ground area used for ditches instead of for cropping.

Profits.—The actual value of farm drainage is indicated by the testimony of owners who have done this kind of work. Many of them state enthusiastically that drainage has doubled and trebled their crops and has increased the value of the land 50 to 300 per cent. The examples cited herein have been selected as typical of the results from properly draining farm lands in the humid region of the United States. Because the reclamation of large swamp tracts frequently involves considerable expense for clearing and sometimes for soil treatment after drainage, the profits shown below are in no way indicative of those to be obtained from large swamp reclamations. Neither should these results be used in considering the drainage of irrigated land in the arid region.

In the coastal plain of North Carolina about 25 acres that were producing nothing were tile drained for perhaps $250, probably not including costs of teaming and of supervision, and since then have produced a bale of cotton per acre. A field of six acres was drained for about $160, and the owner makes good crops on soil worthless without drainage. In the black prairie belt of Alabama, a field that had not been cultivated in years because too wet was drained with tile; then it produced one bale of cotton per acre and repaid the entire cost of drainage the first year. The following year the field yielded 50 bushels of corn per acre, twice the rate from the other parts of the farm. Another drained field produced one bale of cotton per acre, while the undrained land produced only half a bale. A 10-acre field that yielded practically nothing in 1912 was tile drained, and in 1913 produced 60 bushels of oats per acre; in 1914 the rate was again 60 bushels of oats, in contrast to 10 bushels per acre from the adjoining 15-acre field planted to the same grain. The cost of most of the tile drainage in Alabama has been about $25 per acre, some of it as high as $30 to $35, but increases of 50 to 200 per cent in yields and the assurance of good crops every year instead of only in very favorable seasons are very satisfactory returns. The cost of drainage there has usually been repaid in two to three years by the improved crops. In Iowa, a field of 40 acres too wet for planting was tile drained at a cost of $24 per acre, after which it produced 60 bushels of corn per acre. Another field was drained for $23 per acre, thereby increasing the yield from 15 bushels to 40 and 50 bushels of corn per acre. In Arkansas, on one of the State farms, 1 bale of cotton per acre was secured in favorable years, and nothing at all when the early part of the season was wet; the year following the installation of tile the yield was 1½ bales per acre. In Nebraska a tract of more than 700 acres was tile drained at $24.25 per acre, a pumping plant cost $2 per acre, and as part of a larger district the cost of levees to protect from overflow was $9 per acre. The improvement, for a total cost of $35 per acre, immediately increased the crop on about 80 acres of corn 22 bushels per acre, and on another part the increase in two years was from nothing to more than 30 bushels of wheat per acre.

Owners have found that tile drainage has reduced the cost of farming operations 20 to 50 per cent, so the increased production on land cultivated previous to drainage is clear profit. To find the profit upon draining land that has been abandoned, of course the cost of planting, cultivating, and harvesting must be deducted from the gross receipts for the crops raised. Investigations of the cost of producing cotton and of producing wheat indicate that where expensive fertilizers are not used the cost per acre for growing and marketing varies little if at all with the rate of yield.

To compute the actual money value of drainage requires that certain assumptions be made. If the average production of a field is increased about one-half bale of cotton per acre, worth 10 cents per pound, the income is increased about $25 per acre, equivalent to a 10 per cent dividend on $250, or a return of 71 per cent on a drainage cost of $35 per acre. If drainage increases the yield of corn 25 bushels per acre, worth 50 cents per bushel, the returns of $12.50 per acre would be equivalent to a 10 per cent dividend on $125, or 50 per cent annually on a cost of $25 per acre. However, to capitalize the net increase in value of the crops at the regular rate of interest might be a fair measure of the increase in producing value of the land, but this is the result of drainage added to what may be called the unused fertility of the soil. It will be better to consider the increase brought about by drainage in the market value of the property. In the Piedmont section of North Carolina a 55-acre farm was bought about six years ago for $1.900; ditching was started the first year and tile drainage two years later; in 1913 the crops were worth $2,000, and in 1914 the owner refused $5,000 for the farm. In the mountain section of the same state about 22 acres that grew only saw grass and bulrushes were tiled for $35 to $40 per acre, and the owner now values the land at $150 per acre. Another farmer spent about $200 cash, and probably some of his own time, in tile drainage, and thereby increased the market value of his farm $500 to $800. Another man reports the results as 300 per cent increase in the selling price of the land and 40 per cent in the assessed value; still another, who drained 10 acres for about $140, gives the results as one-third increase in assessed value, two-thirds increase in selling price, and more than 100 per cent increase in production. In eastern Maryland tile work costing $500 increased the farm value $1,000, and work costing about $240 increased the value of another farm $500.

In considering the economy of farm drainage it is proper to compare the anticipated results with the probable returns from otherwise investing the money that the drainage work will cost. When a farmer considers investing some of his savings to increase his business a question often to be met is: Shall he buy more land or improve some of what he already owns? If corn land producing 50 bushels per acre sells for $80 per acre, and he has marsh land which cost $10 per acre that produces nothing, drainage at $30 per acre will be profitable if it will make the marsh produce 25 bushels of corn, provided there are no other costs for preparing the land for cultivation. If the whole cost of drainage and other reclamation work is $50 per acre, and the result 50 bushels, the land has been made worth $80 for a total cost of $60 per acre. If land yielding 40 bushels per acre can be made to produce 50 bushels by drainage at $25 per acre, perhaps it would be true economy to buy more good land at the price stated rather than to drain; for $1,000 spent improving 40 acres would yield 400 bushels, while the same money buying 12½ acres new would yield 625 bushels. The difference in value at 50 cents per bushel would be $112.50. However, the increase in cost of farming the larger acreage might be considerable; if it would amount to as much as $3 per acre it would more than offset the difference in total yield, for there would be no increase in cost of farming on the drained land. Actual comparisons of the profits to be obtained from farm improvement and from purchasing improved land will many times show the farmer to be true economy, in spite of seemingly small gross returns. As larger markets raise the prices of agricultural products, land values must increase and larger expenditures per acre for drainage will be profitable.

Cost 35 Miles of Tile Drains.—The following data are given by L. H. Goddard and H. O. Tiffany in Circular No. 147 of the Ohio Agricultural Experiment Station.

*Description of Soil on the Farm Drained.**—Practically all of the soil on this farm is of glacial origin, and has been derived from the drift, which is here composed very largely of pulverized shale. The principal type, called Papakating clay, is a clay loam containing quite a large percentage of silt. The surface soil consists of a pale yellowish or grayish brown clay or heavy silt loam about 9 inches deep, which gradually becomes heavier with depth until at 18 to 24 inches it is mottled yellow and gray or blue clay, which becomes decidedly plastic at a depth of 3 feet. The higher elevations, or knobs, which were occasionally encountered, are somewhat lighter in texture, sometimes approaching a sandy loam, and usually contain some large stones or gravel in both soil and subsoil.

The lower lying soil, called Volusia silty clay loam, consists mainly of a dark colored clay loam or clay, varying greatly in depth and underlain by very

* Prepared by Dr. George N. Coffey of the Ohio Agricultural Experiment Station.

stiff mottled or bluish clay. This subsoil clay was considered by an expert to be of the right quality for tile making.

Near the centers of the main swamp areas there occur small areas of muck and washed-in material. The deposit of muck is shallow and the soil is very porous, allowing the water to disappear readily after rains and storms.

Methods of Procedure.—The work of installing the tile was conducted in the field by the Junior author, and all records were kept and compiled by him. The compilation and the manuscript have been checked by O. E. Brown, who was an assistant on the farm under Mr. Tiffany's management. This work of installation was done in cooperation with the Ohio Experiment Station and the U. S. Department of Agriculture, the regular time blanks of the Department of Cooperation of the Ohio Experiment Station being used. The records given herein are quite accurate so far as they go, and for the conditions under which the work was done.

The planning and laying out of the tiling systems in any given field was done by the Farm Manager, usually just previous to starting tiling operations. In a few instances surveys of the main ditches were made by an engineer to determine the necessary depth of cuts at intervals along the line. Surveys of this kind are especially valuable when a deep cut is to be made. In many instances levels were run on ditches where the amount of fall was doubtful. An ordinary carpenter's spirit level with sights attached was used for this purpose. This method is hardly accurate enough, but on most laterals up to 80 rods in length very good results were obtained. When a main ditch is over 80 rods long and has but little fall the Y level should be used. At the close of the season's operations an engineer was employed to make a plot of the fields tiled, showing the exact locations of all the drains.

All ordinary labor, such as hauling of tile, filling of trenches, etc., was done by men and teams taken from the regular force on the farm.

Tiling Work Done in 1909.—In the season of 1909 the drainage operations were confined to a single field (hereafter designated as No. 2), with the exception of about one-half mile of tiling for which figures are not included in this circular. The outlet for this field, which was an open ditch, had been provided the previous fall.

The surface conditions of this field were somewhat varied. The larger portion of it, or about 30 acres, was upland and quite rolling for this section of the state. The other 10 acres was mostly a clay and muck swamp. On the upland it was comparatively easy to secure a sufficient fall in all ditches, the fall per 100 ft. averaging about 8 inches, but the swamp area the fall would not average over one inch per 100 feet. One main ditch, which was in 12-inch tile, was carried practically on a level for about 800 feet, the grade being determined by the use of water. The condition of the upland portionl of this field would be an average for land in that section that had never been working It was covered with a heavy bluegrass sod which had been pastured for many years. The ten acres of lowland or of swamp area were covered with bulrushes, cat-tails, swamp brush, trees, etc., and in many instances a clearing had to be made before starting a ditch. The cost of this clearing for a ditch was comparatively trivial, however, and is included in the cost of tiling the field.

With the exception of about 160 rods the trenching was all done by hand this year; this 160 rods was dug by a machine rented at an average price of 25c per rod for the trenching alone. This cost of trenching was not deducted and figured separately, but included with the hand dug ditches by using exact figures of cost. Regular workmen employed for spading or trenching were paid from 20c to 22½c per hour for actual time put in. One man of long experience who did the bottoming, grading and laying of the tile received 25c per hour. The distance actually covered by each workman would not average over 8 rods per day under very favorable conditions.

Operations in 1909 were begun in the month of May, and for two months an average of 6 men were employed to dig the trenches. Little work was done, however, during the month of July and early August because some of the workmen were needed for harvesting and because the ground became so hard and dry. No tiling was done later than Oct. 1st. that year. Table I shows a summary of the 1909 tiling operations.

TABLE I.—SUMMARY OF TILING OPERATIONS IN 1909

Total rods, 2,560; total area, 40 acres. Man rate, 15c per hour; horse rate, 10c per hour.

	Total labor			Labor per rod		
	Hours			Hours		
	Man	Horse	Cost	Man	Horse	Cost
Hauling tile	135.5	271	$ 47.42	.053	.106	$0.0186

Totals	.....	...	1,752.11	.....	....	.6844

[1] Man rate varied from 20 to 25 cents per hour. The cost is exact, but hours approximate.

[2] Approximate.

Explanation of Cost Classifications Found in Tables I, II and III.—Of these classifications, figures for machine operator, hauling tile, trenching and laying, laying tile, filling ditches, undivided operations and plotting drains are given in dollars based on the number of hours worked, the cost being obtained by multiplying hours of labor by the rate per hour. Machine charges and other equipment charges include, in addition to labor, cash repairs, interest on investment and depreciation on equipment. The gasoline, oil and cost of tile are straight cash charges and are put in at the actual price paid.

Overhead charges in this work included only the cost of the actual time of the farm manager to lay out and plan the drainage system and to direct the work in the field. The time required to execute this duty varied considerably from day to day. After the system was once outlined and everything working well it did not ordinarily require more than one or two hours a day.

Tiling Operations in 1910.—In 1910 tiling operations were conducted on ten separate fields, covering twelve water sheds. Table II shows that seven of these fields were small, and as several operations were carried on simultaneously in them, it was not practical to keep the cost of each one separately. These contained 21 acres and included 216 rods of water pipe line, sewers and lines for hog barn disposal. The total area drained during the year was 65½ acres and a total of 4080 rods or 12½ miles was installed in that area.

For the work this year a new power tile ditching machine, equipped with a gasoline engine, was purchased early in the spring and nearly all the trenching done during this season was with this machine. One man was required to operate the ditching machine and another man to lay tile, although the tile layer occasionally assisted the machine operator in setting grade stakes,

TABLE II.—SUMMARY OF TILING OPERATIONS IN 1910

Man rate, 15c per hour; horse rate, 10c per hour; machine operator, 20c per hour.

* 12¾ miles.

repairing the machine, etc. The main ditch was first installed and then the laterals were connected to it in a systematic manner. In connecting laterals to the main it was necessary to do some hand digging, because the machine could not be put to the proper grade nearer to the main ditch than 6 or 8 feet, depending, of course, upon the depth of the main. The cost of this necessary hand digging in connecting the laterals with the main ditches has been assembled with other costs in a column called "Undivided operations."

The largest field tiled during the year 1910 contained 29 acres. In it 1591 rods of drains were installed, or an average of 55 rods per acre. During July, August and September the work was much interrupted because of using the men for harvesting and farm work.

This field, which was a heavy blue grass sod, with the exception of about 3 acres of muck swamp which usually was covered with water about half the year, had been used as a pasture for many years. The drains of this field had two outlets; the principle one being a twelve-inch tile leading to an open ditch. The fall of this main for the last 500 feet did not exceed one inch per one hundred feet. In general, however, the topography of the field was quite broken, affording plenty of fall. Indeed there were slopes in which the fall was as much as 8 feet to the hundred.

The second field of importance, which was drained in 1910, was a young orchard which had been set that same spring. There were 10½ acres in this orchard and in it a total of 755 rods of drain were installed, or 72 rods per acre. This greater amount of tile per acre was due to the fact that the trees were set 32 feet apart and that a line of tile was installed between each two rows of trees, whereas in other fields 40 feet apart for laterals was the distance more frequently used. The topography of this orchard field was rolling, but without abrupt breaks. The fall per hundred feet would run about 6 inches, although in a few instances there was a fall of three or four feet to the hundred.

It should be noted in passing that wet weather in April, September and October, interfered quite a little in the operation of the tile ditching machine, due to mud sticking to it.

Tiling Operations in 1911.—During the season of 1911 tiling operations were confined to two fields, Nos. 5 and 31 with the exception of 198 rods in two other fields. In all 4,755 rods of tile were installed in 122½ acres. Table III gives a summary of the work executed this year.

Operations were begun late in March and continued throughout the season until October 31st. The first work was done under very unfavorable conditions. It was the digging of a main ditch which followed the channel of an old open ditch, in which the cut in places was from 4 to 6 feet. The ground was so wet at this time of the year that slipping of the propeller was not infrequent and caving in of the ditch greatly hampered the progress and necessarily increased the cost. In some places the soil where wet was such a waxy clay that it caused considerable trouble by sticking to the machine.

TABLE III.—SUMMARY OF TILING OPERATIONS IN 1911

Overhead charge is 2.3c per rod. Plotting drain charge is 1.58c per rod.

* Not plotted.

Ditching in field No. 5 began in April and continued throughout the summer until August 25th. As shown by the table, the area covered in this field is 54 acres, in which were installed 2,666 rods of tile, making an average of 49 rods per acre. The general topography of this field is rolling. There were two swamps in it; one a cat-tail swamp full of brush and trees and another which covered about 2½ acres. A former owner had attempted to drain this latter swamp a number of years previously, but the attempt was unsuccessful. The soil in these swamps varied from a muck in their center to a heavy, black waxy clay around the outside. In a few places in this field stones were sufficiently numerous to retard the progress considerably but no serious breakage was occasioned.

One of the main ditches in this field is worthy of note. It is 830 feet long with an average depth of cut of about 6.5 feet. The maximum cut was 9.7 feet, which was maintained for a distance of about 300 feet. The machine was operated in this ditch to its maximum depth, which is 4½ feet, and the remainder was dug by hand, using contract labor. The total cost of extra labor on this ditch, after the machine had done its part, was $103.62, or an average of $2.06 per rod. If we add the cost of gasoline, oil and other machine charges, which amount to $10.44, to the other labor charges of $103.62 we have a total cost of $114.06, or $2.27 per rod, which is the installing cost of his main ditch. Approximately 266 cubic yards of earth were excavated in digging this ditch. This would make the cost of excavating 42.9 cents per cubic yard. From the foregoing it will be manifest that outlets are expensive when no natural outlet is available.

Tiling in field No. 31 began at the conclusion of work in field No. 5 and continued until the close of operations on October 31st. The area covered in this field was 65 acres. The field joined field No. 24, which was tiled in 1910. 1,891 rods were installed in it, or about 29 rods per acre. The distance between laterals was greater in this field than in many of the others; varying from 50 to 110 feet, with an average distance of about 90 feet. Fully 35 acres of this field was a swamp, a portion of which had been farmed and nearly all of which had been previously drained. The drains, however, which had been installed from 30 to 35 years previously, had become useless.

Before anything could be done toward draining this field it was necessary to secure a satisfactory outlet. The excavation of this open ditch outlet, which was done by the farm teams and laborers, using slip scrapers, was started in the summer of 1910 and finished in October 1911, the work being prosecuted upon this ditch only at such times as men and teams were not required for farm work. The total length of outlet streams was 1.2 mile, which included about 500 feet of new cuts. When this ditch was finished the bottom of the outlet had been lowered fully 2½ feet. The cost of making this outlet was $558.18 and is not included in summary Table III.

In the ditching of this field a few round stones were encountered in the upland but no trouble or serious delay was experienced. Continued heavy rains during the late fall caused considerable delay, especially in the muck portions. The muck became so full of water that it rushed in from the sides of the ditch so fast that the tile layer had to let the excess run away before he could lay the tile. A few rotted logs, buried beneath the surface in the muck portion of the field, interfered somewhat with the work.

Character and Cost of Tile Used.—The tiles used in all this work were ordinary, medium burned tiles, made from a good quality of clay. All tiles up to a diameter of 10 inches were in foot lengths, but 10-inch and larger sizes were in 2-feet lengths. The breakage of tiles through handling was not large, the maximum amounting to five or six feet per load of 1,000 3-inch tiles. Even with this breakage the over-run amounted to from 3 to 6 per cent, in other words 100 feet of tile paid for at the factory would lay from 103 to 106 feet in the ditch. The larger tiles seemed to have a greater over-run than the smaller ones. The cost of tile per acre for tile drains varies of course in accordance with the size of tile and the number of rods per acre. The average cost of tile per rod in the main fields in Table IV is 24.45 cents, and the cost per acre, with an average of 48 rods, is $11.72.

Cost of Hauling Tile.—Table V furnishes a very good basis for estimating the time required for, and the cost of, hauling tile, especially when taken in conjunction with Table IV. Naturally, the cost of hauling tile would vary with the size of the tile, the length of the haul, and the condition of the roads. Favorable or adverse conditions in connection with any one of these factors may affect the cost materially.

For example, in the case of fields Nos. 29 and 30, in which the haul and weight of tile were practically the same, the roads were so bad when the tile was hauled for field No. 29 that it cost 38 per cent more per rod than it did for field No. 30. Again, in case of field No. 31, for which the haul was much shorter than for No. 29, and for which the roads were in good condition, the expense was much increased by the haul within the field, because it was

necessary to haul much smaller loads, especially through the muck portions of the field. Ordinarily about the same sized loads were hauled on the road and in the field but in the case of field 31 it was necessary to unload a part of the tile and make a second trip through the field.

Had it been possible in all cases to haul tile at no other time than when the roads were good the cost of hauling could have been materially reduced, but in this work it seemed necessary to use the regular farm teams and to try to do the hauling when it was not possible to use the teams at other farm work. This hauling was done with heavy teams, weighing not less than 2,700 pounds, and with wagons having 4-inch tires, thus enabling the handling of heavy loads regardless of the condition of the roads. 100 feet of 12-inch tile or 1,000 feet of 3-inch tile were considered a load on good roads.

The Power Tile Ditching Machine.—The power tile ditching machine, in connection with which these data were obtained was equipped with caterpillar tractor the weight of the machine thus being distributed over a surface of about 24 square feet. This feature enabled the machine to be operated over very wet ground and in many instances to be run through swamps covered with water without having serious trouble from miring.

TABLE VI.—SUMMARY OF HOURS AND COST FOR MACHINE OPERATOR

20c per hour for operator

Uneveness of the ground surface made but little difference in controlling the grade, as the operator had complete control over the machine at all times. In a few instances the depth of cut was changed from 4 feet through a knoll to half that depth within a distance on the surface of about the length of the machine, and in doing this a perfect grade was easily maintained.

The machine was equipped to do work at four different rates of speed, which were used according to depth of digging and stickiness of dirt. A higher speed would dig to a depth of two feet and with very favorable conditions even deeper at practically the same cost. The second speed was used in digging to a depth of 3 feet under ordinary conditions, and in some cases as deep as 3½ feet. The third speed would dig to 4½ feet in depth, which was the limit of the machine. The fourth or slowest speed was not used in connection with this work. Dry ground had no effect upon the machine except to cause the knives to need sharpening more frequently. Soil frozen to a depth of four inches caused but little trouble. Freezing of wet earth to the machine occasionally caused trouble but this was of little consequence. While in some cases, in the early spring or late fall when the ground was soaked full of water and was of a spongy nature, good progress could not be made because of the slipping of the propellers in the soft mud, yet during the greater part of the season the machine could be operated satisfactorily immediately after heavy showers. In most cases the machine was run only one way—from the main up the slope. However, at times when but little water came into the ditch the machine could be operated down the slope just as successfully. Round stones or boulders in the ditch line caused more or less trouble, depending upon the location in the ditch, the size of the stones, etc. Usually boulder the size of a man's head could be removed by the machine with comparative ease, but when larger than this it was necessary to raise the digger wheel and remove them by hand.

Hours and Costs for Machinery Operator.—In Table VI, in which are summarized data regarding the machine operator, it will be noted that the cost per rod varies from 3.57 to 4.21 cents, with an average cost of 3.81 cents.

It should be noted, however, that these prices are figured at 20 cents per hour for operator. This was the price actually paid, but it was lower than that for which an operator could ordinarily be secured, because of the fact that the man used for this purpose was one of the regular farm workmen, who had a natural bent in that direction. Ordinarily the wage of the operator would run from 30 to 40 cents per hour, thus making the cost greater. In order to be able to operate a machine successfully a man should understand the principles of tile drainage, the running of grade lines, etc., and at the same time he should be handy with machinery.

Gasoline, Oil and Grease Costs.—In Table VII is shown a summary of gasoline, oil and grease costs for the entire area trenched with the machine. The average price of gasoline per gallon was 13.3 cents in 1910 and 12 cents in 1911. Cup grease cost 6¾ cents per lb., and oil from 16 cents to 35 cents per gallon. The best grade of gas engine oil was used on the engine but a cheaper oil was used on chains, sprockets, etc. While this factor of the costs may seem somewhat small, yet 3 cents per rod cannot be ignored nor can we ignore the fact that the price of gasoline is advancing constantly.

Tiling Machine Charges.—In Table VIII are summarized the overhead machine charges for the two years within which the machine trenching was done. These charges are classified under four headings, as follows:

1. "Labor repairs" which included cost of labor, usually rendered by the machine operator, in connection with actual repair work on the machine. While of course there are many cases in which a half-hour's time or less was spent by the operator repairing the machine, these have not been separated from the operating charge. All periods of a longer time than one-half hour are charged to "Repairs" and are itemized in this summary.

2. "Cash repairs" includes all repairs for machine, such as bolts, sharpening of knives, batteries for engine, for which cash is paid.

3. "Depreciation" is a variable item, depending upon several influencing factors. In this table it has been figured at 5.1 cents per rod, although at best this charge must be an arbitrary one unless a machine is actually worn out. The number of miles of ditch a machine will dig during its lifetime depends

TABLE VIII.—TILING MACHINE CHARGES. DEPRECIATION, REPAIRS AND INTEREST ON INVESTMENT

			Total costs					
Year	Acres	Rods	Miles tile	Depreciation	Repairs—Labor	Repairs—Cash	Int. on investment	Total
1910........	65.5	4,080	12.75	$208.08	$50.74	$100.00	$81.60	$441.23
1911........	122.5	4,755	14.86	242.50	88.05	365.47	71.15	767.18

	Per rod				
Year	Labor	Cash	Interest	Depreciation	Total av. cost
1910....................	$0.01240	$0.02450	$0.02000	$0.0511	$0.1079

Av. for two yrs.........					$0.1368

upon the depth of digging; condition of soil as regards texture and freedom from stones; care given machine by operator, etc. In determining the arbitrary figure of 5.1 cents per rod it was assumed that the machine would be capable of digging 100 miles of trench within its lifetime. Some machines have dug over 200 miles of ditch. It will be noted, however, that even on the 200-mile basis the cost of depreciation per rod would be 2.55 cents and that the total machine charge would only be lowered from 13.68 cents to 11.13 cents, thus making this, comparatively speaking, a minor point. Depreciation is figured on an initial cost of the machine amounting to $1,632. This price, of course, may vary from time to time. If no larger tile than 8-inch were to be installed it would probably be cheaper to buy a smaller machine unless the ground to be trenched is somewhat stony. In this connection it is interesting to note that the repair charge, especially cash repairs, for the second year was almost three times as much per rod as it was the first year.

4. "Interest on investment," which was figured at 5 per cent, decreases from year to year, as the initial price is cut down by the amount which is charged off annually for depreciation.

Machine Trenching Compared with Hand Trenching.—In Table IX is shown a comparison between the costs of hand and machine trenching, so far as it is able to make such a comparison from the work done on this farm. It will be noted that the cost per rod of machine trenching varies from 30.5 cents to 39.8 cents, whereas the hand trenching cost is 44.9 cents. It should be noted, however, that in these averages, there are more than four times as many rods of machine trenching as of hand trenching. While the cost of machine trenching would, in most cases, be increased somewhat by a higher rate per hour for the machine operator, and probably would be increased by the cash repair charges, yet even with these increases it probably never would overcome the difference between machine and hand trenching, which, as shown by Table IX, is 7.4 cents.

While there may be conditions in the very early spring when the ground is thoroughly water-soaked which make the ditching machine not very satisfactory because of its slipping and of mud sticking to it, yet this is fully offset by the fact that it digs readily in dry weather even though the ground may be so hard that it is almost impossible to trench with a spade. It is very much easier to maintain a uniform grade when ditching with a machine than doing the work by hand. In the trenching which was done by hand in 1909 almost all of the ditches were tested with water before tile was laid. This is, of course, somewhat expensive, especially if the water is not near at hand. A

TABLE IX.—COMPARISON BETWEEN HAND AND MACHINE TRENCHING

Field	Acres	Rods	Total cost except tile and hauling	Per rod machine	Per rod hand

fall of from four to six inches per hundred feet in the ditch line would, however, remove the necessity of testing with water.

One other point in favor of the ditching machine is the speed that can be made with it. By a comparison of Tables I, VI and X, it will be noted that the machine operators use less than one-sixth as much labor per rod in trenching and laying tile as is spent when the work is done by hand. Considering the scarcity of labor and the advancing wages that farmers are being forced to pay, it is evident that even though machine trenching were to cost more than hand trenching they probably would be forced to make use of the machine.

Cost and Time Required to Lay Tile.—In Table X is summarized the cost of laying or installing 7,203 rods of tile upon 163½ acres. This includes placing the tile in the ditch and putting on just enough earth to hold it in place. For various reasons the tile layer is required to excavate by hand occasional short ditches, as for example, in finishing a ditch where the machine could not approach a fence as close as was necessary. In field No. 30 the larger "Tile laying cost" of 7.65 cents per rod is due to hand work of this character, which was not separated from the laying of the tile. From this summary table it will be noted that the cost varied from a minimum of 5.46 cents to a maximum of 7.65, and that the average is 6.75 cents per rod. It will also be observed that one man installed on the average almost 45 rods of tile per day.

TABLE X.—SHOWING HOURS AND COSTS FOR LAYING TILE

Wages, 30c per hour

Owing to the very great importance of having the tile laid properly it is usually deemed advisable to secure for this purpose the services of an efficient man who makes tiling his business. The services of such a man are always in demand and consequently a higher price per hour must be paid to secure him.

In Table XI is summarized the cost of filling the ditches for 7,203 rods of tile installed in 163½ acres. From this table it will be noted that the cost per rod of filling ditches varies from 1.72 cent to 4.4 cents and that the average is

3.43 cents. It will also be noted that two men with a team can on the average fill 140 rods of ditch per day.

TABLE XI.—HOURS AND COSTS FOR FILLING DITCHES

Man rate, 15c per hour; horse rate, 10c per hour

Averages						.1408	.1317	.0343

The cost of filling ditches varies with the condition of the soil and the depth of the cut. It was found advisable to fill the ditches soon after trenching, because they could then be filled about one-fourth faster than if allowed to remain open during a heavy rain storm. The rain packed the soil and made filling much more difficult for both men and team.

A heavy team was used with a specially prepared scraper about 4 feet long, which consisted of a straight board with a steel cutting edge and had a hitch so constructed that when the team pulled taut at right angles to the ditch and the operator bore down on the handles the scraper would move into the ditch all the dirt thrown out on one side of it. It was, of course, necessary to back up the team and move the scraper longitudinally along the ditch for each scraper full. This method was found to be more satisfactory than the use of a plow or a large township road scraper.

Plotting Drains.—The maps or plots of the several drainage systems were made by county surveyors after the system was installed. The charge for this operation includes the engineer's time, expenses in the field and in plotting and blue printing. It was not deemed necessary or advisable to make a plot of a system before installing, but after installing it was thought wise to have such a map for the purpose of affording a ready reference for the location of drains in case of trouble with the system.

* Includes trenching.

In Table XII is given a summary of the preceding tables as regards all tiling operations except hauling, which, in accordance with Table IV, may be figured at about 4c per rod. The cost of tile will vary with size of tile used and other factors, but Table IV will assist in making an estimate of such cost in the absence of figures from the factory. From the foregoing pages it will be manifest that had the trenching for all the 11,395 rods of tile been done by machine the total cost of tile and installation would have been about two-thirds of a dollar per rod, and that with the fifty rods per acre used on this farm, three acres would have cost about one hundred dollars.

Costs of Laying 20 Miles of Tile Drains.—S. C. Hartman gives the following in "The Monthly Bulletin" of the Ohio Agricultural Experiment Station for May–June, 1921.

Twenty miles of tile have been laid on the Washington County experiment farm. Because different systems are used in the work the 20 miles or 6,400.7 rods were divided into five sections. Section I was installed in 1915 and consisted of 955.6 rods; the trenches were dug by hand. The cost of the work is taken from the records of E. J. Riggs, who was then superintendent of the farm. Other sections were dug with the Station traction ditcher during the spring and summer of 1919.

Section II was started on May 17 and consisted of 1,984.8 rods. Section III consisted of 1,202.5 rods and was begun on July 15. Section IV was dug on the farm of H. J. Tresch and consisted of 1,399.6 rods. This work was done under the direction of Mr. Tresch and serves as a check for the work done on the Washington County experiment farm. Section V was installed on the experiment farm after August 8; it consisted of 858.2 rods.

Character of Soil Trenched.—The soil is underlaid with shale and sandstone from which it was largely formed. The soil varies from a comparatively light clay, commonly known as a mixed soil to a heavy red or Upshur clay. There are no boulders but the underlying rock interfered with the work in several places. While the soil has a slight tendency to run together it does not dry out as some of the other soils of the State. The ditcher, therefore, made good progress even in a dry season.

Because of good fall and convenient outlets but a few large tile were required. Two-thirds of the tile were 4-inch. Those laid on the experiment farm in 1919 held out to the number purchased with 15½ feet of tile laid to a rod. A few Y-tile were used for making connections at branches. Sewer pipes were used for the outlets because they are longer than drain tile, are burned harder and are more easily held in place.

Cost of Labor.—The labor available varied with the different sections. The work of digging the trench in Section I was in charge of an experienced ditcher. Practically one-third of the hours of labor were performed by him at 30 cents an hour. The remainder of labor performed for Section I was paid 20 cents per hour. The labor of 1919 was figured at 32 cents per hour. For comparison, the unskilled labor of 1915 is figured at 32 cents also, and the skilled ditcher at 48 cents per hour. The labor employed in 1919 in addition to the farm force was such as one was able to employ, for the second and third sections, at one of the busiest seasons of the year. Because of the scarcity of help it was necessary at times to employ more help than could be used at an advantage that sufficient help might be available when needed. For the fourth and fifth sections which were completed after harvest more help was available.

The trench for practically all the tile was dug 30 inches deep. The large main tile were laid in a deeper trench. Over most of the area drained the tile lines were laid 2 rods apart. Some lines were laid 3 rods apart. Those laid in 1915 were 36 feet apart. About 70 acres were drained by the 5,000 rods on the experiment farm and 20 acres by the 1,400 rods on the Tresch farm.

Various Operations in Drainage.—The various operations in connection with installing the drainage system are conveniently considered as four operations; namely, digging the trench, hauling the tile, laying the tile and back filling.

Digging the trench includes setting the stakes, and a small amount of time at laying off the tile lines. Only where the fall was doubtful or on a deep cut was a level used.

Hauling the tile includes the actual operation of hauling and also laying the tile carefully along the trench so that they could be easily reached by the person in the trench.

Laying the tile followed the ditcher as closely as possible and includes the various operations between the digging and the filling of the trench after the tile are laid; helping the operator of the ditcher by setting stakes, cleaning out the crumbs in the trench, digging for connections where the branches unite with the main tile lines and other places where digging is necessary; the actual operation of laying the tile and binding them or covering them with enough dirt to hold them in place until the trench can be filled. There is always some filling to be done by hand. With hand trench-digging, trenching and laying the tile could not be conveniently separated. In filling the trench the dirt was backed into the trench when possible. The dirt was also rigged over the trench. In some places it was necessary to finish the work by hand. Some time was also spent in refilling the trenches before the work was completed. Such work was included in "filling the trenches." With a considerable amount of fall in some of the tile lines and because of the nature of the soil some of the trenches washed deeply after being filled. In other places it was necessary to again refill before the cropping work could be continued in the field. Such work was not included in "filling the trenches" but charged to drainage maintenance. Other operations in some sections were considered as miscellaneous, such as hauling water and gasoline for the ditcher, measuring and laying off the lines, repair work and other work not closely connected with other operations. These items form a very small part of the work totaling less than 1 cent per rod at the most. In two sections these items were included as most convenient with other operations.

Trenching.—Section I, where the trenching which was done by hand required an average of 1.6 hours for each rod of tile. It was not possible to separate the time spent at digging from that of laying his section. The time and cost therefore of laying the tile in Section I is not easily comparable to laying the tile after the machine trenching in the other sections. In both the second and third sections considerable hand digging was necessary because of the interference of the underlying rock and because of a gas line which crossed many of the tile lines. The distance dug is estimated and the required time determined as accurately as possible. It is a significant fact that the hand digging in Section II required more than twice as much time per rod as that of Section I. Ditching with the power ditcher is often done when conditions are not favorable for hand ditching which therefore must be done at a greater cost than would ordinarily be necessary. The cost of laying the tile after the machine trenching varied but averaged 4.6 cents per rod. The highest cost, that of 5.5 cents in Section IV, was due to the fact that it incluces some miscellaneous work.

Allowing 30 cents per rod for the ditching machine, hand trenching and laying cost from 170 to 180 per cent of the cost of machine trenching and laying, or one and three-fourths times as much, a considerable saving for machine trenching. With hand trenching, an average of 1.6 hours of labor were spent on each rod, with machine trenching .14 of an hour, exclusive of the machine operator. Hand trenching and laying, therefore, required eleven times as many hours of labor per rod as machine trenching.

TABLE XIII.—LABOR AND COST OF DISTRIBUTING TILE

Section number	Tile, rods	Man labor, hours	Horse labor, hours	Man labor per rod, hours	Horse labor per rod, hours	Cost per rod cents
I	955.6	90	60	.094	.062	.04
II	1,984.8	225¼	381¼	.113	.192	.065
III	1,202.5	130	194	.108	.161	.059
IV	1,399.6	140	180	.100	.129	.053
V	858.2	67¾	86	.079	.10	.04
Average	....	.....	.....	.102	.141	.054

Man hours at 32 cents per hour; horse hours, 15 cents.

Hauling the Tile.—A variable factor in the cost of a drainage system is the cost of hauling the tile. The cost varies with the distance and the condition of the roads. Since in this case the tile were delivered to the corner of the experiment farm the cost of hauling to the farm is not considered. Table XIII shows the labor required and cost of distributing the tile from the pile on the farm to the various tile lines as required. The larger factor in the cost of distributing the tile, exclusive of the efficiency of the labor, is the distance necessary to haul the tile. Part of the tile in Section II were hauled directly from the car to the field. The distance was greater and the cost more. The greatest distance necessary to haul the tile in distributing them was less than three-fourths of a mile and the average nearly one-fourth of a mile. The cost varied from 4 cents per rod in Sections I and V to 6.5 cents in Section II. The economy of delivering the tile to as near the place where they will be used as possible is apparent. It is evident from the number of man and horse hours that two men usually worked at hauling with each team. This proved to be the most economical, especially where the hauling distance was not great.

TABLE XIV.—TIME AND LABOR COST OF LAYING TILE

Section number	Rods	Digging and laying by hand Time, hours	Digging and laying by hand Cost, dollars	Laying only Time, hours	Laying only Cost, dollars	Per rod Time, hours	Per rod Cost, dollars

Average for machine dug trenches						.123	.039

* Estimated distance dug by hand, other than that usually required.
† The time required does not include laying the tile but merely the digging.

Laying the Tile.—The most particular work of installing the drainage system is that of actually laying the tile in the trench. Anyone with a little experience can do a good job if they will take care with the work. Unless such a one is available an experienced tiler should be employed. If the tile are not properly laid the expense of tiling is a poor investment. The actual operation of laying the tile in the trench required but little time. The various operations which were for convenience considered with laying the tile required considerable time. Table XIV gives the time and labor cost of laying the tile for each section.

Costs of Laying Tile Drain on Two Jobs.—H. R. Ferris, in Engineering and Contracting, Sept. 13, 1916, gives the following costs of laying 300 ft. of drains of the design and cross-section shown by Fig. 2 (1), all excavation in sandy loam surcharged with water (not quicksand). The ditch required close timbering in certain places. The actual excavation was about 3½ ft. only, as a slight fill covered the top. The work was designed to be permanent, and has been in continual and satisfactory use for over three years. The costs follow:

		Per lin. ft.
Labor:		
Foreman, 5 days @ $ 3.00	$ 15.00	$0.050
Labor, 174 hrs. @ $0.30	52.20	.174
Materials:		
Lumber (2 × 12 cedar), 600 ft. B. M. @ $18.00	10.80	.036
Gravel 25 cu. yd. @ $ 1.50	37.50	.125
Timber (bracing), 800 ft. B. M. @ $12.00	9.60	.032
Tile (4-in. farm), 900 lin. ft. @ $0.03	27.00	.090
	$152.10	$0.507

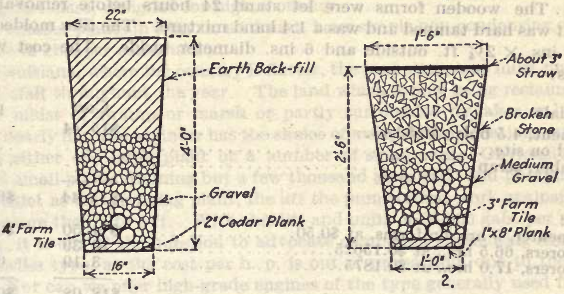

FIG. 2.—Sections of tile drains.

It was not practicable to separate the cost of laying planks, tile, etc. The labor (174 hr.) represents the total time on this work, with the exception of earth backfill, which was done several days later with team and scraper. The prices for materials include delivery along the work. Fig. 2 (2) shows the type of drain construction for the second job, covering 1,900 ft. of drain The costs were as follows:

		Cost. per ft.
Labor:		
Foreman, 98 hrs. @ 40c	$ 36.80	$0.019
Labor, 700 hrs. @ 30c	210.00	.115
Team, 12 hrs. @ 65c	7.80	.004
	$254.60	0.138

Materials:		Cost per ft.
Rough planks (1 × 8), 1,900 lin. ft. @ $8.00	$ 15.20	.008
Gravel, 160 cu. yd. @ $1.00	160.00	.084
Straw, 11 bales	6.60	.003
Tile (3-in. form), 3,800 lin. ft. @ 0.03	114.00	.060
	$295.80	0.155

The prices for materials cover cost delivered along the line of the work. Cost of removing surplus earth is not included. Excavation was in stiff clay, and the work was performed in wet weather. Good foreman and average crew. The costs of excavation, backfilling with gravel, etc., were not separated.

Broken stone (30 cu. yd.) used in the drain was taken from a nearby sewer trench, which had been excavated in rock. This was delivered conveniently along the line of the trench, and the cost of delivery is not included in the above, but the cost, however, of the handling in the trench is included In all about 190 cu. yd. of gravel and rock were used over the tiles.

Making Cement Drain Tile by Hand on an Isolated Job.—R. C. Hardman, in Engineering and Contracting, May 29, 1912, gives the following costs for making 297 lin. ft. of cement drain tile by hand using unskilled Mexican labor.

Two sets of wooden forms were built, each having molds for six sections of tile; these formed the outside. For the core mold, or inside form, a galvanized iron cylinder was used. This cylinder was centered inside the wooden mold and pulled as soon as the cement was placed, to be inserted in another wooden mold. The wooden forms were let stand 24 hours before removal. All cement was hard tamped and was a 1:4 hand mixture. The tiles molded were 8 × 8 ins. × 2¼ ft. outside and 6 ins. diameter inside. The cost was as follows:

Materials:	Cost	Cost per ft.
Cement, 4.5 bbls., at $3.43	$15.44	....
Sand on site	......	....
Lumber, scrap	......	....
	$15.44	$0.0519
Labor:		
Carpenter, 9 hrs. on forms, at $0.50	$ 4.50	$0.0152
Laborers, 66.5 hrs., at $0.15625	10.39	....
Laborers, 17.0 hrs., at $0.1875	3.19	0.0457
	$18.08	$0.0609
Total	$33.52	$0.1128

Centrifugal Pumping Plants for Drainage with Diagram of Plant Costs.—In a paper before the Louisiana Engineering Society, and published in the Journal of the Association of Engineering Societies, H. L. Hutson discusses a type of drainage pumping plant which his experience leads him to believe is preferable to others for conditions as found in Louisiana. The following abstract of Mr. Hutson's paper, is given in Engineering and Contracting, July 3, 1912.

The plant which I should like to see become standard for drainage work in Louisiana would be one of large capacity consisting of two or more large centrifugal pumps, each direct connected to compound condensing engines of the Corliss or 4-valve type; the steam being furnished by water tube boilers using oil fuel. Such a plant, if the units were of 50,000 to 100,000 gals. per minute capacity, would be ideal from the mechanical engineer's standpoint, as the units would be sufficiently large to get good economy, the engines would run at such speed and be of such horse-power that the very lowest prices could be obtained, and the plant would be large enough to employ skilled labor to operate. I realize that this means the use of one plant for a large acreage, say 10,000 to 100,000 acres, and that this in turn means long canals and a high lift, but I will try to show that the cost of operation, even the cost of fuel, will be less per 1,000,000 gals. gotten rid of by the large plant than the small. I am giving only the point of view of the mechanical engineer. There may be conditions known to the civil engineer or to the farmer which would make the use of large plants out of the question in this territory.

The drainage work which I am familiar with is that in Illinois and Iowa and that in Louisiana. The conditions are somewhat different, and these differences are partly responsible for the variations in engineering practice. In Illinois and Iowa the drainage districts lie along the river bottoms and consist of land which have limited natural drainage when the rivers are low but which are subject to overflow. In the formation of levee and drainage districts, the natural boundaries are usually followed so that each district will have a single outlet with a pumping plant to take care of the rainfall during such time as the river is high enough to prevent gravity drainage. The Bay Island Drainage and Levee District No. 1, a district in Mercer County, Illinois, is typical of the larger plants. It has an area of 20,000 acres and takes the run-off of a smaller district of 4,000 acres additional. This plant was designed for a capacity of 200,000 gals. per minute against a lift varying from 0 to 12½ ft., and consisted of two 60-in. units, all the equipment being of the highest class, designed for high economy.

The smaller plants in Illinois, no doubt, have simple non-condensing engines and are of cheaper construction.

In Louisiana, where the country is flatter, the pumping plant must pump off the rainfall throughout the year. The land which is now being reclaimed lies in the midst of swamp or marsh or partly surrounded by lakes or bayous. Being nearly flat, the engineer has the choice of many outfall locations and may install either one large plant or a number of small ones. Obviously, with several small plants draining but a few thousand acres each and pumping to a free outlet at the pumping plant, the lift the pumps must work against is low —not more than 3 to 6 ft. With this lift and units of 36,000 gals. per minute or less, it is out of the question to advocate compound condensing engines of the Corliss type, as the cost per h. p. is out of proportion, due to the small size. Nor can we offer high-grade engines of the type generally used for this horse-power in electric work because the rotative speed of these large pumps is much below that of a generator requiring equal horsepower. No doubt the majority of engineers would consider that a low lift is very desirable and that it means getting rid of the water at a low cost of fuel. As a matter of fact, the fuel for pumping off a million gallons will be less with an economical plant pumping against a 9-ft. lift than with a simple non-condensing plant such as is usually installed pumping against 3-ft. lift. The extra 6 ft. of fall would undoubtedly be sufficient to increase the area which could be drained by from three to nine times the size of that served by the small pump.

The saving in the matter of labor of a large plant over a number of small ones is obvious. The larger plant would require a higher class of help, but this is an advantage as the higher class man is more reliable than the cheaper help. The cost of the machinery for such a plant would be greater than that of several small plants with cheap equipment, but the cost of the complete plant erected would undoubtedly be less for the large than for a number of small plants. There would be many advantages with the large plant and better machinery. If compound engines were used, they would be made to carry great overload if necessary by using live steam in the receiver. If they were cross compound and an accident put one side out of commission, it would still be possible to run; and as the pump is little subject to accident, this feature would practically give a reserve unit.

I have advocated water tube boilers and oil fuel as these features would permit steam to be raised quickly and one fireman could operate a boiler plant of any size required. If the boilers are of the sectional water tube type similar to those used in naval work, steam may be raised in 30 minutes without danger to the boiler. With automatic oil-fuel pumps, one man could, if necessary, operate a plant in an emergency. In fact, there is one irrigation plant of which I know which is operated by one man who attends the boiler and engine. It is a compound condensing engine of 225 h. p.

Cost of Plants.—The question as to the approximate cost of a plant of a certain capacity and lift is often asked by engineers and others who are making preliminary estimates. In fact, this is the first question which the prospective customer is likely to ask. Although we have several rough rules for figuring these costs, none of them is satisfactory as applying to both drainage and irrigation plants. It has been the custom in making rough estimates of pumping plants designed for lifts of from 25 to 40 ft. to figure them at $80 to $100 per water horse-power, but one will readily see that the same figure will not apply to a drainage plant of like capacity pumping against a head of 3 ft., as the cost of the pumps, suction and discharge pipes, etc., would be very nearly the same for the low-lift plant as for the high-lift, whereas the horse-power would be so small as to put the plant in a different class altogether from the one with the higher lift. In order to be able to give approximate figures I endeavored to tabulate the various bids which the concern I am connected with has made on pumping plants within the last ten years, and found that a tabulation, or even a curve, of these bidding prices would be of little value, as in some cases we bid including the building, foundations and even intake work, whereas in others our price was merely for machinery f. o. b. cars, or again for machinery erected on foundations built by the purchaser. To make a comparison, therefore, I decided to take the cost of all the mechanical equipment necessary for the plant, and using our costs sheets as a guide make up curves which would represent these plants erected ready for operation at some point in Louisiana or Texas; in other words, I have assumed, what is very far from the fact, that the cost of freight, barging, foundations, erecting, etc., is a constant percentage. This is done because it is not the intention that this diagram of costs shall be used for obtaining actual costs of plants but that it shall be relative only and be used for the purpose of deciding the most economical size of units to use in a large plant and also for making approximate estimates on the assumption that a plant of two or more units will be a multiple of the cost of a single unit plant. In this diagram, I have not included the building, as the cost of this would depend upon the style of architecture, nor have I included any dredging, intake work, flume or canal work. I did include the building foundation, as it is usually necessary to place a pumping plant in a pit, in which case the pit walls form the building foundation, and the pump foundation, engine-room floor and walls are made monolithic.

For the reasons above given, it will be impossible to make smooth curves using either the water horse-power or the gallons per minute as one of the coordinates. It seems more logical, therefore, and gives data which are much more useful, to divide the plant into two parts, and consider it merely

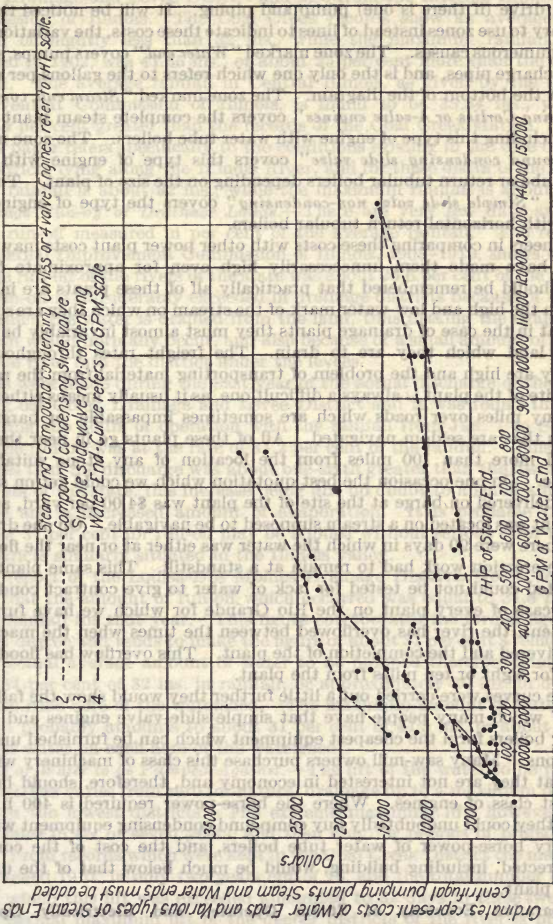

FIG. 3.—Diagram of relative costs of drainage pumping plants.

as a steam-power plant, which drives a pumping plant. I have, therefore, divided the cost into two parts: cost of the "steam end" and cost of the "water end," but showed these on the same sheet. In using this diagram it is very important that this fact should be borne in mind and that the cost of the "water end" should be added to that of the "steam end." The cost of the "water end" is given in terms of gallons per minute at the rated capacity. The cost of the "steam end" is given in terms of indicated horse-power and it is, therefore, necessary to figure this horse-power by assuming the combined efficiency of the engine, drive (if there is one) pump and piping. It will be noticed that it is necessary to use zones instead of lines to indicate these costs, the variation being due to numerous causes. The zone marked "*Water end*" covers pumps, suction and discharge pipes, and is the only one which refers to the gallons per minute scale at the bottom of the diagram. The zone marked "*Steam end, compound condensing Corliss or 4-valve engines*" covers the complete steam plant equipment including this type of engine with water tube boilers. The zone marked "*Compound condensing slide valve*" covers this type of engine with either water tube or return tubular boilers depending on the size of plant. The zone marked "*Simple slide valve non-condensing*" covers the type of engine indicated with horizontal return tubular boilers.

Engineers in comparing these costs with other power plant costs may decide that I have made them unnecessarily high even for approximate figures, but it should be remembered that practically all of these plants are installed between the high and low-water mark of the stream on which they are situated and that in the case of drainage plants they must almost invariably be put in on the land which they are to drain. The freight rates throughout this territory are high and the problem of transporting material from the railroad to the site of the plant is always a difficult one, as it usually means either hauling many miles over roads which are sometimes impassable, or barging on streams that are seldom navigated. All of these plants go in near the coast on land more than 100 miles from the location of any stone suitable for concrete. On one occasion the best quotation which we could get on sand or gravel delivered on barge at the site of the plant was $4.00 per yard, and yet this plant was located on a stream supposed to be navigable. On one drainage plant there were 90 days in which the water was either at or near the floor line and the erection work had to remain at a standstill. This same plant when completed could not be tested for lack of water to give contract conditions. In the case of every plant on the Rio Grande for which we have furnished equipment, the river has overflowed between the times when the machinery was delivered and the completion of the plant. This overflow has flooded the valley for eight or ten miles from the plant.

If the curves were carried out a little further they would show the fallacy of a belief which many people have that simple slide-valve engines and return tubular boilers form the cheapest equipment which can be furnished under all conditions. Many saw-mill owners purchase this class of machinery with the idea that they are not interested in economy and, therefore, should buy the cheapest class of engines. Where the horse-power required is 400 h. p. or above, they could undoubtedly buy compound condensing equipment with the necessary horse-power of water tube boilers, and the cost of the complete plant erected, including building, would be much below that of the uneconomical plant.

Comparative Economy of Steam Operated and Electrically Operated Pumping Plants for Drainage.—An argument for the use of electric power for operating drainage pumping plants is contained in a paper read before the fourth meeting in Jan., 1912, of the Association of Drainage and Levee Districts of Illinois. The following matter is from an abstract of the paper as published in Engineering and Contracting, Oct. 1, 1913.

Amount of Water to be Pumped.—The average rainfall for the lands comprising the districts in the Illinois River may be closely estimated from the records which have been kept since 1899 by the Commissioners of the Coal Creek Drainage and Levee District and also from the Internal Improvement Commission of Illinois. The Coal Creek records show an average yearly rainfall of slightly less than 32 ins., while the maximum rainfall, which occurred in 1902, was 41.55 ins., or about 25 per cent more than the average rainfall. The average rainfall in Central Illinois, as given by the Internal Improvement Commission of Illinois, is found to be 35.34 ins., which is about 9 per cent greater than the records of the Coal Creek station.

This paper refers specifically to the conditions existing in the case of drainage districts lying along the Illinois River, and for these districts the average yearly rainfall is about 32 ins., while the maximum rainfall is about 40 ins.

Average Run-off of Drainage Lands.—There are very few data as to the actual run-off measured in per cent of the average rainfall. The report of the Internal Improvement Commission of Illinois, 1908–1910, shows that the average run-off of the rivers of the state was about 26.6 per cent of the rainfall. This run-off is considerably exceeded in drainage districts because of the ease with which the water is drained from the land, thus making the evaporation less than would normally occur, and also because of a small amount of seepage from the river into the district under the levees.

Tests were made during the past year of the actual discharge of the pumps in the Coal Creek Drainage and Levee District and it was found that after comparing the hours of operation with the rainfall from Jan. 1 to Sept. 25, 1911, the run-off was at the rate of 31.2 per cent of the rainfall. This run-off indicates that the discharge was about one-sixth greater than the discharge of the rivers of the state, this increase being due no doubt to a small amount of seepage and a decreased amount of evaporation. It is probable that the figure of 31 per cent for run-off may be applied without serious error to all of the districts similarly situated in the Illinois valley.

The report of the Louisa-Des Moines Drainage District, No. 4, for 1911, shows that the amount of run-off which occurred was equal to 31.8 per cent of the rainfall for that year. This figure corroborates the former figure to a marked degree and tends to make the figure of about 31 per cent a reliable one.

The actual average amount of water to be pumped therefore amounts to about 31 per cent of 32 ins. in rainfall, or approximately 10 ins. in depth of water on each acre of the watershed. The maximum amount of water to be pumped probably amounts to about 31 per cent of 41.5 ins. or about 13 ins. depth of water on each acre of the watershed.

Head of Water to be Pumped Against.—The lift of the water to be pumped from districts varies from zero for natural drainage up to a maximum of about 21 ft. in the lowest districts. The extreme maximum lift, however, only occurs once in six or seven years, and then only for periods of probably ten days. From records which were kept in the Coal Creek District the maximum lift exceeded 19 ft. in only two years out of 13, and the total number of days during which this lift was exceeded amounted to 31 days in these two years.

The normal maximum lift of the deeper districts of the river is probably about 18 ft. for those districts which never have natural drainage. Many districts are able to drain their land during time of low water simply by opening sluiceways. In these districts the normal maximum lift is about 13 to 14 ft. The average lift through which water has to be pumped varies from 6 to 11 ft.

Maximum Pumping Capacity Required.—S. W. Woodward, in the United States Department of Agriculture bulletin, "Land Drainage by Means of Pumps," concludes after a very thorough examination of this question, that the maximum capacity should be sufficient to remove ¼ in. of rainfall in 24 hours of continuous operation. Pumping plants which have had this capacity have been able to drain successfully their districts in the worst storm conditions, and it would seem therefore that a larger capacity than this only entails useless investment.

Since the maximum lift occurring in any district only occurs once in about six years, and then only for a short period it is not necessary to provide this capacity of ¼-in. per day at the maximum lift. In general, the maximum power required should be that necessary to remove ¼-in. of water in 24 hours against a lift of about 3 ft. less than the highest recorded lift. In other words, if the highest recorded lift be 21 ft. a pumping capacity of ¼-in. per 24 hours against a lift of 18 ft. will be sufficient.

To the lift mentioned above must be added the loss of head due to friction of the water in the suction and discharge pipes and the velocity head.

Types of Steam Pumping Stations.—Most of the pumping stations now used to drain districts are steam driven and the majority of these stations comprise an installation of fire tube boilers, Corliss or four-valve engines either belt-driven or direct connected to centrifugal pumps. The usual arrangement is to have two pumps to a station, the relative capacities of which may usually be one-third and two-thirds, respectively, of the total capacity. The object of having a dissimilarity of sizes is due to operating conditions which require heavy pumping for only about three months of the year. During the other nine months the amount of water to be pumped is far below the capacity necessary for the maximum requirements, and the smaller unit is generally intended to handle the minimum flow of water as economically as possible.

From 60 to 75 per cent of the total work done in pumping the water is ordinarily done from March 15 to June 15, while the remaining 25 or 40 per cent is about evenly distributed over the other nine months of the year. This condition is detrimental to the economy of a steam plant because during a period of about nine months the amount of pumping to be done is far below the capacity of the plant.

Fixed charges are a very appreciable part of the total cost of pumping. For the conditions existing on the Illinois River the item of interest should be taken at 6 per cent, taxes and insurance at 1 per cent and depreciation at 10 per cent, giving a total of 17 per cent fixed charges per year on the original investment. The fixed charges provide for the financing of the pumping plant as a permanent institution so that a sinking fund may be established which will provide money for renewals and rebuilding from time to time so as to maintain the plant continuously in working order. When the fixed charges have been properly taken into account after an adequate pumping station has been built it is never necessary to levy additional assessments from time to time to provide for rebuilding the plant.

The operating expenses, of which the principal items are coal, labor, supplies and repairs, provide merely for the daily operation of the plant, and these operating expenses are in no sense the total cost of operation, as has often been assumed when the cost of pumping is discussed. The actual cost of operating the steam pumping stations of several drainage districts, based on the acreage in the district, is given in Table XV.

TABLE XV.—COST OF STEAM PUMPING

Name of district	H. P. in engines installed	Initial cost of pumping plant	Annual fixed charges	Annual operating expenses	No. of acres in watershed	No. of acres in district	Operating expenses per acre per year	Total cost per acre per year	Operating ratio, per cent
A..........	100	$ 7,000	$1,190	$2,200	2,160	2,160	$1.02	$1.57	65
B..........	275	30,000	5,100	8,412	11,000	11,000	.765	1.23	62
C..........	500	50,000	8,500	5,966	16,000	13,000	.459	1.11	41
D..........	250	25,000	4,250	5,400	7,420	6,800	.795	1.42	56
E..........	325	35,000	5,950	4,700	7,420	6,800	.690	1.57	44
Totals..........							$3.74	$6.90	268
Average..........							$0.748	$1.38	53.6

The average cost of drainage by well designed steam stations draining districts of about 10,000 acres is about $1.25 per acre per year, of which the operating expenses will be about 60 cts. at the present prices of coal and labor.

Types of Electric Pumping Stations.—The types of electric pumping stations now in use in the Illinois River include standard centrifugal pumps belt-driven by constant speed induction motors and the transformers and other electrical equipment necessary for the operation of the motors. The pumping capacity of these plants should preferably be divided into three units instead of two, as is the usual design in a steam plant.

One of the great advantages of the electric pumping station over a steam station is that the pumping units may be properly sized for the work that they have to perform. One of these pumps should be small enough so that it may run for long periods and merely take care of the minimum flow of water. This small unit permits the level of the water in the ditches to be kept practically constant and this water may be pumped out each day without additional expense over letting the water accumulate and pumping it down at a high rate, as is done in steam plants.

The average initial cost of the steam stations given in Table XV is $3.71 per acre. The cost of electric stations for this same work would vary from $2.22 to $2.41 per acre.

The fixed charges of an electric plant are less than the fixed charges of a steam plant and they have been taken as follows: Interest at 6 per cent; taxes and insurance at 1 per cent, depreciation at 6 per cent, giving a total of 13 per cent fixed charges per year on the investment in an electric station. Taking the higher figure of $2.41 per acre as the cost of electric stations, the fixed charges per acre per year amount to 13 per cent of $2.41, or 31 cts. per acre per year.

The total average cost of drainage by steam pumps in Table XV is $1.38 per acre per year, based on the acreage in the district. Subtracting from this figure the 31 cts. fixed charges on an electric station shows that $1.07 per acre per year can be paid for operating expenses including electrical energy, without incurring a higher total cost than the average cost of steam pumping.

Taking the total cost of pumping by well-designed steam stations as $1.25 per acre per year, we find by the same method that the sum of 94 cts. per acre per year may be expended for operating expenses in an electric station before the total cost exceeds the cost of steam pumping.

Following the same process with the minimum attainable cost of $1.10 per acre per year, it is found that 79 cts. per acre per year may be expended on operating expenses without these expenses exceeding the cost of steam pumping.

The items of labor and supplies in an electric plant will not exceed 16 per cent of the total operating expenses. Reducing this figure to terms of the energy required, it is seen that if we combine the energy required with the labor and supplies on this basis an equivalent amount of energy equal to 24 kilowatt hours per acre per year would be required.

On this basis the average steam station given in Table XV could be substituted by an electric station and a rate of $1.07 divided by 24 kilowatt hours, or 4.97 cts. per K W. H., could be paid without the total cost of pumping exceeding the cost given in Table XV.

In the case of the total average cost for well-designed steam stations or $1.25 per acre per year, a district could afford to pay 3.92 cts. per K. W. H. without the total expense exceeding $1.25 per acre per year.

In the case of the minimum attainable cost of $1.10 per acre per year a district can afford to pay 3.29 cts. per K. W. H. before the total cost of operation exceeds $1.10 per acre per year.

All the evidence shows that if a supply of electrical energy can be bought for 4 cents per K. W. H., that the total cost of pumping by electricity does not exceed the total cost of pumping by steam in well-designed steam stations. If a district is able to obtain a lower rate than 4 cts. per K. W. H. for energy they are able to save money over the cost of operating steam stations.

If energy cannot be bought for less than 4 cts. per K. W. H., the question as to how high a rate it is permissible to pay depends on the relative value of electric pumping compared with steam, as measured by the results obtained instead of the money expended. When considering this question from the broadest view, a drainage district is formed for the purpose of raising agricultural products and not for pumping. It therefore follows that the method of pumping should be that which secures the best results, provided the expenses be not too great.

The districts having electric pumping stations are known and recognized as the best drained districts in this locality. The failure of one crop would often pay for the building of three or four power stations, and such failures are less likely to occur with electric drive than from any other type of prime mover.

For this reason electric drive, while it may cost less than steam drive, and it generally does, is worth considerably more money than is steam pumping.

Explanation of Advantages of Electric Drive.—(1) The investment necessary to build well-designed electric pumping stations complete will vary from about $55 to $70 per horse power of the nominal capacity of motors installed. In general an electric station will cost from 55 to 65 per cent of an equally well-designed steam pumping station.

(2) The size of the buildings required to house the pumping apparatus and the auxiliary electric equipment necessary is, roughly, about one-half of the size of a building required for a steam station on account of the elimination of boilers.

(3) It often happens that the pumping capacity of a plant is found insufficient at a time when there is greatest need for power. Should this occur,

additional power may be secured on shorter notice by electric drive than by any other means. This ability to enlarge the power at short notice gives the district added safety against failure of crops due to unusual flood conditions.

(4) An electric station will have a far longer life than a steam station because the rate of depreciation is much less. The pumps will last longer driven by motors than will the same pumps driven by steam engines, because the torque of the motor is perfectly uniform.

In a well-designed induction motor there are no other important materials than iron, copper and insulation. The only reason why a well-designed motor goes out of use is when the motor has been overloaded so as to heat the insulation to the limit of endurance, beyond which the fabric of insulating material deteriorates, and this fabric is always treated by a preserving material, after which it is baked so as to form a solid substance, and is thus protected against moisture, mildew or decay. Theoretically, if the insulation has not been overheated due to overloading, a motor will last indefinitely, when the bearings are renewed from time to time, at small expense. Practically, owing to the fact that in spite of all precautions materials do deteriorate, the life of a motor under these conditions is at least 20 years, and the rate of depreciation is generally from 4 to 5 per cent, and the motor has considerable scrap value for the copper contained at the end of its life.

In a motor there are no cylinders to be bored, valve seats to be refaced, or the usual maintenance that has to be put on engines and also on boilers to insure their continuous operation. The efficiency of motors is retained indefinitely, while the efficiency of every other type of prime mover grows less with increasing wear.

One of the largest items in the cost of operating a steam station is the continual maintenance and repairs to boilers, in fact many boilers in this service have lasted for only five or six years. As the boiler nears the end of its life the pressure on it must be reduced and this therefore lowers the power which can be developed by the engine, and hence reduces the pumping capacity. Boilers are apt to fail at the time of greatest need and when this occurs the loss of one boiler from the service is likely to result in serious damage to crops. The life of boilers in this service is also shortened by the fact that they are idle for such long periods, and as a result the brick work cracks, the boiler setting becomes leaky, and the flues and shell are attacked by corrosion. The electric pumping station enables all boilers to be eliminated and thus the weakest element of a steam plant is not necessary in an electric station.

(5) There is no objection, as stated above, to installing small pumping units which may operate continuously at high efficiencies, as is not the case in a steam plant, because small steam-driven units are not as efficient as large ones.

(6) It is practicable in electric stations to install protective devices which will protect the motors in case there is a temporary interruption of the service, or in case the motors are overloaded.

A no-voltage release effectually protects the motors against temporary interruption of service, and an over-load release or circuit breaker protects the motors against any load greater than that which it is safe to use continuously. It is good practice in electric stations to install in the pumping stations loud-sounding alarms which would operate if the power supply were interrupted temporarily, and in the residence of the attendant, so that in case the motors are stopped from either of these causes then the attendant may restore the service.

(7) An electric pumping station of almost any size now required may be operated by one man, whereas as many as seven men are sometimes required to operate steam plants running 24 hours per day. It is not necessary for an attendant to be on hand when the pumps are operating. In fact, during a large part of the year electric plants can be made entirely automatic by means of float controls when submerged centrifugal pumps are used with a foot valve in the discharge pipe.

(8) Only a few minutes are consumed in getting the station into operation after the attendant has arrived at the pumping station. The only preparation which has to be made before actual pumping is started is to exhaust the air from the pumps by means of a small motor-driven vacuum pump, which operation requires from 5 to 15 minutes.

(9) The motors themselves have only two bearings and these run in a constant stream of oil fed by the oil rings on the shaft. The oil in these bearings need not be replenished except at intervals of several weeks, and the grade of oil necessary to use costs far less than cylinder oil.

The only repairs or renewals necessary to make in the motors are infrequent renewals of bearings and the brushes on the slip rings. The cost of supplies such as oil, waste and packing is greatly reduced in an electric plant.

(10) A volume could be written on the difficulties which have been experienced by drainage districts on having coal and supplies delivered at the pumping station. Many crop failures may be traced to the supply of coal running out at a time when the river was closed to navigation or to other causes beyond the control of the district. The necessity of storing practically a year's supply of coal in the fall results in the loss of interest on a large amount of money, and the heating value of the coal thus stored seriously falls off because of air slacking.

(11) There is less risk from fire with an electric station than with any other type of prime mover, as no fire need be kept around the building except a small heating stove in the winter, if this is desired. The station is adequately protected from lightning entering on the transmission lines by the installation of efficient lightning arresters.

(12) High-speed pumps may be used with electric drive and higher efficiencies may be obtained from the higher speeds. High-speed pumps cost less to install than the slow-speed pumps which are necessary with steam engines. The even torgue given by electric motors insures a longer life to the pump and pump bearings, which with steam engines would, with the constantly changing direction of the forces applied, tend to throw the whole structure out of line.

The steam engine is inherently a low-speed machine, especially when an effort is made to obtain economy by use of four valves in the cylinder. On account of this low speed the pump, if it is to be direct connected, must be made to suit the needs of the engine and thus sacrifice the efficiency which is attainable when higher speed pumps are used. The speed of the pumps in electric stations is not limited by any such consideration and hence the pumps may be designed for high efficiency without a compromise on account of the inherent characteristics of the prime mover.

(13) Electric power companies are generally willing to contract for a supply of power over a long period of years, thus guaranteeing the districts that the cost of power will not increase during that period. The operating expenses of a steam station are almost wholly composed of coal, labor and supplies, and it is certain that the cost of these items will continually increase during the next few years. Electric power is the only kind of power for which a definite

contract can be obtained as to its cost. This feature alone makes electric power supply a very safe one as an insurance against continually increasing operating expenses.

(14) It is impracticable to operate more than one steam pumping plant in a district because of increasing operating expenses, and this fact has controlled the design of the layout of the districts so that the engineers were compelled to bring all of the water to one point.

This feature of a steam station is very unfortunate, because many districts are so situated that if more than one pumping station could be built the cost of canals and ditches would be considerably less. In addition to this advantage, the long and elaborate canal system when all of the water is brought to one point means that the water generally has to be lifted through a greater height to the river than would be the case if two stations could be built.

In other words, electric drive makes possible a revision of the accepted design for drainage systems, because more than one station can be operated without seriously increasing the cost of pumping. One attendant may operate both stations in a satisfactory manner. The added cost due to having more than one station is simply the larger cost of investment because of the separation.

Amount of Energy Required.—The amount of electrical energy required to drain the water from a district depends on the lift, the efficiency of pumps and the amount of water to be removed. As has been previously shown, the average amount of water to be removed is about ten inches. The maximum average attainable efficiency would probably be 70 per cent for the pumps and 90 per cent for the motors, or 63 per cent combined efficiency from the in-put to the motors to the work done by the pumps. An example has been worked out along these lines for a district comprising 7,518.5 acres of watershed, as follows:

Average rainfall, 32 ins.
Average run-off, 31.2 per cent $\times$ 32 = 10.00 ins.
Average static head pumped against, 10.8 ft.
Add 3 feet for frictions.
Total head, 10.8 plus 3 = 13.8 ft.
Water to be pumped per year:

$$\frac{10}{12} \times 43{,}560 \times 7{,}518.5 = 273{,}000{,}000 \text{ cu. ft.}$$

Work done in raising water at 100 per cent efficiency:

$$\frac{273{,}000{,}000 \times 62.5 \times 13.8}{60 \times 33{,}000} = 119{,}000 \text{ H. P. hours.}$$

$119{,}000 \times .746 = 88{,}800$ K. W. H. of electrical energy.

70 per cent $\times$ 90 per cent = 63 per cent maximum combined efficiency motor and pump.

$$\frac{88{,}800}{.63} = 141{,}000 \text{ K. W. H. per year, or } 18.7 \text{ K. W. H. per acre per year.}$$

Energy Required for Various Combined Efficiencies

Combined efficiency	K. W. H. required per acre per year
63 per cent	18.7
60 per cent	19.6
55 per cent	21.4
50 per cent	23.6

The minimum energy requirements for average rainfall conditions are seen to be 18.7 K. W. H. per acre per year. If the average combined efficiency of 63 per cent could not be secured the table shows that the energy requirements would go up to 23.6 K. W. H. per acre per year if the combined efficiency were as low as 50 per cent. The combined efficiency of 50 per cent in this case would mean an average pump efficiency of 56 per cent, which is considerably less than can be attained by good pumps operated with care. The actual energy requirements for average conditions would probably be 20 K. W. H. per acre per year. This figure would correspond to a combined efficiency of about 59 per cent or an average pumping efficiency of about 65 per cent, which can probably be realized.

Cost of Electric Drive.—The average cost of building an electric station is from 55 to 65 per cent of the cost of an equally well-designed steam station.

Conclusions.—It is fair to draw the following conclusions from the evidence presented:

First—The total cost of steam pumping in well-designed plants is $1.25 per acre per year.

Second—If electrical energy can be purchased for 4 cts. per K. W. H. the total cost of electric pumping does not exceed the cost of steam pumping.

Third—Electric pumping has so many advantages over any other kind of power that it is worth more money to drainage districts because of these advantages.

Reference to Cost Data on Pumping and Pumping Plants.—For greater detail and more data on the cost of pumping refer to the chapter on Pumps and Pumping in the "Handbook of Mechanical and Electrical Cost Data" by Halbert P. Gillette and Richard T. Dana, McGraw-Hill Book Company Inc. 1918.

CHAPTER XI

SEWERS

This chapter consists of cost data relating to the construction of vitrified and concrete pipe sewers and larger sewers of reinforced concrete and brick. Further data on sewers may be found in this volume by referring to the index.

There is an extensive section on cost of sewers in Gillettes' "Handbook of Cost Data" and detailed Methods and costs of trenching are given in Gillettes' "Earthwork and Its Cost" and the "Handbook of Rock Excavation."

Cost of Shallow Sewer Trenching with Sewer Excavator.—A. W. Peters gives the following data in Engineering and Contracting, Feb. 28, 1912.

Work was begun on the Moundsville, W. Va., sewer system in May, 1911. Labor troubles developed a few weeks later. The contract time was one year. The cuts called for were as follows: 3½ miles of trench from 0 to 6 ft.; 16½ miles, from 6 to 8 ft. deep; 3 miles, from 8 to 10 ft. deep; and 3 miles of trench in which the cut was greater than 10 ft.

The contractor, finding the soil suitable for machine work, purchased a No. 00 Chicago Sewer Excavator, steam driven. The excavator was fitted with buckets 22 ins. wide, and a separate set of buckets 27 ins. wide was secured. The length of arm was 8 ft., with an extra 2 ft. extension for use in cutting trenches 10 ft. deep. The contractor was then in shape to handle 23 out of 26 miles of his trench work, regardless of labor conditions.

The topography of Moundsville was favorable to machine work; the grades, within the corporate limits, being, very light, The soil was excellent for machine work, being mostly fine sand mixed with loam and unstratified yellow clay, moist enough to stand well with only occasional vertical braces. Where the sand and loam predominated in the mixture, the machine made big daily runs; when the clay predominated, the going was much harder and slower. At places soil was encountered which was as stiff as a glacial drift hardpan, but which contained no boulders, or even small stones.

As the light cuttings handled by this machine were situated between the two trunk sewers, and therefore pretty well bunched, not much time was lost in shifting the machine from one street to another. When an occasional long shift was necessary the machine traveled under its own power at the rate of 1½ miles per hour. Table I gives the operating cost of the excavator. A little explanation is due some of the items:

Superintendence.—Four gangs working, therefore one-quarter of superintendent's time is charged to the excavator.

Sheeting.—Although this item has been figured into the daily cost, yet there were times when no bracing was necessary, the banks standing up well during the backfilling and flushing. For those cases where vertical bracing is not necessary our excavation cost is slightly high, or on the safe side.

Coal.—A steam driven machine was selected by the contractor, because there are three bituminous coal mines within a mile of the city which supply coal, run of mine, at 5 cts. a bushel, 7 cts. delivered.

TABLE I.—DAILY OPERATING COST OF CHICAGO SEWER EXCAVATION AT MOUNDSVILLE, W. VA.

Operation:	
Superintendence	$ 1.50
Engineer and helper	4.75
Watchman	1.75
Coal, 15 bu. at 7 cts.	1.05
Water, 1 single team	2.50
Plumber, service pipes, average	1.00
Total	$ 12.55
Sheeting: Uprights and jacks; no rangers.	
2 men at $1.75	$ 3.50
Lumber, used repeatedly, neglected.	
Maintenance:	
Replacing dull spuds on buckets	$ 0.50
Engineer's time Sunday cleaning up, $3.00/6	0.50
Miscellaneous	0.50
Total	$ 1.50
Depreciation:	
Life of machine figured at 5 years, 9 months to the year, 25 days to the month	$ 4.00
Daily total	$21.55
Hourly total	$ 2.15

TABLE II.—QUANTITIES AND COSTS OF MACHINE EXCAVATION ON SEWER WORK

Run no.	Lin. ft. trench excavated	Aver. depth, ft.	Hours actual run. time	Cu. yds. per hr. actual run. time	Cu. yds. per day	Cost per yd. on day basis

23	400	4.0	6.5	16.6	108	0.200[f]
Totals			203		4,096	

$$\frac{23 \times \$21.55}{4096} = \text{aver. cost per cu. yd.} = \$0.121 \text{ on 10-hour day basis.}$$

$$\frac{203 \times 2.155}{4096} = \text{aver. cost per cu. yd.} = \$0.107 \text{ on actual running time basis.}$$

[a] Broken chain. [b] Bad banks. [c] Long shift. [d] Wet. [e] Bad banks. [f] Long shift.

Depreciation.—In this particular case, no serious breakages have occurred to date, most of the smaller delays being due to the breakage of links in the bucket chain, the defective links being easily replaced. Still a time must come when the breakages, figured not in dollars and cents necessary to replace defective parts, but in delays to the general progress of the work, must convince the contractor that the efficiency of his machine is low enough to allow of its being discarded. It may be that five years is a conservative estimate; if so, then the costs deduced from this depreciation are on the safe side—a good place for them to be.

Table II shows this excavator during a run of 23 consecutive working days, with time lost in making shifts from street to street and delays due to waiting for the pipe layers in wet ditches, handled an average 178 cu. yds. per day, at an average cost of 12 cts. per cubic yard. The maximum yardage per day was 308. It is well to note this figure of 0.063 was made in a run of 530 ft. in 9 hours with an average trench depth of 8.6 ft. This is significantly the maximum depth quoted in this record. In explanation it may be stated that in shallow trench work the upper 6 or 8 ins. of road metal or even solid compacted surface, which in comparison to the rest of the is ditch hard to excavate, forms a considerable percentage of the total material excavated.

Cost of Backfilling the Trench.—The backfill is divided into two parts: first, the foot of earth covering, which is thrown in and tamped by hand, which serves as a protection for the pipe and the cement joints during the 24 hours in which the ditch is left open for the joints to set up before flushing can commence; and. second, the remainder of the backfill which is put in with team and scraper and flushed and settled with water.

Part 1.—Part 1 may be estimated at 16 cts. per cubic yard, although the variation from this average cost was great in some instances. It is readily seen that in estimating the cost of backfill per lineal foot on ditches of various depths, the proportion of this expensive form of backfill varies inversely as the depth. It has also been noted that in shallow trenches the cost per cubic yard of excavation runs higher than the same unit cost in ditches whose depth approximates the maximum reach of the digging arm.

Part 2.—The trench above the 1 ft. covering was filled with a Sydney scraper and team. Water was run into the ditches during this fill, from the hydrants, with a meter on the line. Two men followed behind the scraper, cleaning out the gutter and rounding off the top of backfilled trench.

The daily cost of this part of the backfill is shown in Table III.

Table III.—Cost Per Cubic Yard of Scraper Backfill

Length trench ft.	Depth trench ft.	Backfill, cu. yds.	Actual time, hours	Cu. yds. per hr.	Cost per cu. yd. actual time	Cu. yds. per day	Cost per cu. yd. day basis
150	6.5	65	3	22	$0.055	.....	....
550	4.0	147	7	21	.057	212	$0.057
800	4.0	213	6.5	33	.036	......	....
280	5.0	93	3.5	27	.045	306	.039
600	3.0	120	5	24	.050	(240)	.050
565	5.0	188	5	38	.032	(376)	.032
445	5.0	148	5	29	.041	(296)	.041
							(.044)*
Totals...........		974	35				

$\frac{974}{35} = 28$ = average backfill in cubic yards per hour.

* $0.044 = average cost per cubic yard.

Remarks. Depths taken to top of pipe covering.

The operating cost per day for the scraper outfit was as follows:

Team and driver	$ 4.50
Helper on scraper	1.75
Helper on hose, etc.	1.75
Cleaning up gutter, 2 men at $1.75	3.50
Water. 5,000 gals., at 10 cts. per M	.50
Per day of ten hours	$12.00
Per hour	$ 1.20

Cost of Deep Sewer Trenching with a Carson Machine.—A. W. Peters engineer in charge of sewer construction of Moundsville, W. Va., gives the cost of deep trench work with a Carson machine in Engineering and Contracting, April 2, 1913. The Carson machine is not an excavating machine but is used to convey in buckets on a cable material which is excavated by hand tools.

On the two sections for which costs are quoted, the soil consisted of fine sand mixed with loam and unstratified yellow clay. In the shallow trenches this material could be excavated for a depth of 8 ft., and the ditch left open for several days in ordinary weather without endangering the banks, although in general verticals and trench braces were used. When the contractor opened up his deep ditches in this material he decided to use 8-ft. lengths of sheeting, placed without driving, in the excavated 8-ft. depth. In this way a section of trench 8 ft. deep would be excavated and the sheeting placed; then the next lower 8 ft. of material would be removed, and the second set of sheeting placed with its top butting up against the bottom of the upper section, the banks being carried down approximately plumb. In backfilling, 8 ft. of sheeting would be knocked out and the trench filled, the material being tamped against the trench side wall and not against the sheeting, as is ordinarily necessary.

TABLE IV.—QUANTITIES ON SECTIONS 1 AND 2, MOUNDSVILLE SEWER TRENCHES

	Length, ft.	Depth, ft.	Total excavation, cu. yds.	Excavation per lin. ft., cu. yds.	Actual mach. days	Excav. per actual mach. day, cu. yds.	Cu. yds. per man-day
* Section 1	296.0	31	1,529	5.2	28	55	4.6
† Section 2	135.0	14–16	.....	...	..	..	...
Section 2	65.0	16–18	.....	...	..	..	...

Section 2	137.0	26–28	.....	...	..	..	...
Section 2	92.8	28–30	.....	...	..	..	...
Section 2	615.6		2,526	4.1	31	82	6.8

* Uniform depth of 31.0 ft.
† Average depth of 22.1 ft.

Of course, these Moundsville conditions are particularly favorable to low sheeting costs, and all that that means in deep trench work, so that the results as derived in Table V should be considered in that light.

The material in these two sections was usually picked before shoveling into the buckets, as it could be handled more rapidly in that way. The general progress of the truck work seemed to be fairly good. The buckets were loaded rapidly, the best men being placed at this work. The machine was handled efficiently and the buckets were run back and forth at a fairly high speed.

Regarding the items of which the total cost is comprised a few explanations will be given:

Excavation.—The first 3 or 4 ft. were thrown upon the bank and not loaded into buckets. For the remaining depth two men shoveled into each bucket, usually loosening the material before shoveling.

Machine.—The sub-heading "moving" is made up principally of the cost of moving the machine along the ditch, which required tracklaying, anchorages and hitches ahead.

TABLE V.—TRENCH COSTS ON SECTION NO. 1, UNIFORM DEPTH, MOUNDSVILLE SEWERS

Item	Cost	Per cent total	Cost per lin. ft.	Cost per cu. yd.
Cost bucket loading	559.80	35.2	$1.88	$0.36
Machine moving	$ 13.96	0.9	$0.05	$0.01
Machine engineer	80.40	5.0	0.27	0.05
Machine signal	52.60	3.3	0.18	0.03
Machine coal	18.00	1.1	0.06	0.01
Machine rental	300.00	18.9	1.01	0.20
Cost, conveying	$ 464.96	29.2	$1.57	$0.30
Sheeting	$ 231.42	14.6	$0.78	$0.15
Tamping	97.06	6.1	0.33	0.06
Teams	40.50	2.6	0.14	0.03
Pavem't removal	15.12	1.0	0.05	0.01
Pavem't replacement	41.20	2.6	0.14	0.03
Superintendent	138.45	8.7	0.47	0.09
Cost, misc	$ 563.75	35.6	$1.91	$0.37
Grand tota	$1,588.51	100.0	$5.36	$1.03

TABLE VI.—TRENCH COSTS ON SECTION NO. 2, VARIABLE DEPTH, MOUNDSVILLE (W. VA.) SEWERS

Item	Cost	Per cent total	Cost per lin. ft.	Cost per cu. yd.
Cost bucket loading	$ 639.89	31.7	$1.04	$0.26
Machine moving	$ 62.56	3.1	$0.10	$0.03
Machine engineer	100.33	5.0	0.16	0.04

Superintendent	175.19	8.7	0.28	0.07
Cost, misc	$ 730.04	36.2	$1.18	$0.29
Grand total	$2,017.27	100.0	$3.27	$0.81

Coal.—Due to the nearness of the bituminous mines, three within the city limits, coal could be bought for 5 cts. a bushel at the mine or 7 cts. a bushel delivered. This fact makes the coal item very low.

Sheeting.—Method of placement described under general soil conditions above. Thickness of sheeting 2 ins.; stringers 4 ins. × 6 ins. The cost as given includes placement, removal and depreciation.

Tamping.—This gang consisted of six men, one shoveller and five tampers. The men did not use the heavy iron tampers, but were provided with pieces of 4 ins. × 6 ins., about 2 ft. long, with an old shovel handle set into one end. Better results were secured with these wooden tampers than with the iron ones.

Teams.—This item is made up principally of the cost of removal of surplus dirt, and cost of evening up inequalities in trench depth. On Section 2 the cost of this item is greater than on Section 1, because the trench depths were increasing as the machine moved ahead, so that when the backfill was made under these conditions, a surplus resulted which necessitated the team expense.

Pavement.—Brick on both sections laid on 1-in. sand cushion with 6 ins. of gravel foundation. Very little of the base was saved, so that in the replacement of paving new gravel was necessary. A great many brick were broken on removal or afterwards lost.

Labor.—The wages on these ditches varied from $1.85 to $2.00, about 70 per cent of the men getting $1.85 per day, and the remainder $2.00.

Cost Analysis.—Referring to the tables it will be seen that Table IV is a general table of quantities with unit quantities reduced. Table V gives the trench costs for uniform depth, and Table VI presents the cost on a ditch of variable depth.

For a trench ranging in depth from 14 to 30 ft. in Moundsville, the "Digging Cost," equal to cost of bucket loading and conveying, was found to be 52 cts. per cu. yd., as shown by the sum of "Bucket Loading" and "Conveying" costs in Table VI.

For the trench with uniform depth of 31 ft., the "Digging Cost" at Moundsville equals 66 cts. per cu. yd. See Table V.

Referring to Table IV we see that the yardage per man-day for the variable ditch was 6.8, while for the uniform ditch it was 4.6.

These results, without any further study of the tables, show that we cannot quote a uniform price for all depths of excavation, as is done by the machine people and some authors.

A moment's thought will show that the difference between the lengths of haul in a 10-ft. ditch and a 35-ft. ditch may vary by as much as 15 per cent.

It will also be noticed that the three main divisions of the total cost are approximately equal in each table, both in the case of the ditch of uniform depth as shown in Table V, and in the ditch of variable depth as shown in Table VI. This fact would seem to offer an approximate method of estimating trench costs, by using the "Cost of Bucket Loading" as a starting point. It would seem that this ratio ought to hold in soil conditions different from those encountered at Moundsville, because the three main divisions contain items that are more or less dependent upon each other, so that a change in one would cause a corresponding variation in the others. For example, suppose that a wet ditch is being excavated. It will then take longer to load the buckets and the cost will therefore, be greater; the Conveying Costs will be similarly increased because the Machine Rental, which is a large item, will be greater. It can readily be seen that the Miscellaneous Costs will be increased and the item of Pumping will be added.

In the two Moundsville ditches quoted, the cost of bucket loading varies with the depth, and is almost numerically equal to it. The expression (D + 4) where (D) is the depth of trench in feet, would give the cost per cu. yd. of Bucket Loading for both trenches.

For a trench in "ordinary earth," such as the Moundsville trenches, with either a uniform or average depth, D, the total cost per cubic yard of trench work would then be given by the expression 3 (D + 4).

It is usually the case that excavation in hardpan costs approximately double the excavation of the ordinary earth. With a hardpan trench, therefore, the expression for total cost per cubic yard would become 6 (D + 4).

Of course, it is not expected that this expression will serve as other than an approximate check on estimated costs of deep trench work; neither is it expected that it will meet the demands of a quicksand ditch; but for the ordinary run of ditches it is believed that it will check up in fairly good shape providing the Bucket Loading cost is selected with some care and judgment.

Cost of Deep Trenching by Machine at Glencoe, Ill.—The following is taken from an article in Engineering and Contracting, April 5, 1911, by Don E. Marsh.

The length and depth of the various sizes of pipe for the sewerage system at Glencoe, Ill. are as follows:

15,500 lin. ft. of 8-in. pipe from 8 to 12. ft. cut.
5,600 lin. ft. of 10-in. pipe from 7 to 13 ft. cut.
250 lin. ft. of 12-in. pipe about 13 ft. cut.
1,000 lin. ft. of 15-in. pipe about 16 ft. cut.

4,700 lin. ft. 18-in. pipe from a very shallow cut up to a cut of 30 ft.

Reference to the above tabulation will show that a good percentage of the larger size pipe was placed in very deep cuts. The soil, especially in the deep cuts, was a hard clay. The top fifteen feet was a brownish clay with slight traces of sand. Below this was a hard blue clay. During the fall and winter months this soil becomes extremely hard and difficult to handle, too hard in fact to be dug by hand without the aid of a pick. In some respects the character of the soil was an advantage, since no sheathing was required.

It was determined to utilize the largest size Municipal Excavator. The excavator was constructed to dig a trench up to 25 ft. in depth. Where the depth of excavation exceeded this amount, as it was for a considerable distance as deep as 30 ft., the street was graded down 3 or 4 ft. and the remaining foot or two was excavated by hand in the bottom of the trench and the dirt thrown either into the boom or back upon the completed pipe.

The trench dug by this machine was about 33 ins. in width, giving ample room for the proper laying of the 18 ins. sewer pipe and for securing proper joints and also for the reception of junctions. All joints were calked with oakum and then cemented, to exclude seepage as far as possible, making a wide trench quite necessary, for room in which to operate.

The sides of the trench were smooth and vertical. Vertical plank and pack screws were used for bracing. These were placed about 3 ft. apart in the deep trenches and farther apart in shallow cuts.

Cost.—A record of a few average days, which does not take into consideration the long or short delays caused by break-downs, storm, or otherwise, the cost of labor alone for excavating at a depth of about 25 ft., laying 18-in. pipe and back filling appears about as follows:

	Per day
1 foreman	$ 8.00
Excavating machine, including operator	40.00
1 engineer	4.00
1 fireman	3.00
5 trenchmen at $3.00	15.00
20 laborers, backfilling, at $2.50	50.00
2 teams at $6.00	12.00
Coal	5.00
Repairs and sundry expenses	10.00
Total	$147.00

One hundred and forty-seven dollars for 80 ft. or approximately $1.85 per lin. ft. While working in the deep cuts progress of 60 to 100 ft. per day was made.

It will be noticed that a large amount of the cost is for backfilling. This item can be reduced where it is possible to use teams with slips. If the backfilling can follow close behind the excavating while the dirt is still fresh, one team with driver and one scraper holder will backfill about as much as ten laborers with shovels.

Comparative Cost of Hand and Machine Trench Excavation and Some Miscellaneous Sewer Costs.—The following is taken from Engineering and Contracting, July 9, 1919.

Machine trenching in the construction of the Stanley St. sewer at San Francisco cost about one-fifth as much as by hand trenching.

During construction, where the contour of the ground permitted, a ditching machine was used, which not only produced cheaply a uniform trench in which to lay the heavy cast-iron pipe but speeded the completion and earlier use of the entire system.

The following costs to the contractor of some of the items—office overhead and the necessary insurance and bond not included are taken from the report of M. M. O'Shaughnessy, City Engineer, for the fiscal year ending June 30, 1918:

15-in. iron stone-pipe, per foot	$ 1.65
21-in. iron-stone pipe, per foot	1.79
2 × 3 reinforced concrete sewer, per foot	3.31
2 ft. 6 in. × 3 ft. 9 in. reinforced concrete sewer, per foot	3.51
Brick manholes, each	40.50
Overflow structure	465 65

Trench excavation for the cast-iron pipe was in stiff sandy clay. The cost of that portion of the work done by hand was $0.91 per cu. yd.; the cost by machine was $0.18 per cu. yd., including a fixed charge of $32 per day for the use of the machine.

The 18-in. cast-iron pipe cost $0.228 per foot to lay, yarn, pour and calk the joints.

The prevailing rate of labor during construction was $3.00 per day.

Average Daily Progress in Excavating 37,800 Ft. of Sewer Trenches with Trenching Machines.—Engineering and Contracting, Feb. 10, 1915, publishes the following data given by J. E. Schwaab in a paper before the 30th annual meeting of the Illinois Society of Engineers and Surveyors.

In the construction of the sewer system of Alton, Ill. there were used one small 00 Austin gasoline ditching machine which excavated a ditch 24 ins.

wide. The following out-put data were furnished by G. M. Johnson, of the Lillie Construction Co., sub-contractors, and owner of this machine:

Total amount of work done, lin. ft.	19,800
No. of working days	90
Average cut per day, lin. ft.	220
Maximum cut per day, lin. ft.	800
Average cost per day for operation	$30

Depth of trench averaged 11 ft., with a maximum of 22 ft. and a minimum of 4 ft.

There was also used a Parson's steam ditching machine with backfiller, which excavated a ditch 28 ins. wide. The following figures as to the work done by this machine were computed by the writer and are only approximate:

Total amount of work done, lin. ft.	18,000
Number of working days	90
Average cut per day, lin. ft.	200
Average cost per day for operation, laying pipe, and backfilling	$45.00
Average depth of trench excavated, ft.	11½

The material excavated was clay and sandy clay. The work was done during the summer of 1914.

Progress and Distribution of Time of Force on Sewer Trenching by Machine. W. G. Kirchoffer gives the following information in Engineering and Contracting, April 10, 1912. In excavating for 5,270 ft. of 8-in. Sewer at West Salem, Wis., in a sandy gravelly clay, the contractor used a Parson's trenching machine.

The trench averaged about 8 ft. deep. The total number of days' work put in on the job was 325¾, or an average of 61.8 days per 1,000 ft. of sewer. The trenching machine was operated 20 days out of the total 26 put in upon the work, or an average of 263½ ft. per day. The least distance made in a day was 20 ft. and the maximum distance was 550 ft. of completed sewer. There were five days in which the rate exceeded 400 ft. of sewer per day.

The labor put in upon the work was divided as follows in days per 1,000 ft. of sewer:

Contractor	1.092
Inspector	4.935
Pipe layer	4.315
Foreman	4.270
Engineer	4.79
Fireman	4.412
Team	3.417
Mason	3.75
Water boy	1.993
Common labor	26.04
Tamper	4.13

The greatest number of men employed in any one day was 16 and the smallest number was two.

Cost of Excavating for Large Trunk Sewer with Locomotive Cranes and Automatic Buckets.—Engineering and Contracting, June 29, 1910, gives the following data relative to the excavation of a section of the Louisville, Ky. sewerage system.

The contract under consideration was for 2,723 ft. of sewer through unimproved land. The sewer is of concrete, 12 ft. × 9 ft. for 1,126 ft. in length, and of three centered arch section. For the balance of the length it is horseshoe shaped, and about 9 ft. 3 ins. × 9 ft. in section.

The average depth of excavation was 22.4 ft. and the average number of cubic yards of excavation per lineal foot of trench was 12¼. The material excavated consisted of 6 ft. of blue and yellow clay below which was 6 to 12 ft. of yellow clay and loam and the balance, fine and coarse sand.

In opening the trench horse scrapers were used, and enough of the trench was excavated in this way and used for filling in low land nearby, to take up the amount which would necessarily have to be spoiled. An average of half a dozen teams were used on this work with one team acting as a snap team. The longest haul was about 100 yards.

The main excavating plant for this contract consisted of three ten-ton Browning locomotive cranes, two of which were equipped with automatic buckets, one orange-peel of 1 cu. yd. capacity and one clamshell of ½ cu. yd. capacity. The cranes ran on standard gage track, of 60 and 65-lb. rails, laid along the trench for 600 ft.

Progress and Costs.—The working day is 10 hours. Crane No. 1 operates a ½-cu. yd. Owens clamshell bucket and averages 400 buckets in 10 hours or 200 cu. yds. This bucket handles a full half yard at each operation. The labor cost on this machine is as follows:

1 engineer at	$ 3.50
1 fireman	2.00
1 tagman	1.75
1 signalman	1.75
Cost of labor for 200 cu. yds. (clay)	$9.00

Cost of labor per cu. yd., $0.045.

The second crane handles sand in a ¾-cu. yd. dump bucket filled by hand. It handles 300 buckets or 225 cu. yds. a day. The labor cost on this is as follows:

1 engineer	$ 3.50
1 fireman	2.00
1 foreman	2.00
8 men in bottom at $1.75	14.00
Cost of labor for 225 yds	$21.50

This gives a cost of labor for 1 cu. yd. of $0.095.

The third or backfill crane operates a 1-cu. yd. orange-peel bucket and handles 500 cu. yds. of material in 10 hours. The cost of labor backfilling is as follows:

1 engineer	$3.50
1 fireman	2.00
1 signalman	1.75
Labor cost backfilling, 500 cu. yds	$7.25

Labor cost per cu. yd. of backfilling, $0.0145.

This crane when not backfilling, pulls timbers and sheeting. The average amount of coal used by one crane in a day is 1,200 lbs. Run-of-mine coal is used at $4 per ton. About 160 gals. of water are used per crane per day. The cranes each cost $5,000 new and their annual interest and depreciation is figured by the contractor at 30 per cent.

Cost of Excavating Trench in Granite.—The following data, published in Engineering and Contracting, April 20, 1910, was arranged from a paper by E. A. James in Applied Science for March, 1910.

The excavation was for an 18-in. sewer built at Muskaka, Ont. This sewer had a total length of some 1,300 ft., but only the 550 ft. in rock trench is referred to here. The rock was Laurentian granite and the trench was 9 ft. deep. The excavation was by drilling and blasting, the rock being hoisted by horse derricks and skips and deposited in horse drawn cars operating on track. The haul was some 1,500 ft. for about two-thirds of the spoil and less than 300 ft. for the remainder. The total amount of rock excavation was 1,850 cu. yds., and the itemized cost of excavation was as follows:

	Total	Per cu. yd.
Superintending:		
Walking boss, at 60c per hour	$ 222.45	$0.12
Clerk and timekeeper, at 37½c per hour	158.60	0.085
Foreman, at 45c per hour	608.15	0.328
Total for superintending	$ 989.20	......
Labor—Mucking, loading, hauling and dumping:		
Laborers, at 20c per hour	$2,877.00	$1.555
Teamsters, at 21c per hour	499.70	.270
Teams, at 40c per hour	1,010.60	.545
Cars, at 5c per hour	117.00	.063
Carts, at 5c per hour	65.50	.035
Derricks and power, at 15c per hour	175.50	.095
Handy men, at 27½c per hour	125.15	.067
Total labor	$4,870.45	$2.630
Drilling rock:		
Foot drilling, at 30c per ft	$1,245.00	$0.673
Sharpening drills, at 27½c per hour	250.80	.135
Nippers, at 17½c per hour	382.20	.206
Coal, at $10 per ton	29.00	.157
Total	$1,907.00	$1.171
Explosives:		
Electric fuses	$ 95.95	......
Caps and fuses	23.20	......
Batteries, rent	38.00	......
60% dynamite, at $10 per box	1,020.00	......
Total	$1,117.15	$0.636
Grand total		4.97

To the above total must be added $930. for depreciation of plant or 50 cts. per cu. yd., making a total cost per cubic yard of $5.47. In studying this cost it must be noted that the trench was narrow, and small shots had to be used, making the amount of drilling large; 1 ft. of hole was drilled per 4.5 cu. yds. excavated.

Cost of Hand Drilling Bastard Granite in Trench Work.—Edward B. Roberts gives the following data in Engineering and Contracting, June 15, 1910.

The trench was 2½ ft. wide and 5¾ ft. deep and the rock, a bastard granite, was found in the bottom of an average depth of 2¾ ft. The drilling was done by hand using 1¼-in. drills, 1 man holding and 2 men striking with 8-lb. hammers. A total of 96 ft. of hole was drilled or 3.2 ft. per cu. yd. of work.

The time required was 3.1 hours per lin. ft. of hole. The time work of excavating 35 cu. yds. was:

Item	Per cu. yd.
347 hrs. drilling	9.92
120 hrs. mucking	3.43
Total	13.35

The materials used were as follows:

Item	Per cu. yd.
53 lbs. 60 % dynamite, lbs	1.5
Explosives	2.

A batch of 120 drills were sharpened or 4 per cu. yd., or 1 per 0.75 ft. of hole drilled. The amount of explosive used per foot of hole was ½ lb. Labor estimating does not include backfills.

Progress of Sheeting a Sewer Trench with Light Steel Sheet Piling.—Engineering and Contracting, Nov. 15, 1918, gives the following.

The work was the laying of a terra cotta sewer pipe in the City of Watertown, N. Y. The course of the sewer was in a sandy soil which obtained quite uniformly throughout its length to a depth of about ten feet, underneath which was a wet sand mixed with gravel. The average depth of the sewer pipe below the surface was 15 ft. The nature of the soil necessitated the use of sheeting to prevent caving in of earth and thus permit of a narrow excavation with the minimum of material to be removed. Accordingly, 400 sheets of ⅛-in. Wemlinger corrugated steel sheet piling in 10-ft. lengths were obtained and for driving them a steam-driven pile hammer, weighing approximately 650 pounds, was used. The trench was first excavated for its width to a depth of about 5 ft., which was left unsheeted. The sheet-piling was then carried by hand and set in position on each side of the trench and driven its entire length before any further excavating was done.

An A-frame built of timber straddled the excavation, and from it was suspended a 2-ton triplex differential chain block. It was intended to use the chain block for raising and lowering the pile hammer during the driving and, subsequently, to withdraw the sheet-piling. Throughout the entire operation the work of placing the sheeting, driving it with the pile hammer and pulling and resetting, was done by 3 men for each separate operation. As before stated the sheeting was all handled by manual labor, and it required 1 hr. and 30 min. to set up 32 sheets in position for driving, including the time required to carry these sheets an average distance of about 175 ft. The time required to drive each sheet 5 ft. into sand was from 33 to 37 seconds. The driving was done so fast that the triplex block could not be worked quickly enough to follow the pile hammer, and so it was steadied by hand. No difficulty was experienced in doing the work in this way and the chain block was needed only to hoist the hammer from one pile to another. That this method of handling the hammer proved to be a success is largely due to the fact that it stood only about 4 ft. high on top of the sheet-piling. Including the time required for moving both the hammer and A-frame, an average of 7 ft. of trench was sheeted on both sides per hour.

Average Costs of Sewers, Washington, D. C. 1902 to 1917.—Tables VII and VIII, are given in Engineering and Contracting, April 11, 1917, from the report of A. E. Phillips for the year ended June 30, 1916.

TABLE VII.—AVERAGE COST OF CONSTRUCTING PIPE SEWERS FOR 15 YEARS

Year	8-in. diam. *L	8-in. diam. *M	10-in. diam. L	10-in. diam. M	12-in. diam. L	12-in. diam. M	15-in. diam. L	15-in. diam. M	18-in. diam. L	18-in. diam. M	21-in. diam. L	21-in. diam. M	24-in. diam. L	24-in. diam. M
1902	$0.83	$0.32	$0.97	$0.41	$1.04	$0.46	$1.46	$0.62	$1.74	$0.78	$1.91	$0.96	$2.43	$1.23

Cost of Sewer Construction, Webb City, Mo.—E. W. Robinson gives the following data in Engineering and Contracting, Aug. 14, 1912.

The nature of the excavation encountered in this locality is too rocky to permit the use of a trenching machine. This necessitates that the work all be done by hand except the top two or three feet which can be loosened with a plow or rooter. While there have been a few instances of finding treacherous ground in the nature of joint clay, generally it is very stable and requires very little or no timbering for depths not exceeding 10 ft., except during wet weather. A fair sample of the log for the excavation for a trench 10 ft. deep would be, 0 to 1 ft. black dirt with few small boulders; 1 ft. to 3 ft. boulders varying from the size of a man's fist to the size of a water bucket cemented together with a sort of dried clay; 3 ft. to 5 ft. large flint boulders and ledges with seams of clay between; 5 ft. to 7 ft. red or yellow clay with occasional boulders; 7 ft. to 10 ft. alternate clay and boulders and ledges, with occasional out-cropping of lime rock. As everything except lime rock in masses of 9 cu. ft. or over is classed as earth, one need not be surprised at the cost of excavating in this city compared with that of other localities.

Construction Costs of 8" Sewer.—The following data give the actual cost of constructing one district sewer, and is a fair average for like sewers in this city. Total length of sewer, 2,135 ft.; 1,430 cu. yds. of excavation; 2 flush-tanks, 3 manholes. The items follow for the sewer proper:

Item	Unit cost cts. per ft.
Labor:	
Foreman, 310 hrs. at 35 cts	5.08
Pipe layer, 82 hrs. at 25 cts } Helper, 106 hrs. at 20 cts	1.95
Team hauling, 17 hrs. at 35 cts	0.28
Excavation, 153.5 hrs. at 25 cts., 3,909 hrs. at 20 cts. ($0.5736 per cu. yd)	38.41
Backfilling, 567.5 hrs. at 20 cts. ($0.0792 per cu. yd.)	5.31
Cleaning up, teams, 177.9 hrs. at 35 cts	2.92
Flushing and tamping, men, hose rent, drayage, etc	1.61
Per lineal foot	55.56

Item	Cost	
Materials:		
1,845 ft. straight 8-in. clay pipe at 13.05 cts	$240.77	
156 ft. 6-in on 8-in. Y branches at 71 cts	110.76	
Cement for joints, 30½ sacks at 40 cts	12.20	
Jute for joints, 88 lbs. at 14 cts	12.32	
Picks sharpened, 352 at 10 cts	35.20	
Caps for Ys, 156 at 3 cts	4.68	
Drills sharpened, 3 at 20 cts	.60	
Fuse, caps and dynamite	1.20	
Total materials on sewer pipe	$417.73	19.57
Total labor and materials on sewer proper		75.3

Cost of Manholes.—The walls of the manholes are 8 ins. thick and are made of brick. The bottom is concrete. The manholes are circular in section with an inside diameter of 4 ft. The walls are carried up vertically and are drawn in in the upper 2 ft. 6 ins. to a clear opening of 28 ins. in diameter to admit the cast iron frame and cover. The inside of manhole is finished with three coats of Portland cement grout, and the outside of the wall is plastered with a ½-in. coat of mortar, mixed 1 part Portland cement to 2 parts sand. Wrought iron manhole steps are spaced 15 ins. apart vertically. The itemized average cost of labor and material are here given. The average is based on three manholes of an average depth of 8½ ft. The cost data follow:

Item Labor:	Cost
Excavation, 24 hrs. at 20 cts	$ 4.80
Mixing concrete for base, 2 hrs. at 20 cts	0.40
Bricklayer, 7 hrs. at 40 cts	2.80
Helper, 7 hrs. at 20 cts	1.40
Team hauling, 2 hrs. at 35 cts	0.70
Painting inside with cement wash, 2 hrs. at 25 cts	0.50
Total labor on manholes, average	$10.60
Per vertical foot	$ 1.25

Item Material:	Cost
Brick, 1,066 at $8 per 1,000	$ 8.53
Cement in concrete, 3 sacks at 40 cts	1.20
Cement in mortar, 8 sacks at 40 cts	3.20
Sand in mortar, 16 cu. ft. at 8 cts	1.28
Gravel in concrete, 0.4 cu. yds. at 50 cts	0.20
Water, 2 bbls. at 10 cts	0.20
Cast iron cap and cover	9.50
Wrought iron steps, 3 at 40 cts	1.20
Total material on manholes, average	$25.31
Per vertical foot	$ 2.98
Total labor and materials on manholes average of three	$35.91
Per vertical foot	$ 4.22

Cost of Flush-tanks.—Flush-tank walls are 8 ins. thick and are constructed of brick. The bottom is concrete and the siphon also is set in concrete. The top of the walls are drawn in as in the manholes previously described. The inside surface of the wall is finished with three coats of neat Portland cement mortar, and the outside surface with a ½-in. coat of 1:2 mortar. The inside diameter of the flush-tank is 4½ ft. A 6-in. clay pipe overflow is provided. The overflow discharges into the vertical stack of the 6-in. clay pipe lamp hole placed adjacent to the flush-tank. The lamp hole stack at the base joins the outlet pipe forming the siphon discharge. The flush-tank has wrought iron steps of the type and spacing described for manholes. The following cost data on flush tanks give the average cost of two tanks of an average depth of 8 ft.:

Item Labor:	Cost
Excavation, 19 hrs. at 20 cts	$ 3.80
Team hauling, 4 hrs. at 35 cts	1.40
Mixing concrete for base, 2 hrs. at 20 cts	.40
Bricklayer, 9.5 hrs. at 40 cts	3.80
Helper, 10 hrs. at 20 cts	2.00
Digging ditch for water connection, 64 hrs. at 20 cts	12.80
Tapping water main	3.00
Total labor on flush tanks, average	$27.20

Item Material:	Cost
Brick, 1,232 at $8 per 1,000	$ 9.86
Cement for concrete, 3½ sacks at 40 cts	1.40
Gravel for concrete, 0.6 cu. yds. at 50 cts	.30
Cement for mortar, 12 sacks at 40 cts	4.80
Sand for mortar, 24 cu. ft. at 8 cts	1.92
Water, 2 bbls. at 10 cts	.20
Cast iron cap and cover	9.50
Wrought iron steps, 4 at 40 cts	1.60
Siphon, 6-in. Miller standard	23.50
Corporation cock and lead connection	5.08
Regulator, IXL	4.00
6-in. clay pipe and specials for lamp hole	2.08
Cast iron lamp hole cover	4.25
306 ft. ¾-in. galvanized water pipe at 6.37 cts	19.49
Curb box and cock	2.50
Total materials on flush tanks, average	$90.48
Total cost of sewer, including manholes and flush tanks	$ 1,947.02
Per lineal foot	91.19 cts.

It will be noticed that the above cost of the flush-tanks is rather high. This was partially due to the fact that it was necessary to go so far to make connection with the water main for both tanks.

On the construction of four small (10-in. pipe) public sewers, aggregating 8,551 ft. in length and 4,540 cu. yds. of excavation, two years previous to the construction of the sewer of which data are given above, the total cost complete of sewer proper was 59.8 cts. per lineal foot. For the construction of 28 manholes averaging 8.5 ft. in depth the average cost was $4.01 per vertical foot. However at that time common labor was getting $1.50 and $1.75 per day of ten hours instead of $2.00 as in the later case. An average of three sewers constructed about the same time and under the same labor conditions as given in the foregoing data gave the following unit costs: Total labor and materials on sewer proper, 76.92 cts. per lin. ft.; total labor and materials on manholes, avg. depth 9 ft., $4.14 per vertical foot; labor and materials on flush-tanks, avg. depth 7.5 ft., each, $100.58; grand total, sewer complete, including manholes and flush-tanks, was 95.45 cts. per lineal foot.

Cost of Sewer at Davenport, Ia.—W. S. Anderson, in Engineering and Contracting, Sept. 3, 1913, gives the following:

The sewer construction here described was executed by contract under the Davenport specifications. All work was done by hand.

The method used on most of the work here described was the "step up" system of excavation. Particular attention was paid, on this work, to keeping the pipe close up to the point of excavation, and in keeping a man on the same step, hence the method is referred to as the step up method. By the use of this method the probability of caving was lessened considerably; the foreman was better able to judge the output of each man; each man apparently did a like share of work; the pipe was always up to the point of excavation, which was a helpful factor after a cave in; the pipelayer had more confidence in his safety and was therefore able to do more work. Each man removed only a definite portion, one spade in depth. The excavated material was thrown back far enough to allow walking space between the trench and the material bank.

The first three feet were excavated considerably in advance of the steps, which allowed a greater number of men to be used. One man lowered the pipes, provided the jute and the 1:1 mortar for the joints. The pipe layer in addition to laying and jointing the pipes carried a cut averaging from 15 to 22 ins. in depth, the material from which was thrown directly onto the laid pipe, where it was firmly tamped to prevent any lateral displacement of the pipe. A sand bag was used to remove all projecting material at joints and other loose material.

No staging or platforms were used for a depth less than 9 ft. When used they consisted of planks 8 ft. long supported at the right elevation by trench braces. The pipe was laid on an up-grade as usual so as to make use of the laid pipes for drainage. The trenches were water tamped in nearly every instance.

Contract 1, 1911, Section 1.—Work was started at Section 1. This section lies entirely in pasture land. The length of the 15-in. pipe line laid was 330 ft. The average depth of trench was 6.5 ft. The maximum depth was 8 ft. 9 ins. The minimum depth was 4 ft. The average width of trench was 30 ins. The total yards excavated and back filled were 190. The pipe layer excavated a trench 15 ins. × 23 ins. and averaged 18 ft. of laid pipe per hour. No cave-ins resulted. A Doan scraper was used for back filling. The soil was all yellow clay except the upper foot which was black loam and sod.

The weather was warm and dry. Wages per hour on job A were 40 cts. for foreman, 20 cts. for laborers, 25 cts. for pipe layers and timbermen, and 50 cts. for teams. The following items do not include foremanship, water boy, or incidental expenses which amounted to 3 cts. per ft. of pipe on all sections of this contract.

With these exceptions the costs for Section 1 follow:

Item	Cost per lin. ft., cts.	Cost per cu. yd., cts
29 cu. yds. excavation by pipe layer	0.8	7.6
Laying pipe	2.4	....
161 cu. yds. excavation	10.5	21.4
161 cu. yds. backfill	5.1	10.5
Totals	18.8	49.5

Section 2.—On Section 2 a 327 ft. stretch of 12-in. pipe was laid. This section also lies entirely in pasture land. This section also lies entirely in pasture land. The average cut on this section was 9.3 ft.; maximum 15 ft.; minimum 5½ ft. The weather was very wet. The average width of trench was 26 ins. for 180 ft. and 30 ins. for 147 ft. (This extra width was necessary only where the depth exceeded 12 ft.) The pipe layer excavated a trench 15 ins. × 18 in. for 180 ft. and a trench 23 ins. × 18 ins. for 147 ft., averaging 15 feet, of laid pipe per hour through the shallow cut and 10 ft. through the deep cut. There were no cave-ins to speak of. For the deep cut one platform was required. The cu. yds. of material excavated and back filled were 219.

The costs on this section follow:

Item	Cost per ft., cts.	Cost per cu. yd., cts.
28 cu. yds. excavation by pipe layer	1.2	14.0
191 cu. yds. excavation	21.1	36.1
Laying pipe	3.1	....
191 cu. yds. backfill	6.7	11.5
Totals	32.1	61.6

Section 3.—Section 3 consisted of 390 ft. of 12 in. pipe. The cut on this section varied from 10 feet to 24 ft. Tunnelling was resorted to through the

deep sections. The longest tunnel was 54 ft. while several tunnels 15 ft. in length were put through. The total distance tunnelled was 95 ft., while the open cut distance was 295 ft. The average width of trench was 36 ins. The material was firm clay which stood up remarkably well when tunnelled. Near the bottom a material, which tended toward bog iron, was encountered. The weather was very favorable.

Each tunnel was worked from both ends simultaneously, the excavated material being relayed back into each shaft. In one of the shafts part of the material was deposited onto the pipe, which had previously been laid, while in the other shaft some material for back filling the tunnel was allowed to remain. The excess material was removed to the surface.

The tunnellers were paid 35 cts. per lin. foot tunnelled. The average height of the tunnel was 3½ ft. and the width 3 ft. The tools used were a miner's pick with a "duck bill" on one end, and an 18 in. tile spade, a sharp adz, and a shovel, the handles on these tools being not over 20 ins. long. No timbering of the tunnel was required. The pipes were laid after the entire tunnel section was complete. Grade was teed in from stakes driven at the correct elevation, at each end of the section. The pipe was lowered into the shaft by means of a rope, and slid to the desired point on planks placed on the tunnel bottom. The back filling was carried on by relaying the material in from the tunnel opening and tamping it solidly. The unit costs on the tunnels in Section 3 follow:

Item	Cost per ft., cts.	Cost per cu. yd., cts.
Tunneling, 95 lin. ft. (37 cu. yds.) at 35 cts. per ft..	35.	92.4
Removing 22 cu. yds. material from tunnel........	5.5	28.2
Removing 25 cu. yds. material from shaft..........	17.4	66.
Backfilling tunnel..................................	8.2	21.7
Pipe laying, 95 ft. of 12-in. pipe..................	4.1	....
Totals..	70.2	$ 2.083

The item "removing material from tunnel" includes only 22 cu. yds. The remaining 15 cu. yds, were excavated from the short tunnels, where an additional man was not required for removing the material from the tunnel since the tunnellers were able to throw the material back far enough for the shaft men to reach.

The open cut on this section consisted of a 295 ft. stretch which includes the shafts. This entire length had to be sheeted with skeleton sheeting. The number of ft. B. M. used was 5,920. The average depth of this 295 ft. stretch was 17 ft., minimum 6 ft., maximum 23 ft. The average width excavated was 30 ins. The weather was favorable. The trench bottom consisted of a mixture of clay and sand and water, which made pipe laying as well as excavating very difficult. The back filling was done mostly by hand. The material was so wet, sticky, and heavy that a scraper and team could not move the material satisfactorily. The pipe layer excavated a bench 12 ins. deep and 18 ins. wide, or 16 cu. yds. of material and threw it back on the laid pipe.

The cost of the open cut portion follows:

Item	Cost per ft., cts.	Cost per cu. yd., cts.
Excavation by pipe layer, 16 cu. yds..............	1.3	24.
Excavation, 437 cu. yds............................	99.5	63.1
Sheeting...	10.4	....
Laying 12-in. pipe.................................	3.5	....
Backfill...	15.6	9.9
Totals...	130.3	97.0

The labor of sheeting cost $5.20 per 1,000 ft. B. M.

In comparing the cost of tunnelling with the cost of open cut, one must remember that excavating shafts is more difficult and therefore more costly than straight open work, since the ends of a shaft must be cut square; and the "step-up" method of excavation cannot be used to advantage. Still the costs show that tunnelling for this particular sewer cost less per foot than the open cut. This is evidently true for any sewer excavation below a certain depth.

Section 4.—Section 4 consisted of a 403-ft. stretch of 10 in. pipe. The average cut was 8.5 ft., minimum 6 ft., maximum 9.5 ft. The average width of trench was 24 ins. The bottom was very wet, but no sheeting was required. The pipe layer excavated a bench 15 ins. × 18 ins. The trench was back filled by hand. The unit costs follow:

Item	Cost per ft., cts.	Cost per cu. yd., cts.
Excavation by pipe layer, 28 cu. yds.	0.9	12.4
Excavation, 216 cu. yds.	13.6	25.4
Laying 10-in. pipe	2.2	.....
Backfill	4.5	8.4
Totals	21.2	46.2

Section 5.—On Section 5 a 550 ft. length of 8 in. pipe was laid. The average depth was 11.5 ft., minimum 9 ft., maximum 16 ft. Width of trench 24 ins. The trench bottom was wet for 200 ft. Two caveins resulted, due to insufficient bracing. Skeleton sheeting was provided every 5 ft. The pipe layer excavated a bench 12 ins. deep by 15 ins. wide and averaged 20 ft. of laid pipe per hour. The trench was back filled by hand. The costs follow:

Item	Cost per ft., cts.	Cost per cu. yd. cts.
Excavation by pipe layer, 26 cu. yds.	0.7	16.5
Excavation, 428 cu. yds.	23.4	30.1
Laying 8-in. pipe	2.0	.....
Sheeting	2.3	.....
Backfill	7.9	10.2
Totals	36.3	56.8

2,560 ft. B. M. of sheeting cost $4.97 per 1,000 ft. for labor in placing and pulling.

Section 6.—Section 6 consisted of a 563 ft. length of 6 in. pipe. The average cut was 11 ft., minimum 9 ft., maximum 12 ft. The average width of trench was 22 ins. The pipe layer averaged 30 ft. of laid pipe per hour, and excavated a 12 in. × 12 in. bench. The trench was back filled by hand. The costs follow:

Item	Cost per ft., cts.	Cost per cu. yd., cts.
Excavation by pipe layer, 22 yds.	0.4	10.5
Excavation, 380 cu. yds.	15.2	22.2
Laying 6-in. pipe	1.1	.....
Backfill	6.5	9.7
Totals	23.2	42.4

Section 7.—On Section 7 a 550 ft. length of 8 in. pipe was laid. The average cut was 10½ ft., minimum 9 ft., maximum 11 ft. The average width of trench was 24 ins. The material was a hard and dry clay, which had to be picked for the first 4 ft. The pipe layer averaged 28 ft. of laid pipe per hour and removed a 6 in. × 12 in. bench. The trench was back filled by hand. No sheeting was required. The costs follow:

Item	Cost per ft., cts.	Cost per cu. yd., cts.
Excavation by pipe layer, 20 cu. yds	0.3	16.5
Excavation, 407 cu. yds	22.2	30.0
Laying 8-in. pipe	1.4	.....
Backfill	6.0	8.1
Totals	29.9	54.6

The material which had to be picked cost approximately 35 cts. per cu yd.

Section 8.—Section 8 is 559 ft. stretch of 6 in. pipe. The average cut was 10 ft., minimum 9 ft., maximum 10½ ft. The average width of trench was 22 ins. The pipe layer averaged 36 ft. of laid pipe per hour, and removed a 12 in. × 12 in. bench. The trench was back filled by hand. The costs follow:

Item	Cost per ft., cts.	Cost per cu. yd., cts.
Excavation by pipe layer, 20 cu. yds	0.4	11.5
Excavation, 340 cu. yds	14.3	23.5
Laying 6-in. pipe	1.0	.....
Backfill	6.4	10.5
Totals	22.1	55.5

A 6 in. house connection 56 ft. long was laid at the following costs:

Item	Cost per ft., cts.
Excavation	12.9
Laying pipe	2.0
Backfill	6.4
Total	21.3

The average cut was 8 ft. The average width of trench was 24 ins., the material was yellow clay.

The general expense for all work on this contract, which includes foremanship, water boy and incidentals, was 3 cts. per ft. of pipe. This cost is not included in the foregoing unit costs.

Contract 2, 1912.—Labor was very scarce and wages were high on this job. Laborers were paid 25 cts. per hour, while the pipe layer was paid 27½ cts. per hour. The foreman received 45 cts. per hour.

Section A.—On Section A a 272 ft. length of 10 in. line was laid. The average cut was 9½ ft., minimum 7 ft., maximum 10 ft. The average width of trench was 24 ins. For a stretch of 50 ft. the bottom material was all "muck" and necessitated the use of buckets for its removal. Considerable rain fell before the completion of this section, resulting in two cave-ins. The pipe layer excavated a trench 12 ins. deep and 15 ins. wide. The material encountered was black loam and a mixture of clay and sand. The unit costs follow:

Item	Cost per ft., cts.	Cost per cu. yd., cts.
Excavation by pipe layer, 13 cu. yds	1.6	33.0
Excavation, 170 cu. yds	23.9	38.2
Laying 10-in. pipe	2.8	......
Backfill	6.7	10.7
Water boy	0.8	......
Foreman	4.1	......
Totals	39.9	81.9

Section B.—On Section B a 420 ft. stretch of 8 in. pipe was laid. The average width of trench was 22 ins. The average cut was 9½ ft., minimum 9 ft., maximum 10 ft. The material was so hard that picks had to be used. The pipe layer excavated a 12 in. × 12 in. trench at the bottom. Most of the material was solid clay, making spading difficult. About 250 ft. had to be picked to a depth of 4 ft. The costs follow:

Item.	Cost per ft. cts.	Cost per cu. yd., cts.
Excavation by pipe layer, 15 cu. yds.	1.4	36.2
Excavation, 240 cu. yds.	25.0	43.7
Laying 8-in. pipe	3.2	......
Back fill	7.3	12.8
Foreman	4.0	......
Totals	40.9	92.7

Section C.—Section C consisted of a 292 ft. length of 6 in. pipe. The average cut was 9½ ft., minimum 9 ft., maximum 10 ft. The average width of trench was 20 ins. The weather was very wet. The pipe layer removed a 10 in. × 12 in. bench. The material was sand and clay and was good spading. The costs follow:

Item.	Cost per ft. cts.	Cost per cu. yd., cts.
Excavation by pipe layer, 20 cu. yds.	0.8	11.7
Excavation, 150 cu. yds.	15.4	30.0
Laying 6-in. pipe	1.7	......
Back fill	5.5	10.7
Foreman	4.0	......
Totals	27.4	52.4

Contract 3, 1912.—The rate of wages on Contract 2 was the same as on Contract 1.

Section A.—On Section A a 374 ft. length of 12 in. pipe was laid. The average cut was 9.7 ft., minimum 8½ ft., maximum 14 ft. The average width of trench was 26 ins. The material encountered was a mixture of sand and clay and was good spading. No bracing was required. The weather was ideal. In back filing the back-fill was tamped in layers of 10 ins., one tamper to every two shovelers. The pipe layer excavated a trench 8 ins. deep by 18 ins. wide. The costs follow:

Item	Cost per ft. cts.	Cost per cu. yd., cts.
Excavation by pipe layer, 14 cu. yds.	0.5	13.3
Excavation, 270 cu. yds.	25.4	35.2
Pipe laying, 12-in.	2.3	.....
Back fill	10.8	14.9
Foreman	2.4	.....
Totals	41.4	63.4

Section B.—Section B is 265 ft. long. A 10 in. pipe line was laid. The average width of trench was 26 ins. The average depth was 9½ ft., minimum 8 ft., maximum 11½ ft. No bracing was required. A considerable number of small boulders made excavation difficult. The material traversed was made land and clay. The weather was ideal. The trench back filling was tamped by hand as in Section A. The pipe layer excavated a trench 12 ins. deep by 15 ins. wide. The costs follow:

Item	Cost per ft., cts.	Cost per cu. yd., cts.
Excavation by pipe layer, 12 cu. yds.	0.9	20.0
Excavation, 180 cu. yds.	30.1	44.3
Laying pipe, 10-in.	3.0	.....
Back fill	11.1	16.3
Foreman	4.0	.....
Totals	49.1	80.6

Section C.—Section C is a 10 in. line 330 ft. long. The average width of trench was 24 ins. The average depth was 9½ ft., minimum 8 ft. 6 ins., maximum 11 ft. 3 ins. The weather was ideal. The material was mostly clay with some loam. The back filling was not tamped. The pipe layer excavated a 6 in. × 15 in. trench. The costs follow:

Item	Cost per ft., cts.	Cost per cu. yd., cts.
Excavation by pipe layer	0.3	16.5
Excavation, 175 cu. yds.	22.4	42.2
Pipe laying, 10-in.	2.6	.....
Back fill	3.9	7.3
Foreman	3.2	.....
Totals	32.4	66.0

CONCLUSION

The labor costs of building manholes on Contract 1 show an average cost of 85 cts. per ft. depth, while on Contracts 2 and 3 with higher rate of wages prevailing, the cost averages $1.25 per ft. of depth.

The labor costs of excavating trenches of various depths and widths, supplemented by observation, show that the cost per cubic yard of excavating a trench 22 ins. wide is no greater than is the cost for excavating a trench 24 ins. or 26 ins. wide. From this it appears that a saving can be effected by giving particular attention to the width of the trench to be excavated. Small contractors are, as a rule, prone to choose a constant width for pipe up to 12 ins. in diameter; whereas, a saving would result, in shallow excavations, by following a rule such as: add 14 ins. to the pipe diameter to secure the trench width. In a shallow trench up to about 8 ft. a man can work efficiently if the width is only 20 ins.

The cost of back filling averages 8½ cts. per cu. yd. on contract 1 and 10 cts. per cu. yd. on contracts 2 and 3.

For the purpose of estimating the cost of excavation from trenches up to 10 ft. in depth with labor at 20 cts. per hour, material which requires no picks, and an absence of water may be taken at 25 cts. per cu. yd. When water is encountered the cost may be several times that figure. For the pipe layer 12 cts. per cu. yd. can be used.

The cost per lineal foot for the actual laying of the pipe, which includes the lowering, the bedding of and the joining of the pipe may be arrived at approximately by multiplying the diameter of the pipe in inches by 0.0025 when the pipe layer receives 25 cts. per hour and his helper 20 cts. per hour.

A saving is effected by having the pipe layer carry a cut in addition to laying the pipe. The figures show a reduction of 50 per cent in cost per cu. yd. for this excavation when compared to the cost per cu. yd. of the trench men.

On any sewer construction the most important individuals are the men who lay the pipe and the men on the two benches preceding. Those men set the pace or speed of excavation for the entire gang and should, therefore, be paid accordingly.

The author of this article was foreman on the jobs described, and, also, recorded all the costs given.

Cost of Pipe Sewers and Appurtenances in Water Bearing Sand.—The following data, published in Engineering and Contracting, May 10, 1911, are given by A. P. Melton, who was city Engineer in charge of the work.

During the years 1909–10 three district sewers were laid in Gary, which will be here referred to as Local Sewers Nos. 8, 9 and 10. These sewers were laid, for the most part, in water bearing sand. In some cases water stood in the ground within a foot of the surface. In all cases where water was encountered it was drawn down by pumping. In some cases small hand pumps were sufficient, but in the majority of cases steam power pumps were used.

Suction lines were laid horizontally along the braces and two-way valves were placed in this main every four feet; 1¾-in. well points were driven into the sand with their tops near the water line and their bottoms from 1 ft. to 6 ins. below the grade of the sewer. The points were connected to the suction main at the valves by means of a short piece of flexible hose.

The excavating was done by teams and slip scrapers until the level of the ground water was reached. Below that point, after the water had been pumped out, the excavating was done by hand. The backfilling was done by teams and slip scrapers. The trenches were about 4½ ft. wide and were sheeted in all cases except on about two-thirds of the 12-in. lines in Sewer No. 10, where the cut was small. The cost of backfilling is included in all cases. The labor of sheeting is included unless otherwise stated. The sheeting was all pulled as the backfilling progressed.

European laborers were employed on the common labor and all work was done under labor union conditions.

The standard brick manholes and concrete gutter inlets, are shown by Figs. 1 and 2, respectively.

Local Sewer No. 8

747 ft. of 18-in. Sewer.

	Total	Cost per lin. ft. cts.
Teams and drivers, 49 days at $5.50	$ 269.50	36.08
Foreman, 19 days at $3.00	57.00	7.63
Laborers, 208 days at $2.00	416.00	55.70
Tenders, 30 days at $2.00	60.00	8.03
Pipe layers, 12 days at $2.75	33.00	4.42
Mixers, 14 days at $2.00	28.00	3.75
Sta. engr., 21 days at $3.00	63.00	8.43
Firemen, 21 days at $2.25	47 25	6.33
Pipeline men, 26 days at $2.00	52.00	6.96
Water boy, 6 days at $1.00	6.00	0.80
747 ft. of 18-in. pipe at 37½ cts	280.12	37.47
Hauling pipe at 6 cts. per ft	44.82	6.00
Total	$1,356.69	181.60

Cost of sheeting trench and coal for boiler are not included in the above. This sewer was laid in water bearing sand. Well points were used for pumping. The average depth of cut was 14.5 ft.; maximum cut 18.0 ft.

	Total	Cost per lin. ft., cts.
1,125 ft. of 15-in. Sewer.		
Teams and drivers, 14½ days at $5.50.....	$79.75	7.08
Foreman, 16½ days at $3.00..............	49.50	4.40
Laborers, 235½ days at $2.00.............	471.00	41.85
Tenders, 20 days at $2.00................	40.00	3.55

Well points and small pump used to remove about 6 ins. of water.

Cost of Constructing a Small Submerged Sewer Outfall Into a Stream.—J. C. Schneidwind in Engineering and Contracting, June 14, 1911 gives the cost of constructing the Leland Ave. outfall into the North Shore Channel Chicago as follows:

Briefly the design requires the end of the sewer to be built as close as possible to the water edge where a concrete bulkhead is placed and the sewer carried through it to the face. At a sufficient distance back from the face, an ordinary junction pipe is placed with the connection on the flow line of the sewer. This in turn is joined by means of straight and curved tile pipes to a cast iron water pipe which extends into the water about 2 ft. below the surface. To deflect the sewage into the drain pipes, a brick weir is placed at the joint on the down stream side of the junction, and of sufficient size to care for a quantity equal to two times the dry weather flow plus 10 per cent.

The construction of the Leland Avenue outfall was carried on as follows: after the sewer was built to the site of the bulkhead, the excavation for the latter was completed and filled with concrete to a depth of 6 ins. The junction pipe was then placed in its proper position and held by a block and tackle, while the connection with the cast iron pipe was made. Concrete was

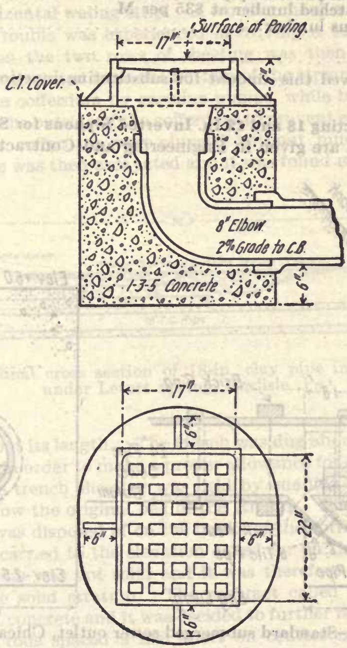

FIG. 2.—Standard concrete gutter inlets, Gary, Indiana.

then placed and securely tamped around the pipes to protect them from disturbance, after which the work was merely a matter of constructing a cradle for the sewer proper and junction pipe. Elevations were taken on the latter to discover a settlement, if any, but none of material importance was observed. The next pipe was then set and in the joint was placed the brick weir. To fit the last pipe flush with the form the exact measurement was taken and a pipe cut to fit. The balance of the work consisted only of filling the form with concrete.

The work was carried on by direction of a foreman, who did the necessary mason work, and a gang of six laborers. The concrete was composed of 1 part Portland cement, 2 parts torpedo sand and 4 parts crushed stone. The temized cost was as follows:

1 foreman 5/8 day at $10	$ 6.25
3 laborers (excavating), 1/2 day at $3.75	5.62
5 laborers (concreting), 1 day at $3.50	17.50
7 cu. yds. crushed stone at $1.65	11.55
4 cu. yds. torpedo sand at $1.50	6.00
11 bbls. Portland cement at $1.50	16.50
5 lin. ft. cast iron pipe at $1.00	5.00
6 lin. ft. 6-in. tile pipe at 10 cts	.60
2 lin ft. 24-in. junction pipe at $1.50	*3.00
100 lin. ft. matched lumber at $35 per M	3.50
Miscellaneous lumber	2.00
Total	$77.52

*Contractor allowed this amount for substituting junction pipe for straight pipe.

Costs of Constructing 18 and 12 In. Inverted Siphons for Sewer Crossings.—The following data are given in Engineering and Contracting, April 29, and

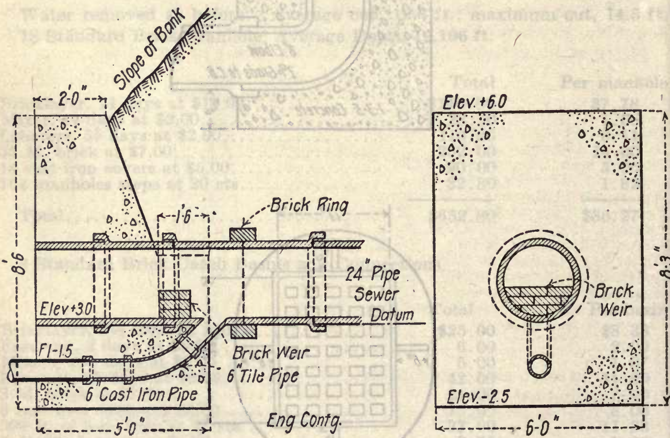

FIG. 3.—Standard submerged sewer outlet, Chicago, Ill.

Aug. 12, 1914, by C. A. Bryan who was resident engineer for the work.

Cost of 18-in. Crossing.—The construction of the outfall sewer serving the northern and the western section of the Borough of Carlisle, Pa., necessitated making a crossing of the Letort Spring, a stream flowing through the eastern section of the borough, in order to connect this sewer with the main outfall sewer.

The width of the spring at the point where the crossing was made was 33 ft. at the water surface. The channel itself was, however, about 15 ft. wide, the remainder of the cross-section being more or less choked with mud and silt, and through this part of the section the velocity of flow was low. The average depth of water in the cross-section was 1.05 ft.

Soundings taken at the crossing showed that the bed of the spring was composed of a stratum of soft mud and clay about 4 ft. deep and underlaying this a stratum of stiff clay through which the soundings were not carried. It was therefore decided to construct this crossing in two sections, and to completely finish and fill in the first section before beginning work on the other.

Work was commenced on the eastern half of the crossing, and a cofferdam built extending from the eastern bank of the spring to a point a little beyond its center. The cofferdam was made about 20 ft. long and 5 ft. wide inside dimensions, and was built by driving two rows of 2-in. plank around the three sides exposed to the water. The plank used were 8 ft. long and were braced by one horizontal waling strip. A wooden maul was used to drive this sheeting and no trouble was experienced in driving it to a sufficient depth. The space between the two rows of sheeting was then filled with a well-puddled stiff clay excavated from the bottom of the stream. Water was then pumped out of the cofferdam by gasoline pumps, while bags filled with sand were piled around the outside of the cofferdam to prevent excessive infiltration. The leaks in this cofferdam were plugged without much difficulty. The trench for the pipe was then excavated and it was found necessary to use tight

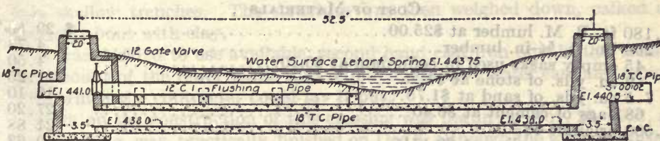

FIG. 4.—Longitudinal cross section of 18-in. clay pipe inverted sewer siphon under Letort Spring, Carlisle, Pa.

sheeting throughout its length. The trench was dug about 3 ft. wide inside to inside of sheeting in order to make a proper allowance for clearance of the bells of the pipe. The trench sheeting was held by one line of horizontal waling strips set just below the original bed of the stream. The material excavated from the trench was disposed of on the banks of the spring. When the excavation had been carried to the elevation called for on the plan, it was found that the foundation was not solid and it was therefore carried about 8 ins. deeper to a more solid stratum. The contract called for surrounding the pipe with 6 ins. of concrete and it was decided to further reinforce this by using 1-in. round iron rods spaced 9 ins. apart on centers underneath the pipe.

Work on the western half of the crossing was started a few days after the completion of the work just described. This work was handled in the same manner. The brick manholes at both ends of the crossing were then built. The water leaking into the cofferdam was handled by two gasoline diaphragm pumps.

In order to provide a method of flushing out this syphon it was decided to connect the manhole on the west bank of the spring with the spring by a 12-in. cast iron pipe resting on the bed of the latter. This pipe was provided with a 12-in. gate valve which was set in a valve chamber built into the manhole.

Work on the construction of this crossing was started on Sept. 12, 1913, and completed on October 1. The itemized cost of this work to the contractor was as follows:

COST OF LABOR

Item	Amount
18 hrs. supervision at $0.80	$ 14.40
188 hrs. foreman at $0.30	56.40
40 hrs. carpenters building cofferdam at $0.35	14.00
40 hrs. carpenter helper on above at $0.17½	7.00
280 hrs. excavation at $0.17½	49.00
80 hrs. stopping leaks at $0.17½	14.00
20 hrs. stopping leaks at $0.20	4.50
153 hrs. driving sheeting at $0.17½	26.78
35 hrs. pipe laying at $0.17½	6.13
11 hrs. pipe laying at $0.27½	3.03
80 hrs. mixing and placing concrete at $0.17½	14.00
5 hrs. mixing and placing concrete at $0.20	1.00
40 hrs. backfilling at $0.17½	7.00
37 hrs. moving pumps at $0.17½	6.48
36 hrs. engineer at $0.40	14.40
44 hrs. mason at $0.30	13.20
44 hrs. mason helper at $0.17½	7.70
25 hrs. cleaning up at $0.17½	4.38
1 hr. cart at $0.27½	0.28
8 hrs. team at $0.45	3.60
3 hrs. hauling 12-in. pipe at $0.45	1.35
Total cost of labor	$268.63

COST OF MATERIALS

1,180 ft. B. M. lumber at $25.00	$ 29.50
200 lin. ft. ⅝-in. lumber	4.73
45 empty sacks used in cofferdam at $0.10	4.50
9 cu. yds. of stone at $1.25	11.25
7.5 cu. yds. of sand at $1.75	13.10
68 bags of cement at $0.40	27.20
2,500 brick at $8.75	21.88
55 gals of gasoline at $0.17½	9.63
52 lin. ft. 18-in. terra cotta pipe at $0.60	31.20
0.448 tons 12-in. c. i. pipe at $24.90	12.28
2 manhole frames and covers at $6.70	13.40
10 manhole steps at $0.35	3.50
1 cut stone at $2.25	2.25
1 12-in. valve at $39.50	39.50
Leading pipe into valve	2.50
Steel reinforcement	3.40
4 diaphragms for pumps at $3.25	13.00
Oil for pumps	1.50
25 days of pumping for gas pumps at $1.00	25.00
Total cost of materials	$269.32
Total cost of labor	268.63
Total cost of crossing	$537.95

The itemized cost of constructing the 12-in. flushing main and valve in the manhole on the western bank of the spring was as follows:

61 hrs. of laborers building cofferdam at $0.17½	$ 10.68
17 hrs. of mason at $0.30	5.10
3 hrs. of teams hauling supplies at $0.27½	0.83
1 12-in. gate valve at $39.50	39.50
450 brick at $8.75 (M)	3.94
1 cut stone	2.25
2 cu. yds. of stone (crushed) at $1.25	2.50
2 cu. yds. of sand at $1.75	3.50
10 bags of cement at $0.40	4.00
300 ft. B. M. lumber at $26.00	7.80
10 gallons of gasoline at $0.15	1.50
Leading pipe into valve	2.50
Total cost of 12-in. flushing device	$ 84.10

Deducting the cost of constructing the 12-in. flushing device from the total cost of the crossing gives $453.85 as the cost of the contractor of constructing this inverted siphon together with the two manholes and other appurtenances.

The length of this crossing was 52.5 lin. ft., or the cost of construction amounted to $8.65 per lineal feet.

Cost of 12-in. Crossing.—The 10-in. branch sewer serving the northeastern section of the borough, joins the main outfall sewer, constructed along the east bank of the Letort Spring, at the corner of North St. and Porter Ave. In order to effect this junction it was also necessary to carry this branch sewer across the spring.

In making this crossing a complete cofferdam was made so that the work could be finished without interruption.

The spring at the point where the crossing was made was about 33 ft. wide and about 1.9 ft. deep in the deepest portion. A timber frame work was first built from 2-in. by 10-in. plank. This frame work, built on the bank, was 32 ft. long and 6.5 ft. wide and 3.5 ft. deep. At the center of the long sides of the frame a flume was built across it. This flume was 5.65 ft. wide and its bottom was 1 ft. 3 ins. below the top of the frame at upper side and with a pitch of 3 ins. in the width of the frame work. When completed the frame work, sheathed on the sides, was placed across the stream, the sides resting in two shallow trenches. The structure was then weighed down, calked and banked about with clay.

It was decided to use available, second hand cast iron pipe in this crossing on account of the fewer joints thus required and the greater ease and rapidity with which the contracter could lay it out.

Work on the construction of this crossing was begun on Nov. 20, 1913, and the crossing was practically finished on Dec 3, although the work of finishing the construction of the various manholes, cleaning up, etc., was not completed until Dec. 19.

The itemized cost of all work at this crossing was as follows:

Cost of labor	Amount
Superintendent, 16 hours at 80 cts	$ 12.80
Foremen, 106 hours at 40 cts	42.40
Foremen, 6 hours at 30 cts	1.80
Excavation, 651 hours at 17½ cts	113 93
Sheeting and bracing, 100 hours at 20 cts	20.00
Engineer, gas pumps, 82 hours at 40 cts	32.80
Mason, 83 hours at 30 cts	24.90
Mason helper, 83 hours at 17½ cts	14.53
Carpenter, 57 hours at 35 cts	19 95
Carpenter helper, 111 hours at 17½ cts	19.43
Sheeting and bracing, 100 hours at 17½ cts	17.50
Laying pipe, 61 hours at 20 cts	12.20
Laying pipe, 50 hours at 17½ cts	8.75
Concreting, 147 hours at 17½ cts	25.73
Backfilling, 80 hours at 17½ cts	14.00
Miscellaneous, 60 hours at 17½ cts	10.50
Cleaning up, 38 hours at 17½ cts	6.65
Hauling material, 4 hours at 45 cts	1.80
Total cost of labor to complete all work at this crossing	$399.67

Cost of materials:	Amount
Bags of cement, 87 at 40 cts	$ 34.80
Cu. yds. of stone, 25 at $1.25	31.25
Cu. yds. of sand, 13 at $1.75	22.75
Lumber for sheeting and piles, 2.0 M. ft. B. M. at $26	52.00
Flanged cast iron pipe, 48 lin. ft. 12-in.	61.44
Gaskets separating pipe, 6 at 5 cts	.30
Gallons of gasoline, 80 at 15 cts	12.00
Manhole frames and covers, 2 at $6.70	13.40
Lamphole frame and cover, 1 at $4.20	4.20
Cast iron pipe, 12 lin. ft. 10-in	6.40
Valve, 1 10-in. at $18	18.00
Brick, 2,000 at $8.75	17.50
Diaphragms for gasoline pumps, 5 at $3.20	16.00
Gasoline torches, 3 at $1.25	3.75
Pumping with gasoline pumps, 25 days at $1.00	25.00
Total cost of materials and plant	$318.79
Total cost of labor	399.67
Total cost of crossing to contractor	718.46

The itemized cost of constructing the 10-in. flushing device to the contractor was as follows:

Labor building cofferdam, etc., 50 hours at 17½ cts	$ 8.75
Mason labor, 30 hours at 30 cts	9.00
Mason helper, 30 hours at 17½ cts	5.25
Gasoline, 10 gals. at 15 cts	1.50
Valve, 1 10-in. at $18.00	18.00
Cast iron pipe, 12 lin. ft. 10-in	6.40
Lamphole frame and cover, 1 at $4.20	4.20
Brick, 300, $8.75 per M	2.64
Stone, 1.5 cu. yds. at $1.25	1.88
Sand, ¾ cu. yds. at $1.75	1.31
Cement, 7 bags at 40 cts	2.80
Lumber, 300 ft. B. M. at $26.00	7.80
Total cost of flushing device	$ 69.53

Deducting the cost of constructing the flushing device from the total cost of the work leaves $648.93 as the cost to the contractor of making this crossing. The length of this crossing from the center of the manhole on the east bank of the spring to the corresponding point on the west bank was 51.5 ft., or the coat of this crossing per linear foot amounted to $12.60.

Cost of Concrete Sewer Pipe at Bellingham, Wash.—H. A. Whitney gives the following in Engineering and Contracting, Feb. 8, 1911.

The city of Bellingham, Wash., is using cement and concrete pipe for storm water sewers. This pipe is made under a guarantee by the manufacturers. While the city does not stipulate any process of manufacture as long as the finished product conforms to the specifications, all the cement pipe used is made by one local concern and gives satisfactory results, as compared to the vitrified clay sewer pipe. All sizes of pipe from 4 ins. to 24 ins. are machine made. The process is as follows:

A flask made in halves is placed around a cast iron core, in a vertical position. The cement is placed in the annular space thus formed in batches, dry mixed, having 8 per cent to 10 per cent water. As the cement is deposited in the mold it is automatically tamped with a wood tamper running at the rate of five blows per second. The core in the meantime is kept stationary while the pipe is revolved around it, thus giving a smooth glazed effect to the inside. The actual cost to the manufacturer is as follows:

4-in. pipe	4 cts. per ft.
6-in pipe	7 cts. per ft.
8-in. pipe	14 cts. per ft.
10-in. pipe	19 cts. per ft.
12-in. pipe	25 cts. per ft.
15-in. pipe	35 cts. per ft.
18-in. pipe	50 cts. per ft.
20-in. pipe	65 cts. per ft.

The above costs are based upon: Cement at $2.30 per bbl.; sand at $1.10 per cu. yd.; gravel at $1.20 per cu. yd.; labor at $2.25 per day, 8 hrs.; foreman at $4 per day, 8 hrs.

The pipe as sold, delivered upon the line of work at the following rates:

4-in. pipe	11 cts.
6-in. pipe	16½ cts.
8-in. pipe	22½ cts.
10-in. pipe	32½ cts.
12-in. pipe	40 cts.
15-in. pipe	60 cts.
18-in. pipe	75 cts.
20-in. pipe	90 cts.

The difference in manufactured and delivered price, represents hauling, breakage and profits.

Cost of 8-Ft. Circular Reinforced-concrete Sewer.—The following labor-cost summary taken from Engineering News, Feb. 18, 1915, is for an 8-ft. circular reinforced-concrete sewer built between electric-car tracks in a street within the commercial district of San Francisco (Howard St. from Second St. to Fourth St., a distance of 1650 ft.):

UNIT COSTS OF 8-FT. SEWER

Excavation	$ 7.86 per lin. ft.	$0.618 per cu. yd.
Lagging	6.450 per lin. ft.	0.106 per sq. ft.
Forms	1.765 per lin. ft.	0.070 per sq. ft.
Steel	1.480 per lin. ft.	0.028 per lb.
Concrete	6.915 per lin. ft.	5.310 per cu. yd.
Brick lining	0.691 per lin. ft.	0.046 per brick
Finishing	0.348 per lin. ft.	0.014 per sq. ft.
Backfill	2.020 per lin. ft.	0.202 per cu. yd.
Miscellaneous	0.567 per lin. ft.	
Total	$28,096 per lin. ft.	

The pavement consisted of basalt blocks on sand. During construction the street was left open to vehicular traffic. Ordinary labor was at the rate of $0.37½ per hr. and superintendence at $0.50 and $0.625 per hr.

Labor Costs on Concrete Sewers.—D. B. Davis, gives the following in Engineering and Contracting, April 14, 1920.

The data show the labor required and the procedure followed in constructing a 48-in. diameter monolithic concrete sewer in Richmond, Ind., on which semi-circular forms were used. The contractor had 100 lin. ft. of the half circle forms, of which he used 50 ft. for invert and 50 ft. for the arch. The concrete was machine mixed; the wheel being about 100 ft. from the mixer to the forms. The men were good workers.

The order of the day's work was as follows:

6:30 a. m. to 9:30 a. m.—Sliding invert forms ahead and setting.
9:30 a. m. to 11:15 a.m.—Pouring concrete invert.
11:15 a. m. to 2:30 p. m. (1 hour for dinner)—Moving and setting arch forms.
2:30 p. m. to 4:00 p. m.—Pouring concrete arch.
4:00 p. m. to 5:30 p. m.—Pouring flow-line strip 2 ft. wide.

The labor required for a day's run of 50 ft. of sewer was:

	Total labor, hours
Invert forms—8 men in gang	24
Pouring invert—12 men in gang	21
Arch forms—6 men in gang	13
Pouring arch—10 men in gang	15
Pouring base strip—10 men in gang	18
Total labor, hours	91

Or 1.82 labor hours per lineal foot.

The organization of concreting gang was:

2 men spreading and tamping concrete about forms.
3 men shoveling gravel in mixer.
4 men wheeling concrete a distance of 100 feet.
1 man running concrete mixer.
2 men setting metal, etc.

The extra men used for pouring concrete were taken from the gangs doing excavation.

The following data shows the labor required to build a 48-in. diameter monolithic sewer, using complete circular forms. The contractor had six sections of form, each section was 6 ft. long. When these were assembled it made a length of 35 ft. The concrete was machine mixed and the wheel for concrete was about 90 ft. The workmen were exceptional and the conditions good.

The labor required for a day's run of 35 ft. of sewer was:

4 men working 2½ hours each removing and resetting six sections of complete circular forms, or total of	10 hours
4 men working 6 hours each and 7 men working 2 hours each pouring concrete for complete circle and for flowline strip, changing runs, etc., or total of	38 hours
Total labor required for 35 ft.	48 hours

Or 1.37 labor hours required for each lineal foot.

The labor required to build 175 ft. of 42-in. monolithic sewer, using the complete circular forms with the same gang as above, was:

	Hours
First day's work, poured flow-line	16
Second day's work, built 35 feet complete sewer	30
Third day's work, moving forms (rain)	10
Fourth day's work, built 35 feet complete sewer	35½
Fifth day's work, built 35 feet complete sewer	30¼
Sixth day's work, built 35 feet complete sewer	31½
Seventh day's work, built 35 feet complete sewer	30
Total labor for 175 ft. of sewer	183¼

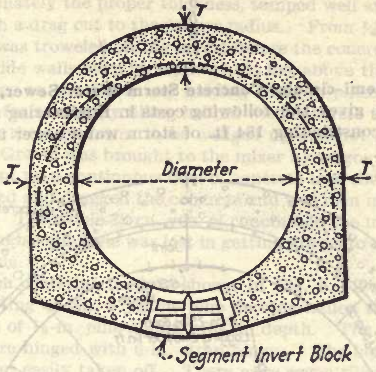
Or 1.05 labor hours required per lin. ft.

In building 245 ft. of 36-in. monolithic sewer using complete circular forms, the gang built 35 ft. of sewer each day.

It required 31½ hours each day for 7 days or total of 220 hours. Or 0.90 labor hours required per lineal foot.

It will be observed that it requires approximately the same number of labor hours on the form labor for the 36-in., the 42-in. and the 48-in. diameter sewers.

Fig. 5 shows the standard type of monolithic concrete sewer construction in Richmond, Ind. and the cost per lineal foot of labor to construct a 36-in., 42-in. and 48-in. sewer.



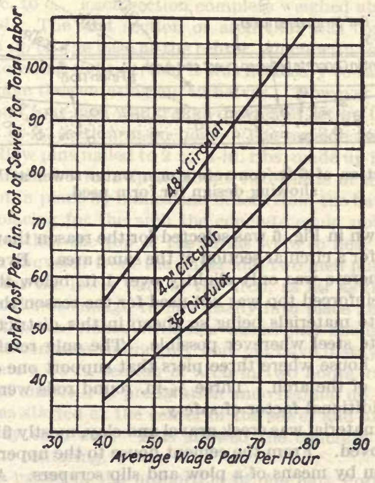


FIG. 5.—**Labor cost of building monolithic concrete sewers of standard section shown.**

In Fig. 5 the costs are plotted on the following basis:

36 in. diam. requires 0.90 hours per lin. ft.
42 in. diam. requires 1.05 hours per lin. ft.
48 in. diam. requires 1.37 hours per lin. ft.

The principal dimensions of the pipe are as follows:

Inside diameter, in.	Thickness "T," ins.	Volume concrete, cu. ft.
36	4	3.5
42	4	5.0
48	5	7.3
54	5	8.5
60	6	11.2
66	7	14.3

Cost of 6-Ft. Semi-circular Concrete Storm Water Sewer, Webb City, Mo. E. W. Robinson gives the following costs in Engineering and Contracting, July 9, 1913, of constructing 184 ft. of storm water sewer through a lumber yard.

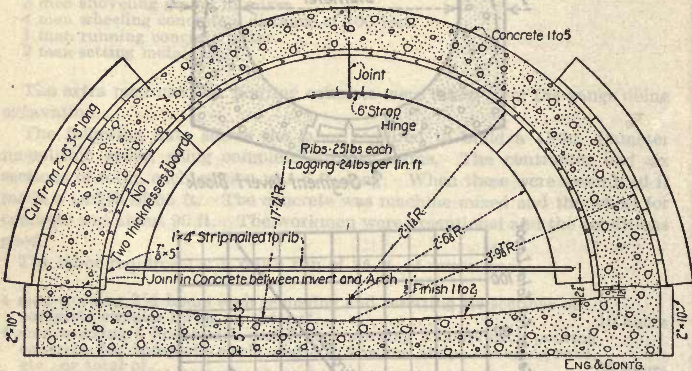

FIG. 6.—Cross section of 6-ft. concrete storm water sewer at Webb City, Mo., showing design for form used.

The section shown in Fig. 6 was selected for the reason that sufficient depth was not available for a circular section of the same area. Even as constructed the top of the concrete was only slightly over 1 ft. below the surface of the ground. A flat reinforced top was not used for the reason that it would have cost more, concrete materials being so cheap in this district that it pays to reduce or eliminate steel wherever possible. The only reinforcing used was under the cement house where three piers that support one end of the house rest on the crown of the arch. Three ½-in. round rods were inserted under each pier as an additional factor of safety.

The excavated material was creek gravel and clay, mostly fill, and was easily loosened and removed. From the cement house to the upper end the excavation was carried on by means of a plow and slip scrapers. All other excavation was taken out with pick and shovel and reshoveled into wagons which were dumped about 100 yds. from the site. No supports were needed under the projecting end of the cement shed for the reason that it was nearly empty all the time and was well supported by numerous other piers. The total cost for excavating 259 cu. yds. was $95.72, or a unit cost of about 37 cts. per cubic yard.

The base or invert was first concreted and allowed to set before the arch was started. Two-by-six pieces were used for the side forms, and were set accurately to line and grade from a line of center stakes. A Coltrin continuous mixer, No. 9, was mounted upon the bank of the trench and the concrete was chuted into the ditch and wheeled some 50 ft. each way. The concrete was placed to approximately the proper thickness, tamped well and shaped to the exact contour with a drag cut to the proper radius. From ¼ to ½ in. of 1 to 2 cement mortar was troweled on the invert before the concrete had taken its initial set. The side walls were brought up 1¾ ins. above the base by laying 2 × 4-in. scantlings on the finish and holding them in place by short pieces nailed to the side forms and by filling behind with concrete to the top. This was done to allow the arch forms to be wedged up and not let concrete flow under the sides. Gravel was brought to the mixer by wagons, and three men at the machine kept up a continuous flow of concrete into the trench. Three men placed, tamped and dragged the concrete and two men mixed and placed the mortar finish. The whole 33 cu. yds. of concrete in the invert was placed in nine hours, though some time was lost in getting gravel to the feeder and in moving the machine.

The form of arch centering used is shown in Fig. 6. Two 16-ft. sections were made, consisting of No. 2 yellow pine flooring nailed to ribs consisting of two thicknesses of ⅞-in. pine about 5 ins. in depth. The ribs were cut at the crown and were hinged with 6-in. strap hinges. The bottoms were held so as to be rigid yet easily taken off. There were seven ribs to each section, spaced 2 ft. 6 ins. c. to c. Each section complete weighed about 750 lbs. and was easily handled. The first section or arch that was concreted was not wedged far enough up off the base at the center, which with the swelling of the wood caused an exceeding tight fit, and it was necessary to take off the hinges at the crown and take the centering out in halves. However no other trouble was experienced, and four men would take down and set up both outside and inside forms for a 15-ft. section in an hour. The outside forms consisted of No. 2 1 × 4-in. yellow pine nailed to 2 × 4-in. ribs, made up in 16-ft. sections. They reached from the bottom up to about two-thirds of the heighth of the arch, and were held in place by stakes and braces from the bank of the trench.

In mixing and placing for the arch the concrete could not be chuted into place for the reason that the top of the forms were so near the level of the ground. One man shoveled from the mixer and two men placed and tamped it. The concrete for the lower part of the arch, as far as the outside forms extended, was mixed wet enough to flow easily into place ahd required little tamping, but the top was mixed with less water, just enough being used to permit tamping the concrete thoroughly and yet have it stay in place. Five men would complete a 15-ft. section of arch in two hours, consisting of one hour actual run and one hour of preparation and cleaning up. The construction of the arch was started at the center of the sewer and alternate sections were built each way each day. This allowed the concrete 48 hours to set before removing the centering.

All concrete was mixed in the proportion of one part Portland cement to five parts of "chats" or "mill tailings." The latter is the by-product of the zinc and lead mines of this district and can be had for the hauling. In this case the nearest suitable pile was at such a distance that 1 cu. yd. an hour was the best the teamsters could do. It consists of crushed white and blue flint ranging in size from 1/16 to ¾ in. in size, with sufficient of the finer material to practically fill the voids in the larger. When mixed wet in the proportion of 1 to 5 a very dense concrete was produced.

The following data give the actual cost, except overhead charges and back filling, reduced to lineal foot of sewer:

	Lineal ft. of sewer	Total lineal ft. of sewer
Excavation:		
259 cu. yds. at 37 cts.	$0.5202	$0.5202
Lumber (two 2 × 6) 2 ft. B. M. at 2¼ cts.	0.0450	
Labor, two men 0.153 hrs. at 22⅜ cts.	0.0338	
		0.0788
Base—concrete in place (1.18 cu. yds. per lin. ft.):		
Foreman, at 30⅝ cts. per hr.	0.0299	
Laborers, 8, at 22⅜ cts. per hr.	0.1304	
Mixing machine, at $1 per hr.	0.0489	
Cement, $1.60 per bbl. on job	0.3152

Total per lin ft. sewer		$2.4835
Total per cu. yd. of concrete		5.956

Nine hours was a day's work and common labor was paid $2 per day for concreting and $1.75 for excavation. The above price for excavation included a foreman at $2.75 per day and teams at $3.50 per day. The mixing machine belonged to a local contractor and was rented for $1 per hour. The work was stopped twice on account of rain, but most of the time the weather was ideal for concreting.

Cost of a Large Concrete Sewer.—E. T. Thurston gives the following in Engineering and Contracting, Sept. 12, 1917.

The work consisted of the complete construction of 450 ft. of 8-ft. 6-in. × 9-ft. standard horseshoe section, reinforced concrete sewer, 100 ft. 8-ft. 6-in. × 9-ft. extra-heavy, horseshoe section, reinforced concrete sewer under a 4-track main line railroad crossing, 908 ft. 7-ft. 6-in. diameter, circular-section, reinforced concrete sewer with vitrified brick invert, and 2,695 ft. 5-ft. 2-in. × 7-ft. 9-in. egg-shape, reinforced concrete sewer with brick invert (including a 90° curve of 21 ft. radius and two 10-ft. taper sections connecting the respective standard sections), representing a total length of 4,173 ft. of sewer. Auxiliary structures comprising 18 standard brick manholes, 26 concrete catch basins and catch-basin connections consisting of 79 ft. of 18-in. vitrified pipe and 1,724 ft. of 12-in. vitrified pipe are not included. The sewer for most of its length runs in a 100-ft. street, its center line being located 22 ft. from the center line of the street, and from 8 to 10 ft. from the center line of a single-track electric street railway, the operation of which was suspended during construction. The required excavation was from 9 ft. to 20 ft. 6 in. deep, averaging 15 ft. 3 in.

For the first 1,000 ft. the excavation averaged 12 ft. in depth through a layer of heavy, black gumbo about 6 ft. thick, overlying black, muddy silt carrying considerable water and in places approximating quicksand. The conditions required close sheeting and heavy timbering and much trouble was had with sloughing sides and seeping water. This changed gradually to stiff yellow clay mixed with black gumbo overlying water-bearing gravel and finally to very stiff yellow clay, difficult for the steam shovel to handle without the assistance of its crowding engine. For two-thirds the length of the trench the ground required constant attention and careful shoring to ensure against cave-ins Ten street intersections were crossed, six of which carried live sewers and water mains and one carried a 4-track, main-line railroad, one a 2-track interurban railroad and one a 3-track electric street railway, a concrete sewer culvert and a network of heavy water mains. The work was commenced in the middle of March, 1914, and was completed with the end of October, 1914.

Organization and Equipment.—The original working equipment consisted of a steam shovel, two concrete mixers supported on trucks, charging barrows, concrete hoppers and chutes, 2-yd. dump wagons, slip scrapers, 2 diaphragm pumps, 1 gas-driven centrifugal pump and miscellaneous small tools such as shovels, picks, mattocks, German hoes, etc. A locomotive crane with equipment of dump buckets was added later.

The working force consisted of a superintendent, a time-keeper, an engineer, 6 foremen (overseeing respectively the finishing of the excavation, the shoring and lagging of the trench, the concrete work, the steel reinforcement, the handling of forms and the extra gang constructing catch-basins and outlying manholes and connections with same, gutters, curbs, etc.), the steam shovel crew, a general mechanic, carpenters and laborers; to which was subsequently added an engineer and a signal-man for the locomotive crane.

The superintendent had active general charge of the work, assisted by the engineer, who in addition attended to overseeing the manufacture and handling of the forms and the bending of steel reinforcement, the forms being designed at the main office, the ribs sawed out to order in a planing mill and the forms made up on the job. Had it not been impossible at the commencement of the work to secure a general superintendent that was competent to read and interpret plans and specifications, the engineer would not been necessary, and during the latter half of the work his services were dispensed with.

The timekeeper kept a carefully segregated record of time, employing a mnemonic system of record and making four round trips per day over the entire work to secure a classified record. He also assisted in keeping track of materials and supplies and made out and forwarded the superintendent's daily report to the head office.

The excavation foreman had charge of a gang of about 30 laborers which followed the steam shovel, shored or lagged the trench, finished the trench to size, line and grade by templet, excavated street crossings and installed the underdrains. The excavated material was handled out of the ditch by stages.

The concrete foreman supervised the work of a gang of 10 men mixing and placing concrete and assisting the foreman carpenter in handling the forms.

The steel foreman had one or two assistants and when not engaged in placing reinforcement the gang was kept fairly busy bending it into the shape required.

The foreman in charge of the extra gang had a dozen or more men, depending on the demands of the more important part of the general work.

General Plan of Operation.—This required that the finishing gang keep close behind the steam shovel, but owing to the fact that the latter was limited in depth of cut to about 16 ft. and as the ground was of an extremely unstable nature and the excavated material very wet and difficult to handle, it was found impossible even approximately to follow this plan. The fact that the street crossings had to be excavated entirely by hand also delayed the progress of the finishing gang. For this reason the numerous delays in the steam-shovel work really retarded the general progress very little. At one time the shovel was 850 ft. ahead of the finishing gang.

After the trench had been finished to exact size and underdrain installed, the invert reinforcement was placed, then the invert forms, after which the first of the two mixers was moved into place and the invert poured. At the expiration of two days the forms were removed and brick invert, if any was required, laid, after which the arch reinforcement was placed; then the arch forms set in place and braced, and the balance of the concrete poured with the second mixer. The sides were poured first and after the concrete had set the wing forms were adjusted and braced and the top poured, the sides and arch generally, but not necessarily, being poured on different days.

After sufficient time, in the opinion of the inspectors, had elapsed, generally about a week, backfilling was proceeded with by means of a team with slip scraper, driver and holder, scraping into the trench that portion of the excavated material that had been dumped alongside for that purpose. The loose fill being thus completed up to within about a foot of the surface of the ground the whole ditch was flooded. Additional fill to bring the trench up to subgrade was brought by team direct from the steam-shovel excavation. The trench being thus filled practically to the level of the pavement it was left until near the end of the job when the entire work of repaving was done as one job.

Excavation.—The main excavation was done with a steam shovel mounted on trussed cross-timbers supported on hardwood rollers running on boards laid on either side of the proposed trench, spanning about 20 ft. on centers, the outfit pulling itself along as required by means of a cable attached to a deadman ahead. The shovel was especially equipped with a 1-cu. yd. dipper on a long dipper stick enabling it as mounted to dig about 16 ft. below grade.

The outfit, assembled as described, just as it had been returned from a similar job some 3 years before was rented for $250 per month on the assurance that the boiler and engine, though dirty and rusty, were in good working order, the boiler having received new tubes just before it was laid up in the yard. Two days overhauling and inspection by a complete crew and the contractor's supervision engineer resulted in a favorable report on the shovel, but, within the rental period, the boiler tubes were rerolled until they had to be reinforced, the boiler required sheathing and a new idler pulley, new bronze gear pinion, new friction strap and shoes, and ultimately an entire renewal of the crowding engine were necessary. Minor troubles, such as chain breakage, were of about daily occurrence and probably doubled the reasonable cost of operation.

Rental was paid for 161 calendar days. Of these, 22 days were required in moving from storage to job and return; 20 days were holidays or rainy days and 15 days were lost on account of jurisdictional disputes between labor unions, leaving 104 days available for actual work. Of these 104 working days 37 were devoted wholly to repairs and renewals, leaving only 67 days or 64 per cent of the working time or 41½ per cent of total time on which actual excavation, together with incidental repairing, was done.

Sufficient material for backfilling was piled on one side of the trench and the balance of the excavated material was dumped direct into wagons moving on the other side. In addition to the shovel crew, three attendants were in general required for miscellaneous work, principally keeping street clean around wagons, watching trench banks for signs of failure, planting and shifting deadmen and attending rollers while moving ahead. Owing to the structural limitations of the machine and the weakness or entire uselessness of the crowding engine, which limited the control and power of the dipper, the cut was not carried as close as desirable to the finish lines on the sides and bottom, and an average of about 6 in. on either side and from 6 in. to 5 ft. in the bottom was left for the finishing gang to remove.

The trench as dug by the shovel varied from 12 ft. to 7 ft. wide and from 7 ft. to 15½ ft. deep, and the material was mostly black gumbo and sandy clay, easy digging except in the last quarter of the work, where stiff, sandy clay, merging into hardpan, was encountered, and with a crippled crowding engine the digging was found difficult.

The shovel crew, working 8 hours per day, 6 days per week, with time-and-half allowance for overtime and double time for working Sundays and holidays, comprised the following:

	Per day and board
1 steam shovel engineer	$6.00
1 cranesman	4.25
1 fireman	3.00
3 laborer attendants	2.50

Coal was $9.00 per ton delivered.

Following the statement of the performance of the steam shovel:

STEAM SHOVEL PERFORMANCE

	Days	Mat'l.	Labor	Total	Per cu. yd.
Investigating outfit	4½	$.....	$ 70	$ 70	$.....
Moving on and off job—					
Moving ¼ mile and loading on car	5	42	318	350	......
Unloading and setting up on job	5½	7	110	117	......
Freight both ways	5	60	......	60	......
Moving off job ¼ mile and loading on car	3½	7	130	137	......
Unloading and returning ¼ mile to owner	3	......	100	100	......
Compensation insurance on labor	.....	40	....	40	......
Totals for moving	22	$ 156	$ 658	$ 814	$0.063
Operation—					
Rental and labor	161	$1,356	$1,494	$2,850	$0.228
Fuel and oil (coal at $9 per ton)	.....	1,063	......	1,063	0.082
Compensation insurance	.....	113	......	113	0.008
Repairs and renewals	37	256	474	728	0.056
Total operation cost	67	$2,788	$1,968	$4,754	$0.366

Note.—Quantity of material handled (13,000 cu. yd.) is given as originally estimated necessary to be done and takes no account of extra material handled because of slides and failure of banks.

The best day's performance of the shovel was 109 lin. ft. of trench or about 345 cu. yd. excavating to a depth of about 12 ft. 6 in. Toward the end of the job, while excavating to its maximum depth of 16 ft., its best day's work was 60 ft. of trench or 220 cu. yd. The shovel averaged 194 cu. yd. for each day in which digging was done and 125 cu. yd. for each available working day. In considering the performance record it should be borne in mind that the necessity for storing a portion of the excavated material along the trench for subsequent backfill enabled the shovel to keep at work regardless of whether the dump wagons were spotted promptly for loading, thus materially reducing what is usually the controlling factor in steam-shovel output.

Hand Excavation and Trimming.—The finishing gang with picks, shovels, German hoes and mattocks, did all the excavation left by the steam shovel, and finished the trench carefully to size, shape, line and grade and laid an underdrain of 4-in. tile covered with gravel which carried the seepage water to sumps constructed at intervals of about 600 ft., which in turn were relieved by an electrically operated, 2-in. centrifugal pump, tended chiefly by the general mechanic. During the first two months the gang comprised about 30 laborers at $2.50 per day (8 hours), a straw boss and interpreter (Italian) at $3.75, and a foreman at $5. The excavated material was shoveled by stages to the surface of the ground and thence into wagons. This portion of the work in particular was in very wet ground, necessitating the construction of dams of sacks of sand and the use of a 2-in. centrifugal pump and a 3-in. diaphragm pump. Latterly, a 5-ton locomotive crane with outfit of dump buckets was secured and mounted on the street car track alongside the trench, greatly facilitating the work. There was less mud to contend with in the portion of the trench served by the crane.

Preceding the finishing gang and immediately behind the steam shovel, a lagging gang of from 2 to 5 men at $2.50 and $2.75 per day, under a foreman at $4 per day, placed necessary shoring and lagging. The bracing, where sheeting, was required, comprised 2 lines of 6 × 8 rangers on either side with 6 × 8 spreaders on 6 to 8-ft. centers and 2-in. × 12-in. sheeting was driven behind these rangers, a total of 29,000 ft. B. M.; 2-in. plank was used for this lagging, very little of which was recovered intact. In addition 16,00 ft. B. M. Oregon pine lumber were used for rangers, spreaders, etc.

The total cost of deepening and finishing trenches to templet after rough work had been done by the steam shovel (except at street crossings which the shovel had to skip and which, therefore, was all hand work) and depositing material either in spoil bank or in wagons (except the section through unimproved street, which was all hand work under superior working conditions and from which all material was spoiled along the trench) was as follows, laborers receiving $2.50 and $2.75 per day and foreman $3 per day:

	Quantity, cu. yd.	Mat'l.	Labor	Total	Per cu. yd.
Hand work, by stages......	1,800	$.....	$4,382	$ 4,382	$2.43
Hand work, crane and bucket..................	3,100	766	3,059	3,825	1.23
Hand work, by stages, through unimproved street..................	1,700	......	1,553	1,553	.92
Tools, etc...............	.....	422	58	480	.....
Total................	6,600	$1,188	$9,052	$10,240	$1.55

The performance of the crane alone is summarized as follows, engineer on crane receiving $6 per day and signalman $5 per day:

	Mat'l.	Labor	Total	Per cu. yd.
Rent, crane (96 days)	$624	....	$ 624	$0.201
Rent, buckets	63	....	63	.020
Freight and cartage	15	....	15	.005
Renewals and repairs	9	$ 37	36	.012
Fuel, oil, etc	55	....	55	.018
Crew (engineer and signalman)	....	854	854	.276
Compensation insurance	69	....	69	.022
Total (3,100 cu. yd. handled.)	$835	$891	$1,726	$0.556

Forms.—The forms for invert, sides and arch of each standard section were constructed of 1½-in. solid and 1¾-in. and 2¾-in. built-up ribs, and 1 × 3 and 1 × 6 tongue and groove sheathing. The ribs were sawn to detail, delivered from mill to job in the knockdown and there, with sheathing, assembled into units. The invert units were made in one piece, but those of the arch in three pieces designed to collapse on removal of separator at bottom and be moved forward in sections. The arch and invert forms for the two 10-ft. taper sections, joining sewers of different shape and size, were built in place on ribs delivered sawn to detail. The forms for a 90° bend of 21-ft. radius were assembled and built in three sections comprising arch and sides intact, and three invert sections, on ribs taken from discarded straight units, and lowered into place bodily.

The forms for the 8-ft. 6-in. × 9-ft. horseshoe-shape and the 7-ft. 6-in. circular sewers were made in units 10 ft. long, but these were found too bulky and the forms for the arch and sides of the 5-ft. 9-in. × 7-ft. 6-in. egg-shape sewer were therefore made in 8-ft. units; 200 ft. of arch and 100 ft. of invert forms were made for the horseshoe-shape sewer, 200 ft. of arch and invert forms for the circular sewer, and 320 ft. arch and 100-ft. invert forms for the egg-shape sewer. The quantity was about right for the last-named, but turned out to be excessive by about 50 per cent for the others, due to erroneous anticipation of working conditions. The mill work on these built-up ribs cost about $23 per M ft. and on the solid ribs $10 per M ft.

The labor cost per foot of sewer built was as follows, carpenter's wages averaging $3.50 per day: Making forms, exclusive of millwork, 10.2 ct.; placing and removing forms 51.6 ct.; making, placing and stripping forms for curve, $8.52 per foot. The forms were greased with crude oil to facilitate stripping and the abutting ribs of adjoining sections were connected by special bolts with loose threads and thumb nuts, thus largely obviating the use of wrenches and accelerating the work of stripping and erecting.

The wing or outer arch forms for the horseshoe and circular sewers were made up in 10-ft. lengths of sheet steel reinforced with flat bars, sufficient to form 50 ft. of sewer. It was considered that these forms, which were so made as to be adjustable, by rebending over a form, to suit the varying extradosal curvature, would serve the entire job, but they proved somewhat awkward to handle and were not used for the egg-shape sewer, wooden forms being substituted.

Reinforcement.—The bars were bent to templet in the material yard close by and brought to the job ready to place. To avoid treading the invert reinforcement into the mud at the bottom of the trench, it was necessary to lay boards in the bottom and to tie the bars to position after the invert forms were in place, after which the boards were removed. The arch reinforcement was placed before the forms were set and rigidly tied and braced to position. The arch bars were required to be bent slightly but sharply 18 in. from each end so that when wired at the angle points to the invert bars they were in exact position. This expedient was noticeably effective in speeding up the work. In all 174,300 lb. of reinforcing steel was used, averaging 56.4 lb. per cubic yard concrete, and cost to handle 68 ct. per 100 lb., with labor averaging \$2.87½ per day.

Concrete.—The specifications provided: "All concrete used in the work shall be composed of Portland cement, sand and broken rock or cement and gravel in the proportion of 1 cu. ft. of cement to 2 cu. ft. of sand and 4 cu. ft. of stone."

The contractor's choice of a concrete plant was governed by the experience of another contractor on a similar job in a nearby locality and by the fact that a complete outfit of two mixers mounted on cross-timbers, with gas-engine power, trucks and rails complete, was ready to hand at a fair rental. The rails were laid on heavy longitudinal timbers on either side of the trench and the mixers mounted directly over the center of the sewer. One mixer was placed ahead to pour invert and the other followed to pour the arch. This plan was adopted to avoid delay involved in moving the heavy machinery back and forth, for the invert progressed at times 200 ft. ahead of the arch.

The outfit was expensive to install (this item amounting to about \$300), difficult and expensive to move (requiring the entire concrete gang, a team of horses and the undivided attention of the superintendent) gave frequent trouble and often flatly refused to perform at critical moments; and the splashing and dripping of the concrete out of the mixer on the workmen beneath rendered the working conditions decidedly unsatisfactory. After three months of trying experience, a new 12-cu. ft. mixer on trucks and equipped with side loader and electric motor was substituted. The new outfit worked alongside the trench and delivered the concrete to the forms by means of open metal chutes. It was specially fitted to be operated, fore and aft, by one man, was easily moved and the labor cost of mixing and placing the concrete was thereby reduced 40 per cent. The progress of the concreting was not chiefly dependent on the capacity of the plant, but on the advancement of other portions of the work, mainly the preparation of the trench.

The forecasting of the work was assisted by the following table (Table I) of roughly approximate unit quantities, from which delivery and placement of material was determined and performance of the gang judged during the progress of the work.

TABLE I.—APPROXIMATE UNIT QUANTITIES

Type.	8′ 6″ × 9′ 0″ —Standard—		8′ 6″ × 9′ 0″ —Heavy—		7′ 6″ cir.		5′ 2″ × 7′ 9″	
Total length, including taper sections	450 ft.		105 ft.		918 ft.		2,700 ft.	
	Invert	Arch	Invert	Arch	Invert	Arch	Invert	Arch
Concrete per ft., cu. yd.	.315	.685	.430	1.000	.185	.630	.148	.500
Rock, per ft., cu. yd.	.27	.58	.37	.85	.16	.53	.13	.43
Sand, per ft., cu. yd.	.14	.29	.19	.43	.08	.27	.07	.22
Cement, per ft. bbl.	.45	.98	.62	1.44	.27	.91	.21	.72
Rock, per 25 ft., cu. yd.	7	15	9	21	4	13	3	11
Sand, per 25 ft., cu. yd.	3	7	5	11	2	7	2	6
Cement, per 25 ft., bbl.	12	25	16	36	7	23	5	18

The cost of the concrete work done by each outfit is shown in the following statement:

Old Mixers:	Material	Labor	Total
Rent	$ 502.00	$........	$ 502.00
Freight and cartage	60.00	157.00	217.00
Repairs and equipment	102.00	36.00	138.00
Gasoline	53.00	....	53.00
Small tools (½ total)	37.00	....	37.00
Plant expense	$ 754.00	$ 193.00	$ 947.00
Concrete (1,405 cu. yd.)	6,930.00	2,241.00	9,171.00
Totals	$7,684.00	$2,434.00	$10,118.00
Totals per cu. yd	5.47	1.73	7.20
New Mixer:			
Depreciation	$ 400.00	....	$ 400.00
Equipment	81.00	$ 33.00	114.00
Small tools (½ total)	38.00	....	38.00
Freight and cartage	13.00	28.00	41.00
Motor rent and installation	57.00	....	57.00
Power	35.00	....	35.00
Plant expense	$ 624.00	$ 61.00	$ 685.00
Concrete (1,686 cu. yd.)	8,317.00	1,598.00	9,915.00
Totals	$8,941.00	$1,659.00	$10,600.00
Totals per cu. yd	5.31	0.98	6.29

The average concrete gang on the original outfit numbered 10 laborers at $2.75 per day, 1 mixerman at $3 and 1 foreman at $5; on the new outfit, 6 laborers at $2.75, 2 men at $3 each and 1 foreman at $5, the latter being displaced ultimately by one of the $3 men raised to $3.50. It may be noted that the labor cost of mixing and placing concrete was 95 ct. under the new arrangement, against $1.59 under the old.

The largest day's concrete work with the old mixers included about 60 ft. of invert and 50 ft. of arch, the invert being 350 ft. in advance of the arch at this stage; 64½ bbls. of cement were used, indicating 43 cu. yd. concrete and the labor was as follows:

1 foreman at $5	$ 5.00
2 laborers at $3	6.00
10 laborers at $2.75	27.50
Total labor	$38.50*

* Or $0.90 per cu. yd.

The largest day's concrete work with the new mixer comprised about 79 ft. of complete arch and 97 ft. of sides only, the work extending over a distance of 176 ft. of sewer; 98¾ bbls. of cement was used, indicating 66 cu. yd. concrete and the labor was as follows:

1 foreman at $5	$ 5.00
2 laborers at $3	$ 6.00
6 laborers at $2.75	$16.50
2 laborers at $2.50	$ 5.00
Total labor	$32.50*

* Or 0.50 per cu. yd.

In each of the foregoing instances, conditions were favorable for rapid work, which consumed an entire day of 8 hours with the men working for a record. Concrete was poured on 62 days by the former plant and 71 days by the latter plant, the average outputs being 22.6 cu. yd. and 23.8 cu. yd., respectively, per day worked.

Cement cost $2.375 per barrel delivered in sacks, with an allowance of 10 ct. each for empty sacks returned in acceptable condition (about 70 per cent of total); sand and gravel $1.40 per cubic yard delivered; water at 7 ct. per cubic yard of concrete—all included in cost of concrete materials as it appears in the statement. The statement covers cost of patching, applying the cement wash specified for the interior and final cleaning out of the sewer in preparation for minute and official inspection.

Brick Lining of Invert.—The invert of the circular and egg-shape sewers was lined with vitrified paving brick, laid flat in mortar composed of 1 part Portland cement to 2 parts quartz sand. This work, necessarily intermittent, had an important influence on the progress of the job, rendering speed, reliability and expertness on the part of the men especially desirable. Slowness or unavailability on call meant direct delay, and an uneven lining would greatly increase the difficulty of making a tight joint between the side arch forms and the invert. The brick mason on this work was paid $8 per day, his hodcarrier $5, and a laborer helper $2.75 for 8 hours, work. The bricks were first piled along either side on the haunch of the invert against the reinforcing bars, and then the surface of the concrete swept and flushed clean and dusted with cement. The hodcarrier mixed the mortar as required and generally assisted the mason, while the laborer kept them supplied with material from above. The labor cost of laying the invert was 4 ct. per square foot, or about $10 per 1,000 brick. Although the wages paid the mason and hodcarrier involved an advance of $1.00 each per day over the standard wages for high-grade workmen, the results are deemed amply to have warranted the extra expense.

Backfilling.—The backfilling was accomplished in part by wagon dump direct from the steam-shovel or other excavation, and in part by shoveling and scraping from the spoil bank left on one side of the trench, using a slip scraper, team and driver at $6.00 per day with generally two men at $2.50 and $2.75 per day to handle the scraper. The trench was filled to a crown as soon as convenient after completion of concrete, puddled by introducing water at the bottom through a pipe attached to the end of a hose and inserted in the ground and allowing to run until water appeared on the surface of the sunken fill, after which it was allowed to stand and partially dry out before adding more fill. Water for this purpose was charged at the rate of 0.7 ct. per lineal foot of trench puddled. It was only after some experimenting and considerable argument that the contractor was permitted to proceed in this manner, for the specifications prescribed tamping in layers; but the method allowed proved very satisfactory. It is estimated that about 8,200 cu. yd. compacted fill was required at a special labor cost of about 26 ct. per cubic yard, which of course ignores the work of the teams that worked directly between the excavation and the backfill. A large portion of this expense, amounting to 10.8 ct. per cubic yard of excavated material, or nearly 10 per cent of the unusually high cost of all the trench work, would not obtain in a well co-ordinated job.

Repaving.—The specifications for repaving contained what the contractor termed a "joker;" for in addition to providing as usual that the pavement where disturbed should be restored to its original condition, it was further provided "That no pavement shall be laid on a foundation of less than 4 ins. of gravel or broken stone below the original pavement." As the pavement was oil macadam of substantially its original thickness of 5 to 6 ins., this meant the somewhat unusual thickness for macadam in this locality of from 9 to 10 ins. Coarse gravel being cheaper than macadam rock, the contractor, with the consent of the engineer, innocently chose the former for the underlying ballast; somewhat to his sorrow, however, for not until it had been plentifully fed with screenings did it form a stable bed for the macadam proper.

The sub-grade was trimmed by hand to show a slight crown and vertical edges and compacted by means of a horse roller, followed by 5 and 10-ton steam and gasoline rollers. The gravel ballast was delivered by rail in gondola cars on a siding about ½ mile average haul from the work. It was unloaded by hand direct into bottom dump wagons, deposited on the subgrade in piles, spread by scrapers, finished with shovels and rolled to a level surface to receive the macadam. The cost of preparing the subgrade was approximately ¾ ct. per square foot, and of spreading and finishing the ballast ½ ct. per square foot.

Hauling of Material by Motor Truck.—The bulk of the macadam rock and screenings was delivered by barges holding from 250 to 350 cu. yd. and equipped with a combination belt-and-bucket conveying system for unloading and discharging into a small wharf bunker of about 15 cu. yd. capacity from which 5-yd. auto trucks were loaded in less than 1 minute. The discharging capacity of the barge machinery was about 1¼ cu. yd. per minute. The hauling of the macadam material was contracted at 30 ct. per cubic yard, but some record was kept of the performance of the trucks which may be of interest.

The first barge-load of 274 cu. yd. was hauled during one day by three good trucks, two 5-yd. and one 4-yd., averaging about three trips per hour. The standard charges for motor-truck service were $25 and $30 per 9 hours work for 4-yd. and 5-yd. trucks, respectively, or say 69 ct. per cubic yard capacity per hour. At this rate, if the trucks had been hired by the day, and had given the employer equally good service, the cost of the hauling would have been 23 ct. per cubic yard.

The second barge-load was, owing to unavailability of adequate motor-truck service during the daytime, hauled between 3:00 p.m. and 2:00 a.m., commencing with one 4-yard truck, to which others were added from time to time until ultimately three 4-yd. and four 5-yd. trucks were in commission. For the three 4-yd. trucks, the total truck hours on the job were 23.33, of which 7.5 were time lost in intervals of 1 hour or more on account of breakdowns or necessity of the drivers, leaving the actual working time, including minor incidental delays, 15.83 hours during which they hauled 132 cu. yd. At the standard service rate this would represent a cost of 33.4 ct. per cubic yard. For the four 5-yd. trucks, the total truck hours were 29.25, of which 20 truck hours represented legitimate work during which they hauled 220 cu. yd., which would have cost at the standard service rate 30¼ ct. per cubic yard.

In addition to the inconvenience of working at night, some of these trucks were not in the best of condition, nor were all the drivers expert. Their variable performance is indicated by the fact that the average times per round trip for the three 4-yd. trucks were 24, 30 and 31 minutes, and for the four 5-yd trucks, 21, 27, 29 and 32 minutes, respectively. The haul of this barge-load averaged about 1½ miles.

Macadamizing.—The macadam rock was for the most part dumped on the ballast, the truck moving ahead while dumping, adjusting the speed so as to effect as nearly as might be the proper distribution of the rock along the trench. Where the rock was left in piles it was spread by means of a fresno scraper and the entire surface of the work in place was finished by laborer with shovels and potato hooks. The screenings were then shoveled over the entire surface sufficient almost to cover all the rock, well sprinkled and rolled successively with a 5-ton and a 10-ton steam or 12-ton gasoline roller. Accompanying the roller, a laborer spread additional screenings to fill the principal surface voids. Road oil was then applied to the specified amount of ¾ gal. per square yard, on which immediately were spread screenings and rolled to a compact surface, rescreening as required to take up all surplus oil.

The cost of spreading the macadam rock and screenings as aforedescribed was 42½ ct. per cubic yard, or nearly 1 ct. per square foot of pavement, with labor at $2.50 and team and driver at $6 per day of eight hours.

The 5-ton roller was rented at $7 per day, the engineer was paid $6 and between $3 and $4 per day was expended for fuel. The 10-ton roller, including engineer and fuel, was rented at $2.50 per hour, and the 12-ton roller at $1.90 per hour, including engineer and fuel. The total cost of the rolling, including subgrade and oiled surface, amounted to about 0.6 ct. per square foot.

The oil was furnished and spread with a standard spraying machine by contract with a local paving contractor at $2 per barrel spread. (Hot oil at retort being quoted at $1.65 per barrel.)

Insurance.—The item of employes' compensation insurance is a considerable one in this class of work, the premium rate being high and many companies refusing to take the risk on deep sewer work. The manual rate, endorsed by the State Insurance Fund, was 14.03 per cent of the payroll, although the company insuring the job cut this rate to 7.72 per cent. Every precaution was taken to avoid accident with the result that only one man was injured sufficiently to require unusual attention or to incapacitate him for work for more than a few hours.

Averaged for 8 months duration of work, the general expense, inclusive of overhead, amounted to $104 for material, and $413 for labor per month, or 2¾ per cent and 12½ per cent of the respective net totals excluding insurance. The fact that this total general expense amounted to 15¼ per cent of the actual cost of material and labor is interesting in view of the engineer's interpretation of the contract provision that extra work should be paid for at "actual cost as estimated by the City Engineer" (making no allowance for the use of tools, plant or general superintendence) "plus 15 per cent for profit" Under the engineer's interpretation the contractor was not permitted to apportion any of the time of the superintendent, timekeeper, or other miscellaneous expense, to extra work. It is a not uncommon notion of engineers and architects that a 15 per cent, or even a 10 per cent, allowance, over and above actual cost of labor and material, is ample to cover general expense and profit on extra work. As a rule extra work imposes on the contractor trouble and expense out of proportion to the average for the job and the fact cannot be too clearly impressed upon the minds of engineers and architects that it is this general annoyance and expense that entitles him to a fair, clear profit over all estimable items of expense entering into the work.

Labor Cost of 8-Ft. Concrete Sewer.—The following data are given in Engineering and Contracting, Feb. 14, 1917.

The reinforced concrete sewer, 96 in. interior diameter was built by contract in an eastern city. The excavation was in sandy loam, not difficult to dig.

There was no pavement removed, for this was a section of the city having few residences.

The earth was loaded into buckets that were lifted by a derrick and dumped alongside or into Koppel cars, such portion going into the cars as was not

TABLE II.—SUMMARY OF COST

	Total costs: Material, tools, etc.	Total costs: Labor	Unit costs: Mat'l, etc.	Unit costs: Labor	Unit costs: Comb'd
Excavation and backfill, 19,600 cu. yd	....	....	....	....	$1.138
By steam shovel, 13,000 cu. yd	$ 2,944	$ 2,694	$ .226	$ .207	......
By teaming, 13,000 cu. yd	....	908	....	....	......

Compensation insurance, 8 months	....	1,731	2¾ %	12½ %	......
Totals	$30,558	$31,496	....	....	......

used in backfilling. The derrick was mounted on the forward end of a platform that spanned the trench and ran on wheels. On the same platform, but at the rear, was another derrick used in handling buckets of concrete.

Water was encountered about 2 ft. above the bottom of the trench, and two Pulsometer pumps were usually kept busy handling this water. The pumps received their steam from the boiler that supplied the hoisting engines.

The following was the organization of the gang engaged in building the sewer:

	Per day
1 superintendent at $6	$ 6.00
1 engineman at $3.50	3.50
1 hoister (one engine) at $2	2.00
2 tagmen at $1.65	3.30
10 men excavating earth at $1.65	16.50
2 men on dump cars at $1.65	3.30
1 bracer (carpenter on bracing) at $3	3.00
2 bracer's helpers at $1.65	3.30
2 men laying bottom planks at $1.65	3.30
and moving pumps, etc., $1.65	3.30
3 men pulling sheeting at $1.75	5.25
16 men mixing and placing concrete at $1.65	26.40
3 men on forms at $1.75	5.25
1 water boy at $1	1.00
Total	$85.40

Coal and oil cost about $5 per working day of 10 hours.

During half a year the actual field cost of the labor on this sewer was $7.86 per lin. ft., distributed as follows:

	Per lin. ft.
Excavation	$1.80
Placing sheeting and bracing	0.58
Placing bottom plank	0.17
Pulling sheeting	0.45
Backfilling	0.33
Making and placing concrete invert	1.17
Making and placing concrete arch	1.54
Laying brick in invert	0.29
Bending and placing reinforcing steel in arch	0.20
Bending and placing reinforcing steel in invert	0.09
Placing and moving forms and centers	0.62
Watchmen, waterboy, etc	0.62
Total	$7.86

The excavated section of the trench was 12½ ft. wide and varied somewhat in depth. When it was 12 ft. deep, the cost was $1,61 per lin. ft., which was 29 ct. per cu. yd. for all labor, excepting the labor of backfilling. When the trench excavation averaged 5.56 cu. yd. per lin. ft., the backfill averaged only 1.7 cu. yd. per lin. ft. and this backfilling was done at a cost of about 20 ct. per cu. yd. of backfill. The backfill was not rammed.

The trench sheeting consisted of 4-in. plank, which was subsequently used as a floor or bottom upon which the concrete invert was laid. This plank floor consisted of two layers of plank, giving a thickness of 8 in.

The sheeting was braced with 6 × 6-in. braces, three of which were used to each 16 ft. length of wale. There were two lines of 4 × 6-in. wales. Hence the trench required about 120 ft. B. M. of sheeting and bracing per lineal foot of trench. Since it cost $0.58 per lin. ft. of trench to place this timber, this is equivalent to $4.80 per 1,000 ft. B. M.

The pulling of the sheeting cost $0.45 per lin. ft. of trench, which is equivalent to about $3.75 per 1,000 ft. B. M. of timber removed. The pulling was done with a light tripod on which was mounted a winch operated by two men. A small wire rope from this winch passed over a pulley at the top of the tripod and was fastened to the sheet pile to be pulled. Two legs of the tripod rested on the ground and the third was supported by a plank resting on the bracing over the center of the trench. There were three men in the gang pulling the sheeting.

The concrete was a 1:2:4 mixture, and about 1¼ bbl. of Portland cement were used per cubic yard. Gravel was used for the aggregate. The invert contained 0.8 cu. yd. of concrete per lin. ft., and the arch contained 1.4 cu. yd. per lin. ft., or a total of 2.2 cu. yd. The mixing was all done by hand. The concrete for the invert was shoveled into dump buckets and lowered to place by the derrick above mentioned. The concrete for the arch was delivered in two wheel dump carts pushed by hand.

Referring to the tabulated labor costs given above, we see that making and placing concrete in the invert cost $1.17 per lin. ft., which is equivalent to $1.46 per cu. yd. of concrete invert. The corresponding cost for the arch was $1.54 per lin. ft., which is equivalent to $1.10 per cu. yd. of arch. The combined cost was $2.71 per lin. ft., which is equivalent to $1.23 per cu. yd. of concrete in the sewer.

The greater cost of placing concrete in the invert was due partly to the presence of the reinforcing rods, which interfere with placing the concrete quickly. The labor of the men on the tag ropes swinging the derrick boom, as well as the labor of the derrick hoister, ran up the cost, particularly as the daily output of concrete was low. A bull wheel on the derrick would have eliminated the men on the tag ropes.

Bending and placing the twisted steel reinforcing rods cost $0.29 per lin. ft. of sewer (invert and arch combined); and, as there were 366 lb. of this reinforcement per lin. ft. of sewer, the labor cost was 0.8 ct. per lb. The cost was frequently as low as 0.6 per lb.

The concrete invert was lined with common bricks set on edge, there being about 40 bricks per lin. ft. of sewer. A brick mason was paid 15 ct. per lin. ft. for laying the bricks, and, in addition to this, the cost of labor mixing and delivering mortar, etc., amounted to 14 ct. per lin. ft., making a total of 29 ct. per lin. ft. of sewer.

The cost of labor for placing and moving forms for the invert averaged 9 ct. per lin. ft., and the corresponding cost for the arch averaged 53 ct., making a total of 62 ct. as above given. Later on these costs were reduced to 5 ct. and 46 ct., respectively, making a total cost of 51 ct. per lin. ft. of sewer. At 51 ct. per lin ft., the labor cost on the forms and centers was only 23 ct. per cu. yd. of concrete.

Cost of Mixing and Placing Concrete by Hand for a Four-foot Circular Sewer.—Engineering and Contracting, July 13, 1910, gives the following:

The work on a 4-ft. circular sewer in Louisville, Ky., was carried on entirely by hand. The sewer was located through a park and near a roadway and materials for the work were placed at convenient points. The invert contained 0.21 cu. yds. of concrete and the arch 0.18 cu. yds. per lineal foot, and each was built separately. A light mixing board was made, and was shifted along by the gang as the work progressed.

The gang consisted of 17 negroes and a foreman whose duties consisted of excavation and concreting for the sewer. The successive steps of their work were alternated with another gang which attended to the forms and reinforcement. The length of concrete laid at one operation was 72 ft. of either arch or invert and the time required to do the work averaged 3¼ hours. The men were divided as follows:

2 men on mortar.
4 men on gravel.
2 men on sand.
4 men on mixing board.
1 man on water and cement.
4 men in trench spading.
1 foreman.

All the men received 20 cts. per hour and the foreman received 35 cts. per hour. The cost of concreting 72 ft. of invert or arch was thus:

17 men at 20 cts. per hour, 3¼ hrs.	$11.05
1 foreman at 35 cts. per hour, 3¼ hrs.	1.14
Cost of laying 72 ft. of invert or arch	$12.19

This gives for 72 ft. of complete sewer a cost of $24.38 which divided by 28.08 cu. yds. gives a cost of 87 cts. per cu. yd. In this work there were about 2.23 lbs. of steel reinforcement per lineal foot of sewer. Two men were employed continually to bend the steel and place it in position in the forms.

Cost of Reinforced Concrete Pipe Sewers at Mishawaka, Ind.—The following data published in Engineering and Contracting, Feb. 15, 1911, are from a paper by Wm. P. Moore, City Engineer, Mishawaka, Ind., before the Indiana Engineering Society, Annual Convention, January, 1911.

In the spring of 1909 bids were received by the city for the construction of the Laurel St. trunk sewer which was 3,480 ft. long and 36 ins. in diameter, the average cut being 10 ft. and the excavation sand and gravel.

The specifications were drawn to include brick, monolithic and reinforced concrete pipe. When the bids were opened it was found the lowest bidder proposed to use the Jackson Reinforced Concrete Pipe Co.'s pipe and was awarded the contract. The cost of construction was about as follows for 3,480 lin. ft. of 36-in. reinforced pipe:

	Cost per ft.
1 foreman, 1,740 hrs. at 40 cts. per hr.	$0.20
2 pipe layers, 3,480 hrs. at 25 cts. per hr.	0.25
1 joint maker, 1,740 hrs. at 20 cts. per hr.	0.10
1 pipe lower, 1,740 hrs. at 20 cts. per hr.	0.10
1 mortar mixer, 1,740 hrs. at 20 cts. per hr.	0.10
2 pipe rollers, 3,480 hrs. at 20 cts. per hr.	0.20
2 sheeters, 3,480 hrs. at 25 cts. per hr.	0.25
1 helper, 1,740 hrs. at 20 cts. per hr.	0.10
6 men excav., 10,440 hrs. at 20 cts. per hr.	0.60
1 team and helper, 1,740 hrs. at 60 cts. per hr.	0.30
1 water boy, 1,740 hrs. at 10 cts. per hr.	0.05
Cement, sand and gravel for joints	0.09
City water for flushing trench	0.02
Amount paid the Jackson Reinforced Pipe Co. for the pipe along line of ditch	1.80
Total cost	$4.16

In the above contract the Reinforced Concrete Pipe Co. made the pipe along the line of the sewer and assumed all risk in regard to the pipe and furnished them to the contractor for $1.80 per lin. ft. measured in the ditch.

In the same year the Common Council also received bids for the Logan Street trunk sewer which has 1,690 lin. ft. of 42-in. and 1,450 lin. ft. of 36-in. pipe. The contract was let with Jackson pipe also, the lowest bid being on their construction.

The average cut was 16 ft. in sand and gravel with a small amount of water bearing gravel in the bottom, but not enough to require a pump. In this contract the contractor built the pipe and furnished all common labor and material and the Jackson Pipe Co. furnished the forms, reinforcement and a competent superintendent to see that the pipe were made properly. Their charge being $1.15 per lin. ft. for the 36-in. pipe and $1.45 per lin. ft. for the 42-in. pipe.

Sand and gravel delivered along the line of the contracts cost 60 cts. per cu. yd., common labor 20 cts. per hour, teams 40 cts. per hour and cement $1.25 per barrel. Calculated on the above basis the cost of construction was about as follows for 1,450 lin. ft. of 36-in. concrete sewer

	Cost per ft.
1 foreman, 725 hrs. at 45 cts. per hr	$0.22
2 pipe layers, 1,450 hrs. at 25 cts. per hr	0.25
1 joint maker, 725 hrs. at 25 cts. per hr	0.12½
1 mortar mixer, 725 hrs. at 20 cts. per hr	0.10
1 pipe lower, 725 hrs. at 20 cts. per hr	0.10
2 men rolling pipe, 1,450 hrs. at 20 cts. per hr	0.20
3 men sheeting, 2,175 hrs. at 25 cts. per hr	0.37½
8 men excavating, 5,800 hrs. at 20 cts. per hr	0.80
1 team and helper, 725 hrs. at 60 cts. per hr	0.30
1 water boy, 725 hrs. at 15 cts. per hr	0.07
Cement, sand and gravel for the joints	0.09
City water for flushing trench	0.02
Total	$2.65

Cost of making this pipe follows:

	Cost per ft.
5 men 411 hrs. mixing concrete, etc., at 18 cts	0.12
280 bbls. of cement at $1.25 per bbl	0.24
217.5 cu. yds. of gravel of 60 cts. per yd	0.09
Royalty for forms, reinforcements, supt. paid to the Jackson Pipe Co.	1.15
Cost of making pipe	$1.60
Grand total	$4.25

The cost of 1,690 lin. ft. of 42-in. concrete pipe sewer was as follows:

	Cost per ft.
1 foreman, 900 hrs. at 45 cts. per hr	$0.24
2 pipe layers, 1,800 hrs. at 25 cts. per hr	0.27
1 man making joints, 900 hrs. at 25 cts. per hr	0.14
1 man lowering pipe, 900 hrs. at 20 cts. per hr	0.11
2 men rolling pipe, 1,800 hrs. at 20 cts. per hr	0.21
1 man mixing mortar, 900 hrs. at 20 cts. per hr	0.11
3 men sheeting, 2,700 hrs. at 25 cts. per hr	0.40
2 men helpers, 1,800 hrs. at 20 cts. per hr	0.21
8 men excavating, 7,200 hrs. at 20 cts. per hr	0.85
1 team and helper exc., 900 hrs. at 60 cts. per hr	0.31
1 team and helper filling, 900 hrs. at 60 cts. per hr	0.31
1 water boy, 900 hrs. at 15 cts. per hr	0.07
Cement, sand and gravel for joints	0.10
City water for flushing	0.02
Total	$3.23

Cost of making this pipe follows:

	Cost per ft.
5 men mixing concrete, etc., 1,400 hrs. at 18 cts.	$0.15
384.5 bbls. of cement at $1.25 per bbl.	0.28
313 cu. yds. of gravel at 60 cts. per cu. yd	0.11
Royalty, forms and superintendent	1.45
Total cost of making pipe	$1.99
Grand total for 1,690 ft. of 42-in. pipe	5.34

In regard to the use of the above information I wish to advise that data is only approximately correct, as we were in no position to obtain the exact cost. The total number of men employed and the number of hours worked are correct, but necessarily in large contracts men are shifted and it was therefore necessary to take the average number of men working in the different positions.

Cost of Tile and of Concrete Sewer.—Work was started in December, 1916, on the construction of the Rideau River interceptor, a 17,900-ft. sewer that will drain a portion of south and east Ottawa. The first section was constructed of segment tile, 60-in. in diameter; the next section is of 54-in. pipe, part segment and part concrete. A third section was built of 48-in. concrete pipe. The following cost data on the work, abstracted from an article by L. McLaren Hunter, City Engineer's Department, Ottawa, in The Canadian Engineer, are published in Engineering and Contracting, Feb. 12, 1919.

The larger equipment used during construction included one 45-HP. boiler, one 40-HP. boiler, one derrick and traveler, three syphons, one 4-in. submerged pump (electric) and one 4-in. suction pump (electric).

The costs of various materials used were as follows:

1917—54-in. concrete pipe, per ft.	$4.34
48-in. concrete pipe, per ft.	3.44
1918—48-in. concrete pipe, per ft.	4.30
30-in. concrete pipe, per ft.	2.35
1917—60-in. Natco tile, per ft.	5.65
1916—Cement, per bag	.43
1917—Cement, per bag	.52
1918—Cement, per bag	.73

On the 60-in. Natco tile section, in 18 ft. of excavation, the costs were as follows:

	Per lin. ft.
Excavation and backfilling	$ 8.240
Pipe laying	.375
Natco tile, including underdrain	7.427
Pumping	.766
Shoring	.652
Grading, plant, sundries	1.744
Total cost per lin. ft.	$19.204
Tunnel section (excavation), per ft.	19.37
Manholes (concrete), each	61.46

The cost of 48-in. concrete pipe section, in 4 ft. 6 in. of excavation, in 1918 was as follows:

	Per lin. ft.
Labor:	
Excavation	$1.37
Shoring	.68
Pumping	.20
Backfill	.60
Culvert drains	.16
Rolling pipe	.29
Running hoist	.33
Derrick and track	.44
Grouting	.12
Pipe laying	.34
Sundries (including Saturday afternoon holidays)	.58
Total	$5.11
Material:	
Pipe (including hauling)	$3.60
Coal	.24
Cement	.11
Sundries	.11
Total	$4.06

The above costs on the 48-in. section were taken on 400 lin. ft. of work which was done in August, 1918. Laborers were paid 35 ct. per hour. On the Natco tile section, laborers were paid 27½ ct. per. hour. The work was done by day labor.

Miscellaneous Costs of Concrete Sewer Construction, Louisville, Ky.—Engineering and Contracting, June 22, 1910, gives the following:

Lining a Concrete Sewer With Brick.—This sewer was of concrete, horseshoe section and about 4 ft. in diameter. The brick lining of the invert and side walls contained 8.3 sq. yds. in 65 ft. of its length. The brick were laid on edge and 8½ bbls. of cement were used in the mortar:

6 bricklayers at 62½c. per hr., 3½ hrs.	$13.12½
6 helpers at 20c. per hr., 3½ hrs.	4.20
Cost of laying 8.3 sq. yds	$17.32½
Cost of laying 1 sq. yd. brick lining	$2.087

Potter Machine on Trench 15 ft. Wide 21 ft. deep:

7 men excavating (sand) at $1.75 per day	$12.25
1 engineer at $3.50 per day	3.50
1 fireman at $3.50 per day	3.50
Rental of machine $200 per mo., at $8.00 per day	8.00
Av. output per day 150 cu. yds	$27.25
Cost per cu. yd. 18c.	

Mixing and Placing Concrete by Hand.—Material had to be hauled 300 ft. in wheel-barrows, and was mixed by hand on platforms over the trench. It was poured through chutes to place. The average wages of these men were 22½ cts. per hour. The concrete men are paid more than the ordinary laborers who receive 17½ cts. per hour:

6 men turning	$10.80
2 men mixing mortar	3.60
5 men wheeling	9.00
1 man on water and cement	1.80
2 men handling chutes	3.60
4 men spading	7.20
20 men placing 30 cu. yds. at	$36.00

This gives a cost of \$1.20 per cu. yd. for labor of placing concrete.

Knocking Down the Blaw arch forms, wooden jacket and invert forms for this sewer, moving them ahead and setting them up required 8 hours for 3 men. One man acted as foreman with two helpers. It required 4 hours to set the invert forms, 2 hours to set the jackets for the walls, and 2 hours to set the Blaw arch forms. This is for a 5 ft. sewer.

Placing the reinforcing steel required the time of the above mentioned squad of 3 men. They set the steel for the invert and sidewalls in 5 hours and for the arch in 1½ hours. The foreman was paid 25 cts. an hour and the helpers 17½ cts. There were 53 lbs. of reinforcing steel per running foot. Striking and settling Blaw forms for 60 lin. ft. of horseshoe shaped sewer, 5 foot section:

1 foreman, 8 hrs. at 25c	\$2.00
2 helpers, 8 hrs. at \$17½	2.80
Total	\$4.80

Striking and settling 60 ft. of forms, cost at ½ cu. yd. per lin. ft., per cu. yd., \$0.16.

Placing reinforcement for 60 lin. ft. of sewer:

1 foreman, 7½ hrs. at 25c	\$1.875
2 helpers 7½ hrs. at 17½c	1.3125
Total	\$3.18¾

Placing reinforcement for 60 ft. of sewer at ½ yd. per lin. ft., cost \$0.106 per cu. yd., and at 53 lbs. per lin. ft., \$0.002 per lb.

A summary of the cost of labor per cubic yard in constructing 60 lin. ft. of 5-ft. sewer was:

Cost per cu. yd. mixing and placing concrete	\$1.20
Cost per cu. yd. striking and erecting blank forms	.16
Cost per cu. yd. placing reinforcement	.106
Total cost of labor per cu. yd	\$1.466

Bricklaying Costs for 5 to 10-Ft. Brick Sewers at St. Louis, Mo.—C. L. French gives the following data in Engineering News, Nov. 12, 1914.

The contract for the third section of the Glaise Creek Joint Sewer, consisted of 7,370 ft. of brick sewer, varying from 5 to 10 ft. in diameter and from 13 to 18 in. in thickness. The total amount of brickwork was 10,264 cu. yd., consisting of 9,600 cu. yd. common and 664 cu. yd. of vitrified brick masonry (to line the invert for the dry-weather flow).

It was found that by planning the work so that a certain number of bricklayers could be constantly employed, the best men could be kept. The importance of this feature is nearly always underestimated by contractors. The difference between the work done by a good man and an average man is at least 10 per cent, and where full time can be made the very best men are obtainable.

The next step was to get the maximum of work from the bricklayers. This meant not harder work, but eliminating lost motion: The essentials were proper working room, sufficient materials in the right place, and safe working conditions. Solving each of these problems required much experiment. Too many or too few bricklayers in a given space was found to be equally expensive.

Materials in the right quantity, just where needed, make it unnecessary for a \$9-a-day bricklayer to wait for a \$2.50 laborer.

The elimination of useless labor was one of the greatest problems. Mortar was mixed by machinery at a cost of less than 1c. per cu. yd. for power. Great care was taken to have this mortar of just the proper consistency. It was found that, everything else being equal, the day's work could be increased 2 or 3% by *having the mortar exactly right all the time.* The mortar was dumped directly from the machine into barrows and then poured into chutes. Thus the bottom man had only to direct the mortar into the boxes below. Mortar mixers and mortar lowerers were thus eliminated. Materials were stored as close to the ditch as possible and in the same quantity as would be used in that length of sewer.

The job was started Nov. 4, 1913, and finished Aug. 18, 1914.

The cost data are based on the following prices for labor and material delivered:

Bricklayer	\$ 1.12½ per hr.
Labor	0.31 per hr.
Brick, common	8.50 per M
Brick, vitrified	16.50 per M
Cement	1.40 per bbl.
Sand	0.85 per cu. yd.
Electricity	0.10 per kw. hr.

The constants for each cubic yard of brick were:

	Unit cost	Cost Per cu. yd.
430 common brick at	\$ 8.50	\$3.66
338 vitrified brick at	16.50	5.58
0.65 bbl. cement at	1.40	0.91
0.35 cu. yd. mortar at	0.85	0.30
0.10 kw. hr. at	0.10	0.01

The mortar was 1 part cement to 3 parts sand.

This makes the material cost \$4.88 per cu. yd. for common and \$6.80 per cu. yd. for vitrified-brick masonry.

The monthly records were as follows:

	Cubic yards laid			Cost per cu. yd.		
Month	Common	Vitrified	Per day of 8 hr. per bricklayer	Labor	Total, common	Total, vitrified
Nov., 1913	768	53	9.3	\$2.25	\$7.13	\$9.05
Dec., 1913	1,444	99	10.8	2.02	6.90	8.82
Jan., 1914	1,260	87	11.7	1.90	6.78	8.70
Feb., 1914	60	4	12.0	3.00	7.88	9.80
Mar., 1914	416	29	10.5	1.90	6.78	8.70
Apr., 1914	1,132	78	11.8	1.78	6.66	8.58
May, 1914	970	68	11.0	2.24	7.12	9.04
June, 1914	1,019	70	9.9	2.26	7.14	9.06
July, 1914	1,912	133	12.6	1.77	6.65	8.57
Aug., 1914	619	43	8.5	2.65	7.53	9.45
	9,600	664				

Average cu. yd. per bricklayer per day of 8 hr.		\$11.05
Average labor cost per cu. yd.		2.02
Average cost of brickwork per cu. yd.	common	6.90
	vitrified	\$8.82

The high cost of labor in May is due to tunnel work at night, when double time was paid to bricklayers. The high cost for June is due to bad working conditions, where frequent cave-ins caused much delay. The last month's figures are not significant, as the best men had left for other jobs and lots of cleaning up was necessary.

Labor Cost of Concrete and Brick Sewer Construction in Toronto.—Engineering and Contracting, June 12, 1918, publishes the following, from an article in The Contract Record by W. S. Harvey and R. T. G. Jack.

The storm sewer known as "Sparkhall Ave. relief sewer" was constructed to relieve the congestion in the district bounded by Danforth Ave. on the north, Bain Ave. on the south, Pape Ave. on the east, and Broadview Ave. on the west. The sewer has its outlet at the River Don and terminates at Logan Ave., with provision for a future extension to Pape Ave.

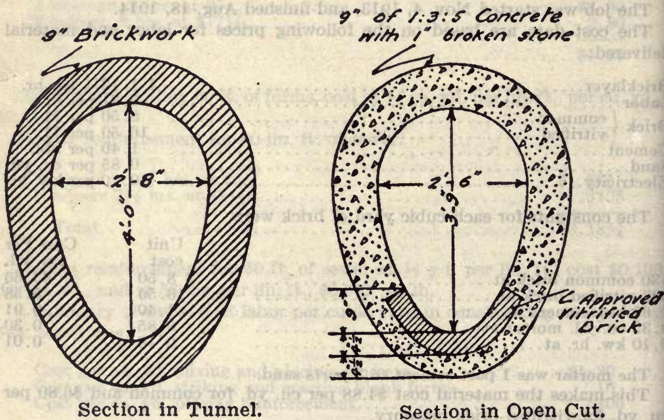

Fig. 7.—Typical cross sections of sewer in tunnel and open cut.

Fig. 7 shows typical cross sections of the sewer in tunnel and open cut. The standard egg-shaped section was adopted as being the most economical under the existing conditions, the ground being good blue clay, which would permit of a minimum width of trench in open cut and minimum dimensions of heading in tunnel, as practically no timbering would be required.

A cross section of the outlet across the Don Flats at Riverdale Park is shown in Fig. 8. A similar section was used under the C. P. R. tracks near the River Don, but heavier reinforcement was required in the roof slab. This section was used on account of the lack of cover available, a minimum of 2 ft. being called for.

Unit Costs.—Under this heading it is the intention to deal with each section of the sewer as constructed and to give a unit cost in hours, using the following key to the distribution of labor:

(A) Excavation; (B) sheeting and timbering; (C) backfilling; (D) handling surplus—excavation; (E) concrete forms; (F) placing concrete, including reinforcing; (G) placing cast iron pipes; (J) pumping; (K) brickwork; (N) mining and sinking shafts; (P) handling supplies; (Q) handling plant; (Z) miscellaneous labor.

Cost of Reinforced Concrete Section, 3 ft. 6 in. × 5 ft.—Work was not commenced until the latter part of the summer of 1916, so that the water in the Don River, which was to be the outlet for the sewer, would be at its lowest elevation. Even with this condition, it gave the contractor a certain amount of trouble. Construction was carried on from the Don to the C. P. R. tracks; here a break was made and resumed on the other side, where, owing to the porous nature of the ground, considerable water was encountered. This portion of Riverdale Park (Don Flats) has been reclaimed by the city with ashes and refuse, and for this reason it was specified that a 2-in. lumber decking be placed in the bottom of the trench before the concrete was poured, and that the trench be tight-sheeted and the sheeting left in place.

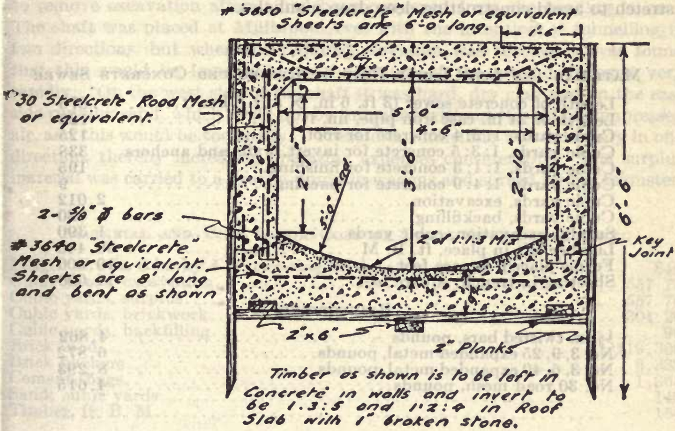

FIG. 8.—Cross section of outlet across Don Flats.

The work was carried on by two distinct gangs of men, each with a separate foreman. One gang attended to excavation, sheeting, handling surplus and backfilling; the other to setting forms, placing reinforcement and pouring concrete.

As the trench was very shallow, no excavating machine was used. The material was cast up on top, where a horse and scraper removed the surplus and spread it out over the park. After the trench had been made ready and the decking and sheeting placed the concreting gang poured the concrete for the invert, leaving it low in elevation so that 3 in. of concrete, mixed in proportion of 1 sand, 1 cement and 3 of very fine stone, could be placed afterwards. When the concrete was properly set forms of the "knock-down" type, made of tongued and grooved sheeting, dressed one side, were placed for the side walls and roof, and all the concrete poured at one running. By this method of working no delays were caused by not having any trench ready, and the concrete gangs were also able to get enough invert concreted, while waiting the required 48 hours for the arch concrete to set, in order to carry on the work successfully.

This procedure was used all the way through this section and good progress was made, notwithstanding the fact that labor and material were scarce and that water gave considerable trouble.

After the concreting of the rough invert side walls and roof had been completed up to the bellmouth (manhole No. 3), the portion under the C. P. R. tracks was completed and the finishing concrete applied. Before doing this, however, a thorough inspection was made, and the invert made perfectly clean, so that a good bond was assured.

While the concrete gang were doing the finishing the excavating gang were placing 24-in. cast iron pipe and building anchors for the support of same, so that the work in this open cut section was practically completed before the severe cold weather set in. The cast iron pipe was used on a short steep stretch to avoid constructing deep drop manholes.

Material and Unit Labor Cost of Reinforced Concrete Sewer

Length of concrete sewer (3 ft. 6 in. × 5 ft.), lin. ft.	876
Length of 24 in. cast iron pipe, lin. ft.	120
Cubic yards, 1:2:4 concrete for roof	125
Cubic yards, 1:3:5 concrete for invert, walls and anchors	338
Cubic yards, 1:1:3 concrete for finishing	195
Cubic yards, 1:4:9 concrete for packing	9
Cubic yards, excavation	2,012
Cubic yards, backfilling	620
Surplus excavation, cubic yards	1,390
Lumber left in place, ft. B. M.	38,440
Forms placed, square feet	10,500
Sheeting in trench, square feet	14,000
Reinforcing	
½ in. twisted bars, pounds	4,862
No. 3, 9, 25 expanded metal, pounds	6,872
No. 3, 6, 40 expanded metal, pounds	8,293
No. 30 road mesh, pounds	4,615

Cost of Two-Ring Brick Sewer in Tunnel (*2 ft.* 8 *in.* × 4 *ft.*)—This section started at manhole No. 4, the tunnel being operated from one portal situated on the east bank and one shaft at Millbrook Ave. Owing to the location of the west portal, it was decided to dispense with an engine and derrick for handling excavation. Tracks were laid along a terrace on the bank and the material brought from the tunnel in cars and dumped over the side of the bank, where it was spread out to make more terraces, thereby beautifying this section of the park. The material used in construction was brought to the top of the bank, where it was stored, and, as required, was lowered down wooden chutes constructed for this purpose, and conveyed into the heading in cars. By this method of procedure the expense of an engineman, engine, and coal was eliminated. At Millbrook Ave. shaft a derrick was erected to remove excavation after it had been conveyed from the heading in cars. The shaft was placed at Millbrook Ave. with the intention of tunnelling in two directions, but when the required elevation was reached it was found that this would be impossible, as the nature of the ground changed very rapidly. On the west side of the shaft it was hard, dry clay and on the east side running sand, which could not be tunnelled without the aid of compressed air, and this would be too costly. Therefore, tunnelling was done only in one direction, thereby increasing operating expenses considerably. The surplus material was carried to a nearby dump in wagons and spread by the teamster.

Material and Unit Labor Cost of Brick Sewer in Tunnel

Cost of Two-Ring Brick Sewer (*2 ft.* 6 *in.* × 3 *ft.* 9 *in.*) *in Tunnel.*—It was the original intention of the City Engineer that the excavating on this section be done in open cut. The contractor, however, decided to carry it out in tunnel, owing to the frost being in the ground to a depth of 4 ft. When the work on the 2-ft. 8-in. × 4-ft. section was completed, the derrick and engine were moved to a point midway on the 2-ft. 6-in. × 3-ft. 9-in. section. Very good progress was made in the east heading, and the required distance would have been completed in tunnel had not the existing local sewer been encountered which necessitated the discontinuance of the work by this method and the completing of same in open cut. In the west heading a layer of wet sand was encountered before the work had proceeded very far, making it more economical to open-cut the work than to proceed with tunnelling.

The material through which the sewer ran was not as good for carrying on the work in tunnel as in the previous section and had to be close-sheeted. The work was done in the same manner as the other section (2 ft. 8 in. × 4 ft.), except that the excavated material was conveyed to the dump in cars after it had been brought to the surface in buckets. The dump was on city property and located close to the shaft.

Cost of Brick Sewer in Open Cut.—When it was found impossible to proceed any further with the work in tunnel, the balance of the 2-ft. 6-in. × 3-ft. 9-in. section was constructed in open cut. The excavating was done by hand, and the material conveyed to the rear of the work in ½-yd. buckets on a traveling car, where it was dumped on the finished work as back-filling. A wet, sandy blue clay was encountered in places, which retarded progress to some degree, and, as an extra precaution against settlement, a plank decking was laid and the sewer constructed with a square base. As the work was being carried on in cold weather, it was decided to construct the sewer entirely of brick, instead of concrete, as called for in the contract. Mixing concrete in winter is expensive and not always satisfactory. The manholes and diversion chambers were built entirely of concrete, with the exception of the chamber at Logan Ave.

OPEN CUT

Length of 2 ft. 6 in. × 3 ft. 9 in. two-ring brick sewer, lin. ft.	208

Concrete Section (2ft. 2 in. × 3 ft. 3 in.) with One Ring of Brickwork in the Invert.—In this section the excavation was carried on in the same manner as in the 2-ft. 6-in. × 3-ft. 9-in. section, but much more rapidly, as the average depth of trench, which was 14 ft., was considerably less and the class of soil through which the sewer ran did not require much timbering. Just as soon as excavation was completed to sub-grade the concrete was placed in the invert and the following day the brick invert was laid. This was done so that the concrete forms, which were made in three sections, could be braced at the bottom. The concrete in the side walls was then run and, if possible, the concrete was placed in the arch on the same day. If this was impossible, a good key was left and the concreting proceeded with from this point the following morning. The mixing was done in a ½-yd. gasoline mixer and placed by means of chutes. The absence of reinforcing simplified pouring of concrete considerably. After the concrete had set sufficiently, the tongued and grooved forms were removed and any necessary finishing was done.

At the end of this section a special diversion chamber was constructed with a leaping weir and a connection for a future extension. This chamber was constructed entirely of brickwork, which was usually found to be cheaper than concrete, as no form work is required, and therefore no waste, and the work could be continued from day to day without any delays.

Material and Unit Labor Cost of Concrete Sewer with Brick Invert

Length of sewer (2 ft. 2 in. × 3 ft. 3 in.), lin. ft.	878

Labor Costs on a 3-Ft. Semicircular Storm Sewer.—E. W. Robinson gives the following records of the actual cost of labor, exclusive of excavation and

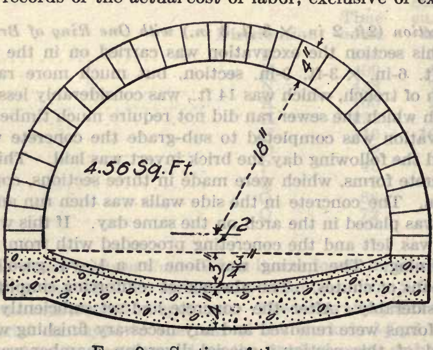

Fig. 9.—Section of the sewer.

back-filling, for constructing 290 ft. of 36-in. semicircular storm sewer, in Engineering Record, Aug. 3, 1912. The arch consisted of one ring of paving brick laid in cement mortar to which had been added a small amount of lime and plastered on the outside to a thickness of about ½ in. The invert was of concrete, 4 in. in thickness, with a ¾-in. surface finish of cement mortar. The centering was made 12 ft. in length, and was wedged up 2 in. from the invert. As soon as this length of sewer was completed, including the plastering, the centering was lowered and pulled ahead and wedged up again, care being taken to avoid disturbing the brick previously laid. Not more than 15 min. was lost each time in shifting the centering.

The concrete for the invert was mixed in the proportion of one part cement to six parts gravel or mine "tailings." A No. 9 Coltrin continuous mixer was used throughout the job and the concrete was shoveled into place from the bank. The mortar for the finish was mixed by hand in the proportion of 1 part of cement to 1½ parts of river sand. The concrete gang consisted of a foreman and seven men.

LABOR CHARGES ON CONCRETE INVERT

1 foreman, 17 hours @ $0.55⅝	$ 9.44
1 finisher, 17 hours @ $0.33⅓	5.67
1 feeding mixer, 17 hours @ $0.22⅜	3.77
1 shoveling from mixer, 17 hours @ $0.22⅜	3.77
1 mixing and carrying mortar, 17 hours @ $0.25	4.25
1 striking-off and tamping concrete, 17 hours @ $0.25	4.25
2 setting forms and trimming bottom, 30 hours @ $0.22⅜	6.67
Total for 290 lineal feet	$37.82
Per cubic yard of concrete	2.35
Per lineal foot of sewer	0.13

The brick-laying gang consisted of two masons and two helpers, who mixed and carried the mortar and carried the brick from piles about 50 ft. from the line of the work. It will be noted that the cost of laying the brick was rather high, which was due to the fact that neither mason was an adept in this class of work, both having done only the roughest kind of work before.

LABOR CHARGES ON BRICK ARCH

2 brick masons, 74 hours @ $0.44⅝	$31.78
2 helpers, 74 hours @ $0.22⅜	16.44
Total for 290 lineal feet	$48.22
Per 1000 brick	$ 4.00
Per lineal foot of sewer	0.166

Costs of Brick and Concrete Sewer Construction.—Engineering and Contracting, June 28, 1911, gives the following data, taken from a paper on Excavation, Foundations and Sewer Work presented before the Western Society of Engineers by Victor Windett.

From an average of 6,000,000 brick laid in two and three ring sewers in and near Chicago it is determined that there are 520 brick required per cubic yard of masonry. This average is taken for brick as counted in cars or wagons, including breakage. As it is customary to lay all bats of one-half brick or greater in the outer rings of the arch, the loss from breakage is trifling. As shipped from the brick yards, sewer brick are uniformly of good quality. Any underburned or soft brick found in the kilns are broken up or sold for building brick. The size of Chicago hard sewer brick will average 8⅜ × 3¾ × 2$\frac{7}{16}$ ins. The use of the bats as indicated is not detrimental to the quality of the work, as the extrados is thickly plastered with cement mortar, and all joints well filled.

Brick Sewers.—The organization of a bricklaying gang is as follows: A foreman, whose duty it is to keep a steady supply of everything needed for the use of the masons, is placed on the berm of the trench. Each 2 bricklayers has a helper in the bottom. According to the depth of the trench there are 1 to 3 scaffold men for each tender and a brick tosser on the bank, and 1 mortar carrier. Two mortar makers will serve 4 masons. From 2 to 6 men are required to take down the arch centering of ribs and lagging, pass it ahead, and set it up again. It is uneconomical to work an odd number of masons, as the same number of auxiliaries can serve 2 masons as easily as one.

The average day's work of a mason working 8 hours was found to be 4,000 brick laid in place. The maximum number laid per day was an average of two days' work on a 2 ft. diameter two ring sewer in a moderately wet trench where an average of 7,583 brick were laid per man. The minimum happened to be on a larger and easier sewer to build where, however, other adverse circumstances cut the day's work to 2,700 brick. A safer average is 3,500 brick per man per day.

Table X, based on 4,000 brick per day, gives the output and rate of construction for various sizes of sewers which ought to be reasonably expected, as it is the rate maintained for four years' time.

TABLE IX.—BRICKLAYING, FORCE AND COST OF 2 RING SEWERS

Diameter of sewer in ft...	2–4		4–8	
	No. men	Cost per day	No. men	Cost per day
Bricklayers	4	$40.00	6	$ 60.00
Tenders	2	7.50	3	11.25
Scaffoldmen	2	5.50	3	8.25
Brick tossers	2	4.50	3	6.75
Brick wheelers	2	4.00	4	8.00
Sand throwers	2	4.50	3	6.75
Mortar mixers	2	5.00	4	10.00
Mortar carriers	2	4.50	4	9.00
Water boy	1	1.50	1	1.50
Team	½	3.00	1	6.00
Foreman	1	5.77	1	5.77
Total	20½	$85.77	33	$133.27
Brick and cement teaming	4½ men at $6.00;	27.00	7 men	42.00
Total	25 men =	112.77	40 men =	175.27
No. of men to 1 bricklayer	6		6½	

TABLE X.—LENGTH OF SEWER PER DAY'S WORK AND COST PER FOOT

	3 Rings		2 Rings	
2 ft.	139 ft.	$0.81	209 ft.	$0.83
2½ ft.	107 ft.	1.05	160 ft.	1.09
3 ft.	102 ft.	1.10	153 ft.	1.15
3½ ft.	88 ft.	1.28	132 ft.	1.33
4 ft.	75 ft.	1.50	112 ft.	1.55
4½ ft.	68 ft.	1.66	103 ft.	1.70
5 ft.	55 ft.	2.08	83 ft.	2.10

Working an odd number of masons is expensive, as 1 tender, tosser, scaffoldman, sand thrower and mortar carrier can attend to 2 masons.

Bricklaying per mason per day, 4,009. (Ave. of 28,177 ft. of work.)

Manholes.—Brick manholes are usually built 3 ft. internal diameter of two bricks in thickness or 9 ins. The inner ring is built with brick standing on end and bonded every fourth course with one course laid flat. The outer ring is built best of half bricks or bats laid flat.

The most economical way of building brick manholes is to use a light wooden *drum*, slightly conical in shape as a *form* against which to lay brick. The taper need not be over ½ in. and is for the purpose of making it easy to raise the form as the brickwork requires. The height of the form or drum is usually 3 ft., so as not to make it too heavy for ease of handling. When iron steps are placed in the manhole, a slot can be cut into the drum 1 in. larger all around than the step for clearance.

In case steps are used they are best spaced approximately 16 ins. apart; a width of 9 ins. is sufficient. The best form of step is that used on telephone poles, in which the foothold or step is bent, or dropped 1 in. below the sides, so as to prevent a user's foot from slipping off sidewise. The ends should project through to the outside of the wall, and bend up 1 or 2 ins.

In building manholes or catch basins, two bricklayers should work together on account of requiring no more helpers than one mason. It is better to *raise* manholes when the bricklayers cannot work on the sewers, so as not to disorganize the main work of the masons; their work is to push construction of the sewer itself at top speed.

Manholes on pipe sewers are best built up to the center line of the sewer as soon as possible after the excavation is made, so that pipe laying may proceed without delay. In some cases it is possible to do this ahead of pipe laying, which is highly advantageous, and then complete the manhole, when the mason is not preparing another *bottom*.

The cost of such holes is shown in Table XI, in which is given average costs for 178 manholes.

TABLE XI.—BRICK MANHOLE COSTS

Size of sewer	Height of manhole	Labor Hours	Labor Cost	Brick	Cement, bbls.	Materials Cost	Total
4 ft. 6 in. brick..	5.8	9.0	$ 5.32	713	1.4	$ 9.70	$15.02
3 ft. 6 in. brick..	5.9	10.4	4.96	727	1.4	9.78	14.74
3 ft. 0 in. brick...	5.3	11.1	4.95	626	1.3	9.81	13.76
2 ft. 0 in. brick...	6.1	9.0	4.80	727	1.4	9.80	14.60
