1 ft. 3 in. pipe...	8.4	31.0	13.75	1,141	2.4	12.81	26.56
1 ft. 0 in. pipe...	7.9	27.9	12.05	1,100	2.2	12.10	24.15
Ave. brick.......	5.7	10.2	4.93	698	1.4	9.83	14.78
Ave. pipe.......	8.2	29.0	12.62	1,168	2.4	12.80	25.42

Height of manholes for brick sewers is measured from extrados of arch; for pipe sewers it is the full height of the brickwork.

A summary of Table XI is as follows:
Average size, 3 ft. diam.; 7 ft. 11 ins. high; 9 in. walls.
No. brick each, 1,080, or 2.52 cu. yds.
No. bbls. cement, 2.3.

Volume of masonry per lin. ft.	0.3
Labor in hrs. per manhole	21
Labor in hrs. per lin. ft. in height	2.65
Labor per cu. yd. masonry hrs	8.3
Labor cost per manhole	$10.67
Labor cost per lin. ft. manhole	$ 1.36
Labor cost per cu. yd. masonry	$ 4.23
Average rate of wages, including masons, helpers and team	$ 0.51

Table XII shows the average costs of concrete manholes.

TABLE XII.—CONCRETE MANHOLE COSTS

Brick Catch Basins.—Brick catch basins are built in Chicago with a 2-in. plank bottom. The basins are 4 ft. internal diameter for 5 ft. 6 ins. height and draw in to a diameter of 2 ft. in 20 ins. of height. A 9-in. half trap is set with the bottom 3 ft. 6 ins. above the planking. The brick work is 8 ins. in thickness.

Catch basins are best built toward the close of piece of sewer work, as usually the soil is then somewhat drained by the sewer.

A small gang of diggers is organized so as to keep just ahead of the masons. Two men are put to digging each hole; no sheeting need be used, as the hole is open for so short a time as to render caving unlikely. The sides are sloped just enough to prevent slides. In case of wet ground, four to six well-points attached to a diaphragm pump will be needed.

As soon as bricklaying is begun, two men are put to digging for and laying the discharge pipes from the basins to the sewer. The work so organized can be cheaply and quickly built.

The cost of basins and connections are given below:

CATCH BASIN COSTS

Number on which costs are based, 212,—4 ft. diam., 8 ft. high.
Soil, sand.

Labor cost, 345 hours	$13.22
Materials—1,100 brick at $6	6.60
60 B.M. lumber at $10	.72
2.2 bbls. cement at $0.636	1.40
19 in. half trap	1.45
1 cover	5.25
Superintendence	1.26
Total	$29.90

The planks for the bottom were cut out of worn-out short sheeting which had done full service in the sewer construction and hence were charged to the catch basins at a low cost.

CATCH BASIN CONNECTIONS

		Per ft.
Labor, 13.1 hrs.		$ 4.23
Materials—9-in. pipe	$5.50	
Cement	.18	5.76
Jute	.08	
		5.76
Superintendence		0.50
Cost per foot, $0.65½		$10.49

COSTS PER FOOT OF MAIN SEWER

	Brick Sewers	Pipe Sewers
Manholes	$0.090	$0.19
Catch basins	0.253	0.253
Catch basin connections	0.089	0.089
Total	$0.432	$0.532

In sewer work the operations naturally fall under three headings, viz.: trenching, masonry, general labor. Trenching includes excavation, sheeting and bracing, pumping and backfilling. The distribution of expense of the various operations of construction is given in Table XIII, which is based on 55,000 lineal feet of work.

TABLE XIII.—PROPORTIONAL DIVISION OF EXPENSES OF CONSTRUCTION

	Concrete Sewers	Brick Sewers	Pipe Sewers
Excavation labor	12.1 %	20.7 %	22.3 %
Sheeting and bracing labor	7.0	10.0	7.2
Backfilling labor	4.9	3.3	6.0
Pumping labor	.5	2.3	10.0
Total trenching labor	24.5	36.3	45.5
Masonry labor	25.0	20.0	4.9
Operating superintendence	4.5	5.2	4.6
Total labor	54.0	61.5	55.0
Materials and supplies	41.6	30.0	29.6
Office expense	4.4	8.5	15.4
Totals	100.0	100.0	100.0

At the time when the invert is placed in the concrete or brick sewers, the work is 57 and 65 per cent, respectively, completed.

Cost of Large Brick and Concrete Sewers in Chicago.—The following is taken from a paper by H. R. Abbott, before the Illinois Society of Engineers and Surveyors, as reprinted in Engineering and Contracting, Feb. 11, 1914.

With the exception of very small stretches, all of the work, described in this paper is built in good stiff blue clay, in the Sanitary District of Chicago.

West 39th Street Conduit.—The total length of this conduit was 2,346 ft., of which 1,868 ft., was plain concrete, a section of which is shown in Fig. 10, and 478 ft. reinforced concrete, the reinforced section being under railroad property. It is 12 × 14 ft. in size, of elliptical section.

Excavation.—Excavation was started in open cut. A Bucyrus 70-ton steam shovel was used with a 1¾ cu. yd. dipper. The shovel was mounted on five 16 × 18-in. timbers, 30 ft. long, with two 2-in. truss rods to each timber.

The top 4 ft. of trench was excavated about 3 ft. wider than the outside lines of the masonry, since no bracing was put in near the top of the trench. Below this the trench excavation was made to the exact width of the masonry, plus an allowance of 4 ins. for sheeting. Although a variation in and out was unavoidable, it did not exceed 2 ins. in either direction. The trench width was 15 ft. 8 ins.; average cut was 23 ft. 6 ins., making an excavation of 13.7 cu. yds. per running foot. On account of the deep cut, the shovel was equipped with a 36-ft. boom and a 54-ft. dipper handle. As there was liability of slides and cave-ins, the excavation was handled in two lifts. On the first run the shovel excavated the top 10 ft., using 9-ft. sheeting with one set of bracing placed about 6 ft. below the ground surface. The shovel dug ahead of the finished cut from 75 to 100 ft., then backed up and excavated the lower 13½ ft. The lower lift was taken out between steel beams, each built up of two 10-in. I-beams with cover plates, 50 ft. long, held in place by screw braces set 7 ft. back from each end. This replaces the ordinary wooden bracing and allows a free movement of the dipper in the trench for three moves or 36 ft. When a section is finished, the beams are carried ahead by the dipper, the wooden braces are replaced on the top sheeting, and another set of 9 ft. sheeting is placed with two sets of braces for the lower portion of the trench, the lower end of the sheeting being at a point where the invert curve meets the side wall. The lower sheeting back of the concrete was left in permanently. The bottom was trimmed and shaped by four or five bottom men, the material being cast ahead where the shovel could reach it. An iron frame or template built to the dimensions of the outside lines of the masonry was set up every 12 ft. as a guide in trimming the sides. The excavated material was loaded direct from the shovel on to 4-cu. yd. dump cars operating on a 3-ft. gage track. Ordinarily, the upper lift made the backfill, and the lower lift was run to a spoil area in McKinley Park, a haul of about ⅜ mile. The sheeting was 2 × 10 in. hemlock, the braces 8 × 8 in. and 6 × 6 in., with stringers 6 × 8 in. of yellow pine.

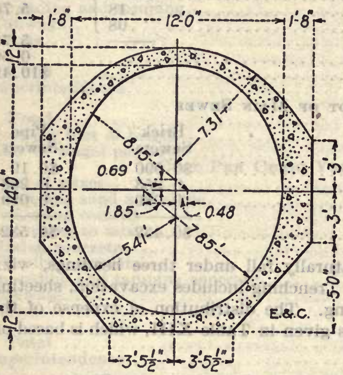

FIG. 10.—Cross section of plain concrete portion of the new West 39th St. conduit, Chicago, Ill.

Concrete.—The concrete mixer was mounted on timbers to span the trench. A No. 2 Chicago mixer, holding 25 cu. ft. of dry material, was used. Adjustable spouts were used for pouring the concrete, the spout-man standing on braces in the trench and deflecting the concrete to any point required. The pouring was made in three runs, each usually being about 16 ft. long. The first or dish extended to 2 ft. above the bottom of the trench; the second, or sides, extended 2 ft. above the springing line; the third or arch completing the section. The invert was shaped up with a wooden template or bulkhead, conforming to the inside and outside lines of the masonry, on which the forms were placed after the concrete was set. The forms were built up of 2 × 6-in.

TABLE XIV.—UNIT COST OF CONSTRUCTING THE PLAIN CONCRETE SECTION OF THE WEST 39TH ST. CONDUIT—SIZE, 12 × 14 FT.—AVG. CUT, 23 FT. 6 INS.

Item	Cost Per lin. ft.	Cost Per cu. yd.

Total	$18.29	$4.133

Cost percentages: For material and plant, 54 per cent; for labor, 46 per cent.

TABLE XV.—CONSTRUCTION, FORCE AND RATES OF PAYMENT ON W. 39TH ST. CONDUIT, TO ACCOMPANY COSTS IN TABLE XIV

Employee	Wage per day
1 superintendent	$8.00
1 shovel engineer	7.00
3 dinkey engineers, each	3.60
1 cranesman	4.50
1 fireman	3.00
3 switchmen, each	2.25
2 flagmen, each	1.75
1 coal passer	2.50
3 foremen, each	4.50
1 hoisting engineer	5.60
4 bottom men, each	3.85
50 to 60 laborers, each	2.50
1 team	5.00
1 carpenter	4.80
1 machinist	3.50
1 machinist's helper	2.50
1 office boy	2.00
1 material man	2.50
1 watchman	2.50
3 water boys, each	1.00

lagging, laid on 6-in. channels, bent to shape. At the springing line, a 6 × 6-in. timber rested on angles bolted to the channel, being held in place by a ⅞-in. pin running through both timber and angle. After the sides were poured and set, the braces were removed and the lagging placed for the crown. The channels for the arch were reinforced with two plates.

No manholes were built and no lateral connections were made, but 24-in. tile were set in the arch at intervals for future connections. The contract specified a concrete composed of 1 part Portland cement, 3 parts sand, and 5 parts crushed stone or gravel; the engineer, under the specifications, having the right to vary the proportions of fine and coarse aggregate, but maintaining the proportion of 1 part cement and 8 parts aggregate. Gravel proved very satisfactory. The mix was fairly wet, except on the crown of the arch, where a dry mix was necessary to prevent the concrete running.

The average progress per day of 9 hours was 30 ft. for both shovel and mixer, for the plain section. This means 420 cu. yds. of excavation, with disposal in backfill or spoil bank. The actual cost of excavation, backfill, and spoiling can be seen by reference to Table XIV. The concrete averages 2½ cu yds. per ft. A daily average of 75 cu. yds. was placed. The average progress per day on the reinforced section was 24 ft. per day, the slowing up being due to the time used in placing the reinforcing steel.

On the same platform with the mixer was mounted a small boom derrick and hoisting engine. This facilitated the removal of stringers and braces, and pulled the mixer platform back and forth. The material for concrete was delivered to a platform laid on the ground alongside of the mixer, being hauled in 4-cu. yd. dump cars by dinky engines an average distance of ⅜ mile.

Reinforced Section.—This section is of the same dimensions as the plain, but was reinforced to strengthen the conduit where it passed under railroad property. The same methods of construction were used as on the plain section. The reinforcing steel averaged 44 lbs. to the cubic yard of concrete.

Backfill.—Backfill was made by the 4-yd. dump cars, track being swung in over the conduit as the filling progressed. Centers were left in until the sides were thoroughly compacted and at least 1 ft. of filling had been placed over the top of the arch. Unit costs on the reinforced concrete portion of this sewer are given in Table XVI.

TABLE XVI.—UNIT COST OF CONSTRUCTING THE REINFORCED CONCRETE SECTION OF THE W. 39TH ST. CONDUIT—SIZE, 12 × 14 FT. AVG. CUT, 22 FT.

Item	Cost Per lin. ft.	Cost Per cu. yd.
Excavation, labor	$ 2.43	$0.194

Total	$23.93	$5.896

Cost percentages: For material and plant, 53 per cent; for labor, 47 per cent.

South 52nd Ave. Sewer (Cicero Section).—This is a three-ring brick sewer with a total length of 10,000 ft., of which 7,300 ft. was 7½ ft. and 2,700 ft. was 7 ft. in diameter; 1,050 ft. of the 7½-ft. section was in tunnel.

With the exception of the tunnel the entire sewer was built on the line of an old 4 × 5-ft. wooden box sewer. The sewage flow was usually held back for periods of 8 to 16 hours, depending on rain fall, by a temporary gate, consisting of an enclosed box 3 × 3 × 12 ft., having a sliding door working vertically about 4 ft. from the upstream end. The old wooden box sewer was first uncovered at a point 600 to 1,000 ft. ahead of the steam shovel. After the top was removed, the gate was lowered into the old box and packed in place with sand bags. The gate was operated by a lever at the ground level, by a night watchman, who generally closed the gate at 6 a. m. and opened it at 7 or 8 p. m. A 45-ton Bucyrus steam shovel, equipped with a 1¼-cu. yd. dipper, excavated the trench, placing the excavated material alongside. The average cut was 21 ft. made in a single cut. The existing box sewer was ripped out by the shovel as the trench advanced.

Sheeting 2 × 10 ins. by 16 ft. long was used with three set of stringers and braces. On about 70 per cent of the work the sheeting and one set of braces and stringers were left in.

During the progress of the work, several severe rainstorms occurred, causing considerable delay and some damage. In a portion of the work where sheeting had been pulled, a severe rain caused the bank to slide, which, together with the added weight of the spoil bank, caused a collapse of 130 ft. of completed sewer. The cost of repairs for this 130 ft. was $11.46 per ft., or 94 per cent of the first cost. On account of storms and the softening of the bank by storm and ground water shorter lengths collapsed. Because of the nearness to building foundations, thereafter, sheeting and one set of braces was left in place at an additional cost of 90 cts. per running ft. of sewer.

On the unpaved portion of the street the excess excavation was spoiled over the street. On the balance of the work it was loaded directly into wagons by the shovel, although a small portion of the excess was handled by a small Thew revolving steam shovel, loading wagons from the spoil bank.

A small amount of pointing-up proved necessary in a number of cases where water was passed over the brick work as soon as laid, and in a special case, when the breaking of the gate had flooded out the bricklayers before the invert could be laid complete. All material was teamed to the work, the average haul being ¾ mile. Connections were made with all lateral sewers and existing house connections.

The average progress per day on the 7-ft. section was 45 ft., equivalent to 330 cu. yds. of excavation, while on the 7½-ft. section the average progress was 70 ft. per day, with 20 ft. cut, or 500 cu. yds. of excavation per day. The difference in the progress between these two sections was partly due to the fact that the 7½-ft. sewer was built in a street 80 ft. wide, with open prairie on one side and unlimited room for work, and the 7-ft. section was built in a 66-ft. street with scant open space adjacent to the street. Tables XVII and XVIII give the unit costs on the 7-ft. and the 7-ft. 6-in. sections respectively.

TABLE XVII.—UNIT COSTS OF CONSTRUCTING THE CICERO SECTION OF THE SO. 52ND AVE. 7-FT. BRICK SEWER—AVG. CUT, 21 FT.

Item	Cost Per lin. ft.	Cost Per cu. yd.
Excavation, labor	$ 2.22	$0.308

Cement	.....	0.57
Sand	.....	0.29
Total	$14.33	$ 8.06

Cost percentages: For material and plant, 49 per cent. For labor, 51 per cent.

The average number of brick laid per day per bricklayer was 4,900 in the 7-ft. section and 5,900 in the 7½-ft. section. Backfilling was done with a Monaghan revolving derrick, equipped with a Page orange peel bucket, capacity 1 cu. yd. This is a very efficient machine for backfilling, but the operator should avoid dropping the load from any distance, as it is liable to crack the masonry, especially when working during wet weather, when the backfilling is saturated with water.

TABLE XVIII.—UNIT COSTS OF CONSTRUCTING THE CICERO SECTION OF THE SOUTH 52ND AVE. 7-FT. 6-IN. BRICK SEWER—AVERAGE CUT, 20 FT.

Item	Cost Per lin. ft.	Cost Per cu. yd.
Excavation, labor	$1.63	$0.226
Excavation, plant	0.28	0.040

Cost percentages: For materials and plant, 53 per cent. For labor, 47 per cent.

TABLE XIX.—CONSTRUCTION FORCE AND RATES OF PAYMENT ON CICERO SECTION OF THE SOUTH 52ND AVENUE 7-FT. AND 7-FT. 6-IN. BRICK SEWERS, TO ACCOMPANY COSTS IN TABLES XVII AND XVIII

Employes	Wage per day
1 superintendent	$ 8.00
2 foremen, each	5.00
1 shovel engineer	8.00
1 hoisting engineer	5.60
1 cranesman	4.70
1 shovel foreman	3.25
1 derrick foreman	2.75
2 pump foremen, each	3.00
1 watchman	3.00
1 bricklayer	12.00
5 bricklayers, each	10.00
3 tenders, ach	3.75
4 cement mixers, each	3.00
5 cement carriers, each	3.25
4 to 8 bottom men, each	3.75
5 bracers, each	4.40
2 center men, each	3.75
1 blacksm th	3.50
1 blacksmith helper	3.00
3 scaffold men each	2.75
3 brick tossers, each	2.25
4 brick wheelers, each	3.00
6 roller men, each	2.80
1 material man	3.00
1 timekeeper	3.00
2 waterboys, each	1.00
10 to 20 common laborers, each	2.00
1 to 3 teams, each	6.00

Some special items may be worthy of mention, such as the cost of hand excavation in a sewer trench of this size, moving plant, etc. At the Illinois Central R. R., where the sewer passed under the tracks, the excavation was made by hand, loaded into wheelbarrows and wheeled to the edge of the right-of-way, at which point it was handled by the orange-peel derrick.

The piling and timbering of the tracks was done by the railroad company at their own expense. This hand excavation cost $1.25 per cu. yd.

In another case the steam shovel could not take out the bottom on account of the proximity of a viaduct. This earth was scaffolded out at a cost of $1.06 per cu. yd., being handled four times before it reached the spoil bank.

The moving of the steam shovel a distance of 1,050 ft. across a railroad yard and over the tunnel section was $560, or 53 cts. per foot. This includes the

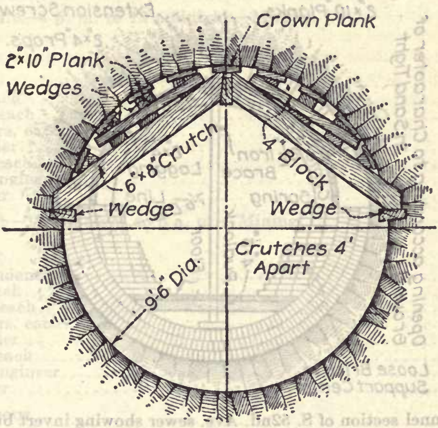

Fig. 11.—Detail of timbering in place to support roof in tunnel section of S. 52nd Ave. sewer.

partial dismantling of the shovel to pass under obstructions. At the start the shovel was taken off the railroad spur, moved ½ mile and placed on timbers to span the trench, at a cost of $750.

Tunnel Section.—The tunnel section, 1,050 ft. long, extends under the Morton Park yard of the Chicago, Burlington & Quincy Railway, and passes directly under five piers of the viaduct carrying South 52nd Ave. over the railroad yard. In places there was only 12 ft. of covering over the roof of the tunnel. The ground was stiff blue clay, containing but one sand pocket, which caused some earth settlement, visible at the ground surface. There were no settlements whatever at the piers. The unit costs for the tunnel work are given in Table XX, and the gang organizations in Table XXI.

The work was carried on by the two night shifts of miners and muckers and one day shift of bricklayers, working 8 hours each, or a total of 24 hours per day. One shaft was sunk, from which two headings were run. In Fig. 11 is shown the method of timbering in good stiff clay. In poor ground, the crutches would be made longer, with the lower end set below the spring line, and the 2 × 10-in. plank at the roof would be placed closer together. The excavated material was dumped from the shaft into railroad cars and hauled 3 miles to Western Ave.

The method of setting up the centers for the arch after the invert is built and timbering removed is shown in Fig. 12. The loose brick seen inside of the invert support the centers, spaced 4 ft. apart; 2 × 4-in. lagging is then placed. The earth at the roof is supported by 2 × 4-in. props resting on the lagging, reinforced by a 2½-in. iron prop extending from the floor of the invert to the crown plank at roof.

The average progress for 24 hours was 12½ ft. in each heading, or 25 ft. per day for both headings. The average number of brick laid per 8 hours per bricklayer was 3,000.

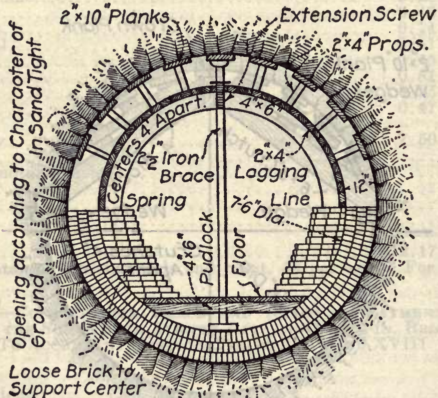

FIG. 12.—Tunnel section of S. 52nd. Ave. sewer showing invert built, timbering removed and centers set for arch.

TABLE XX.—UNIT COSTS OF CONSTRUCTING THE CICERO SECTION OF THE SOUTH 52ND AVENUE 7-FT. 6-IN. BRICK SEWER IN TUNNEL

Total	$19.70	$9.35*

Cost percentages: For materials and plant, 27 per cent. For labor, 73 per cent.

*Note—Masonry runs 1 cu. yd. per lineal foot of sewer.

Table XXI.—Construction Force and Rates of Payment on 7-ft. 6-in. Brick Sewer in Tunnel, to Accompany Costs in Table XX

Note.—The rates are for 8-hour shifts, and each force is for two headings, one-half the force working per shift being in each heading.

(a) First Shift—8 a. m. to 4 p. m.—Bricklaying.

Employee	Wage per day
1 superintendent	$10.00
4 bricklayers, each	10.00
6 tenders, each	3.75
2 assistant tenders, each	3.25
2 cement mixers, each	3.25
2 car pushers, each	2.50
2 shaft tenders, each	2.50
1 hoisting engineer	5.60

(b) Second Shift—4 p. m. to 12 midnight—Mining.

Employee	Wage per day
1 foreman	$6.00
6 miners, each	3.75
4 muckers, each	3.00
2 car pushers, each	2.50
1 shaft tender	2.75
4 laborers, each	2.50
1 hoisting engineer	5.60
1 timekeeper	3.00

(c) Third Shift—12 midnight to 8 a. m.—Mining.

Employee	Wage per day
1 superintendent	$10.00
8 miners, each	3.75
6 muckers, each	3.00
2 car pushers, each	2.50
1 shaft tender	2.75
4 laborers, each	2.50
1 hoisting engineer	5.60
1 timekeeper	3.00

(d) Miscellaneous.

Employee	Wage per day
1 dump foreman	$2.50
6 to 12 laborers, each	2.00
1 blacksmith	3.50
1 electrician	4.00
1 carpenter	4.50
1 carpenter's helper	3.00

The average progress per day was 12½ ft. per heading or a total of 25 ft. per day.

The tables of unit costs given above are intended to cover all field operations, including superintendence, labor, material and plant. Overhead charges of the contractor are not included, such as office expenses, bonding, liability insurance, and discount on municipal bonds on special assessment work.

The item of plant charge is a difficult one. For instance, take the item of steam shovels. There are steam shovels in service today that are 25 years old, whereas others are worth only scrap value at the end of three or four years. Many contractors charge off the entire plant to the job. So far as I see, for machinery such as steam shovels, dinkies, etc., it is fair to spread the plant cost over a period of ten years, allowing interest at 6 per cent on first cost, thus making a depreciation charge of 16 per cent per year. Alterations, fitting up, freight, small tools, etc., are directly chargeable against the job, and should be added to the above 16 per cent on cost of machinery and similar equipment for total plant charges against any piece of work.

In considering the overhead charge to be made, some figures must be taken in making up an estimate. This is more apt to be too small than too large. In Illinois, liability insurance will cost from 7½ to 11 per cent of the payroll, and on work described in this paper, the labor item is about 50 per cent of the total field cost for open cut work, and about 70 per cent for tunnel work. This makes a charge of 3½ to 8 per cent of total for insurance, to begin with. Office rent, telephone, cost of getting work, and other items may increase this to 10 or 15 per cent. Adding 15 per cent for profit, we thus have 25 to 30 per cent to add to the field cost. The cost per lineal foot on the various jobs on which cost data are given in the tables and also the field cost percentages for the component parts of the various jobs are given in Table XXII. With the aid of the data contained in the tables, reinforced by current market quotations on material, the author has made estimates for similar kinds of sewer work, in the aggregate about one-half million dollars. Such estimates agree with the low bid within 4½ to 7 per cent. In transferring the unit costs for work already performed to new estimate, due consideration must be made for differences in the local conditions, character of the soil, increased cost of labor, and the availability of standard types of machine to handle the work.

TABLE XXII.—COST PER LINEAL FOOT OF LARGE CONCRETE AND BRICK SEWERS WITH PROPORTIONAL DISTRIBUTION OF FIELD COSTS

Location	—W. 39th St. conduit—		—So. 52nd. Ave. sewer—	Cicero section	
Size	12×14 ft.	12×14 ft.	7 ft.	7ft. 6 ins.	7 ft. 6 ins.

Cost of Sewer Maintenance at Newton, Mass. (Engineering and Contracting, April 9, 1919.)—During 1918 the city engineer'sdepartment of Newton, Mass., cleaned and repaired 129.78 miles of sewer, the average cost per mile amounting to $75.25. The cost of flushing sewers was $21.20 per mile.

Costs of Operation of a Sewer Cleaner with Motor Operated Cutters.—Engineering and Contracting, March 15, 1911, gives the following:

The cleaner consists of a barrel provided with four runners on which it rides when moving through the sewer. Within the barrel is a water motor, the shaft of which extends out of the front end and carries a series of hook-shaped cutting blades. The rear end of the barrel is provided for a hose connection by means of which the water for operating the motor is delivered. Finally there are rope connections in front and rear. In operation a hose from the nearest hydrant is attached to the barrel and the cleaner is hauled through the sewer between manholes by windlasses as indicated by Fig. 13. As the cleaner advances the cutting blades operated by the motor cut and grind away the sediment which is carried away by the stream of waste water from the motor. The hose has, of course, to be long enough to reach from the hydrant down the first manhole and through the sewer to the second manhole. Four men nominally operate the cleaner, two ahead operating the second windlass to pull the cleaner and two at the first manhole to feed in the hose and back rope.

As indicating the efficiency and cost of operating the cleaner we give the following excerpts from a report by Theodore N. Aish, Engineer in Charge of Comprehensive Sewer System, Kansas City, Mo., of a test run made Dec. 7, 1910: The sewer was an 18-in. pipe sewer and the length cleaned between manholes was 371 ft. At 12:20 p. m., the crew, consisting of 4 laborers, 1 foreman and 1 team began the work of stringing hose to the nearest fire plug, 1,250 ft. distant, and getting rods through the stretch of sewer between manholes No.

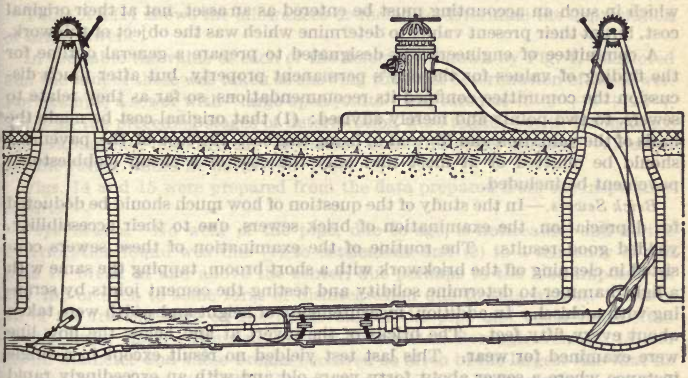

FIG. 13.—Method of using sewer cleaner.

1 and No. 2, preparatory to running the machine through. All preparatory work was done, water turned on and the machine started from manhole No. 2 at 3 p. m. A few minutes after the machine was started a length of hose burst, which caused delay of 12 minutes while a new length was being put in. The machine was taken out at manhole No. 1 at 3:42 p. m. having traversed the 371 feet of pipe in 42 minutes, or deducting the 12 minutes delay for repairing hose, the actual time of cleaning the sewer was 30 minutes. The hose was then taken up and rolled and everything cleaned and put away by 5:30 p. m. That this sewer was actually cleaned was shown by running a Shannon bucket through the sewer after the machine had gone through. In the whole length of this sewer only about ⅓ cu. ft. of dirt was gathered in the bucket. The cost of the cleaning was as follows:

Foreman, 5 hours at 37½ cts.	$1.85
Team, 5 hours at 50 cts.	2.50
Labor, 20 hours at 25 cts.	5.00
Total labor cost	$9.35

The length of sewer cleaned being 371 ft., the cost per foot was 2.52 cts. Another report gives the cost of 14 days' work cleaning 7,801 ft. of sewer as 3.15 cts. per ft., including cost of shifting machine from job to job.

Valuation and Depreciation of the Sewers of Manhattan Borough, New York City.—The following data are taken from an article in Engineering News, Jan. 8, 1914, by Otto Hufeland.

The sewer valuation here described is part of a plan, formulated by the accounting officers of the City of New York, to set up a capital balance sheet which would show the City's assets and liabilities, both bonded and otherwise, offset by its property real and personal, in the same manner as that of a rail-railroad or industrial corporation. The value of such an accounting is not confined to this balance sheet, but is an obvious aid in budget making and in the control of the city's financial affairs.

Among the several classes of "permanent property" owned by the city, the cost of which is largely represented in the outstanding bonds are the sewers. which in such an accounting must be entered as an asset, not at their original cost, but at their present value, to determine which was the object of this work.

A committee of engineers was designated to prepare a general outline for the finding of values for the city's permanent property, but after much discussion the committee confined its recommendations, so far as they relate to sewers, to two points and merely advised: (1) that original cost be made the basis of the valuation and (2) that in fixing this cost, the cost of the pavement should be omitted or at most that only the cost of a cheap (cobblestone) pavement be included.

Brick Sewers.—In the study of the question of how much should be deducted for depreciation, the examination of brick sewers, due to their accessibility, yielded good results. The routine of the examination of these sewers consisted in cleaning off the brickwork with a short broom, tapping the same with a light hammer to determine solidity and testing the cement joints by scraping with a chisel. In addition, measurements of height and width were taken about every fifty feet. The bricks of the invert at and below the flow line were examined for wear. This last test yielded no result except in a single instance where a sewer about forty years old and with an exceedingly rapid flow showed a very slight rounding of the exposed face of the brick at the joints.

A study of the reports of these examinations disclosed that the following defects were noticeable:

1. Cement partly out at water line.
2. Cement partly out above water line.
3. Depressed arch and sewer slightly spread.
4. Large open joints.
5. Loose brick.
6. Bond of brickwork broken.
7. Distorted sides, uneven bottom, joints out of line.

These seven defects show the progressive deterioration of brick sewers in the order in which they occur under the conditions existing here (and probably everywhere else). They are, of course, not sharply defined, and, passing from one step into another and coupled with the difficulty under which sewer examinations are made, cannot be determined with as much accuracy even as would be possible in an exposed structure.

TABLE XXII

Examined by	G	G
Date of construction	1868	1869
Location	46th St. 2nd to Lexington Ave.	Ave. A, 62–66 Sts.
Length in ft	928	1120
Size	4′ × 2′8″	3′0″ arc
Good condition, 0	....	....
Cement out at flow line, 2	x	x
Cement out above flow line 6	x	x
Depressed arch and sewer spread, 12	x	x
Large open joints, 25	x	x
Loose brick, 47	....	....
Bond of brickwork broken, 72	....	....
Distorted sides and joints out of line. Uneven bottom, 100	....	....
Total or average	45	45

Table XXIII shows the allowances deducted to determine the depreciation of brick sewers.

In the table the value of each of the defects, as shown by Fig. 4, was noted and the sum of these was taken as showing the total deterioration of the sewer. For example a sewer with "large open joints" was rated at 45 (2 + 6 + 12 + 25) if all the preceding stages of deterioration were found, but if, for instance the examination disclosed no "depressed arch and sewer spread," valued at 12, the rating would be 33 (2 + 6 + 25).

Figs. 14 and 15 were prepared from the data prepared from the inspectors' reports.

Pipe Sewers.—No wear of the pipe, due to age, is noticeable, and all the deterioration found was due (1) to settlement and (2) to a tendency of the pipe to break at and above the center, due perhaps to the load imposed on the top or even to some form of disintegration due to this weight. Nearly all of the fractures are on the upper half of the pipe and occur more often in the larger sizes. The sizes used in Manhattan Borough were 12, 15 and 18 in. diameter and these breaks occurred so often in the largest size that its use was discontinued in 1887. It occurred less in the 15-in. pipe and still less in the 12-in.

About 2½ miles of various sizes of pipe sewers were examined by "candling," or by fastening a lighted candle to a caliper and slowly pushing this through the sewer from manhole to manhole by means of rods, while the interior thus lighted up was examined by observers stationed at the manholes. The result was unsatisfactory, and furnished insufficient data to be used alone in determining a value.

It was therefore necessary to find some other means before determination could be made. The only data of value, in addition to the little supplied by the examination just described, were those obtained from the experience gained in renewing and repairing such sewers or in inserting spurs for house connections. In this the writer had the benefit of the knowledge of the men who had been in charge of this work for some twenty-five years, and from that and the examinations described, as well as a great many others made under his supervision, the writer formulated the curves shown in Fig. 16.

Due to the varying strength of the three sizes used, three curves were plotted, the 18-in. curve ending at 1887 when the use of such pipe was discontinued. It will be noticed that a rapid decrease in value is shown in sewers built before 1887. This is due to the construction above described. These curves can be used like those for brick sewers, so that values can be directly read off.

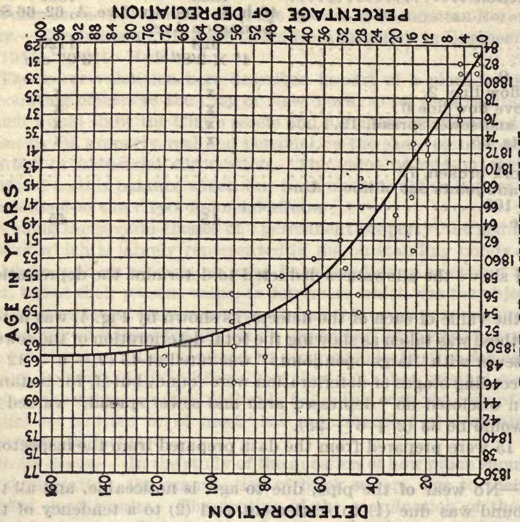

FIG. 15.—Percentage of depreciation based on examination of sewers, use of deterioration curve (Fig. 14) and age of sewers examined.

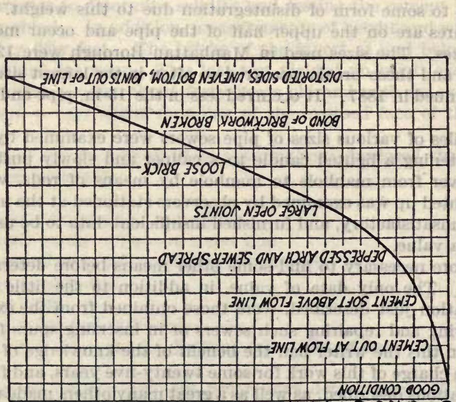

FIG. 14.—Proportionate deterioration from various causes.

FIGS. 14 and 15.—Diagrams used in estimating depreciation of brick sewers due to age, Manhattan Borough, New York City.

Earth Excavation and Backfilling.—In using any of these diagrams, it must be remembered that the deterioration is confined to the structure itself (the pipe and brickwork) and when this has reached a stage where repairs are no longer economical the sewer will have to be rebuilt. This will involve excavation and refilling as well as repaving. The last item has been fixed at the beginning of this statement, but the two preceding ones are important factors in the cost of replacement and consequently in the present value of the sewer.

When such excavation, at the time of original construction, was in earth, the original cost may fairly be used as a basis in the present valuation, because the same quantity of work would have to be done to replace the sewer,

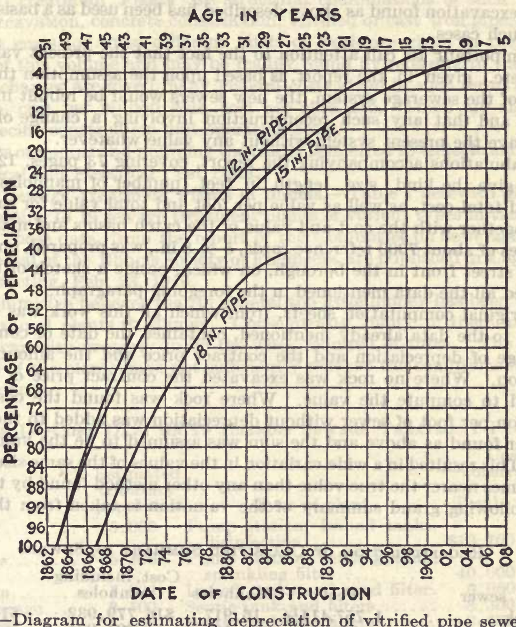

FIG. 16.—Diagram for estimating depreciation of vitrified pipe sewers due to age, Manhattan Borough, New York City.

if the subsequent subsurface structures are omitted from consideration. If, however, the whole or part of the original excavation was in rock, the cost of the reconstruction would be considerably reduced below the original amount, due to its previous removal.

For these reasons I have considered the cost of rock excavation an undepreciated asset and used it as a part of the present value of the sewer. It has been our custom to allow one day's working time for the contractor for every 10 or 12 cu. yd. of rock to be excavated. Such an allowance involved one day's pay ($4) for the inspector as well as increased attention on the part of the engineer in charge and his party in visiting the work and measuring and computing the rock, which may be estimated at $1 per day. Added to the inspector's pay this made $5 for every 10 or 12 yd. of rock excavated, or from 40 to 50c. per cu. yd.

If the cost of earth excavation and refilling be assumed at from 40 to 50c. per cu. yd. it will be offset by the "over-head" charges for rock. For example, if the bid for rock excavation is $4 per cu. yd., the "overhead" charges of 50c. will bring the actual cost to $4.50. If the earth excavation costs 50c. per cu. yd. the difference in cost between the two kinds will be $4, the price bid for rock. If, therefore, in determining the value of a sewer when rock excavation was necessary, the bid price of rock is deducted, the remainder will be the cost of that sewer in earth at the present cost of excavation. The cost of the sewer in earth excavation found as above described has been used as a basis of valuation in such cases.

It is important to call attention to the fact that the present value of the sewers, etc., given in the report, is based upon the assumption that in any changes of the sewerage system, the new sewers would be rebuilt in the same location, and that any such reconstruction involving a change of location would leave the present system without any value whatever.

The tabulations accompanying the report, covering 73 pages, 12 × 13 in. in size, give the kind, size, length in feet, number of manholes, cost per foot, and total cost, as well as value per foot and total value for each size of sewer, together with the cost and value of the catch basins and manholes.

A series of about 7000 reference cards, 5 × 8 in., was prepared, one for each block of street front in the borough, on which, beside a sketch of the block, was noted all the data mentioned in the foregoing paragraph.

The original computation sheets, from which all this work was copied, in addition to the data already mentioned, contained the date of construction, percentage of depreciation and the contract price and the amount of rock excavation. Where no rock was excavated the contract price of the sewer was used to compute the value. Where rock was found the cost of rock excavation per foot of sewer without depreciation was added to the value of the sewer found as above and the sum was assumed to be the value in such cases. This resulted in a wide variation in the values of the same size of sewer. but it comes nearer the true value than any other method found by the writer,

The following grand summary of the valuation is taken from the report:

Recapitulation of Classified Summary of Sewers

Kind of sewer	Feet	Manholes	Cost, including manholes	Value
Brick	1,757,414½	16,917	$16,779,932	$13,532,099
Wood	26,249	168	394,034	334,948
Pipe	767,611½	7,298	5,782,485	4,112,076
	2,551,275	24,383	$22,956,451	$17,979,123
	6172 Catch basins		923,875	685,798
			$22,880,326	$18,664,921
	24,383 Manholes		$ 842,500	$633,304

The foregoing summary includes 125 various sizes of brick sewers, 17 sizes of pipe sewers and 23 sizes of wooden sewers, a total of 165 with all kinds of manholes and perhaps 25 varieties of catch basins.

The work of preparing the report, including the cards, extended over a period of about ten months and involved a total expenditure of $6053. It could probably be kept up to date at an annual expense of about $500.

CHAPTER XII

SEWAGE TREATMENT

Sewage Treatment Plants are structural combinations of such types of work as excavation, concrete construction, vitrified or cast iron pipe, hauling, etc. Unit costs for these different kinds of work are given in the various chapters of this volume and may be readily found by referring to the index.

In this chapter are given many general costs given in such terms as: Cost per capita, cost per million gals, cost per acre, etc. There are also given certain specific construction and operating costs.

For costs of pumps and pumping the reader is referred to Gillette and Dana's "Mechanical and Electrical Cost Data."

Cost of Sewage Treatment Plants in Illinois.—Table I herewith gives cost data pertaining to 19 sewage treatment plants of various types in the state of Illinois. These data, from the report of the Committee on Sewerage and Sewage Disposal of the Illinois Society of Engineers, are published in Engineering and Contracting, Feb. 23, 1916.

The Committee believes that in general too little money has been spent on sewage disposal plants in Illinois. Consequently, many of them are not of sufficient capacity properly to do the work required of them. The result is that some of the plants have not sufficiently relieved the conditions for which they were built.

TABLE I.—COST DATA ON 19 ILLINOIS SEWAGE TREATMENT PLANTS

City	Estimated tributary population	Type of plant	Cost of —construction— Total	Per capita
Moline	5,000	Pump station, Imhoff tanks, disinfection	$10,700	$ 2.14
La Grange	5,300	Pump station, settling tank, sprinkling filter	40,000	7.56
Barrington	1,000	Imhoff tanks and sand filter.	6,000	6 00
North Chicago	3,500	Septic tank and filters	8,300	2.38
Lake Forest	3,000	Septic tank and filters	8,575	2.86
Ft. Sheridan	1,000	Septic tank, sprinkling and sand filters	45,990	45.99
Great Lakes	800	Septic tank and sprinkling filters	35,940	44.80
Morton Grove	1,200	Imhoff tank and sludge bed	12,815	10.70
Sandwich	2,500	Imhoff tank and sand filters.	10,915	4.36
Downers Grove	2,000	Septic tank and sand filters	7,980	3.99
Galva No. 1	800	Septic tank and trickling filter	3,700	4.62
Galva No. 2	1,200	Imhoff tank, trickling filters.	4,700	3.92
Woodstock	4,350	Septic tank, sand filters	10,874	2.50
Harvard	3,000	Septic tank, sand filters	11,980	3.99
Arlington Hgts	3,000	Septic tank, sand filters	11,950	3.98
Aledo	2,000	Septic tank, trickling filters	4,500	2.25
Geneva	2,400	Imhoff tank, Fox River	6,500	2.70
Toulon	2,000	Imhoff tank, trickling filters.	7,790	3.89
Pana	4,000	Imhoff tank, trickling filters.	31,000	7.75

The Committee believes, further, that the engineer should be the first to advise as to the proper size and capacity of plants, and that he should make his cost estimate sufficiently high to cover a plant of reasonable size and proper loadings to do the work for which it was built.

The members of the Committee were Samuel A. Greely, Chairman; Winfred D. Gerber and Frank M. Connolly.

Cost of Sewage Treatment Plants in Ohio.—Tables II, III, and IV are, given in an article published in Engineering and Contracting, Dec. 13, 1911, by R. Winthrop Pratt, formally chief Engineer Ohio State Board of Health.

Cost of Disinfection of Sewage with Hypochlorite.—The following matter is taken from an abstract of the 1912 annual report of the Mass. State Board of Health published in Engineering and Contracting, Jan. 29, 1913.

Three separate counts of bacteria—*i. e.*, total colonies on agar plates incubated four days at room temperature and total and red colonies on litmus lactose agar plates incubated 24 hours at body temperature—have been made on all samples. It has been found that waters in Massachusetts suitable for drinking usually contain less than 100 bacteria per c.c. determined at room temperature, and that the total number of bacteria developing on litmus lactose agar at body temperature is usually less than 10 per c. c., and the number of red colonies on such plates is usually less than 5 per c. c. This we have called the "drinking water" or "100—10—5" standard. For purposes of comparison two other standards containing, respectively, 10 and 100 times as many bacteria as the drinking water standard, and designated the "1,000—100—50" and the "10,000—1.000—500" standards, have been assumed. These latter correspond approximately to the upper and lower limits of bacterial counts on river waters receiving more or less pollution.

Effect of Time of Storage Upon Efficiency of Hypochlorite Disinfection.—In the laboratory experiments, analyses of all samples were made at intervals of 1, 2, 4, 6 and 24 hours after the disinfectant was added, and in the experiments in which the entire volume of settled sewage applied to Filter No. 248 was treated daily with hypochlorites. Many series of hourly samples were collected of the disinfected sewage as it flowed upon the filter. While there is some disagreement in the results of the various experiments, it is possible to determine approximately the relative amounts of disinfectant which would be required to yield similar results with different storage periods. In all cases the greater portion of the work of disinfection occurred during the first hour, after which the elimination of bacteria continued more slowly for some hours. This is especially noticeable in those cases where relatively small amounts of disinfectants were used. A general average of all the results shows the effect of storage to be about as follows: with 2 hours' storage about 84 per cent as much hypochlorite was required to produce the same result as with a storage of 1 hour; with 4 hours' storage about 82 per cent as much hypochlorite was required; with 6 hours' storage about 77 per cent as much hypochlorite was required, and with 24 hours' storage about 61 per cent as much hypochlorite was required to produce the same result as with a storage of one hour.

Cost of Hypochlorite Disinfection.—Commercial bleaching powder or calcium hypochlorite may be obtained packed in sealed drums holding 700 to 800 lbs. each, with a guaranteed strength of 36 to 38 per cent available chlorine, also in smaller drums of 25 to 100 lbs. each, but then bleach of the same strength costs about 1 to 2 cts. more per pound. Commercial bleach losses strength rapidly up to a certain point when exposed to the air, and broken bulk purchases, or drum packages whose contents are not used at once after opening,

TABLE II.—COSTS OF INSTALLATION OF PRINCIPAL OHIO SEWAGE TREATMENT PLANTS

Municipal plants

Location	Population census of 1910	Nominal population or population for which plant was designed.	Cost of installation	Cost Per Capita: Based on tributary population	Cost Per Capita: Based on nominal population	
Alliance (old)	15,083	5,000	$ 22,000	$ 1.80	$ 4.40	Chemical precipitation.
Alliance (new)	15,083	15,000	100,000	8.33	6.67	Sedimentation tanks, contact filters, and secondary filtration through fine cinders.
Ashland	6,795	3,000	6,500	2.16	2.16	Septic tanks, and filters of natural soil.
College Hill	1,979	2,000	20,700	26.00	10.35	Septic tanks, sprinkling filters, and final sedimentation.
Columbus	182,511	200,000	500,000	3.13	2.50	Septic tanks, sprinkling filters, and final sedimentation.
Delaware	9,076	1,600	12,000	3.00	7.50	Sedimentation and contact filters.
Eaton	3,170	2,600	9,400	4.70	3.60	Sedimentation tanks and sand filters.
Fostoria	9,597	4,000	25,000	5.00	6.25	Sand filters and broad irrigation.
Geneva	2,496	1,200	13,500	11.30	11.30	Septic tanks and sand filtration.
Jefferson	1,461	1,600	21,000	26.25	13.12	Septic tanks and sand filtration.
Lakewood	15,181	6,000	24,175	3.02	4.03	Septic tanks and contact filters.
London	3,530	1,300	15,000	30.00	11.50	Septic tanks and contact filters.
Mansfield	20,768	14,000	65,547	5.46	4.70	Septic tanks and contact filters.
Marion	18,232	10,000	43,000	3.58	4.30	Septic tanks, contact filters, and secondary filtration through sand.
Mt. Gilead	1,673	400	3,000	3.75	7.50	Sedimentation and sand filtration.
Oberlin (new)	4,365	4,000	16,000	4.60	4.00	Sedimentation, contact filters, secondary filtration through sand.
Orrville	3,101	4,000	19,000	9.50	4.75	Septic tanks, contact filters, and intermittent sand filters.
Oxford	2,017	2,000	12,000	12.00	6.00	Sedimentation, aeration, and intermittent sand
Ravenna	5,310	3,000	35,000	11.67	11.67	Sedimentation and sand filtration.
Shelby	4,903	1,000	4,000	2.00	4.00	Sedimentation and coarse sand filters.
Wadsworth	3,073	1,500	6,000	4.00	4.00	Sedimentation, contact filters, and secondary filtration through sand.
Xenia	8,706	1,500	6,000	1.00	4.00	Sedimentation and rough sand filters.

*Not quite finished.

TABLE III.—COST OF INSTALLATION OF PRINCIPAL OHIO SEWAGE TREATMENT PLANTS

Institutional plants

Location	Population census of 1910	Nominal population or population for which plant was designed	Cost of installation	Cost Per Capita: Based on tributary population	Cost Per Capita: Based on nominal population	Remarks
Alliance (Fairmount Children's Home)...	150	150	$ 6,000	$40.00	$40.00	Sand filtration without preliminary treatment.
Camp Perry (Ottawa County)..........	1,000[1]	1,000	3,500	3.50	3.50	National Rifle Range. Sand filtration without preliminary treatment.
Circleville (Pickaway Co. Infirmary).....	80	125	1,400	17.50	11.50	Septic tanks and sand filters.
College Hill (Methodist Home for Aged).	75	100	3,000	40.00	30.00	Septic tanks, sprinkling filters and sand filters.
Dayton (Montgomery Co. Infirmary)....	350	350	6,000	17.15	17.15	Sand filtration without preliminary treatment.
Delaware (Girls' Industrial Home).......	600	1,000	12,000	20.00	12.00	Septic tanks, sprinkling filters, sand filters and provision for disinfection.
Gallipolis (Gallia Co. Infirmary).........	40	50	400	10.00	8.00	Sand filtration.
Lancaster (Boys' Industrial School)......	1,000	1,200	8,900	8.90	7.42	Sand filtration without preliminary treatment.
Mansfield (State Reformatory)..........	600	820	1,000[2]	1.67	1.22	Rough sedimentation and sand filtration.
Massillon (State Hospital for Insane)....	1,600	1,600	8,000	5.00	5.00	Sand filtration without preliminary treatment.
Mt. Vernon (State Tuberculosis Sanitorium...........................	100	200	7,500	75.00	37.50	Sedimentation, sand filtration and disinfection.
North Amherst (Ohio Quarries Co.)......	40	100	2,800	70.00	28.00	Continuous filtration through broken stone.
Sandusky (Soldiers' and Sailors' Home)..	1,600	1,200	10,800	6.75	9.00	Septic tanks and sand filtration.
Toledo (State Hospital for Insane).......	1,500	2,000	3,000	2.00	1.50	Sand filtration without preliminary treatment.
Warren (Trumbull Co. Infirmary).......	90	100	1,170	13.00	11.70	Septic tanks and intermittent filtration through fine coke.
Warrensville (Cleveland Tuberculosis Farm Colony)........................	500	1,100	8,000	16.00	7.27	Sedimentation and sand filtration.
Wilberforce (Wilberforce University)....	380	500	2,500	6.58	5.00	Sedimentation and sand filtration.
Wapakoneta (Auglaize Co. Infirmary)...	75	150	5,000	66.67	33.33	Sand filtration without preliminary treatment.
Xenia (Ohio Soldiers' and Sailors Orphans' Home)................................	1,000	1,000	10,000	10.00	10.00	Sedimentation and sand filtration.

TABLE IV.—OPERATING EXPENSES AT FIVE OHIO MUNICIPAL SEWAGE TREATMENT PLANTS

Place	Operating expenses—1907				
			Operating cost per capita		
	Labor	*Total	Based on tributary population	Based on nominal population	Per million gals. per annum
Ashland	$ 302	$ 393	$0.13	$0.13	$ 3.20
Geneva	600	700	0.58	0.58	10.60
Lakewood	229	284	0.04	0.05	1.55
Mansfield	2,800	5,260	0.44	0.38	14.40
Marion	932	1,224	0.10	0.12	5.15

*Interest charges on cost of plants excluded.

will be found to contain less available chlorine. Analyses of a number of samples of broken bulk bleaching powder at the experiment station show that in many cases the strength may be less than 25 per cent available chlorine. The cost of this disinfectant, therefore, depends largely upon the daily amount of hypochlorites required, the extremely large disinfecting plant having the advantage of low price on bleach of guaranteed strength, the full strength of which would be available through immediate use of the contents of the large drums shortly after they were opened. The plant treating a small volume of sewage daily would pay a higher price for smaller packages, or if buying in larger lots to obtain low first cost, would find the ultimate cost increased by loss of strength which the contents of these larger packages would suffer during the period before they were consumed. For the large plant, where large volumes of sewage were to be treated daily, the disinfection costs might be reduced somewhat by the use of sodium hypochlorite manufactured at the plant. Sodium hypochlorite is readily prepared by electrolysis of solutions of common salt. As it exists only in solutions its use has been limited owing to difficulty of transportation. As a disinfectant it is fully as efficient as bleaching powder, and where common salt can be cheaply obtained and the cost of electric power is low there is no reason why the installation of an electrolytic plant should not help to reduce disinfection costs when a large amount of disinfectant is required. For the small disinfection plant, however, the use of commercial bleaching powder would probably be the cheapest in the end. Another factor which enters into the cost of disinfection is the standard of quality required in the effluent from the disinfecting plant.

Assuming a disinfectant containing 33⅓ per cent available chlorine at a cost of 2 cts. per pound, the treatment of a sewage with 0.1 part per 100,000 available chlorine would require 25 lbs. of disinfectant at a cost for chemicals of 50 cts. per 1,000,000 gals. On this basis the cost of disinfecting the various kinds of sewage and sewage effluents to definite prescribed bacterial contents would be about as follows:

To produce complete sterilization the cost would be well over $19 per 1,000,000 gals. for sewages and the effluents from contact and trickling filters, and would vary from $1.50 to over $19 for effluents from sand filters.

To produce a bacterial quality which would conform to the drinking water, or 100–10–5 standard, the cost would vary from $3.75 to over $19 per 1,000,000 gal. for raw sewage and effluents from trickling filters; from \$7.50 to over \$19 per 1,000,000 gals. for settled sewage, from \$15 to \$19 per 1,000,000 gals. for strained sewage and contact filter effluents; would be over \$19 for septic sewage, and would vary between \$1.75 and \$9.50 per 1,000,000 gals. for the effluents from sand filters which were not originally of that quality.

To produce a bacterial quality to correspond to the 1,000–100–50 standard, or one which would be about equal to that of the better class of streams or rivers which are not seriously polluted, the cost would be from \$1.75 to \$5.60 per 1,000,000 gals. for raw sewage; from \$1.75 to \$13 for settled sewage, about \$3.75 for strained sewage; between \$3.75 and \$5.60 for septic sewage; from \$1.75 to \$5.60 for effluents from contact filters, and from \$1.75 to \$3.75 for effluents from trickling filters. The cost of disinfecting sand filter effluents to produce this quality would not be over \$1.75 per 1,000,000 gals., judging from the experimental results.

If it was desired to reduce the bacterial content only to a point where they would approximately correspond with the more polluted rivers, or say within the 10,000–1,000–500 standard, the costs would be from \$1.75 to \$5.60 per 1,000,000 gals. for raw sewages and effluents from contact filters, between \$1.75 and \$7.50 for settled sewages, from \$1.75 to \$3.75 for septic sewage and effluents from trickling filters, and about \$1.75 per 1,000,000 gals. for strained sewage.

These cost estimates are for chemicals only and do not include operating and sinking fund charges.

The Economics of Sewage Filters. *Types of Sewage Filters.*—Sewage filters may be divided broadly into three classes:

(1) Intermittent sand filters or their equivalent. These consist of a body of sand or fairly pervious material of other kinds. The sewage is distributed over the surface of this porous material, and at the bottom the filtered sewage is collected in underdrains. In order to get the benefit of oxidation in the pores of the sand bed, the application of the sewage to the filter is intermittent, with periods of rest and aeration.

(2) The second type is the so-called "contact" filter. This consists of a body of practically any thickness of stone or equivalent material, such as large-sized gravel, pieces of porcelain, brickbats, cinders, or almost any coarse-sized granular material. The sewage is applied to such a filter either from the bottom or from the top, so as to fill the bed. The sewage is allowed to stand in this filter bed for a given time. It is then discharged and the empty bed is allowed to stand for a period.

(3) The third type is the so-called "sprinkling" filter. This consists of a body of stone of a minimum depth of 5 ft., on which the sewage is sprinkled or sprayed and spread by nozzles and distributed in small quantities so that the sewage trickles down over the stones and is collected at the bottom.

All three types of filters effect the purification of the sewage in the same way. Through the action of the bacteria present in the filter bed the sewage is to some extent oxidized and the organic matter is broken up. Unstable forms of matter are changed into more stable forms. While the exact form of action is unknown, it is believed that the three types of filters act in the same way, and the difference is a mechanical one of form of application. rather than one of principle of action. The following article is a reprint publishedin Engineering and Contracting, Oct. 14, 1914, of a paper by George W. Fuller, presented before the annual convention of the American Society of Municipal Improvements.

Performance of Filters.—The output of a filter of any type, measured at any suitable purification unit, is largely a question of local conditions. It depends upon the nature of the sewage, the nature and fineness or coarseness of the filtering material, the method of application of the sewage to the filtering material, temperature, atmospheric conditions, and many other factors. The intermittent sand filter is best used when it is desired to have a very high degree of purification. The other types, the contact filters and sprinkling filters, are used for a rather lesser degree of purification. It is to be understood that the rate of application of the sewage to the various types of filters must be properly proportioned to the ability of these filters to take care of the sewage. By using a suitable rate under suitable conditions any type of filter can be made to give any degree of organic purification that may be desired.

Rate of Application of Settled Sewage to Filters.—The question of the rate of application of sewage to a sand filter is largely tied up with the question of preliminary treatment in the way of tankage or screens. The following tabulation, quoted from Mr. Fuller's book, "Sewage Disposal," gives for several cities in Massachusetts the population whose sewage can be treated per acre of filter bed, and the time of detention in preliminary sedimentation tanks, storage wells, pump wells, or other means of storage. These figures are not to be taken to represent present conditions.

	Period of detention, hours	Population per acre of filter
Andover	1½–3	950
Brockton	12	1,160
Clinton	12	425
Framingham	12	375
Gardner (old)	1½	1,310
Gardner (new)	1½	2,000
Pittsfield	12	605
Stockbridge	8	220
Worcester	1½	1,390
Average of all	6.7	937

The Baltimore Sewerage Commission in 1906 estimated that, using a sand filter with 3 ft. of clean sand over the gravel, an allowance of 150,000 gals. of 6-hour settled sewage per acre in 24 hours, corresponding approximately to 1,200 people per acre, would be a proper rate.

Data for contact filters are relatively scant from American practice, and while many English data are available, the differences, owing to the difference in the strength of the sewage, makes such data rather dangerous as a basis of comparison.

A series of experiments in Columbus, Ohio, indicated that 5-ft. deep stone filters, on the contact principle, could safely be operated at an average rate of 600,000 to 700,000 gals. per acre per day. Reducing this to a 4-ft. depth will give about 500,000 gals. per acre per day, which, on the basis of 100 gals. per capita per day, would give a loading of approximately 5,000 people per acre of stone bed.

A series of tests made at Lawrence on contact beds of various depths from 24 ins. up to 18 ft. showed an average output of some 700,000 gals. per acre per day for a depth of stone on an average about 5½ ft. This is equivalent to an output of about 135,000 gals. per acre for each foot of depth of stone, or, for a 4-ft. depth of bed again, is equal to about 500,000 gals. per acre per day, or say a loading of about 5,000 people to the acre.

The contact filter installation at Plainfield, N. J., with 3.6 acres of stone bed 4½ ft. deep, gave in 1910 an output on an average of 1,700,000 gals. of sewage per day. On the basis of an allowance of 100 gals. per capita per day, this will correspond with a 4-ft. bed, to about 4,200 people per acre of filter.

For sprinkling filters much more satisfactory data can be had. Sprinkling filters have been used very extensively in this country of recent years and their ratings can be fixed with a good deal more dependence than in the case with contact filters. A list of a number of plants or projected plants giving the depths of the stone bed of a sprinkling filter and the loading in population per acre follows:

	Depth of stone in feet	Population per acre of bed
Atlanta	6	20,000
Reading	5	18,000
Columbus	5	18,000
Baltimore	9	20,000
Montclair	7½	15,000
Philadelphia	6	20,000
Fitchburg	10	20,000
Mount Vernon	8	24,000

The average of all these shows a 7-ft. deep bed and an average loading of 19,400 population to the acre.

Not considering special conditions and just taking fair figures, we may safely state the following:

Intermittent sand filters, 3-ft. bed of sand, loading 1,000 population per acre.
Contract filters, 4-ft. depth of stone, loading 5,000 population per acre.
Sprinkling filters, 7-ft. depth of stone, loading 19,000 population per acre.

The rates of loading, then, for these three types of filters, are in the ratio 1, 5, and 9.

Cost of Sewage Filters.—Costs of construction are so much affected by local conditions, such as the amount of excavation necessary, the cost of various classes of materials, the distance from which various classes of materials must be obtained, details of local construction conditions, such as competition, class of work required, and others, that comparative costs for different localities are only to be used with great discretion, and individual cost and even averages are only a guide to comparative costs in various places. Having this limitation in mind, we will examine in a rough way the cost of various types of sewage filters on the per capita basis.

The average cost of the nine Massachusetts intermittent sand filters cited above is $3,260 per acre, as reported in the Massachusetts State Board of Health Report of 1903. This gives a cost per capita connected to the filters of $3.50.

The 1906 Baltimore Sewerage Commission estimates the cost per acre of filters at $6,350, these filters being suitable for a connected population of 1,200 per acre. This corresponds to a per capita cost of $5.30.

The cost of contact filters, varying, of course, with the degree of the fineness of the design, may be taken, for filters equipped with suitable convenient appurtenances, at $30,000 per acre for a 4-ft. deep bed. This corresponds with a loading of 5,000 population per acre to a per capita cost of $6.

For sprinkling filters 7 ft. deep the cost will be about $45,000 per acre. On the basis of a loading of 19,000 population per acre, the cost per capita will be $2.37.

When considering the relatively low cost of the Massachusetts sand filters compared with the estimate made of the Baltimore sand filters, it is to be borne in mind that the conditions in Massachussetts for the construction of sand filters were unusually favorable and do not represent average conditions through the country. In most places the costs would approximate more nearly those estimated for Baltimore.

Taken in a broad way, sprinkling filters are a far more economical installation in the matter of first cost. Intermittent sand filters and contact filters do not stand far apart in this particular.

Relative Costs of Different Depths.—There is not very much known about the relative advantages of filters of shallow or deep construction. The choice of depth is usually made for entirely different reasons from those of obtaining the most economical construction to obtain the desired amount of purification. Very few tests of a comparative kind have been made to give convincing information, and the interpretation of the tests has not been uniform. In some places the conclusion has been made to make filters, say, 10 ft., at other places 6 ft., and some study is worth while to determine what, if any, difference there is in the cost of such construction at different depths, and which would appear to be the better. It is to be assumed in such comparisons that sufficient head would be available in any case for the greatest depth to be considered and that pumping would not be necessitated by building filters of the greater depth.

For intermittent sand filters questions of depth do not arise. The filters are generally made as shallow as is consistent with getting proper results and sand beds are not usually made more than 4 or 5 ft. deep as a maximum. Shallower beds, even, will give about the same output as the deeper beds, and beds are made deep only so that sand may be removed for cleaning without removing the sand for a considerable period.

With contact filters it is recognized that from the nature of the action of the contact filters, where the amount of air that is drawn in between fillings of sewage is practically equal to the volume of the sewage, and where surface clogging cannot be a serious factor and may even be no factor at all, each unit of volume of the stone forming the filter, say each cubic yard, will give the same output of sewage purification, no matter what may be the depth of the filter.

From this it follows that it is economical to build a sewage filter on the contact principle as deep as local conditions of construction will permit, and the limitation of depth which it is economical to use is therefore made by the factors of earth excavation or fill and the possible head available without pumping.

When it comes to sprinkling filters, the problem becomes a little more complicated. The English experience, as recited in the Report of the Royal Commission, seems to indicate that the output per unit of volume of sprinkling filters is the same, no matter what the depth. Our experience in work in this country does not wholly corroborate this information. Our best knowledge seems to indicate that the output per unit of volume of sprinkling filters is somewhat less for deep filters than for shallow filters. For such conditions, with a relatively decreasing efficiency of the stone of the filter beds for greater depths and at the same time a relatively decreasing cost per unit volume of the stone for deep beds, there must come some point where the greatest output per unit of cost will be obtained.

The Report of the Baltimore Sewerage Commission for 1911 gives some information obtained from tests made in Baltimore as to the relative efficiency of various depths of broken stone of sizes of 1 to 2-in. stone, which is the one most commonly used. Figures obtained from that source are as follows:

	Depth of bed 6 ft.	9 ft.	12 ft.
Relative stability	79	87	89
Per cent reduction of oxygen consumed	56	70	72

Giving equal weight to the relative stability and per cent reduction of oxygen consumed, we get the following:

	Depth of bed 6 ft.	9 ft.	12 ft.
Relative stability	1	1.2	1.23
Per cent reduction of oxygen consumed	1	1.25	1.28
Average of the two	1	1.22	1.25
Relative depths	1	1.33	2.00
Relative value of stone per cubic yard	1	.92	.63

Assuming this depth varies at a uniform rate from one end of the curve to the other, we get the following for the relative value of stone per cubic yard

Depth of bed in feet	6	7	8	9	10	12
Relative value of stone per cubic yard	1.0	0.97	0.94	0.92	0.82	0.63

To get comparative figures, then, between the 6, 8 and 10-ft. beds the cost figures for the 8-ft. beds must be divided by 0 94, and the cost for the 10-ft. beds by 0.82, putting them all on the basis of the 6-ft. beds.

For comparative cost a number of factors such as excavation, etc., are naturally omitted, as they are not affected in all places the same way by the depth of the filter. Comparing, then, only those particular costs which are affected per unit of output by the depth of the filter, we get the following:

	Per effective cu. yd. depths 6 ft.	7 ft.	8 ft.
Floor—Take at 40 cts. per cu. yd. for a 6-ft. bed	$0.40	$0.35	$0.32
Tile—Take 11 cts. per sq. ft. for any depth	.49	.44	.40
Walls—Assume cost 17 cts. per cu. yd. for 6-ft. depth	.17	.17	.18
Galleries and Collectors—Assume for 6-ft. depth 25 cts. per cu. yd.	.25	.22	.20
Distribution—Assume 50 cts. per cu. yd. for 6-ft. depth also, as costs theoretically vary only according to quantity delivered, they must be same for all effective depths per cu. yd.	.50	.50	.50
Stone—Assume $1.50 per cu. yd.	1.50	1.55	1.60
Total	$3.31	$3.23	$3.20

Outside factors will depend on quantity only and not on depth.

It appears, then, that there is some slight saving of cost, which, on the figures given in the above tabulation, amount to about 3 per cent in favor of the 8-ft. deep bed as compared with the 6-ft. deep bed. On the other hand, it is to be recognized that a deep bed will give a good deal more trouble with pooling and freezing than a shallow bed. and the advantages in favor of a shallow bed due to this lesser amount of pooling will be considerably more than this 3 per cent difference in cost. Taking everything into account, the writer believes that a sprinkling filter of not less than 6 ft. and not more than 7 ft. in depth will in the greater number of cases prove the most economical to use.

Cost of Constructing and Operating Trickling Filters.—The following is given in Metcalf and Eddy's "American Sewerage Practice."

Capacity of Trickling Filters.—The capacity of trickling filters is dependent upon the strength and character of the applied sewage as well as upon the size and depth of filtering medium. The Royal Commission on Sewage Disposal in its Fifth Report estimated the capacity of coarse filters at approximately 100 to 200 U. S. gal. per day per cubic yard of filtering material, which is equivalent to nearly 1,000,000 to 2,000,000 gal. per acre per day on a bed 6 ft. deep. The maximum limit set by the Royal Commission might be considered a safe estimate for ordinary domestic sewage in the United States, but for industrial wastes or sewage containing unusual amounts of such wastes much lower rates may be necessary.

Fuller has stated that a fair average loading for a filter 7 ft. deep is 19,000 population per acre. (*Proc. Am. Soc. Mun. Imp.*, 1914.) Trickling filters in the United States have been designed generally for between 2000 and 4000 persons per acre per foot in depth. The authors believe that the former is a safe estimate for treating settled domestic sewage by trickling filters 5 to 10 ft. deep composed of broken stone between 1 and 2 in. in size.

Relative Merits of Trickling Filters and Contact Beds.—At Worcester, Mass., where large quantities of sulphate of iron are present in the sewage, it was concluded that four times as much settled sewage could be treated with satisfactory results by trickling filters as by contact beds and that at least 3 contacts would be required to produce as high nitrification by contact beds as by trickling filters.

TABLE V.—COST OF CONSTRUCTION OF CERTAIN TRICKLING FILTERS BUILT OR PROJECTED IN THE UNITED STATES

Place	Area, acres	Depth of stone, feet	Cost per acre	Cost per cu. yd. of filter	Remarks
Reading, Pa (*a*)	1.0	6.3–7.0	$37,500	$3.50	Cost of second unit constructed, including dosing equipment and secondary sedimentation tank.
Columbus, O. (*a*)	10.0	5.3	24,040	2.81	Exclusive of conduits and engineering.
Washington, Pa. (*b*)	1.38	6.8	31,700	2.89	Exclusive of engineering.
Gloversville, N. Y. (*b*)	3.07	4.5	32,632	4.50	Exclusive of conduits, roof and engineering.
Fitchburg, Mass. (*b*)	2.0	10.0	59,650	3.70	Exclusive of engineering.
Chicago, Ill. (*c*)	.....	7.0	45,000	3.98+	Including office and laboratory, excluding engineering.
Paterson, N. J. (*c*)	.....	10.0	50,750	3.14	Complete.
Baltimore, Md. (*c*)	12.0	9.0	50,700	3.49	Exclusive of engineering.
East Orange, N. J. (*c*)	.....	7.5	45,000	3.72	Including foundations and dosing apparatus but excluding engineering. Allowance for foundations $7000.

(*a*) Actual cost.
(*b*) Estimated cost based on quantities from design and contract prices.
(*c*) Estimated cost.

With filters of coarse material not subject to disintegration, the evidence seems to indicate that they will be self-cleansing if properly operated, whereas contact beds usually clog periodically. Hence the cost of treatment by trickling filters is usually much less than that by contact beds.

The effluent from the trickling filter is ordinarily more highly nitrified than the effluent from contact beds and after secondary sedimentation is more uniform in quality than contact bed effluent.

The trickling filter is better adapted for variations in rates of flow than is the contact bed.

The chief advantages in the use of contact beds rather than trickling filters are the relatively low head required, the somewhat simpler method of dosing, minimizing foul odors and avoiding a fly nuisance.

TABLE VI.—ITEMIZED COST OF SEWAGE DISPOSAL PLANT, GLOVERSVILLE N. Y.

	Total cost	Unit cost
Screen chamber substructure	$ 445.27	....
Screen chamber house (total exterior volume, 1,350 cu. ft.)	535.00	$0.40 per cubic foot.
Primary settling tanks (total capacity both tanks, 537,000 gal.)	15,761.45	26.10 per 1,000 gal.
Dosing tank (total capacity, 8,800 gal.)	1,403.52	160.00 per 1,000 gal.
Trickling filters (3.07 acres, area of stone).	106,560.48	34,700 per acre
Secondary settling tanks (total capacity both tanks, 242,000 gal.)	9,292.31	38.40 per 1,000 gal.
Sludge beds (2.63 acres effective sand area).	9,097.23	2,450 per acre
Sand filter beds (2.72 acres effective sand area)	24,716.77	9,090 per acre
Sludge pump well (total capacity, 16,230 gal.)	1,232.61	75.90 per 1,000 gal.
Sludge pump house (total exterior volume, 1,880 cu. ft.)	535.00	0.39 per cubic foot
Sludge pumping machinery	460.00	....
Conduits and pipe lines (sewage, effluent, sludge, water)	11,758.85	....
Grading, drives, walks, trees, cleaning up, etc	3,800.78	....
Creek deepening and straightening	1,396.30	....
Miscellaneous	57.99	....
Extras, claims, incidentals, delays and damages	1,700.00	....
Total cost	$188,753.56	

On basis of 3,000,000 gal. of sewage treated daily, $62,900 per 1,000,000 gal.

Cost of Construction.—The actual or estimated costs of various trickling filters built or projected in the United States are shown in Table V. They vary from $24,000 to $60,000 per acre and from $2.81 to $4.50 per effective cubic yard of filter. Fuller gives the average cost of a trickling filter 7 ft. deep as $45,000 per acre, or $2.37 per capita, based on a population of 19,000 served per acre. (*Proc. Am. Soc. Mun. Imp.*, 1914.) The actual cost of the 10-ft. Fitchburg trickling filter was $58,847 per acre exclusive of excavation, or $2.94 per capita, based on a population of 20,000 per acre of filter. (Hartwell, *Jour. Bos. Soc. C. E.*, vol. ii, 1915, page 221.)

The relation which the cost of trickling filters bears to the costs of the other parts of a trickling filter plant will vary according to the design, as indicated in Tables VI and VII, showing the actual itemized costs of construction at Gloversville, N. Y., and Fitchburg, Mass. The roof system at Gloversville increased the cost of the trickling filter by approxmately $13,336, or $4445 per acre. Of this total, $4406 was for columns, $4550 for beams and $4380 for lumber, etc.

TABLE VII.—ITEMIZED COST OF DIFFERENT FEATURES OF SEWAGE DISPOSAL PLANT, FITCHBURG, MASS.

(Sewage Disposal Commission, Ninth Semi-Annual Report, 1914, page 7)

	Total cost (approximate)	Cost per capita (approximate)
Venturi meter and chamber	$ 2,942.25	$0.053
Imhoff tanks	56,122.53	1.02
Sludge beds	3,054.81	0.055
Dosing tank and apparatus	10,661.52	0.19
Trickling filters	136,545.53	3.41
Pipe lines	9,668.27	0.17
Overflow chamber	901.93	0.016
Secondary tanks	8,969.62	0.16
Pump house and pump	2,007.64	0.036
Effluent channel	1,328.91	0.024
Roadways	10,710.57	0.19
River improvement	5,122.67	0.093
Bonus paid contractor	5,000.00	0.091
Additional work to be done	10,000.00 est.	0.18
Engineering and inspecting	30,000.00 est.	0.54
Total (approximate)	$293,036.25	$6.22

Cost of Operation.—There appear to be few data of the cost of operation of the trickling filters in the United States. In most cases where costs are kept, no attempt has been made to divide the charges among the different parts of the plant.

At Columbus, Ohio, the operation of the entire treatment plant, exclusive of pumping station, for 1913 cost $8286.60; or approximately $2.40 per 1,000,000 gal. of sewage treated during 222 days of the year. (Rept. Div. of Sewage Disposal, 1913.) C. B. Hoover, Chemist in charge, informed the authors that the proportionate cost of operating the different parts of the plant was, approximately, preliminary tanks 4 per cent.; trickling filters, 6 per cent.; final sedimentation tanks, 90 per cent. The comparatively high cost of operating the secondary tanks was probably due to the difficulty of sludge disposal. The sludge from the preliminary tanks was pumped into the river during high stream flow. Hoover has furnished the subdivision of the average cost of operation of the Columbus plant per 1,000,000 gal. of sewage treated, given in Table VIII. The "actual cost" is the total annual expenditure for each of the items divided by the millions of gallons treated, while the "cost for time in service" is the expenditure for each of the items during the 222 days of operation divided by the millions of gallons treated.

TABLE VIII.—COST OF OPERATION OF SEWAGE TREATMENT PLANT AT COLUMBUS, OHIO, PER 1,000,000 GAL. TREATED

	Supervision	Chemical control	Operation of treatment devices	Care of grounds, etc.	All other items[1]	Total
Actual cost	$0.45	$0.32	$0.92	$0.47	$0.43	$2.59
Cost for time in service	0.29	0.21	0.42	0.32	0.30	1.54

[1] Includes transportation, heat, repairs, printing, supplies, light and telephone service.

At Reading, Pa., the net expenditure for maintenance and operation of the sewage pumping and disposal works for 1912 was $15,470.24, equivalent to $9.13 per 1,000,000 gal. of sewage treated. (Rept. City Engineer, 1912.) City Engineer Ulrich advised the authors that the cost of operation of the disposal plant alone for that year was $5215.10, which is equivalent to $3.08 per 1,000,000 gal. treated. E. Sherman Chase, formerly chemist in charge, stated that the labor in connection with the trickling filters was performed by three men working in 8-hour shifts, who act as watchmen, collect samples for analysis and care for the laboratory and grounds. These men are paid $2 per day, so that the labor cost is a little over $1 per 1,000,000 gal. sewage filtered. (*Engineering News*, August 22, 1912.)

Calvin W. Hendrick, Chief Engineer of the Sewerage Commission of Baltimore, stated that the cost of operation of the Baltimore sewage treatment plant, with 12 acres of trickling filters, when working up to its capacity, will probably be between $1.50 and $2 per 1,000,000 gal. The organization at this plant Mr. Hendrick gave as follows: 1 division engineer, who also supervises construction work; 1 mechanical engineer; 1 chemist and bacteriologist; 1 assistant chemist; 3 operating engineers; 1 relief engineer and 4 oilers for the power plant; 1 machinist; 1 carpenter; 1 foreman for laborers; and 12 to 20 laborers.

The organization at the Pennypack Creek disposal works, Philadelphia, Pa., designed to treat 2,000,000 gal. daily, was stated by George S. Webster, Chief Engineer of the Bureau of Surveys, as follows: The assistant engineer of the Sewage Disposal Division has supervision of the operation of the plant, which requires only a small part of his time, and an assistant has immediate charge of maintenance, supplies and records. The force at the plant consists of an operator on duty every day, having immediate charge of the operation, sampling, etc., 4 assistant operators working 8 hours a day, 6 days a week, a watchman for night duty, and a laborer for day duty, such as handling sludge, caring for lawns, shrubbery, etc. The analytical work is done partly at the Bureau of Water laboratory nearby and partly at the Bureau of Surveys Laboratory at the City Hall.

The costs of operating different parts of the plant at Gloversville, N. Y. have been very carefully kept under the direction of H. J. Hanmer, City Engineer. The itemized cost for 1913 and 1914 is given in Table IX. The cost of operating the trickling filters alone constitutes roughly 15 to 25 per cent. of the total for the entire plant. The cost of removing and replacing the roof and sides of the building in which the filter is housed during winter constitutes a substantial part of the trickling filter maintenance charges. The remainder is occasioned by nozzle clogging. About 60 nozzles, or approximately 10 per cent. of those in use, are cleaned each day.

The cost of operation of trickling filter plants, per 1,000,000 gal. of sewage treated, other conditions being equal, will decrease with increasing size of plant. Estimates made by the authors in connection with the joint disposal of sewage from several municipalities in New Jersey ranged from $5.19 per 1,000,000 gal. for an estimated flow of 4,400,000 gal. daily to $2.92 for 14,300,000 gal. E. J. Fort, Chief Engineer of Sewers of Brooklyn, estimated the cost, including interest and depreciation of sinking fund, at $13.81 per 1,000,000 gal. with a flow of 5,000,000 gal. daily, $11.41 for a rate of 10,000 gal., $9.76 for 20,000,000 gal., and $9.50 for 30,000,000 gal.

Thomas Pealer, Borough Engineer of Indiana, Pa., furnished the following information concerning the sewage disposal plant at Indiana, Pa., comprising screen chamber, septic tanks and a trickling filter 220 × 100 × 5½ ft. deep, of ½ to 3½-in. broken stone, with dosing tank and fixed nozzles. It serves 8000 persons and treats 500,000 to 1,000,000 gal. daily of domestic sewage from separate sewers. This plant cost $40,000 and is operated by 1 man at a cost of $750 per annum.

TABLE IX.—COST OF OPERATION OF SEWAGE TREATMENT WORKS, GLOVERSVILLE, N. Y.

	1913	1914
Supervision by city engineer		$ 600.00
Operation of screens, etc.	$ 223.37	574.00
Sludge pumping:		
Labor and repairs	226.00	297.00
Electric power	318.34	214.05
Maintenance of trickling filters:		
Nozzles	897.28	395.00
Removing and replacing covering	278.25	359.00
Maintenance of sludge beds	1,312.46	1,235.00
Cleaning troughs of secondary tanks	35.50	19.63
Maintenance of sand filters	440.33	315.00
Maintenance of grounds	399.97	163.00
Miscellaneous work	169.87	365.00
Chloride of lime and other supplies	835.96	664.27
Telephone		42.00
Cleaning and repairing east primary settling tank (unusual item)		709.00
Total cost for year	$5,137.33	$5,951.95
Cost per 1,000,000 gal. treated, average flow 2,750,000 gal. daily	5.16	5.92
Cost per capita based on estimated population	0.24	0.27
Estimated population	21,600	21,800

The plant at Chambersburg, Pa., as described by Frank H. Clutz, Borough Engineer, consists of Imhoff tanks, a trickling filter 160 × 125 × 7 ft. deep, of 1½ to 3½-in. limestone, with dosing tank and fixed nozzles, and secondary sedimentation tanks. The entire plant cost $46,595.25, exclusive of land, the cost of the trickling filter alone being estimated at $18,500. This plant cares for the sewage from about 5400 persons of the town population of about 13,500, and the average flow of sewage treated, including ground water, is about 1,400,000 gal. per day. Two men are regularly employed, one during the day and one at night, and occasional assistance is required. The cost of operation, maintenance and improvements for 1914 was $4302.54.

The sewage of the State Hospital for the Insane, Norristown, Pa., Oscar L. Schwartz, Steward, is treated by a coarse screen, sedimentation tank, trickling filter 100 × 173 × 6½ ft. deep, of 1½ to 3½-in. limestone, with dosing tank and fixed nozzles, and final sedimentation tanks. The number of persons at the hospital is 3500 and the quantity of sewage treated is 575,000 gal. per day. Two men are employed at this plant and the annual cost of operation is estimated at $1290.

The sewage disposal plant of the State Hospital for the Insane at Warren, Pa., according to Albright & Mebus, consists of an Imhoff tank, a trickling filter 95 × 99½ × 7½ ft. average depth, of stone 2 to 3½ in. in size, with dosing tank and fixed nozzles, and a final sedimentation tank. It serves about 1800 persons and treats about 270,000 gal. per day. The cost of construction was $12,800 or $59,000 per acre. One man is employed about 6 hours each day in caring for this plant.

The trickling filter plant at the United States Naval Training Station, Great Lakes, Ill., according to Lieut. J. B. Earle, Public Works Officer, consists of preliminary septic tanks and roughing filters and 2 trickling filters, each 20 × 60 × 7 ft. 4-in. deep, of ¼ to ¾-in. stone, dosed by splash-plate distributors. The plant serves 900 people and treats 300,000 gal. of sewage per day. The cost of construction of the filters was $35,939.50 and the annual cost of operation is estimated at $300.

Dr. L. Rosenburg, Superintendent of the Montefiore Home County Sanitarium, Bedford Hills, N. Y., reports that the sewage disposal plant at this institution, accommodating 245 persons, consists of septic tanks, 3 small trickling filters of 2-in. stone with 1 nozzle each, and a settling tank for the effluent. This plant cost $10,000 and the cost of operation is stated to be negligible, although the engineer visits the plant each day.

Cost of Intermittent Sand Filtration.—The following is given in Metcalf and Eddy's "American Sewerage Practice."

Where a deposit of free sand or sand and gravel is available in place, it may be used for intermittent filtration by simply grading the surface to receive the sewage. Loam, subsoil and silt are not desirable as filtering media on account of their tendency to hold water by capillarity, preventing successful aeration of the bed, except when very low rates of filtration are used, such as those employed in broad irrigation. Clay and cementitious sands or other comparatively impervious materials are useless for filters.

The removal of loam and subsoil is necessary if any considerable quantity of sewage is to be purified upon beds of a given area. Relative expense will probably determine the extent to which it is desirable to remove the subsoil. Where there are trees, organic matter will be found around their roots at a considerably greater depth than where there are no trees, and care must be exercised to remove this in grubbing out tree roots. Similarly, in gravelly soils containing many large stones, fine sandy material may be found surrounding the stones. Therefore, beds built in such material are not likely to be so homogeneous as those built in ground made up of more uniform material.

The limit for excavation may be determined in several ways: first, by color; second, by loss of weight on ignition, due to the volatilization of the organic matter; third, by taking a small portion of the sand in a glass of water, shaking thoroughly, and permitting it to subside, the amount of organic matter and fine sand found upon the top of the sand, when the material has settled, furnishing a ready guide as to the relative content of objectionable matter.

Uniformity of Material Desirable.—Stratification, or the presence in an otherwise uniform and satisfactory material of sand of different sizes or of cementitious character, is objectionable. When sewage is run onto a bed of uniform material, the suspended matter is arrested upon or near the surface, the water gradually passing through the bed at a comparatively uniform rate without any tendency to clog except at the surface. If the material is stratified, with the coarser sand on top, the bed is likely to become clogged by a film of organic matter on the surface of the fine sand below. This may be caused in part by the passage of very fine suspended matter through the coarser sand and its retention upon the surface of the fine stratum, and also probably by the formation of an organic growth there, due to difference between the quantities of oxygen and water contained in the coarse and fine sands. If the finer material is on top, while there will be no tendency for the fine suspended matter to form a clogging film on the surface of the coarser sand, there may be an accumulation of oxide of iron there due to the difference in the quantities of oxygen present in the two strata. A precipitation of oxide of iron may take place throughout the stratum of coarse material, and if this sand is underlaid with a stratum of fine sand, a film of oxide of iron will form upon the surface of the finer material. An interstratified layer of fine material may act as an air seal, due to capillary action, and thus prevent the satisfactory aeration of the lower portion of the bed.

Cost of Construction.—The cost of constructing filter beds will usually be found to lie between \$2500 and \$5000 per acre, although in some favored localities this cost may not exceed \$1000. If the beds have to be built wholly artificially the cost may reach \$10,000 per acre, if the sand has to be hauled a considerable distance.

Cost of Operation and Maintenance.—This cost will be found to lie ordinarily between \$100 and \$150 per acre, the cost per 1,000,000 gal. of sewage filtered being about \$10, as will be seen from Table X.

TABLE X.—AVERAGE ANNUAL COST OF FILTRATION AREAS IN FOUR MASSACHUSETTS CITIES

(Compiled from Annual Reports)

City	Period	Population	Filter area acres	Mil. gal. filtered daily	Cost per acre	Cost per mil. gal.	Cost per capita
Brockton..........	1896–10	34,500–	21.48–	0.501–	\$178	\$13.50	\$0.10
	....	56,900	35.77	1.297	....	......	.....

	....	6,400	......	0.264	....	......	.....
Worcester[1].........	1904–10	129,500–	3.3–	0.273–	290	10.37	.....
	....	146,000	74.3	4.718	....	......	.....

[1] As only part of the sewage is treated by intermittent filtration, no satisfactory figures of the cost per capita can be given.

Cost of Operating Contact Beds.—The following is given in Metcalf and Eddy's "American Sewerage Practice." Probably the best figures on the cost of operation in America are those obtained at Plainfield, N. J., stated by Fuller (in his "Sewage Disposal") to be as given in Table XI.

TABLE XI.—COST OF OPERATION OF PLAINFIELD SEWAGE DISPOSAL PLANT

Item	1907	1908	1909	1910
Manager-chemist, consulting engineers	....	\$1325.50	\$1818.46	\$1677.67

Total..................................	\$2955.64	....	....	....
Farm products receipts..............	248.65	....	....	....
Total cost of maintenance............	\$2706.99	\$3814.70	\$3536.33	\$3289.80
Improvement of contact beds........	....	....	2032.87	935.36
Repair of septic tanks................	101.14	....	151.89	1011.15

In 1910 the number of connections was 3746; assuming 5 persons per connection, there would be a total of 18,730 persons. The flow amounted to 1,800,000 gal. per day, making the cost \$5 per 1,000,000 gal. or \$0.18 per capita per year. There are 8 primary and 8 secondary beds with a total area of 3.6 acres.

At Mansfield, Ohio (Report Ohio State Board of Health, 1908), the costs of operation during 1906 and 1907 were \$5644 and \$5260 respectively, and included removal of sludge from the septic tanks. Furthermore, about one-half of the cost was for coal used in pumping. These figures made the per capita cost \$0.47 and \$0.44 respectively.

At Manchester, England, very complete cost accounts have been kept. In the 1907 report of the Rivers Department is given a table showing the actual cost of a selected area of 6 acres from the starting of the beds until the filtering material was taken out:

Average number fillings	2,690
Gallons (U. S.) of septic tank effluent dealt with by the 6 acres	4,610,000,000
Total maintenance cost	\$4,085
Total renewal cost (\$0.40½ per cubic yard)	\$13,700
Maintenance cost	\$1.05 per 1,000,000 U. S. gal. filtered.
Renewal cost	\$3.57 per 1,000,000 U. S. gal. filtered.
Actuating valves	\$0.30 per 1,000,000 U. S. gal. filtered.
Total working cost	\$4.92 per 1,000,000 U. S. gal. filtered.

Cost of Preparing and Placing Ashes or Cinders for Filtering Material in Contact Beds.—E. G. Bradbury gives the following in Engineering and Contracting, Aug. 31, 1910.

Filtering material is one of the largest cost items in every sewage disposal plant, in which filtration is made a part of the process of purification. Local conditions naturally control the selection of the material to be used. Sand is frequently so expensive as to be almost out of the question, especially in view of the fact that its exclusive use requires much greater area and consequently larger quantity of material than if a coarser material and one of the high rate types of filter be installed.

For contact filters no material is more satisfactory or economical than a good grade of ashes or cinders, those produced by locomotives being particularly good. These are largely either of a vitrified or coky nature and therefore less liable to disintegration than the softer ash produced by some industrial plants. An excellent ash is produced by many iron and steel mills and furnaces.

This material can frequently be purchased from the railroads and can always be found in quantity in large cities, or those having important industrial plants. In Ohio the market price ranges from practically nothing up to \$3 per car at the place of production, and the railroad companies will often furnish round house cinders for the price of hauling, provided they are not using the product for filling along their lines.

During the fall of 1901 the writer was employed as resident engineer in charge of the disposal plant at Mansfield, Ohio, where 1¼ acres of contact filters were filled to a depth of 4.75 ft. with crushed and screened locomotive cinders, the work being done by day labor and all apparatus and material purchased directly by the city. The figures given below are therefore actual costs in real money and not approximations.

The filter beds are laid out in the form of a circle about 280 ft. in diameter, divided into five beds by radial embankments. The crushing and screening plant was erected close to the outer edge of the circle, and a siding was run alongside the crusher; there was, therefore, no hauling of the raw material and the average haul for the finished product was about 160 ft.

The plant for preparing the material consisted of a coke crusher or sizer, in which the cinders pass between two rolls with corrugated faces, removable in segments, a chain and bucket elevator to raise the crushed material to the screen, and the jigling screen, known to the trade as the Columbian Separator. Power was furnished by a traction engine hired by the day, and the whole apparatus housed and provided with bins and chutes, for economical handling of the cinders. This outfit, which was furnished by the Jeffrey Mfg. Co. of Columbus, Ohio, proved in every way suited to the requirements. The shaking screen is the only one which can successfully remove the dust and flake, as the material is usually moist and requires a hard jolting to separate the particles. The screen stands at an angle of 45° and has a movement as recalled by the writer of about 2 ins. at a rate of about 150 per minute. A wire screen cloth of 3 meshes to the in. removed all dust of less than ⅛ in. diameter, and practically none of greater size, the whole plant producing a beautifully clean material from ⅛ to ¾ in. in dimension.

The cinders were received in flat bottomed coal cars with side boards containing an average of about 30 cu. yds. They were shoveled from the cars onto a platform, beneath which the crusher was set, with its hopper on a level with the floor. The siding was extended beyond the plant a sufficient distance to hold 10 cars and on a grade which allowed the cars to be placed at the platform by gravity after a train was set by the switch engine. The product of the screen, which was set about 40 ft. above the crusher, fell into bins, from which the filter material could be drawn by chutes into wagons or into a small car, while the dust was drawn into the emptied flat cars and hauled away by the railroad free of charge.

A strip around the outside of the beds was first filled by wagons to a sufficient width to lay a movable track on the cinders, and the remainder was handled by means of the small car, which held about 1½ cu. yds., dumped from the side, and was run by hand by two men on the track referred to.

Roundhouse cinders were purchased direct from the Pennsylvania R. R. at a price of $8 per car. The weight per cubic yard is from 1,200 to 1,300 lbs., 439 cars, or about 12,970 cu. yds. of the raw material were required to produce the 9,579 cu. yds. of coarse screenings used, showing a loss of 26 per cent. This is slightly better than can be counted on as the cinders were of exceptional quality. It is not safe to figure on more than 65 per cent. of the raw material.

The total cost, including crushing and screening plant, foreman and all expense of every kind was as follows:

Cost of Outfit:	
Machinery	$ 850.00
Lumber	222.63
Labor on bin	87.30
Side track (labor only)	208.10
Awning	5.80
Total	$1,373.83
Repairs, new parts, etc	281.34
Cost of Material:	
438 cars of cinders at $8	3,512.00

Cost of Operation:	
Labor	$2,573.42
Coal	80.00
Use of engine	101.25
Oil	34.43
Insurance	14.00
Total	$2,803.10
Total cost	$7,970.27
Per cubic yard	0.832

The cost per cubic yard of finished material was as follows:

	Per cu. yd.
Crushing and screening plant, bins etc. (applicable only to similar quantities)	$0.144
Repairs, etc	0.029
Cinders	0.336
Handling	0.293
	$0.832

The last item can be subdivided as follows:

	Total	Per cu. yd.
Labor unloading cars	$ 462.27	$0.048
Labor at crusher and placing cinders	2,111.15	0.220
Power	215.68	0.023
Insurance	14.00	

The cost of placing in filters by means of the small cars was about $0.02 per cubic yard.

The price paid for labor varied from $1.50 to $1.75 per day averaging probably $1.60. The foreman received $2.50 per day and the engine man $3. The entire job was handled carefully and close attention to business is necessary to duplicate the results.

Cost of Sewage Treatment Works at Washington, Penn.—Donald M. Belcher gives the following information in Engineering News, Apr. 11, 1912.

The sewage treatment works for Washington, Penn., were built in 1907–8.

The plant consists of septic tanks, sprinkling filters and settling basins and has a capacity of 3,000,000 gal. of sewage per 24 hours. It is located about three miles below Washington, on the Chartiers Creek, near Arden Station.

Screen Chamber.—The sewage first enters the screen chamber, which is situated on the opposite side of the creek from the rest of the purification works. This chamber is open and divided into two sections, each of which may be shut off by stop planks. The sewage passes through two screens, the first having openings of ⅜ in. and the second openings of ¼ in.

Suction Conduit.—The sewage passes under the creek, through a 16-in. cast-iron inverted siphon, and flows, by gravity, to the pumping station, in a conduit consisting of 20-in. vitrified pipe laid in concrete.

Pumping Station.—The building is of pressed brick with sandstone trimmings, resting on concrete foundation walls, which form the lower portion of the station, in which the machinery is located. The roof is of slate carried by steel trusses.

Under pumping machinery is included one 25-hp. and two 15-hp. Gardner gas engines, one 8-in. and three 5-in. Brooks centrifugal pumps and all piping, valves and appurtenances in the pump pit. The gas engines are of horizontal, single-cylinder, two-cycle type and are fitted with hot tube ignition and compressed-air starting devices. The 5-in. and one 8-in. sewage pumps have a

Table XII.—Unit Prices, Sewage-Purification Works, Washington, Penn.

	Quantity	Unit price
Excavation	14,730 cu. yd.	$ 0.28

Total purification works (including land and engineering)		38,474	

combined maximum rated capacity of 5,040,000 gal. per 24 hours, against a head of 20 ft., and the 5-in. sludge pump has a maximum rated capacity of 1,080,000 gal. per 24 hours, against a 7-ft. head.

The water supply, to furnish water for cooling the gas engines and for flushing purposes, is obtained from two wells which were driven near the station. The water is lifted from these wells by compressed air into a suction well, of 16,500 gal. capacity, just outside of the station, and pumped from this into a concrete storage tank, situated on rising ground about 175 ft. from the station. This tank has a capacity of 4000 gal. and is 13 ft. above the gas engines.

Under this item is included the cost of drilling two wells (125 ft. deep); a 20-hp. Gardner gas engine; a Gould triplex pump of 150 gal. per min. capacity; a Hall air compressor having a capacity of 50 cu. ft. of air per min., against 50 lb. pressure; an air receiver, 2 ft. in diameter by 8 ft. long; air piping to the wells; concrete suction well and storage tank; 4-in. cast-iron pipe line between the station and the storage tank and the necessary valves, piping and appurtenances in the station.

Septic Tanks.—The sewage is lifted approximately 20 ft. through a 14-in. cast-iron main, into the septic tanks. Four compartments are formed, by reinforced-concrete dividing walls, each being 25 × 100 ft. in plan and 11 ft. deep, and they are covered by a 4-in. flat reinforced-concrete roof, carried on beams and piers. Adjacent to the tanks is a small uncovered dosing chamber in which is a float operating a butterfly valve which automatically controls the flow of sewage from the septic tanks to the filters.

From the dosing chamber the sewage flows, by gravity, through a 20-in. cast-iron pipe line to the sprinkling filters.

Sprinkling Filters.—The filters are four in number, each being 100 × 150 ft. in plan, and are surrounded by concrete walls on all sides. Along both sides of each filter are covered galleries, 4 ft. wide and 6 ft. high, and into these extend the ends of the tile underdrains. A 4-in. cast-iron water main runs the length of each gallery to provide for flushing.

The main distributors consist of 15-in. vitrified pipe embedded in the walls of the central gallery and the lateral distributors are 5-in. vitrified pipe carried in the top of small concrete walls.

Five-inch half-tile, laid on a 4-in. concrete floor, form the lateral collectors. The main collectors, which are built of concrete, run the length of each filter and empty into the effluent conduit, which is formed by vitrified pipe embedded in the walls.

The broken-stone filtering material, except the upper 6 in., was taken from a local quarry and was a low-grade limestone, very close grained and hard, but liable to crumble when exposed directly to snow and ice. For this reason, a better grade of limestone, from Ohio, was used for the upper 6 in. Two sizes of stone were used, the larger being 2½ to 4 in. and the smaller 1 to 2½ in. The average depth was 6 ft. 10 in.

Settling Basin.—This is an open basin, with concrete walls and floor, divided into two parts for purposes of cleaning. The sewage passes out of the basin over a weir and flows by gravity through an 18-in. vitrified pipe, to the creek. There is a flap gate at the end of the pipe protected by a concrete headwall.

Sludge Disposal.—An area of about one and one-half acres was graded and underdrained to provide a drying area for the sludge.

The sludge from the septic tanks flows to the disposal area by gravity through an 18-in. vitrified pipe line. The sludge from the settling basins flows through a 10-in. vitrified pipe, laid in concrete, to the pumping station and is pumped from there through a 6-in. cast-iron force main to the drying area.

Unit Prices.—In Table XII are given the unit prices of the principal items.

Stone for the concrete was taken from a quarry located about 1000 ft. from the plant. The sand was Ohio River sand and was mixed with the crusher dust in equal parts.

Costs.—The costs of all the structures are given in Table XIII. These costs are the total costs of the work to the Borough of Washington and not the actual cost to the contractors. In apportioning the costs to the different structures, all pipes, valves, etc., inside of the outside neat lines of each structure, were considered to belong to that structure.

Unit Costs.—In Table XIV are given the unit costs of some of the structures, based on their capacities.

It is estimated that the present purification works will treat the sewage from a population of about 40,000 and the per capita costs, in the following table, are based on this figure.

	Cost of construction	Cost per capita
Pumping station and works preparatory to purification plant	$20,251	$0.51
Purification plant	70,577	1.76
Total purification works (exclusive of land and engineering)	90,828	2.27
Total (including land and engineering)	115,422	2.89

Cost of Earthwork, Concrete, Filter Media and Drains at the Montezuma, Iowa, Sewage Treatment Plant.—The following data are given in Municipal Journal and Public Works, Oct. 18, 1919.

The town contains a population of about 1,500 and the plant was designed for 2,000, assumed as the population twenty-five years hence. The plant consists of an Imhoff tank, siphon chamber, two intermittent sand filters and a sludge bed.

The tank is of the circular type, with an area of gas vent 23.6 per cent of the whole superficial area of the tank. This is a larger area than is found in most plants, but in view of the trouble that has been caused by too small vents and the extreme freshness of the sewage, liberal allowance for both scum and sludge were thought desirable.

The sludge storage capacity up to within three inches of the bottom of the inverted V beam forming the overlap for the vents is about 1.67 cubic feet per capita on a basis of 2,000 future population, and up to the slots is about 1.88 cubic feet per capita.

On the basis of 100 gallons per capita per day (which allows for ground water infiltration) with uniform flow throughout the 24 hours, the settling period in the tank would be 2.42 hours while 1200 population is connected with the sewers, and 1.45 hours when 2,000 are connected; while if all the sewage be assumed to reach the plant in 18 hours, the settling period would be 1.82 hours and 1.09 hours respectively.

One important and rather new feature provided in this tank, is an 8 in. drain just below the sludge outlet. The flow line of this drain is such that the sewage may readily be drawn below the slots in case it becomes necessary to work upon the walls of the settling chamber. It has been found in actual operation of Imhoff tanks in towns of the size of Montezuma, that not infrequently the sedimentation chamber is allowed to become completely sludged up and thus transformed into a small septic tank. In order to clean out the sedimentation chamber, it has been found necessary to lower the sewage below the slots and then force the sludge down through the slots, carefully squegeeing the walls and sloping aprons.

Prof. Dunlap of Iowa State University (the designer of the plant) gives the cost of the plant on the basis of $4.00 for labor per day of ten hours until late fall, after which the same was paid for eight hours; and teams at $7.00 per day of the same length. The length of haul from the railroad siding to the plant was 1.3 miles, over a fair road with no upgrades. Superintendence, overhead and profit are not included.

EARTH WORK

	Type	Estimated cu. yds.	Cost per cu. yd.
Filter beds	Slip work	1060	$0.47
Siphon chamber	½ slip and ½ hand	187	0.78
Imhoff tank	Hand before banks caved	408	0.82
Imhoff tank	After cave-ins with bracing	408	2.70

Sodding berms of filter beds, $0.20½ per sq. yd.

COST OF 1:2:4 CONCRETE, PER CUBIC YARD

	In Cylindrical Walls of Imhoff Tank	In Siphon Chamber Includes only walls and footings; roof and floor omitted
Cement, at 6.4 sacks per cu. yd. f. o. b. Montezuma ($2.28 per bbl.)	$ 3.65	$ 3.65
Hauling by team—to barn, 8½c., to job, 9c.	0.18	0.18
Sand, 0.45 cu. yd. at $2.65	1.19	1.19
Gravel, 0.90 cu. yd. at $3.59	3.23	3.23
Steel reinforcement	1.49	1.59
Setting forms and reinforcement	2.93	2.18
Mixing and pouring; heating sand, gravel and water.	1.98	1.65
Total cost per cubic yard in place	$14.65	$13.67

COST OF FILTER SAND AND GRAVEL, PER TON

	Filter sand	Filter gravel
Cost f. o. b. sand company	$0.35	$1.25
Freight	0.90	0.90
Unloading from cars (mostly box cars)	0.063	0.095
Hauling by team 1.3 miles	0.39	0.39
Unloading from wagons	0.022	0.022
Leveling and spreading	0.131	....
Total cost per ton in place	$1.86	$2.66
Total cost per cu. yd.	$2.78	$3.59
Total amount required for two beds	1390 cu. yd.	194 cu. yd.
Total required for sludge bed	21 cu. yd.	32 cu. yd.

COST OF 6 IN. VITRIFIED FARM DRAIN TILE IN FILTER BEDS

Cost of tile per ft. f. o. b. Montezuma	$0.08
Hauling by team 1.3 miles	0.005
Trenching	0.039
Laying	0.01
Graveling at $2.66 per ton and spreading at $0.04 per ft.	0.44
Total cost per ft. of trench	$0.574

LAYING 15-IN. VITRIFIED PIPE SEWER MAIN, 1425 FT. IN LENGTH

Cost of pipe per ft. f, o. b. Montezuma	$0.65
Hauling by team 1.3 miles	0.033
Trenching, including back-filling	0.376
Laying, including mortar	0.077
Total cost per ft. of trench	$1.14
Cost of taking up old 15-in. sewer and back-filling per ft.	$0.246

Cost Estimates for Intercepting Sewer and Treatment Plant at Detroit, Mich.—Engineering and Contracting, July 9, 1919, gives the following:

Extensive studies of costs and methods of treatment of Detroit sewage have been made in connection with the recent Report of the Consulting Sanitary Engineer on the Pollution of Boundary Waters. One project recommended the immediate construction of two low level intercepting sewers discharging through pumps to two separate treatment plants.

The treatment plant consists of Imhoff tanks, including inflowing and outflowing channels; grit chambers; sludge drying beds; disinfection plant.

Imhoff tanks were proportioned on the basis of a sedimentation period of two hours, when the rate of flow equals 125 per cent of the average rate of flow, and storage room for sludge of 2 cubic feet per tributary person. The estimate for grit chambers, bar screens, etc., was made by making an allowance of 5 ct. per tributary person, this figure having been arrived at from a review of published information regarding existing plants. The area of sludge drying beds required was based on a load of six persons per square foot of net drying bed area.

The total estimated cost of the treatment works for treating 162.7 M. G. D. from a population of 950,000 is $2,077,200. The cost per million gallons for the different elements is as follows:

Imhoff tanks	$ 8,568
Sludge beds	971
Screens and grit chamber	292
Disinfection	600
Covering ventilation and parking	2,336
Total estimated cost per M. G. D.	$12,767

Cost of Sewage Treatment Works at Dallas, Texas.—The Engineering News Record, July 5, 1917, gives the following data:

The disposal works built at this time consist of a grit chamber, 12 Imhoff tanks, a sludge-drying bed and a discharge conduit. The grit chamber is 100 ft. long and is divided into three parallel sections. Its cross-section is such that, combined with the hydraulics of the channel leading to the tanks, the velocity of the sewage in the chamber varies but slightly, despite a considerable variation in the sewage flow.

The channels leading to the Imhoff tanks were designed for a maximum flow of 22,000,000 gal. daily, and it was expected that the present average sewage flow would be about 11,000,000 gal. daily. During the past year, however, the city water-supply has been completely metered and the water consumption thereby reduced 50%. This has affected the sewage flow, so that only 5,500,000 gal. daily reaches the disposal works.

Tanks' One-Way Flow

The Imhoff tanks are of the rectangular horizontal-flow type and have a combined capacity in the settling chamber of 1,312,000 gal. and a sludge-storage capacity of 440,000 gal. The settling chamber of each tank is 45 × 33 ft. in plan, and the sludge chamber is 29 × 19 ft. The tanks are 33 ft. deep. The sewage is divided into 12 parts, each part flowing through one tank. There is but one sludge compartment to each tank, and therefore no provision is made for reversing the sewage flow. Devices for agitating the sewage with fresh water are provided. Sludge is to be withdrawn through 8-in. pipes leading to a central open sludge channel and thence through a 12-in. pipe by gravity to the sludge bed. The slopes of the bottoms of the sedimentation chambers are 1.36 on 1. The flattest slope in the sludge chamber is 1 on 2.25.

The sludge bed is 141 × 145 ft. in plan. It has 14 in. of graded sand and gravel underdrained by 3-in. vitrified pipe laid with open joints 4 ft. c. to c. Sludge is distributed over the bed through seven concrete channels, each carrying a track on which run small dump-cars used to remove the dried sludge.

Clarified sewage from the tanks unites at a central point and passes over a weir into the discharge conduit and thence to the river. A continuous automatic record of the sewage flow is kept. The discharge conduit consists of 300 ft. of 24-in. pipe and 2042 ft. of 36 × 48-in. monolithic concrete sewer.

The complete plans call also for six acres of sprinkling filter followed by secondary settling tanks of the Imhoff type, but funds for this work were not available, as the city's bond limit (at the time of issuing the sewage-disposal bonds) limited the amount of the issue. The plant as constructed is built with provision made for the addition of the final treatment.

The cost of the work was as follows:

Grit chamber	$ 2,030
Influent channel	547
Imhoff tanks	68,647
Sludge bed	17,957
Water supply and buildings	4,435
Miscellaneous	2,269
Total	$95,885

Activated-Sludge Plant at Escanaba, Mich.—Engineering Record, Feb. 10, 1917, publishes the following:

The 1,000,000-gal. activated-sludge plant built at Escanaba, Mich., is located at the south end of the city, at the outlet of a new 3½-mile trunk sewer and about 2 miles from the outlet of the old trunk sewer. The new trunk serves a district which is not as yet very thoroughly settled except at the extreme north end, and will provide a flow for the next few years not to exceed 300,000 gal. per day. The old sewer, which has practically all the connections it will ever have, serves about 10,000 persons using 100 gal of water per day. Plans and estimates have been made for a pumping station and force main to connect the old system with the disposal plant.

Daily Capacity 1,000,000 *Gallons.*—The general layout consists of two long rectangular aërating tanks with a longitudinal vertical baffle, so that the inlet and outlet are at the same end, the end adjoining the two settling tanks. The total capacity of the aërating tanks is 220,000 gal.; and as one-half of the total flow occurs in nine hours, a four-hour aëration period will give a daily capacity of nearly 1,000,000 gal.

The total capacity of the two settling tanks is 86,000 gal., which will give, with the corresponding four-hour aëration period, 93 minutes for the sedimentation period. By decreasing the aëration period to three hours the sedimentation period will be 70 minutes and the capacity of the plant will be 1,300,000 gal. per day.

Filtros plates having an area of 360 sq. ft. are used in the ridge and valley aëration tank, which has an area of 30,000 sq. ft. Thus the diffusion ratio is 1 to 8.3.

Air is distributed to the base of the plates from a Taylor spiral-riveted, galvanized-steel header, diminishing in size from 8 in. to 6 in. and then to 4 in. The drops from the header are 4-in. Byers galvanized wrought-iron pipe. The blower house is located at the opposite end of the aërating tanks from the settling tanks, and inserted in the main is a Venturi meter with U-tube monometer. Two Connersville blowers will furnish the air. The rated capacities are 1200 and 2400 cu. ft. per minute, and the motors driving them are 40 and 75-hp. General Electric 2200-volt motors.

Four 6-in. drain pipes, laid lengthwise of the aërating tanks, have 4-in. openings at each casting. They are connected with a 6-in. Fairbanks-Morse centrifugal pump located in a pump pit under the blower-house floor.

Sludge will be removed from the settling tanks by Harris nozzles through 8-in. cast-iron pipes back into aërating tanks, or to the sludge tank in the press house, where it may be further aërated from a 1-in. wrought pipe grid with perforations in the pipes 1 in. apart. From the sludge tank the sludge will be pumped by a 3-in. motor-driven centrifugal pump into a 6 × 9-in. Worthington filter press. The cakes will be wheeled to a small shed adjacent and stored on racks until disposed of. The supernatant water in the sludge tank

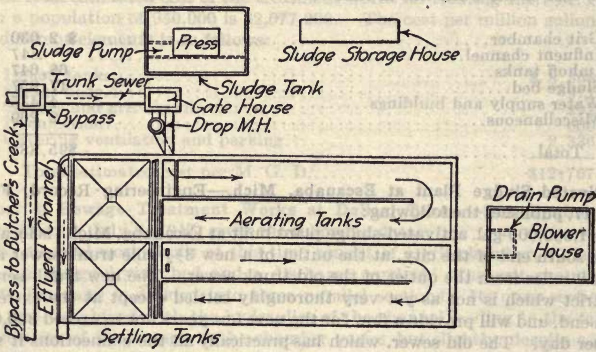

FIG. 1.—Aërating tanks are simple longitudinal basins with single baffle.

will be drawn off by a perforated steel pipe on a flexible elbow, discharging into the drain sump at the blower house.

Excavate Coffer Hydraulically.—High ground-water level was at El. 103, making a head of about 24 ft. for the contractor to work against in getting in the points of the settling tanks. Excavation down to water, (6 ft.) was carried out by team and scraper.

A concrete cofferdam, 24 × 44 ft. in inside dimensions and 5 ft. deep, was then built around the site of the settling tanks.

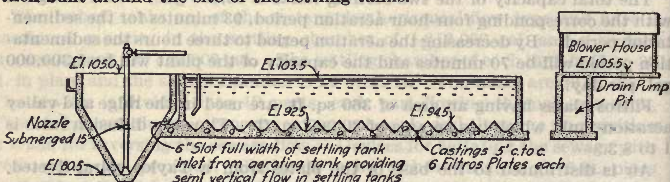

FIG. 2.—Longitudinal section shows connection between settling and aëration tanks.

A 4-in. Morris centrifugal pump, driven by an 8-hp. Novo gas engine, was placed on the cross-bracing. A sump midway between the points of the settling tanks was dug by hand and the pump started. The discharge side had a tee next to the pump, one outlet of which led to the spoil bank and the other to a 1½-in. nozzle on a fire hose. When the water in the sump had been pulled down deep enough, the nozzle was turned on and the sand washed from under the wall into the sump. In this way the first 5-ft. section was lowered its full length. Then a 7½-ft. section was added to it, and after a week's curing pumping was resumed, using this time a 25-hp. motor instead of the gas engine. The cofferdam was sunk as before until the bottom edge reached El. 81.5, when it was a simple matter to place forms and concrete in the dry. The material was uniformly a medium coarse sand. Water from the excavation for the aërating tanks was led to the cofferdam pump, so that one pump took care of practically all the water.

The total cost of the plant, including the press, blowers, motors, and pumps, is $38,750.

Activated-Sludge at San Marcos, Tex.—Henry E. Elrod gives the following in Engineering News, Feb. 8, 1917.

In regular daily service in San Marcos, Tex., there is a practical and highly satisfactory activated-sludge sewage-disposal plant having a capacity for treating 150,000 gal. of domestic sewage per 24 hr. The plant was designed and built by Ashley F. Wilson, engineer-manager for the San Marcos Utilities Co., and has been in operation since about Sept. 1, 1916.

The plant consists of an aëration tank 16 ft. wide by 40 ft. long and about 8½ ft. deep from the flow line of the sewage to the top of the filtros plates. The tank is divided into four channels by longitudinal concrete baffles, each channel having a row of filtros plates 12 in. square at the apex of inverted pyramids down its center. The filtros plates are spaced 3 ft. c. to c., there being 52 plates all told. The opposite end of each channel is open, thus allowing the sewage to flow in series from the inlet at the left to the outlet at the right. The outlet opens into the settling tank, which is 10 ft. wide by 25 ft. long and 25 ft. deep, the walls having a vertical batter of 1 to 2.

Aëration is accomplished by means of a 6 × 10 in. Connersville blower of the Boston type, having a rated capacity for 260 cu. ft. of free air per minute under 5 lb. pressure. It is actuated by an electric motor requiring an average of 4 kw. of current. The sludge lift is operated by air from this blower.

When the plant was first put into operation, the distribution of air through the filtros plates was uniform and satisfactory. Later, however, some of the plates showed signs of erratic action. Upon investigation it was found that one corner of one plate had been cut out by the action of the air and the other plates had become choked to such an extent that their usefulness was destroyed. As each plate failed, a small pipe with its lower end open and the upper end connected to an air line was substituted with satisfactory results.

The total cost of the completed plant, in round figures, was $3500, which sum included the lowering of the bottom of the settling tank after the plant had been in operation for a short time. The plant is near the city, but it produces no offense whatever. The operation of the plant is simple—it requires but a few minutes' attention each morning.

Activated-Sludge Power Costs.—Gustav J. Requardt gives the following in Engineering News, Jan. 14, 1917:

Given the amount of air delivered by a blower (requiring a definite amount of power for operation), the ratio of air to sewage necessary for the degree of treatment desired and the unit cost of power, it is a simple calculation to find the power cost for sewage treatment by the activated-sludge method. When many calculations are to be made at one time, the writer has found that much work may be eliminated by the construction and use of a set of curves in which all factors are considered to vary within limits suited to average conditions.

The curves herewith presented, are from data from only one manufacturer of air blowers (the Connersville Blower Co.) but it is a simple matter to plot on the same sheet the values as given for the several other makes of air blowers and compressors.

Construction of Diagrams.—Fig. 1 is made by plotting as abscissas the power necessary to drive the machine, and as ordinates the corresponding free air delivered, there being separate curves for various air pressures. Plotting thus the information taken from the catalogs of the various makers, a quick comparison of efficiencies may be made.

Fig. 2 is made up from Fig. 1. The ordinates remain the same (free air delivered) while the abscissas are obtained by dividing the power by the

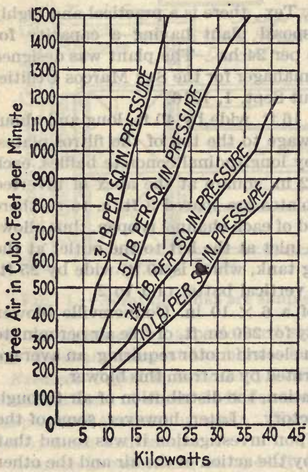

FIG. 3.

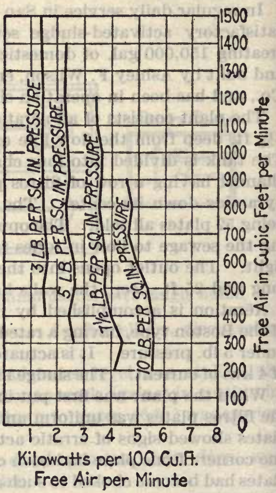

FIG. 4.

FIGS. 3 and 4.—Power required to deliver free air.

corresponding volume of free air in units of 100 cu. ft. For example: At 5 lb. per sq. in. pressure a 22-kw. machine will deliver 900 cu. ft. of free air per minute; therefore, 2.4 kw. of power is required per 100 cu. ft. of free air per minute in a machine capable of delivering air at the rate of 900 cu. ft. per min. It is to be noticed that in the type of blower taken as an illustration for these curves the efficiencies but slightly increase as the machines become larger.

Fig. 3 is made by plotting as ordinates the kilowatts per 100 cu. ft. of free air per minute, and as abscissas the kilowatt-hours per million gallons of sewage, the radiating solid lines giving the various proportions of volumes of free air in cubic feet to volumes of sewage in gallons. The same radiating lines also give relations between sewage flow and volume of free air required for treatment. The relations between kilowatt-hours per million gallons of sewage treated and cost of power per million gallons are also plotted on this sheet, the radiating dotted lines representing the various unit costs of power.

The method of proportioning air supply to sewage flow, volume for volume, is far simpler, in the writer's mind, than any other method. Some engineers prefer to state the volume of air supply to the area of tank surface per unit of time. This brings the dimensions of the sewage tank or container and the length of time of air treatment into the problem, where these elements do not belong; they can be much better handled in the actual design of the plant. It is well to remember, then, in using the curves, that *volume* of air supply is proportional to *volume* of sewage treated, irrespective of the size or shape of tank or of the length of time of air agitation and treatment.

How to Use the Curves.—To illustrate how the curves are to be used, let us assume that the sewage of a city is to be treated by the activated-sludge method and that the cost of power is required. Assume that experiments on the sewage have shown that the necessary purification is obtained by applying 1 cu. ft. of free air per gallon of sewage; that the proper depth of tank requires air

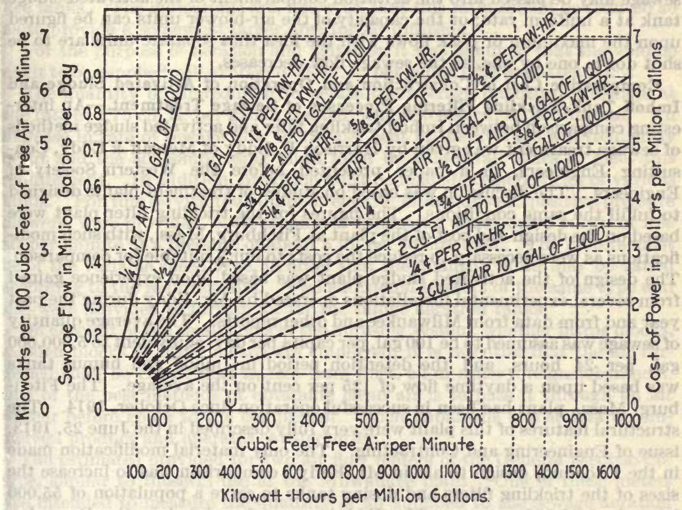

FIG. 5.—Relation between sewage flow, air and power required in activated-sludge plants.
1,000,000 gal. per day = 694 gal. per min.

to be delivered at a pressure of 5 lb. per sq. in.; that current in the locality in question costs ⅞c. per kw.-hr. The sewage flow may be assumed at 1,000,000 gal. per day. It is to be noted here that, for larger flows, a straight-line relation holds between sewage flow and air required and that the air can be supplied by any number of blowers or compressors. Larger problems can thus be split down to smaller units and each solved separately.

With the elements above assumed having been determined, we are now ready to make use of the curves. Enter Fig. 3 at the ordinate for 1,000,000 gal. sewage flow per day and note where this ordinate strikes the radiating solid line for 1 cu. ft. air to 1 gal. liquid, the abscissa at this point reading 694 cu. ft. free air per minute. This determines the size or capacity of air blower required. Now enter Fig. 2 at the ordinate for, say, 700 cu. ft. of free air per minute and note where it strikes the line for 5 lb. per sq. in., the abscissa at this point reading 2.4 kw., of power per 100 cu. ft. of free air per minute. Again using Fig. 3, note where the ordinate for 2.4 kw. per 100 cu. ft. air per minute strikes the radiating solid line for 1 cu. ft. air to 1 gal. liquid. The abscissa at this point reads 400 kw.-hr. per million gallons of sewage treated. Reading upward along this abscissa, note where it strikes the radiating dotted line for ⅞c. per kw.-hr. The ordinate at this point, toward the right-hand margin, reads $3.50 cost of power per million gallons of sewage treated, which is the result desired.

In the example given above, no recognition has been taken of the fluctuation of sewage flow as it reaches the plant. To apply to each gallon of sewage its proper volume of air, a detention chamber can be utilized so that the raw sewage may be passed into the agitation compartment of the activated-sludge tank at a uniform rate; or the capacity of the air-blower units can be figured upon the maximum or peak flows with the idea that separate units are to be shut down, one by one, as the sewage flow decreases.

Comparative Cost of Construction and Operation of Activated Sludge and Imhoff Tank-Trickling Filtering Processes of Sewage Treatment.—An interesting comparison between Imhoff trickling filter and activated sludge methods of sewage treatment was given by Harrison P. Eddy of Metcalf & Eddy, Consulting Engineers, in a paper presented before the Western Society of Engineers. The discussion was based on studies of treatment plants designed to fulfill the same conditions. The figures for the trickling filter plant were based on the design and cost of the plant at Fitchburg, Mass., with such modifications as were necessary to reduce the costs to units suitable for comparison. The design of the activated sludge plant was based upon experience gained from several experimental installations operated by Mr. Eddy during the past year and from data from Milwaukee and other reports. The average quantity of sewage was assumed to be 100 gal. per capita per day, equivalent to 5,500,000 gal. per 24 hours, and the detention period in Imhoff and humus tanks was based upon a daytime flow of 125 per cent on the average. The Fitchburg, Mass., plant has been in successful operation since October, 1914. The structural features of this plant were very fully described in the June 25, 1913, issue of Engineering and Contracting. The only material modification made in the Fitchburg design to aid in Mr. Eddy's comparison was to increase the sizes of the trickling filters and dosing tanks to serve a population of 55,000 instead of 40,000 persons. Mr. Eddy's paper is printed in the December Journal of the Western Society of Engineers, from which the following matter is given in Engineering and Contracting, Feb. 14, 1917.

The plant for the activated sludge process was designed as far as possible to meet the same conditions as those for which the trickling filter plant was built. The same type of structures has been used where applicable, and an effort was made in every way to make the two plants strictly comparable, both being designed to serve 55,000 persons.

The grit chamber, screens and venturi meter equipment are included without change in the activated sludge plant, the requirements being the same in each case.

The sewage aeration tanks were designed to operate on the continuous flow plan. The tanks were rectangular in plan, each unit being 30 ft. wide by 90 ft. long inside, of a type similar to the Imhoff tanks in the trickling filter plant. Compressed air was supplied to the tanks through a piping system leading to a series of filtros blocks located in the bottom of the tank. Each tank unit was divided by means of thin partition walls into four longitudinal channels 7 ft. 2 in. wide. Provision was made for a depth of 10 ft. of liquid above the top of the filtros blocks. It was intended to operate two tank units in series and five double tank units in parallel; that is, the sewage will enter one tank, pass longitudinally back and forth through the four channels in that tank, then to the second tank and back and forth longitudinally through the four channels of that tank to the point of discharge, making a total distance traveled of about 700 ft. Sufficient tank capacity was provided for an average period of aeration of 4½ hours, with sludge capacity amounting to 25 per cent of the total tank capacity. Under these conditions the average horizontal velocity would be about 2.6 ft. per minute. The ratio of total tank floor surface to area of aerating system was 8.5 to 1, which is the basis of the present Milwaukee tanks. The indications are, however, that this ratio should be reduced so as to provide a somewhat larger area for air diffusion.

For the purpose of aeration and agitation it was assumed that the volume of air to be supplied will average 1.75 cu. ft. per gallon of sewage treated.

The quantity of air required to aerate the average quantity of sewage at the rate of 1.75 cu. ft. per gallon treated, will be 6.680 cu. ft. per minute. An increase in rate of sewage flow to 150 per cent of the average will frequently occur and the air compressing plant must be able at all times to meet this requirement. In addition, provision must be made for emergencies of various kinds. For this service four units of electric motor-driven, positive pressure blowers, were provided, each capable of furnishing about 3,200 cu. ft. of free air per minute at a pressure of about 5 lb. per square inch. The motors must be of the variable speed type, in order that the quantity of air may be varied according to the requirements. Two additional blowers of the same type and size were provided to furnish air for the sludge aeration tanks.

On account of the small pores in the diffusing system, whether filtros blocks, wooden blocks or other means are employed, it is essential that the air furnished shall be clean; that is, free from dust, oil or other foreign substances. One of the best methods of obtaining clean air is to pass it through an air washer before going to the compressor. Such apparatus is a standard commercial product and operates satisfactorily.

The estimates provided for two air flow meters of the General Electric Co. type, similar to those in use at the Milwaukee plant. One of these meters was intended to measure the quantity of air supplied to the sewage aeration tanks, and the other the air supplied to the sludge aeration tanks. In a large plant it may be advisable to install additional meters to measure the quantity of air supplied to air lifts, but in the comparison no allowance was made for such additional apparatus.

A building will be required to house the several air compressor units amounting, in this particular case, to six large positive pressure blower units and two small reciprocating units for operating the air lifts. This building may also house the air washer, air meters, transformers and other equipment.

The estimates included six sedimentation tanks. Each was of the vertical flow type, cylindrical in form with inverted conical hopper bottom terminating in a deep well 4 ft. in diameter, similar to the tanks at Milwaukee. The tanks provided for sedimentation for a period of ½ hour, on the continuous flow plan, with space for sludge amounting to 25 per cent of the total tank capacity. The total depth of water and sludge, in the central well, was 35 ft. The tanks at Milwaukee were constructed with hopper bottoms on a slope of 1 to 1, but experience has proven that steeper slopes are necessary if the sludge is to slide easily into the central well. These tanks were so designed that the sewage and sludge will enter the tank at the center, flow downward and under the edge of the distributing cylinder, thence upward and out through collecting weirs arranged around the circumference of the tank. Each of the central sludge wells will be provided with an air lift to raise the sludge from the sedimentation tanks to the sludge aeration tanks, or into the influent of the sewage aeration tanks.

Two units of sludge aeration tanks were provided of a type similar to the sewage aeration tanks, but differing in that the partition walls were made heavy enough to withstand water pressure, thereby making each channel a separate sub-unit. The general dimensions of channels were the same as in the sewage aeration tanks; that is, 7 ft. 2 in. wide and 90 ft. long, provision being made for a depth of 10 ft. The total capacity of sludge aeration tanks provided is 328,000 gal. which is equivalent to 0.8 cu. ft. per capita, or about 60,000 gal. per million gallons of operating capacity.

It was planned to provide one air lift in a well to serve the eight sub-units of sludge aeration tanks, and a similar lift for each of the sedimentation tanks.

It was estimated that the activated sludge process will produce about 4,500 gal. of sludge per million gallons of sewage. Doubtless this quantity will vary considerably under different conditions. It is largely dependent upon the proportion of water contained in the sludge. For the average quantity of sewage for which this plant was designed, 5,500,000 gal. per 24 hours, the quantity of sludge produced daily will be 24,750 gal. For the purposes of this comparison it was assumed that the sludge will be dried on sand drying beds from which it can be removed to a dump.

It is recognized that important experimental work is being done to develop suitable dewatering and drying processes that will make it economically possible to dry the sludge to 10 per cent moisture and thus make it saleable as a low-grade fertilizer or as fertilizer base.

For the purpose of estimates it was assumed that the sludge drying beds can be dosed an average of 15 times per year to a depth of 12 in., thus requiring a total net area of sludge beds of 80,500 sq. ft. To this should be added a sufficient area to care for sludge during the winter months (Dec. 15 to March 15) and to allow for drawing of water collecting on the surface of the sludge. To provide for these contingencies the area should be increased 50 per cent to 120,750 sq. ft., equivalent to 2.76 acres net area, or 2.2 sq. ft. per capita. If sludge bed units of the same size and type as those for the trickling filter plant, are used, there will be required 77 such units, or about 7 times the area required for the trickling filter process. These sludge beds were suitably underdrained and provided with a system of narrow gage tracks and cars for removing the sludge to the sludge dump whence it can be carried to a point of disposal.

Cost of Construction.—The cost of the trickling filter plant was based on the unit costs of construction of the trickling filter plant at Fitchburg, Mass., which was built by contract, bids being received in May, 1913. Cost figures obtained in this way are more nearly representative of normal conditions than if based on the high cost of construction prevailing at the present time. As far as possible the same unit costs of construction have been applied to the estimates of the activated sludge plant, that the two estimates may be comparable.

The estimated cost of the trickling filter plant is given in Table XV. In addition to the main features, a number of items are included which go to make

TABLE XV.—ESTIMATED COST OF IMHOFF TANK-TRICKLING FILTER PLANT

	Cost excl. eng'g and adminis tration. Total	Unit cost, excl. eng'g and administration Per capita	Per M. G. D.
Grit and chamber screen	$ 10,000	$0.18	$ 1,818
Venturi meter chamber	3,000	.05	545
Imhoff tanks, incl. air lifts for sludge	64,500	1.17	11,720
Air compression equipment	800	.01	145
Sludge beds including underdrains	4,800	.09	873
Trickling filters 10 ft. deep (2.75 acres)	188,500	3.43	34,300
Dosing tanks and apparatus	16,600	.30	3,020
Secondary settling tanks	9,000	.16	1,637
Sludge pumping equipment and building	2,000	.04	364
Conduits and pipe lines, incl. overflow	10,600	.19	1,925
Effluent channel	1,300	.02	236
Roadways	9,100	.17	1,655
Laboratory building and equipment	15,200	.28	2,762
Grounds, trees, planting, etc	1,700	.03	309
Miscellaneous work, 4 % of total, excl. land	13,300	.24	2,420
Land	25,000	.45	4,550
Total	$375,400	$6.81	$68,279
Add 15 % for engineering and administration	56,310	1.04	10,221
Grand total	$431,710	$7.85	$78,500

For 55,000 persons = $7.85 per capita.
For 5,500,000 gal. per day = $78,500 per m. g. d.

up the complete plant. It should be noted that the amount included for cost of land, includes not only the land required for the treatment plant, but a total area of about 117 acres, sufficient not only for all purposes of sewage treatment but also more than sufficient to properly isolate the plant. Under miscellaneous work are included such items as extension of the water supply, electric lighting system, and other features of minor importance not covered by the principal items. It is expected that for a plant of this character administration charges may easily amount to 3 per cent and engineering to 12 per cent, making a total of 15 per cent to be added for these items. The total estimate of the Imhoff tank—trickling filter plant for a city of 55,000 population, is $431,710. This is equivalent to $7.85 per capita, or $78,500 per million gallons per day for the assumed flow of 5,500,000 gal.

The estimated cost of the activated sludge plant is given in Table XVI. In addition to the features already described, it will be noted that several items have been included to make the plant complete. As stated in the case of the trickling filter plant, the item of $25,000 for land includes about 117 acres. It may not ultimately prove necessary to isolate the activated sludge plant, in which case a credit in favor of this plant should be made on account of the small area of land required. In this case, as in the other, 15 per cent has been added to cover the cost of administration and engineering charges. It will be seen that the total cost of the activated sludge plant is $313,880, which for a population of 55,000 persons is equivalent to $5.71 per capita, and $57,100 per million gallons per day.

Cost of Operation.—An estimate has been made of the cost of operation of the trickling filter plant, based principally on the experience at Fitchburg, for the years 1915 and 1916. From data furnished by David A. Hartwell, Chief Engineer, deductions have been made for certain expenditures pertaining to construction rather than operation. The items for 1916 (with estimates for November, the last month of the fiscal year) are shown in Table XVII, from

TABLE XVI.—ESTIMATED COST OF ACTIVATED SLUDGE PLANT

	Cost excl. eng'g and adminis-tration. Total	Unit cost, excl. eng'g and administration Per capita	Per M. G. D.
Grit chamber and screen	$ 10,000	$0.18	$ 1,818
Venturi meter and chamber	3,000	.05	546
Sewage aeration tanks	78,100	1.42	14,200
Sludge aeration tanks, incl. air lifts	17,500	.32	3,180
Sedimentation tanks, incl. air lifts	8,300	.15	1,510
Air compressing equipment	22,600	.41	4,110
Air meters—2	700	.01	127
Air washer—1	600	.01	109
Power house	29,700	.54	5,400
Sludge beds, incl. underdrains	31,400	.57	5,710
Conduits, pipe lines and overflow	10,000	.18	1,818
Effluent drain	1,300	.02	236
Roadways	8,300	.15	1,510
Laboratory building and equipment	15,200	.28	2,760
Grounds, trees, planting, etc	1,700	.03	309
Miscellaneous work, 4 % of total, excl. land	9,540	.17	1,735
Land	25,000	.45	4,540
Total	$272,940	$4.94	$49.618
Add 15 % for eng'g and administration	40,940	.77	7,482
Grand total	$313,880	$5.71	$57,100

For 55,000 persons = $5.71 per capita.
For 5,500,000 gal. per day = $57,100 per m. g. d.

TABLE XVII.—ESTIMATED ANNUAL COST OF OPERATION OF FITCHBURG, MASS., IMHOFF TANK-TRICKLING FILTER PLANT FOR THE YEAR 1916

General, including administration	$ 1,800
Laboratory	1,700
Grit chamber	900
Imhoff tanks	1,700
Trickling filters	1,100
Secondary tanks	900
Sludge beds	800
Care of grounds	1,250
Miscellaneous	1,100
Total	$11,250

3 m. g. d. = 1,095 m. g. treated = $10.28 per m. g.
32,500 persons = $0.35 per capita.

which it appears that the total cost of operation has been $11,250, which is equivalent to $10.28 per million gallons treated, averaging 3,000,000 gal. daily, or 35 ct. per capita, on a basis of 32,500 persons actually connected. The total population in 1915 was about 39,656.

Similar figures for the Gloversville trickling filter plant show the following costs of operation per million gallons of sewage treated:

	Annual cost of operation— Per M. G. treated	Per capita
1913	$5.16	$0.24
1914	5.92	.27
1915	5.72	.26

It should be stated here that these expenditures are limited to the barest necessities. No chemical supervision nor other refinements which can be avoided, are included.

The estimate of annual operation cost of the hypothetical Imhoff tank-trickling filter plant to serve a population of 55,000 is given in Table XVIII.

Table XVIII.—Estimated Annual Cost of Operation of Typical Imhoff Tank-Trickling Filter Plant

General, including administration	$ 2,200
Laboratory	1,700
Grit chamber	1,650
Imhoff tanks	3,120
Trickling filters	2,020
Secondary tanks	1,650
Sludge beds	1,470
Care of grounds	1,250
Miscellaneous	2,020
Total	$17,080

5.5 g. d. = 2,005 m. g. treated = $8.50 per m. g.
55,000 persons = $0.31 per capita.

Table XIX.—Estimated Annual Cost of Operation of Typical Activated Sludge Plant

Item		Annual cost
General, including administration		$ 2,200
Laboratory		1,700
Grit chamber		1,650
Tank Treatment—		
1 engineer foreman at $4 per 8-hr. day, 312 days	$1,248	
3 engineers at $4	3,744	
4 laborers at $2.50	3,120	
Repairs	1,278	9,390
Sludge Drawing and Disposal		
Foreman part time	$ 375	
2 laborers at $2.50, 312 days each	1,560	
1 team at $6, 312 days	1,872	
Supplies and repairs	603	4,410
Electric power at 1c per kw. h.		17,040
Care of grounds		1,250
Miscellaneous		2,500
Total		$40,140

5.5 m. g. d. = 2,005 m. g. treated = $20.00 per m. g.
55,000 persons = $0.73 per capita.

The estimated annual cost of operation of the activated sludge plant is shown in Table XIX. Nearly half of the annual operating cost is for electric power, required for compressing the air. It was estimated that in addition to the air required for sewage aeration one-fifth as much would be required for sludge re-aeration and for operating the air-lift pumps. The total annual cost of operation amounts to $40,140, which is equivalent to $20 per million gallons treated, or 73 ct. per capita, based on 55,000 persons.

The item for power is estimated on the assumption that it can be obtained at 1 ct. per kw. h. For many places this is a low price, while for others it is high. Surely it is low enough for use in computing the cost of power in most places upon a project which is to be operated for a generation in the future.

Comparison of Costs.—For the final comparison of costs the interest and depreciation have been computed for both plants, and the total annual cost, made up of operating expenses and interest and depreciation, has been capitalized at 4 per cent and added to the construction cost (Table XX). The result is decidedly in favor of the Imhoff tank-trickling filter plant, in spite of the fact that the estimates of operation of the activated sludge plant have been kept low, probably lower than is justified, that there might be no danger of inflating this cost to the disadvantage of the new process. To eliminate this difference it will be necessary to decrease the operating expenses of the activated sludge treatment by about $11,000, or to decrease them a portion of this amount and in addition thereto to decrease the construction cost materially.

TABLE XX.—COMPARISON OF COSTS OF IMHOFF TANK-TRICKLING FILTER PLANT AND ACTIVATED SLUDGE PLANT

Item	Trickling filter plant	Activated sludge plant
Operating expenses	$ 17,080	$ 40,140
Interest and depreciation*	26,760	19,780
Total annual cost of treatment	$ 43,480	$ 59,920
Total annual cost of operation per m. g.	21.84	29.85
Total annual cost of operation per capita	0.80	1.09
Expenses capitalized at 4 %	$1,096,000	$1,498,000
Construction cost	431,710	313,880
Total	$1,527.710	$1,811,880
Difference		284,170

*Interest at 4 %—Depreciation—Sinking fund at 2½ %.

A reduction in the price of power from 1 ct. to 0.6 ct. per kw. h., the price at which it is estimated power can be purchased at Milwaukee, would effect an annual saving of $6,816. For a plant only large enough for 55,000 persons it is doubtful if power below 1 ct. per kw. h. can be procured in many places.

It is not unlikely that improvements in the methods of diffusion and of holding the air for a longer time in contact with the sewage may result in a decrease in the quantity of air required. This would result in a decrease in cost.

At the present time much attention is being given to methods of converting the sludge into marketable fertilizer. There is reasonable agreement among investigators that activated sludge contains a greater proportion of fertilizing ingredients than the sludges obtained from most other processes of sewage treatment. If the sludge can be converted into commercially dry powder containing only 10 per cent moisture, there is good evidence of a market for it at a moderate price.

If the cost of preparation and sale of sludge should be no more than the return from such sales, the reduction in the foregoing estimates of operation and construction would be $5,030 and $66,000, respectively. If this process should be even more successful and a net profit of $2 per ton or say $1 per million gallons should be derived, the saving thus effected would amount to—

Profit on sludge	$2,007.50
Cost of sludge disposal as per previous estimate	5,030.00
Interest and depreciation on sludge beds	2,270.00
Total	$9,307.50

In addition to this annual saving there would be also the saving in investment cost of $36,000.

Even this profit and saving would not be enough to reduce the cost of the activated sludge process to that of the Imhoff tank-trickling filter process, but the net profit of $1 per million gallons may be substantially exceeded. In any event, this subject should receive, as indeed it is receiving, most careful investigation.

It may be argued that greater economy will be possible in the large plants than in the typical plant designed to serve 55,000 persons. This is undoubtedly true, but it is also true of the trickling filter plant. The proportionate saving in the cost of the activated sludge plant, however, may be somewhat greater.

Further development, particularly in the direction of reducing the quantity of air required, and improving means of distribution, may result in a reduction of construction cost. It seems more probable, however, that the cost of construction will be increased, and in any event there should be no reduction in construction cost at a sacrifice in efficiency.

In spite of the fact that it appears to be somewhat more expensive than other processes, the activated sludge treatment should not be rejected on the ground of cost without giving full consideration to its advantages. It may be that as an oxidizing process it will always be more expensive than the trickling filter, but it may have advantages more important than this disadvantage.

Advantages and Disadvantages of the Two Processes.—If it is assumed that the sludge from the activated sludge process is to be dried and disposed of by means of sludge beds, the total area of land used for the activated sludge plant will not differ greatly from that actually used for the trickling filter plant.

The areas utilized for several trickling filter plants, including a reasonable allowance for walks, drives and general purposes, are shown in Table XXI.

TABLE XXI

Location of plant	Area of land required for plant, acres	Area of trickling filters	Average depth of stone in trickling filters
Fitchburg, Mass.	11.8	2.07	10′ 3″
Schenectady, N. Y.*	19.0	6.1	4′ 7½″
Gloversville, N. Y.	13.5	3.07	4′ 7½″
Typical trickling filter plant, estimated	11.8	2.75	10′ 3″

*Original design; only one-half plant built.

The estimated area required for the typical activated sludge plant is 10 acres, or nearly 2 acres less than that required for the typical trickling filter plant. If some other form of sludge disposal were used, the area would be materially reduced. In the second annual report of the Milwaukee Sewerage Commission, it is stated that the ground area required for the Milwaukee activated sludge plant is 0.4 acre. This plant is capable of treating 1,620,000 gal. of sewage per day, but the area given makes no provision for sludge disposal and practically nothing for walks, drives and other features to be expected in an ordinary, complete plant. As already stated, the activated sludge plant may have some advantage in not requiring as much land for isolation as the trickling filter plant. The corresponding reduction in cost would be to the advantage of the former.

One of the important advantages of the activated sludge process is the small loss of head required for the passage of the sewage through the plant. The resulting saving in cost of sewerage works such as pumping stations and long outfall or intercepting sewers, may be sufficient to make the adoption of the activated sludge process imperative. The amount of head lost in several trickling filter plants is shown in Table XXII.

TABLE XXII.—HEAD LOST IN TRICKLING FILTER PLANTS

Location of plant	Head lost, ft.
Columbus, O	25.34
Fitchburg, Mass	25.40*
Gloversville, N. Y	21.40
Schenectady, N. Y. (original design)	13.70
Schenectady, N. Y. (actual construction)	14.65
Washington, Pa	16.50
Philadelphia, Pa	25.25
Atlanta, Ga., Peachtree Creek Works	20.00

*Actual is 42.1 due to topography.

From this table it will be seen that the head required for a trickling filter plant varies from 14 ft. to a little over 25 ft. The Milwaukee 1.62 m. g. plant requires 0.3 ft. between the inlet to the sewage aeration tanks and the outlet of the sedimentation tank. In addition to this some loss should be added for the grit chamber and screens, but in any event, a total loss of 1 to 2 ft. would appear to be ample.

There is some sentiment hostile to an Imhoff tank-trickling filter plant because of the fear of the dissemination of objectionable odors. That objectionable odors are noticeable in the immediate vicinity of such plants cannot be denied. On the other hand, there is good evidence that they are not noticeable except very close to the treatment plants.

The activated sludge plant appears to have some advantage in this direction. Odors may be noticeable in the immediate vicinity of the aeration tanks, and it is possible that objectionable odors may be given off from some portions of the sludge drying and handling process, whatever it may ultimately be. It is probable, however, that the danger from this source will be less than from the Imhoff tank-trickling filter plant.

The moth flies, so prevalent at certain seasons of the year, are quite objectionable close to the filters, although they are rarely found more than a few hundred feet away from them. While this cause of annoyance may be kept under reasonable control, it is doubtful if it can be wholly eliminated. The activated sludge plant does not seem to be a suitable breeding ground for these pests and therefore has an advantage over the filter.

There is no doubt that the activated sludge process is capable of producing a more highly oxidized effluent than the trickling filter, as ordinarily built and operated, that it will eliminate a much greater proportion of bacteria, and that in appearance its effluent will be decidedly superior to that of the filter. This is a marked advantage under certain circumstances, but these facts alone should not be allowed to control in the adoption of a more expensive process when the accomplishments of the trickling filter answer all purposes.

A disadvantage of the activated sludge process in the minds of many who have studied it is its apparent complexity and need for careful and skillful supervision. While it has been contended by some that this process is exceedingly simple and one which can be operated by a workman of ordinary intelligence, the consensus of opinion appears to be to the contrary. The author's experience in operating several small experimental plants, leads him to feel that of all processes of sewage treatment in practical use in this country today this is by far the most difficult to operate and that it will require the skill of a well-trained engineer or chemist to insure continued satisfactory results with it.

At the present time it appears that the Imhoff tank-trickling filter process is a less expensive means of oxidizing the organic matter of sewage and industrial wastes than the activated sludge process, where oxidation alone is considered. If the areas of land required for isolation, the loss of head in the plant, the danger of objectionable odors and of the fly annoyance, and other disdvantages of the trickling filter process are of marked importance in any specific case the balance may be decidedly in favor of the activated sludge process, even in its present state of development.

Cost of Sludge Removal at Columbus, O. (Engineering and Contracting, July 10, 1918).—During 1917, 2,164 cu. yd. of sludge was removed from sewage treatment works of Columbus, O., at an average cost of 29½ ct. per cubic yard, distributed as follows:

Labor	$0.278
Gasoline	.016
All other expenses	.001
Total	$0.295

The mean cost of labor was 33.1 ct. per hour, and the labor hours per cubic yard were 0.83. The average length of haul was 750 ft.

Cost of Pressing Sewage Sludge.—A comprehensive discussion of the practice of dewatering sewage sludge by filter pressing was presented by Kenneth Allen, Engineer of Sewage Disposal for the Board of Estimate and Apportionment of New York City, in Vol. 1 of the Transactions of the American Society of Municipal Improvements. That portion of the paper relating to sludge pressing, as reprinted in Engineering and Contracting, Feb. 13,1918, follows:

Plate Type of Sludge Presses.—There are several forms of filter presses. That most commonly used consists of a series of parallel plates from 30 to 54 in. square and with depressed surfaces, so that when the rims are in contact they enclose a series of cells from ¾ in. to 2 in. thick. The plates are usually of cast iron from 2 in. to 3 in. thick at the rim and where in contact are machined so as to form a true and tight joint. The depressed surfaces are either grooved vertically, in concentric circles and radially, or else in two directions at right angles to each other forming numerous little pyramids, in order to facilitate drainage. Each plate has a 6-in. hole in the center through which the sludge flows by gravity from a tank or is pumped into a series of cells. The pipe to the press is usually 8 in. in size.

Between each pair of plates there are placed two pieces of cloth with holes 4 in. to 6 in. in diameter in the center, opposite the holes in the plates. The two cloths on the opposite sides of each plate are then sewed or clamped together at the hole to prevent the sludge from entering and escaping between.

A modification of this is the "frame plate" used in Germany, in which a series of plates of uniform thickness, *i.e.*, with plain faces except in the drainage grooves, alternate with frames. The grooves in the plates lead to drainage ducts below and a sieve is placed over each face. The cloth is then folded over each plate and clamped by the adjacent frame. The sludge enters by a continuous duct near the upper edge of the plates and frames.

The plates, usually 50 to 100 in number, are held together tight by tie rods passing through their upper corners or lugs projecting therefrom. A head casting at one end and a follower at the other hold the plates between, while the sludge is subjected to a pressure of from 50 to 120 lb. per square inch. This pressure may be derived directly from the air receiver or it may be applied after the press is filled by means of a screw operated by hand or motor.

As the pressure continues, the drainage liquor, which is putrescible and offensive, flows through a ½-in. hole in the bottom of the plates to a drain pipe by which it is carried back to the sedimentation tank to be again treated with the sewage. Pressure is maintained until the drainage is insignificant, which may be anywhere from 15 minutes to 1½ hours, although at Oberschoeneweide, in order to secure a firm cake from lignite sludge, and elsewhere with greasy sludge, it has been necessary to maintain the pressure for 12 hours or more.

One of the most important sludge pressing plants is that at Leeds, where about 900 tons of cake (containing 317 tons dry solids) are produced in a week of 53 working hours.

The sewage amounts to 21,000,000 U. S. gallons per day, of which 4,600,000 are industrial waste. After passing a screen and a grit chamber, it is dosed with 10 to 100 p.p.m. of lime and the sludge is pumped by Tangye pumps to three sludge tanks of 360 tons capacity, milk of lime being introduced in the pump section, 3⅓ tons per tank. The limed sludge, 90 per cent moisture, is then settled for 12 to 18 hours and the supernatant water drawn off. This usually amounts to from 8 to 12 per cent of the volume. Two pairs of rams 6 ft. in diameter by 12 ft. deep force the concentrated material under a pressure of 100 lb. per square inch to the presses, each feeding four of the eight installed, but this is increased to a final squeeze of about 1,700 lb. per square inch by hydraulic thrust blocks.

Each press has 64 cells 52 in. by 52 in. by 1½ in. in size, and therefore produces about 5 tons per run. The cake drops to bogies below holding 50 cu. ft. each and drawn by a locomotive. Eight laborers attend to the presses and four to the bogies.

At Glasgow the Damarnock plant consists of 18 presses of 41 cells each. The air pressure is 100 lb. 150 tons of cake, 66 per cent moisture, have been produced in five runs per day, equivalent to 2¾ tons or 3¼ cu. yd. per 1,000,000 gal. of sewage. The moisture is reduced from 90 to 66 per cent by the process.

The plant at Worcester, Mass., consists of 4 Bushnell presses of 125 39-in. circular plates each. Sludge is pumped into the presses by two triplex pumps having 6-in. bronze ball valves. Between the pumps and the presses there is a 1,130-gal. equalizing tank supplied with compressed air as a cushion at the top and from the bottom of which a 10-in. main with 6-in. branches feeds the presses. The follower or rear end plate of the press carries a 10-in. hydraulic ram with a 48-in. travel which brings the plates into close contact so as to prevent leakage, and the sludge is then pumped in under a pressure of 80 lb. per square inch. The cake produced is 36 in. in diameter and ¾ in. thick. On falling from the cloths it is carried by a conveyor to a car holding 3 cu. yd., run to a trestle and dumped. Four sludge cars and two motor cars are provided. Each press will produce, with 8 fillings, 16 cu. yd. of cake per day.

In 1916 a daily average of 37,600 gal. of sludge, 93.74 per cent moisture, produced 36.1 tons of cake, 72.8 per cent moisture, containing 1.23 tons of solids per 1,000,000 gal. of sewage. The cost of pressing was $7.05 per 1,000,000 gal. of sewage, or $5.71 per ton of solids.

At Providence there are 18 presses of from 43 to 54 plates each. These are filled with sludge under a pressure of 60 lb. per square inch. The cake, 36 in. square and 1¼ in. thick, amounts to 64 tons per day.

At Spandau the sludge from a population of 80,000 is forced from cylindrical steel receivers under a pressure of 33 lb. per square inch to the 8 presses. The plates and frames are 3.6 ft. square and made of wood. Each plate has 2 inlet slots near the top and vertical drainage grooves leading to drainage ducts in the bottom.

After filling, the presses are subjected to an increased pressure by a hand pump and the sludge is left under a pressure of from 60 to 75 lb. per square inch for 20 hours. The cake is then 1¼ in. to 1½ in. thick and contains 60 per cent moisture. On opening up each press the sludge drops into 4 tip cars for removal. It is then either sold at 4.6 ct. per cubic yard (1913) or air-dried and used for fuel. It has no appreciable odor.

At York, England, where the grease makes the sludge particularly difficult to press, milk of lime is flushed into the press in advance of the sludge, which has already received its dose.

Another plan when dealing with such sludge is to heat the presses by injecting steam and, as at Bradford, heating also the sludge itself in advance. The grease then passes off in large part with the drainage liquor.

It is stated that the cake here contains but 27 or 28 per cent moisture. The power required for pressing is given by Kershaw as from 7 to 13½ b.h.p. per ton (8 to 15 b.h.p. per long ton) of cake pressed per hour, depending on the size of the plant and the moisture and other characteristics of the sludge.

The cloths are a little more than twice the size of the plates over which they are folded. They are made of jute, duck or other fabric; at Worcester of 11 oz. duck 40 in. wide. Their life varies greatly, depending on the sludge, the pressure to which they are subjected, whether they are cleaned periodically, etc., but is usually rather brief from rotting. Elsner states that the life of (probably jute) cloths may be as much as 4 weeks if first treated with a tar composition. At Spandau they were said to last from 1 to 2 months; at Worcester, according to Metcalf and Eddy, 6 to 9 weeks is regarded as reasonable when operating at the rate of 12 cleanings per day of 10 hours. Stated another way, 2.44 sq. yd. of duck are required per ton of dry solids.

A septic sludge or one containing particles of lime—especially if left unslaked—or particles of rust from the plates shortens the life of the cloths. Probably for the last reason wood has been used for plates in Germany instead of iron.

At Leeds it was decided, after trying different cloths, to adopt 54-in. 3-ply twist twilled jute sacking, 30 oz. per yard. Experiments were then made to increase the durability of the cloths, first by shrinking and then by treating with different oils. The best results were secured by oiling an 8-in. strip around the edge of each cloth, around the center hole and where the bosses on the plates meet with "Golden-Bloomless" mineral oil costing 23.7 ct. per gallon or "Black Oil," a crude petroleum costing 10 ct. per U. S. gallon. The effect of oiling seems to be to render the material more elastic and so prevent its rupture under strain. One gallon sufficed for 5 cloths, increasing their average life from 156 to 200 pressings. The saving effected is shown by the following statement:

	Price per yd.	Cost of pressing per ton (2,000 lb.) of cake
Year ending March 31, 1913..............	21.5 ct.	39.8 ct.
Year ending March 31, 1915..............	28.6 ct.	36.5 ct.

It is estimated that about $1,450 is thus saved annually.

After drainage is complete the pressure is released, the plates are separated and the sludge falls or is scraped off the cloths onto a conveyor or into a tip car, by which it is removed for disposal. This operation takes from 10 to 30 minutes or more. The entire operation of filling, pressing and emptying ordinarily takes from 45 minutes to 2 hours.

Sludge Cake.—In practice precipitated sludge is reduced to cake having about 20 per cent its original weight and containing from 50 to 70 per cent moisture. The moisture is not uniform in the cake, being greatest near the point where admitted to the press. The weight of this cake is about 8⅔ tons per 1,000,000 gal. of sewage (Rideal). The cakes run from an inch or less in thickness to 1½ or 2 in. if greasy and well dosed with lime. On breaking it up the weight per cubic yard is reduced to about 1,350 lb. when the voids are found to be about 40 per cent. By air-drying under cover this weight may be further reduced by about 50 per cent.

Analyses of sludge cake as produced at Chorley and Dorking, England, are given in the Fifth Report of the Royal Commission on Sewage Disposal. The sewage in each case is domestic. At Chorley, with combined sewage, 9 grains per Imp. gal. of alumino ferric is used for precipitation, and at Dorking, which is partially sewered on the separate system, 5 grains per Imp. gal. of lime. The cake as delivered contains about 50 per cent moisture, but the samples analyzed were dried at 110° C.

	Chorley	Dorking
Grit	25.30	6.84
Oxides of iron and aluminum	9.37	3.46
Lime	10.32	23.16
Phosphoric acid	0.98	0.66
Nitrogen (total)	1.28	0.89

At Leeds in the year 1913–14 the average composition of the cake was as follows:

	Per cent.
Water	60.1
Volatile matter	16.7
Nitrogen, 5.9 per cent	
Total grease, 6.3 per cent.	
Mineral residue	23.2
Calcium phos., .94 per cent.	
	100.0

The solids from the sewage normally comprised 35.3 per cent of the cake.

The average of 4 analyses of commercially dried (10 per cent moisture) activated sludge, with especial reference to their fertilizing value, are given by William R. Copeland as follows:

	Per cent.
Nitrogen as ammonia	4.68
Available phosphoric acid	0.57

Cost of Pressing Sludge.—The cost of pressing is given by the Royal Commission on Sewage Disposal for two typical groups of towns:

Group I—For towns of 30,000 persons or more employing chemical precipitation followed by sedimentation or sedimentation alone and where no special addition of lime is required on account of industrial waste. Sludges under such conditions will require lime equivalent to from 2 to 4 per cent of the weight of the pressed cake.

Group II—For towns of less than 30,000 persons and for those where, because the sludge is greasy or derived from septic tanks, it is necessary to add lime equivalent to from 5 to 20 per cent of the weight of the pressed cake

The moisture in each cake is assumed to be 90 per cent in the wet sludge and 55 per cent in the pressed cake.

COST OF PRESSING SLUDGE
In ct. per ton of 2,000 lb.

Wet Sludge—	Group I	Group II
Operation	9.6–12.0	14.5–24.4
Operation and fixed charges	13.2–15.6	18.1–28.0
Pressed Cake—		
Operation	43.5–54.4	65.2–109
Operation and fixed charges	59.7–70.6	81.4–125

Moore and Silcock give the cost of pressing in England at from 32.6 ct. to 54.4 ct. per ton of cake; Elsner at $4.50 per 1,000,000 gal. of sewage. According to Schiele the cost of producing 1 ton of cake from 5.8 cu. yd. of wet sludge, including fixed charges, varies from 41½ ct. to $1.28, and averages 85 cts.

In a list of 18 British cities Metcalf and Eddy find the cost of pressing to vary from 6 to 43 ct. per ton of wet sludge or from 27 to 93 ct. per ton of cake.

At the Dalmarnock Works at Glasgow 171,476 tons of crude sludge were pressed to 291,045 tons of cake in the year ending May 31, 1916, at a cost of $2.16 per 1,000,000 gal. of sewage, or 67 ct. per ton of cake.

At the Knostrop works at Leeds in the year ending March 31, 1915, 42,321 tons of cake, 60 per cent moisture, were produced at a cost of $15,480, exclusive of interest and amortization, and $6,681 for disposal or, for pressing, per ton of cake, 36.7 ct.; per ton dry solids, $1.03.

For German conditions, Reichle and Thiesing mention from 63½ to 85 ct. as fair limits (before the war).

Estimates based on foreign practice cannot of course be applied directly to American conditions. The following is the distribution of cost based upon figures estimated for Wimbeldon by Santo Crimp:

	Per cent
Wages	36.0
Lime	40.0
Coal	9.6
Cloths	12.8
Oil, etc	1.6
Total	100.0

American cost data are practically limited to experience at Worcester and Providence, data for which are as follows:

Range	Worcester 1899 to 1912	Providence* 1903	1910	1916
Per mil. gal. sewage	$3.85 to $6.76	$2.44	$4.06	$2.78
Per ton of dry solids	3.39 to 4.64	2 27	2.54	3.38
Per ton of cake	0.91 to 1.37	0.67	0.72½	0.94½

* Costs include disposal.

The above figures are in general based upon precipitated sludge. Owing to the greater amount of lime required it will cost perhaps a third more to press fresh or septic settled sludge.

Disposal of Cake.—The cake may sometimes be disposed of for a nominal sum, say, 10 to 25 ct. per ton, to farmers, but if there is no demand for it, it may be used for filling at about an equal cost. When deposited in depths up to 12 ft. in water-soaked land near Leeds it was observed to shrink about 33 per cent in two years and to generate more or less heat.

While there is more or less odor in the press house this does not carry far, and if kept under cover it is quite inoffensive. Fresh cake kept moist by rain, especially if the weather is warm, will give off a certain amount of odor, but, if first air-dried to 20 or 30 per cent moisture, objectionable odors are usually prevented.

An advantage in lignite sludge, besides being inodorous, is that it can be utilized by burning under the boiler, and experiments by W. L. Stevenson at Philadlephia show that by the addition of a small amount of combustible material to ordinary air-dried sludge from plain sedimentation there will be obtained a material having a moderate value as fuel.

The foregoing remarks have been confined to the plate type of press, often spoken of as the "Johnson" filter press, this having been almost universally used for the pressing of sewage sludge heretofore. There are, however, several other more recent types which deserve mention.

The Kelley Filter Press.—The Kelley Filter Press consists of a steel frame supporting a cylindrical "press shell" at one end and a carriage for inserting into and withdrawing from the other end a series of longitudinal filter leaves. Each leaf consists of a horizontal pipe above connected to a similar pipe below by a mesh of double crimped No. 0.105 gage wire. This wire mesh enters a slot in each pipe for the removal of the filtrate, to which it is strongly riveted or welded. A bag of extra heavy twill or duck is drawn over each leaf and the end sewed up by hand, forming the filtering medium. The leaves are uniformly spaced, but of different heights, depending on their position with reference to the press shell.

At each end of the filter carriage are plates for supporting the leaves, one of these providing the head of the press shell when the leaves are inserted. By means of a groove in the head plate corresponding to an annular projection on the end of the shell, which are forced together on a gasket and held by special locking mechanism, all leakage during operation is prevented.

In operation the carriage and leaves are inserted in the shell and the head is locked. The shell is then filled with sludge by a pipe, while the air is released by an overflow valve at the top. This, it is claimed, takes but about four minutes. When filled the overflow valve is closed and about 40 lb. pressure applied to the sludge pipe. The cake forms on the surface of the bags as the filtrate passes through and is carried off by the frame pipes and drains.

After the cake is built up the sludge supply is shut off and compressed air admitted from above, displacing the remaining wet sludge and aiding in drying the cake. This is then removed from the bags by shaking, by loosening with a wooden spade, or by compressed air introduced through the drainage pipes.

The following data are taken from a circular of the manufacturer:

Size of shell	30″ × 72″	40″ × 108″	48″ × 120″
Capacity of shell—			
Cu. ft.	32	75	120
Gal.	240	560	900
Number of leaves	4–9	6–8	6–10
Filter area, sq. ft.	60–130	180–250	260–450
* Weight of cake 1½ in. thick	667	1,333	3,333
* Average weight of cake in tons per 24 hours	3⅓–6⅔	13⅓–26⅔	33⅓–66⅔

* Assuming weight of cake 66⅔ lb. per cu. ft.

The economies claimed for this press are due to the small amount of labor required, lack of wear on filter cloths and the avoidance of breakage of plates.

The Sweetland Filter Press.—This consists of a number of parallel circular leaves consisting of a heavy wire screen hung from a casting above. Each leaf has an outlet nipple at the top connecting with a drainage duct in the above casting, is bound by a stiff U-shaped frame on the edge and covered with suitable canvas. The entire series of leaves is enclosed in two semi-cylindrical castings, the lower of which can be swung to one side on a hinge.

The sludge is forced in through a channel in the bottom of the lower casting and flows up between the leaves and as the filtrate passes through the canvas and out through the drainage duct the solids form a cake on each side of every leaf. When the process of filtering becomes slow, compressed air is introduced, blowing the wet sludge in the bottom of the cylinder back into the storage tank and drying the cakes. The lower casting is then swung to one side and the dewatered sludge drops out, aided by reversing the air pressure through the leaves. This back pressure serves as well to keep the filter surfaces clean. The operation of dumping is claimed by the manufacturer to occupy but from 8 to 20 minutes.

In a press of this kind used by R. W. Pratt at the Cleveland Sewage Testing Station the leaves were 2 ft. in diameter. The average moisture in the wet sludge was about 86 per cent and that of the cake between 62 and 76 per cent. Mr. Pratt mentions the importance of keeping the cakes from adhering to each other by providing sufficient clearance. Where the leaves were even as much as 3 in. between centers no cake was obtained with less than 70 per cent moisture, and it was concluded that there should be a clearance of not less than 3 in. nor more than 4½ in. Pressures of from 30 to 35 lb. were sufficient except for short periods at the end of the run when as much as 50 lb. were sometimes used. As to the time required the best results were with a half hour for forming the cake, ¾ hour for drying or 1¼ hours for the entire run.

These tests were mostly with Imhoff sludge, but as there is no exposure of the sludge to the air, Mr. Pratt is of the opinion that "in large installations the Sweetland press could be operated without odors or nuisance" with ordinary sludge.

Results of Pressing Imhoff Sludge

Condensed from Table 61, Report Sewage Testing Station, Cleveland, 1914

Number of leaves	16	16	14	14
Spacing center to center	1½″	3″	3″	4½″
Number of runs averaged	4	7	2	4
Time in hours:				
Pressing	.94*	1.15	1.65†	.50
Drying	.12½	.36	.58†	.75
Total	....	1.51	.....	1.25
Specific gravity of raw sludge	1.05	1.06	1.11	1.07*†
Per cent moisture:				
Raw sludge	89	86	82	86
Cake	68	72	75	64
Pressure—lb. per sq. in.	53*†	43	43	42
Lb. cake per run	242*†	314	139	90

* Average from 2 runs. † Result from 1 run. *† Average from 3 runs.

The Worthington Filter Press.—The Worthington or "Berrigan" press has been tried out in particular at Milwaukee in connection with activated sludge.

The sludge is placed in each of a number of unbleached muslin bags inclosed in a bag of special fine canvas. The bags are hung vertically between two plates, which, being drawn together by means of a toggle joint, squeeze the superfluous water from the sludge and through the bags. As the pressure continues, the motion, which is automatically controlled, decreases, but the pressure may be increased very greatly.

The plates are grooved and faced with wire to facilitate drainage. In size they are manufactured 36 in. by 48 in., 72 in. by 108 in., and 96 in. by 120 in.

The Milwaukee experiments were made with a 72-in. by 108-in. press with 10 bags. The sludge, 98 per cent or 99 per cent of water, is first concentrated to 96 or 97 per cent. The best way to accomplish this, whether by decanting the supernatant water after settling from 1 to 3 hours or scraping or sucking up the deposited sludge, remains to be settled. It is a material factor in the economy of operation, as every per cent reduction means a large saving in the volume of sludge to be handled and consequently in the cost of the plant.

The concentrated sludge is fed into the bags without any addition of lime and then subjected to a pressure gradually increasing to about 60 lb. per square inch. After draining the pressure is released, the bags are lifted out and emptied by gravity. They keep fairly clean in this way, but, if sludge adheres to the surface, it is removed by a jet of steam.

The Milwaukee machine will produce from about 2,000,000 gal. of sewage a ton of cake 1 in. thick per run, which, by further drying to 10 per cent moisture, will yield about 1,000 lb. in a condition, after grinding, to be used as fertilizer, for which it is said to be particularly well adapted. The tim required is about 5 hours per operation, so that the above press will produce some 5 tons of cake per 24 hours of 75 per cent moisture.

One laborer, according to Mr. T. C. Hatton, Chief Engineer of the Milwaukee Sewerage Commission, can attend to 5 presses, so that the cost of attendance is low, and as to the power required, the designer, Mr. Berrigan, claims that a 15-h.p. motor will suffice for 5 machines.

The following conclusions were based upon the Milwaukee experiments with activated sludge: "Sludge can be dewatered satisfactorily from 96 per cent to 75 per cent moisture by either a plate press or pressure press without the addition of lime or other base.

"The filter bags used in the presses must be cleansed frequently to maintain efficiency. This can be done by soaking in a bath of dilute caustic soda and hot water.

"Sludge after pressing can be stored in a building without creating offensive odors more than 50 ft. away, and can be easily handled."

After drying (to 10 per cent) this sludge contains from 4.5 to 5 per cent of ammonia, for which there is ample market as a fertilizer.

The cost of a press such as has been described complete is stated to be about $4,000, exclusive of overhead charges, to which should be added $800 for an accumulator, or $500 for a pump of capacity to serve 20 presses.

An estimate of the cost of operation is given by Mr. Hatton in the Report of the Commission for 1916, as follows, based upon a plant capable of handling the sludge from 100,000,000 gal. daily of sewage:

	Per ton of cake
Labor (3 shifts of 8 hours)	$1.36
Bags (cleaning and upkeep)	.64
Power	.09
Contingencies	.16
Overhead charges, 10 per cent of cost	1.21
Total	$3.46

or, since 1,000,000 gal. daily of sewage produces ½ ton of cake, the cost of pressing is about $1.73 per 1,000,000 gal. of sewage.

According to Mr. G. W. Fuller, the cost is about $3 per ton of dry solids, or $2.70 per ton with 10 per cent moisture.

Estimated Cost of Pressing Activated Sludge.—In the Stockyards District, Chicago, by Langdon Pearse and W. D. Richardson. Based on 96 tons of dry material per day. Cost per dry ton.

Supplies:			
Duck at $1.75 per lin. yd., 120 in. wide	$1.37		
Miscellaneous	.24		
		$1.61	
Labor	$1.13		
Power 3.24 h.p., equals 2.42 kw.-hr. at 0.7 ct. per hr	.41		
		1.54	
Operating expenses			$3.15
Fixed charges			2.57
Grand total			$5.72

While this press has been shown to be well adapted to the dewatering of activated sludge, Mr. Berrigan claims that it will also be found satisfactory with plain settled or septic sludges without the addition of lime, but the writer is not aware that this has been conclusively demonstrated as yet.

Conclusion.—Dewatering sewage sludge by filter pressing with the plate type of press has been brought to a point where its efficacy and cost can be closely predicted. With fresh settled or precipitated sludge and the addition of from 0.5 to 3 per cent of lime and a pressure of 70 or 80 lb. per square inch a firm, satisfactory cake can be produced.

Cost of Flushing Sewers.—The following data are taken from an article published in Engineering and Contracting, April 24, 1912.

Methods and Apparatus for Flushing Sewers.—Flushing consists of admitting a sudden rush of water at a high velocity into the sewer. This can be secured by collecting water in a manhole or tank and then suddenly admitting it to the sewer by (a) opening a valve, (*b*) removing a plug, etc., or (*c*) breaking an air seal or lock in a siphon. Filling and discharging the tank may be done automatically, semi-automatically, or by hand.

In the case of very large sewers, the sewage itself may be used instead of water from an outside source. Here a plug or gate is put in the outlet and the incoming sewage allowed to dam up in the bottom of the tank or manhole. When a small head has been accumulated it is allowed to flow down the sewer. This method of flushing has several drawbacks, (*a*) The unsanitary character of the work, (b) the high cost of labor, (c) the time required for the sewage to accumulate, and (d) since the head can be built up it is limited by the grade of the inlet sewer, a low flushing velocity. As a result flushing with accumulated sewage is only employed on mains of large size.

Hand Flushing.—In flushing by hand, several methods of filling can be used: (1) By means of a water cart; (2) by a hose connection to a hydrant; (3) by a permanent connection from the water main.
A stopper is placed in the outlet of the manhole or tank and if it is not a dead end of a sewer a stopper is also placed in the inlet.

When the tank or manhole has been filled by the water from the cart, from the connection to the hydrant or water main, it is shut off, the plug or similar contrivance removed from the sewer and the water allowed to flush it out.

Automatic and Semi-Automatic Flushing.—In flushing by means of automatic apparatus, water is fed to the tank by a service pipe fitted with an appliance for regulating the rate of feed, and discharged by some form of siphon, which flushes when the water has reached a predetermined level in the tank. The operation of the siphon is entirely automatic. The water may be fed to the tank in a continuous stream of such volume that the tank fills and discharges entirely automatically at predetermined intervals of 24 to 48 hours, etc., or else the water may be fed only when desired so that flushing occurs at any frequency whatever. In the first case a regulator controls the feed to the desired rate, and in the second case, this regulator is replaced by a cut-off device designed to permit the filling only when opened by pulling a chain. The flush then follows automatically, and at the same time the feed is automatically cut off. As the name implies with automatic flush tanks no labor at all is required. With the use of the cut-off valve to permit semi-automatic flushing, labor is necessary but it is merely that of pulling a chain from the outside of the tank by means of a hook passed through the manhole cover.

Cost of Flushing.—Three items go to make up the cost of sewer flushing (1) Cost of water; (2) cost of labor; (3) fixed charges against the apparatus.

Items 1 and 2 are independent of the frequency of flushing, that is, whether flushing is performed once a day or once a month, the cost per flush for water and for labor are practically the same. This is not true of item 3. The fixed charges on the apparatus include interest on the money invested and sinking fund. The charge per flush, therefore, is governed by the frequency with which flushing is performed, the interest on sewer bonds and local conditions.

Assume a case where water costs 3 cents per 1,000 gals., and that the amount of flushing water required is 333 gals., so that the cost per flush for water is one cent. This is an extremely low cost for water. This figure can be assumed here, however, as the same cost will be taken in each method of flushing. Where the apparatus used for flushing wastes water, as for instance, where poorly operating automatic tanks discharge 2 or 3, or more, times a day, where once every 2 or 3 days would be sufficient, the money value of the water wasted will add up to a large amount in a year.

Flushing With Water Cart.—Two men with a water cart can flush about 20 tanks per day and the cost for labor is as follows:

2 men at $2.00	$4.00	
2 horses and cart at $2.00	4.00	
Total per day	$8.00	
Labor per flush		40 cts.
Water per flush		01 ct.
Total		41 cts.

To this must be added the fixed charges against the apparatus used for flushing. As we are only making a comparative study and a tank or manhole of masonry of concrete is required in all the methods considered, we can eliminate charges on that investment. The charges against the investment on water carts is included in the cost for horse and cart, which is considered as rental.

Hose Connection.—Using this method the labor to handle about 20 tanks would be:

2 men at $2.00	$4.00	
1 horse, hose and cart at $2.00	2.00	
Total per day	$6.00	
Total labor per flush		30 cts.
Water per flush		01 ct.
Total cost per flush		31 cts.

Flushing Manhole.—The number of flushing manholes or tanks with hand flap valves that may be operated in a day, depends largely on their distance from one another, on the time required to fill them and on the rapidity with which the attendant removes and replaces manhole covers, etc. A special report on the time taken to operate flushing manholes in a large city in the south shows that one man flushed 44 tanks in one day.

Assume as an average, that one man with a horse and wagon can attend about 40 tanks daily. In many cases a horse and wagon might not be used, the attendant walking or riding bicycle from tank to tank. However, as it will be assumed that a horse and wagon are also employed with the semi-automatic tank in the analysis following, it is consistent to set down that item here. The cost per flush would then be made up of the following items:

1 man	$2.00
1 horse and wagon	2.00
Total labor per day	$4.00
Cost for labor per flush	10 cts.
Cost for water	01 ct.
Cost per flush exclusive of fixed charges	11 cts.

To this must be added the fixed charges on the investment for the water connection and the lift valve. Assuming $15 as the first cost for the water connection and flap valve, the fixed charges at 10 per cent = $1.50 per year. The fixed charge per flush depends upon the frequency of flushing. We will first consider a frequency of 365 flushes per year. The cost per flush for various frequencies from 1 to 365 times per year is given by Table XXIII.

TABLE XXIII.—COST OF FLUSHING IN CENTS PER FLUSH, WHEN FLUSHING AT FREQUENCIES FROM 1 TO 365 TIMES A YEAR

Number of flushes per year	Hand operated* cents	Automatic* cents	Cost per flush with flushing manhole cents	Cost per flush with hose connections cents	Cost per flush with cart cents
1	303.00	....	261.0	31.0	41.0
25	15.00	....	17.0	31.0	41.0
50	9.00	....	14.0	31.0	41.0
100	6.00	....	12.5	31.0	41.0
150	5.00	....	12.00	31.0	41.0
200	4.50	2.50	11.75	31.0	41.0
250	4.20	2.20	11.60	31.0	41.0
300	4.00	2.00	11.50	31.0	41.0
365	3.82	1.82	11.41	31.0	41.0

* Cost per flush with semi-automatic tank.

For flushing 365 times a year the fixed charge is $= \frac{\$1.50}{365} = .41$ cents and the complete cost is as follows:

Labor per flush	10.00 cts.
Water per flush	1.00 cts.
Fixed charges	.41 cts.
Total cost per flush (flushing 365 times per year)	11.41 cts.

Automatic Flush Tanks.—With this method, the cost of water per flush is as before, one cent. The cost for labor is zero. The fixed charges on the flushing siphon are dependent upon its first cost, the life of the apparatus and the value of money. The investment for an automatic siphon and regulator as installed would be about $30. Setting down yearly fixed charges at 10 pe cent as before, we have the fixed charge per tank as $3.00 and for flushing 36 times per year, .82 cents per flush. The total cost per flush is then:

Labor	.00 cts.
Water	1.00 cts.
Fixed charges	.82 cts.
	1.82 cts.

Table XXIV summarizes the cost of various methods of flushing at a fre quency of 365 times a year.

TABLE XXIV.—COST OF FLUSHING, IN CENTS PER FLUSH, AT A FREQUENCY O 365 TIMES A YEAR

Method of flushing	Water cost per flush, cents	Fixed charges per flush, 365 flushes per year, cents	Labor cost per flush, cents	Total cos per flush, cents
Water cart	1	0	40.0	41.0
Hose connection	1	0	30.0	31.0
Flushing manhole	1	.41	10.0	11.41
Automatic flush tank	1	.82	0.0	1.82

* For the purpose of comparison fixed charges against the masonry tank c manhole can be neglected and with the flushing manhole and automatic tanl 10 per cent of the cost of the apparatus are set down for interest sinking fund an maintenance.

Semi-Automatic Flush Tanks.—We have now to consider the cases wher flushing is required less frequently, once or twice a week or less. Under thes circumstances, the semi-automatic tank is the most economical method c flushing. Furthermore, this type of tank can be used when desired, as a fu automatic tank, flushing at frequent periods or less frequently, the only labc required for flushing in this manner being the pulling of a chain from th outside of the manhole.

The cost for water is again, one cent per flush. As to labor—a man with horse and buggy, costing in all $4 per day, can pull the chain and set off 20 tanks which would be only five times as many flushes as was assumed with th ordinary flushing manhole. This would make the cost for labor per flush cents. The number of semi-automatic tanks that can be operated in a da by one man, are dependent, as was the case with the flushing manhole, o the distance between tanks and the time consumed in operating the tank itsel With the semi-automatic tank, the time required to pull up the chain is bu a fraction of a minute, as contrasted to the time required to remove a manhol cover, turn on the water, wait till the tank fills, open the flap valve and di charge the tank and replace the cover, as is the case with flushing manhole

To the cost of 2 cents per flush for labor, must be added as before the fixe charges against the apparatus. The first cost of the semi-automatic tank ove and above the first cost of masonry may be set down, as was the case with th automatic tank, at $30 at 10 per cent, so that the fixed charge is $3 per yea The fixed charges *per flush* depend upon the number of times per year th tanks are operated. If set off only once, it will be $3 and adding in the cost c the labor and water, the total cost will be 303 cents. If it is set off 52 time a year, the fixed charges will be 5.77 cents and adding water and labor, th total cost will be 8.77.

In the first column of Table XXIII is set down the number of times per year flushing is performed. Corresponding to these frequencies, are set down the various costs per flush. The second column gives the cost with a semi-automatic tank; when flushing less frequency than 200 times a year the tank is hand operated and at frequencies greater than 200, the tank is operated either automatically or by hand, the cost by both methods being given. The cost with flushing manhole and other methods is also given.

Under practically all conditions either the full automatic or semi-automatic ank is the most economical means of sewer flushing. These figures of course

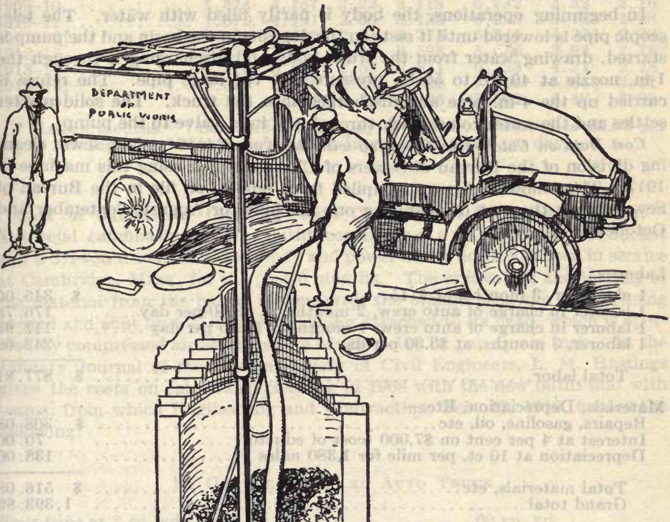

FIG. 6.—Method of cleaning catchbasin with auto-eductor.

are subject to market price of labor in any particular locality. They indicate, however, that where flushing is to be performed more than 15 to 20 times and less frequently than 200 times a year, the semi-automatic tank is the most economical apparatus to use. For flushing at intervals of every 48 or 24 hours or more frequently the full automatic tank is adaptable, and is the most economical.

Cost of Cleaning Sewer Catchbasins with an Auto-Eductor.—A catchbasin cleaning machine working on the hydraulic ejector principle has been employed with excellent success in a number of cities. This machine was invented by George W. Otterson, a mining engineer. It is known as the auto-eductor. It consists essentially of a pump and suction device attached to a Kelly

Springfield motor truck. The suction device is a 4-in. telescopic pipe con nected at its lower end with a 3-in. pipe leading from the discharge of a 4-in American centrifugal pump. A 1-in. nozzle from the 3-in. pipe is led into th 4-in. pipe and turned upward, thus throwing the stream of water at high veloc ity through a contracted throat, creating a vacuum and causing suction. Th pump is driven from a power take-off on the driving shaft of the truck. Th inlet valve on the pump suction is attached to an opening in the bottom of th truck body. This truck body is a water-tight steel box equipped with baffl plates so arranged as to hasten the settling of solid matter in the refuse take from the catchbasin.

In beginning operations, the body is partly filled with water. The tele scopic pipe is lowered until it rests on the deposits in the basin and the pump i started, drawing water from the truck body and discharging it through th 1-in. nozzle at 40 lb. to 50 lb. pressure into the large pipe. The refuse i carried up the 4-in. pipe and discharged into the truck. The solid matte settles and the water comes back through the inlet valve to the pump.

Cost Data on Catchbasin Cleaning with the Auto-Eductor.—The sewer clean ing division of the Bureau of Sewers of Chicago began using this machine i 1917. The following figures compiled from reports on file in the Bureau o Sewers show the cost of operating one machine for August, September an October:

Labor—	
1 chauffeur, 3 months, at $115	$ 345.0
1 laborer in charge of auto crew, 2 months, at $3.60 per day	176.7
1 laborer in charge of auto crew, 1 month, at $4.60 per day	112.9
1 laborer, 3 months, at $3.30 per day	243.0
Total labor	$ 877.8
Materials, Depreciation, Etc.—	
Repairs, gasoline, oil, etc	$ 308.0
Interest at 4 per cent on $7,000 (cost of eductor)	70.0
Depreciation at 10 ct. per mile for 1,380 miles	138.0
Total materials, etc	$ 516.0
Grand total	1,393.8

The average cost per catchbasin cleaned was $1.299; the average cost pe cubic yard material removed was 79 cts. The average cost of cleaning catch basins by hand methods during the past 4 years has been $3.24 each.

During three months the machine cleaned 1,073 sewer catchbasins. Th total mileage of streets traversed was 1,073 and the total yardage of materia removed from catchbasins was 1,763 cu. yd. The machine had a 5-yd.body mounted on a 5-ton truck body.

The city of Louisville, Ky., began cleaning its catchbasins with an auto eductor early last year. During the period from Jan. 17 to Dec. 31, 1917, th machine was in operation 265 days. In this time it cleaned 5,388 basins, a a total cost of $4,573 or 84.8 ct. per basin. The total cost figure is made up o $3,327 for wages of driver and two laborers, gasoline, oil, etc., and $1,246 fo depreciation at the rate of 20 per cent per annum. The average cost o cleaning the basins in 1916 by hand methods was $3.40 per basin.

Cost of Cleaning Catchbasins at Cambridge, Mass.—Cost data on clean ing catchbasins by the Sewer Department of Cambridge, Mass., are given in the 1916 annual report of L. M. Hastings, City Engineer. The figures, covering the period 1905–1916 inclusive, are reprinted in Engineering and Contracting, as follows:

Date	No. of C. B. cleaned	Quantity: Total loads	Quantity: Loads per C. B.	Quantity: Total cu. yd.	Cost: Total	Cost: Per C. B.	Cost: Per cu. yd.
1905	2,169	5,213	2.40	3,909	$6,089	2.80	1.55
1906	2,340	5,609	2.82	4,206	6,050	2.58	1.44
1907	1,948	4,704	2.40	3,528	5,070	2.60	1.44
1908–9*	2,742	5,906	2.15	4,429	8,090	2.95	1.82
1909–10	1,874	4,157	2.22	3,118	6,732	3.32	2.16
1910–11	1,672	4,181	2.50	3,135	6,225	3.72	1.98
1911–12†	1,466	3,676	2.51	2,775	6,344	4.33	2.30
1912–13	1,438	3,463	2.41	2,598	5,656	3.93	2.18
1913–14	1,479	3,802	2.58	2,851	6,223	4.21	2.18
1914–15‡	1,335	3,862	2.89	2,896	7,559	5.66	2.61
1915–16	1,128	3,247	2.88	2,436	7,309	6.48	3.00

* Sixteen months. † September 1911, pay of cleaners increased to $2.25 per day. ‡ October 14, 1914, pay of cleaners increased to $2.50 per day.

Cost of Catchbasin Cleaning With Orange Peel Bucket and Truck.—A special catchbasin cleaning outfit, consisting of a small orange peel bucket and a 3½-ton truck, with steel body and power dump hoist, has been in service at Cambridge, Mass., for the past 6 months. The excavating and loading of the material from the basins is done with the orange peel, the bucket being opened and shut by a piston and cylinder attached to its head, which is operated by compressed air at a pressure of about 100 lb. per square inch. In the January Journal of the Boston Society of Civil Engineers, L. M. Hastings gives the costs on catchbasin cleaning in 1908 with the new outfit and with teams; from which Engineering and Contracting, Feb. 12, 1919, quotes the following:

By Orange Peel and Auto Truck

Four trips at 3 cu. yd. × 5	60 cu. yd.	
Saturday, 2 × 3 × 1	6 cu. yd.	
	66 cu. yd. weekly, or 11 cu. yd. daily average.	
Chauffeur, at $4	$ 4.00	
2 laborers, at $3.25	6.50	
Gasoline, 7 gal., at 25 ct	1.75	
Oil	.20	
Grease	.15	
		$12.60 per day
Tires	$ 250.00	
Repairs	300.00	
Depreciation, $6,000 at 20 per cent	1,200.00	
Interest on investment, $6,000 at 4 per cent	240.00	
Yearly overhead costs	$1,990.00	
Yearly overhead costs / Assuming 250 working days	$1,990.00 / 250 =	7.96
Cost per day		$20.56

20.56 ÷ 11 = $1.87 per cu. yd.

BY HORSE CARTS

5 to 6 loads daily average 5½ loads, 1 1/6 cu. yd. per load.

1.16 × 5.5 loads × 5 days	32.0 cu. yd.	
1.16 × 5.5 loads × ½ day Saturday	3.2 cu. yd.	
	35.2 cu. yd. weekly or 5.86 cu. yd. daily average.	
Labor, 4 men, at $3.25	$ 13.00	
2 horses, at $1.50	3.00	
		$16.00 per day
Interest, $575 × 2, at 4 per cent	$ 46.00	
Depreciation, $575 × 2, at 15 per cent	172.50	
Yearly overhead	$ 218.50	
Working days	$ 250 =	.87
Cost per day		$16.87

$16.87 ÷ 5.86 = $2.88 per cu. yd.

CHAPTER XIII

GARBAGE DISPOSAL

Cost of Collecting, Hauling and Transporting Municipal Refuse.—A very important element in the collection, haul, transfer and transportation of refuse materials is the cost. Many local factors enter into the cost element, and unless these are considered and understood, the cost data are misleading. Standard forms for recording cost data of refuse collection are not used extensively, so that the data presented should not be taken without qualification. Samuel A. Greeley in a paper before the 1914 annual convention of the American Society of Municipal Improvements, gave methods of analyzing the cost of the various parts of the service, and the following matter is taken from a reprint of this paper published in Engineering and Contracting, Oct. 21, 1914.

***Elements of Cost.*—The elements of the cost of each part of the collection service can be segregated and studied advantageously by the following method. The unit quantities used in the computations were assumed for certain local conditions and will not necessarily apply everywhere. They are presented here to illustrate the method of analysis.**

***Loading.*—The cost of loading will vary with the character of the material, the district served, the season of the year, the unit cost for labor in each locality and other local conditions. The method of analysis for loading garbage follows:**

a. Number of people per house or per collection made	10
b. Number of minutes required to make one collection or to give service to ten people	1
c. Interval of days between collections	2
d. Capacity of garbage wagons in tons	2
e. Quantity of garbage produced in tons per 1,000 population per day	0.273
f. Quantity of garbage after two days' interval between collections, tons per 1,000 population per day	0.546
g. To make collections from 1,000 people requires 100 collections, taking 100 minutes' time.	
h. Time in minutes required to load a wagon with two tons of garbage in accordance with the date above equals $\frac{2}{0.546} \times 100$	367
i. The time required for loading is thus 6.1 hours. If the cost of the team, wagon and collector be taken at 75 cts. per hour, the cost for loading one 2-ton wagon will be $4.57 and the cost per ton for loading garbage ($2.28)	2.28

The analysis can be applied to the loading of ashes, rubbish, mixed refuse or any refuse material, if the proper unit quantities and basic data be first determined. The cost per ton for loading other refuse materials in accordance with assumed data will be as follows:

Materials	Cost of loading per ton
Ashes	$0.415
Rubbish	2.62
Mixed refuse	0.56

Motor Trucks.—The cost of loading a motor truck can be studied in similar way. The cost of operation will be greater per hour and the rate of loading will have to be increased proportionately to make the cost comparable with loading a team drawn wagon. The cost of haul by motor truck will be less.

The use of motor trucks in refuse collection service will increase. A relatively high loading cost can be reduced by limiting the motor truck to transportation after the loading of the wagons by the so-called traction and trailer system now being tried on a large scale in New York City and used in quite a number of European cities.

Hauling.—The refuse material loaded in the collection wagon must be hauled to the transfer station or place for final disposal. This will be done by horse-drawn vehicle or by motor. The length of haul will be from the point of last collection to the place of final delivery. This distance or haul must be covered twice for each complete load.

The cost of haul will depend on the rate of travel, the weight of the load and the cost of the team and the driver, or motor and mechanic. The cost of team haul may be analyzed as follows:

Assumed:	Per hour
Rates of travel, miles	3.0
Cost of outfit	$0.75
Cost per mile of travel	0.25
Cost per mile of haul	0.50
Cost per ton-mile haul with a 2-ton load	0.25

The cost of haul by gasoline or motor truck may be analyzed as follows:

Assumed:	Per hour
Rate of travel, miles	6.0
Cost of outfit	$2.40
Cost per mile of travel	0.40
Cost per mile of haul	0.80
Cost per ton-mile haul with a 5-ton load	0.16

The rate of travel will vary considerably from different sections of a large city, being slower through streets congested with a large volume of traffic. In such districts, collection work should be done at night or during the early morning hours.

Transfer Stations.—The operation of transfer stations should also be considered as a part of the cost of transportation. A transfer station to handle 600 cu. yds. a day, or 375 tons, may cost, depending upon type of building and local conditions, about $50,000, including land in a fairly well-built up section.

The annual cost of operation may be estimated as follows:

Interest at 5 per cent	$ 2,500
Depreciation of plant	1,250
Labor:	
1 foreman	1,200
4 laborers	3,600
Repairs and supplies	2,500
Total	$10,800

This is equivalent to a cost of 9.4 cts. per ton.

Cost of Transportation.—The cost of transportation of refuse from the transfer station to the place of final disposal depends upon the method used. The cost for several methods is discussed below.

Trolley Transportation.—Assume a typical transfer station receiving 600 cu. yds. of refuse material per day. Assume trains to be made up of one motor car which carries no load and two trailers. Assume each trailer to have a capacity of 25 cu. yds. To move 600 cu. yds. 24 trailer loads are required. If the place of disposal be so located that each train can make two trips a day, six trains will be required. Assume that three motors can handle the six trains. The daily cost of operation will then be:

	Per day
Motor cost, three at $25	$ 75.00
Trailers, twelve at $6	72.00
Total	$147.00

If the 600 cu. yds. of refuse weigh 375 tons, the cost of trolley transportation will be 40 cts. per ton.

Barge Transportation.—A good, serviceable tug will cost about $30,000 and deck scows about $7,000 apiece. The annual cost of operating a fleet may be as follows:

Annual cost of tug:		
Interest at 5 per cent		$ 1,500
Depreciation on 15-year life		1,389
Labor:		
Captain	$2,100	
Engineer	1,800	
Fireman	1,000	
Deck hands	1,800	6,700
Repairs		2,500
Fuel		3,500
Supplies		1,000
Insurance		200
Total		$16,789
Annual cost of barge:		
Interest at 5 per cent	$ 350	
Depreciation	324	
Deck hands	1,800	
	$2,474	
Assume that 1 tug serves 4 barges		9,896
Total annual cost of fleet		$26,685

If each barge makes one trip per day, carrying 100 tons of refuse, the cost per ton amounts to 22 cts.

In like manner the elements of cost can be determined for other methods of transportation.

Steam Railroad Transportation.—The cost of transportation by steam railroads depends principally upon the switching charges. These will range from $5 to $15 per car. A car will hold about 40 tons of garbage, so that the switching charge will average about 20 cts. per ton.

Available Collection Costs.—Actual cost data should be studied to check the costs estimated above, but these are not available for a large number of cities. The costs for collection service are generally recorded to include both loading and hauling in one figure, while costs of transportation are frequently given separately. The cost data for some cities in which the itemized cost of collection is available have been summarized in Table I.

Chicago Data.—Jacobs and Senfield have made a careful analysis of the cost of collecting garbage, and ashes, and rubbish in Chicago. These data are compiled in excellent detail and accuracy. The average cost for the five years—1908 to 1912—are given in Table II.

TABLE I.—COSTS OF COLLECTION (LOADING AND TEAM HAUL) OF MUNICIPAL REFUSE

City	Year	Population served	Total annual cost	Total annual tonnage	Total annual yardage	Unit cost— Per ton	Unit cost— Per yard	Cost per capita
Garbage:								
Boston	1913	480,000	$131,648.40	54,215	....	$2.43	.....	$0.27
Chicago	1912	2,300,000	381,174.00	119,159	....	3.20	.....	0.17
Cleveland	1912	596,400	127,800.24	43,555	....	2.93	.....	0.21
Columbus	1912	192,700	34,779.23	18,789	....	1.85	.....	0.18
Dayton	1908	110,300	21,000.00	9,941	13,479	2.11	$1.56	0.19
Detroit	1910	465,766	66,865.67	34,065	....	1.96	.....	0.15
Evanston	1910	24,978	3,186.00	2,800	4,670	1.14	0.68	0.13
New York	1910	4,406,000	275,380.00	336,984	....	0.82	.....	0.06
Winnipeg	1911	151,918	19,371.90	15,510	....	1.25	.....	0.13
Ashes:								
Boston	1913	480,000	346,396.01	247,203	....	1.40	.....	0.73
Evanston	1910	24,978	2,174.00	....	13,461	.....	0.16	0.09
Winnipeg	1911	151,958	5,793.73	5,227	....	1.11	.....	0.04
Rubbish:								
Columbus	1912	192,700	47,887.12	....	75,096	.....	0.64	0.25
Evanston	1910	24,978	5,108.00	....	29,479	.....	0.17	0.21
Ashes and rubbish:								
Cleveland	1909	543,000	119,982.00	84,547	202,752	1.42	0.59	0.22
Cincinnati	1909	360,000	116,631.68	87,611	222,634	1.33	0.52	0.32

References: These data are all from annual reports.

TABLE II.—AVERAGE COST OF REFUSE COLLECTION, LOADING AND HAULING, AT CHICAGO, ILL.

Year.	Cost per ton of garbage	Cost per cu. yd., ashes and rubbish
1908	$3.78	$0.56
1909	3.76	0.57
1910	3.43	0.59
1911	3.19	0.62
1912	3.20	0.60

If ashes and rubbish together weigh 1,000 lbs. per cubic yard, the cost of collection per ton amounts to $1.20.

IMPROVED METHODS FOR RECORDING COST DATA

The value of unit cost data for loading, hauling, transferring and transporting refuse materials should be realized by city officials. Accurate records should be kept and published in similar forms in different cities, so that comparisons can be made and a check secured on the efficiency of the local work

Cost of Motor Truck Operation for Refuse Collection.—In connection with a study of refuse collection at Rochester, N. Y., the Rochester Bureau of Municipal Research, Inc., of which James W. Routh is Director, collected a considerable amount of data on the use of motor trucks in municipal service. These data are given in a report issued recently by the Bureau, from which the matter following is abstracted in Engineering and Contracting, July 2, 1919.

In 1914 a 5-ton truck equipped with a specially designed 10-yd. collection body was given a trial in house to house collection of garbage and ashes on a 3-mile haul in the Borough of the Bronx, New York City. It was given a further trial in hauling garbage from relay stations in the outlying sections of the Borough. On the 3-mile haul in making house-to-house collections the truck did not prove as economical as the 1-horse carts generally used. But in hauling from relay stations on the longer haul the truck showed a considerable saving over horse-drawn carts. The haul for this work was approximately 7 miles. The truck made four round trips for a total of 54.2 miles and hauled 27.6 tons of garbage as against about 1½ trips made in the same length of time by a 1-horse cart hauling approximately 1½ tons (9/10 tons per load). On the shorter haul the cart made three round trips per day for a total distance of 18 miles, including house-to-house collections and hauled 5.4 tons; the truck made five round trips for a total distance of 32.7 miles and hauled 23.85 tons.

The poorer showing of the truck on house-to-house collection was attributed to the time spent in loading. Although four helpers were provided the time so spent represented more than one-half the total time. The time spent in traveling to and from the dump was only one-fifth the total time. On relay work, however, the loading time was only 35 per cent of the total time.

The 1-horse cart outfit cost $4.32 per day. The total daily cost of operating the truck was $13.70, distributed as follows:

Item	Total cost	Per cent of total
Gasoline	$ 2.41	17.6
Oil	0.75	5.4
Truck depreciation (cost $5,000, life 5 years)	2.78	20.3
Interest on investment at 6 per cent	0.83	6.1
Repairs, labor, materials, tires, grease and miscellaneous	4.07	29.7
Garaging	0.30	2.2
Driver's pay	2.56	18.7
Total	$13.70	100.0

The New York Department of Street Cleaning has used large tractor-trailer motor propelled collection units to some extent. These are giant outfits hauling 25 cu. yd. of refuse per load. Collections of ashes, rubbish and garbage are made simultaneously, but in separate compartments. The average haul is about 1½ miles. Special equipment is provided for unloading the refuse onto scows. The principal factor tending to produce economy from the collection standpoint is the fact that all refuse is dumped at a common point of disposal. For this reason all refuse may be collected at one time by providing separate refuse compartments on the collection vehicles.

In Philadelphia a part of the collection equipment has been motorized. Five-ton trucks equipped with 12-yd. bodies have proven economical in the collection of ashes and rubbish from sections where the haul to the dump averages 6 miles.

In a report by the Efficiency Division of the Chicago Civil Service Commission made public in July, 1915, it is stated that after a thorough study of the question of motorizing Chicago's collection equipment the continued use of horses in garbage collection was found to be justified. The report states that the data assembled for gas and electric trucks warrant their adoption only for hauling after horse-drawn carts have made the house-to-house collection. These figures are based on a $5.50 daily wage per team. If the cost of teaming were increased to $6 per day, it is stated that there would be a slight saving by using motor equipment, but this would not be sufficient to warrant the change at least for some time to come. The report states that the haul in Chicago varies from 1½ to 5 miles. As between the gasoline and electric trucks, the latter were found to be the more economical. The haul below which a 3-ton electric truck would not be economical when measured against a $5.50 team was found to be 1.8 miles. Against a $6 team it was 0.8 mile. Three-ton gasoline trucks were found to be not as economical as either a $5.50 or $6 team.

The fixed and mileage charges for gasoline and electric trucks were as follows:

Item	Total cost Gasoline	Total cost Electric
First cost of 3-ton truck or tractor	$4,000.00	$ 4,000
Fixed charges:		
Fixed charges on investment per year at 4 per cent	160.00	160.00
Garage	300.00	300.00
Insurance (fire and liability)	190.00	183.00
State license	4.00	4.00
Driver	960.00	960.00
Obsolescence, 5 per cent	200.00	200.00
Contingencies (interest on operating stores, general superintendence, etc.), 2 per cent	80.00	80.00
Total fixed charges per year	$1,894.00	$1,887.00
Total fixed charges per day (1/300 year)	6.31	6.29
Variable expenses per mile:		
Depreciation	$ 0.0573	$ 0.0340
Tires	.0600	.0600
Maintenance and repairs	.0300	.0300
Lubrication (oil and grease)	.0050	.0050
Energy (gasoline 13½ ct. per gal., electricity ½ ct. per kw. hour)	.0344	.0050
Total variable expense per mile	$ 0.1767	$ 0.1340

The cost for hauling with horses was given as follows:

Item	Teams costing $5.50 per day	$6.00 per day
Fixed charges for equipment	$0.021	$0.021
Horses and driver	5.500	6.000
Wagon depreciation, life 22,000 miles	0.084	0.084
Maintenance and repairs at 5 per cent	0.021	0.021
Total daily expense	$5.626	$6.126

In Los Angeles motor trucks are used in the collection of all non-combustible refuse. Two 2½-ton trucks are used to haul garbage from the outlying districts where the haul averages 8 miles or more. One driver and two helpers compose the crew and two loads are collected daily. For the remainder of the city on the shorter hauls teams are still used. The cost of garbage collection with motor trucks on the long hauls is given as $2.76 per ton. On the shorter hauls the cost is $2 per ton using teams.

A certain firm in Rochester employing both horses and motor trucks in lumber and building material deliveries states that the economical low limit of haul for motor trucks is found to be 2¼ miles.

The average cost of truck operation by this firm for the last three years has been $11.20 to $12.30 per day. (This includes the cost of two 3-ton and 2-ton trucks.) Items included are fuel, lubricants, tires, repairs, license fee, liability insurance, garaging, drivers' wages and depreciation. Drivers were paid $17 to $19 per week. Twenty per cent was allowed for depreciation.

C. V. Montgomery, who has charge of a large fleet of motor trucks on paving work in Philadelphia, in a statement appearing in the Engineering News of Jan. 11, 1917, places the cost of operating a 5-ton truck 50 miles per day at $17.91. Fixed charges amount to $5.39 per day or 30 per cent of the total. This cost evidently applies to 1916 conditions. The distribution is as follows:

Fixed charges	Per day	Per cent of total cost per day
Depreciation* ($4,100 first cost—$400 scrap value/1,200 days)	$0.46	2.6
Insurance (liability, fire, collision)	.58	3.2
License fee	.10	0.6
Truck foreman (supervising 3 trucks)	1.25	7.0
Driver	3.00	16.7
Total fixed charges	$5.39	30.1

Variable charges	Per mile	Per day at 50-truck-miles	Per cent total cost per day
Depreciation* ($4,100 first cost—$400 scrap value/15,000 miles)	$0.0629	$ 3.14	17.6
Gasoline at 25 ct. (3 miles per gal.)	.0833	4.17	23.3
Lubricating oil (64 miles per gal.)	.0055	0.27	1.5
Tires	.0386	1.94	10.8
Repairs	.0600	3.00	16.7
Total variable charges	$0.2503	$12.52	69.9
Fixed charges (at 50 miles per day)	0.1078	5.39	....
Total cost per mile	$0.3581	......	.....
Total cost per day	....	$17.91	100.0

* About 15 per cent of first cost depreciates with passage of time, while about 85 per cent is proportional directly to mileage run.

The cost of operating a 5-ton truck used in the delivery of sand and gravel on the Pacific Coast during a 5-months' period in 1917 was approximately $13.40 per day. This includes all charges. Capacity loads were hauled an average distance of 6.1 miles over roads of various kinds, equally divided between gravel and dirt, with many hills, some of them steep. The average distance traveled daily was about 60 miles. The costs were distributed as follows:

Item	Total cost	Per cent of total
Fuel	$ 303.25	18.1
Oil and grease	69.79	4.2
Tires	154.93	9.3
Repairs and parts	21.06	1.3
Wages	508.75	30.4
Interest at 6 per cent	218.78	13.1
Depreciation at 20 per cent	394.66	23.6
Total	$1,671.22	100.0

The cost of hauling paving materials in Detroit with a 5-ton truck during 1917 was $14.85 per day, including all costs. The truck hauled an aggregate of 35 tons in seven trips, the average haul being 4½ miles.

The cost of operating a 3½-ton truck under average service conditions on the roads of Southern California over a considerable period of time was found to be $9 per day. This includes all cost of upkeep, supplies, depreciation, wages of drivers, etc. The first cost of the truck was placed at $3,500 and its life at 10 years, assuming that the truck traveled 25 miles per day. Gasoline was purchased at 16 cts per gallon and the driver's salary was $960 per year. Roads were good and operating conditions generally very favorable. Itemized costs (for the estimated life of 10 years) follows:

Item	Total cost	Cost per day	Per cent of total
Insurance	$ 1,350	$0.45	5.0
License and taxes	380	.13	1.4
Interest at 6 per cent	2,100	.70	7.8
Depreciation	3,500	1.17	12.9
Administration	415	.14	1.5
Storage	960	.32	3.5
Gasoline at 16 ct. per gallon	2,400	.80	8.9
Oil, grease, waste	750	.25	2.8
Tires (less first cost)	2,345	.78	8.7
Driver's salary	9,600	3.20	35.5
Maintenance	3,250	1.08	12.0
Total for life of truck	$27,050	$9.02	100.0

The first cost of a truck with a collection body would be somewhat higher than is here given. As a matter of fact, the city of Rochester awarded a contract to the Selden Motor Vehicle Co. in December, 1917, for two 3½-ton trucks each equipped with a special 6-yd. collection body at $5,031 each. Other costs also have increased proportionately since the above estimate was made. It is believed, however, that a competent driver could be employed at less than $960. It should be possible to employ a truck driver at $900 annually if he were given permanent employment. Also interest rates on the investment should not amount to more than 5 per cent. The life of a truck used in house-to-house collection work would probably not be as long as in other work due to frequent starting, stopping and generally hard usage. A life of 5 years with a daily average mileage of 25 miles would seem to be a fair estimate for the useful service derived from the truck. At the end of that time the estimated scrap value would be $500. With these data the following estimate is made of the daily cost of operating a truck in ash collection.

ESTIMATED DAILY COST OF OPERATION OF A 3½-TON MOTOR TRUCK IN REFUSE COLLECTION

	Total daily cost	Per cent of total
Fixed charges:		
Depreciation: First cost, $5,031.35, life 5 years, scrap value $500	$0.45	3.5
Insurance (liability $120, fire $45 per year)	.55	4.3
Storage	.30	2.4
Driver ($900 per year)	3.00	23.6
Interest (5 per cent annually)	.84	6.6
Overhead supervision (same organization as for city stables	.40	3.2
Total fixed charges	$5.54	43.6

Variable charges:	Per mile	Per day at 25 miles	Per cent of total
Depreciation: First cost $5,031.35, life 5 years, scrap value $500	$0.1027	$ 2.57	20.2
Gasoline at 22 ct. gal. (3 miles per gallon)	.0733	1.83	14.4
Lubricants (oil, grease, waste)	.0100	.25	2.0
Tires	.0500	1.25	9.9
Repairs and sundries	.0500	1.25	9.9
Total variable charges	$0.2860	$ 7.15	56.4
Total fixed charges at 25 mile per day	.2216	5.54	43.6
Total daily cost of operation	$0.5076	$12.69	100.0

It is assumed that a certain small amount of depreciation is due directly to the passage of time. In the estimate, therefore, 15 per cent of the total depreciation is included as a fixed charge and distributed over 1,500 days, the estimated useful life of the truck. The remaining 85 per cent depreciation is assumed as being directly proportional to the mileage run. Operated 25 miles per day with a life of 1,500 days' service, the total distance that the truck would travel would be 37,500 miles. The estimated depreciation for the life of the truck on this basis is 23.7 per cent of the total daily cost of operation. This is rather a big allowance for depreciation, but when the nature of the work is considered it is not high in comparison to depreciation of trucks used in straight commercial hauling work. A truck used in house to-house collection work must be started and stopped many times in the course of each loadting. The motor must be kept in constant motion because each stop is of short duration. On account of the many starts and stops also the truck must of necessity cover a considerable distance each day at a speed much slower than its economical speed of operation. Combined with all of these factors the truck must be operated continuously in the presence of grit and cinders from ashes and dust from street dirt. For these reasons not only is depreciation sure to be high, but the unit cost of fuel, lubrication, tires and repairs is also bound to be more than similar costs under normal commercial operating conditions.

Cost of Collection and Removal of City Wastes in Chicago.—The following data, from a report by the Efficiency Division of the Chicago Civil Service Commission for the removal of garbage, ashes, refuse and other wastes for the year 1914, were published in Engineering and Contracting, Dec. 3, 1913.

During 1912 about 1,400,000 cu. yds. of rubbish were collected and hauled to dumps at an average cost of 60 cts. per cu. yd. During the same year about 119,000 tons of garbage were collected and removed at an average cost of $3.20 per ton.

Dead Animals.—Dead animals are removed and disposed of in Chicago by contract. A contract of this character was awarded in August, 1912, and was for a period of five years, for which the city is paid an annual rate of $25. The contract provides that the contractor shall remove within twelve hours all dead animals from streets, alleys and the river, and dispose of them at least three miles outside the city limits.

An estimate of the number and weight of dead animals removed and disposed of each year in the city is given herewith, as follows:

Total number of dead horses, average weight 1,300 lbs.	9,253
Total number of dead dogs, average weight 25 lbs.	20,782
Total number of dead cats, average weight 5 lbs.	3,603
Total number of other animals, including cows, goats, sheep, rabbits, etc., average weight 100 lbs.	448
Grand total number of dead animals removed	34,086

Total estimated weight of all dead animals removed, 12,611,265 lbs., or 6,305 tons

Quantity of Garbage and Rubbish.—The house collection is made by wagons equipped with covered steel tanks having a capacity of about 2½ tons of

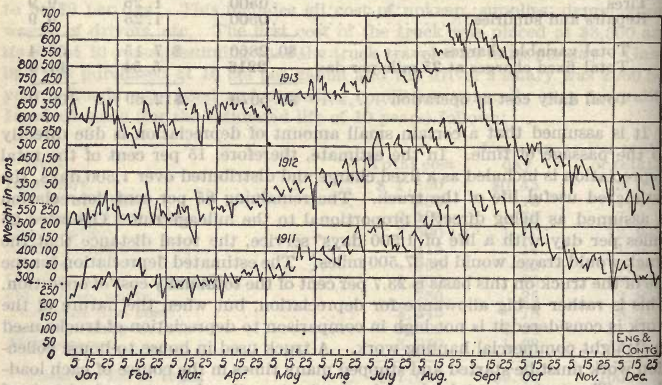

Fig. 1.—Curves showing daily variation in tonnage of garbage in Chicago for the years 1911, 1912 and 1913.

garbage. The wagons and tanks are owned by the city, while the teams are hired from contractors on a per diem basis. Each ward is divided into garbage districts and collections are made from each district according to the density and character of population and district. The wagons are taken to the loading stations from which the tanks are transported to the place of final disposition.

The curves shown in Figs. 1 and 2 indicate the variation in the amounts of garbage and rubbish collected and the problems which must be met in order efficiently to handle this work. These curves indicate that the minimum quantity of garbage is reached during the winter months, and the maximum quantity during the summer months, especially during the month of September. This necessitates that the organization maintained be flexible and easily adapted to the ever-changing conditions. Analysis of the garbage collections made in this city for the past five years indicates that the quantity to be collected from the several districts for different years is not a constant figure, depending upon the local conditions such as change of character of population, growth of residence, business or manufacturing property.

Field study of the average time required by drivers to collect a load of garbage indicates that it takes about 3 hours and 55 minutes to collect a full load of garbage in summer and 4 hours and 45 minutes to collect a full load of garbage in the winter months. These units have been taken as standards

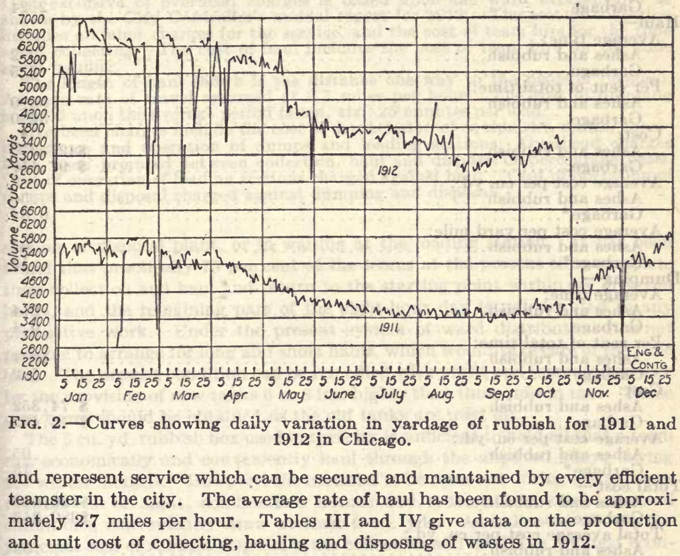

Fig. 2.—Curves showing daily variation in yardage of rubbish for 1911 and 1912 in Chicago.

and represent service which can be secured and maintained by every efficient teamster in the city. The average rate of haul has been found to be approximately 2.7 miles per hour. Tables III and IV give data on the production and unit cost of collecting, hauling and disposing of wastes in 1912.

Table III.—Data on Production of Municipal Refuse in Chicago During 1912

Production	Ashes and rubbish	Garbage
Minimum month	68,023*	6,256†
Maximum month	166,007*	14,960†
Total for year	1,399,716*	119,176†
Total team days	131,475	54,152.5
Total number of loads	271,760	56,048
Average loads per team-day	2.06	1.04
Total average time per load	3.91	7.75
Average haul in miles	2.9	3.4

*Cu. yds.
†Tons.

The larger number of collectors collect one load per day and the remaining time over the 3 hours and 55 minutes is spent in going to and from the loading

TABLE IV.—DATA ON THE COST OF COLLECTING, HAULING, DUMPING AND DISPOSAL OF ASHES, RUBBISH AND GARBAGE IN CHICAGO IN 1912

(Cost Exclusive of Overhead Charges)

Collection—	
Average time:	
Ashes and rubbish	1.3
Garbage	4.8
Per cent of total time:	
Ashes and rubbish	33.7
Garbage	62.9

Total cost—	
Ashes and rubbish	$962,898
Garbage	$510,278
Total average cost per cu. yd.:	
Ashes and rubbish	.69
Garbage*	4.29

Note.—*The unit cost for garbage collection, hauling and disposal is the ton. Cost exclusive of overhead charges is based upon the ward expenditures as shown by the City Controller's annual report for 1912. The cost of collection includes all labor charges for the service, and the cost of team hire for the time spent collecting. The cost of haul includes the cost of team hire for the time spent hauling.

The length of haul shown is the distance one way to the place of disposal. Average rate of travel assumed at 2.7 miles per hour. The cost of dumping is based upon the average period taken, viz.: 25 minutes per load.

Overhead charges include the cost of depreciation of equipment, rental, superintendence and operation of dumps and loading stations. Overhead charges have been prorated between collection, haul and disposal on percentage basis. Cost of operation of loading stations charged against haul. Cost of operation of dumps and disposal charged against dumping and disposal.

station or disposal plant, or in waiting at the loading station. It has been found that practically 75 per cent of the teams at the present time complete their collection and haul and return to the starting point within six or seven hours, and the remaining part of the eight-hour day is not devoted to any productive work. Under the present system of ward distribution it is not possible to arrange for long and short hauls, which would take care of the time lost. The present condition can be remedied with profit and increased service by the provision of new tanks 6 or 8 ins. higher than those now in use. These new boxes should be obtained as the old tanks are used up.

The 5 cu. yd. rubbish box used in this city is sufficient to hold all that a team can economically and conveniently haul through the unpaved alleys during the winter months. However, the material to be removed during the summer months is of light, combustible nature and a team can, under normal conditions, conveniently draw at least 9 cu. yds. As indicated above, the principal cost of rubbish disposal is the collection and haul; the greatest economy will, therefore, result when a team can collect the maximum possible quantity in one load. Wagons designed with lower bodies will allow of larger loads. At the same time the height required to raise the pail to empty the rubbish is reduced, with the result that the efficiency of labor will be greatly increased. Provision whereby sideboards can be hinged to the ordinary rubbish box will adapt the box to a 5 cu. yd. load during the winter months and to larger loads during the summer season.

Economic Methods of Waste Disposal for Cities of Different Sized Populations.—In his report made to the mayor and city council of Davenport, Iowa, John W. Alvord gave the following diagram (Fig. 3) showing the relative availability of various methods of disposal of city wastes under average economic conditions for cities of different sized populations.

It must be remembered that the reduction process is applicable to garbage alone. The cremation process is applicable to garbage mixed with some fuel, while incineration is applicable to and requires the collection of all of the

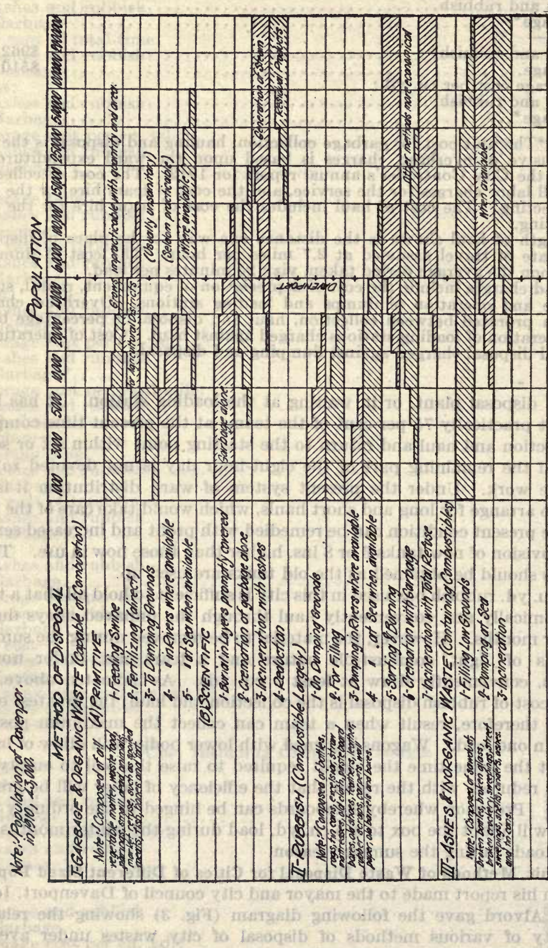

FIG. 3.—Diagram showing economic methods of city waste disposal according to population.

municipal wastes in order to destroy the same by combustion with success. There is, therefore, a fundamental difference between these methods which should not be lost sight of.

Cost of Garbage Disposal by Incineration, Reduction and Feeding to Swine.—Important facts concerning garbage disposal methods and costs in various cities are given in a report prepared by the Springfield Bureau of Municipal Research of Springfield, Mass. The following main features of the report regarding the various methods of disposing of garbage are taken from Engineering and Contracting, Sept. 12, 1917.

INCINERATION

Fuel Used in Incineration.—By incineration is meant the disposal of garbage by burning. The fuel may be only the garbage and other refuse, or it may be coal, wood or other fuel, depending upon the proportion and character of the refuse to be burned. The classes of refuse disposed of in incinerators and the amount of fuel required were as follows in 1915 for the cities named:

	Av. amount burned per day				Amount fuel used per year	
City	Garbage, tons	Ashes, tons	Rubbish, tons	Other mat'l	Amt.	Cost
San Francisco, Cal.—						
Garbage, rubbish, ashes, manure	229	49	188	...[1]	...	......
Cairo, Ill.—						
Garbage	24	...	...	...	360*	$ 720
Fort Wayne, Ind.—						
Garbage, small animals	33.47	...	...	...	1,027*	2,824
Paterson, N. J.—						
Ashes, garbage, rubbish	23	...	...	...	.....[2]	108
Trenton, N. J.—						
Anything combustible	50	...	...	...	250*	750
Wilmington, N. C.—						
Garbage, rubbish, dead animals	3	...	37	...	....[3]	......
Portland, Ore.—						
Garbage, manure, rubbish	123	...	19	...[4]	....[5]	......
Erie, Pa.—						
Garbage, rubbish	24[6]	...	...	...[7]	724*	1,865
Richmond, Va.—						
Garbage, combustible matter 2 (plants):						
	35	...	5	...[8]	290*	1,000
	35	...	5	...[9]	594*	2,050
Spokane, Wash.—						
Garbage, rubbish, manure	9.71	...	4.13	...[10]	144[17]	720
Wheeling, W. Va.—						
Garbage	20	...	...	...	....[11]	1,200
London, Ont.—						
Garbage, ashes	20–50	...[12]	...	...	...[13]	......
Montreal, Que	116	...[14]	...	...	......	......
Moose Jaw, Sask.—						
Garbage, manure	19.2	...	...	...[15]	....[16]	......

*Tons. [1]Manure 31 tons. [2]18 cd. wd. [3]6 tons and 44 cords. [4]Manure 4¼ tons. [5]None. [6]Includes rubbish. [7]Small animals. [8]Small animals. [9]Small animals. [10]Manure and small animals 0.72 tons. [11]25 million cu. ft. gas. [12]Ashes dumped in winter, burned rest of year. [13]None. [14]Includes all refuse. [15]Manure, etc., 22.5 tons. [16]None. [17]Cds.

Thus, 9 out of the 14 cities listed use other fuel in addition to the garbage and other refuse.

Cost of Construction.—The cost of construction varies, according to one report from $600 to $1,000 per ton capacity. The Worcester Commission reports that "the cost per ton daily capacity varies from $230 to $1,000, the average being between $600 and $700." The cost in a number of cities was as follows:

City	Designer or builder	Capacity, tons	Construction cost	Construction cost per ton capacity
Berkeley, Cal	Sterling	50	$61,500	$1,230
Oakland, Cal	Decarie	100	60,000	600
Fort Wayne, Ind	Dixon	40	15,000	375
South Bend, Ind	Dixon	25	6,800	272
Terre Haute, Ind		50–75	15,000	200
Covington, Ky		100	25,000	250
Grand Rapids, Mich	Angle Imp. No. 3	100	14,656	147
Duluth, Minn	Decarie	25	35,000	1,400
Minneapolis, Minn		150	50,000	333
Paterson, N. J	Destructor Co	60	80,000	1,333
Wilmington, N. C	Decarie	40	35,000	875
Portland, Ore	Smith	150	99,900	660
Allentown, Pa	Dixon	25–30	14,700	490
Erie, Pa	Morse-Boulger	100	27,000	270
Richmond, Va., No. 1	Decarie	50	40,000	800
Richmond, Va., No. 2	Morse-Boulger	50	12,000	240
Spokane, Wash	Decarie	120	90,000	750
Wheeling, W. Va	Decarie	50	35,000	700
Milwaukee, Wis		300	210,000	700
London, Ont	Heenan & Froude	50	39,750	795
Montreal, Que	Thackeray	150	41,000	273
Moose Jaw, Sask	Heenan & Froude	50	31,811	636
Average for 22 plants				$ 600

Cost of Operation.—The reports of charges for operation and maintenance were given for the following cities:

City	Total	Salaries	Repairs	Renewals	Supplies, except fuel	Fuel
Ft. Wayne, Ind	$ 7,150	$ 3,680	$ 157	$183	$ 325	$2,824
Paterson, N. J	9,527	7,060	1,849	....	510	108
Portland, Ore	15,383	13,805	1,330	....	248	......

Minneapolis, Minn	43,000*	....	......	....	......	......

* Approximately.

The Ohio State Board of Health reported the following costs including interest, depreciation, maintenance and repair charges, for the cities named for a period of years:

	Per ton
Canton	$1.95 to $2.50
Marion	2.00 to 2.66
Steubenville	1.00 to 1.84
Zanesville	2.58

J. W. Turrentine, of the U. S. Department of Agriculture, reports the average net cost of incineration per ton for a number of cities as $2.11.

Venable gives the operation expenses as about 50 cts. per ton of kitchen garbage destroyed and nothing to $1.00 per ton for maintenance.

From the facts available it appears that the lowest probable cost of disposal of garbage by incineration is $1.59 per ton.

Revenue from Incinerator.—The products of the disposal of garbage in destructors are steam and clinker. The following are the earnings of incinerating plants reported from Milwaukee and Minneapolis:

City	Amount	Use
Milwaukee	$10,000	Operates pumping station.
Minneapolis	27,000	Heats buildings, lights buildings and streets.

As to the utilization of the heat from incinerators for the development of power, the Chicago Waste Commission states that it has not been easy to work out an economical arrangement for the use of steam from incinerating plants because of the infrequency with which the period of need of steam by a plant will coincide with the period of operation of the incinerator. It is difficult to have the incinerator produce steam power during the hours that it is needed by the plant that is to use it, and vice versa. The installation should be so arranged that this source of power may be used to supplement other sources of power. This is done in Montreal, where the refuse destructor is used in connection with a municipal electric light plant. The destructor is operated only at night when additional power is required by the light plant because of the lighting load then in demand.

Minneapolis uses the steam generated to light and heat its hospital and workhouse buildings, and to light 31 miles of streets.

Savannah is reported as saving 96 per cent of the coal fuel formerly used at the pumping station, now providing the power from the destructor and using the clinker in road building.

Sanitary Aspects.—Incineration of garbage is sanitary and where properly conducted, permits of the disposal of garbage without odors. Thus, of the 13 cities disposing of their garbage by incineration, 12 reported no odors and one made no report. This freedom from odor and other insanitary features makes it possible to locate incinerating plants in the central part of a city and decrease the length and cost of haul. Since different kinds of refuse can be disposed of at the same time, they can all be collected at the same time and thus save the added expense of separate collections.

Reduction

Sanitary Aspects.—In theory reduction plants should be operated in a sanitary manner, without creating a nuisance and without carrying offensive odors. In practice they are not so operated.

In the New York State report the following replies were obtained from cities disposing of garbage by reduction to the question as to whether odors came from their plants:

No	New Bedford.
Yes	Schenectady-Pittsburgh.
Slight	Columbus-Dayton.
Occasionally	St. Louis-Bridgeport.
Very little	Utica-Cleveland.
At times	Syracuse.
Much	San Francisco.
Some	Springfield.
40 miles away	Washington.
No reply	New York, Rochester, Cincinnati, Detroit, Baltimore, Boston, Newark, Indianapolis.

Thus, of the 21 cities, 8 did not report as to odors, 10 reported the presence of odors to a greater or less degree, 1 did not state whether there were odors or not but did state that the disposal plant was 40 miles away from the city, and 1 city reported no odors though officials from the city of Springfield visited the plant of this city and noted the odors coming from it. Four of the cities named above operate their own plants and all of them report odors. Thus, the fact of private or public ownership and operation does not appear to affect the nuisance.

That it is the expectation that reduction plants will cause offense and complaints is evident from the location of the plants with respect to the city, as follows:

Name of city	Distance of plant from center of city
Berkeley, Cal	3 miles
Washington, D. C	40 miles
Cleveland, Ohio	8 miles
Columbus, Ohio	4½ miles
Dayton, Ohio	About 6 miles

Cost of Construction.—The cost of construction of reduction plants in cities for which the information is available was as follows:

City	Capacity, tons in 24 hours	Cost of construction and extensions	Cost per ton
Los Angeles, Cal	300	$100,000	$ 333
Chicago, Ill	800	725,000	906
St. Louis, Mo	400	300,000	750
Cleveland, Ohio	20–25	110,000	4,400
Schenectady, N. Y	200	272,000	1,360
Columbus, Ohio	160	236,000	1,475
Dayton, Ohio	50	55,000	1,100

According to the New York State report the cost of construction varied from $1,500 to $3,000 per daily ton capacity.

The average cost of construction per daily ton capacity is $287 for these cities, excepting Schenectady, where the cost was reported to be $4,400.

Cost of Operation.—One authority, Parsons, places the cost of reduction at $1.80 to $2.00 per ton of garbage; Turrentine at $2. 41; the New York State report at $1.50 to $2.50. In Columbus, Ohio, the cost per ton of garbage was as follows for the years indicated:

Year	Cost	Year	Cost
1911	$1.852	1914	$1.589
1912	2.050	1915	1.940
1913	1.910	1916	2.215

In Dayton, the cost per ton was $1.89 in 1916. Under normal conditions it would appear that the minimum cost of reduction per ton of garbage should be placed at $2.00

Revenue from Reduction.—Adequate data concerning receipts and expenditures of reduction plants are available for three cities only:

City	Expenditures	Receipts	Profit
Columbus	$ 48,423	$ 88,564	$40,140
Cleveland	153,084	224,725	71,641
Dayton	30,938	41,200	10,262

The city of Cleveland reports a profit of $1.49½ per ton of garbage. The profit for Columbus in 1916 was $1.836 per ton, while that from Dayton's new plant is $0.63. The annual profit per ton of garbage in Columbus for each of the last six years was:

Year	Profit per ton	Total profit
1911	$1.50	$26,239
1912	1.24	23,224
1913	.83	17,239
1914	1.225	26,501
1915	.477	10,910
1916	1.836	40,140

Those in charge of the Columbus plant have estimated their annual interest and depreciation charge at 6.92 per cent or $21,271. To get a true idea of the relation between revenue and cost of reduction, these items should be taken into account.

Year	Profit	Interest and depreciation charges	Net profit	Loss
1911	$ 26,239	$ 21,271	$ 4,967	....
1912	23,224	21,271	1,963	....
1913	17,239	21,271	....	$ 4,032
1914	26,501	21,271	5,229	....
1915	10,910	21,271	....	10,361
1916	40,140	21,271	18,069	....
Total	$144,236	$127,631	$16,625	....

It is assumed that the depreciation charges were the same for each year since data are not available showing when additions may have been made. The charge of $21,271 was as of 1914 and so does not include additions made since then. So that the inclusion of depreciation and interest charges for items not purchased in the early years should very nearly be counterbalanced by the omission of items purchased after 1914. The net profit for the six years is $16,625, an average of $2,771 per year.

The revenue of Cleveland per ton of garbage was given as $4.695, that of Columbus as $4.051 and that of Dayton, $2.522. Without doubt the amounts for Cleveland and Columbus are large because of the prevailing high prices. The revenue from Dayton is small probably because the plant has recently begun operations. It will be long, however, before prices drop to their former amounts.

Reduction in Columbus, Ohio.—Because the Columbus plant has been so successful, the following data have been taken from the annual report of the disposal plant:

ACTUAL COST OF OPERATION

	For the year 1915	For the year 1916	Per ton garbage 1915	Per ton garbage 1916
Supervision	$ 5,201	$ 3,000	$0.227	$0.137

Municipal vs. Private Operation of Reduction Plants.—The majority of reduction plants are owned and operated privately and dispose of garbage under contract with the city. The arrangement in 22 cities was as follows in 1906:

——Private——		Municipal—
New York	Rochester	Schenectady
Syracuse	Utica	Columbus
Cincinnati	Detroit	Cleveland
Washington	St. Louis	Dayton
Baltimore	Bridgeport	Chicago
Pittsburgh	Boston	
New Bedford	Newark	
San Francisco	Los Angeles	
Indianapolis		

Only two cities that dispose of their garbage under contract with a concern employing the reduction method report any revenue in return for the privilege. These cities are Los Angeles and New York. The reduction company in Los Angeles pays the city $0.51 per ton. New York receives $112,500 a year. It is to be noted that Los Angeles also reports that it received $1.00 per ton from farmers for garbage delivered for feeding to hogs.

Feeding to Swine

Cities Using This Method.—According to the New York report, 34 out of 112 cities were employing this method in 1915. According to the Municipal Journal the following cities of from 100,000 to 300,000 population employ the methods named:

Feeding to pigs	Albany, Cambridge, Denver, Grand Rapids Hartford, Providence.
Reduction	Bridgeport, Columbus, Dayton, Indianapolis, Rochester.
Incineration	Portland, Ore.; Reading, Trenton, Paterson.
Dumping at sea	Oakland, Cal.

Turning Garbage Over to Private Pig Farms.—A city may turn its garbage over to farmers—for nothing or for a remuneration—to feed to pigs, or it may operate its own pig farm. The majority of cities feeding their garbage to pigs do so under the former arrangement. A few cities, including Worcester, Taunton, Brockton and New Haven, operate their own hog farms.

Revenue from Turning Garbage Over to Private Farms.—Many cities not only dispose of their garbage at no cost by the use of this method but also make it the source of a large amount of revenue. The following receipts are reported for the cities named:

Grand Rapids, Mich	45 ct. per ton	$ 4,450
Denver, Colo	Gets its collection and disposal for nothing	
Cambridge, Mass	70 ct. per cd. ft	17,382
Colorado Springs, Colo	Gets its collection and disposal for nothing, and	1,440
Salem, Mass		* 2,651
Somerville, Mass	50 ct. per cd. ft	
Lawrence, Mass	$1.25 per load	† 8,865
Lowell, Mass	$1.25 per load	5,405
St. Paul, Minn	80 ct. per ton	
Los Angeles, Cal	$1 per ton	
Springfield, Mass	Average per year, 1907–1911	4,262

* $13,255 in 3 yrs. † Estimated.

Many cities receive no revenue from garbage so disposed of. Thus, the revenue from this method of disposal varies from nothing in many cities to $17,400 in Cambridge. However, Denver, with a population of 265,000, has its 21,600 tons of garbage collected as well as disposed of by a hog growers' association; and Colorado Springs has its garbage collected and disposed of by hog growers and receives in addition $1,440. Assuming that the cost of collection in these cities was $0.30 per capita, which was two-thirds the per capita cost of collection reported in 1915 by 59 cities, the city of Denver saved $64,500 in 1916 and Colorado Springs saved $9,600 plus the $1,440 actually received.

Feeding Garbage on Municipal Hog Farms.—Worcester, Brockton and New Haven are among the cities that operate farms where they feed city garbage to pigs.

New Haven reports that during 1916 the department of streets fed to pigs the garbage collected from 52,100 of the population. $16,000 was received from the sale of pork.

Brockton paid $29,952 for the collection of its garbage and the operation of its pig farm. It received $15,761 from the sale of swine and of garbage. Thus, it both collected and disposed of its garbage at a cost to the city of $7,191.

From Dec. 1, 1916, to May 31, 1917, the city of Worcester has disposed of its garbage at an approximate cost of $7,500 and has received over $21,000. These figures were given by the superintendent in charge of the hog farm. He also estimated that during the year beginning Dec. 1, 1916, the city will spend $15,000 on account of the pig farm and receive $50,000 from the sale of products, thus making a profit of $35,000 on the disposal of garbage.

Initial Investment.—The probable cost of establishing today a piggery similar to that at Worcester was given as follows by Dr. Frederick Bonnett, Jr., of the Worcester Polytechnic Institute:

Stock	$ 49,700
Buildings	60,000
	$109,700

This means that an investment of $5,485 per daily ton would be required to establish the plant capable of disposing of a daily production of 20 tons. This does not include the cost of land which should run from $5,000 to $10,000.

S. A. Greeley, a sanitary engineer, of Chicago, Ill., submitted in 1916 the following estimate of cost of establishing a hog farm to handle an average daily production of 50 tons:

Pigs	$ 25,000
Buildings and other structures	110,000
Engineering and contingencies	25,000
Land	30,000
	$ 190,000

Cost of Operation.—The cost of operation per year was estimated as follows for Worcester:

Labor	$ 5,760
Grain and bedding	2,640
Medicine and disinfectants	5,040
Miscellaneous	1,000
Administration	2,500
Total	$15,000

At this rate to dispose of an average of 20 tons per day or 7,300 tons per year, the cost per ton of garbage would be $2.65. The cost reported by Greeley was at the rate of $1.98 per ton.

Revenue from Feeding.—The revenue from the Worcester Pig Farm is estimated at $50,000 for 1916. This is at the rate of $6.85 per ton of garbage.

Greeley estimated the yearly revenue from a 60-ton per day plant at $80,000. This would make the revenue per year per ton of garbage $3.65.

The revenue at Worcester is estimated on the basis of present prices; that by Greeley on prices last year. A fair estimate should be $3.75 per ton.

Operation of Garbage Piggery at Grand Rapids, Mich.—The following abstract, of a paper read before the 1912 convention of the Michigan Health

Officers by T. M. Koon, M. D., a member of the State Board of Health, was published in Engineering and Contracting, Sept. 18, 1912.

After the garbage is collected and loaded on cars by the city, the contractor ships the garbage to his farm. The farm, which contains about 100 acres, is located about three miles out of the city, and lies adjacent to the Pere Marquette Railway. The soil is sandy and well drained. There are about 40 buildings on the farm, including the farm house, horse barn, office building, boiler room, garbage kitchen, employes' restaurant, feeding houses, and farrowing houses.

The boiler room is 34 × 36 ft. in plan. The garbage kitchen adjoins the boiler room and is 64 × 40 ft. in plan. There are three cooking pans in this kitchen 24 ft. long, 6 ft. wide and 3 ft. deep, and three cooking pans 30 ft. long, 6 ft. wide, and 4 ft. deep. This kitchen is devoted to cooking garbage and meal for feeding the hogs. The garbage from the entire city is not sufficient to feed the 7,000 to 9,000 hogs kept here, so $1,000 worth of corn is fed each week. The next building is the restaurant where the 20 employes are fed. There are three farrowing houses, each 336 ft. long by 30 ft. wide. These buildings have cement floors and troughs, water throughout and are steam heated. These houses shelter 1,200 brood sows, each having a separate stall; 40 sows bring forth a litter of pigs each week, over 10,000 being born each year. There is another building 234 ft. long by 56 ft. wide. There are over 100 breeding pens with a yard for each. There are two buildings 100 ft. long by 20 ft. wide. They have cement floors and troughs. These building are called the restaurants. Here the hogs are fed cooked corn meal while being fattened for market. A small railroad runs throughout the grounds and buildings to carry the garbage and corn meal to the swine. The granary, numerous yards and ranges and the reservoirs for storing water to supply the buildings, complete the piggery. Everything is well kept and orderly. Here all the garbage from the city of Grand Rapids is disposed of. From this place 200 hogs are shipped to market each week. Over 10,000 fattened hogs are turned out each year. The value of this output is about $135,000 a year.

It has been only a few years that so many hogs could be kept safely on account of the liability of the herd becoming infected with cholera and destroyed. Therefore this method of garbage disposal was very hazardous as a money making undertaking. Now that it is possible to immunize against hog cholera, this danger is obviated. All of the pigs at this place are immunized while nursing, so there is no danger of the herd being destroyed with hog cholera.

More recent information in regard to the disposal of the garbage of Grand Rapids was given in the Conference of the Federal Food Administration held in Chicago, Dec. 7, 1917. The following is given in a report of the conference published in Engineering News-Record, Dec. 27, 1917.

The garbage of Grand Rapids is collected and loaded on cars by the city. Alvah H. Brown ships it every day 27 miles to his 80-acre farm in an isolated section, located on sandy soil. He pays 45cts. per ton for freight and 25cts. to the city. He feeds inside a long building, on concrete platforms, onto which garbage is dumped directly from the cars. Glass from electric-light bulbs are the worst "foreign" matter in garbage. Sheep and cattle have also been fed garbage in winter, but not in summer. Corn silage is fed on Sundays and a cheap "fire sale" grain is usually part of the bill of fare.

Mr. Brown believes that hogs could be fed without nuisance in a building within the city limits if proper attention were given to ventilation. One ton will feed 100 pigs. He employs 12 men to care for 6,000 hogs. Hotel garbage is worth ten times as much as household garbage, in his estimation. Cooking is not desirable, as it reduces the garbage to a slop in which the pig gets no chance to discard grapefruit and things which do not agree with his digestion. All feeders agreed that cooking is a mistake for household garbage. For hotel wastes, rich in recoverable fats, it is practical. Mr. Brown gets daily 500 lb. of bones worth 1c. a pound. In October 1,015 tons of garbage were fed.

Operation of Garbage Piggery at Worcester, Mass.—The following data are from an article by Prof. Frederic Bonnet, Jr. of Worcester Polytechnic Institute, published in Engineering News-Record, Aug. 30, 1917.

Worcester is one of the old and well established cities of New England with a population of about 175,000. It is an industrial city with many diversified industries but with no unusual characteristics. Its foreign population, according to the census 1910, is only 33.5%.

In 1872 (population 44,000) the superintendent of the municipal poor farm began sending a wagon into the city now and then to collect enough garbage to feed the pigs. The work developed with the growth of the city until today about 70% of the garbage of Worcester (20 to 30 tons per day) is taken to the Home Farm and fed to 2,000 to 3,000 pigs. The garbage disposal has developed and continued along this one line for a longer time than has usually been the case in American municipalities. There has been a striking absence of unwise and unsuccessful experiment.

The Home Farm proper consists of 376 acres owned by the city. In addition, the city leases a farm of 220 acres, at a rental of $1,500 a year. The farm is located in the northeastern part of the city. To get to it, the garbage teams coming from the center of the city have to pass over a ridge about 140 ft. high.

The city is divided into 21 districts from which the garbage is collected twice a week without charge to the householders or business men. There is also a special collection for the fish offal and rotten eggs from markets and commission houses, which collection is made daily in special cans with tight-fitting covers. These cans are provided by the dealers. Since this material is not fed to swine but is buried, as described later, no revenue is derived from it and it is a direct tax on the scavenger department of $1,760 per year.

Hitherto, most of the hotel, restaurant and hospital garbage was privately collected, but owing to the recent falling off of the quantity and quality of the garbage, more of this is gradually being collected by the city. Some private collectors also obtain the privilege of collecting in certain outlying districts. All such collectors must first obtain a license from the Board of Health, and this is only given by the board after consultation with the superintendent of the Home Farm, who includes in his duties the supervision of the scavenger department, the sole purpose of which department is the collection and disposal of the garbage collected by the city. The arrangement with private collectors has not been wholly satisfactory.

For the city collectors, one load is considered a day's work. Each collector unloads his wagon and washes it. He also beds down his horses and curries them. The feeding is not done by the collectors but by a farm employee especially assigned to this task.

The teams leave the Home Farm at 7 a. m. and have on an average a 13-mile haul daily (max. 18; min. 10). It requires from 2 to 4 hours to make a load. Owing to the fact that Worcester has practically no alleys the average time per house collection is 1.65 minutes (max. 3.9; min. 0.4).

Of 2,276 hogs sold to a packing house only 11 were condemned by the United Stated Government meat inspectors, an average of only 0.48%, which is much lower than on hogs shipped in from the West to the same packing company.

Operation of Garbage Piggery.—The following description of the operation applies to Worcester's garbage-disposal plant as now operated under the able direction of Thomas Horne, superintendent, who has aided the writer in the preparation of this paper. The garbage as it comes to the farm is neither washed nor steamed. Washing is uneconomical because so much valuable food material is washed away and wasted; it is unnecessary since no material advantage is gained thereby. Cooking or steaming the garbage has been found by experience to be bad since the garbage is thereby made more acid than it ordinarily is and substances are incorporated in the food which are harmful to the hog and which would not be eaten in the raw garbage. A hog is more capable of picking over and culling garbage than any man or machine can be.

Pigs are kept with the sow in individual pens until they are six weeks old, although the pigs begin to eat garbage when about three weeks old. Boars are castrated when about five weeks old and are then left with the mother another week. The pigs remain in pens until they are about 6 months old and are fed from troughs. They then weigh about 75 to 100 lb.

Inoculation Against Cholera.—The entire stock is treated by the so-called double-treatment method (virus and serum). Pigs 5 to 6 weeks old are inoculated with serum only. This treatment carried them for about 7 weeks when, at a weight of about 40 to 50 lb., they are given the double treatment, virus and serum. State veterinarians under the State Bureau of Animal Industry do this work free of charge, the department merely paying for the serum and virus used and for the necessary help. The cost of treatment depends upon the size of the animal since more serum is used the larger it is.

The serum costs 1¾cts. per c.c. and about 20 c.c. are used for a 40 to 50-lb. hog, live weight, so that the total cost of treatment exclusive of help is therefore about 70cts. per pig. The place for injection (between the hind legs) is scrubbed with soap and water containing lysol or similar disinfectant and swabbed with tincture of iodine after puncture. Not one hog in 500 is lost and there is no trouble from ulcer formation if the inoculation is properly done. One veterinary with five helpers can treat 250 pigs of 40- to 50-lb. weight in a day.

To prevent itch the hogs are all sprayed about once in six weeks with a mixture of 3 parts of kerosene and 1 part of turpentine.

Out-of-Door Feeding Platforms.—After six months the pigs which have grown to shoats are turned into hog lots (100 pigs to about 3 acres) with out-of-door feeding platforms made in 8 × 8-ft. sections of 2-in. plank. These are mounted on skids and have a half round timber on two sides to prevent the garbage from being pushed off. The cost per section was $7, with farm labor. Several sections are placed end to end and when the ground around the platforms becomes fouled the sections are skidded to another location and the ground at the former location plowed up. By this means the garbage trampled into the ground is kept from decaying and producing foul odors. The platforms are shovel cleaned daily and the material removed is composted or buried. The hogs are kept for about 15 months, when they are sold. They then weigh 250 to 300 lb. The last lot sold (May, 1917) brought 16.35c. per lb. on the hoof or 21c. per lb. dressed.

The sows are bred by turning about 300 of them into the same lot with about 30 boars for about five weeks. This makes it possible to control the farrowing so that there may be a sufficient number of pens. The first lot of brood sows are put with the boars from about Oct. 20, until Dec. 1. This brings the farrowing at the end of January, February and early March. After a month or six weeks a second lot of sows are bred and so on. During farrowing and sometimes during inoculation a little grain and middlings are fed. Boars are rarely kept more than two years and only prolific sows that are good mothers are kept for repeated breeding.

Old and New Pig Houses and Other Buildings.—Up to 1914, there were 12 pig houses scattered about the farm. Seven of these old piggeries are shelter sheds for outside hogs and have been torn down or are being used for other purposes. At present there are four pig houses in use, the dimensions of which are given in Table V, and two shelter houses. To provide additional pens for late spring farrowing 100 small portable take-down colony houses have been built at a cost of $20 each. These have proven excellent.

The floors of all piggeries are of concrete. At one end of each pen there is a slightly raised wooden platform for bedding to keep the pigs warm and dry.

Piggery No. 1 is the only one which is steam heated and is used for early farrowing. It is a well-built house erected about 25 years ago at an approximate cost of $4,000.

Piggeries Nos. 5 and 6 are identical in construction and were built about 15 years ago at a cost of about $3,000 each.

Piggery No. 11 is the newest, having been built in 1913 at a cost of $3,000.

TABLE V.—PRINCIPAL DIMENSIONS OF GARBAGE PIGGERIES AT WORCESTER HOME FARM

Piggery no.	1 right wing	1 left wing	5	6	11 right wing	11 left wing
Inside dimens., ft.:

* Height to ceiling. † 3 × 3 ft. ‡ 4 × 6 ft.

The pens are cleaned out daily. The cleanings, which consist of pig manure, urine, uneaten garbage and soiled bedding are carted away to the compost heap, which is inclosed by concrete walls. The cleanings, when not properly handled, may give trouble from odor. The commission already mentioned experimented with this material and found that when composted in layers with an equal volume of dry top soil, the rotten manure odor was wholly destroyed and only a slight musty odor remained after 10 days. The cleanings are quite wet and unless spread alternately in fairly thin layers with dry soil it takes a much longer time to mineralize the odor-giving substances. Objectionable odors may be carried a considerable distance when uncomposted material is spread on the ground as fertilizer, while the composted material is unobjectionable.

Since the bad odors are probably highly nitrogenous, composting by retaining these substances and mineralizing them would tend to increase the fertilizing value of the manure. About five cords of cleanings are produced daily (1,500 to 1,600 cords per year) and have a value of about $4 a cord as fertilizer at the farm. The Home Farm has never bought fertilizer in any material quantity for its farm land or truck garden and the scavenger department has never been credited with the value of the pig manure from the piggeries. There are two caretakers in each piggery except No. 11, which has one. One caretaker can care for about 250 to 300 pigs a day—feed them, bed them, and clean out the pens.

Out-Door Hogs Improve The Farm.—The out-door hogs are utilized in cleaning off the scrub from waste land and improving it. They chew and rip off the bark of practically all deciduous trees and thus kill them but coniferous trees are not touched. After chewing and stripping the bark they burrow around the roots, chew this bark and uproot the smaller stumps. In a remarkably short time (about two seasons) the scrub disappears and only the larger stumps must be pulled out before plowing is possible. Most of the cleared land of the Home Farm has thus been cleared and made into a very productive farm. Hog growers claim and it has been the experience at Worcester that such scrub acts somewhat as a tonic for the hogs and keeps them in good condition.

Tables VI and VII give the cost of collection and disposal for one year. Table VIII shows the operating cost and income of the scavenger department over a number of years. Including the years 1902 and 1910, which showed a clear profit over and above the cost of collection, the average net cost of disposal per year for 19 years was $10,169, or $0.074 per capita per year. From Tables VI and VII it will also be seen that the total cost of collection and disposal per year is $60,435. About 1,500 swine are sold each year and with the present price of pork will bring about $40 each or a total of $60,000. This will just about pay for the cost of collection and disposal. Table IX gives the estimated first cost of building and stocking a 20- to 30-ton garbage piggery.

Table VI.—Yearly Cost of Garbage Collection at Worcester, Including Capital Charges

1 Foreman, $45 per month		$ 540
1 Fish offal collector, $42 per month		504
1 Inspector, $2.50 per day (not found)		780
21 Collectors, $37 per month		9,324
6 Helpers, $35 per month		2,520
29 Men's board and lodging, 52 weeks, $5.60		8,445
44 Horses' board, $27 per month		14,256
		$36,368
Interest on investment:		
2 Horses and wagons, $800 each	$ 40	
Depreciation on teams, 10 %	80	
Horseshoeing	50	
Wagon repairs	76	
Veterinary, hardware, etc	32	
Total for 1 team	$278	
For 22 teams		$ 6,116
Total cost		$42,785

TABLE VII.—COST OF GARBAGE DISPOSAL PER YEAR AT WORCESTER, INCLUDING CAPITAL CHARGES

7 pig caretakers, 2 manure men, 1 compost man @ $37 per month	$ 4,440
Additional occasional help	1,320
Grain and bedding	2,640
Medicine (serum, virus, disinfectants)	3,040
Time of superintendent, farm foreman, office*	2,560
Miscellaneous—light, heat, water*	1,000
Interest on investment, 5 %, buildings, $13,000	650
†Stock 2000 hogs, @ $20, $40,000	2,000
Total	$17,650

*Estimated. †Estimated that 2,000 hogs are a necessary minimum for 20 tons daily capacity.

In September, 1915, when the farm was restocked after the hoof-and-mouth disease, 1,200 shoats of an average weight under 20 lb., 100 sows and 5 boars were purchased for $7,700. All the garbage collected was not consumed by this herd and additional stock was purchased, which brought up the total stock purchased to about $10,000.

From September, 1915, to January, 1917, $16,000 worth of pork was sold, and from Jan. 1 to June, 1917, $21,000 worth of pork was sold. There is on hand at the present time stock valued at $50,200.

TABLE VIII.—YEARLY QUANTITIES OF GARBAGE COLLECTED, NUMBER OF PIGS AND FINANCIAL RESULTS AT WORCESTER, 1898 TO 1916

Year	Garbage collected per day, cubic yards	No. of Pigs on Nov. 30 of each year	Financial summaries for each year: Total expenditures	Total receipts	Net cost	Net profit
1898	....	.....	$14,804.34	$ 7,674.02	$ 7,130.32	....
1899	....	.....	17,109.00	10,641.52	6,467.48	....

1916	....	.....	57,680.03	16,692.99	40,987.04	....

* Note.—Hoof-and-mouth disease. For 5 months in 1915 the garbage was buried. Farm restocked late in 1915 and early in 1916.

TABLE IX.—ESTIMATED COST OF GARBAGE PIGGERY WITH CAPACITY OF 20 TO 30 TONS A DAY

Based on conditions existing at Worcester, Mass. Land not included.

Four buildings with a pen capacity of about 300 pens, 6 × 12 ft., including small heating plant for one house, water-supply, drainage, platforms and fencing		$30,000
3 horses, wagons and sleds for disposal work		1,500
Stock on hand June, 1917:		
1,100 swine @ $30	$33,000	
100 sows @ $25	2,500	
800 shoats (50–100 lb.) @ $12	9,600	
900 pigs @ $5	4,500	
30 boars @ $20	600	50,200
Total		$81,700

The feeding method is very plastic and no part of the plant is idle or running below capacity part of the year. When the quantity of garbage becomes less hogs are sold off, and as the quantity increases, the herd increases to take care of it. In winter there are about 2,000 swine on the farm and in summer 3,500. About 100 to 150 pigs, depending upon size, will consume one ton of garbage per day.

Experience has shown that feeding garbage to hogs is the most economical and satisfactory method of disposal at Worcester and that it can be done in a sanitary manner without appreciable odor if given intelligent care.

At the conference on the subject of wastes disposal held in Chicago, Dec. 7, 1917 by the Federal Food Administration, Thomas Horne gave the 1917 figures of operation for the year ended Nov. 30 as follows:

There was sold $51,800 worth of pork raised on 6,501.4 tons of garbage. The cost (after collection) at the farm was $2.30 per ton, leaving a net pork value of $5.66 per ton for the garbage delivered at the farm. Mr. Horne values the equipment at $67,000, itemized as of Nov. 30, as follows: 40 acres land, at $100, $4,000; buildings and platforms, $20,000; 2,096 hogs, $42,000; miscellaneous, $1,000.

Cost and Operating Data of High-Temperature Refuse Incinerators.—The following data are given by Samuel A. Greely in an article published in Engineering News, Aug. 26, 1909.

Cost of Incinerators.—The data presented in Tables X and XI are taken from a paper by J. T. Fetherston, read before the American Society of Civil Engineers, December, 1907; from the "Minutes of Evidence," Vol. 5, 1908, of the Royal Commission on Sewage Disposal, and from "Refuse Disposal and Power Production," by W. Francis Goodrich. The individual results differ widely and show how local conditions affect the cost of construction. There may be conditions for which a top-charged plant is the more economical. In general, however, the results point to the fact that the top-charged incinerators cost about 10% more than bottom-charged incinerators.

A mechanical-charging device fitted to a top-fed plant is an added element of cost. The incinerator at Newcastle, fitted with the Horsfall tub-feed, cost about $48,000, and has a rated capacity of 67 tons; which gives a cost per ton of about $715. At Greenock, the incinerator, with Horsfall tub-feed, cost $95,000, and has a rated capacity of 120 tons, giving a cost per ton of $790. The cost of the mechanically-charged plant at Leeds was only $375 per ton; but this plant was built adjacent to an old hand-charged incinerator where it was possible to use the flues, boilers and chimney of the old plant. Mr. George Watson, of the Horsfall Co., figures roughly on $17,000 as the cost per cell of a tub-fed incinerator. This, on a basis of 26 tons per cell per day, as at Leeds, gives a cost per ton of about $650. These figures indicate that a mechanically-charged incinerator may cost in the neighborhood of $650 to $700 per ton under conditions which would require an expenditure of about $550 per ton for the hand-fired bottom-charged plants. This difference, at 5% annual interest and 310 working days per year, reduces to about 2 cts. per ton. The figures given for the cost of construction are for the whole plant, including cells, building, chimney, runway, crane and hopper; but do not include land or any adjacent electric plants, sewage-pumping stations, etc.

Operation.—Data showing the force required to operate the different types of plants and the cost of repairs have been obtained and are presented in Tables XII and XIII, which follow. Table XII, hand-charged incinerators, gives the tons of refuse which can be handled per man per hour. All of

Table X.—Average Cost of Construction of Bottom-Charged Incinerators

Wiesbaden	5	110	0.90
Average			0.98

the hand-fired plants are grouped together and averaged for comparison with the mechanically-charged plants. There is no great difference in this respect between the hand-fired bottom charged plants and the hand-fired top-charged plants.

Actual quantities of refuse burned, instead of rated capacities, are used in reducing the results to a man-hour basis.

Omitting Accrington, which has a close, poorly ventilated clinkering room where clinkering is hot and heavy work, and Westmount, where the plant is working considerably below the rated capacity, the average output in tons per man-hour is 0.75. Including all the plants the average is 0.66 ton per man-hour.

Mr. Fetherston sums up his study of 27 plants, only one of which was mechanically charged by saying "each man employed would handle 0.88 short ton per hour. At an easy rate of working there should be no trouble in destroying 0.75 ton per man per hour."

These tables indicate that with a mechanical charging device about ⅕ of a ton more per man per hour can be handled than without it. Assuming 25 cts. an hour for labor, this difference amounts to 5 cts. per ton in favor of the mechanically-charged incinerators. For plants fitted with the Horsfall tub-feed this may be slightly greater.

The cost of repairs for incinerators varies considerably from year to year and no very definite results can be expected. The mechanically-charged plants have most of them been built within the last two years and there are very few data on cost of repairs. The plants were grouped in Tables XIV and XV according to whether they are bottom-charged or top-charged, because top charging in general is harder on the grate and hearth and because the top-charged plants are more nearly analogous to the mechanically-charged plants. The costs given in the tables are taken from the testimony of Mr. W. F. Goodrich before the Royal Commission on Sewage Disposal, from Mr. Fetherston's paper, or were furnished by Mr. H. Norman Leaske, of Manchester, England. A few of them were taken from English pamphlets on refuse incineration.

On a basis of 310 working days in a year, these average results reduce to about 0.5-ct. per ton for repairs for the bottom-charged plants and 2.5 cts. per ton for hand-fired top-charged plants, a balance of 2 cts. per ton in favor of the bottom-charged incinerator.

For the mechanically-charged plant at Leeds, now in its fifth year and burning 53.5 tons per day, the repairs for the year 1908 amounted to $90, or about $1.68 per ton per year, which is equivalent to 0.54 cts. per ton of refuse burned.

TABLE XIV.—APPROXIMATE COST OF REPAIRS FOR BOTTOM-CHARGED INCINERATORS

Plant	Tons of 2,000 lbs. burned, per day	Cost of repairs per year Total	Per ton
Aldershot	13	$ 0.90	$0.07
Birmingham	37	40.00	1.08

Royton	16	146.00	9.15
Southampton	45	340.00	7.55
Average			$ 7.90

Mr. Greeley gave tables showing that the annual saving in coal, due to the use of steam generated from incinerators is greater in the bottom-charged than in the top-charged type, the average saving being 31.1 cts. for the bottom-charged and 15.5 cts. for the top-charged incinerators for each ton of refuse burned. This saving will depend upon a number of conditions among which are the use made of the steam generated and the quality of the refuse burned.

Tables XVI and XVII indicate the extent to which the useful heat energy returned is influenced by the method of charging.

Mr. W. F. Goodrich, in his book entitled "Refuse Disposal and Power Production," presents a table showing the number of electrical units generated per ton of refuse destroyed at twenty combined electricity and destructor works. If the top-charged and bottom-charged plants listed in these tables be averaged separately, the results would show an output of 30 kw.-hrs. per short ton for the top-charged incinerators as against 40 kw.-hrs. per short ton for the bottom-charged incinerators.

These results have been bettered considerably in more recent installations. Tests made on the top-charged plants at Bradford and Hackney and on the mechanically-charged plant at Greenock developed 60, 50, and 80 kw.-hrs. per short ton of refuse burned respectively, the average being 63.3 kw.-hrs. per ton. The bottom-charged incinerators at Stoke-upon-Trent, Woolwich, Preston, and St. Albans developed, on tests, 97, 90, 90, and 92 kw.-hrs. per ton respectively, the average being about 92 kw.-hrs.

TABLE XVI.—EVAPORATIVE RESULTS OBTAINED IN TESTS OF HAND-FIRED, TOP-CHARGED INCINERATORS

Mr. Greeley summarized the various points as follows:

1. Cleanliness: Mechanical charging offers the greatest opportunity for cleanliness, within and about the plant, of any type of incinerator and causes no more nuisance to the community.

2. Construction: A mechanically-charged incinerator, other things being equal, will cost about $125 per ton of rated capacity more than a bottom-charged incinerator. This is equivalent to a difference of about 2 cts. per ton of refuse burned.

3. Operation: By using a mechanical-charging device, about one-fifth of a ton of refuse per man-hour can be handled more than with hand firing in bottom-charged incinerators. This is equivalent to about 5 cts. per ton of refuse burned. A mechanically-charged plant may cost from 1 to 2 cts. more per ton for *repairs* than the bottom-charged plant.

4. Value of Output: There is little difference in the value of the clinker from the different types of incinerators. The useful heat energy from the hand-fired bottom-charged plants is worth from 13 to 15 cts. per ton of refuse burned more than the useful heat energy from mechanically-charged incinerators.

Within the range of capacities of the plants investigated (say up to 100 tons daily capacity) and in communities where steam has a distinct value, the evidence presented indicates that hand-fired bottom-charged incinerators are the most economical type. In communities where steam raising is not of prime importance, or where power cannot be readily marketed, mechanical charging has many advantages. Some of these cannot be expressed in terms of money value. Thus for each community, the controlling factors must be determined and the type of incinerator best adapted to these conditions must be selected.

Cost of Collecting and Incinerating Garbage at Racine, Wis.—The following information is taken from an abstract, published in Engineering and Contracting, Sept. 15, 1915, of a paper before the Wisconsin League of Municipalities by P. H. Connolly.

The plans and specifications together with the use of all patent rights in connection therewith for the 40 ton plant cost $1,000.

The site for the incinerator was purchased by the city in April, 1912 for the sum of $2,800. It is a strip of land 57 ft. wide and 240 ft. long. This site is almost the geographical center of the city at the present time. On October 28, 1912, the contract for the construction of the plant was awarded the sum of $21,000.

Description of Plant.—The plant consists of an absolutely fireproof building, two stories in height. The foundations and the lower story are of reinforced concrete and the upper story is of brick. The floors are reinforced concrete, the rolling doors and the window frames and sashes are of steel and the roof is of tile on steel purlins. The building is 40 ft. square. The entire upper floor is used for a dumping floor, except a small space in one corner which is used for an office. The incinerator is on the lower floor and consists of two units with a nominal capacity of 20 tons, each, in 10 hours. The stack is of radial brick and is 150 ft. in height. It is lined with fire brick for its entire height.

Each unit consists of two grates, two drying hearths, two storage bins, two emergency hoppers, a combustion chamber and a dust pit. Each furnace is also equipped with a hot water heater and a steel tank for storing the hot water, which is used for washing the wagons, steel baskets, floors, etc.

Dampers are arranged so that the heat can be turned onto the hot water boilers or direct into the stack. The storage bins are connected with the sewer and all wet garbage is dumped into them. These storage bins are equipped with mechanical stokers, operated by electric motors and the garbage is fed onto the drying hearths as needed. All dead animals and dry combustible refuse is dumped into the emergency hoppers.

The plant was completed and accepted by the city on Dec. 20, 1913. For some time previous to this the city had been burning all garbage that was hauled to the plant but the city did not install its system of collection until Jan. 7, 1914.

Garbage Collection System.—The collection system at the start was an experiment. We did not know the amount of garbage we would have to collect nor the number of men, horses and wagons it would require. The council on July 15, 1913, passed an ordinance regulating the collection of garbage and placed the same under the jurisdiction of the Board of Public Works. This ordinance provides that the garbage shall be collected in the business districts, three times a week during the month of June, July, August and September and twice a week during the balance of the year; and in the residence districts twice a week during June, July, August and September and once a week the balance of the year.

On Jan. 9, 1914, we started collecting with three one-horse wagons, with the driver alone on the wagons. We found that we could not cover the city, as provided in the ordinance, with this force, so on January 20 we put a helper on each wagon. This force was sufficient until May 8, when an additional wagon with driver and helper was put on. Previous to May 18 but one furnace had been in use, but at this time we found it necessary to run both furnaces, so an additional fireman was put on.

On June 1, 1914, we started to carry out the provisions of the city ordinance for a tri-weekly collection in the business districts and twice a week in the residence districts, so two more wagons were started, making six wagons with 12 men collecting and two firemen and the superintendent at the plant, which is the same force that we have at the present time (August, 1915). These men worked nine hours per day. We found that during the months of July, August and September, the amount of garbage increased so much that it was necessary to work the men 12 hours instead of nine. After September, the amount of garbage collected began to decrease and the men were placed again on their regular time and during the winter months some of the wagons were taken off for a portion of a week and only one furnace was used. The men are now working 11 hours per day. Each wagon is making from 5 to 7 loads per day, according to the district the wagon serves.

The city is divided into collection districts and each wagon has certain districts to take care of. The wagons are steel bodied, steel covered dump wagons, with a capacity of 37 cu. ft. The wagons and horses are owned by the city, the barn for the horses being located in the rear of the plant. The cost of collection and disposal is borne by the city at large, provision therefor being made in the annual budget.

When we first began operating the plant, we were handicapped by the fact that we had no scales to weigh garbage, coal, etc., as it was brought to the plant. The city council authorized the Board of Public Works to install a modern 10-ton scale and on Aug. 13, 1914, we started weighing every pound of garbage that was brought to the plant, also all coal, hay, feed, etc.

Quantitative and Cost Data.—From Aug. 13, 1914, to Aug. 13, 1915, there was brought to the plant and disposed of 3,392 tons of garbage, an average of practically 11 tons per day. There was used to incinerate this garbage 807,639 lbs. of soft coal screenings or practically 235 lbs. of coal per ton of garbage consumed.

From Jan. 1, 1914, to Jan. 1, 1915, there was practically 2,900 tons of garbage collected and disposed of, the total cost of which was $10,775.63, being $7,009.44 for collecting and $3,766.19 for incineration, or $2.42 per ton for collection and $1 29 per ton for incineration.

The amount of coal consumed per ton of garbage greatly exceeds the guarantee, which provided for 150 lbs. of coal per ton of garbage. But this guarantee was given on the condition that 500 lbs. of coal for each furnace be allowed before the test was started, to heat the furnace to the proper temperature. If we figured this 500 lbs. to each furnace or 1,000 lbs. for both furnaces, for the 309 days on which we collected garbage, it would mean 309,000 lbs. of coal which, if deducted from the total, would make the amount of coal consumed per ton of garbage about equal to the guaranteed amount.

In figuring the cost of collection I have included all expenses of every kind in connection with the collection and the same is true in connection with the cost of incineration with the exception of two items, viz., the interest on the investment and depreciation. The amount appropriated for garbage disposal for the year 1914 was $9,360 and the total cost was $10,775.63, leaving a deficit of $1,415.63, which was taken from the general fund of the city. The amount appropriated for 1915 is $11,000, and judging from the expenses thus far I think we will have a small credit balance in the fund at the end of the year. However, for the year 1916 I am afraid that the cost of garbage disposal will be nearly double what it will be this year, as then we will be operating under an 8-hour work day law with time and one-half for all overtime. The wages now paid are as follows:

Grade	Weekly wage
Superintendent	$21.00
Fireman	15.00
Assistant fireman	14.00
Head teamster	15.00
Teamsters and helpers	13.00

The city collects garbage only. The clause in the ordinance defining garbage is as follows:

Garbage shall be held to include all refuse, animal, fruit and vegetable matter, and tin cans used for the storage of said animal, fruit or vegetable matter, also all rags, paper and other combustible refuse, and it shall be deemed unlawful to place in the garbage cans any ashes, earth, waste or other materials of a different nature whatsoever.

Annual Operating Record of Refuse Disposal of Palo Alto, Calif.—The following statement from the annual report of the Board of Public Works, Palo Alto, Calif., giving the operating record for the year 1916–17 is given in Engineering News-Record, March 7, 1918.

OPERATIONS OF PALO ALTO REFUSE DESTRUCTOR

Receipts from refuse collection		$6,879.95	
Penalties		18.50	
Sundry material, etc., sold to city departments		190.00	
Miscellaneous receipts		159.80	
			$7,248.25
Destructor plant wages	$1,909.65		
Power	89.04		
Maintenance	15.99	$2,014.68	
Refuse collectors' wages	3,778.63		
Repairs	3.00	3,781.73	
Salaries	480.55		
Printing and stationery	119.00	599.55	
Bond interest		823.09	
Depreciation		700.13	$7,919.08
Net loss			$ 670.83

Remarks:

Number of furnace grates in incinerator	2
Total grate area (sq. ft.)	33
Weight of refuse burned (tons)	2,011.61
Weight of residual clinker, ash, etc. (tons)	400.18
Percentage of residue	19.9
Average amount of refuse burned per hr. (tons)	0.75
Average amount of refuse burned per sq. ft. of grate area per hr. (lb.)	45
Total weight of water fed to boiler (lb.), not including water for cleaning and blowing down boilers	779,539
Water evaporated per lb. of refuse (140 lb. per sq. in. boiler working pressure)	0.19
Horses cremated, 8; dogs cremated, 28; cows cremated, 1.	
Average water per ton of refuse, lb	1,088
Average combustible matter per ton of refuse, lb	512
Average non-combustible matter per ton of refuse, lb	399

The Palo Alto destructor is of the Dundon high-temperature type. It has a nominal daily capacity of 30 tons of mixed refuse and cost about $18,000. The population of Palo Alto is estimated at 5,900.

Cost of Operating Destructor with Steam Utilization, at Savannah, Ga.—The following matter is taken from an abstract (Engineering News, Feb. 11, 1915) of a paper by E. R. Conant read before the American Society of Municipal Improvements, Boston, Mass, Oct., 1914.

The population of Savannah, about 80,000, is some 60% white and 40% colored. From Mar. 23 to Oct. 1, a total of 18,033 tons of refuse was collected, including household, hotel and restaurant garbage and rubbish, paper and rubbish from stores, material from street receptacles, and some household ashes. The mean daily collection varied from 54 tons in March to about 100 tons in July. The average cost of collection was $2.29, including labor, care of stock, repairs to carts and harnesses and the purchase of small appliances for use in collection work. At the height of the watermelon and cantaloupe season, the percentage of garbage, by weight, was about 55%. During the remainder of the year, the percentage of garbage varies from 40 to 45%. In winter the ashes collected do not amount to more than 10% of the total collection, if that. Early in 1913, E. R. Conant, Chief Engineer of Savannah, recommended to the city council that a high-temperature furnace or destructor be installed. This the council decided to do. General specifications were prepared and bids secured. In July, 1913, the council awarded to the

Destructor Co. of New York City, a contract for a 130-ton incinerator of the Heenan (British) type. The final cost of the plant was $126,271, about $970 per ton of rated capacity. The plant was accepted by the city and final payment was made in October, 1914.

General Description of Destructor.—The destructor was located near the city water-works pumping station—60 ft. between building walls, with 140 ft. from the destructor boilers to the main steam header in the pumping station.

The main features of the plant are: A 260-yd. refuse-storage pit, 11 × 32 ft. in plan and 20 ft. deep, into which the refuse is dumped from the collecting wagons; an electric traveling crane and hoisting grab bucket, for lifting the refuse from the pit and carrying it to and dumping it into the refuse containers, located over the destructor cells; two 65-ton destructor units, each having four trough-grate cells about 28-in. wide on the bottom, 34 in. wide on top, 16 in. deep and 8 ft. long; two 200-hp. Wickes water-tube boilers; a Foster preheater; a cylindrical centrifugal fan for supplying forced draft; a radial-brick stack 150 ft. high and 6⅔ ft. in diameter at the top; hydraulically operated clinkering devices, which discharge into clinker carts of special design; a steam turbo-generator for supplying electric current for works light and power purposes; various recording instruments; a wagon scale for weighing the incoming refuse; and a building to house the whole.

The cells have a burning area of 20 sq. ft. over each grate. The refuse containers over the cells have a capacity of about 1 cu. yd. each and are closed by horizontally sliding doors, in two parts, hydraulically operated. Stoking is done through a supplementary door, which makes it unnecessary to open the large clinkering door.

The clinker is pulled out by means of a hydraulic winch, attached to a plate which forms "an upturned hoe placed on the bottom of the grate before the first charge of refuse is deposited in the cell." The sides of the grate diverge slightly from the rear to the stoking door. A clinkering operation is performed in three to four minutes. Usually the clinker is drawn once for each six charges of refuse. The average time burning a charge is 20 min.

During July and August, about 10% of cinders from manufacturing plants were added to offset the excessive moisture in the refuse due to the melon season.

With the destruction of 60 to 75 tons of refuse per day, which comprised the collection in 1914, only one unit was operated, so as to supply steam to the pumping station continuously. The plant is operated in three shifts.

Operating Costs under Working Conditions, Mar. 24 to Sept. 30, 1914.—During a period of just over six months, 14,364 tons of refuse were burned at a total cost of $8,988, including $428 for a weighman and $370 for a laborer at the pit, supervising the dumping of cars. This gives an average cost of 62½c., but in comparing this with the guaranteed cost of 40.4cts., it must be remembered that the guaranteed price was based on the plant working at full capacity. Deducting the value of fuel saved at the pumping station, the net cost was 41.6 cts., per ton.

With dry refuse the clinker varies from 20 to 25% of the refuse, but during July and August it runs from 25 to 30%.

About $3,000, or $500 per month, was saved in fuel from Mar. 24 to Sept. 30. Changes at the plant, it is expected, will raise this saving to $600 per month. Operated at full capacity, it is estimated that the fuel saving would be $1000 per month. It may be added that the pumping-station equipment consists of two 10,000,000-gal. Holly-Gaskell duplex compound pumping engines and two cross-compound air compressors, all of which are operated condensing.

TABLE XVIII.—COMPARISON OF OPERATIONS BETWEEN THE CHICAGO MUNICIPAL REDUCTION PLANT AND THE CLEVELAND MUNICIPAL REDUCTION PLANT

Year	Total green garbage received, in tons	Total tankage produced, in tons	Total grease produced, in pounds	Percentage of tankage to green garbage	Percentage of grease to green garbage	Income per ton of green garbage from products	Total net profit (+) or loss (−) per ton of green garbage	Total operating expense. See Note "A"	Cost of operating per ton of green garbage. See Note "A"
From Chicago Records									
1915	152,892	—See Note "B"—		....	...	$1.19	−0.36	....	......
1916	134,292	9,156	3,792,880	6.8	1.4	2.57	−0.56	....	......
1917	100,000	22,674	4,023,480	22.6	2.0	4.25	−0.31	$456,493	$7.34
1918	84,974	15,774	2,908,580	18.6	1.7	6.73	+0.95	489,570	5.78
1919	82,820	14,618	3,393,360	17.7	2.1	3.46	−3.17	548,687	6.63
1920	80,132	11,410	2,208,620	14.2	1.4	2.56	−6.11	695,247	8.67
From Cleveland Records									
1915	62,357	6,879	3,731,770	11.0	3.0	$3.60	+1.17	$151,503	$2.43
1916	60,717	7,038	3,819,325	11.6	3.14	5.10	+2.54	155,585	2.56
1917	56,121	6,241	3,071,092	11.1	2.36	5.22	+1.81	191,001	3.41
1918	57,754	6,329	2,726,786	11.0	2.56	7.58	+2.97	265,243	4.61
1919	60,932	7,094	3,116,797	11.6	2.56	4.87	+ .96	238,202	3.91
1920	60,645	7,243	3,367,037	10.5	2.45	6.06	+ .58	375,949	5.48

Note "A"—Charges for water, maintenance and depreciation are included in figures tabulated for Cleveland but not for Chicago.

Note "B"—All collections were converted into com. dried garbage.

The destructor-plant steam pressure is carried up to 150 lb. with 100° superheat. As the steam pressure for the pumps is only 90 lb., a reducing valve is used between the destructor and the pumps.

Comparative Operating Costs of the Chicago and Cleveland Reduction Plants.—The following is taken from an abstract in Engineering and Contracting, May 11, 1921, of a report of Major I. S. Osborn upon the means of increasing the efficiency and economy of the Chicago reduction plant.

The reason for using Cleveland was that the total tonnage reduced annually compares more closely with that of Chicago than the total reduced by any other city. Furthermore, the Cleveland plant was the first to be municipally operated, and has been so used for the past 16 years. Thus the results achieved have undergone the test of time more fully than any other municipally operated plant. The data available are therefore, more representative than that of any other city, as to what can be accomplished by municipal management and methods.

Although the "Digester" process, whereby the garbage is first cooked before drying, is not used in Chicago, yet the equipment used by Cleveland for drying and extracting is very similar. This difference of method, however, does not appreciably affect the basis for comparing results.

Comparison of Labor Distribution of Cleveland Municipal Plant with That of Chicago.—Although during the past year the quantity of garbage disposed of by Cleveland was within 12,000 tons of that handled by Chicago; and although the rate of wages paid in Cleveland was higher than in Chicago except in the case of mechanics; the payroll in Cleveland, nevertheless, was less than half. The following comparison of the organization of the employes in the two plants illustrates, in one way, why the Chicago plant is not as economically operated:

Cleveland		Chicago
68,645	Tons garbage reduced in 1920	80,132
	SUPERINTENDENCE	
1 Superintendent.		1 Foreman in charge.
	OFFICE	
1 Clerk and stenographer. 1 Bookkeeper. 1 Laboratory assistant in city chemical laboratory. Note.—Bookkeeper keeps books for both collection and disposal.		1 Head clerk. 1 Principal clerk. 1 Senior clerk. 1 Senior clerk. 1 Junior clerk. 2 Junior stenographers. 1 Senior sanitary chemist. 1 Assistant chemist on payroll as garbage handler. 1 Janitress, G. H. payroll. 1 Office assistant, G. H. payroll. 1 Office boy, G. H. payroll.
	FOREMEN	
3 General foremen—one for each shift.		1 Assistant general foreman. 1 Foreman garbage plant. 2 Foremen garbage handlers. 1 Foreman mill house. 1 Assistant foreman mill house. 1 Foreman extractor plant (1 shift) or (3 shifts).
	ENGINEERS	
3 Engineers (1 for each shift) power plant (electric power generated).		1 Second assistant operating engineer. 2 Third assistant operating engineers. 9 Junior operating engineers. 1 Hoisting engineer (electric power purchased).
	POWER HOUSE	
3 Firemen. 3 Coal passers. 1 Ash handler.		4 Firemen. 14 Garbage handlers used in handling coal and ashes (day shift). 5 Garbage handlers (2nd shift). 4 Garbage handlers (3rd shift).
	MECHANICS	
2 Machinists. 3 Machinist helpers. 2 Steamfitters. 1 Steamfitter helper. 1 Carpenter. 1 Carpenter helper. 1 Electrician.		8 Machinists. 2 Steamfitters. 1 Steamfitter helper. 2 Carpenters. 1 Blacksmith. 1 Blacksmith helper. 6 Electricians (3 used on cranes)
	OPERATORS	
11 Equipment operators for dryers, digesters and extractors.		10 Equipment operators for dryers, extractors, etc.
	WATCHMEN	
None.		2 Watchmen in addition to garbage handlers carried as watchmen.
	LABOR OR GARBAGE HANDLERS	
13 Receiving building. 21 Dryers and digesters. 6 Extractor plant. 6 Mill house. 7 Utility.		28 Receiving building. 22 Dryers. 10 Extractor plant. 39 Mill house and finishing dryers. 22 Utility.
92	Total number employes on payroll	213

Cost of Garbage Collection and Reduction at Cleveland, O.—The cost of collecting and reducing garbage in 1917 at Cleveland, O., increased materially, according to the 1917 report of F. L. Stockberger, Engineer of Reduction.

The amount of garbage collected and reduced during 1917 was 56,121 tons, which is a decrease of 4,596 tons in comparison with the year 1916. The amount of finished material produced from this garbage was 3,071,022 lb. of grease and 6,241 tons of tankage. This is a decrease of 796 tons of tankage and of 748,303 lb. of grease. The decrease, states the report, was caused by the decrease in the quantity of green garbage collected, the high price of all foodstuffs and by the conservation movement which was in vogue during the greater part of the year.

The cost of collection was as follows:

	Amount	Per ton green garbage
Supervision:		
Labor—collecting	$157,071	$2.7988
Labor—shoeing	4,164	.0742
Supplies:		
Shoeing	1,501	.0267
Office	146	.0026
Fuel, light and power	1,529	.0272
Feed	25,330	.4514
Barn	777	.0138
Motor vehicle	2,468	.0438
Mechanical	133	.0024
Cleaning and toilet	33	.0006
Other miscellaneous	147	.0025
Miscellaneous Expense:		
Transportation—employes	....	....
Telephone and telegraph	169	.003
Team hire	1	....
Insurance	736	.0131
Taxes	199	.0035
Rented land	1,919	.0342
Damages	3	.0001
Freight on garbage	12,393	.2208
Other miscellaneous	12	.0002
Total operating cost	$208,741	$3.7189
Maintenance:		
Cars and wagons—labor	$ 3,398	$0.0605
Cars and wagons—material	3,326	.0593
Harness—labor	1,249	.0223
Harness—material	1,608	.0286
Buildings—material	1,820	.0324
Office furniture and fixtures	2	....
Machinery, tools and implements	299	.0053
Motor vehicles	839	.015
Other miscellaneous equipment	2,765	.0493
	$ 15,309	$0.2727
Total collection cost	225,850	4.0243
Loss on horses	1,211	.0216
Depreciation	8,973	.1599
Entire cost, including depreciation	$236,035	$4.2058

CHAPTER XIV

STREET SPRINKLING, CLEANING AND SNOW REMOVAL

Further data on the costs of street sprinkling and cleaning are given in Gillette's "Handbook of Cost Data," pages 457 to 474.

Time Studies and Factors and Standards for Street Cleaning in Chicago.—Time studies were made during 1912–13 in Chicago to determine the effectiveness of street cleaning methods and the efficiency of street cleaners and teamsters. These studies were conducted by the efficiency division of the Civil Service Commission and have been used to compute factors and standards by which appropriations can be attested. They present a number of facts which are of more than local interest and the following matter is taken from an abstract in Engineering and Contracting, Nov. 19, 1913, of the commission's report.

General Conclusions.—Analysis of the time records disclosed that a proportion of the street cleaners had no notion of how to perform their duties with minimum waste of time and energy. It was ascertained that there are at least 38 distinct motions which a cleaner makes in street cleaning work. Of these some were found unproductive, resulting in loss of time and energy. As an example, the practice of hitting the broom on the pavement at the end of each stroke was found unnecessary. By bringing the brush down forcibly at the beginning of each stroke the same result is attained and the labor reduced at least 15 per cent. It was also disclosed that wheeling push carts in to alleys or to other temporary dumping places consumed 20 per cent of the cleaners' time. The time lost by cleaners in dodging vehicular traffic was found not to exceed 8 per cent in streets of dense traffic and not to exceed 2 per cent in outlying business streets. It was disclosed that unnecessary sweeping was done on light traffic asphalt pavements. After the morning cleaning, three-fourths of the area to be covered during the remainder of the day does not require thorough cleaning. The time studies showed that street laborers in gangs did not work as efficiently as single laborers each having his individual assignment; time is lost in conversation and by the pace being set to accommodate the poorest laborer. Generally, the time studies showed that street cleaning is handicapped by lack of control, instruction and supervision and lack of incentive due to non-recognition of ability and efficiency.

From the time studies of 1912–1913, a perfect standard of work was computed; they also showed that able street cleaners working regularly and under instructions in proper methods were able to do more than the *attainable* standard which was set at 85 per cent of the *perfect* standard. Under employment conditions as they exist at present it was felt that the *attainable* standard of 85 per cent could not be expected, and so for 1914 computations are based on a standard of 74.4 per cent.

Standards and Factors.—The conditions and factor which control the amount and frequency of cleaning of any pavements, other conditions being the same, may be summarized as follows:

(1) Density of horse-drawn vehicles and other traffic; (2) width of streets; (3) character of district and population; (4) location of streets: (5) proximity to unpaved streets and alleys; (6) location of public buildings, parks, etc. (7) kind and condition of pavements.

As a result of the study, it has been definitely determined that the density of horse traffic, which is the total number of horses passing through a given street divided by the width of the street, is the principal factor which determines the number and frequency of cleaning which one street should be given. The experiments made to determine what relation the yardage of dirt collected in any street had to the number of cleanings indicates that this factor is not definite, but is a direct function of all the other factors above noted.

As the traffic conditions on a street determine to a great extent the number and frequency of cleanings which should be provided, in order that the service be always distributed uniformly and equitably, it will be necessary that traffic census be made regularly each year in the different streets of the city. Traffic census taken at regular intervals each year will show any changes in the character of the districts and the necessary changes in cleaning service.

From the studies made the street cleaning constants given in Table I were determined.

Upon the above factors the number of cleanings per week which any street having permanently improved pavement will receive is expressed by the equation:

$$N = \frac{E}{C\,W}$$

where N = number of cleanings per week.
E = total number of horse-drawn vehicles per 8-hour day.
W = width of roadway in feet.
C = constant of cleaning.

In the case of streets where investigation gives data of traffic of vehicles and pedestrians and restricted roadway due to standing vehicles and general special considerations which necessitate the modification of the value of the constant C in the above equation the schedule should be arranged so that the cleaning service is in accordance with requirements and standard maintained.

For residence and street railway streets, or streets on which churches, schools, hospitals, playgrounds and general public institutions are located, the application of the constants (Table I) to traffic conditions might give results below the necessary minimum. In such cases the formula is used, but the minimum number of cleanings for streets having these characteristics has been determined by a separate basis, as shown further in Table I.

TABLE I. STREET CLEANING CONSTANTS

Wards—	Av. res.	Av. bus
Inlying	2.1	2.6
Outlying	2.5	2.8

MINIMUM CLEANINGS PER WEEK ON HARD PAVEMENTS

	Cleanings per week
Inlying wards	3.0
Outlying wards	1.0

MINIMUM CLEANINGS PER WEEK ON CAR TRACK STREETS

	Head way up to 3 min.	Head way 3 to 10 min.	Head way 10 min. or more
Inlying wards	6	5	4
Outlying wards	6	3	3

MINIMUM CLEANINGS PER WEEK ON STREETS HAVING PUBLIC BUILDINGS, ETC.

Churches		Schools		Hospitals, parks, public institutions	
L.	6	L.	6	L.	6
M.	3	M.	5	M.	4
S.	2	S.	4	S.	2

L = Large. M = Medium. S = Small.

In cases where the streets or alleys surrounding the foregoing are unimproved, the minimum number of cleanings has been increased by one-twelfth of the number of cleanings calculated for the improved pavements.

From an analysis of the time studies of the work of street cleaners, definite data have been secured upon which is based the relative difficulty of cleaning the different kinds of pavements with varying physical conditions. The standards and equivalent areas which it is assumed can be cleaned by one man in one eight-hour day follow:

Pavement	Condition of pavement	Standards	Equivalent sq. yds.
Asphalt	Good	100 per cent average perfect standard.	34,000
Asphalt	Good	85 per cent attainable standard......	28,900
Asphalt	Good	74.4 per cent of attainable standard assumed for 1914................	21,500
Asphalt	Fair	90 per cent of good asphalt..........	19,300
Asphalt	Poor	80 per cent of good asphalt..........	17,200
Creosote blk.	Good	Good asphalt....................	21,500
Brick	Good	Good asphalt ÷ 1.35..............	16,000
Brick	Fair	63 per cent of good brick...........	10,000
Brick	Poor	50 per cent of good brick...........	8,000
Granite	Good	Good asphalt ÷ 1.60..............	13,400
Granite	Fair	75 per cent of good granite.........	10,000
Granite	Poor	60 per cent of good granite.........	8,000

Analysis of the data also indicates that the presence of car tracks in a street increases the difficulty of cleaning the street, and that under similar conditions, the street car right of way is approximately 15 per cent harder to clean than the pavements outside of the car tracks. In instances where the pavement of the right of way has been found to be different from the pavement of the balance of street, the area of the right of way has been increased by 15 per cent and the paving factors applied.

In cases where alleys are paved with improved pavements and where conditions exist similar to those on streets, the same standards and equivalents as given for the cleaning of streets having similar factors are used, the resulting number of cleanings per week being divided by six. In some instances, the number of cleanings per week that an alley would receive, based upon traffic conditions alone, would give absurd results, and therefore a minimum of two cleanings each week has been fixed for all improved alleys in the city with the exception that the improved alleys in business sections which receive a minimum of six cleanings per week.

Experimental work in connection with the cleaning of improved alleys has demonstrated that the traffic on alleys does not control the number of cleanings to be given, that there is practically no difference in the time required to clean the various kinds of pavements in alleys and that a reasonable eight-hour day's work for an average laborer is eight blocks or approximately one mile of improved alleys.

The oiling of macadam streets during the past few years has had an excellent effect upon the surface of these streets. The surface of many has become sufficiently smooth to require more cleaning than could heretofore be given to the plain macadam streets. Analysis of the standard of work which one man can perform on oiled macadam streets indicates that the rate of cleaning 1¼ miles of oiled macadam in an eight-hour day can be reasonably expected of any man, and this standard has been assumed in the preparation of estimates for the 1914 appropriations. The number of cleanings which are to be given to these oiled macadam streets is as follows:

	Cleanings per week
Inlying wards	3
Intermediate wards	2
Outlying wards	1

The number of cleanings which it has been assumed will be given to the plain macadam and cedar block streets exclusive of country roads is as follows:

Inlying wards	6 times during the cleaning season, or approximately 1 cleaning per month
Intermediate wards	4 cleanings per year
Outlying wards	3 cleanings per year

Analysis of the records of the cost of cleaning the macadam and cedar block pavements has shown the following relationship between the total cost of cleaning such pavements and the cost of the spring cleaning of the same pavements, which is shown under Spring Cleaning. In wards where the macadam and cedar block pavements are cleaned three times per year, the total cost of cleaning these pavements is approximately twice the cost of the spring cleaning. In wards where the macadam and cedar block pavements are cleaned four times per year, the total cost of cleaning these pavements is approximately 2½ times the cost of the spring cleaning. In those wards where the macadam and cedar block pavements are cleaned six times during the cleaning season, the total cost of cleaning of these pavements is approximately four times the cost of the spring cleanup.

A general spring cleaning is provided for all streets of the city which do not receive attention during the winter months. The heavy dirt which is washed from the center of the street and which accumulates in the gutters during the winter season is piled up and removed from the street before the regular block cleaning work is begun.

Study has been made of a number of different methods which are used in the removing of the dirt in the spring cleaning. The unit costs of such work indicate that the assignment of one man to a definite length of street or the assignment of a small gang of not exceeding three men to definite lengths of street are most effective and economical. Where a gang of three men is assigned to this work, team work is developed by the use of one man in removing the dirt from the roadway and one man each for the gutters. On the granite and brick pavements considerable more brooming is necessary on the roadway. The granite and brick pavements and the cedar block pavements require that the dirt be scraped from the center of the street to the gutters before piling of the dirt in the gutters can be commenced.

It has been found that the rate of spring cleaning of the center of streets varies with the conditions of the pavement and that the rate of piling dirt in the gutters is practically independent of the condition of the improved pavements, but varies directly with the traffic. In providing the spring cleaning for improved pavements, standards have been determined which are based on the rates in Table II.

TABLE II.—CENTER CLEANING RATES

Class of pavement—	Car track, sq. yds. per day	Outside car track, sq. yds. per day
Good asphalt	16,500	18,500
Fair asphalt	12,900	14,800
Poor asphalt	9,200	11,100
Good brick	4,400	5,550
Fair brick	3,340	3,700
Poor brick	1,850	2,960
Good granite	4,400	5,550
Fair granite	3,340	3,700
Poor granite	1,850	2,200
Cobblestone	1,470	......

SINGLE GUTTER RATE IN MILES PER DAY

Times cleaned per week	Asphalt	Good brick	Poor brick and granite of all kinds
2	1.8 miles	1.4 miles	1.4 miles
3	1.4 miles	1.1 miles	0.7 miles
6	0.7 miles	0.5 miles	0.3 miles
9	....	0.3 miles	0.2 miles
12	....	0.2 miles	0.2 miles

In preparing the estimate of the cost of spring cleaning of the macadam and cedar block streets, it has been assumed that where the average traffic per eight-hour day is less than 400 vehicles the street has been termed a light traffic street and where the traffic per eight-hour day exceeds 400 vehicles the street has been termed a heavy traffic street. On this basis it has been found that the unit cost of spring cleaning the macadam and cedar block streets of different physical conditions is as follows:

First-class condition, cost for cleaning 100 lin. ft. — Traffic		Fair condition, cost for cleaning 100 lin. ft. — Traffic		Poor condition, cost for cleaning 100 lin. ft. — Traffic	
Heavy	Light	Heavy	Light	Heavy	Light
$1.18	$0.90	$1.97	$1.46	$2.25	$1.69

Cost of Street Cleaning at Philadelphia.—Engineering and Contracting, Sept. 5, 1917, publishes the following interesting data on street cleaning costs at Philadelphia, contained in the 1916 annual report of the Bureau of Highways. Special block tests on various types of pavements were made with machine brooms, the average costs being as follows:

	Per 1,000 sq. yd., cts.
Granite block	24.6
Brick	19.3
Wood block	16.6
Sheet asphalt	15.9
Average per all classes	22.6

The dirt removed per 1,000 sq. yd. of pavement was 0.158 cu. yd.; 98 gal. of water were used per 1,000 sq. yd. cleaned. On the regular work the average cost of street cleaning with machine brooms, based on the district reports, was 28.2 ct. per 1,000 sq. yd.

The unit costs per 1,000 sq. yd. of street cleaning by other methods were as follows:

District, number	Squeegee, Average from block tests	Squeegee, Average from district reports	Flushing, average from district reports	Hose flushing, average from district reports	Blockmen, average from district reports
1–A	$0.131	$0.223	....	......	$0.083
1–B	.174	.204	....	......	.081
2	.130	.196	.156	......	.179
3	.118	.094	.157	$0.474	.282
4–A	.176	.126	.174	......	.216
4–B	.115	.115	....	......	.140
5	.218	.192	.148	......	.111
6	.137	.182	.150	......	.174
Average	$0.148	$0.156	$0.157	$0.474	$0.152

The squeegee used 240 gal. of water per 1,000 sq. yd. cleaned and the flusher used 522 gal. The amount of dirt per 1,000 sq. yd. removed by the squeegee was 0.031 cu. yd. the blockmen removed 0.051 cu. yd. per 1,000 sq. yd.

The squeegees were used on sheet asphalt and wood block streets only.

Flusher dirt was removed by blockmen.

The cost of labor and equipment per day was assumed as follows:

Superintendent	$4.00	Squeegee	$ 6.00
Foreman	2.50	Auto flusher	15.00
Gangmen	1.75	Dirt—	
Blockmen	1.50	Wagon	5.00
Dumpmen	1.50	Cart	3.50
Machine broom	5.50	Sprinkler	5.00

Street Cleaning Costs at Houston, Texas.—Engineering and Contracting, Sept. 5, 1917, gives the following data taken from the 1916 annual report of the Street and Bridge Commissioner of Houston, Tex.

Street Sprinkling.—The motor sprinkling covered 250 blocks twice daily and 57 blocks four times daily. The total yardage sprinkled each day was 1,083,000 sq. yd. In 1916 the motor sprinkler was in operation for 262 days. The total yardage sprinkled was 283,746,000 sq. yd. and the total cost was:

	Per day	Total, 262 days
Chauffeur	$3.00	$1,080
Gasoline	1.80	372
Lubricants	.50	131
Repairs and renewals	4.20	1,255
Total	$9.50	$2,838

This gives a cost of approximately 1 ct. per 1,000 sq. yd. of street surface sprinkled.

About 1,632,000 sq. yd. of street surface were sprinkled each day by mule-drawn sprinklers. Six of these outfits were in use at a daily cost of $25, made up of the following items:

6 drivers	$12.00
12 mules	12.00
Renewals	1.00
Total	$25.00

The team outfits sprinkled 350 blocks twice daily and 97 blocks four times daily, and were operated for 300 days, making the total area of street sprinkled in this way 489,600,000 sq. yd. The cost was as follows:

300 days operation	$7,500
66 days idle mules	780
Total	$8,280

This makes the cost per 1,000 sq. yd. 1.75 ct.

Street Sweeping.—The street sweeping was carried out with mule-drawn sweepers, truck-drawn sweepers and combination sprinkler-sweepers. The unit costs by each of these methods were as follows:

	Per 1,000 sq. yd., ct.
Mule-drawn sweepers	12½
Truck-drawn sweepers	12⅛
Combination sprinkler-sweeper	6⅔

In all 177,000 sq. yd. of street surface were swept daily by three mule-drawn sweepers preceded by one team sprinkler. These outfits operated 294 days in 1916, during which time 52,000,000 sq. yd. of street were swept. The cost of the work was:

	Total per day	Total, 294 days
4 men	$8.00	$2,352
8 mules	8.00	2,352
Brooms, renewals and repairs	2.20	740
½ foreman	1.50	490
Total		$5,934
8 mules, idle 72 days		506
Total		$6,440

The trucks, each trailing one sweeper and preceded by a motor sprinkler, cleaned 300,000 sq. yd. of street surface daily. These outfits operated 270 days at a daily cost of—

2 chauffeurs	$ 7.00
Gasoline	3.60
Lubricants	1.00
Repairs and renewals	4.00
Broom repairs and renewals	4.35
2 men riding brooms	4.00
½ foreman	1.50
	$25.45
Motor sprinkler ahead	9.50
Total	$34.95

The two combination sprinkler sweepers covered 161,000 sq. yd. of street surface each day and were operated for 294 days in 1916. The cost was as follows:

	Total per day	Total 294 days
2 men	$4.00	$1,176
4 mules	4.00	1,176
Broom renewals and repairs	1.70	288
Total	$9.70	$2,852
4 mules, idle 72 days		288
Total		$3,140

White Wings and Pick Up.—In the business district a force consisting of 13 men and a foreman cleaned 222,000 sq. yd. of street surface daily except on Sunday, when they cleaned about one-half this amount. The total cost was as follows:

Men, $185.90 weekly	$10,126
Supplies	500
Total	$10,626

About 47,645,000 sq. yd. were cleaned in the year, making the cost 22½ ct. per 1,000 sq. yd.

The force employed on pick-up work on the business streets consisted of the following:

	Per day
6 men	$12.00
6 mules	6.00
Renewals and repairs	1.00
Total	$19.00

This gang picked up sweepings last year from 20,878,000 sq. yd. street surface at a cost of 33¼ ct. per 1,000 sq. yd. surface. It removed 6,184 cu. yd. sweepings at a cost of $1.10 per cubic yard.

General pick-up work was handled by an outfit consisting of two trucks, two chauffeurs, 10 men and foreman; also six mule teams, 12 men and foreman.

Daily cost operating two trucks—

Two chauffeurs	$ 7.00
Gasoline	3.60
Lubricants	1.00
Depreciation, renewals and repairs	4.00
Foreman	3.00
Ten men	20.00
Total	$38.60

Picking up daily sweeping from 128,700 sq. yd. street surface. Removing 20 cu. yd. sweepings.

Operating cost working 270 days last year picking up sweepings:

Two chauffeurs	$ 2,160.00
Gasoline	972.00
Lubricants	362.00
Renewals and repairs	1,080.00
Foreman	936.00
Ten men	5,400.00
Total	$10,910.00

Picked up last year (270 days) sweepings from 34,750,000 sq. yd. street surface at a cost of 31¾ ct. per 1,000 sq. yd. Removing 5,700 cu. yd. sweepings at a cost of $1.91 per cubic yard.

Daily cost of six-team pick-up equipment—

12 men	$24.00
12 mules	12.00
Foreman	2.50
Repairs and renewals	2.00
Total daily	$40.50

Picking up sweepings from 185,900 sq. yd. street surface. Removing 45 cu. yd. sweepings.

Team pick-up equipment cost last year, operating 294 days—

12 men	$ 7,056.00
12 mules	3,528.00
12 mules, idle 72 days	864.00
Foreman	810.00
Repairs and renewals	600.00
Total last year	$12,858.00

Street Cleaning Practice in Cities of From 50,000 to 100,000 Population.—The following notes, taken from Engineering and Contracting, Sept. 20, 1911. were given by the officials of the various cities.

TABLE III.—SUMMARY OF GENERAL PRACTICE IN MACHINE CLEANING

City	Number of sweepers to a sprinkler	Area covered by sweeper in working day,* sq. yds.	Total length of street covered in miles per day*	Number of men sweeping behind each machine sweeper	Number of men picking up sweepings for each machine sweeper	Number of carts picking up sweepings for each machine sweeper
Altoona, Pa	2	....	68[1]	6	4	2[2]
Bayonne, N. J	1	95,000[3]	3½	10	4[4]	3[4]
Charleston, S. C	1	465,000[5]	....	12	5	5
Dallas, Texas	..	....	....	1	1[6]	2[6]
Des Moines, Ia	2	98,000	....	2	3	3
East St. Louis, Ill	..	....	2	4	8	4
Fort Worth Tex	..	........[1]	....	....	1	1
Hoboken, N. J	1	63,347	4	12	5	5
Houston, Tex	4	75,200	1½	....	5½	..[7]
Huntington, W. Va	2	82,400	2⅗	4	4[8]	2[8]
Jacksonville, Fla	2	....	....	2⅓	..[9]	..[9]
Oklahoma City, Okla	3	....	....	....	1	1
Springfield, Mass	2	50,000	....	2	2	1
Troy, N. Y	3[10]	30,000	4[11]	2[13]	..[13]	..[13]

* Altoona, Pa. and Huntington, W. Va. have 10-hr. day, all others have 8-hr. day.

[1] 68 blocks for one sweeper; 85 blocks for two sweepers. [2] 2-yd. dump wagons. [3] On bitulithic; on Belgian block about one-fifth less. [4] Three carts with one additional man to help load. [5] Per week; includes granite blocks and cobbles. [6] The night force of 4 men, 8 teams and 1 foreman handles the sweepings [7] Double teams with wagons [8] Large drop bottom dump wagons, 2 men to each wagon. [9] Sweepings picked up by regular garbage carts in morning, 45 carts being engaged for 1½ to 2 hours taking up sweepings of entire area swept. [10] 3 to 5 sweepers. [11] 4 miles for gang. [12] 2 men follow gang of 3 machines. [13] Sweepings gathered into cans by patrolman on his beat and removed by teams that gather house refuse.

As to the comparative costs one city reported that the cost of sweeping by machine and by hand was about the same, while 12 cities reported that machine sweeping was not more expensive than hand sweeping. At Charleston, S. C., the cost of sweeping with horse sweeper and gang was placed at 74 cts. per 10,000 sq. ft. This cost does not include new equipment but does include removal of sweepings.

Patrol System.—Practically all of the 21 cities, reported, employ the patrol system in cleaning the streets by hand sweeping. At Altoona, Pa., the patrol system is used on 51 blocks of streets, the area covered by one man being eight blocks. The patrolman uses a broom and a scraper to lift the sweepings into patrol carts.

At Bayonne, N. J., one man generally covers a given section but sometimes two men are used, depending on character of section. One man covers about 10,000 sq. yds. in residential sections in the working day. For cleaning up the dirt the patrol sweepers use brooms with can and carriers. Hand pickup machines with a revolving drum have been used by the patrol sweepers at Bayonne with fair results.

At Charleston, S. C., five patrols cover about 36,800 sq. yds. of brick pavement per day. For gathering up the dirt the patrol sweeper uses a scraper on asphalt pavements, a hand pickup machine on brick, and a broom and push cart on granite block pavement. The results obtained with the hand pickup machine are reported to be very satisfactory. Five of these machines each day cover 36,800 sq. yds. of brick pavement, and the report states that the streets are swept cleaner with the machine than by hand. The cost of the cleaning with the hand pickup is about 27 cts. per 10,000 sq. ft.

At Dallas, Tex., a day force of 46 "white wings" is employed to cover all paved streets of the city. The men are assigned to districts the size of which depends on the traffic. In connection with the day force 16 one-horse carts are employed. Each cart takes about five loads of sweepings per day. The average area covered by each patrol sweeper is 6 or 8 blocks. Both brooms and scrapers are used for gathering up the dirt.

Des Moines, Ia., has a "white wing" service in the business district, each man being assigned about three blocks or 1,200 lin. ft. of street. The patrol sweeper uses broom and scraper to gather up the dirt.

At Harrisburg, Pa., the crew engaged in hand sweeping consists of 110 sweepers, three foremen and 11 horses and carts. The total length of streets covered by this gang per day is 43.28 miles. Each sweeper is assigned a section, depending in sizes upon the amount of travel. For gathering up the dirt, the sweeper uses a broom in the business section, and a broom or scraper or both in residence sections.

Hoboken, N. J., uses the patrol system on every street not swept by machine. About 18 men are employed in the 18 districts. The men are equipped with push carts and can and clean the district once a day. The average area of a district is 14,700 sq. yds. For gathering up the dirt brooms are used on wood block and Belgian block pavement; on asphalt scraper and broom are used.

Houston, Tex., employs hand sweeping only in the business district, the work being done during the daytime. The patrol system is employed, each man being assigned four blocks or 1,200 ft. of 60-ft. street. A broom and scoop is used to gather up the dirt into can carriers.

At Huntington, W. Va., the patrol gang, consisting of seven men, covers 8,500 ft. of 53-ft. street per working day. A scraper is used to gather up the dirt.

Jacksonville, Fla., employs hand sweeping only on the principal business streets, about 36 blocks being covered in this way. Each patrol sweeper has four or five blocks to cover. Hand push brooms are used to gather up the dirt.

At Lawrence, Mass., the hand sweeping is done by 33 patrol sweepers, each man covering an area of about 1,100 sq. yds. Three single teams and nine men are employed in taking care of the sweepings. For gathering up the dirt the patrol sweeper uses a broom with scraper back.

New Bedford, Mass., employs both the gang and patrol systems in hand sweeping. The gangs are composed of from six to ten men, each gang being given a district. The area covered by a patrol sweeper is from 6,000 to 10,000 sq. yds. Brooms are used for gathering up the dirt.

At Portland, Me., the area covered by a patrol sweeper is 700 sq. yds. Brooms are used for gathering up the dirt.

At St. Joseph, Mo., 100 blocks of streets are cleaned by hand sweeping, the patrol system being employed. Each patrol sweeper covers about five blocks and uses both broom and scraper in gathering up the dirt.

Springfield, Mass., employs both gang and patrol systems in its hand sweeping. The city is divided into four sections, six men and two single teams being assigned to each section. This is for the macadam and gravel streets. The cleaning is done with brooms and hoes. Horse sweepers are also used in cleaning the macadamized streets. About two miles of streets are covered in a working day; about ¼ mile is covered per man. Brooms and short-handled shovels are used to gather up the dirt.

At Troy, N. Y., a patrol sweeper is assigned from 3,000 to 4,500 sq. yds. according to traffic. They use both broom and scraper for gathering up the dirt. This city has tried the hand pickup machine with revolving drum. The machine gave satisfactory service but was not used on large enough scale to get any figures as to costs, etc. It was found, however, that the machine takes off the fine dust better than brooms.

Hand Sweeping by Gang System.—Of the 21 cities reporting, East St. Louis, Ill., and Fort Worth, Tex., appear to be the only cities employing the gang system alone in hand sweeping. East St. Louis employs hand sweeping on only the down town streets, the area covered in a working day being about two miles. The sweeper uses broom and scraper to gather up the dirt. At Fort Worth, Tex., hand sweeping is employed on the two principal streets and on the cross streets between these two. Hand sweeping is used in the daytime and the streets are washed at night. In the hand sweeping the men are worked in gangs of three, one man on each side of the street and one cart man. The gang begins at one end of street one day and doubles back if they have time. The next day the gang begins at the other end and doubles back. Each gang covers 64 blocks (200 ft. to block) of 60-ft. street, or 768,000 sq. ft. per day. A large pan and small broom are used for gathering up the dirt.

Flushing With Hose.—Of the 21 cities six reported that they flushed their streets with hose. At Altoona, Pa., this work is done by a gang of six men, covering about 10 blocks per day. Six 50-ft. lengths of fire hose with 1⅛-in. nozzle are used in the work.

Flushing by Machine.—At Fort Worth, Tex., a flushing machine is being used to clean a brick-paved street. This pavement is in bad shape, being full of holes and depressions, and the street will soon be repaved. On the street the machine in a working day covers 10 blocks, each block being 200 ft. long and 60 ft. wide. Six tanks (600 gals. to the tank) of water to the block are used for cleaning this street. In the work one man cleans up after the machine, scraping gutter, and one team is used to haul off the dirt. The cost of cleaning this 10 blocks of street averages as follows:

1 team at	$ 3.75
1 laborer at	2.00
1 team at	3.50
36,600 gals. water at $3 per 1,000	10.80
Total	$20.05

This makes the cost per 1,000 sq. yds. about $1.51. Regarding the success obtained with the machine the report states that it is "rather unwieldy to handle but does the work."

At Reading, Pa., 18 to 20 blocks are flushed every night in the week except Sunday. Flushing machines, 600 gals. capacity, are used. About 1,500 gals. of water are used per block. The material is flushed into the gutter and is swept up by regular cleaners in that section in the morning.

Machine flushing is also employed at Troy, N. Y., the area covered per hour by one of the flushers being 3,500 sq. yds. The machines have proved very satisfactory. At Troy all dirt from these machines is taken care of by the patrol sweepers.

At Springfield, Mass., the squeegee is used for cleaning smooth-surface pavements. The success obtained at Springfield with the machine is reported to be very good, and much better than the old method of hand flushing. The squeegee is used at night with the best results. The patrol sweepers take care of the dirt swept up by the machine.

Fort Worth, Tex., at present has two squeegees in operation and will soon put in a third. The daily cost of operating one of these machines in Fort Worth is stated to be as follows:

1 team at	$ 3.75
1 laborer at	2.00
1 team at	3.50
26 tanks of water, 400 gals. per tank, 10,400 gals. at $3 per 1,000	3.12
Total	$12.37

The average length of street covered per working day is stated to be 24 blocks. These machines have proved very satisfactory in Fort Worth.

Cost of Street Cleaning at St. Paul by Patrol System.—Engineering and Contracting, Sept. 4, 1918, gives the following:

During the season of 1917, 58 miles of streets (1,347,051 sq. yd.) of pavements were cleaned by the patrol system (White Wings). The other paved streets were cared for by the ward crews. The total cost of the patrol system, according to the 1916 annual report of M. N. Goss, Commissioner of Public Works, was $70,178 or an average cost of $52.09 per 1,000 sq. yd. per season. The above figures include the cost of shovelers and teams hauling away the street sweepings. The area handled by one man was from 3,200 to 17,600 sq. yd. The force consisted of an inspector at $100 per month, an assistant inspector at $90 per month, from 105 to 125 sweepers, 14 teams at 66⅔ cts. per hour and 15 shovelers at 25 cts. per hour. The working day was 8 hours.

Life of Street Push Brooms.—Engineering and Contracting, Mar. 19, 1913, states that in a discussion of a paper on street cleaning in downtown Chicago, presented before the Western Society of Engineers, Richard T. Fox, General Manager of the Citizens Street Cleaning Bureau said that he had found that the average life of a push broom when used in cleaning granite pavement was 7 days. On asphalt the life of a broom ran up as high as 12 to 15 days. On asphalt in addition to the broom, the sweepers use a scraper with which most of the work is done, so that the broom is not in use continuously. The broom generally used by the Citizens Bureau is made of two rows of African bass with a row of Bahia grass on either side. Heavier brooms, made entirely of African bass, have been used, but it was considered that these did not pick up the fine dust as well as brooms with fine fibrous material on the outside.

Motor-driven Squeegees for Street Cleaning Show Saving.—Engineering and Contracting, March 1, 1916, publishes the following data which are based on tests made by the Municipal Research Bureau of Milwaukee, Wis., comparing costs of horse-drawn and motor-driven squeegee street cleaning:

The cost data show the operating expense of the horse-drawn and the motor-driven squeegees, and that the latter type will perform twice the amount of work of the former at a reduced unit cost.

A careful analysis of the traffic condition of the streets cleaned by squeegees shows that 1,105,324 sq. yd. are subject to this process of cleaning and that from the total yardage the amount of

413,825 sq. yd. should be cleaned 6 times,
308,133 sq. yd. should be cleaned 3 times, and
385,365 sq. yd. should be cleaned 2 times

each week, or a daily cleaning of approximately 700,000 sq. yd.

Average square yards cleaned per day by motor-driven squeegee	80,000
Cost per 1,000 sq. yd., cts	16.5
The assessment per front foot based on a street 30 feet wide and cleaned 50 times a season would be	1.37

The average yardage covered per day by a horse-drawn machine being 35,000 sq. yd., it will require 20 machines, or an additional 8 over the present equipment, to perform the work; but if the motor-driven type were substituted the purchase of only four machines would be necessary.

The difference in operating cost of the two types would be as follows:

Horse-drawn type, average cost per 1,000 sq. yd., cts	25.5
Motor-driven type, average cost per 1,000 sq. yd., cts	16.5
Reduction in cost per 1,000 sq. yd., cts	9

If the motor-driven squeegees were not available, the cost of operating the eight additional horse-drawn machines would be greatly in advance of the motor-driven type, as the following data shows:

8 machines × \$9.635 cost per machine = \$77.08 × 150 days = \$11,562.

By operating these 8 machines it would eliminate the service of—

9 white wings at \$2 per day × 150 days	\$ 2,700.00
8 sprinklers at \$6.34 per day × 150 days	7,608.00
Total	\$10,308.00
Twice weekly squeegee cleaning	3,854.00
Grand total	\$14,262.00
Less the cost of operating 8 squeegees	11,562.00
Effecting a season's saving of	\$ 2,700.00

4 motor-driven machines × \$13.26 cost per machine × 150 days = \$7,956.

Saving over cost of operating 8 horse-drawn machines = \$11,562 − \$7,956, or a saving of \$3,606.

With the same services eliminated for the motor-driven as for the horse-drawn squeegee, the total saving would be

\$14,262 − \$7,956 = \$6,306.

*This item is included because certain streets are only cleaned twice a week that require the service six times weekly; and if performed the maximum number of times would eliminate the stipulated number of white wings and sprinklers.

Cost of Cleaning with Vacuum Cleaners, at San Diego, Cal.—In some of our western and southern cities where the problem of street cleaning is largely one of removing dry dust, vacuum street cleaners have been successfully employed. Engineering and Contracting, Oct. 3, 1917, gives the following data furnished by F. M. Lockwood, Manager, Operating Department of the city of San Diego, Cal.

The city of San Diego, Cal., has operated vacuum street cleaning machines for the past four years. The first machine was purchased in the fall of 1912 and the second in March, 1913, at a cost of $2,200. The apparatus is drawn by three horses; the vacuum arrangement being run by a small gas engine. The outfit is handled by one gas engineer and one teamster. The machines are worked two shifts a day. The costs of street cleaning with the vacuum machines for the first 7 months of 1917, were as follows:

Vacuum No. 1

	Operation	Maintenance	Total cost	Yardage cleaned	Cost per 1,000 sq. yd.
January	$ 317.61	$ 33.16	$ 350.77	2,923,000*	$0.12
February	397.19	41.34	438.53	3,654.417*	.12
March	398.33	86.47	484.80	4,048.069	.11976
April	406.44	44.73	451.17	2,292,853	.196772
May	418.46	137.61	556.07	3,130,837	.17761
June	41.43	493.07	534.50	In shop	....
July	365.78	186.35	552.13†	2,257,354	.244593
Totals	$2,345.24	$1,022.73	$3,367.97	18,306,620	....
Averages	335.03	146.10	481.13	3,051,103	$0.18397

Vacuum No. 2

	Operation	Maintenance	Total cost	Yardage cleaned	Cost per 1,000 sq. yd.
January	$ 350.74	$ 20.77	$ 371.51	3,377,364*	$0.11
February	294.13	23.44	317.57	2,887,000*	.11
March	369.19	16.43	385.62	4,174,581	.092373
April	431.03	38.85	469.88	4,256,759	.11038
May	373.75	27.08	400.83	3,442,492	.116436
June	356.62	.85	357.47	2,985,323	.119743
July	263.74	8.29	272.03	2,947,462	.0923
Totals	$2,439.20	$ 135.71	$2,574.91	24,070,981	....
Averages	348.46	19.39	367.85	3,438,712	$0.106974

* Estimated; no figures available for actual yardage. † This total cost includes a complete overhauling and rebuilding of the entire apparatus.

The above costs include teams at actual cost of feed, care and maintenance of harness, labor, fuel, oil and repairs, but do not include depreciation or interest on the investment.

Suggested Procedure and Cost with Machine Flushers.—The following useful suggestions on motor flushing procedure, published in Engineering and Contracting, Feb. 5, 1919, are given in a report on street cleaning at Rochester, N. Y., submitted by the Rochester Bureau of Municipal Research, Inc., of which James W. Routh is Chief Engineer.

Motor Flushing Practice and Costs at Rochester.—In 1916 the city purchased one motor flusher of 1200 gal. capacity, and in 1917 an additional one of 1,500-gal. capacity was put into service. The first of these is mounted on a 5-ton truck; the second has a 5½-ton truck. A comparison of the two flushers follows:

	Flusher No. 1	Flusher No. 2
Capacity	1,250 gal.	1,500 gal.
Weight filled	12 tons	13½ tons
Indicated horsepower	30	40
Speed (estimated)	6 to 10 miles	10 to 15 miles
Pump (centrifugal)	Direct conn.	Direct conn.
Nozzles	4	4
Strainer	None	2½-in. crane
Time to connect, fill and get away	5 minutes	7½ minutes
Time to empty tank (2 nozzles)	3½ minutes	3½ minutes
Working pressures (on level ground)—		
2 nozzles	18 to 30 lb.	30 to 42 lb.
3 nozzles	18 to 23 lb.	26 to 30 lb.
4 nozzles	10 to 15 lb	22 to 25 lb.
Fuel used per shift—		
Gasoline	7 gal.	9 gal.
Oil	1 pint	1 pint

The two machines are used for flushing some of the main streets. Two men, a driver and an assistant, are used on each machine. The assistant makes the hydrant connections and operates the nozzle levers. When the 1917 season started the flushing was done with new operators on the machines. Both men were experienced motor drivers, but neither knew anything about street flushing; as a consequence they did not always obtain the best possible results.

During the four months, June, July, August and September, 1917, the two machines flushed a total of 12,399,734 sq. yd. of pavement, the total number of flushing miles traveled being 1,319.18, of which machine No. 1 covered 533.52 and machine No. 2,785.66. The average cost per 1000 sq. yd. for the flushing was 9.62 ct. This figure does not include the costs of the water. An average of 338.6 gal. of water was used per 1000 sq. yd. flushed. The average yardage flushed per hour amounted to 14,515 sq. yd. Of the total yardage flushed, 5,777,000 was asphalt pavement, 600,000 sq. yd. of Medina block and 6,000,000 sq. yd. asphalt and Medina block. On the asphalt pavement the average number of gallons of water used per 1000 sq. yd. was 299.2, and the average yardage covered was 14,976 sq. yd. per hour. The average cost per 1000 sq. yd. was 10.124. In flushing the Medina block an average of 365.4 gal. of water per 1000 sq. yd. was used. The average yardage flushed per hour was 13,171 sq. yd. The average cost was 8.57 ct. per 1000 sq. yd. The cost of operating the flushers for the four months was as follows:

	No. 1 machine	No. 2 machine
Gas*	$ 99.63	$142.71
Oil†	4.84	14.75
Labor	462.75	467.69
Flushing, miles	533.52	785.66
Miles flushed per gal. gas	1.375	1.471
Labor cost per mile	$ 0.8673	$0.5953
Total cost per mile	$ 1.0722	$0.7956

* 388 gal. for No. 1 machine, 534 gal. for No. 2. † 9.75 gal. for No. 1 and 30 gal. for No. 2.

General Comments as to Motor Flushing.—In general, it appears, as a result of tests made, that only two nozzles should be used together on either flusher. In order to save one trip, three nozzles may be used on a narrow street or for flushing the center of a very wide street, if an effective pressure can still be maintained. This qualification is important because it was found that where three nozzles were used together instead of two, less effective pressures, and consequently less side wash, were obtained. The result was that dirty spaces sometimes were left near the center of the street. When four nozzles were used together, water was wasted and, moreover, the nozzles were not all effective, because the two in front interfered with each other and pushed the water straight ahead instead of to one side. The resultant loss of pressure alone is sufficient cause to prohibit the use of four nozzles together at any time, with these machines. A suggested combination of nozzles for different conditions is indicated in Fig. 1.

The efficient operation of flusher trucks depends to a large extent on the drivers, who have expensive pieces of apparatus in their care. Flushers will give good service only when carefully handled and kept in good repair.

Motor Flushing Results.—The cleaning results obtained by motor flushing, with 30 lb. pressure or more, proved to be very satisfactory on asphalt streets. This was not the case, however, on Medina block pavements. These pavements are laid on a sand cushion, and the joints of most of them are not grouted; hence the sand and dirt work up from the bottom through the interstices and make them difficult to clean and hard to keep clean. Where car tracks are paved with Medina blocks without a concrete base, the area included is still harder to clean, because the rails are all on a level, and because dirt and sand deposited on the rails are caught in the grooves. On a rainy day it can be seen plainly how much cleaner are the sides of such streets than is the car track area.

As the motor flushing results obtained on these Medina block car track streets were not all that might be desired, means should be provided for improving the work. With the present apparatus, better results could be obtained by making more trips on such streets. The flushing strokes then could be lapped more. This would make them narrower and more effective, because the side throw would not have to be so far for each individual stroke. (Increasing the number of trips, of course, would increase the cost in direct proportion to the number of extra trips.)

In order to aid in obtaining the desired results, diagrams, based on past performances of the local motor flushing apparatus and needs, have been prepared in the hope that they may be adopted for the guidance of flusher operators. These proposed procedure diagrams, for motor flushers producing a maximum pump pressure of 40 lb., are shown as Fig. 1. If additional flushers are purchased, higher working pressures should be specified. The use of such apparatus would necessitate a modification of the suggested procedure, as fewer trips would then be necessary to obtain the same results. Higher pressures thus would tend also to reduce the unit costs for the work.

As experience elsewhere has proved that on rough pavements the best results can be obtained by hose flushing, it is suggested that certain Medina block pavements be flushed by hose rather than by machine, even if the suggested procedure for motor flushers be adopted and new machines are purchased. Streets paved with Medina block require the use of more water, because they are rougher and dirtier than other pavements. With hose, the water can be concentrated on the dirty spots, and rough places can be given special attention.

Suggestions for Bettering the Service.—The following suggestions are made with reference to obtaining better results from present equipment, as well as to point out desirable factors in purchasing and operating new equipment:

As much valuable time is lost in filling the tanks with water, 4-in. intake pipes and hose, instead of the 2½-in. size now used, would save considerable time. It takes 7½ minutes to stop and fill a 1500-gal. tank, and only 3½ minutes to empty it. Many of the local hydrants now have 4-in. connections, and 4-in. strainers and hose can be obtained on specifications. A recent quotation on 4-in. rubber hose capable of withstanding 140 lb. pressure was $2.21 per foot, without connections. It weighs 2 lb. per lineal foot. This question should be given consideration in purchasing new equipment.

Mileage records are necessary for obtaining good cost data. No speedometers are used on the flushers, and it has been shown that they are hard to keep in order, on account of the vibrations of the trucks. However, hub odometers will give satisfactory service on trucks of this size, and should be supplied so that the proper records can be kept.

A worth while saving could be made in gasoline consumption if the motor were stopped while the tanks are being filled, which is approximately one-half of the time. As starters are little used on heavy trucks, the engine would have to be cranked 25 or 30 times a shift in such an event.

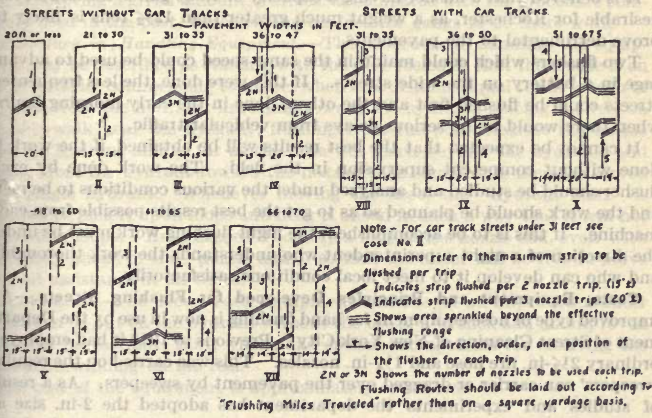

FIG. 1.—Proposed machine flushing procedure for equipment developing a maximum of 40-lb. pressure.

The following data were obtained from a consumption test on the No. 2 flusher to determine the amount of gasoline wasted by running the engine while filling the water tanks:

Total time of test	1 hr. 17½ min.
Less time not running	11 min.
Time to consume ½ gal	1 hr. 6½ min. including 6 starts
Time to consume 1 gal	2 hr. 13 min. or 133 minutes

At 7½ minutes a filling for 28 fillings per 7-hour shift, the flusher is standing 210 minutes. This means that the machine is standing half the time and is then consuming one gallon every 133 minutes. For 210 minutes a shift, the possible saving should be 1.58 gal. For the 65 shifts in a season, the saving would be 102.7 gal., costing $26.70 with gasoline at 26 ct. a gallon. The total gasoline cost for this one truck for the 1917 season was $142.71, and if this were reduced by $26.70 there would be a saving of 18.7 per cent. This saving, of course, would be multiplied by more extensive use of one flusher and by the use of several flushers.

The life of hose could be prolonged if more care were exercised in turning on the hydrants slowly, and also if hanging the hose over one hook were discontinued. If possible, the hose should be hung around the tank of the flusher without kinks. (These points are largely matters of instruction and discipline which should be given constant attention.)

Sometimes sprinkling 15 to 30 minutes before flushing would increase the effectiveness of the results obtained, especially in removing horse droppings. This would soften up the dirt, which then could be flushed off readily. However, the necessity for sprinkling should be determined by the judgment of the man directly in charge of the flushing work.

It is believed that a flusher having a capacity of 1,500 gal. is the largest size desirable for Rochester, as a weight much greater than 12½ tons is likely to prove detrimental to the pavements.

Two flushers which could maintain the same speed could be used to advantage in a battery on the wide streets. If this were done, the less frequented streets could be flushed first and the others done in the early morning hours, when there would be no serious delays from vehicular traffic.

It cannot be expected that the best results will be obtained if the work is done without competent supervision in the field. The work done by each flusher should be studied and analyzed under the various conditions to be met, and the work should be planned so as to get the best results possible from each machine. If this is to be accomplished, the night flushing work must be under the direction of a night superintendent who understands the work thoroughly and who can develop it to meet local conditions satisfactorily.

Costs, Equipment and Principles Developed for Flushing Streets.—An improved type of hose equipment for hand flushing is now in use by the Department of Street Cleaning of New York City. Previous to 1915 it had employed ordinary 2½-in. fire hose and 1¼-in. nozzles. This was carried on the regular sweepers' can carrier or dragged over the pavement by sweepers. As a result of studies and experiments the department has adopted the 2-in. size as standard for the city, and has developed a new hose reel and new hydrant equipment. Engineering and Contracting, Jan. 3, 1917, gives the following description of the New York equipment and principles taken from a paper by Raymond W. Parlin, formerly Engineer with the New York Bureau of Municipal Research, prepared for the 1916 annual convention of the American Society of Municipal Improvements.

As a result of the experiment the following general principles for hand flushing appear to have been established:

General Principles of Hand Flushing.—(1) The economical size of equipment is dependent upon the hydrant pressures available and the length of hose used.

2. When the pressure at the nozzle is in excess of 25 lb. per square inch, water is delivered through a ¾-in. or 1-in. nozzle faster than it can be properly used by two men and it is accompanied by excessive splashing.

3. When the pressure at the nozzle is less than 18 lb. per square inch, water is not delivered fast enough to keep up with the men nor with force enough to enable them to do effective work.

4. The smallest size hose which will give pressure at the nozzle between 18 and 15 lb. is the most economical for use.

5. Better results can be secured by spraying ahead as far as the stream will

reach, to give the material on the street a preliminary soaking prior to the direct flushing, than can be secured by the direct flushing of a dry pavement.

6. Larger quantities of water are required to clean rough pavement than smooth, and therefore a slightly larger nozzle may be used to advantage. (It is estimated that a ¾-in. will be satisfactory for asphalt and a 1-in. for rough Belgian block.)

7. Shut-off nozzles are necessary whenever working in traffic, both to save water and to prevent accidents.

8. Where water mains are large enough for proper domestic and fire supply, flushing will not interfere with the ordinary household use.

9. A hose reel will enable the gangs to do more work with the same expenditure of energy and at the same time lengthen the life of the hose.

10. By the adoption of procedure which prevents any "back tracking" of the equipment, over four miles of walking can be saved per gang per 8-hour day in covering a given amount of street, as compared with the procedure commonly used in the past, which saving enables the gangs to do more work.

Procedure in Handling Equipment.—The procedure in handling the equipment may be described as starting with the hose reeled so that the nozzle is on top or outside; commencing to unreel when at a distance equal to the length of the hose from the hydrant; unreeling toward the hydrant; placing the reel on the side-walk near the hydrant; flushing from the point nearest the nozzle past the hydrant and as far as the hose will reach beyond the hydrant; and reeling from the hydrant toward the nozzle; thus completing the area served by a single hydrant. Whenever moving the hose, the "hydrant man" is required to pick it up in loops and drag it ahead in such a way that it will not cross other loops. He is expected to keep a loop at the nozzle end, even with or slightly ahead of the "nozzle man," so that the latter will be free to move without assistance at all times.

Equipment.—The New York equipment consists of an improved reducer which can be put on the hydrant without the use of a wrench and an improved reel with its tool box, third wheel, and special arrangement for receiving the reducer in winding on the reel.

The cost of the equipment is approximately as follows:

Three 50-ft. lengths 2-in. rubber hose at 60 ct. per ft.....	$ 90.00
One ¾-in. shut-off nozzle..............................	7.00
One 2½-in. to 2-in. reducer, hand swivel type..........	2.25
One hydrant key..	.15
One hose reel..	30.00
	$129.40

(Rubber-covered hose is preferable to cotton-jacket hose for this work.)

The cost of operating with this equipment is as follows:

Annual and Unit Costs Based on 200-day Season and One 8-hour Shift Per Day

Dirty Belgian block pavement; night work.
Force, 1 gang.
First cost equipment, $130; hose, $90.
Life hose, 250 working days; other equipment, 1,200 working days.
Interest at 5 per cent. Water at 5 ct. per 1,000 gal.
Area flushed per shift, 23,000 sq. yd.
Area flushed per year, 4,600,000 sq. yd.

Fixed Charges

	Per year
Depreciation reserve (hose not included)	$ 7.00
Interest	6.50
Maintenance:	
Repairs and painting	15.00
Storage:	20.00
Operations:	
Hose	72.00
Laborers, 2 at $2	800.00
Water, 900 gal. per 1,000 sq. yd	207.00
Total annual cost	$1,127.50
Cost per 1,000 sq. yd	24.5 cts.

When cleaning 30,000 sq. yd. per day the cost per 1,000 sq. yd. is 19.8 cts.

Upon less heavy work and smooth pavements, New York gangs have been able to flush effectively 30,000 or more square yards in 8 hours, making as many as 45 connections to hydrants.

Comparison of Various Types of Street Flushing Equipment.—Mr. Parlin also gives comparative annual and unit costs for cleaning with various types of equipment. These figures are based upon actual experience in the following cities, with equipment noted: Automobile pressure pump, Chicago, Los Angeles, Cal., and Rochester, N. Y.; Street car, pressure pump, Worcester, Mass.; Horse-drawn, pressure pump, Detroit, Mich., and Milwaukee, Wis.; Horse-drawn, air pressure, Detroit, Mich., and Washington, D. C. He concludes that the most economical examples of the various types of equipment as shown by the cost comparisons are: 1. New York, hose equipment. 2. Milwaukee, horse-drawn equipment. 3. Chicago, auto equipment. 4. Worcester, street railway equipment.

To determine the relation of these various types of equipment to each other a diagram, Fig. 2, was drawn, which shows the unit cost of cleaning various areas with the four types of equipment. The data used in constructing the diagram were based upon that obtained from the cities noted above and the assumption that the area represented the schedule area to be covered each day for 200 days.

This diagram shows that hose flushing on small areas was the most economical method; that up to 40,000 sq. yd. the horse-drawn equipment was next in economy; that from 40,000 sq. yd. to 90, 000 sq. yd. the hose was about as economical as the automobile; that from 90,000 sq. yd. to 120,000 sq. yd. the automobile was supreme, and for daily schedule areas of over 120,000 sq. yd. the automobile and street car equipment give nearly the same economy.

This means, states Mr. Parlin, that small cities which do not have over 40,000 sq. yd. of hard pavement to clean each day can better afford to use hose equipment if hydrants are close enough together and plenty of water is available. If local conditions prevent the use of hose, then horse-drawn equipment is economical if only flushing is required. If both flushing on the hard pavements and sprinkling on the macadam or gravel streets is desired, the automobile appears to be by far the most economical equipment.

In large cities there appears to be no doubt that the automobile and street car equipment are the most economical, perhaps with the possible exception of those small or inaccessible areas which the larger equipment cannot reach. On such areas hose equipment can well be used as auxiliary to the machines.

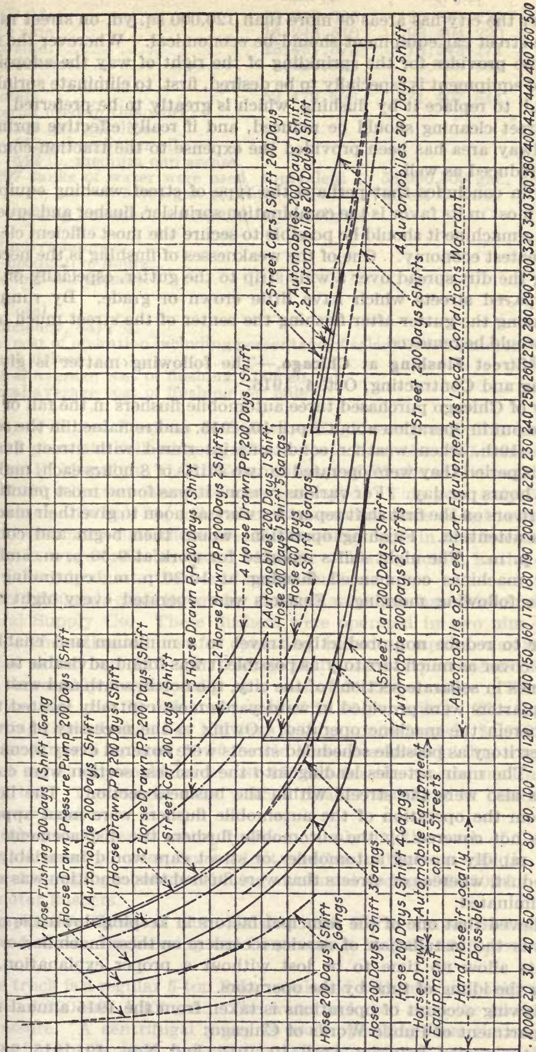

Fig. 2.—Comparison of various types of street flushing equipment.

Wherever the city has areas of more than 120,000 sq. yd. on street railway streets the street car equipment should be economical. Wherever the street car franchise provides for the sprinkling of the right of way the adoption of this type of equipment is especially to be desired, first, to eliminate sprinkling, and, second, to replace it by flushing, which is greatly to be preferred. The costs of street cleaning should be reduced, and if really effective sprinkling of the railway area has been provided the expense to the traction company should be reduced as well.

Mr. Parlin concludes that perhaps the type of street washing equipment which has most in its favor is the combination sprinkler, flusher and squeegee. With such a machine it should be possible to secure the most efficient cleaning and the greatest economy. One of the weaknesses of flushing is the necessity for leaving the dirt spread over a wide strip to the gutter, especially on dirty smoothly paved streets which have little crown or grade. By running a squeegee along the gutter after flushing the center of the street much of this objection would be removed.

Cost of Street Flushing at Chicago.—The following matter is given in Engineering and Contracting, Oct. 4, 1916.

The city of Chicago purchased three automobile flushers in the fall of 1914. These were put in operation about April 10, 1915, and remained in the service until Nov. 19th, when weather conditions interfered with street flushing. During this period they were operated in two shifts of 8 hours each, making a total of 16 hours per day. For various reasons it was found most practical to have the drivers on the first shift report for work at noon to give their machines one hour's attention. Flushing operations would then begin and continue until 9:30 p. m. The night shifts reported for work at 9:30 p. m. and after caring for machines commenced flushing at 10:30 p. m., continuing until 7 a. m. the following morning. Flushers were operated every night except Sunday.

In order to reduce non-productive travel to a minimum and enable the flushers to cover as much territory as possible it was found advisable to house the machines in separate sections of the city, the north, south and west sides. Suitable quarters were provided in ward yards most centrally located to the section wherein the machine operated. Owing to the necessity of covering as much territory as possible scheduled streets were covered every second day or night. The main arteries leading into the business section were covered nightly, as also were the streets within the business section. The benefits derived from the operation of the automobile flushers were most apparent. On streets not covered by the automobile flushers the displacement of air caused by rapidly moving automobiles or street cars would invariably raise a cloud of dust, whereas on streets that were flushed this condition was almost entirely eliminated.

It is believed that one of the principal factors in keeping down the cost of flushing was the installation of service recorders on these machines. These instruments allow no time to be lost without a proper explanation, thus preventing the idling of time by the operators.

The following account of operations is taken from the 1915 annual report of the Department of Public Works of Chicago:

During the period between April 10, 1915, and Nov. 19, 1915, 9,939.52 miles of streets were flushed, with a total of 271,407,644 sq. yd. cleaned, divided as follows:

	Lin. ft.	Sq. yd.	Cost
North side	19,213,606	96,961,529	$ 3,303.45
South side	16,248,540	93,404,220	3,375.15
West side	15,491,575	73,543,171	3,161.87
Loop district	1,525,976	7,768,661	946.40
Totals	52,479,696	271,407,644	$10,786.87

Material used in this work:
12,547 gal. gasoline.
572 gal. cylinder oil.
642 lb. medium cup grease.

39,297 tanks of water were used, equivalent to 58,990,500 gal., or an average of 5,865 gal. of water per mile of street flushed.

The working hours are accounted for as follows:

	Hours
Productive hours	7,745.08
Non-productive hours	435.01
Time lost (all causes)	1,356.45
Total	9,536.54

Efficiency, 83⅓ %.

Total cost of operation including percentage of salary of head motor truck driver	$11,209.87
General average cost of flushing 1,000 sq. yd.	.041
General average cost of flushing per mile	1.13

Cost of Motor Flushers at Ottawa.—Engineering and Contracting, April 3, 1918 gives the following significant facts from the 1917 annual report of Andrew F Macallum, C. E., Commissioner of Works of Ottawa.

In 1916 82 street sweepers were employed. This year only 55 sweepers were hired, although 2¾ miles of new pavements were added to the sweeping area. Assuming that there are 170 working days in the season, the total saving in wages will be about $12,400. This reduction in the cost of the work is largely due to the use of motor flushers.

Two 1,200-gal. capacity motor flushers were purchased in April from the General Supply Co. These flushers were operated in two nine-hour shifts daily. The estimated cost for operating, including repairs, was $32 per day, and the actual cost $31. An average of 18 miles of pavements of all widths were thoroughly washed daily at a cost of $1.72 per mile. (The estimated daily average was 20 miles at a cost of $1.60 per mile.) The total cost for operating these flushers for 150 days will be approximately $4,650.

These flushers replaced 20 of the old horse-drawn sprinkling wagons which, if used regularly, would have cost $16,800 for the season, making a saving of $12,150. The streets were washed cleaner and kept in better condition than ever before.

In other words, each motor flusher not only did the work of 10 sprinkling wagons drawn by horses, but made it possible to dispense with the services of 14 street sweeping laborers, effecting an annual saving of $8,500 for each of the two motor flushers.

Comparative Costs of Auto Flusher and Horse-drawn Sweeping Outfit, Portland, Ore.—Engineering and Contracting, May 31, 1916, gives the following:

The truck is a regular 5-ton Riker equipped with tank, capacity of which is between 1,200 and 1,300 gal. The water is forced onto the street under 50 lb. pressure. A centrifugal pump is used, operating from the engine. The tire equipment is 40 × 6 Goodrich Demountable all around. This truck cost the city $5,500, complete, and operates with a crew of three men at a cost of $0.1384 per 1,000 sq. yd. It leaves very little refuse for carts to pick up, the largest portion of this going into the sewers. By this process the streets stay clean longer, as no sediment is left to turn to dust as in the case with sweepers. The sweeping outfits represent an outlay of $5,620 as follows:

3 sweepers	$1,200
1 sprinkler	400
Carts	500
12 horses at $250 each	3,000
8 sets of harness at $50 each	400
4 sets of harness at $30 each	120
	$5,620

The sweeper required a crew of 12 men and the average cost per 1,000 sq. yd. was 31 cts.

Portland has 370 miles of paved streets, with 20,800 square yards to the mile. One of the trucks will cover 6 miles a day at a cost of $17.27. The sweepers covered the same ground in an equal time at a cost of $38.69. Thus the truck is saving the city $21.42 in a working day of eight hours. Allowing two eight-hour shifts with an average of 300 days to the year, it will be seen that a saving of $6,426.00 is effected, or enough to pay for the truck. These operating costs do not include depreciation.

Costs of Flushing and Scrubbing at St. Paul, Minn.—The following is taken from Engineering and Contracting, Nov. 1, 1916.

The equipment used by the Bureau of Sanitation of St. Paul, Minn., for flushing and scrubbing paved streets consists of five Studebaker power flushers, two 2-horse-drawn Hvass squeegees, one 2-horse Kindling squeegee and one 3-horse Hvass squeegee. According to the annual report of M. N. Goss, Commissioner of Public Works, the area of paved streets flushed and scrubbed in 1915 was 1,493,000 sq. yd. This does not include the pavement laid in 1914 or 1915 on which very little flushing was done in 1915. The cost of this service was as follows:

Team hire	$6,389	
Labor	2,504	
Gasoline, 9,308 gal	912	
Lubricating oil	123	
Water (32,145,850 gal.)	1,285	
Repairs	1,469	
		$12,685
Miscellaneous labor	357	
4 new engines for flushers	1,400	
1 Hvass squeegee	950	
1 Kindling squeegee	1,200	
		3,907
		$16,592

The Street Railway Co. paid its proportion of this cost which was 24.2 per cent, or the ratio of the street railway area to the entire area of streets flushed.

In the congested business district bounded by St. Peter St., Eighth St. and Third St. and Broadway all streets are flushed every night during the season. This district comprises 7.12 miles of streets or an area of 146,400 sq. yd. The crew consists of one foreman, three teams at 60 ct. each per hour and two gutter cleaners at 25 cts. each per man. The cost of one night's flushing (8 hour shift) in this district amounts to $27.61. This includes gasoline, lubricating oil and water, but not repairs, interest or depreciation. This is 19 ct. per 1,000 sq. yd. for one flushing. The flushers are used on the day shift on streets outside of the so-called congested district. The day shift work nine hours. Paved streets are flushed or scrubbed at least once a week during the season.

As a matter of comparison of cost, the W. Seventh St. district, with an area of 89,700 sq. yd., 68,000 sq. yd. of which is sandstone, on the level, with street car tracks and very heavy traffic and with intersecting traffic streets as follows: 8,500 sq. yd. of asphalt, 10,800 sq. yd. of creosoted wood block and 2,400 sq. yd. of brick, costs for one flushing $39.80 or 44 ct. per 1,000 sq. yd. This district is flushed once a week and is one of the hardest districts to clean.

The E. Seventh St. district with an area of 150,400 sq. yd., of which 109,800 sq. yd. are brick, steep gradient, street car tracks, automobile traffic and light miscellaneous traffic with intersecting streets as follows: 25,600 sq. yd. of asphalt and 15,000 sq. yd. of sandstone, cost for one flushing $43.56 or 29 ct. per 1,000 sq. yd. The crew in each of the above cases was one foreman, three teams and two gutter cleaners working one 8-hour shift.

The squeegees are operated only in the day time on smooth pavements, such as creosoted wood block or asphalt. The 3-horse squeegee scrubs 42,000 sq. yd. of pavement in one 9-hour shift and uses 11,000 gal. of water, the resulting cost being 17½ ct. per 1,000 sq. yd. scrubbed. The 2-horse squeegees do a slightly less amount. The total amount of water used for street flushing purposes during the 1915 season was 32,145,850 gal. for which the department was charged $1,286.

Street Flushing at Worcester, Mass., by Trolley Flushers.—Engineering and Contracting, April 4, 1917, gives the following:

For many years the city of Seattle has been celebrated for its cleanliness and low death rate (8 per 1,000). Seattle has used flushing wagons that hurl powerful streams of water upon the pavements and wash them as clean as a kitchen floor. The flushers work at night. Worcester, Mass., has adopted the same method, but with a variation that is worthy of notice. In Worcester trolley cars, instead of wagons, are used.

Each flushing car has a 2,900-gal. tank that is filled from sub-surface hydrants. For flushing, a centrifugal pump on the car, driven by a 45-H. P. motor, delivers 600 gal. per min. at a pressure of 80 lb. per sq. in. Three nozzles on the car itself and two on swinging arms that reach almost to the curb, flush the widest street clean.

The best results are obtained by sprinkling the street with the car about an hour before flushing, for this softens up the dirt. A 40-ft. street requires about 3,000 gal. per mile for the sprinkling and 10,000 gal. for the subsequent flushing, or a total of 13,000 gal. per mile. A car will sprinkle and flush 9 miles of street (averaging about 30 ft. wide) per night of 8 hours, using 95,000 gal. of water.

The American Car Sprinkler Co., of Worcester, has the contract for this work, and its annual charge for a 30-ft. street is about $550 per mile.

A few push-cart men clean up the gutters in the morning, but the rest of the street is left perfectly clean by the flushing.

Previous to the use of the trolley flushers, when day sprinkling was required, three car sprinklers, making several trips over each street every day, covered the same area now covered by the two flushers, which make one trip nightly for sprinkling and flushing combined. The flushers work 8 hours and the sprinklers under the old method 14 hours.

The amount of water used under the flushing system is about 60 per cent of that used under the old style day sprinkling, while the present combined sprinkling and flushing uses about 85 per cent of the amount.

The cost of catch basin cleaning has been just about doubled on streets which are flushed. The average cost per catch basin per year for cleaning was $1.95, and on streets flushed this has been increased to $3.90.

The method of flushing by cars is not only cheaper than hand cleaning with brooms, but what is even more important is the fact that flushing is far more effective than brooming. Moreover, sprinkling during the day is no longer necessary to keep down the dust.

Comparative Costs of Street Sprinkling with Motor Trucks and Horse Drawn Tanks.—Engineering and Contracting, Sept. 5, 1917, publishes the following comparative costs of street sprinkling with motor-driven sprinklers and with team-hauled tanks, given in a report of the Board of Public Works, Los Angeles, Cal.

Savings in money and water, more efficient sprinkling and relief of traffic conditions were among the benefits reported after a year's use of the motor-driven trucks.

Teams:	
Total team days of 8 hours each	10,910
Loads of water used, 550 gal. per load	303,722
Average loads of water used per day (per team)	*27.8
Miles of streets sprinkled	47,209.7
Miles of streets sprinkled per day, average (per team)	4.33
Cost for team hire	$51,301.16
Cost for team hire per mile of street sprinkled	$ 1.087
Motor Sprinkling:	
Total truck days of 8 hours each	1,178.25
Loads of water used, 1,200 gal. per load	49,618
Average loads of water used per day (per truck)	†42.11
Miles of streets sprinkled	20,303.38
Miles of streets sprinkled per day, average (per truck)	17.23
Cost for truck hire	$17,519.98
Cost for truck hire per mile of street sprinkled	$ 0.863

* This is a rate of a load in 17 min. for the team tank, sprinkling 820 ft. of street.

† This is a rate of a load in 11 min. for the truck tank, sprinkling 2,170 ft. of street.

Comparative Cost of Bituminous Surface Applications and Water Sprinkling in New York City.—Engineering and Contracting, May 15, 1912, gives the following data from a paper by William H. Connell before the A. S. C. E.

The results from tar have been very satisfactory, about ⅓ or ½ gal. per sq. yd. being applied and covered with torpedo sand or fine wash gravel. This formed a very desirable surface, at a cost of $0.035 for ⅓ gal. and $0.045 for ½ gal. per sq. yd. In these treatments the tar was applied cold.

The Grand Boulevard and Concourse was treated with a heavier tar, which was applied under pressure through a hose at a temperature of 220° F., ⅗ gal. per sq. yd. being used, and then covered with torpedo sand or fine washed gravel. This road has been in use for 6 months, and although it has been subjected to very heavy, high-speed automobile traffic, it is now in first-class condition. The cost was $0.138 per sq. yd., which is high, owing to the lack of proper facilities for handling the bituminous material and the numerous delays which occurred. In the Borough of the Bronx a fair cost would be from $0.09 to $0.10 per sq. yd. for this treatment. Before the application of tar in these treatments, the road was thoroughly swept with horse-drawn and hand brooms.

Asphalt road oil of about 20° Baumé gravity was applied to a number of macadam roads, using ¼ gal. per sq. yd. On roadways having light or medium traffic, one application a year was sufficient to keep the road dustless; heavily traveled roadways required two and, in some instances, three applications. The cost of this treatment was $0.013 per sq. yd. when ¼ gal. per sq. yd. was used. The oil was applied with a pressure distributor on a number of roadways, and the cost was $0.009 for ⅕ gal. per sq. yd. This method of treatment is both economical and desirable. Just enough pressure was applied (about 15 lbs.) to drive the oil into the interstices of the stone to a sufficient depth to avoid having a mushy road surface. Before the application of the asphalt road oil, the surface was swept with a horse-drawn sweeper only.

Preparations are now under way to equip the Bituminous Application Division with a sufficient number of pressure distributors to do all the bituminous surface work in 1912. For the cold treatments, the distributing device can be attached to an ordinary water sprinkler. The heavier materials will require the use of heater wagons.

The bituminous material applied to the different roadways was selected from the standpoint of its adaptability for each particular case. The stone used consists largely of Rockland Lake and Clinton Point crushed trap rock.

The following table gives a comparison of the cost of surface treatments and water sprinkling in the Borough of the Bronx, the water sprinkling being based on sprinkling from three to four times a day for 180 days, at $5 per day for a team, and water at $0.10 per 100 cu. ft.:

Tar, ⅓ gal. per sq. yd.	$0.035
Tar, ½ gal. per sq. yd.	0.045
Asphalt road oil, about 20° Baumé gravity, ¼ gal. per sq. yd.	0.013
Two applications	0.026
Asphalt road oil, about 20° Baumé gravity, pressure distributor, ²⁄₁₀ gal. per sq. yd.	0.009
Two applications	0.018
Water sprinkling	0.051

The following figures relate to material and wages paid to laborers in the Borough of the Bronx:

Foreman, per day	$4.00
Laborers, per day	2.25
Average price of tar at freight yard, per gal.	0.061
Average price of asphalt road oil at freight yard, per gal.	0.04
Torpedo sand on work but not spread, per cu. yd.	1.30

With the use of pressure distributors in 1912, the cost of applying the tar will be greatly reduced. The former method required the services of three laborers, whereas a distributor will need only one man to operate it, and moreover the time required to apply the tar will be reduced.

Further costs of oiling road surface are given in Chapter XV.

Cost of Calcium Chloride as Dust Preventive on Gravel Roads.—The Connecticut Highway Commission has obtained excellent results from the use of calcium chloride as a dust preventive on gravel roads passing through sparsely settled sections. The methods employed in making the applications are described by W. Leroy Ulrich, Superintendent of Repairs, of the State Highway Commission, in Public Roads, from which the matter following is abstracted in Engineering and Contracting, June 4, 1919.

The material is put up in metal drums, holding about 350 lb. per drum, and costs at the present time between $20 and $30 per ton at the point of shipment.

The price varies with the amount purchased. The drums will be painted by the shippers without extra charge if requested. If this is done, material may be stored for future use in any reasonably dry place. If it is not done, the drums, being very light-gauge material, quickly rust out, exposing the chloride to the air, from which it immediately attracts moisture and solidifies, in which form it is very expensive to handle. If properly sealed and handled, when the drum is opened it will roll out in the form of kernels about the size and appearance of popcorn.

In order to obtain the best results the surface of the road to be treated should be kept in shape by the use of a drag for about two weeks previous to the application of the material. This will insure proper cross section and a reasonably smooth surface for receiving the material. The application may be made by laborers spreading with shovels, but this is not satisfactory on long sections as it is too slow and expensive. A uniform distribution can not be obtained by this method. Any ordinary lime sower will spread the chloride, but it is economical to purchase a special machine for this purpose. These machines may be purchased in different widths for use with a single horse or a pair.

In making application with the use of horses the drums are distributed along the road at regular intervals, one at a point if a narrow machine is used, and two if the wider. The necessary interval is determined by the amount of material to be applied. About 1½ lbs. per square yard is necessary for the first application, which should be followed by a second treatment at 1 lb. per square yard. The interval between applications depends upon the quality and condition of the surface on which the material is spread and the character and volume of the traffic carried. Under moderate traffic a good surface would not require more than two applications per year; under heavy traffic three may be necessary. The best results are obtained if the material is spread on the road after a rain, when it is wet, as a better penetration is obtained at this time.

In making an application with a 2-horse machine with a spread of 10 ft., two drums are distributed every 220 ft. This machine will hold the contents of two drums and after filling is run up one side and down the other and then up the middle of the road, stopping at the point where the next two drums have been placed. This applies a little less than 1 lb. per square yard on each edge of the road and nearly 2 lb. on the center 10 ft. This method has proven more satisfactory than making an even distribution over the entire surface. The same method may be followed with the one-horse machine.

In order to eliminate the necessity for the distribution of the drums, the machine may be hauled behind and fed directly from an automobile truck. Eighteen drums may be carried on a 3-ton truck, which, running continuously in one direction, will cover one width for about 6,200 ft. Three trips will complete the treatment of this length of road. This has proven a little more economical than distributing the drums and spreading with horses.

During the handling of the material, all workmen should wear rubber boots, as the chemical action of the chloride is very detrimental to leather. It is also well to provide cotton gloves, otherwise the hands will soon become sore. The hoofs and hocks of the horses, which are working on the distributor, should be cleaned and greased night and morning. After the chloride is melted on to the surface of the road, it will not cause injury to horses or to automobile tires.

Proper application of calcium chloride results in a smooth and practically dustless surface, making a road with almost ideal riding qualities. While not considered as a binder this treatment does toughen the surface, making it less liable to ravel. One of the great advantages of roads treated in this manner is the ease with which the resulting surface may be maintained. All that is required is a light dragging at intervals in order to keep the surface smooth. On account of the moisture held in the surface this may be done whenever necessary without waiting for a rain.

The surface of most gravel roads softens up in the spring when the frost is leaving the ground and the calcium treatment does not overcome this condition. The results in Connecticut show that the treated roads do not mud up any more than untreated roads of the same quality and not as much as roads of this quality which have geen treated with a nonasphaltic oil. The continued use of chloride has an accumulative effect. After two or three years, with two applications per year, the effect of the material is plainly noticeable in the spring, after the road has settled.

During the year of 1918, with labor at approximately $2.75, teams at $7.50, 3-ton trucks at $25, the cost of this treatment in Connecticut per square yard per year (two applications) has been $0.031, divided as follows: Chloride $0.026, handling and application $0.005.

Snow Fighting vs. Snow Removal at New York City.—The following is given in Engineering and Contracting, July 4, 1917.

New methods of snow removal inaugurated in New York City by Mr. J. T. Fetherston, Commissioner of Street Cleaning, have more than trebled the rate of removal and also have reduced the cost 68 per cent. Under the new plant the old system of removal by contractors has been amended so that the city now does the larger part of the work by the direct employment of labor and the use of department equipment. The following outline of the methods employed is taken from the recently issued report of the Department of Street Cleaning, covering the year ending Dec. 31, 1916:

Owing to contracts in existence when the present administration assumed direction, application of the new principles was confined in the winter of 1913–1914 to a limited use of sewers for snow removal. As a result of the winter's experience and tests that were made, it became apparent that the city had had available for years a possible solution of the problem of rapid snow removal, through the extensive use of sewers, not alone after a snowfall, but during the progress of the storm. The experience of that winter demonstrated to the satisfaction of the administration that snow work should be started with the storm and clean snow dumped into the sewers as it falls. Such methods imply an attempt to keep pace with a storm, instead of trying to dig the city out after a block has occurred.

In the summer and fall of 1914 the Department made preparations to apply during the following season its new programme for handling snow. This preparation included a thorough survey of the city's sewer system, specialized instruction of the Department's forces, enlargement of standard equipment, enrollment of emergency workers as "snow fighters" and the plotting of the city so that practically 50 per cent of its entire area could be cared for by the simultaneous attacks of the "snow fighting" gangs, within four hours after the call to go to work. Plans called for pushing snow into sewer manholes by the use of panscrapers operated by hand, and drag-scrapers, each drawn by a single horse.

These plans did not eliminate contract snow removal, as large quantities of snow still had to be carted to the river dumps or main sewers; nor did they release the city railways from their obligations to clear the snow from certain streets carrying railway tracks. But up to this time the city had depended upon trucks alone to haul snow from the streets to water front dumps and, consequently, the speed of snow removal had depended upon the supply of trucks available for the work.

Results of the application of the new system during the winter of 1914–1915, as compared with preceding winters, showed the rate of removal doubled as compared with the best previous record, and that the cost per cubic yard decreased 67 per cent compared with lowest previous unit cost record. The total fall of snow for the winter was 22.4 in., and the total cost of removal was $523,892. If the entire snowfall of the winter had been handled by contractors' trucking forces alone, at the lowest previous contract rate ($0.367 per cubic yard), the cost of the season's work would have amounted to $1,584,822. The total area of the streets in the three boroughs scheduled for snow work in in the winter of 1914–1915 was 32,607,081 sq. yd., or 927 miles of streets.

When the first snow of the winter of 1915–16 arrived, it found the Department further strengthened by valuable additions to its equipment and better trained organization; but the beneficial effects of these improvements were counteracted, to some extent, by the shortage of labor available for emergency snow work. Schedules called for 14,737 emergency laborers, working in 9-hour shifts, while storms were in progress. The average number of men secured was 9,060, or 61 per cent of the required number. Use of snow plows, designed by the Department and attached to commercial motor-driven trucks, aided in reducing the effect of the shortage of labor. These plows were used for piling snow in the center or on the sides of streets.

Over 50 in. of snow fell during that winter, compared with the average fall of 32.2 in. The total area scheduled for snow work in the three boroughs had increased to 33,311,899 sq. yd., which represented 946.17 miles of streets. Nearly 12,000,000 cu. yd. of snow (truck capacity basis) were removed at a gross cost of $2,521,299.55, or at the rate of 21.2 ct. per cubic yard. This was more than double the quantity (truck capacity basis) removed by the city during any previous winter season, and the cost was less than half the average cost per cubic yard for the previous 7 years. No serious complaints were made regarding snow removal during the season, which is creditable to speedy action in opening main arteries with automobile snow plows, employment of the largest procurable force of emergency laborers during storms and the use of sewers for the disposal of snow.

Including the statistics of the snow storm of Dec., 1917, the total fall of snow for the calendar year 1916 was 54.6 in.; average for the previous 47 years, 32.16 in. The daily rate of removal during 1916 was 198,000 cu. yd., compared with the grand average, 1907 to 1915, inclusive, of 71,886 cu. yd. Rate of daily removal during and following the storm of Dec. 15 last surpassed all previous records. There was a snowfall of 12 in. The cubic yards removed totaled 2,178,301. Nine days were required for completion of the task, the daily removal approximating 242,000 cu. yd. This record was achieved despite a shortage of labor, because of the almost perfect working of the system established by the Department. An important feature was the use of 120 city snow plows driven by commercial motor trucks.

The following tables present statistics of snow storms and snow removal work during 1916. The tables showing the area assigned to each of the three forces engaged upon snow work show only slight changes from the tables showing corresponding statistics in 1915.

TOTAL AREA AND MILEAGE OF STREETS

Borough	Street area, sq. yds.	Length, miles
Manhattan	16,201,019	460.25
The Bronx	3,774,456	106.89
Brooklyn	13,250,053	376.68

*Carried on auto trucks for making minor repairs to auto plows in the field.
†Carried in stables for making repairs to auto plows.

The average daily rate of removal for the two years under the old method was 51,390 cu. yd., at an average cost to the city of $0.535 per cubic yard. Under the new method, the average daily rate of removal for the two years was 234,211 cu. yd., at an average cost of 0.188.

Cost of Snow Removal by South Park Commissioners, Chicago, was given by H. F. Richards, in a paper presented March 4, 1918, before the Western Society of Engineers. Extracts from the paper, as given in Engineering and Contracting, April 3, 1918, follow.

The areas covered by the South Park Commissioners in their snow cleaning work include about 67 miles of drives and 175 miles of walks and 90 to 95 acres of skating ice.

The South Park snow handling equipment includes five 3-wheeled tractors fitted with detachable V-shaped plows having wing extensions and with detachable revolving street brooms, one 4-wheeled tractor equipped with both V-shaped and straight moldboard attachments, some very large snow hauling wagons, 20 large 4-wheeled iron plows of the road grader type, 17 large wooden 4-wheeled tractors fitted with detachable revolving street brooms, one 4-wheeled tractor equipped with both V-shaped and straight moldboard attachments, 17 large wooden, 4-wheeled plows similar to the road graders, 6 small iron-wheeled plows used mainly for cleaning snow off sidewalks around the smaller parks, several straight moldboard attachments for auto trucks, and a considerable number of large ajax scrapers, triangle plows, ice shaving machines, etc., for cleaning the fields of skating ice.

The following statement shows the cost of cleaning snow from the park driveways, the time required for carrying out the work being 3 days:

First Day (*A. M.*).—Plowing snow to the gutters from Washington Park stables to 12th St. and Michigan Ave., over the following driveways:

	Width, ft.	Area, sq. yd.	Miles
Washington Park (part)	40–50	30,000	1.20
Grand blvd. (center drive)	55	64,416	2.00
South Park ave. (35th to 33rd)	42	6,122	0.25
33rd st. (South Park to Michigan)	42	8,282	0.31
Michigan ave. (33rd to 12th)	50	67,320	2.25
	.....	176,140	6.01
Cubic yards of snow on drive, at 4 in.			19,571
Cubic yards of snow on drive, at 6 in.			29,357

For a 4-in. snowfall it is estimated that 40 horses (5 right 4-horse hitches and 5 left 4-horse hitches) will be required to plow these drives in 5 hours before noon. At the rate of $6 per 8-hour day for team and driver, the cost will be $75.

For a 6-in. snowfall it is estimated that 48 horses (6 right 4-horse hitches and 6 left 4-horse hitches) will be required. At the rate of $6 per 8-hour day for team and driver, the cost for 5 hours' work will be $90.

Cost of Plowing Snow Off Above Driveways

	Per mile of drive	Per 1,000 sq. yd. pavement	Per cu. yd. of snow
For 4-in. snowfall	$12.49	$0.427	$0.00384
For 6-in. snowfall	14.98	.512	.00307
Total cost (without overhead) for 4-in. snowfall			$75.00
Total cost ((without overhead) for 6-in. snowfall			90.00

First Day (*P. M.*).—In the afternoon half of the teams which plow from the park stables to 12th St. and Michigan Ave., in the morning will plow snow to the sides of the drives on—

	Width, ft.	Area, sq. yd.	Length, miles
Drexel Blvd. (both drives)	40*	70,224	3.00
Oakwood Blvd	50	17,060	0.50
Washington Park (part of drives)	40–50	20,000	0.80
The other half of the teams will plow..			
Garfield Blvd. (South Park to State)	40	11,733	0.50
Michigan Ave. (55th to 33rd)	50	82,228	2.75
	..	201,245	2.75

* Each.

Cubic yards of snow on drive at 4 inches	22,360
Cubic yards of snow on drive at 6 inches	33,541

The cost of the afternoon's work (5 hours) will be the same as for the morning's plowing—$75 for a 4-in. snowfall and $90 for a 6-in. snowfall. These drives will not be gone over twice, but it is intended to go over the drives between the Washington Park stables and 12th St. on Michigan Ave. twice in order to get them as clean as possible, as the first trip over the drives usually does not remove all of the snow.

COST OF PLOWING SNOW OFF DRIVES CLEANED IN THE AFTERNOON OF THE FIRST DAY

	Per mile of drive	Per 1,000 sq. yd. of pavement	Per cu. yd. of snow
For 4-in. snowfall	$ 9.94	$0.373	$ 0.00336
For 6-in. snowfall	11.93	.448	.00268
Total cost (without overhead)			$75.00
Total cost (without overhead)			90.00

Second Day (*Nine Hours' Work*).—Half of the teams will plow to the gutters on—

	Width, ft.	Area, sq. yd.	Length, miles
Garfield Blvd. (south drive—State to Western)	40–25	56,691	3.00
Garfield Blvd. (north drive—South Park to Western)	40–25	68,424	3.50
Other half of the teams will plow snow on—			
A. M.—(From park stables to 79th St. and Bond Ave.)—			
Washington Park (part of drives)	40–50	10,000	0.40
Midway (south drive)	40	21,910	1.00
Jackson Park (part of drives)	40	44,000	2.00
Yates Ave. (71st St. and Bond Ave. to 79th St.)	32–38	36,500	1.75
P. M.—In the afternoon over the following drives:			
Fifty-first St. (including Drexel Sq.)	40	31,976	0.94
East End Ave	50	18,700	0.65
Jackson Park (rest of drives in "outer" circle)	40	70.000	3.00
		358,201	16.24

Cu. yd. of snow on drive: At 4 in., 39,800; at 6 in., 59,700.

As this is a 9-hour day, the cost of plowing the snow after a 4-in. snowfall, using 40 horses, will be $135, at the rate of $6 per 8-hour day for team and driver; in case of a 6-in. snow the cost will be $162, 48 horses being used.

COST OF PLOWING SNOW OFF DRIVES CLEANED ON THE SECOND DAY

	Per mile	Per 1,000 sq. yd.	Per cu. yd.
For 4-in. snowfall	$8.31	$0.378	$0.00340
For 6-in. snowfall	9.98	.453	.00272
Total cost (without overhead) for 4-in. snowfall			$135.00
Total cost (without overhead) for 6-in. snowfall			162.00

Third Day (*Nine Hours' Work*).—One-half of the teams will plow snow to the sides on the following drives:

	Width, ft.	Area, sq. yd.	Length, miles
66th and 67th Sts. (Jackson Park to Ashland)	28	67,518	4.10
* Normal Ave	32	63,580	2.10
Other half of the teams will plow—			
Grand Blvd. (side drives)	25†	58,432	4.00‡
Washington Park (rest of "outer" circle of drives)	40–50	45,000	1.60
		234,530	11.80

* Cu. yd. of snow on drive: At 4 in., 26,060; at 6 in., 39,090. † Each. ‡ Together.

At the rate of $6 per 8-hour day for a team and driver, the cost of plowing a 4-in. snowfall, using 40 horses, will be $135; for a 6-in. snowfall the cost will be $162, 48 horses being in use.

COST OF PLOWING SNOW OFF DRIVES CLEANED ON THIRD DAY

	Per mile of drive	Per 1,000 sq. yd. of pavement	Per cu. yd. of snow
For 4-in. snowfall	$11.44	$0.576	$ 0.00518
For 6-in. snowfall	13.74	.692	.00415
Total cost (without overhead) for 4-in. snowfall			$135.00
Total cost (without overhead) for 6-in. snowfall			162.00

The above costs are based on a rate of 75 ct. per hour—$6 per 8-hour day—for a team and driver. They do not provide for finished cleaning over the various driveways of the South Park system, but cover primarily the clearing away of the "roughage" after snowstorms, such as can be accomplished by a single trip of the battery of plows over the different drives. Where two teams are used on a grader plow, the second driver operates the plow adjustments, so no laborers are necessary in such cases. As will be seen, the cost per mile for cleaning, outside of the downtown district, ranges from $8.331 per mile as the minimum for a 4-in. snowfall to $14.98 per mile as the maximum cost for a 6-in. snow, two teams being used on each grader.

In some instances but one team is used on a grader and then a laborer is required to man the plow. It has been found that this reduces the cost of a single trip, cleaning of a certain driveway, making it from $5.40 per mile for a snow of 4 to 5 in. to $7.20 per mile for a fall of from 5 in. to 1 ft., when the team hire is $6 per 8-hour day and the rate for labor is 30 ct. per hour.

Use of Tractors.—Carefully kept records show that the work of cleaning snow off drives with tractors after ordinary snowfalls can be done at a cost somewhat less than with horse-drawn machines and with them the work progresses much more rapidly, too. In breaking up packed snow and ice the tractor outfits have proved themselves particularly adapted, while they are able to pile the snow over the curbing better than horseplows, leaving the gutters open.

Operating Cost of 20-Ton Caterpillar Tractor in Snow Removal Work.—(Engineering and Contracting, March 3, 1920).

Ten Caterpillar trucks operated in Michigan during the winter of 1919–20, on duties incidental to snow removal and the keeping of state trunk line highways open for traffic. These machines equipped with a 120 hp. motor are rated as a 20-ton tractor, their weight being 13 tons. The following statement from a bulletin of the State Highway Department shows the operating costs for a 2-weeks' period for one of the tractors, used in pulling snow roller and plow:

Gasoline, 175 gal. at 25 ct.	$ 43.75
Lubricating oil, 36 qt. at 17 ct.	6.12
Grease, 3 lb. at 12 ct.	.36
Alcohol, 20 gal. at 90 ct.	18.00
	$ 68.23
Labor, 52 days at $4.00	208.00
Total	$276.23
Number of miles of road opened, 55.2.	
Unit cost per mile of road, $5.004.	

The above costs do not include fixed charges. There were no repairs or renewals during this period.

Cost of Snow Removal With Rotary Plow.—The following is from Engineering and Contracting, May 5, 1920.

A rotary snowplow has been used at Outremont, Que., in clearing the streets of snow. The plow is mounted on sleds, and is drawn by horses.

The blades are operated by a 60-HP. marine engine. The snow is pulverized by the blades and projected upward and then out through specially devised outlets. In a discussion of a report presented to the 1919 convention of the American Road Builders' Association, Capt. J. A. Duchastel, City Engineer of Outremont, gave the following data on work done by the machine in 1917–18:

In one instance the work consisted of removing a bank of snow on each side of Cote St. Catherine Road. This snow had been piled up at a distance of 10 ft. from the car track by the Montreal Tramways snow leveler. The bank was about 10 ft. wide and 1 ft. 9 in. high; the snow was very compact. The cost was worked out in the following manner:

After allowing a depreciation of 10 per cent on the cost of the machine, interest at the rate of 7 per cent, and $241 per year for repairs, it was figured that the fixed charges per day for the machine for a period of 50 working days during the season, was $14. Figuring the cost of gasoline, the time of the operator, the corporation teams and helpers, as well as the time of a grader and snowplow used in connection with this work to remove whatever accumulation of snow was deposited on the sidewalks by this machine, it was found that the cost per lineal yard of cleaning one side only was 7.65 cts. This work covered a period of 23 hours and a bank of snow 6,775 ft. long, 10 ft. wide, and 1 ft. 9 in. high, was cleared in that time. Naturally that was not continuous work.

As a parallel to this work, the cost of removing snow on the same date on another section of the same road, under exactly the same conditions, was kept, the snow being loaded by hand in sleighs and removed to a dump less than ¼ of a mile away. The cost per lineal yard was 23.7cts. This work covered a period of 10 hours and a bank of snow 950 ft. long, 10 ft. wide, and 1 ft. 9 in. high was cleared. As a check on these figures, the cost of clearing Cote St. Catherine Road by the second method in the previous year was looked up, and it was found that the cost was 27.4 cts. Probably the bank was, on the average, a little bit higher.

Cost of Loading Snow by Steam Shovel at Rochester, N. Y.—John T. Child gives the following data in Engineering and Contracting, April 7, 1920.

After snow had accumulated on the ground for over two months a local contractor put his steam shovel grader into commission and attacked the huge accumulations of snow to prove the value and desirability of a steam shovel for loading heavy snow. The results obtained are summed up as follows:

Equipment—

Keystone steam shovel with ½-yard skimmer bucket on 18-ft. boom.

Shovel Cost per Day—

Rent, including operator and fireman	$40.00
Coal, ⅓ ton at $8.75, supplied by city	2.25
2 men to release bucket and help move—hired by city	6.08
Total daily cost	$48.33

This cost is equivalent to 16 men at $3.04—the prevailing rate here when the work started. The rate is $3.36 a day now, which would reduce the equivalent to 14 men.

Working Conditions—Day shift—8 hours.

Straight work loading from a bank of compact snow 3 ft. or 4 ft. high and 8 ft. to 10 ft. wide. Motor and electric railway—traffic heavy on Main St., East, near Stillson St.

Work Done—

Loaded 155 3-yard wagons in 8 hours, or 465 cu. yd.
Cost per load, $0.314.
Cost per yard, $0.104.
Time per load, 480/155 = 3.1 minutes.
Actual loading time—2 min. 6 buckets to a load.

Corresponding Labor Costs are $0.107 and $0.12 for hand labor at the two rates.

After the successful try outs with the ½ yd. bucket the contractor purchased a 1 yd. bucket so as to speed up the loading capacity of the shovel. The first few days several moves were necessary and 30 to 40 per cent of the time was lost because there were not enough trucks available to keep the shovel busy. Under these more or less unfavorable conditions as many as 44 9-yd truck loads were easily handled at a cost of 12.2 ct. per cubic yard.

This shovel was not used early enough in the season to make any prolonged record but it has proven its value under certain conditions and undoubtedly all the available local apparatus of this kind will be listed for emergency snow work next year.

In any event, the steam shovel can be used as a substitute for men at the same cost or less. The larger bucket decreases the actual loading time, and it has several advantages over hand labor. A longer boom will be used next year to reduce the number of moves and give more clearance in loading.

The advantages of the steam shovel for snow loading may be summarized as follows:

1. It can work 3 shifts and better at night in lighter traffic.
2. It could be used to advantage with railway flat cars.
3. It will remove ice and compact snow to the pavement where hand work requires picking and breaking up of the lumps at a greatly increased cost.
4. It can load a higher and hence larger hauling unit.

Motor Trucks for Snow Removal in Chicago.—Motor trucks gave excellent service during the winter of 1917–18, stated W. J. Gilligan in a paper presented before the Western Society of Engineers. In fact, it was found that one motor truck would haul as much snow as five teams.

The following matter, given in Engineering and Contracting, April 3, 1918, is from Mr. Gilligan's paper.

The blizzard of Jan. 6, followed by the storm of Jan. 12, made it necessary for the Bureau of Streets to use methods other than those ordinarily employed. As the budget of the Bureau did not carry a provision for the employment of motor trucks in snow removal work, consent was obtained from the City Council to use motor trucks and the rate fixed at $25 for a 9-hour day. Only patent dump trucks of large capacity were used. The trucks were made up into squads of ten each, each squad being in charge of a ward superintendent, a card puncher and two subforemen. Five loaders were assigned to each truck. In that way trucks were quickly loaded and kept moving, and by working day and night shifts the principal streets in the loop were cleaned in 72 hours. For the reason that transportation lines were scouring the haunts of labor, bidding as high as $1 per hour and meals, and because of the extremely cold weather, it was difficult for the Bureau to keep men at work after it got them, and in order to compete somewhat with the other agencies that were bidding frantically for help it picked out the likely looking material, kept them for the night forces and paid them time and a half, which amounted to $3.97 for 8 hours. In addition, on the coldest nights hot coffee and sandwiches were distributed to the gangs under the direction of a hastily organized commissary department.

The employment of motor trucks in the work of snow removal has shown to the officials of the Bureau of Streets that the results obtained by their use is far superior to that of teams. The large amount of creosote block pavement in the loop made the handling of teams extremely difficult. Unskilled drivers and poorly shod horses made the task of proper maneuvering very hard, and as a consequence traffic was constantly interrupted. With motor trucks no such situations were encountered. The limited dumping spaces handy to the loop is also a strong factor in favor of the employment of motor trucks. The Graham & Morton docks at the foot of Wabash avenue is the largest loop dump, and it will accommodate about 75 teams. At the height of a snow-dumping day or night this spot was a bedlam of yelling, cursing drivers, with the work being often interrupted by staggering and falling horses. It was also necessary to shovel the snow from the tail end of the wagon into the river, while bottom dump wagons deposited their loads on the dock, making it necessary to rehandle it into the river. As many as 66 trucks, which equals 330 teams, used the Graham & Morton dock in one night, coming in and out of the dump without a minute's confusion or delay.

The labor this year was fairly plentiful and of a high caliber. The suspension of building and allied industries threw many good laborers on the market, and the Bureau was able to use them to advantage in loading trucks. The Italian laborer, who comprises 95 per cent of the regular street cleaning force, being as a rule too short and overclothed to be efficient in that kind of work, was carefully excluded from our loading forces. The rapidity with which the Bureau was enabled to handle snow with motor trucks can be judged by the record of Jan. 29, a typical night at the Graham & Morton docks, when 680 loads of snow were dumped in the river by trucks in 480 minutes, an average of one load every 45 seconds for 8 consecutive hours. It might be of interest to note that the record of delivery at the dock was distributed as follows:

Hours between	Loads
6 and 7	118
7 and 8	96
8 and 9	76
9 and 10	70
10 and 11	97
11 and 12	85
12 and 1	75
1 and 2	63

It will be noticed the number of loads decreased as the vitality of the loaders ebbed until after the time coffee and sandwiches were distributed, when it took a strong upward turn.

During the blizzards of Jan. 6 and 12 the Bureau hauled out of the loop 14,611 wagon loads of snow, or 67,202 cu. yd., together with 5,644 motor truck loads, containing 44,179 cu. yd., a total of 20,255 loads, of 111,381 cu. yd., at a cost of $61,004.11. This averaged about 54 ct. per cubic yard.

Snow Removal from Connecticut Highways.—Engineering and Contracting, Nov. 6, 1918, gives the following:

About $40,350 was expended by the State Highway Department of Connecticut for removal of snow from trunk highways in 1917. The mileage covered was 970, and, including the cost of equipment, the rate per mile was about $45. Under normal conditions of snowfall, this cost would probably have been less than $30 per mile. For its work last winter the Department planned to use 18 snow plows attached to the front of its trucks. These proved inadequate because of the unusual winter conditions, and were supplemented by tractors and road machines. On heavily traveled routes practically all the snow was removed while on mixed traffic roads about 3 in. were left. As the result of experiments made in 1917, the Department found that the removal of snow decreased the cost of bituminous repairs the following spring by at least one-third. This is accounted for by the fact that when the snow is not removed the truck traffic is confined to one or two sets of ruts, which ultimately are worn into the road surface.

Costs of Breaking Country Roads with Snow Rollers.—Charles A. French gives the following in Engineering News-Record, Nov. 23, 1918.

Snow rollers have been successfully used by the street department of Laconia, N. H., for several winters past. Four were in operation during the past winter. The rollers are 6⅓ ft. in diameter made in two sections 5-ft. long and have an effective snow-compacting width of about 12 ft. At present prices such rollers would cost $150 to $200 each. The roller weighs 4,750 lb. with nothing on it. When the snow is not too deep it can be operated with four horses and one man. The rollers are used chiefly in breaking country roads. For that purpose they are sent out when there is a snowfall of 4 in. or when a lesser depth has drifted. One man drives the four or six horses attached to the roller and others are sent to shovel when drifting occurs. Sliding places and chuck holes are roughly leveled by the shovelers, and the roller passing over compacts the snow so that it will hold up a team, and the road requires no more attention until the next storm.

An average trip requires six horses, three to four men, and they cover 12 to 15 miles in nine hours, so that, with labor at $2.75 and team with driver at $6.00 for a 9-hr. day, the cost is about $20.75 for 15 miles of road, or about $1.40 per mile. Of course the character of the snowstorm varies this cost.

In this climate if the roads are rolled after each snow or blow they build up through cuts where snow drifts so that the snow blows over the roadway and little hand labor is required. They make a hard path which is wide enough for sleighs to turn out when meeting without getting into the soft snow. Rollers also pack the snow on exposed places that would blow bare and spoil the sledding. In many places we have excellent roads on top of drifts 6 to 8 ft. deep.

In the spring, when the snow softens, some of the deeper drifts have to be cut out with a road machine mounted on runners, but it is surprising how much is saved in hand labor by the use of rollers.

CHAPTER XV

ROADS AND PAVEMENTS

References.—Additional matter on the cost of constructing roads and pavements is given in Gillette's "Handbook of Cost Data" pages 258 to 474, also in Gillette and Thomas' "Highway Construction and Maintenance." Further data on the methods and costs of excavation and grading may be found in "Earthwork and Its Cost" and "The Handbook of Rock Excavation" by Gillette.

Estimating The Cost of Paved Surfaces for Highway Improvement.—Robert E. Thomas of the Illinois State Highway Department, gives the following discussion in Engineering and Contracting, May 2, 1917.

In some instances where bonds have been issued for road building, or where such action is pending, it has been deemed advisable to conduct the program in two distinct steps: one complete issue for the grading and building of all drainage features, and at a later date, another for the construction of the paved surface. Because of the fact that such surfaces often amount to as much as 75 per cent or 85 per cent of the total financial value of the work, it is imperative that investigation should be made relative to the probable cost of this feature before any concerted action is taken. It is hoped that the following information not only will be of assistance in making such an investigation, but also will furnish a method whereby reasonable results may be obtained without a detailed consideration of every individual element.

Because of the many operations and the several ingredients necessary in constructing a paving slab, it appears feasible to divide the estimate of cost into two parts, namely, that on materials and that on labor.

Materials.—The quantities of materials necessary in building a slab of any type are calculable with comparatively slight chance of error after an inspection of the cross-section to be used, and a study of the specifications relating to the same. This is particularly true for such types as macadam (either waterbound or bituminous) or gravel, where the quantity of stone is merely the volume of the completed slab, increased by an allowance for compaction due to rolling. This allowance will vary with the condition of the subgrade, the quality of the stone and the manner of rolling, but under normal conditions will average approximately 20 per cent. The volume of stone screenings for waterbound macadam is also subject to variation, but can safely be estimated at from 15 per cent to 20 per cent of the total amount of macadam stone required. In the case of screenings for bituminous macadam, a proportionately greater quantity is necessary, and the percentage will probably vary from 20 to 25. Practically all specifications state the amount of bituminous material to be used per square yard for bituminous macadam, so no difficulty will be encountered with this item.

The materials making up a cement grouted brick pavement either with a sand or a sand-cement bed, or of the monolithic type, can be estimated by applying a few well-known principles. By reason of the size of brick usually specified for paving purposes, and the space provided for grouting, it will be found that 40 bricks are needed to cover a square yard. For the concrete base it is first necessary to determine the volume of concrete required. By an application of Fuller's Rule, or reference to tables published in any first-class book on concrete, it is possible to secure the quantities of cement, fine and coarse aggregate in a cubic yard of rammed concrete of any desired proportions. In this connection, it might be well to add that the table based upon there being 3.8 cu. ft. of cement in a barrel and 40 per cent voids in the coarse aggregate will most nearly fit average conditions. The product of the total volume in the base and the three figures obtained from the table will be the corresponding quantities of materials necessary. If a sand cushion is specified, the volume is directly obtainable from its dimensions. When the bed is to be a mixture of sand and cement, the quantities of each may be calculated, by using the proper table, in a similar manner to that described for the base. It is practically impossible to compute the quantity of sand and cement to be used for grouting, but experience has shown that a barrel of cement, in a 1 to 1 mix, will cover from 20 to 25 sq. yd. of pavement.

Cement concrete slabs present no difficulty, as the ingredients are computed identically as is the base for a brick pavement.

The materials in a wearing surface of bituminous concrete can usually be computed directly from information contained in the specifications. It may be possible so to modify Fuller's Rule as to make it applicable without gross error to mixtures of this type. The base course of a bituminous concrete pavement is usually of cement concrete or of macadam, and can readily be analyzed by the methods already given.

Undoubtedly some allowance should be made for loss of materials in handling and in transporting, and although a fixed percentage may be greatly in error for any particular case, it is thought that from 5 per cent to 10 per cent for coarse and fine aggregate will represent good practice.

When the estimated quantity of all material has been computed, prices of each F.O.B. the railroad station or siding nearest the improvement site should be obtained. Simple calculation will then permit the total material estimate to be reduced to a square yard basis.

In the foregoing discussion no mention has been made of water, a very important factor not only physically, but, in many instances, financially as well. The availability and cost of water is so affected by local conditions that but few generalities are possible. However, it can be safely stated that a pipe line laid along the right-of-way, supplied by water from nearby streams or driven wells, through the medium of a small pump, will prove uneconomical on types of roads other than those involving the use of cement concrete. When this method is proposed, some use has been made of various formulæ for estimating the cost. On macadam and gravel roads where water is applied in conjunction with the rolling, it is customary to haul the water in sprinkling wagons, and in such cases it is usually secured by pumping from streams or from neighboring farm wells. The cost by either method is incurred mostly by labor, and has been provided for in the data under that division.

Table I has been compiled with the object of giving some idea relative to the amounts of materials in highway surfaces regulated by specifications of proven satisfaction.

Labor.—It has been found by combining the estimated cost of the various operations involved in constructing slabs of different types for highway improvement, that the total labor cost, including the team haul on materials, for any rate of labor, or for any length of haul, may be expressed in terms of an equation:

$$P = ALH + BL + CH + D$$

where,

P = total labor cost per square yard in cents.
H = length of average haul in miles.
L = index number representing labor and team rate per hour.
A-B-C-D = constants for a particular type of slab.

TABLE I.—QUANTITIES OF MATERIALS PER SQUARE YARD OF PAVEMENT

	Brick (sand cushion)	Brick (sand-cement bed)	Brick (monolithic)	Cement concrete	Bitu. concrete, concrete base	Bitu. concrete, macadam base	Bituminous macadam	Water-bound macadam	Gravel
Brick, No.	40	40	40	....	....	....	....	....	....
Cement, bbl	.147	.188	.169	.313	.111	....	....	....	....
Bitumen, gal	....	....	....	....	2.55	2.55	2	....	....
Sand, cu. yd	.092	.087	.070	.092	.094	.037	....	....	....
Screenings, cu. yd	....	....	....	....	....	.042	.068	.060	
Gravel, cu. yd	.099	.099	.099	.161	.167	....	....	....	.240
Broken stone, cu. yd	.099	.099	.099	.161	.167	.250	.270	.272	....
Filler, lb	....	....	....	....	9	9	....	....	....

The quantity "P" in this equation is graphically represented by the ordinate to a warped surface that had first been defined and located by computing the total labor cost for all limiting conditions. The equation was derived through the assumption of a straight line variation between the computed limits, and this theory has been corroborated by comparison with a number of actual cases.

It was deemed advisable to indicate the labor and team rate by an index, as the numbers involved would be smaller and calculation therefore facilitated. For rates other than are represented in Table II the corresponding indices may be determined by proration.

The estimating data used in establishing the various constants for A, B, C and D, as shown in Table III, are entirely trustworthy for conditions as those existing in Illinois, and have been used for the guidance of bidders on a vast amount of highway work.

TABLE II.—INDICES FOR VARIOUS LABOR RATES

Labor per hr., cts.	15	17½	20	22½	25	27½	30	32½	25
Teams per hr., cts.	30	35	40	45	50	55	60	65	70
Index No. "L"	0	1	2	3	4	5	6	7	8

TABLE III.—CONSTANTS FOR VARIOUS TYPES OF PAVED SURFACES

Type—	A	B	C	D
Brick: Sand-cement bed or sand cushion	.9633	4.082	5.779	29.494
Monolithic brick	.9051	3.172	5.431	24.032
Cement concrete	.8341	2.909	5.005	23.452
Bituminous concrete, concrete base	.7481	4.353	4.488	30.120
Bituminous concrete, macadam base	.8646	3.664	5.187	22.985
Bituminous macadam	.9189	2.832	5.513	17.992
Water-bound macadam	.8450	2.281	5.070	13.689
Gravel	.6900	1.635	4.140	9.810

Finally, to obtain the total estimated cost per square yard for the slab, it is only necessary to combine the two costs as determined for materials and labor.

It must be remembered that no provision has been made, as yet, for profit, so before a final figure is established, an allowance should be made for this item that is entirely commensurate with the work to be done.

As an example, assume that for a particular case it is proposed to improve 4 miles of graded and drained roadway by the addition of a cement concrete slab. Sand and stone are available F.O.B. a railroad siding 1 mile from the nearest end of the improvement at $1 per cu. yd., and cement under the same conditions at $1.65 per barrel net. Assume, furthermore, that the prevailing rates are 20 ct. per hour for labor and 40 ct. for teams. An analysis to determine the probable cost per square yard could be conducted some what as follows:

Materials:	
.313 bbl. of cement at $1.65	$0.52
.092 cu. yd. of sand at $1	.09
.161 cu. yd. of stone at $1	.16
	$0.77
Profit	.08
Total for materials	$0.85
Labor:	
H = 3 B = 2.909	
L = 2 C = 5.005	
A = .8341 D = 17.452	
P = (.8341 × 2 × 3) + (2.909 × 2) + (5.005 × 3) + 23.452 = 5.0046 + 518 + 15.015 + 23.452	$0.49
Profit	.10
Total for labor	$0.59
Total estimated cost for the slab, $1.44 per sq. yd.	

There are several items such as depreciation and repairs on machinery, the cost of which is directly traceable to the slab or metaled way, but which has not been included heretofore. Rather than reduce these items to a yardage basis, it is more satisfactory to provide a lump sum covering the whole improvement.

Cost of Maintenance of Road Building Outfits (Engineering and Contracting, June 4, 1913).—During the years 1908–1912 the Illinois Highway Commission built 1,022,159 sq. yds. of experimental roads. Of this total 397,244 sq. yds. were bituminous macadam. The 1912 report of the commission gives the following data on the cost of maintenance of the road outfits, owned and operated by the commission for the construction of the experimental roads:

Cost of 11 macadam outfits	$37,579
Cost of 6 bituminous outfits	6,628
Cost of 2 concrete outfits	5,381
Total	$49,588
Cost of maintenance of macadam outfits	$ 3,272
Cost of maintenance of bituminous outfits	1,273
Number of outfit seasons covered by maintenance charges on macadam outfits	52
Number of outfit seasons covered by maintenance charges on bituminous outfits	12
Cost per season for outfit for maintenance of macadam outfits	$ 61.80
Cost per season per outfit for maintenance of bituminous outfits	106.00
Cost per sq. yd. for maintenance of macadam outfits	0.003
Cost per sq. yd. for maintenance of bituminous outfits	0.003

Depreciation Charges on Road Building Equipment.—According to Engineering and Contracting, Sept. 3, 1919, the regulations governing work of the State Highway Department of Arizona provide that upon completion of a project depreciation shall be charged to the project, the equipment being rated on the following basis:

	Per cent per year
Engines, gas and steam	20
Fresnos	100
Graders	20
Mixers, concrete	20
Mules	10
Pile drivers	20
Plows	20
Rock crushers	20
Steam shovels	10
Tents	75
Wagons	20
Wheelbarrows and concrete carts	50

Trucks on daily rate on basis of life of three years. All small equipment such as picks, axes, shovels, etc., on value at time of transfer to new project. The following data, are from Engineering and Contracting, Jan. 3, 1917.

With the exception of mules, the life of the equipment is not solely dependent on the lapse of time. The length of the road building season, the continuity of the work and the care given in handling and maintenance, are all important factors in determining the life.

As for tents, it is not unusual to have them whipped to ribbons by strong winds in three months or less. On the other hand, if used only in dry weather, and where winds are not high, a tent may last several road building seasons.

In this connection it seems wise to point out that annual depreciation rates, such as those above given, are often assumed to include current repair costs, although usually the depreciation rate is intended to relate solely to the loss of life of the entire machine and not to loss of life of its parts. Railway locomotives, for example, have had an average life of about 25 years, or a straight-line depreciation rate of 4 per cent per year, assuming no scrap value. But the current repairs on railway locomotives have averaged about 18 or 20 per cent per annum.

Apparently the rates of annual depreciation above given do not include current repairs. Yet, if not, why is the annual depreciation of a steam engine put as high as 20 per cent? A steam engine will surely last as long as a steam shovel, yet the latter is given a depreciation rate of 10 per cent.

The fact is that not a great deal has been published on the lives and maintenance costs of construction equipment. Dana's "Handbook of Construction Plant" gives data on this subject. The startling fact is brought out there that for one year (1908) repairs on steam shovels on the Panama Canal amounted to nearly 50 per cent of their first cost! This was equivalent to nearly 3 cts. per cubic yard excavated. This, of course, was under unusually expensive conditions and where the work was continuous. Dana puts the average life of a steam shovel at 20 years.

In calculating depreciation and repairs, it is usually desirable to separate the two. Estimate depreciation for the full years, but estimate repairs by the month of actual work. Thus, in the case of a steam shovel, the annual depreciation may be estimated at 6 per cent, and the repairs may be estimated at 2 per cent per month of single-shift work. Then if it is estimated that the shovel will actually work six months during a year, the depreciation amounts to 1 per cent and the repairs 2 per cent per month of actual work.

Roadbuilding equipment averages less than 6 months' actual work in the northern states—probably about 4 months. This runs up the interest and depreciation charges per month of actual work. Thus, with annual interest at 6 per cent and depreciation at 12 per cent, we have 18 per cent for the year, or 4.5 per cent per working month if charged entirely against the working time. Add to this, say, 2.5 per cent for repairs, and we have a total of 7 per cent per working month for interest, depreciation and repairs.

Many a road building contractor has "gone broke," and many a highway engineer has erred grievously in his cost estimates, through failure to estimate correctly fixed charges and repairs on road building equipment. Add to this sort of underestimate one or two others of similar nature, and we have an almost complete explanation of why a new crop of road-building contractors buds forth each spring only to wither permanently each autumn.

Costs of Grading in Earth Road Construction.—The following is given in a U. S. Dep't of Agriculture bulletin on "Earth, Sand, Clay and Gravel Roads" prepared by Charles H. Moorefield of the U. S. office of Public Roads and abstracted in Engineering and Contracting, April 18, 1917.

TABLE IV.—GRADING MACHINE WORK

Assumed conditions: Original cross section flat; team to consist of six to eight well-trained horses; no material moved longitudinally.

Character of soil	Cost per mile
Light prairie, free from stumps, roots, etc.	$ 60 to $ 80
Average clay loam	100 to 150
Heavy clay, moderate amount of sod and roots, plowing necessary throughout	200 to 250
Heavy clay, exceptionally difficult conditions	From $250 up
Crowning and shaping road which has been graded with scrapers, etc.	50 to 75

TABLE V.—EXCAVATION AND EMBANKMENT

Assumed conditions: All material to be loosened with plows or by blasting, and to be moderately dry when handled. Hauling to be done by means of drag scrapers, wheeled scrapers, or wagons.

Kind of material	Average haul length, feet	Method of hauling	Average cost per cubic yard, cents	Remarks
Light sandy loam, free from roots, etc.	50	Drag scrapers	10 to 15	Material assumed to be such that little or no plowing is necessary.
	100	Drag scrapers	12 to 20	
	300	Wheeled scrapers	16 to 25	
	1,000	Wagons	25 to 40	
Average clay loam free from roots, etc.	50	Drag scrapers	15 to 20	Material such as to be loosened with plow drawn by two horses.
	100	Drag scrapers	17 to 25	
	300	Wheeled scrapers	23 to 35	
	1,000	Wagons	32 to 50	
Heavy clay	50	Drag scrapers	18 to 25	Four horses required for plowing.
	100	Drag scrapers	21 to 30	
	300	Wheeled scrapers	28 to 38	
	1,000	Wagons	40 to 55	
Hard pan or loose rock.	300	Wagons	40 to 65	Low prices apply where material may be loosened with 4 horses and hardpan plow. High prices where blasting is necessary.
	1,000	Wagons	45 to 75	
Solid rock	300	Wagons	$0.65 to $1.50	High prices apply where stone is hard and excavation shallow.
	1,000	Wagons	.75 to 1.75	

Tables IV and V are intended to furnish a rough guide in making estimates of grading cost at a flat rate per cubic yard. They are based on labor at 15 cts. per hour; horses at 12½ cts. per hour. The depreciation of grading equipment and repairs are figured at 5 per cent per month while in use, and it is expected that the force will be organized economically and managed efficiently.

Cost of Small Steam Shovel Work in Road Grading, California.—J. E. Bonersmith, gives the following in Engineering and Contracting, July 19, 1916.

The work described was on the California State Highway between Tormey and Eckley in Contra Costa County, California, and was done in 1915. The road graded was four miles in length and contained 72,000 cu. yd. of excavation through a rather rough country. The material consisted of earth, soft and hard shale.

The method of work was as follows: After the culverts were constructed, two fresno gangs (each gang having a six-horse plow and from four to six fresnos) were started and made the fill over the culverts; also moved the dirt in all cuts where the hauls were 200 ft. and less. A Model 31 Marion Revolving Shovel followed the fresno gangs and loaded all the material that had to be hauled into dump wagons. The number of wagons varied from six to twelve. Behind the steam shovel, a small fresno with four muckers did all the finishing work.

The road was graded to a width of 21 ft. and through the thorough cuts the shovel had to turn through a full 180°. On this work, the average output of the shovel for an 8-hour day was 375 cu. yd., as there was considerable loss of time in spotting the wagons; but where the shovel was only going through 90°, it handled 510 cu. yd. The local water was the cause of some delay and since the water is a very serious question in the cost of equipment on any job, we now make it a rule to have the water analyzed and the proper boiler compound on hand before the shovel starts to work.

Costs to job in day rentals: Horses rented to job at $1.25 per working day; fresnos, wagons, etc., at $0.25 per working day; wagon and fresno drivers at $2.50 per day; Marion steam shovel, including fuel, runner, etc., $50 per day. These costs of equipment are used on all our work as we have found from many years of experience that it is the only way we can arrive at a true cost. Take the shovel as an example; its rental is based on the following charges:

First cost, $8,200; life of shovel, 1,000 working days in six years; cost per day	$ 8.25
6 per cent interest on $8,200 for three years, $1,476; interest per day	1.48
Repairs (when the shovel is broken down the engineers', firemen, etc., time is charged to repairs), per day	2.00
Freight, knocking down, etc. (this cost was arrived at by cost kept on another shovel), per day	3.00
Fuel, ¾ ton of coal per working day at $12 per ton	9.00
Water wagon with four horses and driver, per day	7.75
Water and oil, per day	.85
Engineer per day	6.75
Fireman, per day	3.00
Two pit men at $2.50 per day	5.00
Incidentals	2.92
Total cost per day	$50.00

Following is the total cost of the above mentioned grading of the State Highway between Tormey and Eckley:

Horses, 8,756 days at $1.25 per day	$10,945.00
Equipment, 1,842 days at 25 ct. per day	460.50
Driver labor, 1,842 days at $2.50 per day	4,605.00
Steam shovel 104 days at $50 per day	5,200.00
Foreman 120 days at $5 per day	600.00
Timekeeper 4 months at $75 per month	300.00
Muckers and slopers, 500 days at $2.25 per day	1,125.00
Muckers, slopers, etc. 212 days at $2 50 per day	530.00
Purchases (picks, shovels, lanterns, oils, etc.)	182.60
Insurance	280.00
Total cost	$24,248.10
Cost per cu. yd	$ 00.3367

Costs on Street Grading with a Steam Shovel, in Minneapolis, Minn.—Fred T. Paul gives the following data in Engineering and Contracting, June 7, 1916.

The work under consideration was done by force account in 1915 under the City Engineer's Department, W. J. Walsh, Acting Engineer in charge. The material moved was a conglomerate with a medium fine sand predominating. The cut was from 2 to 15 ft. deep, 70 to 80 ft. wide, and about 3,500 ft. long. A Marion-Osgood No. 18, ¾-cu. yd. traction steam shovel placed the material in ordinary 1½ cu. yd. dump wagons, and these in turn deposited it in the fills on the street, making an average haul for the job of 1,000 ft.

The work was started June 12 and finished on Aug. 20, covering a period of 55 full working days of eight hours each, and five part days. On these part days, little, if any, dirt was moved, but the engineer, foreman, fireman, watchman and timekeeper received full time—while the laborers and teams were given only part time. A total of 21,500 cu. yd. of material were handled in the 55 full days, making an average day's output of 391 cu. yd. The maximum was reached during five days in the heaviest cut when 611 cu. yd. per day was moved.

The total material cost of the job was $199.56, distributed as follows:

27.45 tons of soft coal at $5.05 per ton	$ 138.62
50 gal. steam cylinder oil at $0.294 per gal	14.70
Blacksmith repairs	17.64
New shovel parts	.82
Miscellaneous, including waste, packing, hose, grease, etc	27.78
	$ 199.56

The average daily pay roll was as follows;

1 foreman at $4 per day	4.00
1 engineer at $6 per day	6.00
1 fireman at $2.50 per day	2.50
1-20th timekeeper at $4 per day	.20
1 watchmad at $2.50 per day	2.50
2 laborers on dump at $2.50 per day each	5.00
2 laborers in pit at $2.50 per day each	5.00
1 laborer on coal and water at $2.50 per day	2.50
6 laborers straightening and leveling up at $2.50 per day each	15.00
7 teams on dump wagons at $5 per day each	35.00
Total average daily payroll	$ 77.70
Grand total payroll for sixty days	4,553.61
Total material as above	199.56
Interest and depreciation on plant	70.00
	$4,823.17

DISTRIBUTION AND UNIT COSTS

	Amount	Per cu. yd.
General—		
Foreman. 60 days at $4	$ 240.00	$0.01116
1-20th timekeeper, 60 days at 20 cts	12.00	.00056
Total general	$ 252.00	$0.01172

EXCAVATING AND PLACING MATERIAL IN WAGONS

Labor—		
Engineer, 60 days at $6	$ 360.00	$0.01674
Fireman, 60 days at $2.50	150.00	.00698
Watchman, 60 days at $2.50	150.00	.00698
2 pit laborers 58 days at $5	290.00	.01349
Laborer on coal and water, 58¼ days at $2.50	145.61	.00676
6 laborers on cleanup, 58 days at $15	870.00	.04047
Total labor	$1,965.61	$0.09142
Material and supplies as above	199.56	.00928
Interest and depreciation on plant, 10½ per cent on $4,000 for 60 days	70.00	.00325
	$2,235.17	$0.10395

HAULING, INCLUDING PLACING IN DUMP

7 teams, 58½ days at $35	$2,046.00	$0.09516
2 laborers, 58 days at $5	290.00	.01349
	$2,336.00	$0.10865
Grand totals	$4,823.17	$0.22432

Based on the total cost of moving 21,500 cu. yd. an average distance of 1,000 ft., the cost per cubic yard hauled 100 ft. would be .0221. However, the actual hauling cost per cubic yard per 100 ft. was only .0108.

Steam Shovel Excavation in Shallow Cut for Road.—Engineering and Contracting, June 21, 1916, gives the following:

A road grading cut 1.6 miles long and nowhere exceeding 18 in. in depth was made Oct. 1 to Dec. 10, 1915, or in 54 days, for a brick on concrete base pavement on Ocean Ave., Deal, N. J. The total amount of excavation was 30,000 cu. yd. The shovel used was Bucyrus with ⅝-cu. yd. dipper, and between the dates named it excavated 17,704 cu. yd. Working a 10-hour day, the greatest yardage was 477 cu. yd.; the average yardage, excluding lost time, was 33 cu. yd. per hour. During the 54 working days 25½ hours were lost, due to rain or other causes. Some partial records were as follows: In 9 days two blocks 700 ft. long and 50 ft. wide were cleaned up. Again, in one week, in a cut running from 9 to 18 in. deep, an advance of 200 ft. per day was registered, or an average of about 350 cu. yd per day. The haul averaged about a half mile. The shovel had to wait for wagons at times from two to three minutes.

Methods and Costs of Constructing Three Sections of Sand-clay Road.—Engineering and Contracting, April 28, 1915, publishes the following:

The work considered is three sections of sand clay "object lesson" road built in 1912 in North Carolina. The construction methods are described and the costs are computed from data given in the Report for 1913–14 of Joseph Hyde Pratt, State Geologist, North Carolina.

The first section of road extends from Calypso, N. C., southeast toward Kenansville. The adjacent land is slightly rolling and the soil is sandy throughout the length of the section. The grading consisted in plowing the ditches and bringing the road to the proper cross-section with a road machine. A small amount of material was moved for an average distance of 50 ft. with drag scrapers. For 1,650 ft. the road was graded 24 ft. wide and surfaced 14 ft. wide, making the area graded 4,400 sq. yds. and the area surfaced 2,563 sq. yds. The crown of the finished roadway was three-fourths inch to 1 ft. Clay to the amount of 248 cu. yds. was hauled an average distance of 2,400 ft., and 55 cu. yds. of sand was hauled an average distance of 1,760 ft. Farm wagons having an approximate capacity of 1 cu. yd. were used for hauling both sand and clay. They were loaded and unloaded with shovels. Two corrugated-iron culverts were ordered for this work, but were not received before the surfacing was completed.

The equipment consisted of 1 road machine, 1 rooter plow, 1 turn plow, 1 split-log drag, 2 drag scrapers, 1 disk harrow, farm wagons, and hand tools Labor cost $1 and $1.50 per day and teams cost $1.20 and $2.50 per day. The cost of grading and shaping 4,400 sq. yds. of subgrade was $3,860 or 0.88 cts. per square yard. The costs for 2,563 sq yds. of surfacing proper were as follows:

Item	Cost
Loading sand	$ 3.75
Hauling sand	6.25
Spreading sand	1.50
Loading clay	22.65
Hauling clay	49.25
Spreading clay	5.50
Mixing clay and sand	4.80
Final shaping with drag	1.60
Total	$ 95.30
Add grading	38.60
Grand total	$133.90
Cost per square yard, 5.21 cts.	

The second section constructed extends from Cooleemee northeast to Jerusalem, N. C. The land adjacent to the road is rolling and the soil varies from "black-jack" gravel to micaceous clay. This road had been graded to a width of 24 ft. in cuts and 18 ft. in fills, and the drainage structures were all completed before the object-lesson work was begun.

The sand for use in surfacing was loosened with plows, loaded with hand shovels, hauled approximately 1¼ miles in slat-bottom wagons, and spread with grader and by hand. The subgrade prepared for surfacing was 20,020 ft. long and 16 ft. wide, making a total area of 35,590 sq. yds. The same area was given a sand-clay surface 6 ins. thick after compacting, with a crown of ¾ in. to 1 ft. For the surfacing 4,820 cu. yds. of material were used, about 3,000 cu. yds. of which were purchased. The wages per day were labor $1.25, and teams $3. The costs were:

Item	Cost
Loading sand at 6.05 cts. per cu. yd	$ 291.61
Mixing surfacing at 0.1 ct. per sq. yd	37.25
Shaping at 0.15 ct. per sq. yd	53.25
Spreading sand at 1.37 cts. per cu. yd	66.00
Hauling sand at 25.46 cts. per cu. yd	1,227.00
Sand pits	105.25
General expense	19.25
Total	$1,799.61
Per square yard, 5.06 cts.	

The cost of superintendence, which is included above, was 6.33 per cent of the total cost.

The third section of road was constructed in Lexington, N. C. The adjacent land is rolling and the natural soil is clay of a plastic nature, but lacking in toughness. The first work was grading. The earth was loosened by a traction engine and a road plow; loaded and hauled with drag scrapers, wheel scrapers, and wagons, and spread with shovels. The maximum cut was 4 ft. and the maximum fill 3 ft. The maximum grade was reduced from 3 per cent to 1 per cent.

The equipment consisted of three No. 2 wheel scrapers, six No. 2 drag scrapers, two plows, three 1½-cu. yd. dump wagons, one 12-HP. traction engine, picks, shovels, etc. The average haul for excavation was 150 ft. and the maximum haul 400 ft. The sand mixed with the clay for surfacing was obtained from a pit and hauled for an average distance of 3 miles in 1-cu. yd. slat-bottom wagons. The quality of the sand was excellent for the purpose for which it was used. Free labor cost $1.25 and $1.50, and foreman $3 per 10-hour day. Convict labor was estimated at $1 per day, and teams cost from $2 to $3 per day.

The total length graded was 3,000 ft., and the width graded, both in cuts and fills, was 30 ft., making the total area graded 10,000 sq. yds. The entire length of 3,000 ft. was surfaced for a width of 18 ft., making the area surfaced 6,000 sq. yds. The compacted depth of surfacing material was 4 ins. and the crown ¾ in. to 1 ft. The earth excavation amounted to 3,975 cu. yds., and the sand used for surfacing amounted to 815 cu. yds. The cost of the work was:

Item	Cost
Excavation at 11 cts. per cu. yd.	$ 440.35
Hauling sand at 80 cts. per cu. yd.	652.00
Spreading at 1.6 cts. per cu. yd.	12.75
Mixing sand and clay	60.60
Sprinkling	6.00
General expenses	5.75
Total	$1,177.45
Per square yard, 19.6 cts.	

Methods and Cost of Constructing a Sand-Gumbo Road in Nebraska.—Engineering and Contracting, Feb. 4, 1914, gives the following data, taken from Bulletin No. 53 issued by the U. S. Department of Agriculture.

On August 19, 1912, work was resumed on the construction of the sand-gumbo road extending northwest from the Platte River toward Columbus, Neb. A section of road 3,002 ft. long was added to the section constructed during the fiscal year 1912. The roadbed was graded to a width of 32 ft. in cuts and 24 ft. on fills. A sand-gumbo surface 16 ft. wide was constructed having an area of 5,337 sq. yds. The section was completed on Sept. 4, 1912.

Earthwork.—The maximum grade was reduced from 13.2 per cent to 4.4 per cent. The adjacent land is level and the soil is sandy. The earth was loosened with plows and hauled in drag, Fresno and wheeled scrapers. The average haul was 160 ft. and the maximum haul was 350 ft. In the excavation 760 cu. yds. of earth were moved and the maximum cut was 1.3 ft. and the maximum fill 2.7 ft.

The construction outfit consisted of 4 drag scrapers, 2 Fresno scrapers. 1 wheeled scraper, one 8-horse road machine, 1 steel road drag, 1 plow, 1 disk harrow, 1 spike harrow and the necessary hand tools. Labor cost $2 and teams $4 per 10-hour day. Table VI gives the cost of the earthwork.

TABLE VI.—COST OF EARTHWORK FOR SAND-GUMBO ROAD IN NEBRASKA

Item—	Amount	Unit cost per cu. yd	Unit cost sq. yd. wearing surface
760 cu. yds. excavation	$120.00	$0.158	$0.0225
Shoulders and ditches	46.40	.....	0.0088
5,337 sq. yds. shaping subgrade	28.20	.....	0.0052
Miscellaneous	1.40	.....	0.0002
Superintendence	4.20	.....	0.0008
Total	$200.20	.....	$0.0375

Materials and Methods Used in Making Wearing Surface.—The surfacing material consisted of a good quality of black gumbo and sharp clean sand. The gumbo was spread to a depth of 7½ ins. and the sand to a depth of 6 ins., both measured loose. The two materials were then mixed by means of plows and harrows and shaped with a steel drag and a road machine. The compacted depth of the finished surface was 8 ins. and the crown was ¾ in. per foot. In this work 1,165 cu. yds. of gumbo and 890 cu. yds. of sand were used. The gumbo was hauled approximately 2 miles in slat bottom dump wagons having a capacity of 1 cu. yd. The sand was hauled a distance of 4,000 ft. in the same wagons. The cost of the wearing surface was as given in Table VII.

TABLE VII.—COST OF SAND-GUMBO WEARING SURFACE FOR A ROAD IN NEBRASKA

Item—	Amount	Unit cost per cu. yd.	Unit cost sq. yd. wearing surface
Purchase of gumbo pit	$ 41.35	$0.035	$0.008
Loading gumbo	180.40	0.155	0.034
Hauling gumbo	698.80	0.600	0.131
Spreading gumbo	34.00	0.029	0.006
Loading sand	93.60	0.105	0.018
Hauling sand	299.00	0.336	0.056
Spreading sand	10.60	0.012	0.002
Mixing sand and gumbo	37.20	0.018	0.007
Shaping	4.00	.....	0.0025
Rolling	13.60	.....	0.001
Miscellaneous	12.60	.....	0.002
Superintendence	37.80	.....	0.007
Total	$1,462.95	.....	$0.2745

The following is a summary of the cost:

	Amount	Unit cost per sq. yd. wearing surface
Earth work	$ 200.20	$0.0375
Wearing surface	1,462.95	0.2745
Total	$1,663.15	$0.3120

Data on the Construction of 23 Sand-Clay Roads.—Table VIII, taken from Engineering and Contracting, Jan. 17, 1912, is based on data given in the annual report of Logan Waller Page, Director of the Office of Public Roads, for the fiscal year ending June 30, 1911.

Macadam Road Construction Using Industrial Railway for Hauling.— R. P. Mason gives the following matter regarding the construction of a macadam road about 9.5 miles long in Delta County, Mich., in Engineering and Contracting, April 7, 1915.

The hauling outfit consisted of a 30 HP. locomotive and 50 Koeppel side dump cars. There was also one track laying car which carried the track, which consisted of 15 ft. sections of 24 gage track, 20-lb. rails, with 7 steel ties to the section. In all there were 4 miles of track with necessary curves and switches.

Cars were loaded with 1¼ cu. yds. of stone which when dumped at a standstill just made one course of large stone. The haul averaged 3½ miles each way and, at first, with 20 cars, 8 trips were made per day. After the operation was running smoothly 25 cars were handled on each trip.

The stone was spread with road machine hauled by 2 teams. Unloading the stone took about 10 mins. and the machine finished the spreading while the train made another trip. Very little dressing with rakes put the surface in A1 condition for rolling and the machine spreading gave a uniform distribution and smooth roadway. However, it is only by handling a large volume of stone per day that this system can be made profitable. It is necessary that all units of the force be proportioned and kept busy and as it takes two teams to handle the road machine it is essential that they have enough stone to make it an object.

After the preliminary rolling a train of screenings was poured from the train in motion, making a windrow near the track sufficient to cover the course and spread by hand. This pouring, with the help of the spreaders, took about the same time as dumping the stone.

Three 10-ton rollers worked constantly and by utilizing all the lost time of the train due to bad weather, moving, and shortage of stone and occasionally working nights, they were able to keep up their end. Two sprinklers, filled by a gas rotary pump, were used and, as the water was convenient along the road they furnished abundance and it was not always necessary to work them both.

All the ordinary hazards of road building entered into this job, wet weather, soft subgrades and a number of railroad crossings which meant delay as well as extra expense for watchmen. A hill 5.1 per cent, 1,000 ft. long with a 16° curve about the center made it necessary to put in a spur at the foot and take the train up in two or three sections. As this work was entirely new to this locality an entire crew had to be broken in and it is evident that costs can be materially lessened in the future, now that the organization is complete. The fastest mile was laid in six days towards the end of the season, compared with the first mile on the same haul which took fourteen days. The crew required was about as follows:

Loader	4 men
Train	2 men, engineer and brakeman
Spreading	2 teams and teamsters
Spreading	5 to 7 men
Rolling	3 men
Sprinkling	2 teams and teamsters
Foreman	1
Watchmen	1 or more
Tracklaying	4

Wages were $2 per day for laborers, $5 for teams with teamsters, $3 for rollermen, engineer, $90 per month.

Compared with team haul the method described shows a saving of about 30 cts. per cubic yard, or nearly $700 per mile. We also saved 39 cts. on our stone and 10 cts. on the unloading, making a total of about $1,800 per mile over previous prices. The saving on haul alone would be more marked on a longer haul. We also used the outfit in grading where material had to be moved some distance and found it extremely convenient and economical. Another very decided advantage of road building by this method is seen in the fact that there is no hauling over the road during construction and it is opened to traffic in perfect condition. It is also easier to keep the subgrade from being cut up and therefore takes less stone for a given thickness.

The costs in Table IX include everything that is a proper charge to the work, the cost of moving outfit from one point to another, laying up, and tracklaying includes taking up as well. Loading includes setting up loader and in one case building a siding 1,000 feet long. The number of watchmen makes the hauling cost high; a greater output will cut down the spreading and the overhead in this case is high on account of the short season.

TABLE IX.—MACADAM COST SHEET, DELTA COUNTY, MICHIGAN

No. of days worked	93
Miles of finished road	9.44
No. yards stone used	21,920
No. yards stone used per mile	2,310
No. days to build mile of road—average	9.4
No. yards stone per day	236
Cost of tracklaying per mile of finished road	$108.10
	Cost per cu. yd.
Cost of stone at our siding	$ 0.860
Loading trains	.052
Tracklaying	.047
Engineer	.020
Brakeman	.013
Watchmen	.017
Coal	.012
Oil, grease and waste	.002
Repairs	.003
Total	$ 0.114
Interest and depreciation on hauling outfit	.052
Spreading	.114
Sprinkling	.043
Rolling	.082
Foreman and timekeeper	.030
Total	$ 0.269
Int. and dep. on all other machinery	.040
General expense	.031
Total	$ 0.071
Total cost per yard (loose) of finished road	$ 1.418
Cost per mile	$3,275.58

Cost of Constructing Macadam Pavement at Hamilton, Ont.—The following figures, published in Engineering and Contracting, Sept. 4, 1918, from the report of E. R. Gray, City Engineer of Hamilton, Ont., for 1916–17 show the unit cost of constructing 2,361 sq. yd. of macadam on the northerly half of Burlington St. The macadam consisted of 5 in. of bottom stone and 3½ in. of top stone, requiring 897 cu. yd. stone and screenings loose measurement, or 559 cu. yd. in place. This was 1.6 cu. yd. of stone, loose measurement, for each cubic yard in place. The cost of work was as follows:

Operation	Quantities, etc.	Cost	Cost per sq. yd.
Grading	2,361 sq. yd	$ 347.52	$0.147
Bottom stone	45 loads tailings at $1.50	67.50	
	169 loads bottom stone at $2.20½	372.65	.186
Hauling bottom stone	221 loads at $1.87½ ($7.50 per day, 4 trips). Incline tickets $13.00.	427.37	.181
Laying bottom stone	520 hours at 35 cts	181.93	.077
Rolling bottom stone	2 days	13.60	.006
Top stone	From Dundas, 7 cars	400.25	
	From quarry, 19 loads at $2.95½	56.15	.193
Unloading from cars and hauling 370.8 tons, 156.3 loads		142.48	.060
Hauling from quarry	19 loads	34.44	.015
Spreading top stone		31.22	.013
Screenings	34 loads from quarry at $2.02½	74.98	
	18 loads from Ward 6	43.73	.050
Hauling screenings		85.04	.036
Placing screenings		36.57	.016
Road roller, foreman, time keeper, watchman, coal, etc.		139.92	.059
		$2,455.35	
5 per cent on labor for tools, 5 per cent of $1,360		68.00	.029
		$2,523.35	$1.068

The labor cost of unloading the stone from cars using hoppers was 22.8 ct. per ton or 54 ct. per load, the latter averaging 2.37 tons. The labor time for nuloading 370.8 tons from 7 cars was 24½ hours at 35 cts. per hour.

Effect of Length of Haul on Cost of Surfacing Macadam and Gravel Roads.—The following curve, taken from an article by K. I. Sawyer in Engineering and Contracting, June 17, 1914, is based on costs of road construction in Michigan.

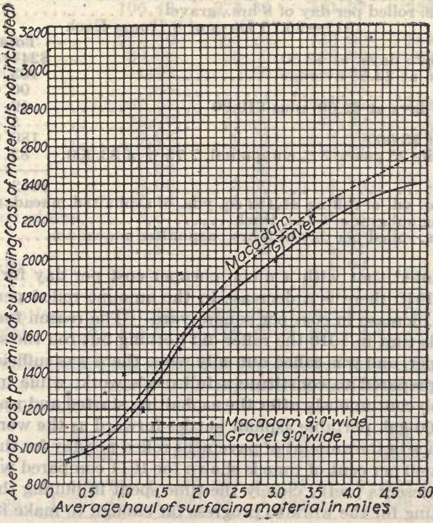

Fig. 1.—Curve showing the effect of length of haul on the cost of surfacing.

Cost of Operating a Steam Road Roller.—E. W. Robinson, gives the following costs of operating a 15-ton macadam road roller for the two seasons of 1910 and 1911 in Engineering and Contracting, March 20, 1912. The roller was bought new in 1906 at a cost of $3,000, these two years making the fourth and fifth seasons, respectively, in use. In all it has been used to roll 150,000 sq. yds. of water bound macadam, gravel and asphalted macadam pavements, and in addition was used on some three or four miles of county road work. It has also been used to a small extent to pull plows and rooters in opening side ditches and making street excavation, and for rolling down refilled sewer trenches. As nearly all the macadam roads and pavements in this locality are constructed of hard flint rock the large wheels are pretty well worn and will need replacing after another season or two. With that one exception the roller is in very good condition, considering the number of different men who have handled it, and only a few minor renewals have been necessary.

1910—67.4 Days of 8 Hours Each

	Total	Per day
Engineman, 67.4 days, at $2.50	$168.50	$2.500
Coal, 32.59 tons, at $4.00	130.36	1.934
Water, free	00.00	0.000
Repairs and supplies	105.26	1.562
Interest, 6 % of $3,000	180.00	2,671
Depreciation, life 25 years, 3 % compound, 2.75 % of $3,000	82.50	1.224
Total	$666.62	$9.891
Cost per sq. yd. of rolling 26,006 sq. yds. of asphalted macadam, including subgrade, 6 ins. thick		$0.0156
Cost per sq. yd. of rolling 15,062 sq. yds. of gravel pavement, including subgrade, 6 ins. thick		0.0126
Average sq. yds. rolled per day of 8 hrs., asphalted macadam		630
Average sq. yds. rolled per day of 8 hrs., gravel		787

1911—96.75 Days of 8 Hours Each

	Total	Per day
Engineman, 96.75 days, at $2.50	$241.88	$2.500
Coal, 40.5 tons, at $2.55 average	103.26	1.067
Water, free	00.00	0.000
Repairs, 11.85 days at $2.50, plus $19.90	49.53	0.512
Oil and grease	5.40	0.056
Interest, 6 % of $3,000	180.00	1.858
Depreciation, life 25 years, 3 % compound, 2.75 % of $3,000	82.50	0.851
Total	$662.57	$6.846
Cost per sq. yd. of rolling 34,152 sq. yds. of asphalted macadam, including subgrade, 6 ins. thick		$0.0176
Average sq. yds. rolled per day of 8 hrs., asphalted macadam		388

It will be noted that with a much cheaper cost per day for operation in 1911 than in 1910 there is a decrease in the amount rolled per day, with a corresponding increase in cost per square yard. The reason for this seeming inconsistency is that in 1910 the roller did nothing but roll the sub-grade and pavement proper, and was called out only when there was sufficient sub-grade or pavement prepared to constitute a full day's work, while in 1911 it was kept on the job continuously after the asphalting started and was also used to pull the two 500-gal. portable asphalt kettles forward as the work progressed. By the difference in the amount of pavement rolled per day for the two seasons a loss of about 40 per cent of time is shown for 1911 compared with 1910, and that figure represents pretty closely the time spent in pulling the kettles and lying idle waiting for the work to progress far enough to make it worth while to move back and roll the completed pavement.

There are several reasons for the difference in cost of operation per day for the two seasons. The same engineman was employed both seasons at the same wages, and that item as well as interest and depreciation remain the same for both years. In 1910 the coal was purchased of local dealers at retail prices, while in 1911 a far better grade was obtained at a much lower price by buying a full car. The reason for the large difference in cost of repairs and supplies was due to the fact that the man who ran the roller in 1909 did not take proper care of it and when the present engineman took hold in 1910 a pretty thorough over-hauling was necessary. It might be well to state that the average man whose only experience has been with a threshing engine is not very apt to be fit to run and maintain in good condition a road roller. The present engineman, who is an old locomotive engineer and a good machinist, did practically all the repairing on rainy days and Sundays, and the roller had to be taken to the machine shop only once in the last two years. The reason so good a man was secured at such a low price is because he gets straight time the year around, and when not out with the roller is employed at other work.

Cost of Road Roller Operation and Maintenance.—Engineering and Contracting, Jan. 1, 1913 publishes table X taken from the annual report of the Board of Public Works of Grand Rapids, which shows the cost of maintenance and operation, during the fiscal year ending March 31, 1912, of five steam road rollers owned by the city.

TABLE X.—COST OF ROAD ROLLER MAINTENANCE AND OPERATION FOR ONE YEAR

	No. 1 Roller	No. 2 Roller	No. 3 Roller	No. 4 Roller	No. 6 Roller
Maintenance:					
Total maintenance	106.48	275.30	581.27	259.80	124.36
Operation:					
Labor, running	717.10	681.20	743.00	769.10	809.20
Labor, cleaning	30.00	26.00	30.00	60.00	18.40

Hose	....	....	....	....	5.80
Total operation	1,061.13	980.99	1,068.92	1,007.85	1,146.89
Grand total	$1,173.61	$1,256.29	$1,650.19	$1,267.65	$1,271.25

The total maintenance and operating expenses for these rollers for the year ending March 31, 1911 (taken from Engineering and Contracting, May 22, 1912) were as follows:

	No. 1 Roller	No. 2 Roller	No. 3 Roller	No. 4 Roller	No. 6 Roller
Total maintenance	$ 466.74	$ 479.23	$ 421.11	$ 255.33	$ 159.53
Total operation	1,251.42	1,290.29	1,188.87	1,149.38	1,162.48
Total	$1,718.16	$1,769.52	$1,609.98	$1,404.71	$1,322.01

The average cost of maintenance was $356.39 for 1911 and $269.44 for 1912.

The weight of the rollers and number of hours operated in the year ending March 31, 1912 are as follows:

	Weight, tons	No. hours operated in year
No. 1 roller	15	1,793
No. 2 roller	13	1,703
No. 3 roller	14	1,857
No. 4 roller	8	1,922
No. 6 roller	10	2,023

The cost of maintenance and operation of these rollers per hour in operation were as follows:

	Total	Per hour
No. 1 roller	$1,173.61	$0.605
No. 2 roller	1,256.29	.737
No. 3 roller	1,650.19	.888
No. 4 roller	1,267.65	.659
No. 6 roller	1,271.25	.628

A full day's work at Grand Rapids was 10½ hours: 10 hours actual operation, and the balance firing up in the morning.

Comparative Cost of Operating Steam and Gasoline Rollers. (Engineering and Contracting, Feb. 26, 1913).—The road building outfit of the Highway Commissioners of York County, Ontario, includes two 12½-ton and two 11½-ton steam road rollers and a 12-ton 2-cylinder gasoline road roller. In the report of the Commission covering the year 1912, E. A. James, Chief Engineer of the Commission, gives the following figures to show the cost as nearly as can be judged of operation of the steam and gasoline machinery, both rollers working under similar conditions:

Cost of Operating Steam Roller

For 10 Hours' Rolling

Fuel—	
Kindling wood	$0.05
Coal, 380 lbs. at $6.85 per ton	1.30
Water—600 gals.; hauling 3 hrs. at 50 cts. per hr	1.50
Oil, etc	0.05
Engineer—11½ hours at 30 cts. per hour	3.45
Total	$6.35

For 10 Hours' Spiking and Scarifying

Fuel—	
Kindling wood	$0.05
Coal, 480 lbs. at $6.85 per ton	1.64
Water—800 gals., hauling	2.00
Oil	0.05
Engineer—11½ hours at 30 cts	3.45
Total	$7.19

Cost of Operating a Gasoline Roller

For 10 Hours' Rolling

Fuel—12 gals. gasoline at 15 cts. per gal	$1.80
Water—Cooling	0.12½
Oil	0.07
Engineer—10¼ hours at 30 cts	3.07½
Total	$5.07

For 10 Hours' Spiking and Scarifying

Fuel—20 gals. gasoline at 15 cts. per gal.	$3.00
Water—For cooling	0.15
Oil	0.07
Engineer—10¼ hours at 30 cts.	3.07
Total	$6.29

Cost of Shaping Up and Rolling Old Macadam.—Engineering and Contracting, Sept. 4, 1918, gives the following:

The cost of dressing up 12-ft. wide limestone macadam roads in Putnam County, Indiana, with a steam roller having a scarifier attachment ranged from $9.24 to $5.35 per mile in 1916. The average cost for the months of May, June, July and August of that year was about $7.08 per mile. The average total cost per day for the roller for this period, including coal, was $6.73. The cost of coal per day was $1.39. The above figures are based on the following costs:

Coal	$3 per ton
Roller operator	30 ct. per hour
Helper	25 ct. per hour
Teams for hauling coal	35 ct. per hour

The average number of days operated per month was 24.6, the average number of miles covered during this time being 23.5 or about 0.95 mile per day.

Cost of Renewing Surface of Old Macadam.—Engineering and Contracting, Nov. 7, 1917, gives the following:

Most of the suburban roads in the District of Columbia are water-bound macadam which have had a surface treatment either of oil or light tar. Three methods of renewing the surface on these old and worn macadam roads are employed, depending upon the condition of the road to be repaired.

When the surface has been treated formerly with oil or tar and is in generally good repair, except for a few potholes or ruts, these places are patched with a mixture of stone, of a size corresponding to the depth of the depression, and a cold bituminous material. This material may be either a tar of the heaviest consistency which can be used cold, such as Tarvia K-P or Ugite C; or it may be an asphaltic emulsion such as Headley's Cold Patching Material No. 1. The largest size of stone possible is used, well mixed with about 1 gal. of bituminous material to each cubic foot of stone. The patches are rolled with a steam roller and covered with a thin coat of stone chips to prevent adhesion to wheels while they are still moist.

When the surface of a macadam road, which has been previously treated with oil or tar, is very much worn or rutted, the entire surface is loosened to the depth of about 2 in. with a scarifier, as much as possible of the top coat containing the bituminous material being entirely removed. The fine stone may be screened out of the material which is removed if it is sufficiently pulverized, but it is usually reserved for use in repairs to little traveled roads. Sufficient new stone is then added to restore the proper cross section of the road, and the surface is brought to the condition of new water-bound macadam. This is opened to travel and kept watered until the surface is firm and compact. It is then swept clean of dust and the new surface is treated with the bituminous material in the same manner as a new road. About ¼ gal. per square yard of bituminous material (either oil or tar) is spread by means of a sprayer, and the surface is then covered with stone chips or pea gravel.

When the surface is much worn and it is desired to renew it with a strong new surface, the old macadam road is scarified to a depth of about 3 in. and reshaped to a surface about 2 in. below and parallel to the finished surface. A layer of 2-in. stone is then added and rolled to restore the cross section. About 1½ gal. per square yard of hot tar of heavy consistency is then applied, covered with stone ¾ in. to 1 in. in size, and rolled. After this a second coat of tar of about ⅔ gal. per square yard is applied and covered with ½-in. stone chips and rolled. This is, of course, the well-known penetration method, applied to the re-surfacing of old roads, and its use is advisable in cases where the road sustains a fairly heavy traffic of both horse-drawn and motor vehicles of all classes, say from 500 to 1,500 vehicles in 24 hours for a roadway 20 ft. wide.

The cost of the above treatments depends largely upon the condition of the roads when repaired, and also upon the cost of labor and material at the particular location under consideration. In a general way, in the District of Columbia, the mixed bituminous material used in the first method costs from $1.40 to $1.50 per cubic foot in place in the road. If it will average 1 in. deep, then it will cost 12 to 12½ cts. per square foot or $1.08 to 1.12½ per square yard of patch (not of roadway surface). This applies to small patches. Larger patches would cost somewhat less per square yard. To patch a roadway, 2 per cent of whose surface required repair to an average depth of 1 in., will therefore cost about 2 cts. to 2½ cts. per square yard of roadway surface.

The second method will cost probably 10 cts. per square yard for the preliminary work and from 5 to 6 cts. per square yard for the new surface treatment, or a total of 15 to 16 cts. per square yard of roadway surface.

The third method, including the work of scarifying and reshaping and the cost of material and labor, will cost from 60 to 75 cts. per square yard, depending on many and various factors.

The costs are based on labor at about 30 cts. per hour, teams at $5.50 per day, stone at 10 cts. per cubic foot at the road, and bituminous materials at 10 cts. to 15 cts. per gallon at the work.

Repairing Ruts in Macadam Roads.—Engineering and Contracting, May 29 1912, gives the following method used by the Road Commissioners of Alger County, Michigan, L. E. Adams, County Road Engineer, in repairing ruts which had developed in some of the macadam roads of the county road system: The macadam was loosened with a pick to the bottom course of rock and the hole cleaned out. Rock from 1½ to 2½ ins. was placed in the hole, well wet and tamped so that the top was a trifle above the level of the surrounding road. Screenings were then placed on the rock, thoroughly dampened and tamped with a 25-lb. iron rammer. The ruts on about 3½ miles of road were repaired in this way at a cost of $60 per mile. Screenings and rock were delivered in cars on spurs near the work for 10 cts. per cu. yd., and were hauled in wagons and deposited along the side of the road where needed. The average haul was one mile. Team and driver cost $4.50, foreman $2.50 and labor $2 per day.

Cost of Maintenance of Macadam with Roller and Scarifier.—George E. Martin gives the following matter in Engineering Record, Nov. 4, 1916.

Putnam County, Indiana, has a very large mileage of macadam roads. Many of these roads were built with but little attention to grades or drainage. Greencastle, the county seat, is in the center of a region producing a good grade of road-building limestone, and comparatively large amounts of stone have been placed on the roads of the vicinity.

The county, in 1915, purchased a steam roller with a scarifier attached to it.

This outfit has been used to dress up the roads at the following costs for operation:

	Total cost per day	Coal cost per day	Miles operated	Days operated	Cost per mile
May	$6.56	$1.23	16.75	23.6	$9.24
June	6.69	1.54	19.50	25	8.56
July	7.25	1.35	27.75	25	6.84
August	6.43	1.85	30.25	25	5.35
Average	6.73	1.49	23.56	24.65	7.50

The costs are based on coal at $3 per ton; wages of roller operator, 30 cents per hour; wages of helper, 25 cents per hour; and teams for hauling coal, 35 cents per hour.

The roads were about 12 ft. wide. In most cases they were both graded and rolled at this cost. About 50 per cent of the mileage was scarified and 12 miles were rolled only.

The work was done under the direction of Alva E. Lisby, Putnam County road superintendent, who collected the data quoted.

Maintenance Cost of Water Bound Macadam at Hartford, Conn.—Interesting data on the maintenance of waterbound macadam streets at Hartford, Conn., were given by Leon F. Peck, Superintendent of Streets of that city, in a lecture delivered Jan. 9, 1920 before the post-graduate students in civil engineering at Yale University. The matter following is abstracted from the address in Engineering and Contracting, Feb. 4, 1920.

Waterbound macadam comprises 73 per cent of the streets of all kinds, paved and unpaved, in the city of Hartford. The macadam maintained over the 10 fiscal years 1907 to 1916, inclusive, averaged 97 miles per year. In area this amounted to 1,321,000 sq. yd. per year. Probably 50 per cent of of these streets have been macadamized more than 20 years. Over most of this 10-year period, labor cost 25 ct. per hour, and a team with driver 62½ ct. per hour.

	Per sq. yd. per year
Average cost for the 10 years of maintenance, including restoration or renewals	$0.0343
Cost of depreciation at 10 per cent and interest at 4½ per cent on $13,400 worth of equipment	0.0015
Total, including depreciation and interest, averaged over the entire macadam area	$0.0358

The average annual cost, not including interest and depreciation for the first three years of this 10-year period, was $0.0340 per square yard, for the middle four years $0.0365 per square yard, and for the last three years $0.0317 per square yard.

Thus it is seen that the direct cost of maintenance did not increase during the 10 years notwithstanding the great increase in the number of motor vehicles.

During the next three years the cost of labor, teams and materials increased until the rates for the fiscal year ending March 31, 1919, stood as follows:

Labor, 37½ ct. per hour, an increase of 50 per cent.
Teams with drivers, 87½ ct. per hour, an increase of 40 per cent.
Repair materials increased about 40 per cent.

The actual cost for that year of maintaining 107 miles of macadam or 1,416,000 sq. yd. was $0.0551 per square yard, an increase of 60 per cent over the average for the 10-year period. This percentage of increase is in excess of that for labor and materials. It is believed that the excess is entirely due to the fact that war restrictions prevented the securing of the customary amount of asphaltic road oil, thus the usual maintenance benefit of the oil was lost.

Taking the present cost of new macadam at Hartford, which is 99 cts. per square yard and distributing it over a period of years long enough to bring in the average maintenance costs, say 20 years, then the ultimate cost can be determined as follows:

Interest at 4½ per cent on first cost for 20 years = $0.045 × $0.99 × 20, per sq. yd.	$0.8910
Sinking fund to repay original outlay at end of 20 years, compounded annually at 4 per cent = $0.03358 × $0.99 × 20	.6649
Present annual cost of maintenance including depreciation and interest, $0.0566 per square yard, for 20 years. $0.0566 × 20 =	1.1320
Ultimate cost per square yard for 20 years	$2.6879
Ultimate cost of Hartford's macadam per square yard per year	0.1344

Rate of Scarifying Macadam Road with "Allen" Scarifier.—In a paper, presented at the 1918 annual conference of Ontario Road Superintendents, R. Crawford Muir described the reconstruction of Dundas Street, the chief means of access to Toronto.

The old road was scarified 4 to 6 in. deep for its full length and width, and the loose stones were drawn to the sides to form the shoulders, thus reducing the crown necessary for the new surface.

The type of scarifier used was the "Allen" attached to the side of the roller. This scarifier consisted of 2 picks or teeth and was capable of picking up 800 to 1,200 sq. yd. a day.

Estimating Gravel Road Material Quantities and Cost of Hauling.—Engineering and Contracting, Jan. 5, 1916, publishes the following extract from Iowa State Highway Commission Service Bulletin December, 1915.

TABLE XI.—NUMBER OF LINEAR FEET OF 9-FT. ROAD A LOAD OF A GIVEN SIZE SHOULD COVER FOR VARIOUS LOOSE DEPTHS

Weight of load— Granite, lb.	Limestone, lb.	Size of load, cu. yd.	Length spread for loose depth in inches— 3-in.	4-in.	5-in.	6-in.
2,800	2,500	1	12 ft.	9 ft.	7.2 ft.	6 ft.
3,500	2,125	1¼	15 ft.	11.25 ft.	9 ft.	7.5 ft.
4,200	3,750	1½	18 ft.	13.5 ft.	10.8 ft.	9 ft.
4,900	4,375	1¾	21 ft.	15.75 ft.	12.6 ft.	10.5 ft.
5,600	5,000	2	24 ft.	18 ft.	14.4 ft.	12 ft.
6,300	5,625	2¼	27 ft.	20.25 ft.	16.2 ft.	13.5 ft.
7,000	6,250	2½	30 ft.	22.5 ft.	18 ft.	15 ft.
7,700	6,875	2¾	33 ft.	24.75 ft.	19.8 ft.	16.5 ft.
8,400	7,500	3	36 ft.	27 ft.	21.6 ft.	18 ft.

TABLE XII.—NUMBER OF CUBIC YARDS OF MATERIAL PER MILE TO MAKE GIVEN LOOSE DEPTH FOR VARIOUS WIDTHS OF ROAD

Depth of loose material in inches	Width of surfacing— 9-ft. cu. yd.	14-ft. cu. yd.	15-ft. cu. yd.	16-ft. cu. yd.	18-ft. cu. yd.
1¼-in. screenings)	180	280	300	325	367
3-in.	440	684	733	782	880
4-in.	587	913	979	1,043	1,174
5-in.	734	1,141	1,222	1,304	1,468
6-in.	880	1,369	1,466	1,565	1,760
Square yards of surface per mile	5,280	8,213	8,800	9,387	10,560

Knowing the cost of gravel in any community the cost of the material for the road can be easily determined. The cost of hauling the gravel varies also between rather wide limits but the following may be considered as average prices where teams cost forty cents per hour and where ordinary earth roads are hauled over:

TABLE III.—AVERAGE COST FOR HAULING GRAVEL BASED 40 CTS. AN HOUR FOR TEAMS

Length of average haul	Cost, cts. per cu. yd.
One-quarter mile	21
One-half mile	28
One mile	40
Two miles	63
Three miles	86

Motor Truck, Scarifier and Road Graders on Gravel Road Maintenance.— Thomas H. Edwards gives the following data in Engineering Record, July 15, 1916:

Montgomery County, Ala., has 650 miles of public roads, 450 miles of which are of gravel. In 1914, in order properly to maintain them, the County Board of Revenue decided to motorize the maintenance work. Material economies have been effected. One truck, it has been found, takes the place of from 16 to 20 mules for pulling a scarifier. The five trucks now in use make it possible to scrape practically the entire system after each rain, each truck pulling three road machines and being able to make 30 miles a day. A great saving has been accomplished in the hauling of the gravel. Four trailers are provided for each truck for this purpose.

Scarifying.—The use of the motor truck has made scarifying a comparatively easy matter. As previously stated, where formerly from 16 to 20 mules were required to pull the scarifier, one of the trucks now accomplishes the work with ease.

Recently there has been completed 6 miles of scarifying and reshaping at a cost of $24 per mile. This includes rebinding. The writer understands that in a neighboring county a contractor bid as much as $400 per mile for similar work. The detailed costs follow:

COSTS OF SCARIFYING 6-MILE ROAD

Gasoline for truck, 146 gal., at 25c	$ 36.50
Oil for truck, 35 gal., at 56c	19.60
Laborers' time, 31.5 days, at $1	31.50
Engineer's wages, 7 days, at $3	21.00
Foreman's wages, 7 days at $3	21.00
Total cost of scarifying	$129.60
Cost per mile	21.60
Cost of shaping 6 miles with truck followed by road machine	14.78
Cost of shaping per mile	2.46
Total cost, per mile, of finished road	$ 24.06

It is very important, in the maintenance of gravel roads, to scrape them after each rain. With the five trucks now in use it is possible to cover practically the entire system before the roads become too dry to accomplish any good.

With the truck we are in position to completely scrape 30 miles of road per day. To do this there is hung to each truck a fleet of three road machines. A round trip completes the road.

The cost per mile of this class of work is about 50 cents. The cost for the 30 miles is:

Truck driver	$ 3.00
Laborers, 3 at $1	3.00
Foreman	3.00
Gasoline, 20 gal. at 25 ct	5.00
Oil, 2 gal. at 50 ct	1.00
Total for 30 miles at 50 ct	$15.00

The replacing of chains, repairs to trucks, etc., necessary to truck upkeep cost about $400 per year.

Hauling Gravel.—In connection with each truck there are four Troy reversible 3-yd. trailers. While the truck and two of the trailers are at the dump the other two trailers are being loaded. Therefore only about ten minutes are lost per trip, this being consumed in loading the truck.

By this method of hauling, it has been possible to place gravel on the roads for from 7 to 11 cents per yard-mile, as against from 30 to 40 cents for mule haul, and includes spreading the material on the road.

With an increase of late in the price of gasoline from 11 to 25 cents per gallon it has been possible to keep the costs per yard-mile around 10 or 11 cents.

The unit costs of operating one of the trucks for hauling gravel during a week, shows a gasoline consumption of about 35 gal. per day. This is from 10 to 12 gal. more than the truck uses on the average haul, due to very long 12-per cent grades on the particular road traveled.

The first truck, a White 6-cylinder, latest type road truck was purchased in the latter part of 1914. It proved such an economy to the county that four others were purchased, together with trailers and equipment. All of the trucks are of 5-ton capacity.

Cost of Boulevard Oiling in Kansas City, Mo.—C. W. Redpath gives the following data in Engineering and Contracting, Nov. 20, 1912.

Approximately 50 miles of macadam roadways are oiled twice a year by the Park Board of Kansas City. The method of oiling employed has been very successful and economical.

Nearly the entire boulevard system is of 12-in. macadam, constructed of native limestone, which is used both for base and wearing surface. The roads have been carefully constructed, have a 12-in. crown on a 40-ft. roadway, and have excellent drainage.

The conditions for oiling are as follows:

(*a*) Before oiling, such repair work as is necessary should be done on the roadway, as the oil forms a cushion over the patch and protects it from raveling.

(*b*) The road surface should be hard and clean and all loose material removed.

(*c*) The road surface should be dry.

(*d*) Only one-half of the roadway should be oiled at a time, if for no other reason than a protection and courtesy to the public.

(*e*) The weather should be warm, with no prospects of rain, as rain on a freshly oiled surface will wash away much of the oil, sometimes completely ruining the job.

The oil used is a residuum of Kansas oils, which has an average specific gravity of 93 at 60° F. and which must register 19 to 21° B. by high grade hydrometer. The oil is received in tank cars from the Standard Oil Co. and pumped into two steel receiving tanks of 8,000 gals. capacity each, whence it is heated by steam coils and discharged by gravity into distributing tanks.

The cost of the oil this year, including freight, was about 2¼ cts. per gallon. It was charged out at 2½ cts. per gallon, the difference being the approximate cost of operating the distributing station.

The oil is distributed by steel tank wagons, of about 600 gals. capacity. To the back of each wagon is attached a sheet iron trough into which the oil is discharged by three 2-in. valves, flowing evenly upon the roadway through small holes in the bottom of the trough.

On all previously oiled roadways, with which this article deals, a smooth oil cushion has been built up. This surface is thoroughly swept with a rotary street broom, preparatory to distributing the oil. The oil is distributed lightly from the tank wagon upon the roadway, and the tank is immediately followed by the rotary street broom, which spreads the oil over the surface in a thin even coat. Two to four men with hand brooms are necessary to keep the oil from running into gutters, and to spread oil on uneven places in roadway, and at intersections with streets.

The oiled surface is then covered with a thin coat of limestone dust, the finest product of the crusher. This is spread from the rear of an ordinary wagon by two men working from the ground with No. 2 scoop shovels. The dust coat first protects vehicles and pedestrians from the dangerous and nasty oiled surface, and after a few days under traffic forms with the oil a cushion surface.

TABLE XIII.—COST OF BOULEVARD OILING AT KANSAS CITY

	Benton Blvd. 55,010 sq. yds.		Paseo. 51,200 sq. yds.		Gillham Road 19,920 sq. yds.	
	Hrs.	Per sq. yd.	Hrs.	Per sq. yd.	Hrs.	Per sq. yd.
Foreman	19½	$0.00026	26	$0.000159	8	$0.00013
Man-hrs. on brooms	58½	.00011	86	.000419	24	.00031
Man-hrs. spreading dust	89½	.00040	122	.000595	39	.00048
Man-hrs. oil wagons	19½	.00009	26	.000127	8	.00010
Man-hrs. extra water, etc	28½	.00011	39	.000190	15	.00019
Team-hrs. on dust	77	.0007	75½	.000737	37½	.00094
Team-hrs. on broom	21½	.00019	27	.000263	8	.00010
Team-hrs. oil wagons	31	.00029	34	.000332	14	.00035
Cost of delays	....	.00005	....	.000062	.....	.00010
Oil, at 2½ cts. per gal.	3,590*	.00163	4,828*	.002357	356*	.00170
Dust, at 30 cts. per cu. yd	54†	.00029	54†	.000316	24†	.00036
		$0.00412		$0.005557		$0.00476

* Gallons. † Cu. yds.

Average haul miles

	Benton Blvd.	Paseo.	Gillham Road
Dust	2	2.5	1.0
Oil	1.75	1.0	2.0

Rates of wages—Foreman .... $2.50 per day
Labor .... 0.25 per hr.
Teams .... 0.50 per hr.

The oiling crew usually consists of one foreman at $2.50 per day, two to four men hand brooming oil, four men spreading dust, one man spreading oil, one extra man, two oil tank teams, two to four teams hauling and distributing dust. All labor is paid at the rate of 25 cts. per hour, but teams including drivers at the rate of 50 cts. per hour.

Daily reports are made out by the foreman; from these reports Table XIII has been compiled. This table is for three boulevards which represent average conditions when haul of materials is taken into account.

Under ordinary circumstances, the cost per square yard for oiling on The Paseo should be between \$.004 and \$.005, but on this boulevard there was 8,280 sq. yds. of new roadway, which requires much more oil and labor than the old cushion surface. There are also 4,968 sq. yds. of this boulevard used as a traffic way, on which the travel is exceptionally heavy, so that more labor is required in cleaning same, and a thick coat of oil and dust is required.

Cost of Applying Emulsifying Oil in Carlisle, Pa.—John C. Hiteshew gives the following data in Engineering and Contracting, June 9, 1915.

In 1914 Emulsifying Oil was selected because of its previous success. It had very little odor and after a few hours dried sufficiently not to track onto the sidewalks. Also the price played a large part in the selection.

The manner of applying the oil was as follows: An overhead siding was used from which the oil was run from tank car to sprinkler by gravity. An ordinary water sprinkler of 500 gals. capacity was used, and filled about one-half full, the sprinkler was then taken to the block to be oiled and the other half filled with water at the nearest fire plug. The oil and water were the thoroughly mixed with a hoe, but later on it was found that time was saved and as perfect a mixture was secured by placing the hose connected with the fire plug in the bottom of the sprinkler and turning on full pressure of the water, which would then literally "boil up" and thoroughly emulsify.

The sprinkler distributed the oil so uniformly that no brooming was required after oiling. The streets were lightly swept before oiling in order to clean them but to leave sufficient dust for the oil to take hold or penetrate.

The cost of oiling approximately 160,000 sq. yds. or 34 blocks, or eight miles of street averaging 45 ft. in width, giving the whole two applications, was as follows:

Materials—	
26,509 gals. emulsifying oil at .0446cts	\$1,182.31
Demurrage	16.00
Total	\$1,198.31
Labor—	
Foreman, 5 hrs. at 20 cts	\$ 1.00
Labor, 65 hrs. at 16 cts	10.40
Labor, 97 hrs. at 15 cts	14.55

Team, 103 hrs. at 15 cts	15.45
Team, 25 hrs. at 10 cts	2.50
Collector, 21 days at \$1.00	21.00
Collector, 6 days at \$1.50	9.00
Total	\$ 74.40
Grand total	\$1,272.71
Per square yard	\$0.008

Cost of Asphaltic Oil Surface Treatment at Portland, Me.—During the season of 1912 an area of 39,066 sq. yds. of macadam at Portland, Me., was given a surface treatment with asphaltoilene. The following costs on this work, given in Engineering and Contracting, Oct. 1, 1913, were rearranged from the annual report of the Commissioner of Public Works. The asphaltoilene cost 7½ cts. per gallon. Labor was \$2 per 9-hour day, and team and driver \$5.

Job No.	Cleaning and application	Sanding	Asphalt-oilene	Total cost per sq. yd.	Gals. per sq. yd.
5	$0.008	$0.003	$0.019	$0.030	0.26
7	.004	.005	.025	.034	.33
1	.010	.002	.027	.039	.36
2	.006	.005	.029	.040	.39
8	.006	.004	.030	.040	.40
4	.013	.003	.031	.047	.41
6	.013	.006	.031	.050	.41
3	.018	.005	.048	.071	.64

Cost of Tarvia Treatment at Queen Victoria, Niagara Falls, Park System (Engineering and Contracting, Dec. 5, 1917).

About 28,000 sq. yd. of the Niagara River Boulevard in the Queen Victoria Niagara Falls Park System, Ontario, were given a surface treatment with tarvia A in September, 1916. The cost of the work was 6.6 ct. per square yard, according to the annual report of the Park Commission. The average haul was 1½ miles, and the surface treated was 18 ft. wide and 14,000 ft. long. About ¼ gal. of tarvia was applied per square yard of surface. The detailed cost of treatment was as follows:

Labor	Cts. per sq. yd.
Teaming, ½-in. stone	0.69
Loading and spreading stone	.56
Sweeping and brushing roadway	.10
Heating tarvia	.40
Distributing and rolling	.10
Miscellaneous	.09
Total labor	1.94
Materials:	
½-in. stone chips, 348 tons at $1.10	1.37
Tarvia A, 6,500 gal. at 10 cts	2.32
Freight, $115; car service, $19	.48
Coal, 19.7 tons at $7	.49
Total materials	4.66
Grand total	6.60

Teams were paid for at rate of 45 cts. per hour; laborers received 20 cts. per hour and foremen 30 cts. per hour.

Cost of Asphalt Macadam Construction with Telford Base at Carlisle, Pa.— C. A. Bingham gives the following data in Engineering and Contracting, Dec. 20, 1911.

During the season of 1911 the Street Department of Carlisle, Pa., under the direction of the writer constructed about 10,000 sq. yds. of asphaltic macadam, of which 6,129 sq. yds. was on new work with a telford base and 3,529 yds. was on an 8-in. resurfacing on old macadam.

The grading for the new work was considerable, one grade being reduced from 5 per cent to 2.40 per cent, necessitating cuts up to 7 ft. for the full width of the 60-ft. street. This work was done by heavy plowing by double teams or power and hauling in dump wagons to fill adjacent streets. The grading force averaged eight men and 4,150 cu. yds. was cut at a cost of 32 cts. a yard as shown in the table following.

Simultaneously another gang of about eight men quarried 4,425 perch of limestone (a perch is 25 cu. ft. in this locality) at one of the town quarries near by. This cost 31 cts. a perch, not including stripping of clay which was done in opening a new street. The average rate was 7 perch per man day in low breast work. Only four perch was obtained from a pound of dynamite on account of much blistering.

The rock was then crushed by the department crusher into bins and hauled to this and other jobs. The crusher had a 10 × 22 opening and was portable and low setting. Sufficient power could not be produced by a 13-ton roller so a 16 H. P. traction engine was leased. Three men loaded three carts on a 400-ft. haul and three men fed the crusher and one man operated bins. The average amount crushed was 86 perch in ten hours and the cost was 27 cts. a perch. Coal was purchased by carload and a half ton per day was used.

Owing to a large amount of necessary work in other sections the laying of telford was given to a contractor whose quarry and plant was on the street and who could bid even with the department and yet make considerable profit. All other work was done by the municipal forces.

Prior to laying the telford the entire subgrade was trimmed to crown and contour and rolled thoroughly by a 13-ton three-wheel roller. At the same time the banks in deep cuts were sloped back to the building lines which will account for the large cost of 11 cts. per sq. yd. for trimming. The telford stones were broken about 8 ins. in height and were laid very close and well keyed with stone wedges. The average amount laid was 40 sq. yds. per man in 10 hours. After a stretch of 300 ft. (36 ft. between curbs) was ready it was rolled in a day by the large roller which crushed off projecting corners and imbedded the stones until the telford was 6 ins. above subgrade as called for. About 4 ins. of 1½ to 2½-in. stone was then spread over by a spreading wagon and when rolled into the interstices of the base there remained room for 2 to 3 ins., loose, of ¾ to 1½-in. stone. This top course was only rolled two or three times to smooth it up and no screenings were allowed.

The representatives of the asphalt company claimed that the top stone should be about 2½ ins. in size, but upon experiment it was found that this size required nearly 50 per cent more asphalt and produced only slightly better penetration and gave more danger of a flat stone tilting up. It was also claimed that no rolling whatsoever on the top course should precede the pouring but it was found that undulations would then not be found until too late for correction except at considerable cost.

The force used on the asphalt work was only five men. One man attended the wood fires, two men carried the hot asphalt and one man poured. The fifth man spread screenings, leveled stones ahead of pouring and on close work helped to pour. Fires were started at sunrise and pouring commenced at 7 A. M. The gang took very little time for lunch and at night always filled the kettles with fresh asphalt for the next day's work.

The kettles used were two caldrons on tripods holding nearly a barrel apiece and one 150-gal. asphalt heating tank on wheels. With this meagre outfit an average of over 400 sq. yds. a day was maintained. During the hot weather the barrels were suspended on trestles over the caldrons and set directly on the large kettle and thus emptied by gravity, but as the weather grew cooler this was too slow a process and the barrels were broken apart and the asphalt cut up in chunks. This of course could not be done in warm weather. It was found that with the time gained and by the burning of the broken barrels that more money was saved than by the slow method and the buying of fuel wood and returning the barrels. The barrels which had been drained in warm weather were well cleaned, when it became cooler by jarring the asphalt loose which had clung to the inside.

The only fault found with the material was the foreign matter contained in the barrels; sometimes a quart of paint or a dipperful of sticks would be found in one barrel which sometimes clogged the valve of the barrel and once caused a leakage of half a barrel, and necessitated a constant cleaning of the can spouts.

The asphalt was of natural lake origin and was heated to 360° F. so that it would reach the road at nearly 350° F. The weather temperature was from 80 to 98° F. The shipments of asphalt were so delayed that some extra work on an approach had to be completed when the temperature was down to 40°.

The asphalt was all poured by hand and was carried in large buckets and poured into the spreading can which had a fan-shaped spout 4 ins. wide and a ⅜-in. opening. A good 2-in. penetration was secured with 1⅛ gal. to the square yard by heating to a high temperature and having the stone clean and warm. Screenings from ¾-in. down were then spread over a depth of about ½ in. and the surface thoroughly rolled with a 6-ton tandem roller until the road was solid and set. At first a board was placed along the concrete curbs to protect them from splashings of asphalt, but after a little practice the men could spread along the curb without the board. The asphalt cost 15 cts. per sq. yd. and applying cost 6 cts. per sq. yd. It is hoped that next spring an appropriation will be made to clean off the screenings with a horse sweeper and place a seal coat over the entire street.

The resurfaced section was done in two layers, each of about 6 ins. loose which rolled to 4 ins. making the completed work average 8 ins. Every 20 ft. cross-stakes were set 6 ft. apart to correct crown and the road metal was placed about 25 per cent higher than the required depth to allow for compression. Every load of stone was dumped a few feet away from the desired location and then shoveled back to place so that no solid cores would be formed. This gave a smoother surface even on the resurface work than was produced by spreading wagons on the telford section. The stone for resurfacing was 1½ to 2½ ins. except top course of 3 ins. (loose), which was ¾ to 1½ ins. The resurfacing cost 24 cts. per sq. yd. This section was rolled and asphalted similar to the telford section.

In the following cost table data are given on a section of water-bound macadam which was placed at the end of the asphalt work and will make good comparison. It will be noted that no sprinkling cost is given, the reason being that the department sprinklers are operated by fire department horses and the water is also free because of semi-municipal ownership. As all macadam streets here are thoroughly wet until waves run ahead of the roller the sprinkling item if paid for would bring the water-bound macadam up to 37 cts. a yard. In other words, we construct an asphalt macadam for 8 cts. per yard additional over a water-bound macadam, or for the amount spent in annual repairs for two years on the inferior road we can build it right and enjoy a perfect road for many times that period.

The detailed cost of constructing the asphalt macadam was as follows:

QUARRYING STONE (4,425 PERCH)

	Rate, cts.	Per perch
Labor, 6,933 hours	17	$0.2663
Dynamite, 1,035 lbs	14	.0327

* 14 and 15 cts. †10 and 24 cts. *† $3 to $6.

Summarizing we have the following costs:

ASPHALT MACADAM WITH TELFORD BASE

	Per sq. yd.
Excavation	$0.2166
Subgrading	.1113
Telford and macadam	.4300
Asphalt binder	.2142
Total	$0.9721

ASPHALT MACADAM ON 8-IN. RESURFACING

	Per sq. yd.
Resurfacing, 8-in	$0.2424
Asphalt binder	.2142
Totals	$0.4566

The following costs were for the construction of a section of resurfaced water-bound macadam at the end of the asphalt macadam work. The total area was 2,240 sq. yds.

	Rate, cts.	Per sq. yd.
Labor, 322 hours	14 to 20	$0.0208
Carts, 97 hours	24 to 35	.0147
Roller engr., 103 hours	25	.0115
Crushed stone, 923 perch	59 to 90	.2727
Coal, 7,500 lbs	2	.0066
Total		$0.3265

Output and Organization Used in Operating Asphalt Mixer in Constructing 2-in. Asphaltic Concrete Surface.—The following data are taken from an abstract published in Engineering and Contracting, April 3, 1918, of a paper by R. Crawford Muir presented at the 1918 annual conference of Ontario Road Superintendents.

Mr. Muir described the reconstruction of Dundas Street which is the chief means of access to Toronto.

The wearing surface mixture was prepared in a Cummer standard 1-car protable paving plant of 2,000 sq. yd. of 2-in. top per day (10 hours) rated capacity, having a twin-pug mill (10 cu. ft.) capable of handling a 1,000-lb. batch of material. The total weight of this plant ready for transporting is 100 tons.

When the plant is working at its full capacity, 3 tons of coal are required per day.

The organization at the plant is as follows:

1 Foreman.
1 Engineer.
1 Fireman and 1 blacksmith.
2 Men at scales weighing materials.
2 Men feeding stone to elevator to drier.
2 Men feeding sand to elevator to drier.
2 Men shoveling stone from car.
2 Men shoveling sand from car.
2 Men stripping barrels, etc.
1 Man with horse, conveying sand from pile to elevator.
1 Man with horse, conveying stone from car to elevator.

On a good day's work (8 hours) the following quantities of material were used: 16 tons of asphalt, 132 tons of stone, 47 tons of sand, 11 tons of dust or filler, making a total of 206 tons of mixture.

The materials were mixed in a batch as follows:

	Weight, lb.	Per cent
Stone (½-in.)	625	64.10
Sand	225	23.07
Dust (filler)	50	5.13
Asphalt cement	75	7.70
		100.00

These weights, of course, were modified from time to time, in order to take care of the variations in the materials as delivered. Special care was exercised to see that there was always a high percentage of filler and that the mix carried all the asphalt cement possible without being sloppy.

When the quantity of asphalt cement in the mixture exceeded 7¾ per cent of the total weight there was trouble in some places with waving and ridges in the pavement, also with more or less bleeding. On the other hand, if the percentage fell below 7, the pavement had a tendency to crack.

The hot mixture was hauled from a portable plant, which was located at a railway station, to the road in the usual asphalt spreading wagons, dumped on the foundation at a temperature varying from 250° to 350° F. and conveyed to its final resting place by means of shovels. In shoveling the hot mixture into place, the material was shoveled from the bottom of the pile, thereby preventing the lower layer of the pile from becoming chilled. When the lower part of the pile becomes chilled, an uneven distribution and compression results. On a number of loads, especially on a long haul the larger particles of the mixture settled to the bottom of the load; when this occurred, the mixture on being dumped was remixed by turning over with hot shovels. The mixture, after having been deposited roughly in place by shovels, was spread by means of hot iron rakes to a depth of 2¾ in., thus allowing for an ultimate compression of 2 in. During this operation the rakers did not stand on the hot mixture any more than was necessary. Care was taken that all lumps were broken and a uniform consistency and even grade maintained, so as not to have depressions in the finished pavement. Raking is a most important factor in the construction of an asphaltic concrete pavement. With a hot mixture, 300° F. or more, 4 to 6 minutes were necessary for raking, but with a cold or stiff mixture 10 to 20 minutes were sometimes required. Cold or extra stiff mixtures should be avoided as insufficient compression and inconsistency results.

The largest number of loads dumped in one day was 65 (228 tons), covering an area of 1,800 sq. yd. or a length of 940 lin. ft. This was on the shortest haul, ⅓ of a mile. On the longest haul, 2 miles, 36 loads (126 tons) were dumped, 9 teams each making 4 trips in 8 hours, covering an area of approximately 1,130 sq. yd. On an average on a full day's work, 46 loads (106 tons) were deposited on the road, covering an area of approximately 1,300 sq. yd. These quantities would have been increased had the contractor placed more teams on the work.

Cost of Asphaltic Macadam at Waynesboro, Pa.—Engineering and Contracting, Oct. 4, 1916, publishes the following data, relative to the street improvements at Waynesboro, Pa., carried out by the city street force undei the supervision of G. C. Brehm, City Engineer.

The organization consisted of two foremen at 21 cts. per hour, a roller engineer at 25 cts. per hour and labor at 18 cts. per hour.

Of the 25,000 sq. yd. of asphaltic pavements laid, one block (1,170 sq. yd.) was constructed on Cleveland Ave., the cost of which follows:

It was found upon examination that the old macadam was so badly worn than an entire new base was necessary, and in order to bring the contour of the road to its proper place, about 8 in. of grading had to be done, the rough grading being handled by means of the road roller and plow. The average haul was 1 mile.

Upon the thoroughly rolled sub-base, run of crusher limestone 6 in. thick (after compression with a 10-ton roller) was used as a base.

Three inches of crushed stone (after compression) 2 to 3 in. in size was placed upon this base and after being thoroughly rolled with a 10-ton roller the asphalt, which was Aztec, was applied by means of pouring cans. Just enough ¾-in. stone to take up the voids was then spread over the hot asphalt and the whole was again thoroughly rolled. After applying ½ gal. of asphalt per square yard, the surface was covered with ½-in. chips and rolled.

The ¾-in. and ½-in. stone contained a great deal of dust and screening was necessary before they could be applied to the road. The cost of the work was 85 ct. per square yard, as follows:

Total	$0.8501

Cost of Removing an Asphaltic Macadam Road Surface, Reworking the Old Material and Relaying it as Asphaltic Concrete.—G. C. Dillman published the following data in Engineering and Contracting, Dec. 9, 1914.

A poured process asphaltic macadam surface 16 ft. wide was laid on the extension of Woodward Ave., Detroit, in 1912. This road is a trunk line between Detroit and Pontiac and is subjected to a heavy traffic. Holes began to appear in the surface soon after its completion.

The original improvement was made by Royal Oak township of Wayne Co. Mich., which did not make the repairs required by the state reward road law and in July, 1914, the surface was reconstructed under the direction of F. H. Rogers, state highway commissioner. The new work consisted of tearing up the old asphaltic surface, heating it with necessary new material added and relaying on the old slag macadam base.

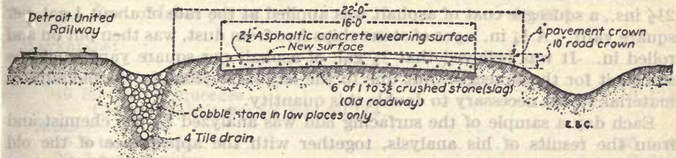

FIG. 2.—Typical cross section of roadway improved.

Removing Old Surface.—The asphaltic surface to be removed was first swept clean. Twelve men, picking, lifted and picked into small chunks and shoveled into wheelbarrows, the material covering about 250 lin. ft. of roadway surface each day.

In scalping off the old bituminous top, two places were broken up at the same time to hasten the work. At first the men picking stood on the surface already broken up, pulling the chunks as picked up, toward them. This did not work out satisfactorily so another method was tried, in which the men stood on the old surface, driving the pick beneath the broken edge. The surface coat was then readily lifted and broken into pieces that could be handled. These large pieces were then thrown back where three men picked them into still smaller ones to save time in the mixers. The old material broke up readily in the morning but towards noon softened and more time was needed in breaking. Although the depth of penetration was far from being uniform, the bituminous top separated readily from the slag foundation.

Long stretches of the old surface were laid when the foundation was wet, and the bad effects of water present could be seen. The asphalt had not penetrated to a sufficient depth, and there was practically no bond in the pavement in such places. In other places a 6-in. penetration was observed.

When the old surface was broken up the stone was often covered with moisture and the asphalt could be peeled from the stone. This presence of moisture may be partially accounted for in that the general drainage of the road was poor, yet it is probable that the foundation had not been in a dry condition since the pavement was laid. When the road was resurfaced, the foundation was allowed to dry out and the general drainage was also taken care of.

Mixing and Placing.—The equipment for mixing and placing consisted of 2½-cu. yd. hot mixers, 1 500-gal. heating kettle, 1 5-ton roller, carts, small tools, etc.

The old surface picked into small chunks was delivered to the mixers in wheelbarrows. An average batch consisted of sufficient material to lay 3½ sq. yds. of 2½ in. surface, and contained 728 lbs. of old top, 252 lbs. of new stone and 15.92 lbs. of new asphalt.

The old top was charged into the mixer with about 25 per cent. of ½ to ¾ in. stone added and about 0.45 gals. per square yard, or about 1.6 gals. per batch, of new asphalt. Mixing was usually continued 8 mins. at the end of which time the temperature of the material would average about 240° F. Two high-wheeled carts were used to convey each batch to the point where it was to be laid.

The base, after removing the surface material, was found to be very rough due to the original poor grading, and to the varying depths of penetration of the asphalt. All depressions in the bottom layer were filled with ¾ in. stone, after which it was thoroughly compacted by rolling.

After the bituminous macadam had been laid and rolled to a thickness of 2½ ins., a squeegee coat of asphalt was applied at the rate of about 1 gal. per square yard. A ¼ in. layer of stone chips free from dust, was then put on and rolled in. It was believed that ½ gal. of asphalt per square yard would be sufficient for the squeegee, but due to the large size stone in the old surface material, it was necessary to double this quantity.

Each day a sample of the surfacing laid was analyzed by the chemist and from the results of his analysis, together with the appearance of the old material, the mix was determined. Almost constant attention had to be given the mix on account of the varying composition of the materials. An attempt was made to keep the per cent of bitumen between 5 and 6, but it was low at times due to the large stones in the sample tested.

The road was closed to traffic July 13, 1914 and opened to traffic August 12, 1914, about an hour after completion. Thirty-eight men were required 24 working days to tear up, remix and relay 9,055 sq. yds. In a 10-hour day a maximum of 510 sq. yds. was laid.

Cost and Personnel.—Table XIV gives an itemized statement of the costs per square yard of pavement laid. These figures were compiled from the daily expenses as gathered by the state inspector and are very close to the exact cost. The contract price for laying the bituminous pavement was 73 cts. per square yard, $500 being allowed for the extra asphalt used for squeegee.

The prevailing rate of wages was $2.25 a 10-hr. day for ordinary labor; $2.50 and $3.00 being paid enginemen, firemen and rollermen, and $4.00 for raker. The teams cost $5.00 per day

The estimate for foreman is based on 30 days at $10.00. The contractors had two foremen on the work at all times, both being members of the contracting firm.

The equipment cost cannot be stated in exact figures, since it was owned by the contractor, but the figures given represent an average rental price.

TABLE XIV.—UNIT COSTS OF WORK

		Cost per sq. yd.
LABOR:		
Preparing old bituminous top—		
2 engineman		$0.016
2 firemen		0.014
2 platform men		0.013
6 wheelers		0.029
12 pickers		0.064
Total	$0.136	
Placing new material—		
4 cartmen		$0.020
1 kettleman		0.008
1 raker		0.013
1 rollerman		0.008
Total	$0.049	
Preparing grade—		
3 grademen		$0.015
Putting on squeegee and chips—		
3 squeegeemen		$0.021
Other labor—		
2 helpers		$0.012
1 waterboy		0.003
1 nightwatchman		0.007
Incidental labor		0.016
team (steady)		0.017
Total	$0.055	
Cost of labor per sq. yd	$0.276	
MATERIALS:		
Asphalt—		
20.53 tons in mix		$0.051
49.80 tons in squeegee		0.123
Cost of asphalt per sq. yd., $0.174.		
Stone—		
325.9 tons in mix		$0.068
90.5 tons in chips		0.019
12.7 tons in grade		0.003
Cost of stone per sq. yd., $0.090.		
Incidentals—		
Fuel, insurance, freight on equipment, etc		$0.073
Equipment (estimated)—		
Roller and kettle		$0.023
Two mixers		0.100
Small tools		0.006
Total	$0.129	
Foreman (estimated)		$0.033
Grand total		$0.74

SUMMARY

Item	Average for 2,586 batches	Totals
Length surfaced, lin. ft	1.97	2,586

New stone in mix, lbs	252	651,790
New stone in mix, per cent	24.3	....

Comparative Cost of Mixing Bituminous Road Materials by Machine and by Hand.—In an article in Engineering and Contracting, Feb. 26, 1913, Herbert C. Poore gives the following costs:

Mixing work previous to the 1912 season has generally been done by hand on wooden platforms with hot shovels. During 1912, however, 18 mechanical batch mixers were used. These mixers are portable and are either set up in connection with the crushing plant or else moved along the road as the work advances. To handle the stone economically the crusher bins at a stationary plant discharge directly to both wagons and to the mixer hopper by gravity and the mixer discharges the coated stone to the wagon by dropping from a spout.

The apparatus most generally used is one manufactured by the Municipal Engineering & Contracting Co. of Chicago, known as the Chicago Improved Cube Mixer. When provided with the Austin oil torch heating attachment the stone may be dried for use in bituminous road construction. The machine consists of an iron cube, revolving on its diagonal axis and gear driven from a steam engine mounted on the same portable frame. A small belt-driven air compressor furnishes the necessary pressure for operating the crude oil torch. The two ingredients are mixed in the cube chamber by kneading and folding rather than by stirring and the action is rapid and complete.

The broken stone is first dumped or shoveled into the measuring hopper which is then raised on an inclined slide by a small cable hoist. After depositing the charge in the mixing chamber the stone is turned for several minutes under the oil torch blast before the hot Tarvia is poured in. To discharge the mixture, the engineer operates a single lever which tips the revolving cube and allows the material to drop by gravity to the wagon or wheelbarrow.

The mixers, generally of ½ yd. capacity, in unit with the stone crusher, run three batches in 10 to 15 mins. with four men; namely, an engineer, a tar man, a loading man and a helper. A wagon of 1½ cu. yd. capacity waits for the three batches to be mixed and then hauls them to the road, unually not more than a mile distant from the plant.

When the mixing machine is used on the road, the stone is dumped on a board platform at the mixer, placed some 200 ft. ahead of the point where the tar macadam is being laid, and moved as the work progresses. The loading skip of the mixer is filled by hand and the mixed macadam wheeled in barrows to the road. Portable kettles holding 100 or 200 gals. are in use at both the stationary and portable plants. The Tarvia is shipped in steam coiled tank cars, run off into barrels, and conveyed to the road in the barrels to be used as required. Contractors are asked for bids on both water-bound macadam and tar macadam. The latter price is always stated in a square yard price over and above the cost of water-bound macadam. For example, on a 6,300 sq. yd. job a price was give of $3.25 per cubic yard of stone in place with 18 cts. per square yard for bituminous work. On this 6-in. road, 1.18 gals. of Tarvia were used in the top 2 ins. of hand-mixed macadam, making a total cost of $0.935 per square yard of finished road. The contract prices average about $7,600 per mile for a 14-ft. road, or approximately $0.92 per square yard exclusive of binder. The following are the contract prices on several roads:

Coventry, R. I., length road 3.16 miles; contract price, including binder, $1.01 per square yard; Warwick, R. I., length road 4.00 miles; contract price, including binder, $0.98 per square yard. Foster, R. I., length road 4.88 miles; contract price, including binder, $0.87 per square yard. These sections were mixed by machine and the work progressed from 150 to 400 ft. per day.

The following figures, based on careful observation of the various jobs, are a close approximation of the relative costs by the two methods:

No. 1—Portable Plant on Resurfacing—2 Ins. Thick, 440 Sq. Yds.

	Per day
Foreman, ½ time	$ 2.50
Engineer	2.50
6 laborers at $1.85	11.10
Kettle man	2.25
2 men spreading at $1.85	3.70
	$22.05

This gives a cost of $0.05 per square yard for labor of mixing and spreading stone and Tarvia. The mixer turned seven to eight batches per hour, which covered 50 sq. yds. of surface. Observation of two other portable plants gave approximately the same labor cost.

No. 2—Hand Mixing on Board Platform: Resurfacing 2 Ins. Thick, 280 Sq. Yds.

	Per day
Foreman, ½ time	$ 2.50
10 laborers at $1.85	18.50
1 kettle man	2.25
	$23.25

This gives $0.085 per square yard as the cost for labor of mixing and spreading.

In work of similar nature done by the writer the labor cost for mixing and spreading a finished 2-in. course has varied from $0.12 to $0.18 per square yard. The difference of $0.05 and $0.085, or $.035, per square yard, is further increased by the saving in bitumen in the machine mix over the hand mix, amounting to .75 gal. per square yard, of approximately $0.06 per square yard. On the other hand the machine mix costs are increased by interest and depreciation and the cost of installing and moving the plant.

Cost of Asphaltic Macadam Construction on the Boulevard System of Kansas City, Mo.—C. W. Redpath gives the following in Engineering and Contracting, May 21, 1913.

The boulevard system of Kansas City (in 1913) comprised some 55 miles of improved roadways practically all of which were of macadam construction, maintained by the use of road oil which tested 19/21 B. by high grade hydrometer. This oil was applied hot from a tank by gravity or by spraying at a pressure of about 20 lbs. This was essentially an improvement in maintenance and while satisfactory to a degree has had several drawbacks, viz.:

(*a*) Oiling must be done from two to four times a year at an average cost of 1 ct. per square yard per application.

(*b*) Constant oiling has built up a thick oil cushion.

(*c*) Satisfactory repairs are impossible on this cushion.

(*d*) The thick cushion has become wavy and uneven under traffic.

Some of these roadways have been reconstructed by removing 2 ins. of the top course and replacing with a 2-in. asphalt bound wearing surface applied by the penetration method. This has proved a satisfactory solution for the improvement of the old oiled macadam pavements.

First Method.—8,300 sq. yds. of macadam were put down on Gillham Road and bound with asphalt, the asphalt being applied by the penetration method.

Most of the asphalt was received in car lots on a railroad siding near by and was hauled by wagon to a large asphalt agitator tank. It was loaded into this tank with a hand derrick, after as many of the hoops and staves as possible had been removed, the remaining pieces of the barrel being taken from the tank when the asphalt was melted.

The liquid asphalt at about 350° F. was then pumped into a small portable kettle of about 300 gals. capacity, which was supplied with a fire box to keep the asphalt at the proper temperature for pouring, and in this kettle was hauled by team to a convenient location for distribution. Here it was loaded into small hand kettles and carried to the man who poured it upon the prepared rock surface.

It was necessary to have an engineer at $3.00 per day on the agitator tank to fire and operate the pump. Only one portable kettle was used and some time was lost by the pouring gang each time it was taken away to be filled. This has been made note of in Table I, which is the complete cost report on labor and materials for applying two coats of asphalt on 8,300 sq. yds. of pavement.

Several types of small hand kettles were tried, but one which gave the best results holds 5 gals. and was made specially for this work. The liquid asphalt is spread from this kettle with a long swinging motion of the arm from right to left. The asphalt used was Texaco 96 Paving Cement, which weighs 8.25 lbs. per gallon and costs $21.30 per ton, f. o. b. Kansas City. It was delivered in ordinary wooden barrels and was very hard to strip when the weather was warm.

TABLE XV.—COST OF LABOR AND MATERIALS—APPLYING ASPHALT ON MACADAM BY PENETRATION METHOD

	First coat		Squeegee coat	
8,300 Square yards	Hours	Cost per sq. yd.	Hours	Cost per sq. yd.
Foreman, 31.2 cts. per hour	56	$0.00210	46	$0.00173

Total labor	......	$0.03196	....	$0.01900
Asphalt ... gals.	12,732[1]	$0.13478	4,283[2]	$0.04534
Joplin flint ... cu. yds.	57[3]	.00890	89.3[4]	.01397
Total materials	......	$0.14368	.....	$0.5931
Total labor and materials	......	.17564	.....	.07831

[1] 1.534 gal. per sq. yd. [2] .516 gals. per sq. yd. [3] 18.6 lbs per sq. yd. [4] 29.1 lbs. per sq. yd.

The first coat of asphalt was covered with a layer of ¼ or ¾ in. Joplin flint, a very hard stone which is found in the lead and zinc mines at Joplin, Mo. It costs $.048 per 100 lbs., f. o. b. Kansas City, or $1.30 per cubic yard. A cubic yard of the flint weighed about 2,700 lbs. This also was received in cars on a railroad siding near by. After rolling this first coat thoroughly, all the loose Joplin flint was swept off by hand with street brooms and the road surface was ready for the second or squeegee coat of asphalt, which was applied in the same way as the first coat and covered with Joplin flint. After rolling, the surface was ready for traffic and while some loose screenings were removed afterward, most of them worked into the asphalt under traffic. All finish rolling was done with a 7-ton Springfield-Kelly tandem roller. The engineer was paid $3.00 per day and the roller is charged in the cost report at 50 cts. per hour.

As this was the first work of this kind done, some difficulty was experienced in training the laborers to handle and pour the asphalt. The foreman was paid $2.50 per day, two engineers at $3.00 per day and all labor at 25 cts. per hour. Teams were paid for at the rate of 50 cts. per hour. When asphalt was poured only part of the day, the gang was put at other work.

Second Method.—In continuing this work, 6,184 sq. yds. of pavement were laid just as the above with the exception that a different method of heating and distributing the asphalt was used. The advantages of these changes is shown in Table XVI in the reduced cost of labor per square yard. Part of this difference, however, is due to the better organization and greater skill pouring and handling the asphalt.

TABLE XVI.—COST OF LABOR AND MATERIALS—APPLYING ASPHALT ON MACADAM BY PENETRATION METHOD

6,184 Square yards	First coat Hours	First coat Cost per sq. yd.	Squeegee coat Hours	Squeegee coat Cost per sq. yd.
Foreman, 43.8 cts. per hour	27	$0.00191	16	$0.00113
Stripping barrels	27	.00109	18	.00073
Loading and firing kettles	80	.00324	45	.00182
Loading hand kettles	27	.00109	17	.00069
Carrying hand kettles	65	.00263	38	.00154
Pouring asphalt	53	.00214	30	.00122
Wheeling Joplin flint from piles to work	28	.00113	42	.00170
Spreading Joplin flint	15	.00061	27	.00109
Roller, 50 cts. per hour	27	.00219	17	.00138
Joplin flint from car to work		.00166		.00259
Asphalt from car to work		.00134		.00048
Brooming Joplin flint from first coat	115	.00465		
Total labor		$0.02368		$0.01437
Asphalt, gals.	8,720[1]	.12390	3,210.5[2]	.04560
Joplin flint, cu. yds.	41[1]	.00859	64[1]	.01341
Total materials		$0.13249		$0.05901
Total labor and materials		.15617		.07338

[1] 1.410 gals. per sq. yd. [2] 0.519 gals. per sq. yd. [3] 17.9 lbs., or 0.00663 cu. yds. per sq. yd. [4] 27.94 lbs., or 0.01035 cu. yds. per sq. yd.

Two large kettles of 500 gal. capacity and supplied with fire boxes were manufactured to order, at a cost of $300 apiece. They proved very satisfactory. The kettles were placed side by side with space enough between for a platform, the top of which was about level with the top of the kettles. A long incline plane was attached to the platform so that it could be readily removed. The barrels were stripped from the asphalt, which was rolled up the plane to the platform where it was cut up and dropped into the kettles. One kettle was loaded while the liquid asphalt was taken from the other.

The melting plant, as above described, could be quickly moved as the work progressed, so that when the distance between the kettles and the point of pouring became more than 150 ft., it was moved.

The advantages of this asphaltic macadam pavement are:

1. It does not disintegrate under impact or suction.
2. It is not slippery.
3. It is entirely waterproof.
4. Its wearing properties are excellent.
5. Its surface can be readily renewed by another squeegee coat.
6. It is easily cleaned.
7. Cuts can be quickly and neatly repaired.
8. The disagreeable feature of oiling two or more times a year is eliminated.
9. The maintenance cost is low.

The results obtained on this roadway have been very satisfactory and after six to nine months under heavy traffic it affords a smooth, resilient, waterproof and dustless pavement, which shows very little wear. It is now proposed to gradually change the entire boulevard system of Kansas City from a water bound macadam maintained with road oil to an asphaltic macadam by surfacing with a 2-in. asphalt wearing surface.

Cost of Tarvia-Macadam at Fredericton, N. B.—The following data, published in Engineering and Contracting, March 15, 1911, were given by J. L. Feeney.

During the past season two blocks of tarvia-macadam were laid by the city of Fredericton, N. B., the total amount being 5,582 sq. yds.

The broken stone used in the work was nearly all 1½ to 2-in. trap rock, though a small amount of sandstone was of necessity used. The stone was purchased from the city roads and streets department at a cost of $1.30 per ton for crushed trap rock and $1.00 per ton for sandstone.

The binder material, Tarvia X, was applied hot, the penetration method being used. Two applications of the binder were used on the wearing course and also on the top dressing. The amount of Tarvia used per sq. yd. of surface was 3.07 U. S. gals. Of this amount, 2.4 gals. were used on the wearing course and .67 gal. on the top dressing. The Tarvia cost $5.25 per cask of 48 U. S. gals., delivered in Fredericton. The total amount of Tarvia purchased was 378 casks. Of this amount, 357 casks were used in constructing the two blocks of pavement, leaving 21 casks in stock. Of the empty casks, 345 were returned to the company, this netting the city $94.15. Thus the total net cost of the Tarvia used in this work will be seen to be $1,780.10, or about 10.4 cts. per U. S. gal.

Sand was spread on the finished surface of the pavement, the amount used per 100 sq. yds. of surface being 1.55 cu. yds. The total amount of sand used was 45 loads. The cost of the sand was $1.25 per load.

The following tabulation shows the cost of material and labor for constructing the macadam, this work including a small amount of grading:

	Per sq. yd.
1,603 tons crushed trap rock at $1.30	$0.372
130 tons sandstone at $1.00	.023
Labor	.083
Teaming	.074
Rolling	.021
Engineering and superintendence	.054
Sundries	.008
Totals (5,582 sq. yds.)	$0.635

The following is the average organization of the gang engaged in grading and constructing the macadam proper:

11 laborers at $1.50 per day	$16.50
2 double teams at $3.50 per day	7.00
2 single teams at $2.25 per day	4.50
Total	$28.00

This force placed on an average 180 sq. yds. of macadam per 9-hr. day.

The cost of the tarvia treatment was as follows:

	Per sq. yd.
17,136 gals. tarvia at 10.4 cts	$0.319
Labor, heating, applying, etc	.057
Cost of plant, tools, etc	.024
45 loads sand at $1.25 per load	.010
Totals (5,582 sq. yds.)	$0.410

The gang employed in heating and spreading the binder was as follows:

6 laborers at $1.75 per day	$10.50
1 single team at $2.25 per day	2.25
Total	$12.75

With this force the binder was applied to about 185 sq. yds. of macadam each 9-hr. day. The total thickness of the completed Tarvia-macadam was 7 ins. and its total cost was $1.04½ per sq. yd. This is a rather low cost when it is considered that this Tarvia-macadam work was the first attempt in the city in the construction of this kind of pavement. The cost of the Tarvia was also somewhat high, being 12½ cts. per imperial gallon, whereas the same product can be obtained at less cost in New England cities. The essential features in the low cost of construction were the comparatively low cost of crushed stone, the short haul (the cost of hauling amounted to 31 cts. per ton mile) and the small amount of excavation necessary.

Costs of Plant and Equipment for Building Bituminous Roads.—The cost of a portable plant for asphaltic concrete roads in Chicago is given in Engineering and Contracting, Oct. 14, 1914, as follows:

Within the city limits of Chicago there are approximately 500 miles of macadam streets and roads. To accomplish the work of resurfacing the outlying roads a portable, one-car asphalt plant with a rated capacity of 2,500 sq. yds. of 2 in. asphaltic concrete in 9 hours was purchased from the Warren Brothers Co., Boston, Mass., at a cost of $13,000.

The plant was put in operation in May, 1914, and since that time has operated continuously. The rated capacity has been exceeded upon several occasions, 3,240 sq. yds. of surfacing being the maximum output in one day.

Several changes were made in the plant after its erection by W. H. Barton, the foreman, to better adapt it to the work in hand. The whole plant was changed so as to use fuel oil for heating purposes, avoiding the smoke and other inconveniences from burning coal. Also all the small lubricators were displaced by one central steam pressure lubricator with lead pipes to the various points requiring lubrication.

Operation.—In operation, the sand and stone mixed in the proper proportions are run into the dryer where the mixture is heated to 300° F. From there it is conveyed to the storage bins and thence to the measuring bins, whence it is drawn off as required to the 15-cu. ft. mixing drum. Materials are proportioned by weight.

The force employed at the mixer consists ordinarily of 1 foreman and 34 men, as follows: 1 chief drum man, 1 drum man, 1 kettle man, 1 mixer man, 1 timekeeper, 1 material man, 25 laborers, 1 assistant chemist, and 2 watchmen. The total cost of labor employed at the mixer averages $90 a day.

To facilitate the quick delivery of material at the plant a car tracer is employed who locates and keeps the cars in transit. This tracer uses a motorcycle and usually covers a distance of 75 miles each day.

Mixture.—The mixture used averages approximately as follows:

Item	Percentage
Bitumen	6.5
Sand	37.2
Stone	52.3
Filler	4.0
Total	100.0

The stone aggregate consists of clean crushed Wisconsin granite ranging from ¼ to 1 in. in diameter which cost delivered $2.25 per cubic yard. Torpedo sand is used. Portland cement serving as filler to make up the deficiency in fine material. The Mexican liquid asphalt used for binder (penetration 60 to 70) is delivered in tank cars.

Hauling.—Ordinarily about 18 teams are employed in hauling. Recently, however, 5 ton Pierce-Arrow motor trucks have been used to advantage. Material hauled in motor trucks is handled more quickly and arrives at the point where it is to be laid in better condition than when hauled by teams. The newly laid road is, however, subjected to excessive loads due to their use, all materials being, as far as possible, hauled over the completed surface.

Laying Surfacing.—Surfacing material is delivered hot in tarpaulin covered wagons, or motor trucks, and dumped directly into the prepared base. The material is raked, smoothed and tamped, to a uniform surface 2 ins. thick and finished by rolling with a 6-ton tandem roller. No paint, or finish coat of bitumen is applied, a slight roughness of surface being desired.

Force Employed.—The day labor force employed in preparing the old surface and laying the asphaltic concrete is ordinarily organized as follows: 1 asphalt foreman, 2 rakers, 2 smoothers, 2 tampers, 15 helpers, 2 watchmen, and 2 roller engineers. By far the larger part of the work consists of laying the surfacing.

Output and Cost.—As a rule, in excess of 2,000 sq. yds. of 2-in. surfacing, or about 1,000 lin. ft. of roadway 18 ft. wide, has been covered each working day of 9 hours. The average cost of all work completed, including the preparation of the old roadway and laying the 2-in. asphaltic concrete surface, has been approximately 70 cts. per square yard.

Suggestions for Selection and Use of Bituminous Paving Equipment.—The following matter is taken from a paper by W. S. Godwin and published in the Proceedings A. S. C. E., Vol. XXXIX, and reprinted in Engineering and Contracting, Dec. 31, 1913.

Hot Surfacing and Penetration Methods.—If pressure distributors are equipped with interior steam coils, and sufficient steam is supplied to keep the bituminous material at a uniform temperature of about 280° F., they are capable of distributing the heavier grades for either the hot surfacing or the penetration methods of construction.

The equipment generally used in the penetration method has been portable or semi-portable melting kettles, having capacities ranging from 50 to 500 gals., and hand-distributing pots. This method of heating and applying is expensive and the results obtained are invariably crude. The bituminous material is often too cold, and, in some cases, is overheated and damaged.

The arrangement and equipment for penetration work is most satisfactory when the contractor receives the bituminous material at the nearest railroad siding, in 6,000, 8,000, or 12,000-gal. tank cars, equipped with interior steam coils. A 20-HP. boiler may be attached to the steam coils in the tank car and thus heat the material to the desired temperature. If this arrangement is provided at the railroad siding, the hot material may be run by gravity into the distributing wagons. If this is not practicable, the material may be pumped from the car to the wagons. A horse-drawn distributing wagon may be hauled from the railroad to the work and then may be attached to a steam roller. Bituminous material received in barrels costs the contractor an additional sum of at least 2 cts. per gal. for each barrel and also the freight on the barrels, which is about 15 per cent of the gross weight. Besides, he has two or more melting kettles to operate and a very large bill for fuel to heat them.

A 20-HP. boiler and a 600-gal. distributing wagon will cost about $1,000, and, with an average haul from the railroad siding, should cover 800 sq. yds. per hour. Two 400-gal. melting kettles, at $400 each, and a dozen buckets and pouring pots will cost about $850, and will not cover one-half as great a yardage.

Should the extent of the work not warrant the purchase of such a plant, there should be secured a strong, well-built 500-gal. melting wagon and a hand distributor, having a capacity of at least 30 gals. mounted on wheels, and having a regulating distributor at least 20 ins. wide. A distributor of this kind costs $65, and should pour 250 sq. yds. per hour, using 1½ gals. in the initial pouring and ½ gal. in the flush coat. The use of pouring pots should be avoided if possible.

Mixing Method.—The cost of heating and mixing plants depends principally on their capacity and the care and material used in their construction. A small portable batch heater and mixer, similar to a concrete mixer, and capable of heating and mixing about 7½ tons per hour to a temperature of 200° F., costs $1,500. Mixers of this class are only capable of mixing stone which is larger than ¼ in. As the bituminous material is placed in these mixers hot, a 500-gal. melting kettle is required. For close or dense mixtures, stationary, semi-portable and railroad plant are used. Semi-portable plants, comprising the heating drum, mixer, melting tank, etc., cost $7,500, exclusive of any building, and have a capacity of about 75 sq. yds., or 7½ tons, of sheet-asphalt mixture per hour. The improved railroad plants, which cost about $12,000, are capable of heating and mixing sufficient asphalt and sand to a temperature of 325° F., to lay 175 sq. yds., or 17½ tons, of sheet asphalt mixture per hour. The modern duplex stationary plant, in which the large dryers, 15 cu. ft. mixers, conveyors, etc., are operated with independent motors, cost about $33,000, including a steel building. These plants have a capacity of 500 sq. yds., or 50 tons, of sheet-asphalt mixture per hour.

As mixtures of stone are laid at a lower temperature and require less bituminous material than sheet asphalt, the capacity of plants increases about 18 per cent when heating and mixing for paving of this class.

In buying a bituminous mixing plant of any kind, the contractor or municipality should receive bids only from companies which have had considerable experience in the manufacture of such machinery. It should be required that the plant be erected and operated under the direct supervision of the builder until it has met the guaranteed requirements. The guaranty should be for a certain number of pounds of properly heated paving mixture at a specified temperature, per day of 10 hours, and not a certain number of square yards. As all dense bituminous mixtures, when compressed to 2 ins. weigh very nearly 200 lbs. per sq. yd., this portion of the guaranty can easily be changed from square yards to something which is definite and easily ascertained. The contract should also state the maximum quantity of fuel to be consumed in 24 hours, and last, but not least, the date when the finished plant will be completed, erected, tested, and ready to run to the guaranteed capacity.

Cost of Asphalt Block Pavement Laid on Sand and Loam Base.—Engineering and Contracting, Feb. 6, 1918, publishes the following data:

Asphalt block pavements laid at Savannah, Ga., on a natural base have proved remarkably successful. The earliest pavement of this type was put down on Gaston street in 1906 and is now in excellent condition. On several streets where this pavement has been laid there has been no maintenance cost.

The success at Savannah is attributed largely to the character of the soil upon which the block is placed. This foundation consists of sand intermixed with a small amount of loam. Where clay has been encountered there have been some failures, due to moisture getting under the blocks and allowing a rocking motion. With the sand loam streets excellent drainage is afforded, which is absolutely necessary for the success of asphalt block pavement laid on the natural base. It is stated that success is not attained if the block is placed upon pure sand, for there is a creeping movement and the blocks are not held firmly in place.

The method employed in Savannah in laying the asphalt block pavement is as follows:

The street upon which the block is to be laid is graded to approximately the established sub-base grade, curbing and catch basins are installed and then the street is thoroughly puddled and then rolled over and over with a 10-ton roller. If any portion settles below the sub-grade base, material is added and this is compacted firmly by rolling and puddling. Grade pegs are then instrumentally set and the surface is carefully screeded or shaped to the sub-base grade with templates, care being taken that no foreign material is left upon the surface of the base. After this the blocks are carefully laid, one man following the pavers driving the blocks on the edge so as to have as tight joints as practicable. Then the surface of the block is rolled with the 10-ton roller. River sand is then used for filling the joints, and is left on the surface for 10 days to two weeks before it is cleaned off.

The average cost per sq. yd. of asphalt block pavement laid in 1916 was as follows:

	Per sq. yd.
Labor:	
Watchman	$0.010
Grading	.080
Shaping base	.010
Rolling foundation	.010
Laying block	.112
Paving backs at street intersections	.002
Placing sand and filler	.002
Cleaning up	.008
Total	$0.234
Material:	
Asphalt block	$1.540
Sand	.005
Use of equipment	.030
Small tools, coal, etc	.001
Total	$1.576
Grand total, per sq. yd	1.81

The asphalt block paving gang consisted of a foreman who was paid $4 per day, block layers paid $3 per day and ordinary laborers at $1.75 per day. The steam roller men were paid $3 per day. The size of the gang usually consisted of 20 to 25 laborers, including the drivers of teams or carts.

Cost of Asphalt and Brick Pavements, at Flint, Mich.—The following data are taken from an article by Clarence E. Ridley in Engineering Record, June 10, 1916.

Quantity of Work Completed.—The total amount of pavement built by the city by day labor during the 1915 season was 90,031.8 sq. yd., of which 73,799.6 sq. yd was sheet asphalt. In addition the city also constructed sewers, sidewalks, bridges and other work, bringing the total cost to $322,920.08. At the same time there was spent on contract work $135,320.42, thus making the total cost of improvements for the fiscal year ended Feb. 29th, 1916, $458,240.50.

The overhead engineering on all of the foregoing work amounted to $7,095.76, or 1.5 per cent of the value of the work done.

In order to afford a comparison of the figures on unit costs there are given in Table XVII the cost of materials and labor used in the construction of pavements, all the material prices being f.o.b. Flint, except that for cement, which is the price delivered on the line of work.

TABLE XVII.—UNIT COSTS OF ROAD WORK

Asphalt, per ton:	
Bermudez	$29.36
Standard	13.91
Trinidad	21.37
Texaco	14.11
Fluxing oil, per ton	8.85
Binder stone, per ton	1.28
Limestone dust, per ton	4.10
Asphalt sand, per cu. yd	1.09
Concrete gravel, per ton	0.83
Paving brick, per sq. yd	0.88
Cement, per bbl	1.29
Laborers, per hr. for 10-hr. day	0.25
Teams, per hr. for 10-hr. day	0.55

As the total excavation for paving was more than 50,000 cu. yd., and as but one steam shovel was available, it was necessary to use hand labor on about two-thirds of the work. In the selection of streets the hand labor was favored at all times, which makes the saving shown by the steam shovel even larger than is indicated by the figures in Table XVIII. In addition to the excavation it was, of course, necessary to have a hand crew working ahead of the steam

TABLE XVIII.—COMPARATIVE COSTS OF STEAM-SHOVEL AND HAND EXCAVATION

Steam-Shovel Excavation	
Total cubic yards	16,838.9
Labor cost	$ 4,965.01
Average cost per cu. yd	0.295
Average cost per sq. yd., finish grading	0.042
Total average labor cost per cu. yd	0.377
Average cost of fuels, oils, etc., per cu. yd	0.015
Reimbursement of equipment fund for depreciation and repairs	0.033
Total average cost of excavation per cu. yd	0.425
Hand Excavation	
Total cubic yards	34,464.5
Labor cost	$15,913.43
Average cost per cu. yd	0.46
Average cost per sq. yd., finish grading	0.063
Total average labor cost per cu. yd	0.570
Reimbursement of equipment fund for depreciation and repairs	0.028
Total average cost of excavation per cu. yd	0.598

roller putting the subgrade in condition for concrete. It will also be noted that the cost of this finished grading on work done by the steam shovel is one-third less than on the streets excavated by hand.

These costs show that had all the excavation been done by steam shovel a saving in cents of 17.3 times 34,464.5 would have been made, which amounts to $5,962.36. Thus, if a new machine had been bought, its cost would have been saved in a single season.

Cost of Curb Work.—With the exception of six streets on which brick pavement and stone curbing were used, and two others having straight concrete curbs, a combined curb and gutter was used. Two gangs of fifteen men each were working on this feature of the paving almost all season. By having a finisher on either side of the street the graders could follow the curb gangs very closely. An average of 400 ft. per day was placed. The unit cost of labor and material for this work is as shown in Table XIX.

TABLE XIX.—COST OF COMBINED CURB AND GUTTER

Total lin. ft. curb and gutter	47,967
Total number of wagon loads (1½ cu. yd.) gravel	2,371
Average cost gravel per load at pit	$0.93
Average cost of delivery on job per load	0.93
Average length in ft. built per load of gravel	20
Average cost of gravel per ft	$0.0924
Average length in ft. of curb and gutter per bbl. of cement	10.7
Average cost of cement per ft	$0.1206
Average cost of labor	0.1300
Reimbursement of equipment fund for depreciation and repairs	0.0214
Total average cost of curb and gutter per ft	$0.3644

Cost of Concrete Foundations.—A 6-in. concrete base of 1:3:6 mixture was placed on all the streets. The gravel was unloaded from cars and delivered on the line of the work by teams and wagons. The average length of haul was 0.47 miles, and the average cost per ton-mile was 39.6 cents. It will be noted that for this length of haul the cost falls very close to the ton-mileage curve plotted for hauling asphalt. Table XX gives the cost of the concrete work for the year.

TABLE XX.—COST OF CONCRETE FOUNDATIONS

Total number sq. yd. foundation	90,031.8
Total number carloads gravel	554.0
Total weight of gravel, in tons	26,420.0
Average weight of gravel per car, in lb	95,300.0
Average cost of gravel on tracks per car	$39.55
Average cost of unloading cars:	
(1) Shovelers (hand)	4.50
(2) Teaming	9.00
Total number wagon loads (1½ cu. yd.) gravel	10,819.0
Average number wagon loads per car	19.5
Average weight of wagon load, in lb	4,880.0
Average cost per wagon load on track	$ 2.03
Average cost per wagon for delivery on job	0.69
Cost of gravel on tracks per ton	0.83
Average cost of unloading gravel per ton	0.091
Average cost of hauling gravel per ton	0.182
Amount of gravel per sq. yd. foundation, in lb	587.0
Cost of gravel per sq. yd. on track	$ 0.244
Cost of unloading and delivering on street per sq. yd	0.08
Total average cost of gravel per sq. yd	0.3240
Cost of water per sq. yd	0.0075
Number of sq. yd. foundation per bbl. cement	5.47
Average cost of cement per sq. yd	$ 0.2350
Amount of depreciation on equipment	0.0007
Average cost of labor per sq. yd	0.0850
Total average cost of foundation per sq. yd	$ 0.6522

Brick Surfacing.—It has already been stated that but 16,232.2 sq. yd. of brick pavement was laid. As this amounted to only about 18 per cent of the total paving and was made up of comparatively small jobs, its cost is not as low for this class of work as the main surfacing costs are for asphalt paving work. The average cost of brick paving, with a stone curb and 6-in. foundation, excluding the cost of excavation, was $2.128 per square yard. The amount of material per square yard of surface was 40 brick, $\frac{1}{40}$ bbl. of cement. $\frac{1}{25}$ load of cushion sand and $\frac{1}{200}$ load of slushing sand. The cost of material and labor for these items per square yard is shown in Table XXI.

Table XXI.—Cost of Brick Surfacing

Brick, f. o. b. Flint	$0.88
Delivering brick on line of work	0.08
Cement	0.03
Cushion sand	0.04
Slushing sand	0.01
Fixing sand bed, laying, rolling and slushing brick	0.16
Total average cost of brick surface	$1.20

Saving on Sheet Asphalt.—The greatest saving was made on sheet-asphalt surface. Enough money was made on this work alone to more than pay for the plant and equipment twice over. Exclusive of grading, the average cost of asphalt paving was $1.51 per square yard. All of the sheet-asphalt pavements were laid in residence districts with widths of 24 and 26 ft. Texaco asphalt was generally used in the binder with an average penetration for the season of 75.5. Mexican asphalt mixed half and half with either Bermudez or Trinidad was chiefly used in the top with an average penetration of 65.3. An average of 24.9 per cent of the sand used passed an eighty-mesh screen, and 29.3 per cent of the total aggregate used passed this screen.

The percentage of bitumen for the season averaged 10.9. The total cost of the plant and equipment is listed in Table XXII.

Table XXII.—Cost of Asphalt Plant

Original cost of plant erected	$9,245.00	
Cost of foundation	380.76	
Kettle shed	493.92	
Buildings (office, engine room and limestone dust shed)	742.88	
Flux oil tank	302.89	
Miscellaneous equipment for plant and street	638.14	
Total cost of plant and equipment		$11,803.59
Cost of five asphalt wagons	$ 824.76	
Cost of asphalt roller	2,350.00	
Total cost of street equipment		$3,174.76
Grand total		$14,978.35

Of the above items of plant, the equipment, asphalt plant, wagons and roller were allowed a depreciation of 20 per cent, and the rest a depreciation of 10 per cent, amounting in all to $2,803.63. The asphalt plant is located on the Pere Marquette Railroad, as near the center of the city as possible. The average hauling distance during the past season was 0.96 miles, but one haul of more than 2 miles and one of less than $\frac{1}{4}$ mile occurred. The average cost of delivering the asphalt during the year amounted to 23.7 cents per ton-mile. The asphalt surfaces placed consisted of $1\frac{1}{2}$ in. of binder and a 1-in. top. The average amounts of material used and cost per square yard of surface are given in Table XXIII.

The total yardage of sheet asphalt, 73,799.6, times the difference in the contract price offered for the work and the actual cost, 38 cents per square yard, equals $28,043.85. Less $2,803.63 depreciation, this amounts to $25,240.22 saved on the asphalt surfacing alone.

TABLE XXIII.—AVERAGE AMOUNTS OF MATERIAL USED, AND TOTAL COST PER SQUARE YARD

	Amount per sq. yd.	Cost per lb.	Cost per sq. yd.	
Binder Material				
Texaco asphalt	5.47 lb.	$0.007055	$0.03859	
Fluxing oil	.15 lb.	0.004425	0.00066	
Sand	16.35 lb.	0.000425	0.00695	
Binder stone	89.70 lb.	0.000640	0.05740	
Cost of material in binder				$0.1036
Top				
One-half Trinidad and one-half Mexican	18.50 lb.	0.008820	0.16317	
Fluxing oil	2.20 lb.	0.004425	0.00973	
Sand	147.15 lb.	0.000425	0.06254	
Limestone dust	15.20 lb.	0.002050	0.03116	
Material in top				$0.2666
Coal, electric power and water				0.0200
Labor at plant				0.0844
Labor on street				0.0668
Teaming				0.0330
Salary of expert, engineer in charge and assistants				0.0300
Total average cost of asphalt pavement per square yard				$0.6044

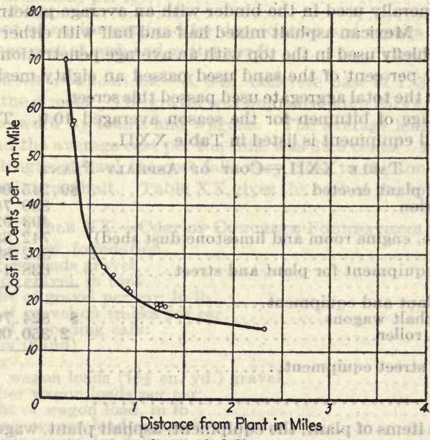

FIG. 3.—Cost of delivering asphalt.

Cost of Sheet Asphalt Pavement at Montreal, Que.—Engineering and Contracting, Jan. 3, 1917, publishes the following data.

The introduction of a cost keeping system and a consequent better method of handling construction has resulted in a marked reduction in the cost of sheet asphalt pavement in the city of Montreal, Que. In 1914 the total cost of this pavement was $2.79 per square yard. In 1915 it was $2.13, a reduction of 23.6 per cent over the cost of the previous year, and in 1916 it was $1.93. The pavement consists of a 6-in. 1:3:6 concrete base, a 1-in. binder and a 2-in. wearing surface. The city has the following asphalt plants:

Division	Plant built, year	Daily capacity, yds.	Cost
East	1903	1,000	$16,000
West	1909	1,500	22,000
North	1914	2,000	28,000
Portable	1914	1,500	26,000

During 1915, 600,000 sq. yd. of sheet asphalt pavement were laid. The detailed cost of the work, according to a paper presented at the annual convention of the American Society of Municipal Improvement by Paul E. Mercier, Chief Engineer of the city, was as follows:

	Per sq. yds., cts.
Grading	
Foremen	2.4327
Timekeepers	.1166
Engineers	.1590
Layers	.0477
Drillers	.0689
Water boys	.0742

Total surface	64.4754

	Grading, per sq. yd., ct.	Foundation, per sq. yd., ct.	Surface, per sq. yd., ct.	Total per sq. yd., ct.
Labor	49.2953	29.1590	8.7839	87.2382
Material	......	59.1755	52.2193	111.3948
Sundries	3.6994	7.0785	3.4722	14.2501
Total	52.9947	95.4130	64.4754	212.8831

The cost of material and the wages in 1915 were as follows:

Bitumen—$14.25 per ton f.o.b. plant.
Sand—75 to 98 cts. per ton f.o.b. plant.
Stone—$1.10 to $1.70 per ton f.o.b. plant or works.
Stone dust—$5.45 per ton f.o.b. plant.
Flux—10¾ cts. per imperial gallon.
Cement—$1.71 per barrel f.o.b. plant or works.
Laborers—25 cts. per hour.
Teamsters—60 cts. per hour.

As noted previously, the unit cost of the sheet asphalt laid in 1916 was $1.93 per square yard. In further detail the cost was—

	Grading, per sq. yd., ct.	Foundation, per sq. yd., ct.	Surface, per sq. yd., ct.	Total, per sq. yd., ct.
Labor	32.8257	26.9681	12.8364	72.6302
Material	.6571	50.3405	60.6638	111.6614
Sundries	3.8084	3.7504	1.4692	9.0280
Total	37.2912	81.0590	74.9694	193.3196

The cost of material and wages for 1916 was as follows:

Bitumen—$19.33 f.o.b. plant.
Sand—75 cts. to $1.10 f.o.b. cars or wharf.
Stone—$1.00 to $1.40 f.o.b. plant or works.
Stone dust—$4.90 f.o.b. plant.
Flux—10¼ cts. f.o.b. plant per imperial gallon.
Cement—$1.76 f.o.b. plant or works per barrel.
Laborers—25 cts. per hour.
Teamsters—60 cts. per hour.

Cost of Constructing an Asphalt Surface Drive with Sunken Concrete Curb.—W. T. Colman and M. H. West furnished the following information and costs published in Engineering and Contracting, Feb. 15, 1911.

Among the numerous improvments and extensions made in the drives of Lincoln Park, Chicago, was the construction of a 40 ft. drive, which extended the Sheridan Road pavement for a distance of 4,631 ft. The design of the street is unique in that it is so built as to allow the water to run off the street onto the lawn at the side, which is graded so as to form a hollow along each side of the road. The road is 40 ft. wide with a 7-in. crown, and has 2 ins. of asphalt on an 8-in. base of crushed stone. At the sides of the drive are reinforced concrete curbs 5 ins. thick, extending from the surface of the street 24 ins. deep. The top ½ in. of the curb is surfaced with a grout containing ½ lb. of lamp black per bag of cement, for the purpose of giving the top of the curb the same appearance as the asphalt street.

The material upon which the road was built consists of a gumbo clay. A stretch of about 300 ft. of this had to be taken out to a depth of from 3 to 5 ft. because the 15-ton roller, used on the crushed stone base, could not produce a satisfactory surface on account of the soft clay. A 15-ton Springfield roller was used for the stone and a 5-ton roller on the asphalt. The stone was brought in barges from the Artesian Stone Co.'s plant on the Chicago Drainage Canal and landed at the park docks. At the docks the barges were unloaded with a clamshell bucket operated by a derrick and the material dumped into an elevated bin of about 10 cu. yds. capacity. Troy wagons were driven under the bin to receive their loads. The road work paralleled the shore line of the lake at only a short distance from it so the length of haul was not great.

Curb.—The concrete curb was formed by 16 ft. panel forms of which there were about 500 lin. ft. employed. The curb was reinforced with three ½-in.

square bars as shown in the accompanying section of the street. These were 20 ft. long and lapped 6 ins. at the ends. They were suspended in the forms in templets made of a ¼-in. piece of pine, which was left in place to form the expansion joint.

The cost of excavation for the curb is included in the cost given for the curb itself, and that for placing the stone includes the cost of the preparation of the road bed for receiving the stone. In this work a large amount of local rubble stone was mixed in with the crushed stone, the object being to fill up the deeper places, as far as possible, with local material.

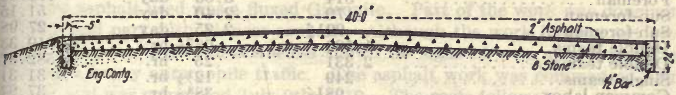

FIG. 4.—Section of asphalt surfaced drive showing sunken concrete curb.

The building of the concrete curb was started on April 14, 1910, and was completed June 29th. The costs of the 9,263 lin. ft. of curb follow. Foremen's rates are monthly and sub-foremen daily:

Labor	Time,	Rate		Total
Engineering	hrs.			$ 136.47
Foreman	91	$125.00	mo.	48.60
Sub-foreman	666½	3.00	day	222.16
Dump wagons	343	.66⅔	hr.	228.67
2-wheeled wagons	112	.12½	hr.	14.00
Common labor	24	.38½	hr.	9.20
Common labor	932	.30	hr.	279.60
Common labor	382	2.50	day	106.11
Common labor	17,500	.25	hr.	4,395.00
Skilled labor.				
Carpenters	253	.62½	hr.	157.50
Carpenters	56	.60	hr.	33.60
Timekeepers	13	55.00	mo.	3.06
Timekeepers	73	55.00	mo.	20.40
Teamster	3	2.62½	day	.87
Teamster	320	60.00	mo.	81.56
Tools				19.24
Total cost				$5,881.59
Labor cost per lin. ft.				$0.64

Material	Quantity	Price
Cement at $1.25 per bbl.	495	$ 621.88
Crushed stone at $1.50 per cu. yd	318	477.00
Torpedo sand at $1.60 per cu. yd	213	340.80
Lamp black at $0.08 per lb	124½	9.94
Reinforcement rods at $43.00 per ton	12.64	543.52
Total		$1,993.14
Cost of material per lin. ft		.21

The cost of form lumber is not included.

Crushed Stone Base.—The work of placing stone was carried over from the previous year at which time some stone had been deposited for use at various intervals of time. The stone was placed on the road about 8 ins. thick and covered an area of 23,160 sq. yds. The costs of this work, which follow, include the local rubble stone which was also placed in the work to help fill out.

Labor	Time, hrs.	Rate		Total
Engineering	....	....		$ 220.37

Miscellaneous	.046
Total labor	$0.498
Material per sq. yd	.394
Total cost per sq. yd. 8″ deep	$0.892

The 70 ct. stone was that brought by barges from the Drainage Canal and the price is for stone at the quarry. The $1.00 stone was purchased from a material yard and does not include hauling. The other stone items show the prices paid for stone delivered from various material yards at different seasons of the year.

Asphalt.—The total amount of asphalt upon the street amounted to 22,318 sq. yds. and was placed 2 ins. thick. The material was mixed in a Link Belt Co. asphalt mixer in the following proportions:

	Lbs.
1 part torpedo sand	168
1 part bank sand	168
3 parts ½" stone	504
Asphalt	81
Total 7 cu. ft. or 1 box	921

The asphalt used was a fluxed Gilsonite. Part of the work was done with Sarco and part with Pioneer asphalt. Although the work has not yet been laid one year, it has nevertheless shown no signs of wear or deterioration under a heavy automobile traffic. The asphalt work was commenced April 29th, and was completed July 9th, 1910. The costs follow;

Labor	Time hrs.	Rate		Total
Engineering				$ 57.18

Material	.394
Total cost per sq. yd	$0.746

SUMMARY OF COSTS

Labor on stone, per sq. yd.	$0.498
Labor on asphalt, per sq. yd.	.352
Stone for base, per sq. yd.	.394
Asphalt material, per sq. yd.	.394
Total cost per sq. yd.	$1.638
Labor cost on curb, per lin. ft.	.64
Material cost on curb, per lin. ft.	.21
Total cost of curb per lin. ft.	$0.85

The above figures are based upon a nine hour day.

Plant.—The plant used on the work is the property of the Lincoln Park System. All repairs and operations are charged into the work but no charge for depreciation is made against the work.

The cost of the plant is as follows:

Link Belt Co., asphalt mixer	$ 5,590
Gasoline tractor	1,200
6-ton roller	1,800
15-ton roller	1,500
Asphalt tanks and tools	1,000
Total value of plant	$11,090

Cost of Asphalt Street with Concrete Base and Gutters.—The following data, given in Engineering and Contracting, March 15, 1911, refers to a half-mile extension of a street bordering Lincoln Park, Chicago. The work comprised the removal of an old pavement, the preparation of the subgrade for the new pavement 27 ft. wide with a 6-in. concrete base and 2-in. wearing surface of asphalt and a combination concrete curb and gutter.

The work was done by force account by the Lincoln Park Commissioners, of which M. H. West was Superintendent and Fred Howitt Engineer of Parkways.

Curb and Gutter.—The concrete curb and gutter work was commenced Sept. 29 and completed Dec. 1, amounting in all to 4,708 lin. ft. The cost was as follows:

Labor	Cost per lin. ft.
Engineering	$0.0196
Foreman, per mo. $75	0.0270
Double teams, per hr. $0.66⅔	0.0091
Single teams, per hr. $0.33⅓	0.0000
Common labor, per hr. $0.25	0.1908
Skilled labor, per hr. $0.30	0.0925
Timekeeper, per mo. $65	0.0019
Total labor	$0.3409

Material	Cost per lin. ft.
117 cu. yds. gravel at $1.50	$0.0373
98 cu. yds. torpedo sand at $1.60	0.0331
24 cu. yds. stone at $1.50	0.0076
273 bbls. cement at $1.35	0.0782
Lumber	0.0079
Steel	0.0172
Lamp black	0.0045
Tools	0.0015
Total material	$0.1873

Excavating Subgrade.—The excavation and preparation of the subgrade was not begun until the curb and gutter work was about half completed on Nov. 1. The preparation of the subgrade involved the removal of old macadam and some old cedar block pavement. It is estimated that the entire area was excavated about 6 ins. deep. The surplus material was loaded by hand into wagons and was carted about ½ to ¾ mile to the lake front. A 15-ton roller was used to finish the subgrade. The costs of this work were as follows:

	Cost per sq. yd. pavement
Engineering	$0.0035
Foreman	0.0144
Skilled labor	0.0124
Common labor	0.1378
Teams	0.1328
Timekeeper	0.0015
Steam roller, 20 days	0.0122
Total	$0.3146

Concrete Base.—Following upon the preparation of the subgrade the 6-in. concrete base was placed. This work was started Oct. 31 and completed Nov. 22. The materials were distributed along the street and the mixer was moved forward as the work progressed. One of the interesting parts of this work was the use of a wood template. It was with difficulty that the men were induced to use this template in beginning the work, but after a few days the men found it indispensable. The boards used to shape the pavement are arranged to be raised and lowered by means of thumb screws. By this means the layers of the concrete base were shaped up, and later, the asphalt. During the construction of the concrete base, each day's work was covered with manure and canvas as it was feared that freezing weather might suddenly set in. The cost of the concrete work follows: There were 7,427 sq. yds. 6 ins. thick or 1,238 cu. yds.:

Labor	Cost per sq. yd.
Engineering	$0.018
Foreman	0.017
Double teams	0.004
Single teams	0.007
Common labor	0.133
Skilled labor	0.108
Totals	$0.197

The cost per cubic yard for labor was thus $1.182.

Materials	Cost per sq. yd.
Cement at $1.35 bbl	$0.206
Stone at $1.40 yd	0.294
Torpedo sand at $1.50 yd	0.004
Lumber, expan. joints, etc	0.007
Wood template	0.004
Tools and sundries	0.003
Mixer, rent $162, hauling $15, fuel $12	0.025
Canvas	0.007
Oil and waste	0.0004
Totals	$0.550

The cost per cubic yard for materials was $3.30.

Asphalt.—The asphalt used consisted partly of Sarco brand and partly of Pioneer brand. A Link Belt Co. asphalt mixer, which was purchased by the park at a cost of $5,590, was used. It was operated by belt from a gasoline traction engine. A 6-ton roller was used on the asphalt, giving a compression of 266 lbs. per sq. in. The asphalt work consisted of 7,427 sq. yds. of 2-in. surface. It was started on Nov. 7 and completed Dec. 1, 1910. The costs were as follows:

Labor	Cost per sq. yd.
Engineering	$0.009
Foreman	0.016
Teams	0.032
Common labor	0.240
Skilled labor	0.043
Timekeeper	0.003
Total	$0.343

Materials	Cost per sq. yd.
Stone at $1.40	$0.085
Sand at $1.60	0.050
Sand dug at site $1.00	0.022
Asphalt, "Sarco," at $24 ton	.....
Asphalt, "Pioneer," at $19.44 ton	0.301
Lumber for exp. joints	0.002
Brooms, 4	0.001
Coke	0.033
Gasoline	0.008
Engine oil, waste, etc	0.002
Tools	0.004
Steam roller	0.009
Link Belt mixer	0.027
Total	$0.544

A summary of the costs of the road work is as follows:

Labor per sq. yd. concrete base	$0.197
Material per sq. yd. concrete base	0.55
Labor per sq. yd. asphalt	0.343
Material per sq. yd. asphalt	0.544
Preparation of subgrade per sq. yd	0.314
Total	$1.948

Cost of Asphalt Paving Repairs in St. Paul, Minn.—Engineering News, July 9, 1914, gives the following data from the report of the Commission of Public Works.

In 1912 the city of St. Paul, Minn., purchased a municipal asphalt plant at a cost of about $15,000. The plant consists of a Warren Bros. portable asphalt plant, one 8-ton asphalt steam roller, one scarifier, one Lutz surface heater, one fire wagon, one gyratory stone crusher, two portable melting kettles, six 2-cu. yd. steel-lined asphalt wagons, four ¾-cu. yd. concrete spreaders, one set of curb cutter's tools, nine asphalt rakes, testing scales, and the necessary small tools. The accompanying table gives an itemized cost of the plant.

	No.	Rate	Cost
Warren Bros'. portable asphalt plant...........	1	....	$4850
Steam roller, 8-ton..........................	1	....	2250
Scarifier....................................	1	....	365
Lutz surface heater..........................	1	....	1800
Fire wagon...................................	1	....	112
Melting kettles..............................	2	$425.00	850
Asphalt wagons, 2 cu. yd.....................	6	171.50	1029
Concrete carts, ⅔ cu. yd.....................	4	117.00	468
Koehring concrete mixer, No. 14..............	1	....	1950
Tandem steam roller, 8-ton...................	1	....	2200
Koehring paver, No. 14.......................	1	....	1900
Chain belt paver, No. 15.....................	1	....	1770
Chicago concrete mixer, No. 5................	1	....	481
Tinius-Olson brick tester....................	1	....	475

The plant was put into operation Apr. 25, 1912, and during the season of 1912 was worked a total of 92 days. The amount of asphalt pavement turned out during the season was 19,428 sq. yd.; 15,040 sq. yd. of this was cut out work and 4388 sq. yd. burner work. Besides this, 5459 sq. yd. of asphalt pavement were put down for paving contractors in repairing pavements built under a guaranty; of this, 2363 sq. yd. was cut out work and 3095 sq. yd. burner work. The total cost was $6013, which was charged to and collected from the contractors.

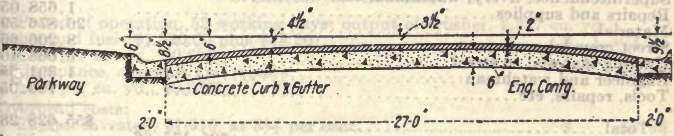

FIG. 5.—Cross section of street and gutter.

All asphalt-paving repairs during the year 1913 were made by this municipal asphalt plant. The plant was put in operation March 30, and during the season worked 178 days. Asphalt paving to the amount of 44,194 sq. yd. was turned out; 43,296 sq. yd. of this was cut out work and 897 burner work. Asphalt repairs for contractors were made to the extent of 16,832 sq. yd., of which 16,039 sq. yd. was cut out work, and 793 sq. yd. was burner work. The total cost was $21,613, which was collected from the company which had guaranteed the pavement.

For the City Ry. Co., 7370 sq. yd. of asphalt pavement were laid, and the cost, $11,031, collected from the company. For other public-service corporations, 1250 sq. yd. of asphalt pavement and 148 sq. yd. of concrete foundation were laid. This work cost $2340, which was collected from the various corporations.

About 246 sq. yd. of asphalt pavement was laid on bridges on which the city maintains the wearing surface; this cost $430, and was charged against the bridge building and repair fund at $1.75 per sq. yd. Small repairs were made for other city departments and charged against those departments at $1 per sq. yd. The repairs to asphalt pavements on which the guaranty period had expired and for which the city paid, amounted to 14,487 sq. yd. of cut out work. This repair work cost the city $18,490, an average of $1 per sq. yd.

The following shows cost and relative data regarding asphalt repairs for the year 1913.

Total area of pavements on which repairs were made in sq. yd.	222,327
Area or repairs in square yards	18,733.18
Per cent. of area repaired	8.42
Cost of repairs	$ 18,921.34
Average cost per square yard of total area	0.085

Cuts in asphalt pavement made by the City Water Department, heating, lighting and telephone companies, sewer contractors and others, were repaired, at a cost of $2340, which was collected from the various companies.

Cost of Operation.—The operating crew at the plant consisted of one foreman, one engineman, one tank man, four laborers, and a night watchman. Four teams were employed hauling asphalt from the plant to the work.

The street crew was made up of one foreman, one timekeeper, one roller man, two rakers, two tampers, one smoother and one cement man laying new pavement; and two shovelers, six scrapers and two teams removing and hauling old paving. The total expense was divided as follows:

Operation of plant, labor		$ 5,889.02
Fuel		1,024.47
Hauling material		1,559.18
Superintendence, livery, watchman, etc		3,164.21
Repairs and supplies		1,658.05
Material		26,876.59
Street crew labor		8,206.66
Hauling material to street		5,068.40
Engineer and watchman		1,391.65
Tools, repairs, etc		790.05
Total		$55,628.28
Total labor	$25,175.66	
Total material	30,452.62	
		55,628.28
Charged to outside parties	$34,194.23	
Charged to bridges	430.49	
Material on hand	2,512.71	
		37,137.43
Total cost to city of work		$18,490.85

Cost of Operating Municipal Asphalt Plant of District of Columbia.—Engineering and Contracting, June 6, 1917, publishes the following:

All minor repairs of asphalt pavements in the District of Columbia are made from the output of a portable municipal asphalt plant. This plant also is employed in furnishing product for the construction of an asphalt macadam wearing surface on old macadam streets. The plant, a Warren Bros.' portable asphalt plant, with a nominal capacity of 100,000 lb. per day was purchased and installed in 1912 at a cost of $6,900. Since that date it has been operated from 220 to 240 days per year, with an average output of about 80 per cent of its capacity.

During the fiscal year ending June 30, 1916, the plant was operated 236 working days, with an average daily output of 715 cu. ft. and a total output of 168,684 cu. ft. Old material was used to considerable extent. Old asphalt topping removed from the streets in resurfacing was crushed to a finely broken product to which was added the new material. The use of this old topping resulted in a substantial saving. A Noyes crusher was used for breaking up the old material. The cost of the crusher, including a portable engine and boiler, was $1,910.

The following data on the work of the municipal asphalt plant for the fiscal year are taken from the report of the operations of the Engineer Department of the District of Columbia:

The following amounts of materials were purchased for use in manufacturing the output during the year:

Sand, 2,160.50 cu. yd. at	$ 1.03
Asphaltic cement, 461.74 tons at	10.00
Limestone dust, 205 tons at	2.53
Screenings, 855 tons at	1.32

There was purchased for use in operating the crusher and mixer the following large items:

Fuel oil, 23,927 gal. at	$0.031
Coal, 170 tons at	3.45
Wood, 80 cords at	5.00

The costs of operation, including material and labor, are kept from day to day, and the summary of this data for the fiscal year ending June 30, 1916, develops the following unit costs for the year's operations:

OPERATION OF CRUSHER

Period of operation, 52 working days; output of crusher, 2,327 cu. yd.	
Labor and fuel ($1,320.06 plus $83.20)	$ 1,403.26
Cost per cu. yd., $0.603.	
Maintenance, renewals and repairs	83 04.
Cost per cu. yd., $0.0357.	
Overhead costs:	
Capital invested, $1,910, at 3½ per cent	$ 66.85
Obsolescence, 5 years, at 20 per cent	382.00
Cost per cu. yd., $0.193.	
	$ 448.85
Cost of crushed product, per cu. yd.:	
Labor and materials	$ 0.603
Repairs to plant	.036
Overhead	.193
	$ 0 832

OPERATION OF PLANT

Period of operation, 236 days; total output, 168,684 cu. ft.	
At plant:	
Labor (3.56 cts. per cu. ft.)	$ 6,004.18
Fuel oil (0.50 cts. per cu. ft.)	776.68
Coal (0.27 cts. per cu. ft.)	455.80
Wood (0.13 cts. per cu. ft.)	223.60
Binder stone	82.50
Tool repair (0.20 cts. per cu. ft.)	329.66
Total (4.71 cts. per cu. ft.)	$ 7,872.42
Haul from plant to street:	
Labor (3.85 cts. per cu. ft.)	$ 5,904.05
On street:	
Labor (12.3 cts. per cu. ft.)	$18,905.53
Painting joints (0.15 ct. per cu. ft.)	236.00
Wood (0.13 ct. per cu. ft.)	223.60
Tool repair (0.10 ct. per cu. ft.)	164.63
Total (12.68 cts. per cu. ft.)	$19,529.96

Maintenance and repairs:	
At plant (0.22 ct. per cu. ft.)	$ 365.93
On street (0.15 ct. per cu. ft.)	228.94
Total (0.37 ct. per cu. ft.)	$ 594.87
Overhead:	
Capital invested, $6,900, at 3½ per cent	$ 241.50
Obsolescence, 5 years, at 20 per cent	1,380.00
Total (1 ct. per cu. ft.)	$ 1,621.50
Supervision:	
Foremen and overseers (3.7 cts. per cu. ft.)	$ 6,239.67
Total manufacturing costs per cu. ft.:	Cents
Plant, labor	4.71
Hot haul	3.85
Street work	12.68
Maintenance of plant and tools	.37
Overhead—	
Interest and obsolescence	1.00
Supervision	3.70
	26.31

The sand used was bought under a contract at 44 ct. per cubic yard and hauled from the wharf to the plant at a cost of $1,266.26 for 2,160.5 cu. yd., or 59 ct. per cubic yard, a total of $1.03 per cubic yard. All other material was delivered at the plant site at the costs shown below.

The cost of cubic foot of old material mixture was as follows:

0.67 cu. ft. crushed material, at 83.2 ct. per cu. yd	$0.0206
0.27 cu. ft. sand, at $1.03 per cu. yd	.0103
3.89[1] lb. asphaltic cement, at $10 per ton	.0195
Total material	$0.0530
Manufacturing and placing cost	.2631
Total (cu. ft.)	$0.3161
Asphaltic concrete mixture:	
0.5 cu. ft. screenings, at $1.32 per ton	$0.0330
0.5 cu. ft. sand, at $1.03 per cu. yd	.0190
4.2 lb. limestone dust, at $2.53 per ton	.0053
9.16[1] lb. asphaltic cement, at $10 per ton	.0458
Total material	$0.1031
Manufacturing and placing costs	.2631
Total per cu. ft	$0.3662

[1] Includes 10 per cent tare.

The plant operating force consisted of one foreman at $100 per month and the following per diem employes:

1 Steam engineer (operating mixing plant) at	$3.50
1 Steam engineer (operating crusher) at	3.00
1 Timekeeper at	3.00
7 Laborers (operating plant) at	1.75
12 Laborers (operating crusher) at	1.75
4 Laborers (miscellaneous, including watchman) at	1.75
12 Carts* (hot haul) at	2.50

* Hauling hot material from plant to street operating or patching gangs.

There are two patching gangs, each of which consists of the following units of per diem employes:

1 Foreman at	$4.00
5 Skilled laborers (1 shoveler, 2 rakers and 2 tampers) at	2.25
5 Skilled laborers (rollermen, cutting out and miscellaneous) at	2.00
10 Skilled laborers (miscellaneous) at	1.75
2 Wagons (hauling old material to dump and hauling barricades) at	5.00
1 Cart (hauling tool and fire wagons) at	2.50

In connection with the supervision of the above there are two inspectors, one of whom is employed at a salary of $125 and the other at $100 per month. These men are held responsible for the character and performance of all the work, prepare all statements and reports in connection therewith and map out the various routes to be followed.

Reference Note: In Engineering and Contracting, March 5, 1913, data are given on the operation of municipal asphalt plants in 20 cities as abstracted from the report of David E. McComb upon an investigation of the desirability

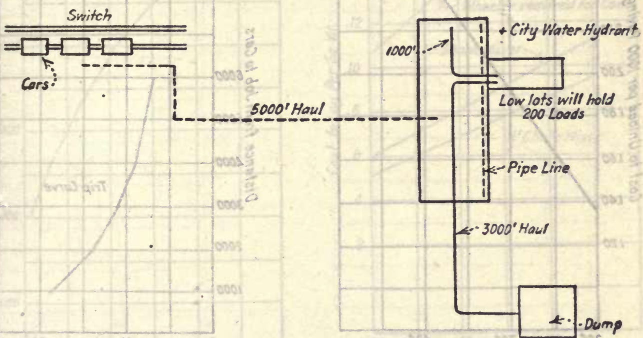

FIG. 6.—Sketch showing various conditions relating to paving job.

and cost of establishing a municipal plant for the District of Columbia.

Labor Hour Requirements on Brick Paving Work.—D. B. Davis gives the following in Engineering and Contracting, May 5, 1920.

In estimating the cost of paving work, while the labor market is constantly changing from month to month, estimators who have an indefinite knowledge of the labor hour requirements for the divisions of work necessary, are liable to have their estimates incompatible with the true value of the work. A knowledge of the labor hours necessary to do a certain work together with accurate price quotations on the materials which enter into it, will give the estimator much more faith in his estimates.

In making an estimate of a certain work a chart showing the various conditions relating to the work will help to guarantee against omission of important details. This chart can be a rough sketch, which in case of a brick paving job in a city, will show the length of haul from the nearest switch to the job; the length of haul from the closest dump to the job; the kind and nearest water supply and other matters of interest one will record on making an inspection of the site. An example of a chart of this kind is shown in Fig. 6.

A brief study for determining the labor hour requirements for some divisions of work connected with a brick paving job in a city will be undertaken. The excavation in this case will be assumed to be completed.

To estimate the cost of unloading and hauling brick from the cars to the job, it is first necessary to figure on the cost of unloading them. It has been the experience of the writer on a number of his jobs that a working unit consisting of five men loading from the cars to the wagons and six men at the job, unloading these wagons as they come, will unload approximately on an average of 19,300 paving brick in a 10-hour day. Or it requires approximately 5.7 labor hours to handle the brick from the cars to the pile. Fig. 7 shows the cost to unload brick to the pile at different rates of wages for labor

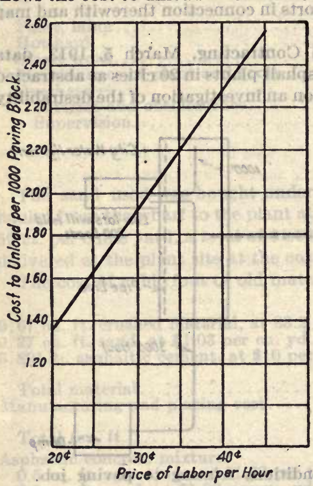

FIG. 7.—Cost of unloading brick from cars and on job.
Assumption: 5.7 labor hours per M.

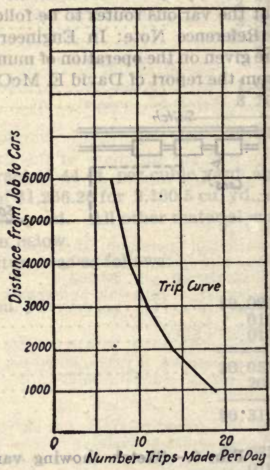

FIG. 8.—Curve showing number of loads per day.
Extra wagons provided to prevent idle time.

To haul the brick from the switch to the job, extra wagons are provided, so that the teamster after having hauled the loaded wagon to the street to be unloaded can immediately hitch to an extra empty one and proceed back to the switch. In this way no team time is lost while waiting for loading or unloading the wagons.

The number of loads that can be hauled in a given length of time can be determined by the formula:

$$\text{Number of loads hauled} = \frac{T}{\frac{L}{r} - z}$$

In which T = total working time in minutes.
L = length of haul (round trip).
z = lost time in minutes, unhitching, etc. (this will average 17 minutes).
r = rate of team travel (180 ft. per minute).

Fig. 8 shows this formula plotted for different lengths haul.

Now to find the teams required; find from Fig. 8 the number of trips per day corresponding to the length of haul. Then the number of trips × the capacity of each load equals the number of brick that one team will haul. Then

$$\frac{19{,}300}{\text{number brick hauled by one team}} = \text{number of brick required.}$$

Fig. 9 shows the cost of hauling brick for various lengths haul. In this case team hire is figured at 80 cents per hour and the capacity of each load at 665 brick.

The total cost of handling and hauling the brick may be found by adding the values from Figs. 7 and 9.

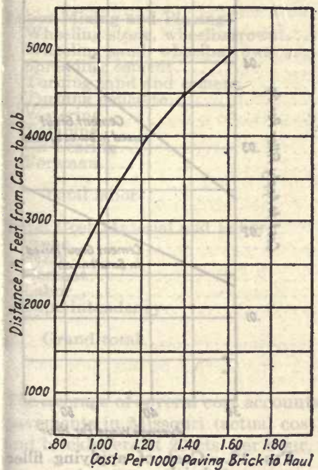

FIG. 9.—Cost of hauling brick. Team, $8 per day; 665 brick per load.

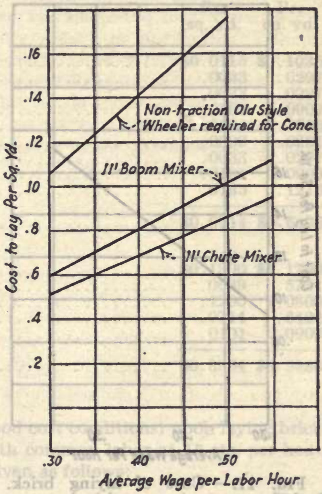

FIG. 10.—Cost of laying 1 : 7 6-in. concrete base.

To estimate the labor required to lay a concrete base 6 in. thick the required organization should first be outlined. Such an organization, where the concrete mix is 1 part cement and 7 parts gravel and a 1-sack steam chute mixer is used, is as follows:

1 Engineer mixer.	3 Gravel wheelers.
1 Fireman mixer.	3 Gravel shovelers.
2 Concrete spreaders.	1 Water boy.
1 Handling cement.	1 Foreman.

This gang will lay concrete base requiring approximately 0.20 labor hours per square yard. Fig. 10 shows values platted when using a 1-bag chute, boom and an old-style non-traction mixer which requires men to wheel the 1-bag mixed concrete from the mixer to the bed.

To estimate the labor required to lay the brick in the pavement, it is well to remember the divisions of labor required. For the ordinary city pavement it will require five divisions. The following table gives these divisions with coefficients relating to each:

Sand bed mixers	0.00742
Brick carriers	0.01320
Brick setters	0.00214
Batting in closures	0.00200
Cement grouting, by hand mix	0.00797
Cement grouting, machine mix	0.00460

To find the number of men needed for each division of work to balance the whole gang, multiply the required output by the factors opposite each division in the table and take the closest even number.

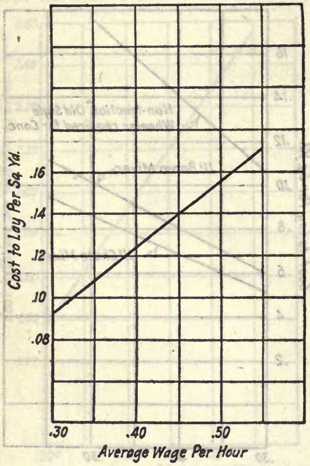

FIG. 11.—Cost of laying brick. Includes preparing sand-bed, carrying brick, laying brick, batting in closures and foreman.

Assumption: 0.31 labor hours per sq. yd.

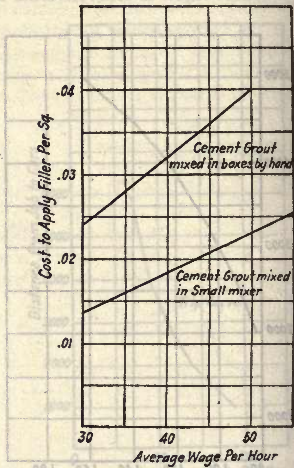

FIG. 12.—Cost of applying filler to brick pavement.

Assumption: Mixing by hand, 0.080 hrs. per sq. yd.; mixing by machine, 0.046 hrs. per sq. yd.

For example, to find the number of men needed to carry brick in order to lay 1,000 sq. yd. in 10-hour day: Multiply 1,000 yd. by 0.0132, which makes 13.2 or 13 men needed.

Fig. 11 shows the costs of laying brick in pavements at different rates of wages. It is figured on the assumption that the operations named require 0.31 labor hours per square yard.

Fig. 12 shows the cost of applying cement grout filler. The lower line shows the cost when using a small grout mixer and the upper line shows the cost when using the old-style grouting boxes, which require mixing by hand. With labor at 50 ct. per hour it can be seen that a saving of 1¾ ct. per square yard is made by using the gasoline grout mixer.

The labor hours required for these various operations were obtained from the writer's experience and represent work that has been done by energetic, enthusiastic workmen. The proximity which another gang could approach these values would depend wholly on the morale of the workmen and the experience and "pep" of the man in charge.

Cost of Brick Paved Roads.—The following data, published in Engineering and Contracting, May 29, 1912, have been taken from a Road Bulletin of the Highway Department of the Missouri State Board of Agriculture. The following figures are the actual cost, not including miscellaneous items, etc., upon 12,000 sq. yds. (1,333 cu. yds.) of hand-mixed 1:4:7 street concrete base 4 ins. thick, put down under average good conditions in Missouri.

	Per sq. yd.	Per cu. yd.
Labor Mixing and Placing:		
Wheeling stone, wheelbarrows	$0.0115	$0.1035
Wheeling sand, wheelbarrows	.0033	.0297
Spreading cement	.0033	.0297
Turning sand and cement	.0101	.0909
Turning concrete	.0134	.1206
Watering	.0029	.0261
Tamping	.0033	.0297
Off-bearing	.0101	.0909
Foreman	.0135	.1215
Total labor	$0.0714	$0.6426
Total Cost Material and Labor:		
Stone	$0.1300	$1.1700
Sand	.0639	.5751
Cement	.1200	1.0800
Labor	.0714	.6426
Superintendency	.0101	.0909
Grand total	$0.3954	$3.5586

The average of several cost accounts (good cost conditions) upon laying brick pavements in Missouri (actual cost) with common labor at 15 cts. per hour and bricklayers at 20 cts. per hour, is given as follows:

	Per sq. yd.
Labor for Laying Brick:	
Preparing sand cushion	$0.0095
Stacking brick	.0060
Wheeling brick	.0105
Laying brick	.0075
Culling brick	.0035
Batting and grouting	.0045
Cleaning	.0030
Foreman	.0025
Total labor	$0.0470
Material:	
Sand	$0.1000
Brick	.7000
Grout	.0180
Total material	$0.8180
Superintendency	.0050
Grand total, labor and material	$0.8700

Other costs for brick pavement on concrete base show the following:

	Per sq. yd.
Shaping subgrade	$0.10
Concrete base, 4-in.	.45
Sand cushion, 2-in.	.10
Brick, 45 per sq. yd.	.95
Total	$1.60

Labor Cost of Monolithic Brick Pavement.—The following data are taken from Engineering and Contracting, Sept. 4, 1918.

Monolithic brick pavement was constructed on the Highline Road in King County, Washington, at a labor cost of about 23 cts. per square yard. The paved section was 20 ft. wide. The concrete base was a 1 : 3 : 6 mix, 3 in. thick at the sides and 5½ in. at the crown. The blocks for part of the work were vertical fiber bricks, 4 × 8½ in. × 2¾ in. deep; for the remainder standard paving blocks 4 × 8½ in. × 3½ in. deep, laid flat, were used. The average labor cost for 91,500 sq. yd. of pavement laid between June and October, 1916, was as follows:

	Per sq. yd.
Concrete base, 4⅜ in. thick	$0.086
Sand-cement cushion	.018
Laying brick	.072
Grouting	.033
Sprinkling	.005
Curb forms	.012
Total	$0.226

The above figures include the cost of covering the completed pavement with 1 to 2 in. of earth and removal of same. The average paving crew was as follows:

	Per day
Superintendent	$6.00
Mixer crew:	
1 foreman	4.00
1 mixer engineer	5.00
2 subgrade men	2.75
4 shovelers	2.75
8 wheelbarrow men	2.75
2 cement men	2.75
2 concrete spreaders	2.75
1 concrete rodder	2.75
Cushion crew (5 men)	2.75

	Per day
Brick crew:	
1 bricklayer	$7.00
1 batter-in	3.00
1 liner	2.75
6 carriers	2.75
4 pilers	2.75
Grout crew (8 laborers)	2.75
Covering, uncovering and sprinkling (2 men)	2.75
Curb forms:	
1 man	4.00
1 helper	2.75
1 water boy	1.50

The concrete for the base was mixed in a 21 cu. ft. Koehring mixer of the boom and bucket type. The 1 : 3 sand cement cushion was mixed in a 3-ft. Little Wonder mixer. The bricks were handled by laborers with brick clamps.

Organization and Output of Brick Paving Gang in Vermilion County Roads.—Engineering and Contracting, Sept. 4, 1918, gives the following.

In the construction of the monolithic brick pavement for the Vermilion County, Illinois, Bond Issue Roads, the average gang consisted of 32 men distributed as follows:

CONCRETE GANG	PAVING GANG
Ahead of Mixer:	1 Brick setter.
1 Form setter.	3 Stackers.
5 Wheelers.	1 Starter (also helps with tamping).
3 Shovelers.	1 Batter.
1 Cement man.	5 Carriers.
At Mixer:	1 Culler.
Mixer operator.	1 Roller.
Fireman.	3 Men grouting.
Behind Mixer:	1 Man wetting down pavement and pulling forms.
2 Men spreading concrete.	
1 Man tamping concrete and carrying forward boards for mixer runway.	

With this organization about 800 sq. yd. of pavement was laid per day. The pavement is 10 ft. wide and consists of a 4-in. wire-cut-lug paving brick laid directly on a fresh concrete base 4 in. thick at the side and crowned 1 in.

The gang, as given above, did not deliver the materials from the freight cars to the road. Materials were delivered on a narrow gage (2 ft.) track laid alongside the pavement. The sand and stone were dumped from cars on the subgrade, and the brick was stacked in piles on the other side of the track. In stacking brick and in delivering brick onto the road, the bricks were handled with tongs.

Labor Cost of Brick Paving on Country Roads.—The following data, based on the experience of the New York State Highway Commission, were published in Engineering and Contracting, Feb. 19, 1913.

The cost of brick paving on country roads varies according to local conditions. Highway contractors make use of various labor-saving devices to decrease the cost of construction. All unloading of stone and sand is done by machines. Many contractors are using traction engines for the hauling of material; some use small gage tracks with locomotives and cars. A modern concrete mixer is very necessary.

From the data obtained from various roads, a fair estimate of cost, based on labor at 17½ cts. per hour, teams at 50 cts. per hour, and foreman at 35 cts. per hour, would be as follows:

Labor cost per square yard, brick paving in place, exclusive of concrete base:

	Per sq. yd.
Unloading and piling brick	$0.035
Hauling brick one mile	0.040
Laying and rolling	0.070
Making sand cushion	0.020
Grouting	0.028
Expansion joints	0.007
Culling, replacing, etc.	0.005
Total labor	$0.205

No office or incidental charges are included in the above.

The manipulation of the concrete for the base varies from 40 cts. to 60 cts. per cu. yd., using batch machines and depending on gravel or stone concrete. (The average bid price for brick pavement in Western New York, including concrete base 5 in. thick, but excluding excavation, was $2.05 per sq. yd.)

Cost of Vitrified-brick Pavement on an Old Macadam Base, Carlisle, Penn.—John C. Hiteshew gives the following matter in Engineering News, Dec. 24, 1914.

During the 1914 season 2,493 sq. yd. of vitrified-brick pavement were laid by the Street Department of Carlisle, Penn., under the supervision of the writer.

Track Section.—The section paved comprised one block on High St., the main business street, through which the tracks of the Cumberland Valley R.R. run. The railroad company was unwilling to pave between and along the tracks, but it agreed to construct a concrete curb, 6 × 18 in., set 2 ft. from outside face of curb to rail. The concrete was a 1 : 2 : 3 mix with a 1 : 1 finish coat, and was constructed by contract at a price of 35c. per lin. ft.

Pavement Base.—The old macadam with which the street was paved was used as a base for the new brick paving. The macadam had a depth, before excavation, of at least 18 to 20 in.

In grading, the old macadam was spiked up with a 13-ton steam roller, excavated to subgrade, and thoroughly dry rolled, as with wet rolling the macadam showed a tendency to push ahead of the roller, causing waves.

In shaping the base spikes were set to subgrade at 7-ft. intervals across the street, and the final shaping done by hand picking. After rolling, new spikes were set, which supported the 3 × 8-in. by 16-ft. guides for a striking template.

Concreting Filled-in Trenches.—The Gas & Water Co. had recently renewed a great many trenches along the street, and poor foundations existed in the old gutters, so it was deemed advisable to fill all these new trenches and the gutters with concrete 5 in. deep.

Stone Cushion.—The cushion was composed of limestone dust and screenings, 1½ in. in thickness; and was struck off by means of a short striking template drawn by three men. The cushion was then rolled with a 250-lb. roller drawn by hand.

Laying Bricks.—The bricks were laid by one foreman and two men, one of the men breaking half-brick to fill in ends of courses. Usually there were three men carrying to each brick layer. An average of 7000 bricks were laid by each man per day. Vitrified-shale paving blocks were used.

Rolling Bricks.—Rolling was done with a 5-ton horse roller drawn by 12 men.

Grouting.—The joints were grouted with a 1 : 1½ portland-cement grout.

Expansion Joints.—A ¾-in. "Elastite sandwich" joint was used longitudinally along the four curbs and transversely over 75 ft.

"Elastite" was found to be a great improvement over the old pitch expansion-joint filler, doing away with the boards, wedges, heating the pitch, etc., and the first cost of the joint was practically the entire cost, as it took very little time to place it in position.

Sand Covering.—The green pavement was covered with ½ in. of sand for several days. Traffic was turned on the pavement at the end of five days.

Cost Data.—The following is an itemized list of cost data:

	Cost per sq. yd. of pavement
Unloading and hauling brick	$0.0777
Grading and rolling subgrade	0.1126
Concreting trenches	0.0848
Crushed stone cushion	0.0543
Brick	0.8600
Laying brick	0.0376
Rolling brick	0.0062
Grouting	0.0845
Expansion joints	0.0356
Covering with sand	0.0047
Total	$1.358

Dump wagons were charged at the rate of 10 and 15c. per hr. The reason for this was that they were fire teams; one was paid 10c. per hr.; for the use of the other the Street Department paid the driver's salary, which was $1.50 per day, or 15c. per hr.

The bricks were purchased in March at a reduction of $1 per M. The great advantage in this was that we got a better run of bricks and had them when needed, and we saved $1 per M, or $100 on the year's work.

All macadam excavated was used in resurfacing streets adjacent to the work. Approximately 20,000 sq. yd. were thus resurfaced.

It will be noticed that a stone cushion was used instead of sand. The reason was that when first tried as an experiment the stone formed a compact cushion without becoming too solid, and at the same time reduced the cost by one-half.

During the season of 1913 5,689 sq. yds. of vitrified brick pavement were laid. Mr. Hiteshew gives the cost of this work in Engineering and Contracting, April 15, 1914, as follows:

COST OF BRICK PAVING AT CARLISLE, PA. IN 1913

Item—	Cost per sq. yd.	
Unloading, hauling & piling bricks	$0.065	
Grading & rolling macadam base	.091	
Stone cushion and rolling with 500-lb. roller	.052	
227,560 brick at $21 per M	.840	
Laying and rolling brick	.034	
Cement grout filler	.068	
Expansion joint	.010	
Totals	$1.16	
Total number of sq. yds.		5,689
Cost per sq. yd.		$1.16

Note.—An average of 7,000 brick per man per day were laid.

COST OF LABOR AND MATERIALS FOR BRICK PAVING AT CARLISLE, PA.

Item—	Rate
Foreman, per hour	$ 0.25
Laborers, per hour	0.16
Roller engineer, per hour	0.25
Cement, per bbl. (net)	1.32
Sand, per ton	1.50
Brick, per M	21.00

In 1909 the cost of 2,070 sq. yds. of similar pavement, given in Engineering and Contracting, Feb. 2, 1910 by C. A. Bingham, was as follows:

SPIKING UP AND CARTING OFF OLD MACADAM

	Per sq. yd.
Roller engineer, 45 hrs. at $0.20	$0.0046
Foreman, 55 hrs. at $0.17	.0048
Laborers, 261 hrs. at $0.14	.0188
Carting, 192 hrs. at $0.25	.0238
Coal, 2.5 tons at $4.00	.0052
Total (1,935 sq. yds.)	$0.0572

RAKING, LEVELING, ROLLING, ETC., MACADAM BASE

Foreman, 34 hrs. at $0.17	$0.0029
Roller engineer, 39 hrs. at $0.20	.0040
Laborers, 56 hrs. at $0.14	.0041
Crushed stone, 69 cu. yds. at $0.98	.0349
Coal, 2 tons at $4.00	.0041
Total (1,935 sq. yds.)	$0.0500

Dust Cushion

Foreman, 25 hrs. at $0.17	$0.0020
Laborers, 50 hrs. at $0.14	.0033
Crusher dust, 66 cu. yds. at $0.98	.0312
Total (2,070 sq. yds.)	$0.0365

Unloading, Hauling, Stacking Blocks

Foreman, 45 hrs. at $0.17	$0.0037
Laborers, 390 hrs. at $0.14	.0264
Carting, 363 hrs. at $0.24	.0421
Total (2,070 yds.)	$0.072

Block

85,660 at $19.00 M.......... $1,627.54 or $0.786 yd.

Laying Blocks

Foreman, 127 hrs. at $0.17	$0.0104
Laborers, 402 hrs. at $0.14	.0271
Total (2,070 sq. yds.)	$0.035

Rolling and Inspecting

Team, 15 hrs. at $0.20	$0.001
Laborers, 63 hrs. at $0.14	.004
Total (2,070 sq. yds.)	$0.005

Grouting

Cement, 44 bbls. at $1.20	$0.0254
Sand, 11 tons at $1.40	.0074
Foreman, 32 hrs. at $0.17	.0071
Laborers, 106 hrs. at $0.14	.0091
Sand covering, 5 tons at $1.40	.0034
Total (2,070 sq. yds.)	$0.0459

Recapitulation

	Per sq. yd.
Excavation	$0.057
Grading	0.050
Cushion	0.036
Haul, etc	0.072
Blocks	0.786
Laying	0.037
Rolling	0.005
Grouting	0.046
Grand total	$1.089

Cost of Grouting Brick Pavements.—H. E. Bilger, Engineer of the Illinois State Highway Department gives the following data in an article published in Engineering and Contracting, Dec. 6, 1916.

Quantity of Grout Required per Unit Area.—With a grout composed of 1 part cement and 1 part sand, it has been found that 1 barrel of cement, with an equal volume of sand, will make sufficient grout to cover the areas below under the two types of bed for the brick:

4-In. Brick on Ordinary Sand Cushion

32 sq. yd. if repressed brick is used.
24 sq. yd. if wire-cut lug brick is used.

4-In. Brick on 3/8-in. Mortar Bed

30 sq. yd. if repressed brick is used.
22 sq. yd. if wire-cut lug brick is used.

It will be noted that by using the mortar bed instead of the customary sand cushion, an equal volume of grout covers a smaller number of square yards, this being due to the fact that when the sand cushion is used, some of the sand finds its way up between the brick and prevents the entrance of the grout for the full depth of the brick.

It has been found that 10 gals. of water are necessary to build complete a 4-in. brick pavement with a grout filler on a 4-in. concrete base.

Labor Cost for Grouting Brick.—In some of the state jobs the labor cost varies from about 1.6 cts. per square yard to 3.9 cts. These matters are so dependent upon the efficiency of the organization rather than upon the rate per hour, that the cost is largely dependent upon the foreman in charge. As a fair average figure for estimating purposes, when labor is 25 cts. per hour, the actual labor cost without making any allowance for overhead, etc., is about 2½ cts. per square yard of brick pavement.

Cost of Grouting Brick Pavements.—Engineering and Contracting, Oct. 20, 1915, publishes the following:

The cost of 1-1 grout filling for 58,000 sq. yds. of brick pavement at Centerville, Iowa, as reported by M. A. Hall, city engineer, was as follows:

Item	Cts. per sq. yd.
Screening sand at 20 cts. per hour	0.05
Dry mixers at 22½ cts. per hour	0.15
Wet mixers at 20 cts. per hour	0.20
Rubbers at 20 cts. per hour	0.43
Wheelers at 20 cts. per hour	0.13
Other men at 20 cts. per hour	0.03
Water boy at 10 cts. per hour	0.04
Foreman at 40 cts. per hour	0.14
Total labor	1.17
0.017 bbl. cement at $2	3.40
0.034 ton sand at $1.05	0.35
Total materials	3.75
Grand total	4.92

On 26,500 sq. yds. of this pavement the labor cost of grouting joints is reported to have been only 0.9 ct. per square yard.

The costs of 1-1 *grout filling* and *sand covering* for six sections of the Byberry and Bensalem service test road built by the Philadelphia department of public works are reported as follows:

Section 4	Cts. per sq. yd.
Cement at $1.30	3.51
Sand at $1.885	3.67
Labor	3.49
Total:	10.67

Section 8	Cts. per sq. yd.
Cement at $1.30	3.64
Sand at $1.885	3.34
Labor	2.08
Total	9.06

Section 10	Cts. per sq. yd.
Cement at $1.30	3.65
Sand at $1.885	3.32
Labor	3.50
Total	10.47

Section 13	Cts. per sq. yd.
Cement at $1.30	3.66
Sand at $1.885	3.31
Labor	1.86
Total	8.83

Section 18	Cts. per sq. yd.
Cement at $1.71	3.56
Sand at $2.015	4.67
Labor	3.14
Total	11.37

Section 26	Cts. per sq. yd.
Cement at $1.65	4.56
Sand at $1.82	3.24
Forms at $32 per M	0.32
Labor	3.63
Total	11.75

The volumes, per square yard, of sand used for *grout and covering* on these six sections were as follows:

Area, sq. yds.	Cu. yds. sand	Sand, cu. yds. per sq. yd.
462.5	9	0.0195
535.5	9.5	0.0177
534.4	9.4	0.0177
621.4	10.9	0.0175
430	7.6	0.0177
1,004.4	17.87	0.0177

The cost at Carlisle, Pa., of 1-1½ grout filler for brick pavement laid in 1913, with wages at $1.60, cement at $1.32 and sand at $1.50, was 6.8 cts. per square yard.

The labor cost of grouting brick pavement laid at Fort Worth, Tex., in 1914, was 1.7 cts. per square yard. The methods were: The grout for the filler was composed of equal parts of cement and sand and enough water to make it flow properly. An average of 0.021 bbl. of cement per square yard was used. Two grout boxes were used when a full gang was working, and where the work was extensive and the weather permitted fast bricklaying, a third box could have been used to advantage. To keep the men around the boxes from standing idle waiting for a batch to be mixed, the cement and sand were mixed dry on the concrete base or on the finished pavement and wheeled to the boxes as fast as needed. This shortened the length of time of mixing in the box and made it about equal to the time it took for the other box to be emptied, thus keeping the whole gang employed. To keep the cement and sand from separating the grout was agitated continuously until the last bit had been dipped out. The first pouring was made thin enough to flow into all cracks and was kept swept ahead by means of steel street brooms. After the first pouring had progressed 25 to 40 ft., depending upon the weather and whether or not the brick were thoroughly dry, one box was turned back to apply the second and final coating. This second pouring was mixed thicker than the first and rubber squeegees were used to fill the joints flush and keep the blocks free from surplus grout. To obtain the ¼-in. joint at the rail it was necessary to fill it flush with the top as with the rest of the pavement and then, before it has set hard, to clean the grout out with pointed stick or trowel. Soon after the second coat of grout was placed the whole surface was covered with about ½ in. of damp sand. On dry, hot days the brick were well sprinkled before pouring the grout, considerable water being used for this purpose.

Labor Cost of Laying Brick Gutter.—The following costs, published in Engineering and Contracting, May 1, 1918, cover the work of laying 850 sq. yd. of brick gutter, 12-in. wide, and include all labor except for the delivery of materials. The gutter was laid as a water course for asphalt pavement on a very flat surface. The curb and base were, of course, previously in place. The items covered include sorting and laying bricks, cleanup, grouting, sand cushion, etc. The work was done during good weather by a good foreman but indifferent crew. The total hours for the three items listed are correct, but the work of spreading cushion, laying brick, etc., was not separated, and is, therefore, included under the single item of "Labor." The usual standard specifications governed the work and they were strictly enforced, particularly as regards grouting. The cushion was spread dry 1½ in. thick, previously thoroughly mixed in the proportions of 1 part cement to 5 parts sand. Grout was mixed 1:1 in small quantities to the consistency of cream, and spread immediately after mixing. The labor cost of the work was as follows:

	Per sq. yd.
Foreman, 85 hrs. at 50 ct	$0.049
Labor, 729 hrs. at 30 ct	.257
Cleanup, etc., 61 hrs. at 36 ct	.021
Total (850 sq. yd. brick gutter)	$0.327

Cost of Tearing up and Replacing Brick Pavement for Trench.—F. L. Shidler gives the following data in Engineering and Contracting, June 2, 1915.

The trench was as near as possible to the curb and crossed under two sets of street car tracks and two street intersections. The costs given are for tearing up brick pavement down to grout base, trenching sand cushion and replacing same, relaying brick pavement and slushing with cement filler for laying a wire conduit for ornamental street lights. They also include the cost of sixteen 1 ft. 4 in. square holes about 16 ins. deep, cut through cement and stone sidewalks, filling these holes with concrete and setting four base bolts in each hole. The cost for the post holes, etc., was as follows:

Item	Per hole
Labor cutting, 25 hrs. at 50 cts	$0.78
Labor concreting	0.31
Total labor	$1.09
12 wood templets for base bolts	0.19
2 cu. yds. concrete at $3.60	0.45
Miscellaneous	0.07
Total materials, etc	$0.71
Grand total	$1.80

The cost of the trench 1½ ft. wide and 1,130 ft. long was as follows:

Item	Lin. ft.
Tearing up and cleaning brick	$0.019
Relaying brick	0.025
Teaming	0.004
Total labor	$0.048
2 cu. yds. cushion sand	......
4 bbls. cement	......
300 new brick	......
Miscellaneous	......
Total materials	$0.016
Grand total	$0.064

Removing Block Pavement Between Track Rails by Plowing.—(Engineering and Contracting, June 7, 1916.) For two years the Cleveland Ry. Co. has used a special plow for rooting up block pavement between rails whenever reconstruction of track was required. The plow first built was experimental and somewhat crude in detail. The apparatus consists of a cast steel spear-shaped blade with shallow mold boards attached to the front end of a steel frame truck mounted on car wheels. The truck has a wooden body in which the necessary counter weighting load can be placed. In operation the truck is pulled by a work train and the plow blade loosens the pavement as illustrated. The designer of this plow, Chas. H. Clark, Engineer Maintenance of Way, Cleveland Ry. Co., furnishes the following data: Cleveland Railway Co. has had one of these pavement plows in operation for the past two years, during which time we have made some very remarkable records; the following are only a few of the many instances in which the plow has worked and the time in which it has taken up the pavement:

4,500 ft. on Woodland Ave. in 28 minutes.
3,200 ft. on Woodland Ave. in 30 minutes.
1,500 ft. on E. 55th St. in 12 minutes.
1,000 ft. on Euclid Ave. in front of Hotel Statler to E. 9th St. in 4 minutes.
1,475 ft. on Lorain Ave. in 13 minutes.

Cost of Cleaning Old Paving Brick by Compressed-Air Hammers.—Charles S. Butts gives the following data in Engineering News, July 23, 1914.

The construction of the Rocky Branch joint district sewer at St. Louis, Mo., involved the disturbance of a considerable extent of paved street. The work is 5,724 ft. long (on Blair, Palm and Glasgow Aves.) and was done by the James Black Masonry & Contracting Co., at a price of about $500,000.

Of the total length, 4,600 ft. was in streets having brick paving grouted with cement, the paved width being 17 to 30 ft., and the total paved area being about 10,000 sq. yd., with about 530,000 brick. The specifications require the contractor to repave the streets and leave them in as good a condition as before the construction of the sewer.

The question was (and always has been) whether it pays to clean vitrified paving brick (cement grouted) for use in repaving streets. In cleaning them by hand a man can clean about 300 a day. And at $4.50 per 1,000 (which was paid for this method of cleaning) he would make only $1.35 per day. In order to make it any inducement to clean them by hand about $9 per 1,000 would have to be paid. The contractor finding this method not only slow but also unsatisfactory, abandoned the hand-cleaning method and adopted the following machine method which has proved very satisfactory.

An old vacuum-cleaning wagon was obtained and set up in a convenient location at the pile of brick to be cleaned and used as an air compressor. A ½-in. supply pipe was run to a cleaning board, and to it were connected ¼-in. hose, to each of which was attached a 6½-lb. stone-mason's vibrating air hammer. The hammers had 1-in. chisel points for cleaning the portland-cement grout from the brick. A bench was built and about 70 bricks placed on it with the side upward. One side and one end were cleaned first; then they were turned and other side and other end were cleaned. As there was no cement on top or bottom it required only one turn to complete the cleaning. The capacity of this particular machine is three hammers, and, as the following table shows, the more hammers operated, the cheaper the brick can be cleaned.

	1 hammer	2 hammers	3 hammers
No. brick cleaned per day	1,200	2,400	3,600
Cleaning brick, $2 per 1,000	$2.40	$4.80	$7.20
Turning brick, $1 per 1,000	1.20	2.40	3.60
Gasoline for machine	1.40	1.40	1.40
Cost	$5.00	$8.60	$12.20
5 % for care of tools, etc	0.25	0.43	0.61
Total cost	$5.25	$9.03	$12.81
Cost per 1,000 brick	4.375	$3.762	$ 3.3558

The difference in cost per 1,000 is due to the gasoline used, it costing $1.40 per day to run the machine whether one, two or three hammers are used. To the above costs per thousand for cleaning must be added about $2 for hauling to the pile and back on the street, which would make the cost (using the two-hammer price) $5.76 per 1,000. This against $16 per 1,000 for new brick makes a saving of $10.24 per 1000 for the small-size brick (2¾ × 4 × 8¼ in.). The large paving brick now in use (3¼ × 8½ × 4⅜ in.) would cost about $4.50 per 1,000 to clean, plus $2 for hauling, making $6.50 per 1,000 against $22 for new brick, a saving of $15.50 per 1,000.

Cost of Cleaning Paving Brick by Compressed Air Power.—C. G. Cummings gives the following matter in Engineering and Contracting, March 7, 1917.

An interesting application of a portable, self-contained, engine-driven air compressor was developed some four years ago by C. F. Crowley, Commissioner of Public Works, of the city of Troy, N. Y. This consists in removing and cleaning old paving brick. The equipment used for this work, which was purchased in 1913, consisted of a 15-H.P. Sullivan Class WK-3, portable, single stage air compressor, the compressor being operated by a gasoline engine, mounted on the same truck with the compressor, and operating the compressor through a gear and pinion.

This outfit furnished compressed air for a Sullivan "DA-15," 25-lb. plug drill, and a Sullivan "DB-13" hand bushing tool equipped with bits like that on a cold chisel. The larger of the two tools is used for tearing up the brick, and the smaller for cleaning the old mortar and grout from them. With the plug drill one man can remove 4 sq. ft. of pavement in 15 or 20 minutes, taking the bricks up either one brick at a time or several, as desired. When doing this work by hand, the workmen were frequently obliged to break several bricks, which were perfectly good, in order to get out one, so that the loss was considerable.

Before the purchase of this outfit the cost of removing and cleaning bricks by hand was $24 per thousand and a crew of 10 men was able to handle about 1,000 bricks per day. The detailed cost of operating the compressor and drill outfit was as follows:

1 compressor engineer	$ 3.00
7 gallons of gas at 18 cts	1.26
4 operators at $1.85	7.40
Lubricating oil	.25
Total cost per day	$11.91

The above, of course, does not include interest or depreciation. Mr. Crowley estimates that about 2,000 bricks are removed and cleaned in eight hours with the two tools. This brings the cost of taking up and cleaning to $5.96 per thousand bricks. On work done with this outfit in 1914 a crew of 40 men was cut down to 18 men. It is estimated that this outfit pays for itself on every 100,000 bricks taken up and cleaned. Savings included labor on the brick, saving in the sand cushion, saving in time in making the bed under the brick and in laying the brick. Cement and grouting are also saved.

Mr. Crowley gives the following table showing the number of bricks cleaned each year and the saving made by the use of this outfit:

	Brick cleaned	Saving
1913	229,000	$ 4,122
1914	82,200	1,480
1915	356,000	6,400
1916	100,000 (Est.)	1,800
	767,200	$13,802

Cost of Toothing Brick Paving with Air Compressor.—The Highways section of the Department of Public Improvements of Baltimore, Md., is using air compressors in connection with its work of toothing brick pavements. The following information on this work, given by R. M. Cooksey, is published in Engineering and Contracting, April 4, 1917. In doing this work by hand, stone cutters are employed in preference to laborers, this having been found to be more economical, as the latter class ruined much good paving. The average day's work for a stone cutter is 25 lin. ft. of toothing at $4.50 per day, which equals 18 cts. per ft. The average day's work by machine is 300 lin. ft. of toothing at a cost of $6.79 per day or about 2.26 cts. per ft. The cost of the machine work includes the following items:

5 gal. of gasoline	$10.5
1 gal. cylinder oil	.26
1 gal. Polarine oil	.23
1 special laborer	2.50
1 special laborer	2.75
Total	$6.79

The equipment consisted of one No. 2 portable compressed air outfit, with hose connections for hammers, made by Chris. D. Schramm & Son, Philadelphia, Pa., and two No. 2 Thor chipping hammers. The city purchased three Thor hammers, so that it would have one in reserve, should the one in use get broken or out of order.

Cost of Concrete Road, Allen County, Ind.—The following data, are taken from Engineering and Contracting, Feb. 6, 1918.

The road was built in the period from June 11 to Oct. 12, 1917. The pavement was 12,263 ft. in length and 16 ft. wide, the total surfaced area amounting to 21,801 sq. yd. The average spacing of the transverse expansion joints was 25 ft. Armored joint protection plates and ⅜-in. joint filler were used. The average thickness of the concrete was 7.3 in.

The equipment employed on the paving work include a Koehring No. 11 paver of the boom and bucket type, a Ward gasoline pressure pump and 3,000 ft. of 2-in. water line. Wooden sideforms and wooden stakes were used.

The concrete was a 1:2:3 mixture, washed sand up to ¼ in. in size and washed gravel ¼ in. to 1½ in. being used for aggregate. The organization of the paving gang was as follows:

No. of men	Distribution (variable)
2	Setting forms.
1	Installing armor plates.
2	Handling cement.
10	Handling aggregates.
2	Operating mixer (1 fireman).
2	Placing concrete (sometimes 3 or 4).
1	Finishing pavement.
1	Foreman.

One team hauled the cement. The subgrade usually was kept leveled by one or more men. When necessary one man was specially detailed for grading. The forms were removed and the pavement covered by the entire force.

The cost of the materials, all prices being f.o.b. Fort Wayne, Ind., was as follows:

Cement, per bbl., net	$1.69
Aggregates, per ton	0.5275
Protection plates, per joint-foot	0.125
Joint filler, per ft.	0.04

A 10-hour day was worked, the wage basis being as follows:

Motor trucks (3- and 4-ton)	$30.00
Teams	6.00
Experienced men	3.00 to 3.50
Ordinary labor	2.75
Foreman	4.50

Grading.—This covered the bringing of an old gravel roadbed on red clay soil to the proper grade. The material was loosened with plow and road grader and shoveled into dump wagons. It was spread with shovels and road machine. The cost was as follows:

	Per cu. yd.
Loading wagons	$0.26
Plowing and grading	0.083
Spreading on dump	0.076
Hauling first 100 ft.	0.06
	$0.479

Hauling Aggregate.—The hauling was done with 3-ton and 4-ton trucks, the average length of haul being 1.7 miles. A 5-ton Galion power unloader was used in handling the material. The cost of loading the trucks was approximately 9 cts. per cubic yard. The actual cost of hauling was 42 cts. per cubic yard.

Paving, Labor Costs.—A 2-bag batch (12 cu. ft.) was mixed in drum from ½ to ¾ minute. Five No. 2 wheelbarrows were used for supplying the mixer. The batch of concrete was dumped from the bucket and shoveled into place. The surface of the pavement was hand floated, the joints luted and troweled and the edges of the slab rounded. The maximum cost of this work was 16 cts. per square yard or 79 cts. per cubic yard of concrete. The minimum cost was 9.6 cts. per square yard or 47.3 cts. per cubic yard.

Covering Pavement.—Earth ranging in texture from loose top soil to hard soil was shoveled from the berms and ditches and spread on the concrete. The average depth of the covering was 2 in. The maximum cost of covering was 3.1 cts. per square yard, and the minimum cost was ½ ct. per square yard.

Summary of Costs.—The following summary represents the average cost for 20 days' work:

Item	Cost per sq. yd. pavement	Cost per cu. yd. concrete
Cement	$0.54	$2.66
Cost of aggregates	0.19	0.95
Hauling aggregates	0.011	0.54
Loading aggregates	0.023	0.115
Expansion joint complete	0.063	0.31
Paving operations	0.133	0.651
Covering pavement	0.015	0.074
Removing earth cover	0.005	0.024
Overhead and miscellaneous	0.065	0.319
Totals	$1.144	$5.643

The item "Miscellaneous" includes fuel, oil, repairs, depreciation and one-way moving expense of plant.

The total number of hours on the work was 1,065. The number of hours lost due to rain, lack of materials, and miscellaneous delays was 498. This makes the actual number of working hours 567. The miscellaneous delays include minor delays due to mechanical troubles of plant, short intervals of waiting for materials, etc. The average yardage of pavement laid per working hour was 38.4 sq. yd.

Cost of Arizona Federal Aid Concrete Road.—The following data given in Engineering and Contracting, Feb. 4, 1920, relate to the construction of a concrete pavement on the Phoenix-Temple, Ariz., highway, Arizona Federal Aid Project No. 2. The work was done during January and February, 1919, by forces of the Arizona State Highway Department under the supervision of Clyde E. Learned, Senior Highway Engineer, U. S. Bureau of Public Roads, who furnished the matter in this article.

The cost data cover about three-fourths of the length of road construction. The work involved 2.92 miles of 18-ft. wide, 5-in. thick, 1:2:4 concrete pavement. The total number of cubic yards of concrete placed was 4,397, equivalent to 31,658 sq. yd. of pavement, giving a ratio of 1 cu. yd. to 7.2 sq. yd.

The subgrade was composed of an old surfaced road of caliche conglomerate and mixture of decomposed granite and caliche, which was very hard to work. The preparation of the subgrade for the concrete was very expensive, but an exceptionally good piece of work was performed.

The mixing was done with a new No. 22 Koehring paving mixer, using a 3-bag batch. 1.57 bbl. of cement were used per cubic yard of concrete in place; 0.48 cu. yd. of sand, and 0.89 cu. yd. of stone. The wooden side forms were 2 in. × 5 in. and were left in place.

Water was pumped a maximum distance of 1½ miles. Trouble was experienced with the pumps as they were of too small a capacity. The pipe was old, and the line was poorly laid.

Common labor and teamsters were paid $3.50 per 8-hour day. State teams were used and were figured at $6 per day for team and driver. The hauling costs were exceptionally high due to poor handling of teams. The crushing costs also were high, due to poor setting of crushing plant, constant breakdowns and changing of foremen.

The organization of the concrete gang was very good, the average daily run being 450 lin. ft. and the maximum daily run 540 lin. ft. The gang was made up as follows:

	Per day
1 foreman	$ 6.00
1 mixer engineer (gas engine)	5.50
1 bucket man on boom of mixer	4.00
1 pump man	4.00
2 finishers, rolling, belting and finishing joints	9.00
2 strike board men (screening and tamping) at $4	8.00
2 concrete spreaders at $3.75	7.50
1 handy man, installing joints, wetting subgrade, etc	3.50
4 men wheeling and loading stone wheelbarrows at $3.50	14.00
2 men wheeling and loading sand at $3.50	7.00
4 extra men loading stone to wheelbarrows at $3.50	14.00
1 extra man loading sand to wheelbarrows at $3.50	3.50
1 man, cement to hopper, from side forms	4.00
1 water boy, also spotting piling of cement	3.00
1 watchman wetting down concrete	3.50
2 men dyking for curing and wetting down concrete at $3.50	7.00
27 men. Total	$103.50

An additional pump man required nights for about one-third of time.

The itemized cost of the pavement was as follows:

	Cost per cu. yd., concrete
Labor:	
Supervision (foreman and timekeeper)	$ 0.08
Preparation of subgrade, including dragging, rolling, wetting down, harrowing and trimming	0.57
Setting wooden side forms, including trenching for same. (Forms remain in place)	.45
Loading materials, mixing, placing and curing concrete, pumping water, watchman, cleaning off pavement and cutting expansion joint filler	1.12
Dumping and spreading sand and stone on subgrade	.06
Pipe line, hauling, laying and removing (estimated)	.16
Assembling and dismantling mixer (estimated)	.01
Total labor	$ 2.45
Concrete Materials:	
Cement—	Per bbl.
F. o. b. Phoenix (net)	$ 3.17
Loading and unloading	.13
Hauling, average haul 1 mile	.11
Return freight and bag losses (estimated)	.05
Total cost per bbl	$ 3.46
Cost (1.57 bbl.) per cu. yd. concrete	5.43
Sand—	Per cu. yd.
Premium	$ 0.10
Hand screening at pit (part of supply)	.40
Loading at pit (total supply)	.40
Hauling pit to crusher (¼ mile bad haul)	.32
Screening at crusher (part of supply)	.20
Hauling to road (3-mile average haul)	1.40
Cost per cu. yd. on road	$ 2.82
Cost (0.48 cu. yd.) per cu. yd. concrete	1.35

Gravel (State Plant):	Per cu. yd.
Premium	$ 0.10
Loading at pit	.48
Hauling, pit to crusher (¼ mile bad haul)	.32
Crushing and screening	1.02
Hauling to road (3-mile average haul)	1.40
Cost per cu. yd. on road	$ 3.32
Crushed Stone (Tempe Commercial Plant):	
Cost in bin, $1.85 per ton × 2460/2000	$ 2.28
Haul to road (3-mile average haul)	1.40
Cost per cu. yd. on road	$ 3.68
Composite price of gravel and crushed stone	3.50
Cost (0.89 cu. yd.) per cu. yd. concrete	3.11
Total cost cement, sand and stone, per cu. yd. concrete	9.80
Expansion joints (Carey's Elastite)	.10
Materials and Repairs:	Cost per day
Mixer—	
Gasoline, 22 gal. at $0.25	$ 5.50
Oil, grease, waste, etc	1.00
Cost of 50 days	300.00
Pumps—	
Gasoline, 8 gal. at $0.25	2.00
Oil, grease, waste, etc	.50
Cost per day	$ 9.00
Cost of 50 days	450.00
Crushing Plant:	
Coal, ¾ ton per day at $7.50	$ 5.00
Oil, grease, waste, etc	1.00
Cost per day	$ 6.00
	Lump sum
Repairs on mixer (estimated)	$ 20.00
Repairs on pumps (estimated)	200.00
Repairs on crusher (estimated	500.00
Total cost, fuel and repairs	$1,470.00
Side Forms and Stakes:	Per station
Side forms, 200 ft. B. M. at $45.00	$ 9.00
Stakes and nails	1.00
Total cost for 28 yd. concrete	$ 10.00
Interest and Depreciation:	Lump sum
Mixer cost, $4,360, at 10 per cent	$ 436.00
Two pumps and engines, $400, at 10 per cent	40.00
Pipe line, connections, etc., $5,000, at 10 per cent	500.00
Car subgrader, $400, at 10 per cent	40.00
Small tools, hose, etc., $500, at 50 per cent	250.00
Cement house, $300, at 50 per cent	150.00
Crushing outfit, $4,000, at 15 per cent	600.00
Dump wagons, $3,000, at 10 per cent	300.00
Total interest and depreciation	$2,316.00

SUMMARY OF COST

	Per cu. yd. concrete in road
Labor	$ 2.45
Cement	5.43
Sand	1.35
Gravel and crushed stone	3.11
Expansion joints	.10
Materials and repairs for plant	.33
Side forms and stakes	.36
Interest and depreciation on plant	.40
Total per cu. yd. concrete	$ 13.53
Total cost of concrete pavement per cu. yd	13.53
Total cost of concrete pavement per sq. yd	1.88

The finished concrete road was an exceptionally good piece of work.

Cost of Federal Aid Concrete Pavement in Colorado.—Engineering and Contracting, Feb. 4, 1920 publishes the following information given by Clyde E. Learned, of the U. S. Bureau of Public Roads, under whose supervision the road was built.

Colorado Federal Aid Project No. 1 comprised the construction of a concrete pavement on the Denver-Littleton road. The pavement was a 1:2:3 mix, 16 ft. wide, and 5½ in. thick at sides, and 6½ in. thick at the center. The total number of square yards was 36,974 which required the placing of 6,325 cu. yd. of concrete giving a ratio of 1 cu. yd. to 5.85 sq. yd. of pavement. The work was done by contract. It was commenced in July, 1918, and finished in November of that year.

The mixing was done in a No. 514 Smith Chicago paver with rotary distributor. The size of batch was 3½ bags. This mixer had been in use for 7 years. The side forms were wood, and they were used over again.

The fine grading and preparation of subgrade were very poor, and this occasioned delays in front of the mixer. The concrete pavement work was delayed considerably owing to lack of facilities for furnishing materials fast enough to keep the mixer in continuous operation.

Common labor and teamsters were paid $4 to $4.50 per 9-hour day. Team and driver were paid at the rate of $7 per day. The average haul on cement was ¾ mile; on sand ¾ mile, and on gravel ⅞ mile.

The size of the concrete gang was dependent, to a great extent, on the ability of the contractor to get and keep enough laborers to carry on the work. From the beginning of the pavement work on July 19 to the last of August, the concrete gang was made up as follows, and the following scale of wages prevailed per 9-hour day:

	Per day
1 foreman	$ 7.00
1 mixer operator (attends to firing)	6.00
1 man regulating water for batch and dumping mixer	4.00
1 boy on revolving distributor spreading concrete and wetting subgrade	3.75
1 man spreading concrete and assisting installing joints	4.25
2 men on strike board, striking off and tamping concrete, at $4.00	8.00
1 finisher, rolling, belting, hand floating and edging	6.00
1 man shaking out and bundling cement sacks; also assisting finisher to belt concrete and move bridge	4.00
2 grade men around mixer leveling up subgrade and tamping where necessary, at $4.00	8.00
2 men moving and setting forms also installing joint material, at $4.00	8.00
2 men carrying and putting cement into mixer hopper, at $4.00	8.00
2 men on mixer hopper assisting in dumping wheelbarrows, moving mixer runways, and taking care of hose from pipe line to mixer, at $3.75	7.50
6 men on two sets of gravel wheelbarrows, loading and wheeling, at $4.25	25.50
2 men on one set of sand wheelbarrows, loading and wheeling, at $4.25	8.50
2 extra men loading gravel in wheelbarrows, at $3.75	7.50
1 extra man loading sand in wheelbarrows	3.75
3 men covering and wetting concrete, at $3.75	11.25
1 water boy	1.50
1 night watchman, wetting concrete and taking care of fire on mixer	4.00
33 men. Total	$136.50

The average daily run of this gang, when material was on hand, was 480 lin. ft. of pavement per day, the maximum run being 70 lin. ft., the above runs being equivalent to the placing of 146 and 173 cu. yd. of concrete.

From the first part of September to the end of the work on Nov. 5, the concrete gang was smaller, averaging about 25 men, and differed from the above organization as follows:

The man spreading concrete was eliminated, his work being done by the strike board men, who were advanced to $5 per day.

Where two men had previously been used, one man was now used on each of the following: grading in front of the mixer, handling cement to material hopper, and moving and setting forms. These men were advanced 50 cts. to $1 per day. The men used for covering up were eliminated, as this work was performed each morning by the whole gang before any concrete was laid. One of the extra men loading wheelbarrows was also eliminated, and the pay of the wheelbarrow men was raised to $4.50 per day.

The total wages per day for these 25 men were $112.50, and the average and maximum daily runs were 420 and 505 lin. ft. of pavement, this being equivalent to the placing of 128 and 154 cu. yd. of concrete. This gang had the maximum weekly run of 2,370 lin. ft. of pavement, which was accomplished in 5½ working days.

The organization of the concrete gang was very good, and the work went along very smoothly, the only serious trouble being the lack of materials.

The following table shows the cost of the pavement:

	Cost per cu. yd., concrete
Labor:	
Supervision (foreman and timekeeper)	$0.175
Preparation of subgrade for concrete	.059
Setting and moving forms	.066
Loading, mixing, placing and finishing	.994
Covering, cleaning off, cutting joints	.095
Pipe line, hauling, laying and removing	.063
Assembling and dismantling mixer	.012
Mixer—to and from job—Denver	.010
Total labor	$1.472
Concrete Materials:	
Cement—	Per bbl.
F. o. b. mill	$1.98
Freight	.32
Loading, hauling and unloading	.15
Freight return bags and losses	.05
Total cost per barrel	$2.50
Cost per cu. yd. concrete (1.70 bbl.)	4.25
Sand—	Per cu. yd.
Average cost screened in piles or at pit	$1.00
*Loading and hauling to road	.50
Cost per cubic yard	$1.50
Cost per cu. yd. concrete (0.60 cu. yd., which allows for waste)	.90
Gravel—	
Average cost screened in piles or at pit	$1.20
*Loading and hauling to road	.60
Cost per cubic yard	$1.80
*Loading and hauling combined, as drivers helped load materials.	
Cost per cu. yd. concrete (0.80 cu. yd., which allows for waste)	1.44
Total cost cement, sand and gravel per cu. yd. concrete	$6.59
Water—From Denver and Littleton water mains	$0.06
Joints—Carey's Elastite, ¼ in. premoulded asphalt	.065

Materials and Repairs:		Cost per cu. yd. concrete
Mixer—		
Coal, price $8.00 per ton		$0.051
Oil, waste and packing		.006
Repair parts		.012
Total mixer		$0.069
Side Forms—Lumber and pins		.016
Total cost of materials and repairs		$0.085
Interest and Depreciation:		
Mixer, $2,300.00, at 15 %	$345.00	$0.055
Pipe line and connections, $750, at 15 %	112.50	.018
Small tools, hose, etc., $140, at 50 %	70.00	.011
Total interest and depreciation		$0.084

SUMMARY OF COST

	Per cu. yd. concrete in road
Labor	$1.472
Cement	4.250
Sand	.900
Gravel	1.440
Water	.060
Joints	.065
Materials and repairs foı plant	.069
Side forms	.016
Interest and depreciation on plant	.084
Total per cu. yd. concrete	8.356
Total cost of concrete pavement per cu. yd.	$8.356
Total cost of concrete pavement per sq. yd.	$1.427

Crew Organization for Concrete Pavement Work.—An organization capable of turning out 600 to 700 sq. yd. of concrete per day for road construction under conditions prevailing in Western Washington is outlined in Concrete Highway Magazine, from which the matter following is abstracted in Engineering and Contracting, Oct. 2, 1918.

Materials.—In many cases sand and pebbles have been obtained near the road to be paved, and as a rule the sand and gravel banks have sufficient elevation to allow sluicing the material into bunkers. With the many streams in western Washington, water is usually near by in large quantities.

Under these conditions and with the following crew at the pit and bunkers, 250 cubic yd. per day can be turned out.

1 man for pump and engine.
1 man at nozzle sluicing in pit.
1 man helping nozzle man removing large rocks, roots, etc.
1 man at bunkers looking after sand box and keeping chutes clear.

Grading.—Supposing the road to be paved is a well developed highway with proper grades established, and that only light grading is to be done prior to paving, the following men will do the rough and fine grading:

1 foreman in charge of grading and ribbon setters.
1 engineer for caterpillar and roller.
1 teamster for Fresno and wheeler.
4 laborers, pick and shovel work.

When caterpillar is hooked to road grader and scarifier one of the above laborers is used on grader as helper. One of the above laborers also is used at times as teamster's helper.

Ribbons.—The grading foreman has:

1 man setting ribbons.
1 man helper.

Placing Material.—Where the maximum haul is 4 miles, 3 five-ton trucks will handle the output of bunker and put material on ground to run 1 three-sack batch mixer.

Final Subgrade.—Two men are required back of mixer bringing subgrade to exact depth and dragging subgrade template on ribbons.

MIXER CREW FOR THREE SACK MACHINE

1 foreman in charge of concrete crew.
6 men used on wheelbarrow for gravel, 3 wheelbarrows with 2 men to each barrow.
2 men are used on wheelbarrows for sand, 1 man for each wheelbarrow.
2 men are used for cement, 1 man carries cement to bench, 1 man empties sacks into hopper.
2 men for spreading concrete.
2 men for rodding.
1 man for finishing.
1 engineer on mixer if gas engine is used. If steam mixer is used a fireman is necessary.
2 men for covering finished concrete with 2 in. of earth.
2 men watering earth covering on concrete less than 10 days old.
1 man watering subgrade.
1 man for water supply to mixer.

Presuming that the road to be paved is 20 ft. wide with a 1:2:3 mix and a thickness of 6-in. side and 8-in. center, the crew of 23 men as outlined above should lay 600 to 700 sq. yd. of pavement per day.

Four Examples of Concreting Gang Organization for Road Work.—The following information, collected by special committees of the National Conference on Concrete Road Building is given in Engineering and Contracting, Feb. 23, 1916.

Example I: Pennsylvania, Easton—Bethlehem Model Road.—The best results were obtained with a gang organization as follows:

Gang	Cost per day
1 foreman at $3	$ 3.00
1 mixer operator at $3	3.00
1 fireman at $2.50	2.50
2 templet men at $2	4.00
3 men spreading at $2	6.00
2 men floating at $2	4.00
1 man finishing at $2	2.00
2 men on forms at $2	4.00
1 man changing chute at $2	2.00
2 men handling cement at $1.75	3.50
7 men on wheelbarrows at $1.75	12.25
7 men shoveling at $1.75	12.25
1 utility man at $1.75	1.75
1 waterboy at $1.50	1.50
32 men in total gang	$61.75

This list schedules the men according to their special duties. The first task in each day's work was from the previous day's work to bring forward the forms and other working appliances and to cover the previous day's concrete with earth. All men, such as templet men, floaters and finishers, were employed in this task. The three men handling concrete also placed the expanded metal reinforcement and the expansion joints. Laying a slab 7 in. thick and holding the material in the drum for a 90 sec. mix, this gang averaged 525 sq. yd. per day at a cost of approximately 11.7 cts. per square yard. A No. 16 Koehring paving mixer, with boom and bucket delivery, was used. With a shorter mixing time, say 45 sec., it is suggested that the gang be increased three to five men on wheelbarrows; with such an increase it is estimated that the yardage could be increased 50 per cent. Data reported by William D. Uhler, Chief Engineer, State Highway Department.

Example II: Illinois State Aid Road Work Practice.—The data given are based on experience on 25 to 30 jobs of state aid road work representing approximately 500,000 sq. yd. of pavement. Assuming excavation complete and all material delivered on the work and that the subgrade is in average condition, the following crew is considered to be most efficient under average conditions on work similar to state aid road work in Illinois.

General—	Number
Superintendent	1
Foreman	1
Front End of Mixer—	
Wheeling sand	2
Wheeling stone	4
Extra shovelers	2
Handling cement	2
Bundling cement sacks	1
Trimming subgrade	1 or 2
Rear End of Mixer—	
Shovelers	3 or 4
Finisher	1
Curing concrete	2
On Mixer—	
Engineer	1
Fireman	1
Forms—	
Setters	2
Water—	
Pumpman	1
Miscellaneous—	
Watchman	1
Waterboy	1
Total	27 or 29

The list given needs some explanation to be entirely plain. First the assignment of only one or two men to trimming subgrade assumes that the subgrade is already practically correct. Of the three or four shovelers at the rear end of the mixer, two also handle the strike-board and one also occasionally assists the finisher. At times of any delay in mixing operations, practically the entire gang is turned to covering the concrete with earth. Under ordinary conditions, however, it is necessary to assign two men to covering and sprinkling concrete in addition to the work done by the whole gang. The gang is for a two-bag batch mixer, and with this machine its average daily output of 18 ft. wide and 7 in. thick pavement is about 800 sq. yd., working day 9 hr., mixing time per batch, 35 sec. The average cost of mixing and placing concrete and of setting forms and joints is 10 cts. to 12 cts. per square yard. A single day's cost may run as low as 8 cts. per square yard, but an average job of any size, figuring repairs, fuel and depreciation on mixer, brings the cost between 10 and 12 cts. where labor receives from 20 to 25 cts. per hour. A smaller gang will reduce the unit cost slightly if no account is taken of interest, overhead,

62

etc. The slower progress, however, runs up these fixed charges so that in the end, the cost is greater rather than less. Data reported by H. B. Bushnell, Division Engineer, State Highway Department.

Example III: Wisconsin, Milwaukee. County Roads.—An efficient gang organization for conditions prevailing in Milwaukee County has been found to be about as follows:

Gang	Cost per day
1 foreman at $5	$ 5.00
1 timekeeper at $5	5.00
1 engineer at $5	5.00
1 fireman at $2.50	2.50
1 pumpman at $2.50	2.50
1 form setter at $2.50	2.50
1 finisher at $3	3.00
2 strikeoff men at $2.50	5.00
2 puddlers at $2.50	5.00
2 cement handlers at $2.50	5.00
1 boy bundling sacks at $1.50	1.50
1 waterboy at $1	1.00
6 sand laborers at $2	12.00
12 stone laborers at $2	24.00
1 man removing forms at $2	2.00
2 men covering concrete at $2	4.00
1 man sprinkling at $2	2.00
1 man trimming subgrade at $2	2.00
38 men Total	$89.00

The particular road on which this gang worked contained 17,280 sq. yd., was 18 ft. wide and averaged 7 in. in thickness. The subgrade was clay and required little sprinkling before laying the concrete. Wheelbarrows were wheeled directly on the subgrade without planks. Sand and gravel were placed in the middle of the road and cement on the side. Water was available at the job and was pumped through 2-in. pipe by a steam pump. A 16-ft. paver was used with an open spout for distributing the mixed material. The mix was 1:2:3½, two bags of cement being used to a batch, and 11 cu. ft. of aggregate. Protected joints were placed every 50 ft.

The actual number of days consumed in the construction of this particular piece of work was 33, of which five were Sundays. Of the remaining working days, two were lost because of rain and a defective pump. This left 26 days for actual construction work. During this period, the maximum output for one day was 1,000 sq. yd. and the minimum 264 sq. yd. The average output was 665 sq. yd. per day or 332½ lin. ft. per day. The actual labor cost for mixing and placing was $0.1396 per square yard, which included labor incurred in supplying water covering and sprinkling concrete and also a watchman during the construction period. The cost to the contractor for lost time, moving plant to and from the job, the laying of pipe, etc., amounted to $0.0201, giving a total cost per square yard for labor of $0.1597. The timekeeper looked after the ordering of materials, spotting of cars and unloading and placing of materials on the job. A cheaper engineer might have been employed but it is believed that the results obtained justified the additional expense. The man employed in trimming the subgrade saved more than enough in materials to pay for his wages. Data reported by F. W. Whitlow, Superintendent of Construction, County Highway Commission, Milwaukee County, Wisconsin.

Example IV: California Highway Commission.—(1) Specific crew organization employed on recent jobs.

DIVISION III—MAINTENANCE REQUISITION 155, AUBURN BOULEVARD

Concrete Crew:

1 mixer engineer at $4.00	$ 4.00
1 foreman at $4.00	4.00
1 water boy at $2.00	2.00
1 cement man at $2.75	2.75
2 finishers at $3.00	6.00
2 men on tamp. at $2.75	5.50
4 spreaders at $2.75	11.00
15 laborers at $2.50	37.50
Total	$72.75

Average for 20 good days' run = 118.9 cu. yd. per day.

$$\frac{\$72.75}{118.9} = \$0.613 \text{ cu. yd.}$$

Note.—Mixer rent of $10 not included in above.

DIVISION III—STANISLAUS COUNTY, ROUTE 13, SECTION A

Concrete Crew:

1 mixer engineer	$ 3.63
1 foreman	4.50
1 finisher	3.00
6 spread tampers at $2.75	16.50
13 shovelers and wheelbarrow men at $2.50	32.50
Total	$60.13

16 days' average run = 101.4 cu. yd.

$$\frac{\$60.13}{101.4} = \$0.592 \text{ cu. yd.}$$

2. Conditions and amount of work, plant used and other reasons influencing choice of organization employed.

See (3) for conditions and amount of work. No special conditions influenced the choice of organization. The organization (see 1 above) is customary where a two-bag mixer is used, and an output of from 100 to 150 cu. yd. per day is expected. The following crew can probably be considered as typical of work throughout the state:

1 foreman	$ 4.00
1 mixer engineer	4.00
1 cement man	2.75
1 finisher	3.00
2 tampers and strike off men at $2.75	5.50
6 men spreading, shoveling up loose materials, checking up subgrade, etc., at $2.75	16.50
13 men on wheelbarrows and shovels at $2.50	32.50
25 men. Total	$68.25

This crew could easily turn out an average of 125 cu. yd. of concrete per day at a cost of $0.54 per cubic yard. Delays due to shortage of material, supplies, water and mixer trouble generally tend to keep the average from 10 to 20 cts. per cubic yard higher. The figures given above are for average conditions, and for the average run of labor. There have been times when contractors with an especially capable and experienced crew of men and no other difficulties have been able to mix and place concrete for as low as 40 cts. per cubic yard, and even lower, and on force account work (work done by the State under day labor) we have done the work for as low as 48 cts. per cubic yard on a single day's run. But out of over twenty contracts under way in Division III this summer not one mixed and placed concrete as low as 50 cts. per cubic yard, and the average was much higher.

The Auburn Boulevard job consisted of laying a concrete base 4 in. thick, for the most part, on an old oil macadam base. The old pavement was first scarified and the top 2 in., which consisted of a mushy mixture of oil, dirt and a small amount of rock, was removed. The remaining base, on account of the amount of rock and oil contained, was rather difficult to prepare accurately for a 4-in. base. On this account the header and subgrade charge is higher than is customary on work of this nature.

3. Records of output or costs indicating efficiency of crew organization as employed.

M. R. No. 155 Auburn Boulevard

		Per cu. yd.
1. Length of concrete pavement, 18,273 lin. ft. = 3.46 mi. (Part 18 ft. × 4.5 in.; part 15 ft. × 4 in.)		
2. Total yardage, 3,963.5 cu. yd.		
3. Labor cost of mixing and placing (not including water supply or curing or repairs)	$2,994.73 =	$0.730
4. Cost of curing concrete	837.23	0.211
5. Cost or running pump and water supply	310.09	0.076
6. Cost of laying and removing water pipe	95.43	0.024
7. Cost of headers	1,277.89	0.322
8. Cost of shaping subgrade	1,073.50	0.270
9. Cost of unloading and hauling rock, sand and cement	4,480.35	1.130
Total cost		$2.763

10. Average haul = 0.7 miles.
Items 3 to 9 = $11.069.22, or $3,200.00 per mile.

The mixer used on the Auburn Boulevard was old and as the work progressed the break-downs were numerous, causing disorganization of crew and consequent increased costs. Delays due to shortage of materials toward the latter end of the work added unfairly to the cost of the concrete. The total cost of $2.76 per cubic yard of concrete in place is not excessive, but is higher than should be on a large job and where there are no serious difficulties to be overcome.

6. Discussion of specific or general questions of crew organization that experience indicates needs enlightenment or investigation.

No suggestions can be made along this line, as there are no particular crew organization problems connected with concrete paving work. The only real problem is the problem of the superintendent always to organize the layout of his work so as to prevent serious delays in any one part of the organization. Thus, he must plan his grading crew to keep ahead of the subgrade crew, the finishers must keep ahead of the hauling of materials, and the material men must keep ahead of the concrete crew. If each outfit can see only one day's work laid out ahead, there is from 25 per cent to 50 per cent loss of efficiency. On the day labor work in Stanislaus County, Contract D-50, the work was so regulated at the start that each unit of the work was at least one-half mile (representing four or five days' work) ahead of the other units. Data reported by A. B. Fletcher, Highway Engineer, California Highway Commission.

Summary from Examples.—Using modern paving mixers, a concreting gang for road work will consist of from 30 to 40 men. These are round numbers.

In instances fewer than 30 men will suffice and in more rare instances a greater number than 40 may be required. The exact number will depend upon the nature of many controlling conditions. Also the number of men allotted to the several duties required to be performed is likewise determined by the nature of these conditions. As illustrating the vagaries of organization recorded in practice, Table XXIV has been compiled from data readily at hand. Doubtless some of the wide variation exhibited is due to inequalities of organizing skill but with all reasonable allowance for this cause, there remain important differences caused entirely by differences in conditions controlling the concreting work.

TABLE XXIV.—DISPOSITION OF MEN IN CONCRETING GANGS FOR CONCRETE ROAD WORK

Job		Genl.	Front	Rear	Mixer	Forms	Water	Misc.
I		1	16	9	2	2	..	2
II		2	12	7	2	2	1	2
III		2	22	8	2	2	1	2

VII	Base	1	9	5	1	..	..	..
		(2)	(13)	(11)	(3)	(2)	..	..
	Top	1	4	6	2	2	..	..
VIII		1	10	11	3	2	..	..

Concreting is but one operation in the process of concrete road building. The economic target is the lowest cost for the whole process, and the concreting operation must so co-ordinate with other component operations that the mark is hit. It may often be, therefore, that the most efficient concreting gang organization is not the one that would mix and place most cheaply a cubic yard of concrete in finished road slab considering this one operation as the beginning and end of all effort. The law of co-ordination has influence in an even more minute way. Consider for the moment the concreting operation to be independent of all others. On the Pennsylvania road work described later, it is the requirement that the batch shall turn 90 sec. Under this requirement, the most efficient gang organization has been found to be that of column one in Table XXV. Could the mixing period be cut in half the most efficient gang organization would be that of column two in Table XXV. Again, considering the gang organization for Illinois road work as given in Example II. By reducing this gang by a few men it is stated that a

TABLE XXV.—GANG ORGANIZATION AND OUTPUT AS INFLUENCED BY TIME OF MIXING

Thus—	1	2
Mixing time, seconds	90	45
General labor	1	1
Men in front	16	21
Men in rear	9	9
Men on mixer	2	2
Men on forms	2	2
Miscellaneous	2	2
Total men	32	37
Output sq. yd. average	525	787

smaller unit labor cost could be obtained but the slower progress would increase interest and overhead costs enough to exceed the saving.

Gang organization is determined then, first by the controlling construction conditions and second by the work organization as a whole. These determining factors are seldom constant outside of a single job and are often variable on a single job. No general formula is possible for solving all problems of concreting gang organization. The organization of each gang is a separate problem and must be so solved.

Bonus System Cuts Cost of Laying Concrete Pavement.—Engineering and Contracting, June 5, 1918, gives the following:

The city of Flint, Mich, is constructing 10 miles of pavement and 30 miles of sewers by day labor under the direction of the city engineer. Common laborers' wages are $3.50 a day, and the men engaged in paving were not efficient until a bonus system was applied. For example, a gang of 16 men and a foreman operating a concrete mixer averaged only 47 cu. yd. of concrete base (6 in. thick) per day, when actually working, at a cost of $1.23 per cu. yd. for labor; but upon the payment of a bonus system a gang of 12 men and a foreman averaged 90 cu. yd. a day when actually working, and at this rate the labor cost, including the bonus, was less than 60 ct. per cu. yd., or 10 ct. per sq. yd.

The bonus payment was 1 ct. to each of the 13 men for each square yard of concrete in excess of 500 sq. yd. per day. At this rate, if 600 sq. yd. were laid in a day, each of the 13 men would earn $1 bonus, but each of these extra 100 sq. yd. would cost the city only 10 ct. for labor.

It is well within the capacity of a gang of 13 men to run 100 sq. yd. of 6-in. concrete per hour, and this rate was attained.

There are few classes of construction work to which it is so easy to apply a "bonus system" as to paving work. This is because of the fact that the number of units of work done each day is readily ascertained and because each gang is usually engaged continuously upon the same sort of work. In view of this it is rather astonishing that some sort of bonus payment is not made to all gangs engaged in laying pavements. Engineers in charge of pavement construction by day labor should invariably apply a bonus system. Otherwise the men are almost certain to loaf, for they reason that the city, or county, or state for whom they are working can afford to foot any bill and is not likely to scrutinize the cost very closely, anyway.

Method of Reducing Labor Cost of Concrete Mixing.—A novel method employed by the Independent Asphalt Paving Co. of Seattle, Wash., in handling aggregate for the construction of 3½ miles of concrete pavement on the Pacific Highway in Thurston County, Washington, made it possible for the company to materially reduce the size of its mixing crew. The plan is described in the Concrete Highway Magazine, and abstracted in Engineering and Contracting, May 1, 1918, as follows:

The company was well equipped with all kinds of road-making machinery and had a number of automobile trucks for the delivery of material. At the town of Lacey, which is approximately in the center of the work, they received their sand and pebbles by railroad. At this point a stiff leg derrick with ¾-yd. clamshell bucket was erected. This derrick lifted material directly from cars to stock piles of approximately 3,000 cu. yd. of gravel and 2,000 cu. yd. of sand. No paving was started until about this amount of material was on hand, it being intended that when concreting commenced it should be continuous.

While this reserve of material was being assembled a small loading bunker was built, designed to hold about 5 yd. of sand and 10 yd. of gravel, filling being accomplished by means of the stiff leg derrick. It was equipped with 5 measuring boxes for sand and 5 for gravel, so situated that they would discharge simultaneously by gravity 5 measured batches of sand and gravel into compartments built into the truck bodies for this purpose. Each batch of sand contained 6 cu. ft. and each batch of gravel 9 cu. ft., this being the necessary sand and gravel to make up a batch of 1 : 2 : 3 mix for the 3-sack mixer used on the job.

The trucks for delivering the material were of 3-yd. capacity, having their bodies or boxes divided into 5 compartments by means of wooden partitions. Each compartment received one full batch of sand and gravel for a 3-sack mix. The lower half of each partition was hung on strap hinges and was held in place by a simple catch, which could be easily released when the body was raised ready to discharge into the hopper of the mixer.

The partitions and sides of the truck were built up 6 in. above the required depth necessary to hold a batch, in order that when the body was raised for discharging the material would not run from one compartment to the other.

The trucks were accurately loaded at the bunkers, transported 5 full batches of sand and gravel to the mixer and dumped these batches directly into the loading hopper of the machine, a batch at a time, without even letting the material touch the subgrade.

The contractor was able to reduce his mixing crew of men from 22 to 10, and the 10 men easily accomplished the work. All question of material loss on the subgrade was eliminated, and the resulting concrete was entirely free from clay balls or other foreign material.

From actual timing records kept on this work, each truck is delayed at the mixer from 9 to 10 minutes on each trip, or for 25 per cent of the working time. The commercial rate for this size truck if rented would be $2.50 per hour. Thus the waiting time of 4 trucks necessary to keep the mixer going, at 2 hours each, or a total of 8 hours, would at the rate of $2.50 per hour be $20 per day; while under the usual system there would be necessary to accomplish the same work 12 men, costing, at $3.25 per day, $40; to which should be added the loss of material, amounting to at least $10—or a total of $50 per day.

It is thus seen that an approximate saving of $30 per day, or a little better than 5 cts. per square yard, has resulted from this plan of operation, originally intended to meet an expected shortage in labor.

Concrete Delivered Wet by Motor Trucks Shows a Large Saving as Compared with Customary Methods.—The following matter is taken from Engineering News-Record, May 1, 1919.

Delivery of wet concrete, from a central crushing and mixing plant, to the road surface, by motor trucks, over hauls ranging from ¼ mile to four miles, was satisfactorily accomplished on the Belair Road of the Maryland State Road Commission. By this method extensive rehandling of materials was dispensed with, thus reducing the cost, and the speed of the trucks was such that for the distances named there was no apparent injury to the quality of the concrete mixture. The maximum time required to transport the concrete from the mixer to the road was 35 minutes.

The work under consideration, was the building of a 3-ft. strip of concrete 8 in. thick on each side of the macadam road and connecting it with the old road with new macadam. It was undertaken to overcome the spreading action of the traffic by giving support needed at the edges and at the same time widen the road which had become too narrow for the heavy motor truck freight route.

After both shoulders were completed, the entire road received a seal coat of bituminous material and stone chips, which was allowed to cover the concrete shoulder, giving a pavement 20 ft. wide of uniform appearance.

As there was excellent stone in most of the hills adjacent to the road, the contractor decided to save handling labor by mixing the concrete at the quarry and hauling it to the road in motor trucks. A location about midway of the contract was selected, a quarry was opened and a crushing and mixing plant was set up.

Two portable boilers of the locomotive type were used; one, a 25-hp. boiler and engine, furnished power to run the crusher and mixer, the other, an 18-hp. boiler, furnished steam for the rock drills at the quarry and for pumping the necessary water for the boilers and the concrete.

A jaw crusher was placed under the platform upon which the stone from the quarry was dumped. After being crushed, the stone was elevated into the bin and separated into the desired sizes by a rotary screen. There were three general sizes of stone: The chips which passed a ¾-in. screen went into the sand bins; the crushed rock passing a 2½-in. screen went into the coarse aggregate bin, while the larger stone went out as tailings. What tailings could not be used for repairs on the construction road were taken out and again fed through the crusher. As the crusher did not produce enough fine material, sand was also delivered upon the platform and fed through with the stone and elevated into the sand bin.

Gravity was utilized to the utmost throughout the operations, from the quarry to the mixed product in the truck body. The plant was situated at the foot of a hill down which the quarried rock was hauled in carts to the crusher platform. After crushing, the stone and sand were fed directly into the mixer from the bins, care being taken to proportion them properly. Water was supplied from the elevated tank shown in the sketch. The bin and the platform for the concrete mixer were placed at such height that the mixer could discharge directly into the trucks.

On the road the dumping of the concrete followed a different plan than would be employed if the entire road section were being covered, as in the case of constructing a concrete road. As the shoulder which was being constructed was of small section, it was necessary to dump the mixed concrete upon the surface of the old road and shovel it into the forms on the side. One truck load of concrete filled about 35 ft. of forms, and extra handling was necessary, which of course increased the cost above what it would be if an entire road surface were being built.

Convict labor was utilized for common labor upon this road, a camp being built at the quarry to house and feed the laborers. Guards were provided by the prison officials for watching the convicts, but the contractor furnished the foremen to supervise the work. The contractor reported that this labor was quite satisfactory. In the construction of the shoulders steel forms were used.

Approximate costs for carrying work on under this system are given in the following table, based upon an average haul of 3.5 miles and the construction of 6,975 ft. of shoulder which was laid in a period of 13 working days. The average days work was thus 535 lin. ft. or 179 sq. yds. The cost per day of equipment include interest and depreciation.

Itemized Cost of Laying Three-Foot Concrete Shoulders for Macadam Roads

Quarrying and Crushing Stone per Day

1 foreman at 65cts. per hour	$ 5.85
1 engineer at 44⅘cts. per hour	4.00
1 blacksmith at 44⅘cts. per hour	4.00
17 laborers at 27⅐cts. per hour	42.50
3 carts at 55⅚cts. per hour	15.00
Equipment at $7.50 per day	7.50
25 lb. dynamite at 30cts. per pound	7.50
Total cost per day for 36 cubic yards of stone and 4.4 cubic yards of dust	$86.35
Cost of rock per cubic yard in quarry	$ 2.137
Royalty	.15
Total cost rock per cubic yard	2.287

Sand per Day

Sand in pit, 13.6 cubic yard at 85cts. per cubic yard	$11.56
Hauling sand and cement by truck, $30 per day	30.00
Three laborers at 27⅐cts. per hour	7.50
Total cost per day	$49.06
Total cost per cubic yard	$ 3.61

Mixing Concrete per Day

3 men at 27⅐c. per hour	$ 7.50
Equipment $7.50 per day	7.50
Total cost per day for 40 cubic yards	$15.00
Total cost per cubic yard	.375

Hauling Concrete to Road per Day

1 truck at $18.00 per day	$18.00
1 truck at 25.00 per day	25.00
1 truck at 27.50 per day	27.50
Total cost per day for 40 cubic yards	$70.50
Total cost per cubic yard	$ 1.762

Placing Concrete per Day

1 foreman at 55⅚cts. per hour	$ 5.00
2 laborers, build forms 27⅐cts. per hour	5.00
Placing, 4 laborers at 27⅐cts. per hour	10.00
Total cost per day for 40 cubic yards	$20.00
Total cost per cubic yard	.50

Cost of Concrete in Place per Square Yard

Cement, 1.5 bbl. at $2.50	$ 3.750
Sand, 0.34 cubic yard at $3.60	1.227
Dust, 0.11 cubic yards at $2.287	.252
Stone, 0.9 cubic yard at $2.287	2.058
Mixing, per cubic yard	.375
Hauling, per cubic yard	1.762
Placing, per cubic yard	.500
Total cost per cubic yard	$ 9.924
Total cost per square yard, 8 in. thick	2.205

Grading per Square Yard

1 foreman at 55⅚cts. per hour	$ 5.00
8 laborers at 27⅐cts. per hour	20.00
Total for 180 sq. yd	$25.00
Cost per square yard	$ 0.138
Total cost per square yard	2.343

The construction cost upon the Baltimore-Washington Boulevard for similar work but using the ordinary methods was $3.24 per sq. yd. The largest saving was in handling materials. Mixing, placing, forms, curing and protection on the Boulevard cost 84 cts. per sq. yd., while the same operations on the Belair Road cost about 20 cts. per sq. yd. (The average haul for the entire road was about 2½ miles, and the costs given were taken for an average haul of 3½ miles. This would also decrease the average cost per square yard in place for the entire road.)

Time Cost of Reinforced Concrete Pavement Construction at Plymouth, Wis.—W. G. Kirchoffer gives the following in Engineering and Contracting, Aug. 6, 1913.

Description of Pavement.—The pavement was 40 ft. wide between gutters, which were 18 inches wide built integral with the curbs: making total width of roadway between curbs 43 ft. The base of the pavement was a 6-in. layer of concrete composed of 1 part of cement, 3½ parts of sand and 6 parts of crushed rock. Upon this base the reinforcement was laid, which consisted of American Steel Wire & Fence Co.'s woven wire mesh No. 7. This was laid in strips at right angles to the direction of the street and covered the entire surface from gutter to gutter.

The surface or wearing coat was 1½ ins. in thickness and was placed directly upon the fabric. It was composed of 1½ parts of crushed granite and 1 part of cement. The crushed granite was in two sizes; ½ to ¾ in. and ¼ in. down to dust. These were proportioned so as to make the most dense mixture.

The surface coat was troweled smooth after being brought to the proper crown by a screed. It was then sprinkled with dry cement, if in a wet condition, after which the surface of the pavement was covered with granite chips ranging in size from ½ to ¾ in. These were cast on by hand or with a shovel. Wherever these did not sink into the surface of the pavement, they were lightly tamped with a float or trowel.

The pavement was cut up into squares 40 ft. each way by expansion joints. In place of the usual joint of tar or asphaltum, 1-in. "pecky" cypress boards were used. These were 8 ins. wide and placed along each gutter and every 40 ft. at right angles to the street. "Pecky" cypress is a species of cypress that has the appearance of being worm eaten or partially rotten. It was adopted because of its durability.

Methods of Construction.—The curb and gutter were constructed previous to the excavation for the pavement. After the subgrade has been completed and rolled for a distance of a block or more, the laying of the pavement was begun. The cypress boards which were to constitute the expansion joints were used as an outside form for the curb and gutter and as templates in forming the crown of the street, thus saving the use of considerable lumber as well as time in placing and removing it.

The base concrete was laid in sections 40 ft. square and enough in advance of the wearing coat to allow the cement to get its initial set. Then the reinforcement and wearing coat were placed in 40-ft. sections. No travel was allowed on the completed work for a period of 10 days after laying and the surface was kept moist by spraying with garden hose.

Time to Complete Work.—Work on the excavation for curb and gutter was begun May 25, 1910, and on the curb and gutter proper June 4 and was complete on June 12, a total of 25 working days. The grading for the pavement was begun June 13 and the laying of the pavement on July 19. The entire pavement was complete Sept 3, a total time of 80 working days from the time of beginning the curb and gutter.

During the time this pavement was under construction, a careful record was kept of the actual time put in upon each kind of work. The total number of square yards in the pavement was 10,786.22 and the total number of feet of curb and gutter was 4,648.2; the time required to perform each part of the work and the hours required to lay 1,000 sq. yds. of pavement or 1,000 lin. ft. of curb and gutter is given in the accompanying table.

This pavement is now nearly three years old, has passed through three winters and there is not the sign of a crack or a flaw in it any place, not even along the street car tracks.

The use of the woven wire mesh has demonstrated the fact that it is possible to construct a concrete pavement so that it will not crack along the center of the street, a thing which has happened so generally in other places. This new form of surface is not slippery and does not wear perceptibly. The expansion joints have worn off some but not enough to show any abrasion of the concrete along the edges of the boards.

This pavement was designed by Mr. Kirchoffer, and was constructed by contract under his supervision. The contract price was 48 cts. per linear foot for the curb and gutter and 1.23½ per square yard for the pavement complete, including the excavation.

TABLE XXVI.—ACTUAL TIME IN HOURS PER 1,000 SQ. YDS. AND PER 1,000 LIN. FT. FOR CONSTRUCTING CONCRETE PAVEMENT AND CURB AND GUTTER, PLYMOUTH, WISCONSIN

	Grading for curb and gutter	Concrete work for curb and gutter	Grading for pavement	Laying concrete pavement	Totals for pavement	Totals for curb and gutter
Teams	4.3	159.4	48.3	108	156.3	163.7
Laborers	271	93.5	212	696	908	364.5
Foreman	19.4	140	9.3	98	107.3	159.4
Timekeeper	15.2	6.0	.....	41.8	41.8	21.2
Engineer and roller	15.2	.....	16.5	.....	16.5	15.2
Carpenter's setting:						
Forms for curb and gutter	.....	125	.....	.....	.....	125
Expansion joints and stakes	.....	.....	.....	39.1	39.1	.....
Engineer and mixer	.....	6.0	.....	56.8	56.8	6.0

Total square yards pavement, 10,786.22; linear feet of curb and gutter, 4.648.2. Wages paid: Laborers, $1.90 per day; foreman, $4.00 per day; timekeeper, $2.00 per day; engineers, $2.25 per day; teams, $4.50 per day; carpenters, $2.00 per day.

Cost of Concrete Road with Bituminous Wearing Surface in California.—The following data, taken from an article by C. L. Rakestraw published in Engineering and Contracting, Feb. 11, 1914, were accumulated in constructing 14 miles of state highway from Healdsburg to Santa Rosa, California.

Breaking up Old Roads.—Most of the construction was over old roads, and the breaking up of the old road surface was necessary. These old surfaces were often quite hard, due to years of compacting by traffic. When old macadam is 6 to 10 ins. thick and has been compacted from three to five years, it is practically impossible to break up the crust by teams and plows. First, the line of teams (16 to 20 horses) will be so long that three or four drivers are necessary, and it is much trouble to turn the line around. Second, the power from this line of teams will be so unsteady that it is very hard for the four plow men to guide the rooter or plow. The following, based on actual work, is the cost of hard rooting, using teams:

Item—	Cost per day
20 head, rent with harness, at 50 cts	$10.00
20 head, feed and lodging, at 50 cts	10.00
4 teamsters, at $3.25	13.00
4 plow men, at $2.75	11.00
Depreciation on equipment	0.32
Sharpening 10 plow points, at 20 cts	1.00
Supervision, supt. $1 and foreman 50 cts	1.50
Total	$46.62

This outfit would root about 1,000 ft. per day, and the cost per lineal foot was therefore about 4.7 cts. Compared with this, an 18-ton Kelly Springfield road roller would, with the same rooter and points, but with only three plow men, root 1,500 ft. per day at the following cost:

Item	Cost per day
Roller, including depreciation	$10.00
Engineer	4.00
Fuel, oil, grease	2.35
Depreciation, plow and points	0.32
Sharpening 13 plow points, at 10 cts	1.30
Supervision, supt., $1, and foreman, 50 cts	1.50
3 plow men at $3.75	8.25
Total	$27.72
Total per lineal foot	1.85 cts

Comparison of the two statements shows in favor of road roller rooting a saving of 2.83 cts. per lineal foot, or $149.42 per mile of road. These figures are for hard rooting. When a roadway has only about 2 ins. of macadam on the surface it can easily be rooted with twelve head of horses and a road plow or rooter at a very reasonable cost, as shown by the following statement:

Item	Cost per day
12 head rent with harness, at 50 cts	$ 6.00
12 head, feed and lodging, at 50 cts	6.00
2 teamsters, at $3.25	6.50
3 plow men at $2.75	8.25
Depreciation in plow, points, etc.	0.32
Sharpening 15 points at 10 cts	1.50
Supervision, supt., $1, and foreman, 50 cts	1.50
Total	$30.07
Total per lineal foot	1.67 cts

This outfit will plow 1,800 ft. per day, and the unit cost given above is based on this output of work. For thin macadam, rooting by horses is the cheapest method, and it has the additional advantage that the travel of the horses breaks up the clods from the plow. When a rooter is used for rooting it is generally the practice to run a 6-horse plow back and forth through the material until all the larger lumps are broken, and it is in shape for the road graders and fresnoes to handle readily. The difference in hardness of the macadam will not affect the output of the steam roller, because the roller has a fixed rate of speed, and can accomplish only the fixed amount of rooting, whether in a soft or hard material.

Rough Grading.—After breaking up the old road surface, it was rough-graded to within 0.1 ft. of the required grade when rolled for the whole width of the road, including the shoulders. If the shoulders are graded at this time the material is handled with fewer teams than if the grading is done after the concrete is laid. Also the constant compacting of the shoulders by work teams during the concreting puts them in better shape, and ensures a more uniform appearance.

Staking and Placing Side Forms.—After the rough grade had been brought to within 0.1 ft. of exact elevation, the grade and line stakes were set. The road being particularly described had a 15-ft. pavement 4 in. thick with a 4½-ft. shoulder on each side. The concrete base has a crown of 2½ ins., the arc of the crowning being a parabola. From the edges of the concrete slab the shoulders slope straight, dropping 4 ins. in 4½ ft.

The location of the side forms was 7½ ft. from the crown, and with their top edges 2½ ins., or 0.21 ft., lower than the crown elevation shown in the profile. Two lines of grade stakes were employed, a line 9½ ft. each side of the center line and 2 ft. out on each side from the side forms for the concrete roadway. These 2-ft. intervals gave ample room to set and peg the side forms without disturbing the grade stakes; also the carpenters in setting the side forms with a 30-in. spirit level could notch the level 2 ft. from the end, and with it alone adjust the form board both to distance and grade, working from the grade stakes. The carpenter setting side forms required only a spirit level and a hammer.

The side forms were handled usually by two men at $2.75 per day and two men at $2.50 per day. These could place, line up and fasten about 800 ft. on each side, or 1,600 ft. of side forms per day at the following costs:

Item	Cost per day
2 carpenters at $2.75	$ 5.50
2 helpers at $2.50	5.00
* 1,680 ft. 2 × 4-in. plank at $26 per M ft. B. M.	9.27
Nails, etc.	0.23
200 stakes at 1 ct	2.00
Interest and depreciation	0.15
Superintendent, $1; foreman, 50 cts	1.50
Total for 800 ft. of road	$23.65
Per lineal foot of road	2.96 cts.

* Boards used three times, so one-third of total cost is charged.

Subgrade Construction.—After the side forms were placed and checked, material was filled between them to the proper depth to give the correct cross-sectional profile when properly rolled. When the rolling was completed, the surface was checked by means of a template and when there were variations of consequence from the true grade the surface was harrowed and material added or removed as required.

The cost of reshaping subgrade varies so much with the material that its tabulation by items is impossible. It runs, however, about ¾ ct. per square foot for a 15-ft. pavement; this cost is exclusive of grading, excavation and fill. Excavation, where it consists of shaving off a thin layer of crust here and there, costs about 80 cts. to 90 cts. per cubic yard.

Mixing and Laying Concrete.—The specifications called for a 1:2:4 broken stone concrete and stated the sizes of stone and sand. With the undertaking of work it was found that a natural gravel pit existed at Healdsburg and that the company operating this pit had facilities for furnishing promptly this gravel in any quantity demanded by the work. The gravel was exceptionally clean washed gravel, well graded and dense. Gravel was, therefore, substituted for broken stone. It cost delivered to any railway siding along the work 72 cts. per cubic yard. The average haul from railway to the work was 1½ miles, and the cost of hauling was 63 cts. per cubic yard, or 41 cts. per yard mile. This cost of haul seems high, but it is accounted for by the weight of the gravel, 3,300 lbs. per cubic yard, and by the fact that crooked roads prevented haulage in wagon train by traction engines and made team hauling necessary.

Using this gravel and a 1:6 mixture, it was determined that 96 sacks of cement would make 100 ft. of 15 ft. by 4 in. pavement. The plan adopted was to pile the gravel continuously along the middle of the subgrade and place the cement in four-sack piles spaced 4 ft. apart. A cleat was riveted to the inside of the mixer charging hopper to indicate a two-sack batch of 1:6 mix. Six men using square-pointed shovels charged the gravel and one man charged the cement. Golden Gate cement in cloth bags was used; paper sacks broke easily and carried water, and also the fog loosened the paste, letting the sacks open and admit dampness.

The mixer traveled on 3 ft. × 3 in. redwood sills, which could be shifted easily and often enough to guide the mixer well. This runway was located midway between side forms, which shifted the discharge chute slightly off center, but not enough to inconvenience the concreters. As the mixer was operated some 1½ days behind the subgrade finishing crew, the subgrade surface had opportunity to dry out, and consequently it was wetted down ahead of the concrete laying, so that moisture would not be sucked by the soil from the concrete.

The concrete was distributed by the chute, and also shoveled against the side forms, special care being taken to well spade and dump the concrete against the forms, so as to ensure an exceptionally dense and strong concrete next the shoulders, where severest wear comes. No expansion joints were used.

By leaving out the expansion joints and letting the expansion of the pavement itself break the pavement, we have the maximum of this pavement in the largest possible slabs. Now, after cleaning the concrete slab for the application of the wearing surface, specially clean these cracks and pour hot or heavy asphaltic road oil into them; this will form a perfect expansion joint.

The cost of the concrete base laid as outlined above was as follows:

Item	Cost per day
1 foreman at $4	$ 4.00
1 engineman at $3	3.00
10 shovelers at $2.75	27.50
1 cement man at $2.75	2.75
2 finishers at $3	6.00
Depreciation of plant and tools	9.00
Cost of water	6.13
Total	$57.38

The average daily run of concrete pavement was 550 lin. ft., or 101.85 cu. yds. The above statement of costs is a statement of costs with concrete materials—cement and gravel—delivered onto the subgrade ready for use, and they give the following unit costs:

Per lin. ft., 15-ft. roadway	10.4 cts.
Per cu. yd. of concrete	56.3 cts.

Method and Cost of Securing Water.—All water used on this work had to be pumped. A line of 2-in. boiler pipe in 8-ft. lengths was laid along the work and provided with 1-in. taps at 50-ft. intervals. This pipe line was torn up and laid ahead as pumping stations were moved and as the work progressed; two men at a daily cost of $5 were employed continuously at this work. All pumping stations but one were located at adjacent streams, and the water supply cost nothing except for pumps and pumping. In one case an 180-ft. well was bored at a cost of $380; this well supplied 100,000 gals. per day during the driest part of the year for about five miles of the road. The cost per day of supplying water was as follows:

Item	Cost per day
1 gas engine pump man at $2.75	$ 2.75
2 gas engine pump men at $2.50	5.00
2 pipe layers at $2.50	5.00
Int. and dep. on 17,000 ft. of pipe and engine	2.00
Fuel and oil on gasoline pump	2.15
Superintendent, $1; foreman, 50 cts	1.50
Total	$18.40

Water was used in about equal quantities for (1) mixing concrete; (2) curing concrete and (3) wetting subgrade; of the above total cost, therefore, one-third or $6.13, was charged to each service.

Finishing and Curing.—Several methods of finishing and curing the concrete slab were investigated. The first plan was: Six hours after placing to broom with a steel broom the surface and so roughen it that the bituminous covering would cling. After twelve hours sprinkling began and the concrete was kept moist. While this plan might have been satisfactory in winter or wet weather it did not give good results in the summer which was the time of year the work was done. The concrete could not be kept evenly moist and also much water ran off and was wasted. The second plan was to broom the concrete as in the first plan, then build earth dams along the pavement edges, then wet down the concrete, then cover it with 2 ins. of earth and water the covering until saturated and the water showed in pools. By this plan the moisture was better distributed, it was more obvious to common laborers when more wetting was needed, and there was less loss of water by evaporation and run off. A third plan tried and abandoned was: after brooming the concrete, to sprinkle it and cover it with heavy building paper held down by clods and stones. The idea was to remove the paper, resprinkle and replace the paper every night for seven nights, the standard curing period. It was anticipated that the paper would prevent evaporation, reduce labor as compared with shoveling in earth and building dams, be quick in application, eliminate attention during the day and offer several other advantages. The plan did reduce labor but the paper was torn off in places by the wind and did not protect the pavement from drying out in spots. It was no better than the first plan.

A fourth plan was finally devised which eliminated most of the faults of preceding plans. First, levees were built along the edges and over the side forms in such position that about one-third the width of the embankment fell inside the form board and over the concrete. These side levees were built high enough to hold a depth of water of 2 ins. over the crown of the slab. At suitable intervals depending upon the grade, cross levees connecting the side levees were built. These levees divided the pavement into a series of basins which could be filled with water. On superelevated curves in addition to cross levees a number of parallel longitudinal levees were built.

Referring to some of the details noted above: The purpose of building the side levees two-thirds outside the side forms is two-fold: First, about one-third the width of the levee becomes saturated and this third is over the concrete slab which requires wetting. Second, the form boards can be lifted out for reuse leaving two-thirds of the levee intact to maintain the reservoir. Besides being required for hydraulic reasons the division by cross levees into small basins serves the purpose of confining loss of water by a levee break to a small area of pavement; restoration is also thus facilitated. Also in construction the workman can let one basin be filling while he is building the succeeding levees.

This method of watering concrete pavement had the following advantages over the second described and next most successful method: (1) It required less labor to construct cross levees than to cover the slab all over with 2 ins. of earth; (2) the wetted black earth covering suffers greater loss by evaporation than does the heat reflecting water surface; (3) all the pavement is water covered while an earth covering may dry out in spots and absorb water from the concrete; (4) all work is done at night when water is needed for no other purpose, while an earth covering has to be sprinkled continuously; (5) one filling of the basins suffices for the total curing while an earth covering has to be wetted frequently; (6) the levees suffice as barriers notifying drivers not to cross the work, while with earth covering separate barriers are necessary; (7) the filling of the basins, however, must be more carefully done so as not to wash the concrete than when earth covering is used; the best method is to let the hose stream run on a sack laid on the pavement.

The cost of curing concrete pavement by the methods described are given by Table XXVII; in this table method three being considered not practical is omitted, also its cost is about the same as that for method one. It is seen from Table XXVII, that method four is far the cheapest.

TABLE XXVII.—COST OF CURING CONCRETE PAVEMENT

	Method No. 1	Method No. 2	Method No. 4
1 man at \$2.75 per day	......	\$ 2.75	\$ 2.75
Men at \$2.50 per day	\$12.50	17.50	10.00
Depreciation, shovels, etc	0.40	0.80	0.65
Cost of water	6.13	6.13	6.13
Supervision, supt. & foreman	1.50	1.50	1.50
Total cost 1st day	\$20.03	\$28.68	\$20.53
Lineal feet covered	300	550	650
Cost per lin. ft., 1st day	\$0.067	\$0.052	\$0.037
Cost of each consecutive day	0.067	0.052	0.005
Total cost of curing, 7 days, per lin. ft. pavement	0.469	0.364	0.067

The side form boards were removed seven days after placing the concrete; this work cost about 1 ct. per lineal foot of pavement. The earth levees were left in place about a week longer and were then removed, usually with a four-horse road scraper and at a cost of about 0.3 ct. per lineal foot of pavement. With the same scraper the shoulders were brought as near as practicable to grade and then they were finished by hand. Constructing shoulders cannot easily be figured in cubic yard units but if they are brought to shape with the rough grading as previously described the work will cost exclusive of rolling, about 5 cts. per lineal foot of pavement and including rolling about 6 cts. per lineal foot of pavement.

SUMMARY OF COST

Summarizing the costs previously given, the following tabulation is obtained:

	Per ft. road
Tearing up old roadway with rooter and plows	$ 0.0283
Placing form-boards (after exc. and emb. have been done)	0.0296
Handling and preparing sub grade with rolling	0.0375
Cost of pouring and finishing 4-in. concrete base	0.1043
Cost of curing and finishing (Method No. 4)	0.0670
Cost of removing form-boards	0.0100
Cost of cleaning earth off pavement	0.0030
Cost of preparing shoulders	0.0600
Actual cost per lineal foot	$ 0.3397
Actual cost per mile	$1,793.62
10 pct. for contingencies	179.36
Total cost per mile	$1,972.98

These costs are exclusive of costs of materials and of excavation and fill.

Organization and Output of a Gang Laying Concrete Base for Asphalt Pavement.—W. D. Jones gives the following in Engineering and Contracting, July 5, 1916.

In paving a street with 6 in. of concrete, 1 in. of binder, and 2 in. of asphalt wearing surface at Los Angeles Harbor, California, the contractors for the work, had the following output, plant and organization for one working day of 8 hours with good clear running and no important stops.

The mix was 1:3:6 of cement, sand and crushed rock, respectively, and was mixed in batches by a No. 14 Chicago Street Paver having a charging skip and a revolving spout for discharge. The base on which concrete was laid had previously been prepared and stakes driven with tops 2 in. under the subgrade in order that they might be worked over. Planks 2 in. × 10 in. were laid out ahead and concrete materials, in quantity necessary per foot of street, piled on these for ease in shoveling to wheelbarrows. Cement was piled alongside the street at intervals necessary for handling to the mixer, as the work progressed, by hand. Fourteen wagons hauled the necessary materials from stock piles about ¼ mile away, over dirt road. Occasionally an extra load had to be brought in close to the mixer or one taken away in order to correct error in gaging the quantity necessary, by wagon loads, but as a rule the measurements checked out pretty well. Two men shoveling into one sand barrow and four men into two rock barrows kept the mixer supplied with sand and rock, the men taking turns at wheeling the barrows up the incline to dump into charging skip. One cement man fed mixer and his helper carried sacks from the storage piles mentioned above to the platform on which he stood. One wagon with body removed, one teamster and two men were kept busy taking out planks after the mixer had passed over and before they were covered with concrete, and hauling them ahead and placing them for additional material as the work progressed. One man put in and maintained the header boards which limited the edge of the pavement and another was kept busy between grading and cleaning up in the wake of the mixer and in driving stakes to the grade of the finished surface of the street; this was done by measuring up from the tops of stakes previously driven below

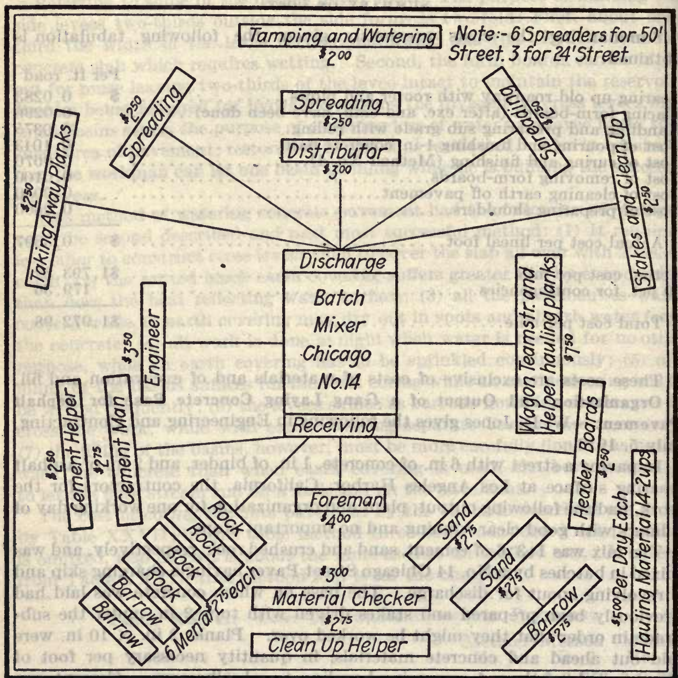

FIG. 13.—Diagram of gang organization.

subgrade, all stakes having been driven the same distance below finished grade. One man attended to the discharging spout and three men to leveling and working the concrete to place 3 in. below the finished surface of the street. Three men took care of this end when the street was 24 ft. wide or narrower but more men were necessary in laying a wider pavement, six being necessary on a 50-ft. street, the cost having been observed on a 24-ft. section. One man followed up after concrete was fairly hard and roughened the surface of the concrete with a triangular stamp in order to give a better bond with the binder; he also put up barriers and wet down the concrete. In eight working hours 13,000 sq. ft. of 6-in. base was laid with this mixer and organization. This amounts to 241 cu. yd. for the day and to 1 cu. yd. every 2 minutes. The organization and cost summarized is as follows:

1 foreman at $4	$ 4.00
1 engineer at $3.50	3.50
1 checker at $3	3.00
1 cl. helper at $2.25	2.25
14 teams and drivers at $5	70.00
6 rock men at $2.75	16.50
3 sand men at $2.75	8.25
1 cement man at $2.75	2.75
1 cement helper at $2.50	2.50
1 header, boards, at $2.50	2.50
1 team, driver and helper at $7.50	7.50
1 plank man at $2.50	2.50
1 stake man at $2.50	2.50
1 spout man at $2.50	2.50
3 leveling at $2.50	7.50
1 tamp and water at $200	2.00
Total labor	$139.75
241 cu. yd ... Per cu. yd.	0.58
Total labor exclusive of hauling material to site	69.75
Total labor exclusive of hauling material to site. Per cu. yd.	0.29

The diagram, Fig. 13, shows distribution of organization about the mixer.

Comparative Cost of Concreting Pavement of Street Railway Right of Way, Using Batch Machine, Continuous Mixer and Hand Mixing.—The following costs, given by S. Gausmann, formerly Roadmaster of the Brooklyn Rapid Transit Company, New York, in Engineering Record, April 10, 1915, are based on doing work with no car interference. These costs will be somewhat increased under car operation, with machines outside the tracks, or decreased with machines of larger capacity.

The freight rates for hauling machines to and from work are in accordance with rates approved by the Public Service Commission of the State of New York, First District, and include the total cost of maintenance of the car equipment, cost of trackage and overhead line rights and office expenses of the freight department. These rates vary according to the length of haul, the figures given being for an average haul. This haulage cost would be considerably reduced where the track department does its own handling of material, etc., and where only the wages of crews are charged against it instead of having the freight department make a general charge per car-mile.

Cost with Batch Mixer.—The batch mixer, for which the following costs for operation are given, is of 0.5 cu. yd. capacity. It can be bought for $1300, mounted on a car, and is electrically operated as to mixing only, so that it must be hauled to and from the work daily.

The number of men employed and their rates per hour in operating a machine of this character are: One assistant foreman, 25 cents; one operator, 25 cents; four laborers, 20 cents; six laborers, 18 cents; fourteen laborers, 16 cents; one checker of time and material, 15 cents, or a total cost of $47.70 for one day of ten hours. This cost is distributed to the various operations as follows:

COST PER DAY FOR GANG ON ONE BATCH MACHINE

Operation of the machine	$ 2.50
Watching mix and dumping	4.25
Handling material to the machine	13.50
Removing and placing the track	22.10
Ramming and tamping under the rail	3.85
Checking	1.50
Total	$47.70
Add other charges:	
Overtime for cleaning	$ 0.90
Interest on investment	.58
Freight to and from work	6.25
Lubricants, repairs and incidentals	2.33
	$10.06
Total	$57.76

A gang of this size will average in a ten-hour day approximately 675 ft. of single track with concrete 7 in. deep. The area, with 6 × 8-in. × 8-ft. ties spaced 2 ft. center to center is equal to 94.22 cu. yd., making the unit cost $0.613 per cubid yard, exclusive of material.

Cost with Continuous Mixer.—A good continuous mixer of a standard make can be purchased for $560. Although such mixers are supplied on wheels for use at the side of the track, a good car with old pony wheels and a wooden frame can be made for approximately $30, thus bringing the total cost to less than $590. This cost is for a gasoline-operated machine, but an electrically operated one is preferable. Provided an old motor is obtainable, the first cost will vary but little from gasoline, whereas the cost of operation will be less.

As a machine of this kind is easily derailed it need not be removed from the street daily, and can be left on the work continuously ready for use at any time, with no outlay for freight charges until it is required at other points.

The number of men employed, and their rates per hour, in operating one of these machines are: One assistant foreman, 25 cents; one operator, 25 cents; two laborers, 20 cents; three laborers, 18 cents; eight laborers, 16 cents; one checker of time and material, 15 cents, or a total cost of $28.70 for a ten-hour day. This cost is distributed to the various operations as follows:

COST PER DAY FOR GANG ON CONTINUOUS MIXER

Operation of machine	$ 2.50
Handling material to machine	10.20
Distributing in track	12.10
Ramming and tamping under rail	2.40
Checking	1.50
	$28.70
Add other charges:	
Overtime for cleaning	$ 0.50
Interest on investment	.26
Freight to and from work	1.25
Gasoline, oil and repairs	2.25
	$ 4.26
Total	$32.96

This gang will average 430 ft. of single track per ten-hour day, with concrete 7 in. deep. This area, with 6 × 8-in. × 8-ft. ties spaced 2 ft. center to center is equivalent to 60.054 cu. yd., making the unit cost $0.5488 per cubic yard, exclusive of material.

Mixing by Hand.—Of course, in mixing by hand the number of men employed may vary, but for an illustration we may assume that as many are employed as on the continuous mixer, exclusive of the operator. The cost then would be distributed to the various operations as follows:

Mixing by Hand

Distributing material and mixing	$10.50
Distributing in the track	11.80
Ramming and tamping under the rail	2.40
Checking	1.50
	$26.20

This number of men in a ten-hour day will average 225 ft. of single track with concrete 7 in. deep which, with 6 × 8-in. × 8-ft. ties spaced 2 ft. center to center, amounts to 32.77 cu. yd., equivalent to a unit cost of 80 cents per cubic yard.

The foregoing figures were obtained from many years' experience in this line and from carefully collected data. While they may not apply to all locations, the costs can be easily adjusted to meet any conditions from the information given.

Portable Frame for Canvas Covering for Concrete Road Construction (Engineering and Contracting, Dec. 3, 1919).—A simple portable frame for supporting the canvas covering used in concrete road construction before the earth protection is applied is described in a recent issue of The Concrete Highway Magazine. Details of the arrangement are shown in Fig. 14.

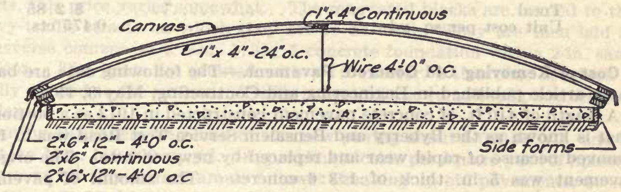

Fig. 14.—Cross section showing construction of frames and methods of supporting them on side forms.

A sawhorse of the required height was set up in the center of a completed section of concrete road and 1 by 4-in. transverse members laid across it. The ends were then bent down until they touched the side forms and nailed to 2 by 6-in. longitudinal runners. A 1 by 4-in. continuous strip was nailed to the truss members at the top so as to hold them rigidly and uniformly spaced.

The lower or horizontal wire was attached to one side by winding it around a cleat securely nailed in place. In order to spring the other side into position, a crowbar was used. The wire was wrapped around a cleat and then attached to the bar, which was used as a lever until the wire was taut enough and the cleat had been nailed down. This was continued until all horizontal wires had been placed. Additional strength and rigidity were obtained by connecting the crown of the truss with the horizontal wire by a vertical wire. Cleats 2 by

6 by 12 in. were placed under the side braces at intervals of 4 ft., to facilitate handling. Eight of these supports were made in units 25 ft. long.

The cost of 200 lin. ft. of the supports was:

Lumber, 1,500 ft. B. M. at $50	$ 75.00
Wire, nails, etc.	3.00
Labor, 3 men, 2 days, at $4	24.00
Total (200 lin. ft. at 51 cts.)	$102.00

The frame was devised by G. J. Lynch of Reagon & Lynch, Contractors Uniontown, Pa., and was used on the construction of a portion of State Highway Route No. 116, near Smithfield, Pa. Mr. Lynch gives the following figures showing the cost of shifting the canvas:

Eight men and one foreman working one hour were necessary to shift 200 ft. of canvas until these supporting frames had been devised. Now the same work is accomplished in 15 minutes. The covering is moved three times a day. The following table gives comparative costs between old and new methods:

Cost of shifting canvas without supports:	
8 men, 3 hours, at 40 cts.	$ 9.60
1 foreman, 3 hours, at 60 cts.	1.80
Total	$11.40
Average daily yardage	600
Unit cost per sq. yd	1.9 ct.
Cost of shifting canvas with supports:	
8 men, ¾ hour, at 40 cts.	$ 2.40
1 foreman, ¾ hour, at 50 cts.	.45
Total	$ 2.85
Unit cost per sq. yd	0.475 cts.

Cost of Removing Old Concrete Pavement.—The following data are based on an article published in Engineering and Contracting, May 3, 1916.

A length of 410 ft. of concrete pavement constructed in 1913 as a portion of what is known as the Byberry and Bensalem Service Test Road was in 1915 removed because of rapid wear and replaced by new concrete. The original pavement was 5 in. thick of 1:3:6 concrete. The amount of pavement removed was 792 sq. yd. or 110 cu. yd. It was removed by hand using bars and sledges. The cost of removal was 29.67 cts. per square yard or about $2.08 per cubic yard. The labor cost of reconstructing this pavement was 21.46 cts. per sq. yd., thus the cost of removing the old concrete cost about 38.2 per cent more than the labor cost of a new pavement.

Cost of Redressing Granite-Blocks for Pavements.—The following data, published in Engineering and Contracting, Oct. 14, 1914, are taken from a discussion of the use of blocks from old granite block pavements by Wm. A. Howell before the American Society of Municipal Improvements.

The old blocks used on the 1914 jobs in Newark range in length from 10 to 14 ins.

A blockmaker can in a day's work of 8 hrs. nap and reclip 175 large blocks into 350 small ones. It costs the contractor $15.00 per thousand for the small blocks, or $30.00 per thousand for the large ones. These blocks run 21 to the square yard, or 42 to the yard for the small ones.

A rough detailed estimate of the cost of this kind of pavement, which would permit of a variation of possibly 10 to 15 cents, would be about as follows:

Item	Cost per sq. yd.
Paid city at 3 cts. each	$0.63
Paid clippers for work	.63
Laying and handling	.20
Sand	.05
Concrete	.65
Grading	.10
Hauling	.10
Grouting	.12
Cost per sq. yd. (21 blocks required)	$2.48

The following is taken from Engineering Record, Dec. 14, 1914. During the last two years extensive areas of granite block pavement have been taken up, redressed and relaid by the Baltimore Municipal Paving Commission. The expense of removing, dressing and relaying the block has been less than two-thirds the prevailing price for new granite-block surface.

The old stones were of the usual heavy type, many as large as 14 in. in length, 6 in. in width and 8 in. in depth. The broken blocks are from 4½ in. to 6 in. deep, and those which are less than 3 in. in either surface dimension are not used.

As much of the old block was laid on streets bearing a light traffic only, little trouble is experienced because of the operations of the working gangs. From the old pavements the blocks, which are sand filled, are removed with crowbars and placed convenient to the cutters, who work in the street, producing about 225 of the small blocks per 8-hr. day. The price for redressing is about 2½ cents per block, although, as the work has been let in many contracts, this price varies somewhat. The renovated blocks are carried to the heavy-traffic streets on which they are to be used. They are then laid in transverse courses on a 6-in. 1:3½:7 concrete foundation with a 2-in. sand cushion. The joints are grouted with a 1:1 mortar, a thin coat of which is finally applied to the surface. Traffic is kept off the completed pavement for 14 days.

During 1913 there were laid of this new paving about 5,000 sq. yd., and in 1914, to Nov. 1, 3,900 sq. yd. Approximate costs per square yard of finished pavement for this surface are as follows: Breaking up old pavements, $0.09; recutting, $1.00; hauling, laying and grouting, $0.71; total unit cost, $1.80. As the old blocks have practically no value unless used in this way, the cost of laying the recut prisms, exclusive of foundation, may be compared with that for improved granite block, exclusive of foundation. As an average figure for the latter in Baltimore is $2.80, recutting means a saving of 36 per cent.

Paving Blocks Cut from Old Granite Block Wall (Engineering and Contracting, July 3, 1918).—The problem of disposing of a masonry wall around the old City Hall at San Francisco was solved by cutting the stone into paving blocks. The work was done by hand and the paving blocks were produced at a cost of $37.50 per 1,000. The men were paid $6 per day. About 75,000 6 in. deep by 7 to 8 in. long and 3 to 4½ in. wide paving blocks were obtained.

Cost of Grouting Granite Block Pavement.—The following matter is given in Engineering and Contracting, Nov. 3, 1915.

The value of grout joint filler for granite block pavement has been much discussed with great difference of opinion. Grout filling is extensively employed and this discussion considers only that fact in presenting methods and costs of grouting. As no general and much less no standard practice has been determined, information is best given by citing individual examples. These do not cover all places in which grouted granite block paving is employed but they fairly represent grouting practice.

Lawrence, Mass.—The method of grouting is as follows: After the blocks, 3½ to 4 ins. wide, 7 to 8 ins. deep and 11 to 13 ins. long are set, they are stiffened in place by ramming with a small amount of pea gravel, perhaps an inch in depth, in the joints. The grout is a 1 cement and 1 sand mixture and is mixed in iron boxes designed and patented by Paul Hannagan, Director of Engineering. When thoroughly mixed, the grout is discharged onto the pavement and then broomed grout is removed from the tops of the blocks. In a test made in 1912, it was found that 0.108 bbl. of cement was used per square yard of pavement. The cement cost $1.08 per barrel; pea gravel cost about $2.30 per cubic yard and sand cost $1.00 per cubic yard. With wages at $2.25 per day, the labor cost of grouting was 6.4 cts. per square yard of pavement; the total cost per square yard was 26¾ cts. Data reported by City Engineer Arthur D. Marble.

Lowell, Mass.—This city has about 8½ miles of grouted granite block pavement on concrete base. The average cost of grouting joints is 24¼ cts. per square yard. The amount of material per square yard of 4½ ins. deep blocks is 0.295 bags sand and the same volume of cement. The essentials for securing good grouted granite block pavement are stated as follows:

1. Have sub-grade well rolled and all soft places eliminated; 6 ins. of crushed stone spread over the sub-grade and rolled to a true crown; mixture for foundation, 4 parts sand and 1 part cement.

2. Sand to a uniform thickness of 2 ins. should be spread over the foundation.

3. The blocks, after careful culling, should be well rammed and at the same time pea stone should be broomed into the joints.

4. For the grouting, be sure the cement is good and the sand clean and sharp. A small percentage of clay is good to use as a binder.

5. Be careful to use the correct proportions of sand and cement. Use 1 part cement and 1 part sand for mixture.

6. If a mixing machine is not used, keep the mixture constantly agitated in the box. Remove the grout from the box with scoop shovels. Never dump the contents of the box upon the street. Whenever this is done there will be a bare spot in the grouting.

7. Wet blocks thoroughly before applying grout.

8. As the grout is poured upon the blocks throw in pea stone and broom it into the grout, bringing the whole to an even smooth surface.

9. Never do any grouting during cold or frosty weather. Good results can seldom be obtained after Nov. 15 in New England.

10. If the grouting is done during very hot weather, precautions should be taken to keep grout moist. This can be done if the weather is extremely hot by covering it immediately with ½ in. of sand and frequently sprinkling with water.

11. Do not allow any traffic upon pavement for at least seven days after grouting.

12. For best results use a medium soft granite, similar to New Hampshire granite.

13. If old blocks are used, see that they are thoroughly cleaned before

grout is poured; this mixture being one part cement and two parts sand to give best results with old blocks.

Data reported by Stephen Kearney, City Engineer.

Worcester, Mass.—Grouted pavement in this city requires per square yard about 0.36 cu. ft. of cement and 0.36 cu. ft. of sand mixed with enough water to run freely. The mixture is spread with pails or spout and is broomed into place, the brooming being continued until the joints are filled and the surplus is largely removed from the tops of the blocks; trap rock screenings are finally employed to prevent tendency of the grout to run. Grouting costs about 24 cts. per square yard of pavement, including materials and labor. Data reported by F. A. McClure, City Engineer.

Albany, N. Y.—The following information is reported for grouting dressed granite block of the following size, length 6 to 10 ins., width 3½ to 4½ ins., depth 4¾ to 5¼ ins., end and side joints not exceeding ½i n. in width The grout or filler is one part of fine, clean, sharp sand and one part cement, no pea stone being used in the joints. Preparatory to grouting, the entire gang is first put to filling bags with sand, and placing same alternately with bags of cement along the curb adjacent to the space to be grouted. This is usually done half to three-quarters of an hour before starting the machine. This gives a good start. Three men are left filling bags and distributing same, and one on cement. The gang on the machine, which is a Marsh-Capron grouting mixer, consists of:

2 men carrying cement and sand to machine.
1 man carrying water.
1 man emptying material into machine.
1 man ahead of spout brooming in grout.
1 man operating.
3 men on sand bags.
1 man on cement.

10 laborers—total for operation.

A gang of this size will grout at least 1,100 sq. yds. per day, at the following cost:

10 laborers 8 hrs. each—80 hrs. at 20 cts. per hr......	$ 16.00
1 foreman..	4.00
107 bbls. cement at $1.10 per bbl....................	117.70
16 cu. yds. sand at $1 per cu. yd.....................	16.00
	$153.70

Including material and labor, this is a cost per square yard of 13.9 cts. or 14 cts. The cost of labor per square yard with machine for a total of over 2,000 sq. yds. has been on an average of $0.015 compared to $0.0525 by hand or a saving of over 3¾ cts. per square yard. For full 4-in. joints without pea stone it requires 0.4 bag cement and same amount sand (1 to 1 mix) per square yard of pavement. Data reported by Frank R. Lanagan, City Engineer.

Cost of a Wood-Block Pavement, Cambridge, Mass.—L. M. Hastings gives the following matter in Engineering News, May 21, 1914. The work consisted in repairing with wood block having cement grouted joints a portion of Massachusetts Ave., and was done in 1912 and 1913.

Base.—The base was formed of 5 in. of cement concrete mixed by machine in 1:2½:5 proportions. Bank sand and power-screened gravel stone were used for aggregates, the gravel being of excellent quality and somewhat cheaper than broken stone.

Blocks.—The blocks were of southern long-leaf yellow pine, having 80 per cent heart wood of satisfactory texture and containing not less than five annual rings per inch. The wood was impregnated with 20 lb. of preservative oil per cu. ft. of wood, by any satisfactory process which would give the required results. The oil had a specific gravity of not less than 1.12 at 38° C. and contained not more than 5 per cent of soluble matter and was free from petroleum or asphaltic residues.

During the hot weather of the first year, "bleeding" of the heavy oil from the blocks occurred. A heavy coat of sand was spread over the pavement where needed, which absorbed the tar and made a tough sheet or scat, some of which still adheres to the wood blocks as a kind of wearing surface.

Laying Blocks.—The blocks were laid on a 1-in. bed of equal parts of cement and sand mixed dry, "struck" by a movable board to a true surface. After laying, the blocks were given a final inspection and any imperfect ones were thrown out. The blocks were finally thoroughly rammed by hand rammers. Expansion joints were placed at each curb, and transverse expansion joints were put in every 30 ft. These joints were ½ in. to ¾ in. wide and were run nearly full of an asphaltic compound, which was fairly soft and elastic, yet did not run in hot weather, making a very satisfactory filler indeed. At the first rain after the blocks were laid, many of these joints closed up entirely and in some a slight raising of the paving occurred. With continued traffic, however, most of the joints were forced back into place.

The joints between blocks were thoroughly filled with a 1:1 cement and sand mixture applied dry in two layers; afterward the pavement was wet with a hose and thoroughly flushed, and the grout broomed into the joints, the water causing the cement in the joints and bed to fill all interstices.

One portion of Massachusetts Ave. was unusually wide and carried a rather heavy traffic; upon this portion, 4-in. blocks were used, the rest of the blocks were 3½ in. in depth.

Pavement Crowns.—The street has a longitudinal grade of about 0.60 per cent. It was found that a crown of 1¼ in. per ft. gave excellent drainage and made the most effective looking street. This crown was adopted as standard where possible. The crown as actually used varies from ⅛ in. to nearly ⅝ in. per ft. This last seems and looks excessive but as a matter of fact it has not been found to make the pavement dangerously slippery.

With regard to that bugbear of wood-block pavement—*its slipperiness*—experience here indicates that trouble from the cause is usually exaggerated. When conditions make the pavement slippery, the remedy is simple, viz., sprinkling with sand. This is not often required. During the two winters of 1913 and 1914, sanding was required only 8 or 10 times each season.

Cost Data.—The entire work of excavating, grading, laying the base, laying blocks, ramming, grouting, etc., was done by city day labor without much previous experience, working 44 hr. per week at $2.25 per day, or at about 31cts. per hr. for common labor. The 4-in. blocks cost by contract $2.59 per sq. yd. and the 3½-in. blocks cost $2.29 per sq. yd., delivered on the work. In all 15, 276 sq. yd. of 4-in. block pavement was laid at a total cost of $4.11 per sq. yd., and 12,051 sq. yd. of 3½-in. block pavement was laid at a cost of $3.81 per sq. yd.

Cost of Wood Block Pavement in Wenatchee, Wash.—F. J. Sharkey gives the following data in Engineering and Contracting, Oct. 20, 1915.

During the summer and fall of 1913 Wenatchee Ave., the main business street of Wenatchee, Wash., was paved with creosoted wood block. The improvement is approximately ¾ of a mile in length, the south ½ mile being 62 ft. between curbs and 90 ft. between property lines, the balance being 53 ft. between curbs and 70 ft. between property lines, making a total of approximately 27,500 sq. yds. of pavement, including intersections.

Concrete Base and Sand Cushion.—The pavement consists of a 5-in. concrete base, a 1-in. sand cushion and 4-in. creosoted wood blocks. The concrete in the base is mixed 1:3:6, the specifications for cement, sand and gravel or broken stone being the usual standard specifications for such materials. The specifications for gravel or broken stone called for material ranging uniformly in size from that which passed a 2-in. ring to that which was held on a ¼-in. ring.

Wood Blocks.—Immediately after the preparation of the cushion the wood blocks were laid, culled and rolled with a five-ton roller.

Due to the fact that the blocks were allowed to stand for some time in piles at the side of the street, in the hottest part of the summer, before being laid, a large number of the blocks curled slightly, even though kept damp in the piles at all times. These blocks split in two when rolled, but a number of the split blocks were used as bats at the beginning of courses. The expense of culling, however, was materially increased over what it would have been had the blocks been laid and filled immediately upon arriving on the street.

Five longitudinal rows of blocks were laid next to the curb on each side of the roadway for gutter courses, and the remainder were laid perpendicular with the curb. Three ½-in. expansion joints were placed on each side of the roadway. These expansion joints were cast the required thickness, from the filler asphalt, by laying a wood strip of the required width and thickness in a bed of damp sand, removing the strip and filling the resulting trench with asphalt. The expansion strips thus made were 3½ ins. wide by ½ in. thick and were laid on the cushion between the longitudinal or gutter courses of blocks. No transverse expansion joints were provided for. The remaining ½-in. between the top of the expansion strip and the surface of the blocks was filled with hot asphalt, to seal the surface.

An asphalt filler with a high melting point was used. It was heated in a portable kettle of 400 gals. capacity and was poured over the blocks with hand pouring pots. As soon as the asphalt cooled and congealed it was cleaned off the blocks with hot shovels, collected in small piles and again placed in the heating kettle. Immediately following the filling the pavement was covered with a ½-in. layer of sand.

The costs of laying wood block pavement are given in Table XXVIII.

Maintenance.—Due to the fact that the work of filling was not completed until after extremely cold weather set in, the asphalt did not fill the joints as thoroughly as was desirable. In the spring of 1914 the pavement was cleaned, the sand cover and excess asphalt filler that had been forced out by the expansion of the blocks being removed. This was later found to be a mistake, as it developed that the blocks were in a more serious condition, from being improperly filled, than had been judged. A large percentage of the joints had received very little asphalt, and as a consequence the blocks became loose in the pavement. To remedy this condition, which was rendered more serious from the fact that a loose sand cushion had been used, a 1-inch covering of fine sand was spread over the surface and allowed to remain until worn off by traffic. This seems to have solved the problem as far as filling the joints and tightening the blocks are concerned, but it has caused some trouble in making the pavement heave, due to lack of proper provision for expansion.

In the spring of 1915 several heaved places were noted. All the trouble experienced, however, seemed to be caused by transverse expansion, and occurred within 8 ft. of the curbs on each side of the street, affecting approximately 300 sq. yds. of pavement in all. This heaving was taken care of in two ways: Where the blocks were heaved badly, they were taken up and relaid, a good grade of pitch filler being used in refilling the joints; while where the heaving was only slight the joints were blown out with dry steam from the road roller, at a boiler pressure of 200 lbs., and the blocks were rolled down to place and the joints refilled with paving pitch.

The latter method was in the nature of an experiment, but has accomplished the purpose satisfactorily and at a trifling cost. To supplement this work and provide against future heaving at the same locations a ¾-in. expansion joint has been dug out with a chisel in the gutter courses of blocks along each place where heaving occurred, this joint being filled with paving pitch. Also eight courses of blocks have been taken up clear across the street each 400 ft. in length of street, and the blocks have been cut off for a 1-in. expansion joint, relaid with equal spaces between the blocks and refilled with paving pitch. The blocks have also been kept damp all summer by flushing the street at night and sprinkling in the daytime when necessary. This has kept the blocks from drying out and shrinking and has also kept further sand and dirt from the joints. From the present excellent condition of the surface of the street, no further heaving is anticipated.

TABLE XXVIII.—DISTRIBUTION OF COSTS OF WENATCHEE AVENUE WOOD BLOCK PAVEMENT

Division	Materials: Kind and unit	Unit cost	Units per sq. yds.	Cost per sq. yd.
Base	Gravel, cu. yd.	$ 1.30	.0973	$0.1263
	Sand, cu. yd.	1.00	.0486	.0486
	Cement, bbl.	2.10	.125	.2625
	Water	....	......	.01
	Mixer (Int. & Depr.)	....	......	.0152
Cushion	Sand, cu. yd.	1.00	.0278	.0278
Top	*Blocks, sq. yd.	1.794	1.0	1.794
	Asphalt filler, ton	37.75	.0031	.1153
Total per sq. yd.		....	......	$2.3997

Division	Subdivision	Labor: Sq. yds. per hour foreman	Sq. yds., per hour labor	Labor cost per sq. yd.
Base	Mixing	120.5	8.9	$0.0523
	Placing	253	19.9	.0205
Cushion		.....	21.8	.0141
Top	Laying	.....	87.2	.016
	Helping	.....	88.0	.0435
	Rolling	.....	73.7	.0159†
	Filling	.....	5.9	.0599
Total per sq. yd.		.....	....	$0.2222

Labor, $2.50 per 8-hr. day; block layer, $10.00 per 8-hr. day. Block layer was foreman of cushion, laying, and filling gangs. *Wood blocks, $1.75 per sq. yd., f.o.b. Wenatchee, × $1.10 per M for unloading and hauling (42¼ blocks per sq. yd.). †Including roller rent, $3.50 per day.

Operating Costs of Tractor, Trucks and Sand Screen and Loader in Road Maintenance.—Engineering and Contracting, Jan. 1, 1919 publishes the following information given in a bulletin of the Colorado Highway Department by James E. Maloney, Chief Engineer.

In maintaining county roads in the vicinity of Denver the Colorado Highway Department is employing a tractor, trucks, and a sand elevator, screen and loader. The complete outfit consists of the following: One C. L. Best caterpillar gas tractor of 40-h.p. drawbar capacity, weight 28,000 lb., costing $6,000; one grader with scarifier and blade attachment, costing $800, and two light drags; 2 White 5-ton trucks and a Kelly-Springfield 5-ton truck, costing $6,000 each; and a Gallion sand elevator, screen and loader, costing $1,500.

The tractor, grader and one drag are generally used together and can be operated by two men. If the work is simply dragging, or smoothing with the grader, a distance of 20 miles might be covered; that is, if one round trip is made they would cover 10 miles of road; if two round trips were necessary, then 5 miles of road would be covered. The latter figure might be taken as an average in all kinds of materials for the dragging.

In many places it is necessary to scarify the surface in order to reshape it and remove the chuckholes and waves. On work of this latter class the tractor and grader are used very successfully, except on macadam or very solid gravel roads, where it is found that the scarifier is too light and it is necessary to use the heavy-toothed scarifier. On scarifying and reshaping it has been found that about ½ mile per day would be an average day's work.

The sum of $50 per day has been taken as the cost of the operation of this particular outfit. This figure is obtained as follows:

Caterpillar tractor, expense per day:		
Gas and oil	$17.00	
Maintenance	9.50	
Operator	5.00	
Depreciation (based on assumption of life of 4 years for engine and 180 working days in each year)	8.50	
		$40.00
Grader and scarifier, expense per day:		
Maintenance	$ 3.00	
Labor	4.50	
Depreciation (based on 180 working days per year)	2.50	
		$10.00
Total		$50.00

Some unsatisfactory features should be noted: The tractor is very heavy and an unsafe load on many of the old bridges. It is unwieldy, requiring a cross-road intersection or a full width road for turning. The lighter size tractor of 25 h.p. at the drawbar is free from these objections, and will do most of the work that can be done with the larger size.

The two trucks and screening and loading plant have been used in resurfacing some pieces of road with sand and gravel, and the trucks have used the drags occasionally. The use of the trucks on anything but the lighter forms of drags has not been entirely satisfactory, so the Department employed them largely on hauling and spreading materials for repairs of surfacing. The trucks are both of the dumping and spreading type and are working satisfactorily.

In charging up the work to the various roads the following has been adopted:

Expense for the year:	
Operator, 10 months, at $100	$1,000
Maintenance, oil and gas	2,000
Depreciation, 25 per cent of the cost	1,500
Overhead and incidental	900
Total	$5,400

For 180 working days this equals $30 per day. This charge for the sand elevator and loader is based on the following:

Operator, 180 days, at $3.50	$ 630
Gas and oil, 180 days, at $1.50	270
Repairs and maintenance	450
Depreciation, 20 per cent of cost	300
Overhead, labor, teams and incidentals	2,850
Total	$4,500

For 180 working days this equals $25 per day, and this rate is charged to the road upon which the work is being done.

Cost of Removing Asphalt Pavement with Hammer Drills.—Hand air-hammer drills were used by P. J. Moran, a contractor of Salt Lake City, Utah, for removing a strip of asphalt and concrete pavement alongside the tracks of a street railway so that the rails might be shimmed and new pavement laid. A description of the job is given in Mine and Quarry, Dec., 1916 from which the following notes are taken.

In order to reduce time and labor in this work, Mr. Moran purchased two Sullivan DC-19, 40-lb. hammer drills, operated by a small steam-driven air compressor.

A line was laid out a foot from the outside of the rails and the drills were equipped with a special channeling bit to cut off the asphalt. When a sufficient distance had been channeled a gadding bit was used and the surfacing material was removed, exposing the concrete. The gadding bit was again used in breaking up the concrete. This was done by holding the drill in a nearly vertical position for wedging off pieces of the concrete. In this manner pieces from 4 to 8 in. square were broken off.

One man with the Sullivan drill was able to take up the asphalt and concrete at an average rate of 6 lin. ft. in 15 minutes; while the three men, "double-jacking," by the old method of hand work, required an average of 40 minutes to remove a like amount; that is, hand work required two hours to accomplish the same results secured in 15 minutes with the machines.

The following comparison, based on the job described above, may be interesting:

MACHINE WORK COSTS

(Based on costs and prices in June, 1914)

Cost of Plant

1 Sullivan WK-3 portable compressor outfit (20 h.p.)	$1,780.00
2 DC-19 hammer drills	170.00
Hose, steel, etc	50.00
Total	$2,000.00
Interest on plant at 6 per cent	$ 120.00
Depreciation, 15 per cent	300.00
Total	$ 420.00
Operating, 175 days per year, per day	$ 2.40
Engineer, per day	3.50
2 drill operators at $2.50	5.00
Gasoline, 20 gal. at 23 cts	4.60
Oil, waste, etc	.50
Total	$ 16.00
Progress per day, 8 hours	384 ft.
Cost per foot of work	$ 0.0416

HAND WORK COSTS

6 laborers at $2.25	$ 13.50
Progress per day, 8 hours	144 ft.
Cost per foot of work	$ 0.0937
Saving on machine over hand work, per foot	.0521

Cost of Cutting Pavements with Pneumatic Machine.—The following is taken from Engineering and Contracting, July 24, 1912.

Trials were made at Los Angeles this spring by the Los Angeles Ry. Co. in cutting street pavements with a pneumatic machine. The company used a truck equipped by the Rix Compressed Air & Drill Co. with a gasoline engine and compressors and by the Hardsocg Wonder Drill Co., Ottumwa, Ia., with a pneumatic machine. The experiment was described by A. S. E. Beall in Western Engineering. After a number of trials with different cutting devices on the asphalt and concrete a chisel tool, 4 ins. wide, and gads of 1¼-in. steel, 18 ins. long, with shanks on each to fit the machines were used. In removing grouting or pavement laid under older specifications, the minimum figures of actual cost, with hand labor, per lineal foot of trench was 17 cts. In removing pavement laid under the latest specifications and consisting of 5 ins. hydraulic concrete base, 1 in. asphalt binder and 2 ins. asphalt wearing surface, the actual cost per lineal foot of trench by hand labor was 20 cts. These figures are based on a trench 18 ins. wide. In the experiments of the Los Angeles Ry. Co. the asphalt pavement cut had been laid under the latest specifications. The results of the experiment were as follows:

One Hardsocg machine, with two men at 15 cts. each per hour, cut 46 lin. ft. of trench in asphalt per hour, the cost per lin. ft. being .6 ct.; one Hardsocg machine, with three men at 15 cts. each per hour, cut 45 ft. of trench in the concrete per hour, at a cost of 1 ct. per lin. ft. The cost of the plant to operate the three Hardsocg machines was $1,600, and the three machines cost $225, making a total of $1,825. Interest on this investment at 6 per cent, and allowing depreciation at 10 per cent, makes $292 per year. On the basis of 300 working days in the year interest and depreciation would amount to 97 cts. per day or 12 cts. per hour for an 8-hour day. The operating expenses of the plant were:

	Per hour
Engineer, per hour	$0.30
Feed and lubrication	.35
Total	$0.65

Adding the 12 cts. per hour for interest and depreciation brings the cost to 77 cts. per hour. The average execution per hour for one machine was 45½ ft., and the cost of operating the plant (77 cts) divided by three (the number of machines working) gives a cost of .56 ct. per lin. ft. of trench for plant operation. Summarizing we have:

	Per lin. ft.
Cutting asphalt, 2 men at 15 cts	$0.0060
Cutting cement, 3 men at 15 cts	.0100
Engineer	.0022
Fuel and lubrication	.0024
Interest and depreciation	.0010
Total	$0.0216

In the experiments it was noticeable that several improvements could be made to benefit the operating materially. For instance, the men used for this work were Mexicans from the track gang. They were pick and shovel men only; better labor would give better results. A slight rearrangement could be made that would facilitate the work by utilizing the weight of the men, which would make the work very light and assist the machine materially. When the work was being finished, a run was made with the asphalt cutters in concrete, instead of using the gads, and it was found that they worked much faster and better. No doubt a number of such improvements could be made that would expedite the work and so lower the cost.

Pneumatic Hammers for Tearing Up Street Pavements.—Frank Richards in Engineering News, Aug. 10, 1911, states that four men each operating a pneumatic hammer accomplished as much work as 16 to 20 men working entirely by hand. The work in question consisted of cutting out solid hard concrete along the tracks of The City Tram Co. of Zurich, Switzerland.

In cutting an asphalt pavement in Brooklyn, N. Y. for opening a trench for laying gas mains the following results were obtained.

From observation of about 3,000 linear feet of cut (1,500 ft. of trench), with two men and sometimes three using the hammers, the average asphalt cut was 20 ft. per man per hour.

On June 1, 1911, on a 45-minute hand test (hand-held chisel and sledge) we cut at the rate of 12 ft. per man per hour, but the men were exhausted and had to stop.

The material under the asphalt was macadam, close and hard, and for breaking up this also the "coal picks" did good service. The chisels were exchanged for pointed picks for this work.

Reference to "Handbook of Cost Data."—On pages 442 to 445, of Gillette's "Handbook of Cost Data," quantities of materials required for constructing sidewalks are given, and on pages 446 to 457 further cost data on walks and curbs may be found.

Maintenance Cost of Plank and Tar Concrete Sidewalks.—According to Engineering and Contracting, Oct. 11, 1916, an investigation by the City Engineer of Newton, Mass., shows that an average of 3 per cent of the total area of coal tar concrete sidewalks in that city have been repaired each year during the past 7 years and that the average cost of maintenance of these sidewalks is about 2 ct. per square yard per year. The cost of maintenance of the plank sidewalks has been about 14 ct. per square yard per year.

Cost of Resurfacing Macadam Walks with Asphalt, Lincoln Park, Chicago, is given by M. D. Blumberg, Engineering and Contracting, June 9, 1915, as follows:

In Lincoln Park proper there are about 50,000 sq. yds. of walks built principally of cinders, limestone macadam, and gravel macadam. In 1913 the attention of the commissioners was drawn to the difficulty of keeping these walks in condition for foot travel. In wet weather pools of water would stand in the walks, in dry weather the protruding large stones caused a great deal of discomfort to the pedestrians, thereby causing many of them to walk on the grass, while in winter the removal of snow was unnecessarily difficult. In deciding upon what methods to use to eliminate the above difficulties the following considerations were born in mind: (1) Low first cost and low maintenance; (2) The walks should be in harmony with the park surroundings; (3) The utilization of the foundations of the walks as they stood; (4) The walks should be of such a nature as to induce people to use them rather than the grass.

With these considerations in view the choice was narrowed down to building Portland cement concrete walks or resurfacing with an asphaltic mixture. It was finally decided to build some experimental sections with an asphaltic top. These experiments proved so successful in 1913 that in 1914 enough money was appropriated to cover nearly 40,000 sq. yds. of walks with an asphaltic wearing surface.

The plant used for this job consisted of one portable asphalt plant of 1,600 cu. yds. capacity (inch thick) manufactured by the Link Belt Co. and a combination roller which furnished the power for the plant. The material was wheeled in barrows up an elevated platform from which it was dumped into the hopper. The plant was centrally located and the binder and top were hauled to the job in two-yard dump wagons. The wagons were covered with canvas to retain the heat in the mixture. The average haul was one-half mile. Sufficient teams were used to keep up with the output of the plant. The greatest number used per day was five teams.

About one-third the area, or 13,329 sq. yds. of walk, were sufficiently compact and rough to pave with a wearing surface only. The balance, or 26,657 sq. yds., required a binder and top. The binder used was composed of ½-in. to ¾-in. stone and asphalt. A number of tests showed that the percentage of asphalt used by weight was as follows: Minimum 3.85 per cent, maximum 5.15 per cent, average 4.25 per cent. The binder was laid so that it was ¾ in. thick after being rolled with a 5-ton roller. The wearing surface mix consisted of asphalt, limestone screenings, stone dust and bank sand in the following proportions:

	Per cent.
Asphalt	10.50
Passing 200-mesh	12.50
Passing 80-mesh	18.00
Passing 40-mesh	36.00
Passing 10-mesh	13.00
On 10-mesh	10.00
	100.00

The wearing surface was laid ¾ in. thick after being rolled with a 5-ton roller. Immediately after rolling Portland cement was brushed over the surface and then rolled with the 5-ton roller. The cement fills the minute voids in the surface and also improves the appearance of the walks.

It will be noticed from the cost report, Table XXIX, that there is a torpedo sand charge. At the beginning of the work it was found that the mix contained too large a percentage of coarse material. Limestone dust was substituted in place of the torpedo sand and the mix proved very successful. No forms of any kind were required for the work.

From the cost report it can be seen that asphalt walks can be laid at approximately 60 per cent of the cost of concrete walks where both binder and top are used, and at about 35 per cent of the cost of concrete where a wearing surface only is used.

TABLE XXIX.—COST OF BASE AND WEARING SURFACE FOR 26,657 SQ. YDS. OF WALK, LINCOLN PARK, CHICAGO

BASE

	Per sq. yd.
Labor:	
Shaping bed of walk	$0.023
Mixing	.080
Spreading	.020
Rolling	.006
Total	$0.129
Material:	
Asphalt	$0.050
Stone	.051
Coal	.012
Miscellaneous supplies	.002
Total	$0.115

Teams:	
Hauling (surplus material after shaping walk)	$0.014
Hauling (binder)	.019
Total	$0.033
Overhead charges:	
Plant	$0.015
Superintendence	.004
Total	$0.019
Total cost per sq. yd.:	
Labor	$0.129
Material	.115
Teams	.033
Overhead charges	.019
Total	$0.296

WEARING SURFACE

	Per sq. yd.
Labor:	
Mixing	$0.054
Spreading	.021
Rolling	.006
Total*	$0.081
Material:	
Asphalt	$0.105
Screenings (limestone)	.028
Stone dust	.016
Sand (torpedo)	.001
Sand (fine)	.043
Cement	.001
Miscellaneous	.001
Coal	.013
Total	$0.208
Teams:	
Hauling	$0.018
Overhead charges:	
Plant	$0.019
Superintendence	.004
Total	$0.023
Total cost per sq. yd.:	
Labor	$0.081
Material	.208
Teams	.018
Overhead charges	.023
Total	$0.330

* In 13,329 sq. yds. not included in the above there was an additional labor charge for "shaping bed of walk" 0.022. The total cost of this section was $0.35 per sq. yd.

Cost of Cement Tile Sidewalk at St. Paul, Minn.—The following data are taken from an article by E. G. Briggs, Engineering and Contracting, Oct. 6, 1920.

The constructing, relaying and repairing of cement sidewalks in the city of St. Paul has for several years been done by contract, the work being let by the City Council to the lowest responsible bidder. The volume of work executed through the City Department increased approximately 400 per cent during the 4-year period prior to the world war, when in 1917 the total cost of sidewalk work executed by the contractor amounted to approximately $100,000.

Approximately 98 per cent of all walks constructed are of the pre-cast tile method. These tile are constructed under careful city inspection at the shop of the successful bidder, generally during the winter months and made in sizes, 2 ft. square or 4 sq. ft. and 1½ ft. square or 2.25 sq. ft., thus allowing three squares of one for a 6-ft. walk, designated as a standard width of three squares of the other for a 4.5-ft. walk, which is often approved for narrow streets or where walks are less frequently used.

The construction cost, of cement tile sidewalks, includes the cost of the tile, the cost of excavating 8 in. for foundation, the foundation and finishing of the walk. The foundation consists of 4 in. of broken stone, brick, gravel or cinders thoroughly rolled and brought to a smooth surface with rammed gravel or cinders. On this frost vent a 2-in. layer of 1:5 mortar is laid and upon the foundation thus prepared the tile are laid to a true surface and grouted. The tiles are 2 in. thick, the lower three-fourths is composed of 1 part Portland cement and 4 parts of clean, sharp sand, thoroughly mixed and carefully rammed into the molds to a uniform depth. The upper one-fourth is composed of 1 part Portland cement and 2 parts of clean, sharp sand, placed immediately upon the lower part and thoroughly rammed to the proper thickness.

In the manufacture of the tile according to this specification, it has been found that 1 bbl. of cement will average 80 sq. ft. of tile, one bag averaging 20 sq. ft. or five 2 × 2 ft. tile. The sand required for the 2 × 2 ft. tile totals 0.66 cu. ft. or 0.165 cu. ft. of sand per sq. ft. of tile. The sand used has been screened, not washed, and by analysis the voids approximately equal the quantity of cement specified.

The cost of materials was as follows:

Material:	Cu. ft.	Sq. ft. of tile
Cement, $1.90 per bbl.	$0.475	$0.0237
Sand, 0.50 per cu. yd.	0.0185	0.0030
Total cost per sq. ft. for material	....	$0.0267

The labor cost, including curing and overhead follows:

Item	No.	Tile mnfd. sq. ft.	Cost per day
Foreman	1	....	$ 5.00
Tile makers	4	1600	12.00
Mixers	2	....	5.00
Laborers	4	....	9.00
Curing, superintendence, overhead, depreciation	..	....	9.00
			$40.00
Total cost per square foot for labor curing and overhead,			0.0250

The total cost of tile per square foot on racks in yard is therefore:

Material	$0.0267	
Labor, including curing and overhead	.0250	
Total	....	$0.0517

For the actual construction of sidewalk the following calculation is obtained. The tile are generally delivered on the street with a 5-ton motor truck averaging four truck loads per day. This has been found to be the most economical method of delivery. The average load consists of 320 sq. ft., weighing approximately 7,000 lbs. The laborers in the yard at the factory with the assistance of the driver, load the truck and the driver is assisted by the sidewalk crew in unloading the tile at their destination. It will be noted that an average of 1,280 sq. ft. of tile are delivered on the street during the 8-hour day. The cost has averaged approximately 1 ct. per square foot of tile for this delivery.

The construction of the walk as calculated on the average of construction shows that four men and one foreman average 100 ft. of 6 ft. walk per 8-hour day.

Cinders for the base have been obtained free at the gas plants and other places where considerable coal is consumed. The cinders have been delivered at the site of the construction in 3-yd. dump wagons and an average of four loads per day have been received. Sand for the concrete between the cinder base and the tile has generally been obtained near the place of construction. A team with driver is required part time with each crew to plow and assist in preparing the base, remove the surplus material, haul sand and move forward water tanks and form material incidental to the construction. For the total field operations to complete the walk, the following table gives an average of the costs involved:

AVERAGE CONSTRUCTION COST

Item	No.	Total cost	Total sq. ft.	Cost per sq. ft.
Delivering tile	1,280 sq. ft.	$12.80	1280	$0.0100
Cinders	12 cu. yd.	6.00	960	.0062
Concrete sand—Included in price of team.				
Cement	3.75 bbl.	7.12	600	.0118
Laborers	4	9.00	600	.0118
Foreman	1	5.00	600	.0083
Team	1 ½ time	3.00	600	.0050
Total cost per square foot for construction				$0.0563

For a tile constructed sidewalk, according to the specifications, we have a total estimated cost for the completed work as follows:

Cost of tile in stack at yard per square foot	$0.0517
Cost of delivering tile, cinders and constructing walk, per square foot	0.0563
Total cost per square foot	$0.1080

Table XXX gives the contract prices covering operations for the past four years on sidewalk work and incidentals connected with the construction from which considerable additional revenue has been received.

TABLE XXX.—CONTRACT PRICES FOR SIDEWALK CONSTRUCTION AND EXTRAS, 1916 to 1919, ST. PAUL

Item	1916	1917	1918 Dist. 1	1918 Dist. 2	1919 Dist. 1	1919 Dist. 2
Cement blks., new, per sq. ft.	$0.094	$0.108	$0.105	$0.12	$0.0975	$0.105

Cement walk surfaced in place	0.15	0.16	0.14	0.20	0.15	0.20

The contracts for 1916, 1917 and district No. 2 in 1918 were executed by one contractor.

Cost of Grading and Constructing Sidewalks, Los Angeles, Cal.—E. E. Glass in Engineering and Contracting, April 4, 1917, gives the following:

The work, consisting of the improvement of the streets in a hilly suburban tract by grading and constructing about 7 miles of concrete walks, curbs and gutters, was done in Nov. and Dec., 1916. As the soil was a heavy, stiff clay, the contractor pushed the work with all possible speed in order to beat the winter rains and the excavation was practically complete and the concrete work half finished when the first rain fell in Dec. Thereafter some delay was experienced because of wet ground.

Grading.—Two elevating graders were employed for ordinary grading, one drawn by a gas tractor and the other by 16 mules (six pushing). A steam shovel was used in the heavier cuts and handled about 3,000 cu. yd. of hard-pan. As the cut became deeper and the clay harder, the shovel could not fill with less than three tries, so blasting had to be resorted to. The maximum cut was only 9 ft. Holes were sunk by two men on a churn drill and sprung at grade by a stick of 40 per cent dynamite. The spacing was about equal to the depth of hole and the average load was a half keg of black powder fired by an electric battery and a stick of dynamite. The best shots merely heaved the ground, but occasionally a hole would "blow up," and as the streets were in a residence district it was found necessary to lay old planks over the holes to prevent chunks of clay flying and damaging property.

The business-like handling of earth sales is worthy of notice. When the work was awarded, the contractor sent salesmen with blank contracts to the owners of property in the district. They received a commission and sold excess yardage for as much as 40 ct. per cu. yd. for filling lots. Any reasonable terms were considered, with the property as security. This appears to be a far better arrangement than the more common wasting of earth where the contractor does not get the price he wants and spot cash.

All hauling was done in 1½ cu. yd. dump wagons. An item which tended to increase the cost of the earth-work was the inability of the graders to work around power and telephone poles where light cut or fill made their removal unnecessary. This required plowing the cut between the pole line and property line and slipping the earth out into the street, where the grader picked it up.

Because of short notice to the local water company, many pipes and some mains were broken and work had frequently to be discontinued on a street until it could drain and dry out. This water standing in new fills and ditches causes much inconvenience on a grading job and is easily avoided.

Concrete Work.—The curb, walk and gutter gangs began at the same point and followed in the order named, about a week apart.

The county's resident engineer, in charge of the work, had an inspector with each of the three gangs. Each inspector filled in the day's run of work in feet, size of crew and amount of cement used, on the progress report form shown in Fig. 15 which also gives a typical day's run of the curb outfit, hand-mixing. The resident engineer worked up the balance of the cost, from which the final cost of the job was accurately determined.

The greater portion of the curb work was made by hand mixing. The materials were turned three times dry and three times wet on a 3 ft. × 10 ft. sheet iron strips laid together to form a good mixing platform, readily moved along the street as the work progressed. Ten-bag batches were mixed, which ran about 75 lin. ft. of curb, depending upon the number of openings left for driveways and the amount of low grade (giving overdepth of curb). All concrete on the work was 1:2:4 and mortar was specified 1 part cement and 2. parts sand with 1 lb. of lamp black per barrel of cement used. On the curb finish, the contractor found it necessary to use more cement in the mortar to trowel smoothly.

Carey expansion joints were placed every 40 ft. in curb, walk and gutter and the facing cut through to expose the felt. The curb was 5 in. wide at top, 3 in. at base and 15 in. high, with ½ in. of mortar on top face and ¼ in. of mortar on 4 in. of back and 3 in. of the front face. The gutter line was 8 in. below top of curb on the greater part of the work, the gutter being 5 in. thick and 2 ft

FIG. 15.—Inspector's concrete report with typical day's run of curb crew.

wide, but Ditman street drains the district and here curbs were given 10 in. face and gutters were 5 in. thick by 3 in. wide. All gutters were floated rough and marked every 3 ft. to correspond with the curb marks.

The walk was built 4 in. wide with a 3 in. base of 1:2:4 concrete and a ½-in. top of 1:2 mortar as before described. A Chicago paving mixer was used and gave good results. In all the work both sides of the street were carried along together, the concrete being wheeled from the platform or mixer to the forms in barrows.

All cement work was promptly covered with earth which was kept moist for two weeks.

The cost of this work is given in Table XXXI, see Fig. 15, for unit costs of materials and labor.

TABLE XXXI.—ROAD DISTRICT IMPROVEMENT NO. 124, STREETS IN OCCIDENTAL HEIGHTS, LOS ANGELES COUNTY ROAD DEPARTMENT

Work done—Grading, cement sidewalks, curbs and gutters.
Total length, 4.2 miles.
Average haul, 6 miles.

Actual Cost to Contractor:		
Excavation, 38.563 cu. yd. at $0.279		$10,758.75
Concrete for culvert, furnishing, hauling and placing, 4 cu. yd. at $23.04		92.17
Reinforcing steel for culvert, furnishing, hauling and placing, 330 lb. at 5 cts		19.50
Sidewalk, 3½ in. by 4 ft., furnishing, hauling and placing, 141,050 sq. ft. at $0.07		10,402.64

Repairs	.0058	
Total	$0.2110	
Total cost of work		$35,054.67
Less 2,910 bb . cement at $1.47 furnished by county		4,277.70
Actual cost to contractor		$30,776.97

The above does not include interest, insurance or overhead expense.

One Course Monolithic vs. Two Course Concrete Sidewalks.—Maj. F. S. Besson, in Engineering and Contracting, May 4, 1921 gives the comparative advantages, costs, etc., of constructing both 1 and 2 course concrete sidewalks. In concluding his article Maj. Besson gives the following summary:

A 5 in. one course walk of gravel concrete, proportioned 1 bag of cement (one cu. ft.), 2¼ cu. ft. sand and 3⅜ cu. ft. gravel, presents all the advantages of a two course walk and none of its disadvantages. This is accomplished with (1) a saving of from 100 to 200 bags of cement per 1,000 sq. yd. of walk, (2) a labor saving of 6 men in an organization capable of approximating 350 to 400 sq. yd. of walk per day, (3) an increase, with a given type of concrete mixer, of from 10 to 12 per cent in daily yardage, and (4) a saving of the first cost and maintenance of a mortar mixer.

Output of Gang in Constructing One Course Concrete Sidewalks (Engineering and Contracting, Jan. 1, 1919).—The one-course type was decided upon for the subdivision of the American Steel & Wire Co. at Donora, Pa., where an extensive concrete housing development is being completed. Contract was let for approximately 25,000 sq. ft. of 5-ft. walk, 4½ in. thick. The work was handled in much the same way as one-course concrete road construction.

Of especial interest are the steel dividing plates used to separate concrete into 5-ft. slabs, as the plates must not extend above the sidewalk surface if the roller method of finishing is to be followed.

Where wooden side forms were used, 3/16-in. steel plates 5 ft. long by 4½ in. in depth were spaced at 5-ft. intervals. Near the top at each end of the plate a small hole was provided so that the plate could be removed with hooks. To prevent concrete from pushing these plates out of position, they were staked near the ends and at the center with steel pins.

On part of the work the forms were of steel. The type of dividing plate used with these patented forms had a projecting part in the shape of a hook on each end which fitted over the vertical web of the channel-shaped side form, the upper flange being cut through to make that possible. Only one stake on level ground, or two on grades, were needed with this type of plate.

Concrete was mixed in proportions of 1:2:3, using crushed blast furnace slag ranging in size from ¼ in. to 1½ in. as coarse aggregate. This gave particles larger than are ordinarily used in sidewalk construction, but little trouble was experienced from this cause when the concrete was finished with a heavy roller.

Care was taken to make adequate provision for expansion. Every 50 ft. a strip of prepared filler ½ in. in thickness was placed across the sidewalk, and where the walk abutted a street curb two thicknesses of filler were used. Between houses and walks a ½ in. joint was placed.

Concrete was deposited directly on the clay subgrade and struck off ½ in. high with a template. Following this, concrete was rolled longitudinally with a 10-in. roller 5 ft. 5 in. long, which weighed 2¼ lb. per lineal inch. Since this roller rested on the side forms after concrete had been compacted to the proper level, it was satisfactory although heavier than is used ordinarily. Immediately after rolling the surface was finished with wood floats, dividing plates were removed, joints grooved and the sidewalk edged.

The concreting crew was made up of 14 men, including the superintendent; five men were employed in the mixing crew, three wheeled concrete, two set forms and three did the finishing. Twenty-one hundred square feet was the largest day's work done, while 1,800 sq. ft. was a fair daily average. The mixer was a two-sack batch side dump machine. Usually it was moved four times daily.

Cost of Constructing a Wide Concrete Sidewalk, Harrisburg, Pa.—Joel D. Justin gives the following data in Engineering and Contracting, Sept. 1, 1915.

In connection with the construction of a series of reinforced concrete retaining walls along the river front, the City of Harrisburg completed, in 1915, a concrete sidewalk 10,600 ft. long and 12 ft. 3 ins. wide.

The sidewalk which was built by contract under rigid inspection, was constructed in alternate blocks 6 ft. 1½ ins. square and 6 ins. thick, with 1 part of cement, 2½ parts of sand and 4½ parts run of crushed limestone, maximum size 1 in. The mixture was made so dry that considerable heavy ramming was necessary to bring moisture to the surface. This concrete was then deposited in a block compartment and screeded and thoroughly tamped. The top coat mixed 1 part cement to 1½ part quartz sand, was mixed so dry that it is necessary to squeeze a ball of the mortar in the hand to bring moisture to the surface. The top coat is then spread over the concrete base and screeded and rammed into place, either with tampers or by striking heavily with the flat of the shovel. The surface is then finished off hard and smooth with floats and metal trowels.

It is essential that both concrete base and top coat should be placed fairly dry, as if either is wet, there is formed a minute layer of laitance between the base and the top coat. This causes a dividing plane, which frequently explains the peeling off of the top coat of sidewalk work as generally constructed.

The writer has placed over one hundred thousand square yards of top coated concrete in the manner here outlined, where weather conditions are exceptionally severe and none of it has come off. He is firmly convinced that the method secures a perfect bond between the concrete and the top coat. Blocks placed in this manner have been broken up and removed and it was found impossible to separate the top coat from the base, the fracture in every case occurring elsewhere.

The sidewalk was located at the foot of a bank varying in height from 12 to 15 ft. A two bag batch steam driven mixer of the Milwaukee Paver type was stationed on the bank and moved from place to place under its own steam as the work progressed. Set ups were from two to three thousand feet apart. Sand, stone and cement were delivered by team on an asphalt street within 20 to 75 ft. of the mixer. The cost of cement delivered on the job was $1.10 per barrel net, including deduction for lost and stolen bags. Crushed stone cost 90 cts. per ton delivered on the job and sand $1.30 per ton.

After mixing, the concrete was dumped through a chute into Koppel cars, running on a narrow gage track beside the sidewalk. From the cars, the concrete was dumped directly into place. The top coat was mixed on the sidewalk and transported in wheelbarrows to the points required.

Each block 6 ft. 1½ ins. square and 6 ins. thick contained 0.695 cu. yds., requiring 1.25 bbls. of cement, 0.822 bbls. of this being in the concrete base and 0.428 bbls. in the top coat. The average was thus 1.8 bbls. per cubic yard including the top coat.

An itemized statement of the organization and cost per unit is given in Table XXXII. The average output per 10-hour day was 100 blocks or 69.5 cu. yds. or 417 sq. yds.

It should be noted that no allowance has been made for overhead or depreciation. All other charges to the contractor are included.

TABLE XXXII

	Cost per day	Per cu. yd.	Per sq. yd.
Supplying Mixer—			
Cement, 1 man @ $1.50	$ 1.50	....	......
Stone, 6 men @ $1.50 per 10-hr. day	9.00	....	......
Sand, 2 men @ $1.50 per 10-hr. day	3.00	$0.194	$0.032
Mixer Running—			
1 engineer @ $2.50	2.50	....	......
1 fireman @ $2.00	2.00	0.065	0.011
Transporting Concrete—			
2 men on cars at mixer @ $1.50	3.00	....	......
3 men on train @ 1.50	4.50	....	......
1 horse @ 2.00	2.00	0.130	0.022
Placing and Ramming Concrete—			
4 men placing, ramming, screeding @ $1.50	6.00	0.086	0.014
Mixing Top Coat—			
5 men mixing @ 1.50	7.50	0.108	0.018
Transporting Top Coat—			
3 men wheeling @ $1.50	4.50	0.065	0.011
Placing and Screeding Top Coat—			
4 men @$1.75	7.00	0.101	0.017
Finishing Top Coat—			
1 man @ $3.00.			
1 man @ 2.00.			
1 man @ 2.00	7.00	0.101	0.017
Setting Templets—			
1 foreman @ $3.00	3.00	....	......
3 carpenters @ $2.00	6.00	....	......
2 helpers @ $1.75	3.50	0.180	0.030
Finished Grading—			
1 foreman @ $2.00	2.00	....	......
8 men @ $1.50	12.00	0.201	0.034
Total labor cost	$85.50	$1.23	$0.205
Coal for mixer @ $3.10 ton	0.78	0.011	0.009
Use of mixer, tracks and cars	......	.0444	0.024
Grand total (aside from overhead)	$87.28	$1.26	$0.210

	Per cu. yd.	Per sq yd.
Cost of Materials—		
1.4 tons stone @ 90 cts	$1.26	$0.210
.7 ton sand @ $1.50	.91	.152
1.8 bbls. cement @ $1.10	1.98	0.330
Cost materials	$4.15	$0.696
Total labor, mixer-coal	1.26	0.210
Total cost	$5.41	$0.902

6 sq. yds. = 1 cu. yd. (6 ins. thick).

Cost of Concrete Sidewalk in Chicago.—N. E. Murray gives the following in a paper before the Illinois Society of Engineers and Surveyors, Jan. 26–8, 1910, abstracted in Engineering and Contracting, Feb. 2, 1910.

The ordinary concrete sidewalk gang in Chicago is usually composed of six men paid as follows:

1 finisher 8 hours at 65 cts	$ 5.20
1 helper 8 hours at 47½ cts	3.80
4 laborers 8 hours at 37½ cts	12.00
Total	$21.00

Under favorable conditions this gang will construct 900 sq. ft. of walk per day. From information furnished me by several of the leading contractors, each employing on an average of six gangs of men, a gang of six men will average only 600 sq. ft. per day for an entire season. This figure will be used as a basis for computing the cost of labor in the following table:

Cinders (allow for 20 % shrinkage), 20.83 cu. yds. at 50 cts.	$10.42
Base 4¼ inches thick—Mix 1-2½-5:	
Cement, 9.77 bbls., at $1.20	$11.72
Sand, 3.47 cu. yds., at $1.75	6.07
Gravel, 6.85 cu. yds., at $1.50	10.28
Total	$28.07
Wearing coat ¾ in. thick—Mix 2-3.	
Cement, 5.56 bbls., at $1.20	$ 6.67
Sand, 1.17 cu. yds., at $1.75	2.04
Total	$ 8.71
Water at 1 mill per square foot	0.60
Labor, one gang one day	21.00
Use of tools, waste of material, etc., at 2 %	1.37
Supt. and office exp. at 5 %	3.51
Profit at 10 %	7.36
Total	$81.04

The average cost per foot when 600 sq. ft. per day are laid divided into unit cost per sq. ft. is as follows:

Cinders	$0.0174
Base:	
Cement	$0.0195
Sand	.0101
Gravel	.0171
Total	$0.0468
Top:	
Cement	$0.0111
Sand	.0034
Total	$0.0145
Water	$0.0010
Labor	0.0350
Tools, waste, etc., 2 %	0.0023
Supt., 5 %	0.0058
Profit, 10 %	0.0123
Total	$0.1351

In the above the cost of materials and water amounts to 7.97 cts. per sq. ft., which will remain constant, while the cost of labor, superintendent, etc., will vary according to the number of square feet laid per day per gang:

Av. sq. ft. per day.	700	800	900	1,000
Cost of labor, supt., etc	$0.1291	$0.1248	$0.1213	$0.1185

Cost of Cutting Edge of Concrete Walk.—H. R. Ferris gives, in Engineering and Contracting, Oct. 4, 1916, the following:

During the work on some street widening improvements, it was found necessary, in order to make room for a granite curb, to trim about 3 in. off the outside edge of a 4-in. concrete walk, and for a distance of 512 ft.

The work was done by an unusually good workman, using a medium hand hammer and ordinary cold chisels.

The cost follows:

Foreman marking and lining edge of walk, 2 hr. @ 62.5 cts.	$ 1.25
Laborer cutting edge of walk, 24 hr. @ 30 cts.	7.20
Removing old concrete—	
Labor, 4 hr.	1.20
Teams, 1 hr.	.65
	$10.30
Cost per lineal foot	2 cts.

Cost of Raising Sunken Concrete Walk.—H. R. Ferris gives the following note in Engineering and Contracting, Oct. 4, 1916.

In the course of some construction connected with street widening improvements, it was found necessary to raise to its original level 240 ft. of concrete walk which owing to defective earth foundation had sunk 5 or 6 in. on the outside edge. The walk was 12 ft. wide, 4 in. thick, with a mesh reinforcement, and although over 15 years old was still in perfect condition. It was possible that its settlement had been foreseen by the constructors, as 5-in. "I" beams had been placed cross-wise underneath it, at intervals of 8 ft.

In order to make room for a granite curb, the "I" beams which projected beyond the edge of the walk, were cut by hand with a hack-saw. The labor cost of cutting these I-beams was 48 ct. each. A concrete pier (see sketch) was placed under the outside edge of the walk after it had been raised to its original position. Twelve jacks were used for the work. The costs follow:

Labor—	
Foreman, 3 days @ $4	$12.00
Labor raising walk, 112 hr. @ 30 cts	33.60
Labor concreting, 56 hr. @ 30 cts	16.80
Labor cutting "I" beams (30), 48 hr. @ 30 cts	14.40
Labor on forms, reinforcement, 14 hr. @ 30 cts	4.20
	$81.00
Materials—	
Cement, 16 bbl. @ $2	$32.00
Sand, 6½ cu. yd. @ $1	6.50
Gravel, 13 cu. yd. @ $1.10	14.30
Hack saw (frame and blades)	3.50
Reinforcing steel, 500 lb. @ 3 cts	15.00
Renting jacks	6.00
	$77.30

Cost of Constructing Concrete Combined Curb and Gutter.—Fig. 16 shows the dimensions and mix used in constructing the combined curb and gutter

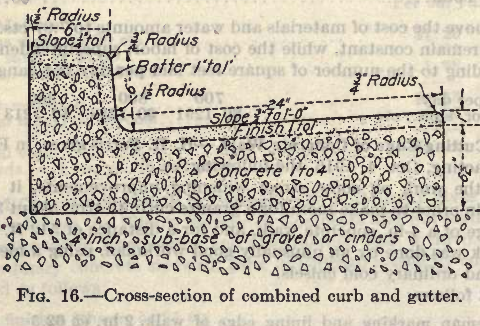

FIG. 16.—Cross-section of combined curb and gutter.

at Webb City, Mo. Costs for typical examples of this type of construction are given by E. W. Robinson in Engineering and Contracting, May 15, 1912, as follows:

The costs given have been compiled from the daily report blanks turned in each day by the city inspectors. It will be noticed that there is considerable variation in the cost of the different items for different jobs, though the totals agree pretty closely. There are several reasons for this. In the first place there was considerable difference in the efficiency of the men and methods employed. Also on this kind of work it is not always economical to have a gang organized so that each man does only one or two things, and such frequent switching of men is hard to follow in trying to keep the time on each operation. In some cases the foreman made a hand wherever the men got behind, in others he did no actual labor. Then the personal equation of the inspector entered in no small degree in the manner of the division of labor on the different items. However the totals give a fair average of the cost of this work in this city for the last two years.

(1) 6-In. Curb and Gutter, 2,959 Lin. Ft.

(Concrete mixed by hand. Good foreman and well organized gang. Includes setting forms, mixing and placing only. Public contract.)

	Cost per lin. ft.
Labor:	
1 foreman, 145½ hours at $0.333	$0.01637
1 finisher, 141½ hours at $0.555	0.02654
2 asst. finishers and mortar mixers, 72 hours at $0.25, 17 hours at $0.222	0.00736
1 mortar mixer, 48½ hours at $0.277	0.00453
3 form setters, 9 hours at $0.277, 100½ hours at $0.25, 147½ hours at $0.222	0.02040
4 concrete mixers, 714 hours at $0.22	0.05357
Total labor	$0.12877
Material:	
Cement, concrete and mortar, 1,445½ sacks at $0.35	$0.17097
Sand, mortar, 484.1 cu. ft. at $0.08	0.01309
Gravel, concrete, 338.4 cu. yds at $0.50	0.05717
Water, 1,838½ cu. ft. at $0.005	0.00311
Total material	$0.24434
Total for labor and material	$0.373

(2) 9-In. Curb and Gutter, 2,089.5 Lin. Ft.

(Concrete mixed by hand. Includes setting forms, mixing and placing only. Work interrupted by rain frequently. Foreman did no actual work. Public contract.)

	Cost per lin. ft.
Labor:	
1 foreman 115½ hours at $0.666	$0.03687
1 finisher, 115½ hours at $0.444	0.02454
1 mortar mixer, 115½ hours at $0.278	0.01535
2 form setters, 226 hours at $0.25	0.02704
5 concrete mixers, 544 hours at $0.222	0.05787
Total for labor	$0.16168
Material:	
Cement, mortar and concrete, 1,114½ sacks at $0.35	$0.18670
Sand, mortar, 361½ cu. ft. at $0.08	0.01384
Gravel, concrete, 240 cu. yds. at $0.50	0.05744
Water, 1,169 cu. ft. at $0.005	0.00280
Total for material	$0.26078
Total for labor and material	0.42247

(3) 9-In. Curb and Gutter, 1,279.2 Lin. Ft.

(Concrete mixed with Coltrin continuous mixer part of time, rest with Eclipse batch mixer. Includes sub-base, setting forms, mixing and placing only. Does not include water and gasoline. Good weather. Public contract. Good foreman, did no actual work.)

Labor:	Cost per lin. ft.
1 foreman, 63 hours at $0.666	$0.0328
2 finishers, 64 hours at $0.444, 40½ hours at $0.278	0.0309
2 form setters, 132 hours at $0.222	0.0233
1 mortar mixer, 62 hours at $0.222	0.0107
1 feeding mixer, 62 hours at $0.222	0.0107
2 off-bearing, 71 hours at $0.222, 5 hours at $0.278	0.0133
2 placing and tamping, 110½ hours at $0.222	0.0192
Total for labor	$0.1409
Material:	
Cement mortar and concrete, 626 sacks at $0.40	$0.1957
Sand, mortar, 217 cu. ft. at $0.08	0.0136
Gravel, concrete and sub-base, 132.3 cu. yds. at $0.50	0.0517
Total for material	$0.2610
Total for material and labor	$0.4019

(4) 9-In. Curb and Gutter, 2,900 Lin. Ft.

(Concrete mixed with Eclipse batch mixer. Includes sub-base, setting forms and mixing and placing, but not water or gasoline. Late fall of year and some work lost because of frost. Well organized gang.)

Labor:	Cost per lin. ft.
1 foreman, 99 hours at $0.666	$0.0228
2 finishers, 95 hours at $0.30, 14 hours at $0.50	0.0123
2 form setters, 198 hours at $0.2333	0.0159
2 mixing and placing mortar, 198 hours at $0.233	0.0159
5 mixer men, 464 hours at $0.222	0.0356
Total for labor	$0.1024
Material:	
Cement, mortar and concrete, 1,291 sacks at $0.40	$0.1767
Sand, mortar, 457½ cu. ft. at $0.07	0.0116
Gravel, concrete, 122 cu. yds. at $0.50	0.0210
Gravel, sub-base, 161.1 cu. yds at $0.50	0.0278
Total for material	$0.2371
Total for labor and material	$0.3395

(5) 4-Ft. Sidewalk, 436 Sq. Ft.

(Concrete mixed by hand. Includes setting forms, mixing and placing only. Foreman was also contractor and finisher. Private contract.)

Labor:	Cost per sq. ft.
1 foreman and finisher, 9 hours at $0.50	$0.0103
4 mixing and placing concrete, 24 hours at $0.222	0.0122
1 mixing and placing mortar, 7 hours at $0.222	0.0036
Total for labor	$0.0261
Material:	
Cement, mortar and concrete, 33 sacks at $0.35	$0.0265
Sand, mortar, 25 cu. ft. at $0.08	0.0046
Water, 6 bbls. at $0.10	0.0014
Gravel, concrete, 4 cu. yds. at $0.50	0.0046
Total for material	$0.0371
Total for material and labor	$0.0633

(6) 4-Ft. Sidewalk, 4,934 Sq. Ft.

(Concrete mixed by hand. Includes setting forms, mixing and placing only. Foreman did some finishing, but was attending to other business most of time. Otherwise gang was efficient. Lost 50 ft. of finish by rain. Public contract.)

Labor:	Cost per sq. ft.
1 foreman and finisher, 42 hours at $0.555	$0.0047
1 finisher, 17¼ hours at $0.444	0.0015
3 mixing and placing mortar, 107 hours at $0.222	0.0048
4 mixing concrete, 151¾ hours at $0.222	0.0068
2 placing concrete, 82 hours at $0.25	0.0042
2 setting forms, 58 hours at $0.222	0.0027
Total for labor	$0.0247
Material:	
Cement, concrete and mortar, 414 sacks at $0.40	$0.0336
Sand, mortar, 444 cu. ft. at $0.08	0.0072
Gravel, concrete, 49.6 cu. yds. at $0.50	0.0050
Water, 9 tanks at $0.50	0.0009
Total for material	$0.0467
Total for material and labor	$0.0714

(7) 4-Ft. Sidewalk, 12,504 Sq. Ft.

(Concrete mixed with Coltrin continuous mixer. Includes setting forms, mixing and placing only, but not gasoline. Efficient gang. Foreman was member of firm and helped at all times; 50 lin. ft. lost by rain. Public contract.)

Labor:	Cost per sq. ft.
1 foreman, 18 days at $5.00	$0.0072
2 finishers, 105¼ hours at $0.555, 45 hours at $0.333	0.0059
2 mixing and placing mortar, 262 hours at $0.222	0.0047
4 mixer men, 505½ hours at $0.222	0.0090
1 water boy, 94 hours at $0.111	0.0008
Total for labor	$0.0275
Material:	
Cement, concrete and mortar, 853 sacks at $0.40	$0.0273
Gravel, concrete, 113 cu. yds. at $0.50	0.0045
Sand, finish, 853 cu. ft. at $0.08	0.0053
Water, 152 bbls. at $0.10	0.0012
Total for material	$0.0384
Total for labor and material	$0.0659

(8) 4-Ft. Sidewalk, 9,566.7 Sq. Ft.

(Concrete mixed with a Coltrin continuous mixer. Includes setting forms, mixing and placing only. Does not include water and gasoline. Fairly efficient gang. Foreman did no actual work but was a hustler. Was also the contractor. Public contract.)

Labor:	Cost per sq. ft.
1 foreman, 54½ hours at $0.666	$0.0038
1 finisher, 63½ hours at $0.444	0.0030
2 mixing mortar, 104 hours at $0.222	0.0024
2 feeding mixer, 109 hours at $0.222	0.0025
2 wheeling mortar and concrete, 125 hours at $0.222	0.0029
2 placing concrete and mortar, 119 hours at $0.222	0.0028
Total for labor	$0.0174
Material:	
Cement, concrete and mortar, 748 sacks at $0.40	$0.0313
Sand, mortar, 467 cu. ft. at $0.08	0.0039
Gravel, concrete, 97 cu. yds. at $0.50	0.0051
Total for material	$0.0403
Total for labor and material	$0.0577

Cost of Laying Granite Curb.—Engineering and Contracting, June 5, 1918, gives the following:

Granite for the 5108 ft. of curb was delivered on the work, in blocks from 5 to 8 ft. long, of the dimensions shown on the sketch. The stones were bedded in 1:3:5 concrete as required by the specifications, laid to a true line and grade, and joints exceeding ¼ in. were not permitted.

A good working foreman, with an indifferent Italian crew, performed the work. Stones were placed entirely by hand, with the aid of crow-bars, jacks, etc. The contractor thinks it probable that considerable economy might have been effected by using a small portable derrick.

The costs follow:

	Per lin. ft.
Curb, setter, 307 hours at 50 cts	$0.030
Helper, 307 hours at 40 cts	.024
Labor, 1,850 hours at 30 cts	.108
Total	$0.162

A snatch team was used at odd times for moving around stones which had not been conveniently distributed. This cost is not included in the figures given above.

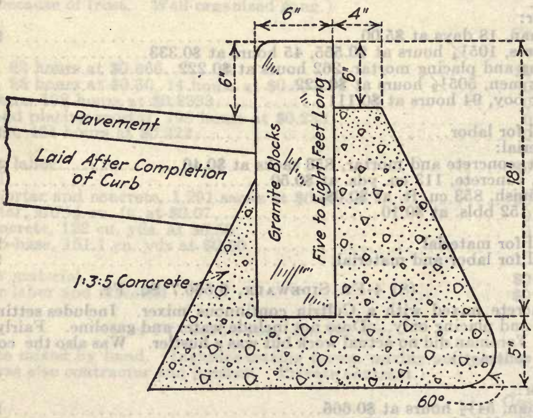

FIG. 17.—Sketch showing dimensions of granite curb.

Labor Costs of Laying Curved Granite Curbs at Street Intersections.—H. R. Ferris gives the following data in Engineering and Contracting, Jan. 3, 1917.

The costs cover the labor of laying 44 returns (630 lin. ft.) of curved granite curb at 11 street intersections. The stones were 20 in. deep, 6 in. wide at top and dressed for 5 in. on the face. At the bottom they were generally 7 or 8 in. wide. Each piece came in lengths varying from 4 to 7 ft. and were conveniently delivered within a few feet of their final location. The bottom 12 in. of the curb were imbedded in 1:3:6 concrete.

The work was done by an energetic and competent curb-setter and helper who handled their part of the work well. The common labor, which included the excavation of the trench, moving stones, mixing concrete, etc., was very inefficient, however, and probably 35 per cent of this cost could have been saved with first class laborers.

The curbs were laid under strict inspection. No joints over ¼ in. were allowed, and the bottom of all curbs had a true setting bed in order to "secure a uniform depth throughout." The workmen were required to set the stones so that they would be "free of depressions and wind, and true to line and grade." The stones were set to a 9-ft. radius.

The labor costs follow:

Cost of Laying 630 Lin. Ft. Of Curved Granite Curb

Curb setter, 84 hours @ 40c	$ 33.60
Helper, 56 hours @ 35c	19.60
Labor, 342 hours @ 25c	85.50
	$138.70
Total cost per lin. ft. of labor	22 cts.

Cost of a Cobble Lined Gutter, California.—E. Earl Glass gives the following in Engineering and Contracting, June 6, 1917.

To prevent cutting by storm water, the Los Angeles County Road Department recently constructed a cobble lined gutter on each side of a steep hillside road. The adjoining property owners furnished the cobbles and gravel, which they hauled from a nearby stream bed.

The gutter (3 ft. wide and 7 ins. deep at center) was roughed out with plow and slips and shaped with shovels. The soil being a very sandy silt furnished an excellent bed for the stones. Excepting the team work on rough grading, all the work was done by three laborers with part of the time of a road foreman.

The best stones for this work are hard, clean, stream cobbles, about 6-in. × 10-in. faces and 4 or 5 in. thick. Cobbles are often laid vertically or at a slight angle as on street pavements, but we laid this work flat, thus effecting a great saving in time and material, and getting practically the same results.

After 400 ft. of gutter had been laid, one of the men would go back and wet the gutter until water showed between the stones. He then tamped every stone with a sledge. He mixed half-bag batches of coarse mortar (1:3:5) in a mortar box and shoveled the soupy grout onto the wet stones. Another laborer swept the mortar along with a street broom, filling all voids between the stones with the concrete and leaving the gutter section smooth but showing all rock faces. As soon as the mortar was sufficiently set, an inch depth of earth was spread over the finished gutter and kept damp for a week.

At all driveways and in front of residences where a deep, open gutter would be objectionable, the property owners provided 14-in. concrete pipe which were laid in shallow trenches with open joints. The gutter was flared to connect with these pipe culverts, providing substantial and artistic head walls, with generous capacity for entry and delivery of a full stream of storm water.

The cost of the improvement was as follows:

	Pipe	Gutter	Total
Length, ft.	224	4,656	4,880
Excavating and backfilling	$ 16.50	$218.75	$235.25
224 lin. ft. of 14-in. concrete irrigation pipe @ 33 ct. delivered	74.00	....	74.00
30 tons (25 cu. yd.) of bank gravel for grouting	....	8.00	8.00
367 tons of clean, granite cobbles for paving gutter	....	103.00	103.00
Laying stone for pipe end walls and paving gutter	17.50	243.50	261.00
Grouting end walls and gutter	4.50	60.70	65.20
Cement for end walls and gutter, 28½ bbl. @ $2.00	3.50	53.50	57.00
Supervision	18.00	87.00	105.00
Total	$134.00	$774.45	$908.45
Total cost per lin. ft.	$ 0.60	$ 0.166	$ 0.186
Total cost per sq. ft. of paved surface	....	$ 0.04¾	....

Note—Labor, $2.50 per 8-hour day.

Twenty-three yards of 1:3:5 concrete were used in grouting, which is a rate of 0.14 cu. yd. per 100 sq. ft. of cobble-gutter surface. Labor only for laying and grouting (no grading) was $6.60 per 100 lin. ft., or the three men finish 114 lin. ft. per day, exclusive of excavation.

CHAPTER XVI

HIGHWAY BRIDGES AND CULVERTS

This chapter contains costs and other economic data relative to constructing highway bridges. In the following chapter other data will be found which may also prove of value in connection with highway bridge construction. Many data on this subject are also given in the voluminous section on bridges in Gillette's "Handbook of Cost Data."

Economic Highway Bridges and Culverts.—The following is taken from an abstract, published in Engineering and Contracting, July 28, 1920, of a paper presented at the Canadian Good Roads Convention at Winnipeg, June, 1920, by M. A. Lyons.

In selecting the type of structure three factors will influence this choice, viz., economy, service and appearance, and of these the first two will generally, but not always rightly, be the deciding factors. It is impossible to estimate the value of the æsthetic in design, and, as this value cannot be expressed in concrete symbols, it is frequently not understood, and, consequently, beauty of appearance is not given full value in deciding on the type of structure. It is a question as to how much additional money should be spent in order to achieve a pleasing appearance. The cost of a bridge is, however, soon forgotten, but an unsightly bridge cannot be forgotten, for it remains as a constant unpleasant jar on the senses.

Comparative Costs of Timber, Steel and Concrete Bridges.—In selecting the most economical type of bridge, first-cost upkeep and value of non-interruption of traffic must be considered. The timber structure is in about every case the cheapest in first cost, but in the long run it does not generally prove to be as cheap as steel or concrete. A wooden pile bridge, if suitable for the site, is no doubt the cheapest bridge in direct cost.

For example, a 50-ft. pile bridge will cost today about $1,500. Allowing 6 per cent interest, a yearly payment of $270 would be required to keep this bridge in condition, made up as follows: Flooring to be renewed every 3 years, first cost $270, yearly payment for 3 years $101; stringers to be renewed every 6 years, first cost $270, yearly payment $55; remainder of bridge to last 12 years, first cost $960, yearly payment $114; total yearly cost $270. Indirect costs, such as delay to traffic during repairs, loss of traffic through neglect of repairs, liability to accident or fire may run the total cost far beyond the direct costs. At best, the pile bridge is very unsightly and only to be considered where first costs are of prime importance, as they sometimes are.

In many cases stream conditions are such that it is not permissible to have piles in the stream bed and a clear opening of long span is required. The type of structure may then be a choice between a wooden span, a steel span or a concrete span. Unless the wooden span is to be placed on piles, which, in many cases, is not feasible, the cost of the substructure for the three types will be about the same, so that it will only be necessary to compare the relative costs of the superstructure. Again selecting a 50-ft. span for comparison, and assuming wooden flooring to be renewed every three years, wooden stringers to be renewed every six years, painting wood and steel to be carried out every four years, the life of concrete and steel to be over 30 years and the life of a wooden truss to be over 15 years, we have the following relative costs:

FIRST COSTS

Wooden Truss—	
12,400 ft. B. M. timber at $100 per M	$1,240
3,000 lb. steel at 15 cts. per lb	450
Painting	250
	$1,940
Steel Bridge—	
17.6 tons steel at $220	$2,772
4,600 ft. B. M. timber at $80 per M	368
	$3,140
Concrete Bowstring—	
68 cu. yd. concrete at $35 per cu. yd	$2,380
11,600 lb. steel at 10 cts. per lb	1,160
1,850 sq. ft. mesh at 20 cts. per sq. ft	370
1,000 lb. structural steel (bearings, etc.), 20 cts. per lb	200
Crosby clips and handrail	200
	$4,310

YEARLY COSTS

Wooden Truss—	
Flooring 2,800 ft. B. M. at $80, cost $224, yearly payment based on 3-year life	$ 84
Stringers, 3,200 ft. B. M. at $80, cost $256, yearly payment based on 6-year life	54
Remainder of bridge $1,210, yearly payment based on 15-year life	125
Yearly cost of painting every 4 years	72
Total yearly cost	$ 335
Steel Truss—	
Timber, 4,670 ft. B. M. at $80, cost $374, yearly payment based on 3-year life	$ 140
Yearly payment on steel truss for 30 years (cost $2,772)	201
Yearly cost of painting every four years	36
Total	$ 377
Concrete Bridge—	
Yearly payments on concrete bridge for 30 years (cost $4,310)	$ 311

It thus appears that the concrete superstructure, for spans of this length at least, is cheaper than either wood or steel. It must also be noted, in the case of steel and concrete bridges, that at the end of 30 years the bridge is paid for and the yearly payments cease (except for the repairs on the steel bridge), while in the case of the wooden bridge the yearly payments still go on.

Every Bridge a Problem in Itself.—For bridges of any size it is impossible to make any general statement that one class of bridge is cheaper than another, as every bridge is a problem in itself, and the foregoing is given as an example of a method of obtaining relative costs. The question of the nature of the foundations, cross-section of the stream-bed, condition of stream flow, waterway required, availability of materials, relative cost of materials, relative costs and availability of labor, relative cost of substructure to the superstructure, ice conditions and economical and suitable length of span must be taken into account when deciding which is the economical bridge.

Wooden bridges are confined chiefly to two types, the pile trestle and the Howe truss. For steel bridges of clear span of 30 ft. or under, simple stringer spans are cheapest; from 30 ft. to about 45 or 50 ft., plate girders; from 50 ft. to 80 or 90 ft., low or pony trusses; 400 or 500 ft., trusses with subdivided panels; beyond this, cantilever or suspension bridges, with steel arches, coming in any place in the list.

Every concrete bridge is a study in itself. In Manitoba there have been constructed, or are under way, slab and girder bridges up to 30-ft. span, through girders up to 50-ft. span, barrel arches up to 100-ft. span, open-spandrel arches up to 60-ft. span, through arch or rainbow type up to 90-ft. span and bowstrings up to 90-ft. span. These are, however, only given as an example of different types of concrete bridges.

Culverts, Types and Costs.—Coming to the small but important culverts, there are, in general, four types in common use: First, wooden culverts; second, steel or iron culverts; third, concrete pipes; and fourth, concrete culverts cast in place. The wooden culvert is undoubtedly the cheapest, but the objection to this is that it is out of commission or unsafe about most of the time. In point of cost, concrete pipe culverts come next. These, however, must be placed where no water will freeze in or around them, and they must have a good, solid bed. Considerable saving has been effected in Manitoba by the use of concrete pipe, and the results have been quite satisfactory. The cost of manufacture last year ran about as follows:

	Per lin. ft.
10-in. diameter	36 cts.
12-in. diameter	45 cts.
15-in. diameter	50 cts.
18-in. diameter	83 cts.
24-in. diameter	$1.22
30-in. diameter	1.75

The breakage in handling ran about 1 per cent.

Corrugated steel or iron pipes have been used extensively where lack of suitable materials or labor prevent the making of concrete pipes. These can be laid in places where it would not be suitable to lay concrete pipes. We have also used semi-circular reinforced culverts cast in place with success. These cost about the same as the corrugated iron pipes. We seldom use pipe culverts of over 30-in. or 36-in. diameter. Above that we advocate reinforced concrete box culverts.

Diagrams for Estimating Materials Required for Standard Steel and Concrete Spans of the Illinois Highway Department.—The following is given by G. F. Burch in Illinois Highways, June, 1915, abstracted in Engineering Record, July 7, 1915.

These diagrams give the weight of steel and the amount of concrete in steel truss spans from 50 to 160 ft. long, with a 4-in. concrete floor, in reinforced-concrete girder spans from 30 to 60 ft. long, and in reinforced-concrete slabs from 5 to 30 ft. long. In addition curves are given for the amount of concrete in the abutments, both plain and reinforced.

Material in Superstructures.—The steel trusses are of the ordinary Pratt truss type with parallel chords and riveted connections. The design provides for a 4-in. concrete floor, with a wearing surface assumed to weigh not less than 50 lb. per square foot. On account of the weight and rigidity of the concrete floor no allowance is made for impact. Floor systems are designed to carry a 15-ton traction engine in addition to the dead load. Trusses are designed to carry a uniform load of 100 lb. per square foot of road surface for spans from 50 to 150 ft., and a uniform load of 85 lb. for spans exceeding 150 ft. long. The usual A. R. E. A. unit stresses are used in the design. Pony trusses are used for spans of from 50 to 85 ft., and through trusses for spans of from 90 to 160 ft.

Reinforced-concrete through girders are used for spans of from 30 to 60 ft. This type of structure is designed to carry either a uniform load of 125 lb. per square foot, or an engine load of 24 tons.

Plain Concrete Abutments.—In preparing curves to show the quantities in abutments it was found that there were many variables which might be con-

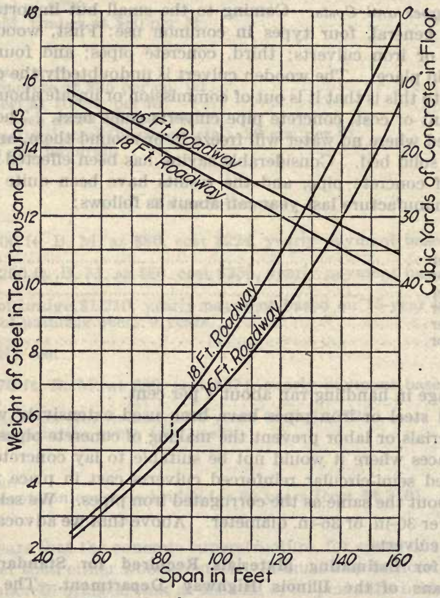

FIG. 1.—Steel truss superstructures.

sidered, but which if used would produce such complex formulas as to make the curves of little use in the field. It was found that curves giving reliable results might be obtained by plotting the cubic yards of concrete in two abutments against a formula which represented a measure of the quantities desired. The variables in this formula are H, height of abutment from bottom of foundation to top of roadway; R, clear width of roadway on superstructure, and W, length of average wing wall. For plain concrete abutments the best results were obtained by using the term $H^2 (R + 2W)$.

Plain concrete abutments for steel bridges are designed with a footing width of one-third of the height over all, and the thickness of the footing is usually from 18 to 24 in. The width of the base of the abutment and wing walls at the top of the footing is made approximately one-quarter of the height of the walls. The back of the abutment wall is vertical and the face of the wall is battered to a top width of from 30 to 38 in. The wing walls are battered on both sides and have a top width of 12 in. Fig. 4 shows the curves from which the yardage of plain concrete abutments for steel bridges may be obtained. When field measurements are made to determine the necessary height of abutments, and the width of roadway is decided upon, it is easy to estimate the length of wing walls which will be required. These figures are then used in the formula and the yardage of concrete is read directly from the curve.

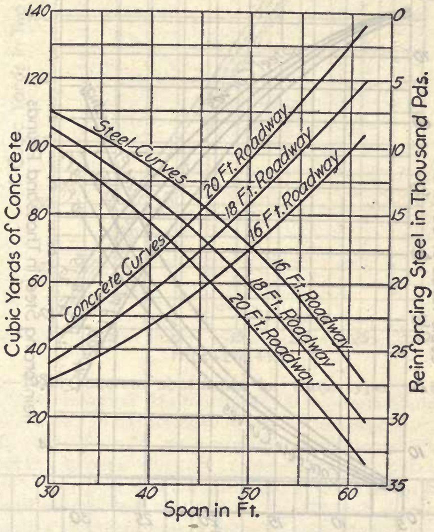

FIG. 2.—Reinforced concrete through girder superstructures.

The design of plain concrete abutments for girder bridges is similar to the design for steel bridges, except that the wing walls are battered on the face side only, and the top width of the abutment wall is 18 in. Plain concrete abutments for slab bridges differ slightly from the preceding design. The width of footing on the abutment wall is limited only by the safe bearing capacity of the soil, with a minimum of 3 ft. This width may sometimes be less than one-third.

Curves for Estimating Steel Bridge Quantities.—Engineering and Contracting, April 25, 1917, abstracts the curves shown as Figs. 5 and 6 from a Bridge Manual prepared under the direction of John H. Lewis, State Engineer of Oregon, for the State Highway Commission. They are intended for handy reference, to determine within reasonable limits the approximate quantities or weights of the materials which enter into the construction of the types of bridges for which the curves were prepared.

The diagrams are based on through Pratt bridges, designed according to the standards of the Oregon State Highway Department for the loadings given.

They are in no way intended as a substitute for careful estimating when the question of any crossing enters the contract and construction stage. The final estimates should always be made up on accurate plans and details worked out for the particular bridge in question to cover any special conditions.

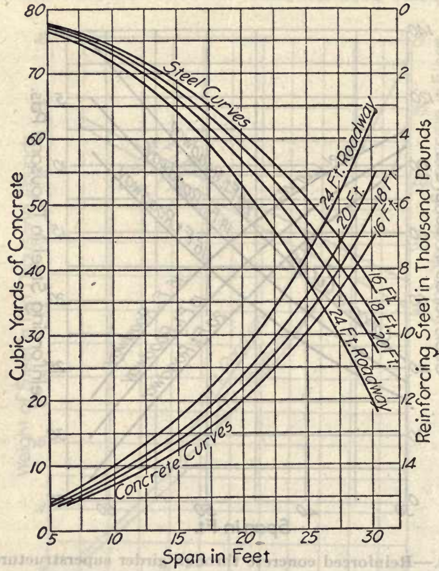

FIG. 3.—Reinforced concrete slab superstructures.

Men in the field, however, are often called upon to prepare an estimate on short notice upon which definite construction programs may be authorized without further delay. After the quantities of materials are obtained, prices and labor costs can be judged in the field on the basis of local conditions, perhaps better than anywhere else, and the rough estimate be made up in a short time.

The curves give the weight of steel in both medium and heavy traffic bridges of spans ranging from 60 to 260 ft.

The bridges are of the pony or low truss type, from 60 to 90 ft., and through Pratt trusses from 100 to 260 ft.

Roadways are taken at 16 ft.

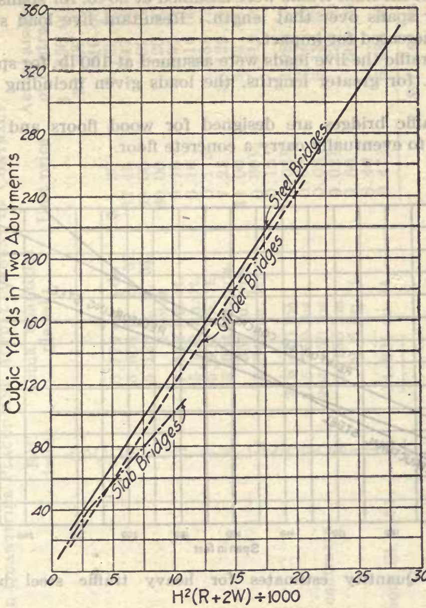

FIG. 4.—Plain concrete abutments for three types of bridges.

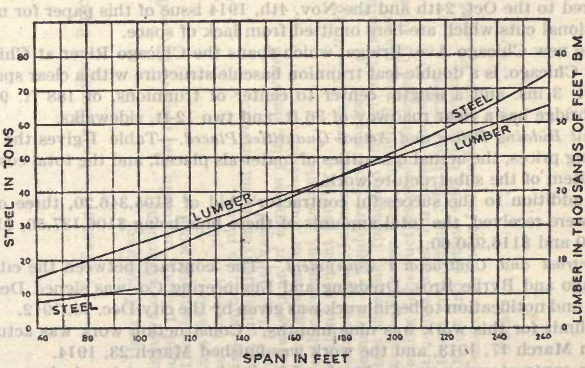

FIG. 5.—Quantity estimates for medium traffic steel bridges.

Live loads for medium traffic were assumed at 60 lb. for spans up to 150 ft., and 50 lb. for spans over that length. Resultant live load stresses in the trusses were increased for impact.

For heavy traffic the live loads were assumed at 100 lb. for spans up to 150 ft., and 75 lb. for greater lengths, the loads given including provision for impact.

Medium traffic bridges are designed for wood floors and joists: heavy traffic bridges to eventually carry a concrete floor.

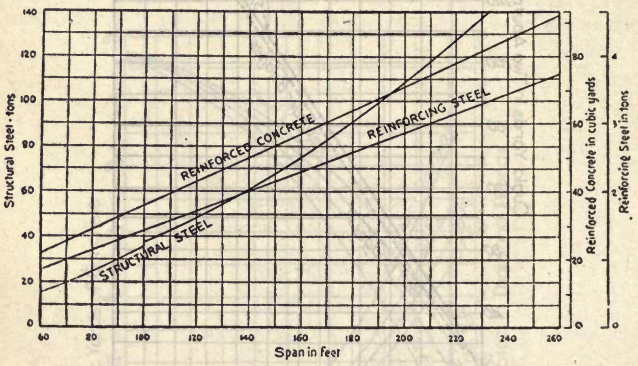

Fig. 6.—Quantity estimates for heavy traffic steel bridges.

Costs of Substructure of the Double-Leaf Trunnion Bascule Bridge at Chicago Ave., Chicago, Ill.—Carl O. Johnson gives the following detailed labor costs in Engineering and Contracting, Nov. 4, 1914. The reader is referred to the Oct. 24th and the Nov. 4th, 1914 issue of this paper for many additional cuts which are here omitted from lack of space.

The new Chicago Ave. Bridge, which spans the Chicago River at Chicago Ave., Chicago, is a double-leaf trunnion bascule structure with a clear span of 161 ft. 3 ins. and a length, center to center of trunnions, of 188 ft. 9 ins. The bridge has a clear roadway of 36 ft. and two 12-ft. sidewalks.

Unit Bidding Prices and Actual Quantities Placed.—Table I gives the unit bidding prices, the actual quantities of materials placed, and the total costs of each item of the substructure work.

In addition to the successful contractor's bid of $105,346.20, three other bids were received, the total amounts of these bids being $106,137.50, $107,-100.00 and $116,950.00.

Contract and Contractor's Equipment.—The contract between the city of Chicago and Byrne Bros. Dredging and Engineering Co. was signed Dec. 2, 1912, and notification to begin work was given by the city Dec. 13, 1912. The time limit for this work was nine months. Construction work was actually begun March 17, 1913, and the work was finished March 23, 1914.

The contractor was required to furnish all labor, material and plant necessary for the construction work, and was made responsible for all damages due

TABLE I.—UNIT BIDDING PRICES, ACTUAL QUANTITIES PLACED AND ACTUAL AMOUNT OF CONTRACT

Item of contract	Ref. letter	Actual quantities placed	Unit price	Actual amount of contract
Remove obstructions	A	....	....	$ 650.00
Build, protect, maintain and remove two cofferdams	B	....	....	22,300.00
Miscellaneous work	C	....	....	910.00
Excavation	D	6,774 cu. yds.	$ 1.29	8,738.46
Oak timber, in place	E	5,564 ft. B. M.	62.40	347.19
Pine timber, in place	F	5,128 ft. B. M.	39.00	199.99
Test piles, delivered and driven	G	4 piles	30.00	120.00
Oak piles, delivered	H	7,182 lin. ft.	0.18	1,292.76
Norway pine or cypress piles, delivered	I	5,100 lin. ft.	0.16	816.00
Driving piles for foundation	J	9,902 lin. ft.	0.115	1,138.73
Portland cement concrete	K	3,604 cu. yds.	7.25	26,129.00
Portland cement mortar	L	357 cu. yds.	11.00	3,927.00
Concrete shaft foundation, from El. —20 to El. —45	M	18,648 cu. ft.	0.39½	7,319.34
Removal of boulders from shafts	N	....	0.12	....
Steel sheeting, furnished and driven in shafts	O	279.470 lbs.	0.02½	6,986.75
Steel reinforcing bars, furnished and placed	P	145,710 lbs.	0.02	2,914.20
Setting substructure steel, furnished by superstructure contractor	Q	204,550 lbs.	0.03	6,136.50
Structural steel, furnished and set	R	9,136 lbs.	0.02½	228.40
Divert and extend 5-ft. brick sewer	S	69.6 lin. ft.	9.60	668.16
Divert and extend 4-ft. brick sewer	T	....	8.40	....
Concrete cylinder foundation, from El. —45 to rock, about El. —81.	U	14,601 cu. ft.	0.47½	6,935.48
Total	..	....	....	$97,757.96

to the construction of the substructure. The construction plant consisted of the following equipment:

One 6-cu. yd. "Marion" dipper dredge.
Two dump scows, 500-cu. yd. capacity each.
Two dump scows, 250-cu. yds. capacity each.
One derrick scow equipped with a 12-in. sand pump.
Two deck scows.
One floating pile driver.
One shore pile driver.
One stiff-leg derrick with 40-ft. wood mast and 80-ft. boom.
One stiff-leg derrick with 40-ft. steel mast and 90-ft. boom.
One 22-HP. hoisting engine.
One 30-HP. hoisting engine.
One 80-HP. locomotive firebox boiler.
One ½-in. cu. yd. concrete mixer.
Three 8-in. centrifugal pumps.
One 6-in. submerged centrifugal pump.
One 4-in. piston pump.

Rates of Wage and Division of Labor.—The following rates of wages were paid the rates being regulated principally by agreement with the labor unions:

Superintendent, $200 per month.
Timekeepers, from $1.50 to $3.75 per day; average rate, 35.9 cts. per hour.
Watchman, $2.50 per day.
Hoisting engineers, 75 to 80 cts. per hour; average rate, 76.2 cts. per hour.
Firemen, 46 cts. per hour.
Winchmen, 52½ cts. per hour.
Signalmen, from 40 to 50 cts. per hour; average rate, 45½ cts. per hour.
Carpenter foremen, 75 cts. per hour.
Carpenters, 65 cts. per hour.
Carpenters' helpers, 48 cts. per hour.
Labor foremen, from $4.50 to $7.00 per day; average rate, 58.2 cts. per hour.
Laborers, from 25 to 60 cts. per hour; average rate, 44.2 cts. per hour.
Iron worker foreman, $1.14 per hour.
Iron worker straw boss, 93¾ cts. per hour.
Iron workers, 68 cts. per hour.
Machinists, 65 cts. per hour.
Sewer brick layers, $11.00 per 8-hour day.
Pile driver crew, 10 men at 8 hours each, $43.76 per day (ordinary work).
Pile driver crew, 10 men at 8 hours each, $53.08 per day (driving steel sheeting)
Dredge crew, 7 men at 12 hours each, $33.00 per day.
Dredge crew, 10 men at 12 hours each, $38.46 per day.
Derrick scow engineer, 75 cts. per hour.
Derrick scow fireman, 30 cts. per hour.

A day, or shift, was 8 hours. The superintendent, timekeepers, and labor foremen worked 8 to 12-hour shifts. The average rate of wage for all classes of labor for the entire job was 53 cts. per hour.

Table II gives the division of labor on the work, classified both as to time and cost.

TABLE II.—DIVISION OF LABOR ON JOB

Kind of labor.	Percentage of total hours worked	Percentage of total cost of work
Superintendent, timekeeper, watchman, etc.	8.5	8.2
Engineers and firemen	12.4	15.7
Carpenters	10.6	13.2
Laborers	50.5	43.4
Iron workers	0.8	1.2
Machinists	0.1	0.1
Bricklayers	0.1	0.2
Pile driver crew	14.4	16.2
Dredge crew	2.4	1.7
Derrick scow crew	0.2	0.1
Total labor	100.0	100.0

Time and Cost Data for Various Labor Items.—In all the cost data given in this article, only *actual job labor costs* have been considered. No charge has been made for tug service, plant rental or depreciation, interest, or central office overhead charges, etc.

Tables III to IX, inclusive, contain accounts which were prorated among the contract items as shown. These tabular data give essential information on the cost and the time required to complete various parts of the work.

The average rate for the work indicated in Table III was 54 cts. per hour. The items given in Table III were prorated among all items where the pile driver crew was used according to the number of hours worked, as follows:

Item	Total hours	Total cost
Cofferdams	875	$ 474.00
Steel sheeting for concrete caissons	454	245.00
Miscellaneous	41	22.30
Pine timber	41	22.30
Oak timber	11	4.66
Test piles	11	4.55
Pile driving for foundation	289	156.00
Removal	247	137.00
To Table VIII	82	44.60
To Table IX	11	4.55
Total	2,062	$1,114.86

TABLE III.—PILE DRIVING EQUIPMENT

Item	Total hours	Total cost
Rigging floating pile driver No. 1	60	$ 32.86
Unloading and erecting shore pile driver No. 2	193	109.37
Rigging and erecting shore pile driver No. 3	730	360.89
Removing wrecked pile driver	164	90.98
Rebuilding shore pile driver	535.5	313.15
Removing steam hammer for another job	11.5	7.51
Wrecking old pile driver	112	56.86
Repairing pile driver scow	216	121.36
Storing pile driver	40	21.88
Total	2,062	$1,114.86

Unloading the steel cofferdam sheeting, the steel caisson sheeting and the reinforcing bars for the concrete work, hauling this material from the cars to the scow, towing the same about 1,500 ft., and unloading the material on the docks required 344 hours, at a cost of $171.50, the average rate of wage for this work being 50 cts. per hour. These items were prorated according to the amount of steel used for the various parts of the work as given in Table IV.

TABLE IV.—HANDLING STEEL

Item	Total hours	Total cost
Cofferdams	189	$ 94.41
Steel caisson sheeting	100	49.70
Reinforcing bars	55	27.40
Total	344	$171.51

Unloading coal for the plant on the west side of the Chicago River required 64½ hours, at a total cost of $28.57, the average rate of wage being 45 cts. per hour. This item was prorated as given in Table V.

TABLE V.—HANDLING COAL

Item	Total hours	Total cost
Pumping water from cofferdam	58	$25.71
Excavation	6½	2.86
Total	64½	$28.57

The cost and the time required to sort the old lumber used in the cofferdams are given in Table VI. The average rate of wage for this work was 47 cts. per hour, and the work was prorated 50 per cent to each cofferdam.

TABLE VI.—SORTING LUMBER

Item	Total hours	Total cost
Sorting lumber	281½	$131.42

The time and cost data on the labor which may be classified as superintendence is given in Table VII. This item includes the work of the superintendent, timekeepers, watchman and the unclassified time of the carpenter and labor foremen. It amounts to 12.1 per cent of the net pay roll, the average rate of wage being 53 cts. per hour.

TABLE VII.—SUPERINTENDENCE

Item	Total hours	Total cost
Superintendence	9,612	$5,010.01

Table VIII gives the cost and the number of hours worked on items pertaining to the work of the derricks.

TABLE VIII.—WORK PERTAINING TO DERRICKS

Item	Total hours	Tota cost
Clearing space for west plant	47	$ 18.80
Driving five 28-ft. piles for derrick foundation	85	46.50
Framing west derrick, 40-ft. mast, 80-ft. boom	40	26.00
Rigging and erecting west derrick	195½	106.91
Housing boilers	371½	189.84
Wrecking west derrick and plant	114	57.82
Cleaning up site of plant	30	12.00
Prorated amount from Table III	55	29.74
Total (average rate of wage, 52 cts. per hour)	938	$ 487.61
Driving three 45-ft. and two 30-ft. piles for foundation of east derrick	40	$ 21.88
Cutting and framing bent to above piles	12	7.80
Building crib for foundation of derrick sill	36	14.40
Rigging and erecting east derrick, 40-ft. mast. 90-ft. boom	291	153.91
General work on east plant	1,094½	628.49
Prorated amount from Table III	27	14.86
Total (average rate of wage, 56 cts. per hour)	1,500½	$ 841.34
Unloading east and west plants	74	$ 33.35
General work on east and west plants	154	92.92
Total (average rate of wage, 55 cts. per hour)	226	$ 126.27
Grand total	2,666½	$1,455.22

As the items given in Table VIII were charged principally to the derrick plant, they were prorated among the contract items according to the "derrick engineer" hours charged against these items, as follows:

Item	Total hours	Total cost
Cofferdams	320	$ 174.57
Miscellaneous	160	87.34
Excavation	480	260.12
Concrete	586½	320.04
Mortar	134	73.78
Caissons above El. —45	320	174.57
Caissons below El. —45	533	291.02
Setting substructure steel	133	73.78
Total	2,666½	$1,455.22

The cost and the time charged to the concrete plant are given in Table IX.

TABLE IX.—CONCRETE PLANT

Item	Total hours	Total cost
Loading and unloading sand scow	357½	$ 151.00
Placing protection over east pit floor	8	3.60
Cleaning rubbish and concrete from east pit floor	144	73.40
Clearing space for east concrete mixing plant	20	8.15
Erecting east concrete mixer and 85½-ft. tower for same, using 4,454 ft. B. M. lumber	965	549.89
Handling concrete chutes	270	139.53
Removing east concrete mixing plant	100	50.00
Removing east concrete tower	62	32.55
Prorated amount from Table III	11	4.55
Unloading stone scows	332	144.98
Clearing storage space for sand and stone on west side of river	37	14.80
Setting west concrete mixer and running water pipe line	72½	43.24
Resetting concrete mixer in second position	138	70.08
Resetting concrete mixer in third position	141	74.22
Changing concrete chute to west side	93	45.20
Removing west concrete mixing plant	25	10.00
Building and removing platform for stone storage on west side	332	144.98
Unloading stone from canal boats on west side	373	191.50
Clearing rubbish and concrete from west pit, etc	438½	207.33
General repairs to concrete plant	270½	122.72
Miscellaneous, moving of cement	153	69.19
Total (average rate of wage, 50 cts. per hour)	4,182	$2,117.03

The items given in Table IX were charged against "concrete" items, as follows:

Item	Total hours	Total cost
Concrete	3,027.35	$1,532.44
Mortar	243.33	123.10
Concrete caisson foundations between El.—20 and El.—45	501.97	254.25
Concrete caisson foundations below El. —45	409.35	207.24

Discussion of Construction and Cost Data and Unit Costs.—A description of the work done under each subdivision of the contract, together with a discussion of the cost data will now be given. Each item is referred to by the reference letter given in the specifications and shown in Table I.

"*A*"—*Removal of Obstructions*.—This item included all work done in removing obstructions which interfered with the construction of the substructure. The work consisted principally of removing a rubble masonry pier containing 103 cu. yds., timber and pile approaches, parts of brick sewers, and concrete walks. The lump sum bid for this work was $650. The construction plant used consisted of a pile driver, a derrick scow and a deck scow. The actual labor costs for this work were divided as follows:

Item	Total hours	Total cost
Removal of timbers, piles, etc	1,733	$ 831.38
Removal of stone, brick, concrete	748	282.05
Prorated charge	247	137.00
Total	2,728	$1,250.43
Superintendence, etc., 12.1 per cent	330.1	151.30
Grand total	3,058.1	$1,401.73

Average labor cost, 46 cts. per hour.

"B"—Cofferdams.—The cofferdams, which were of the single-wall type, were built of steel and wooden sheeting, and entirely enclosed the main piers and small walls. The lump sum for building, maintaining, protecting and removing the two cofferdams was $22,300.

The west cofferdam had maximum dimensions of 86.7 ft. by 55.3 ft., enclosing an area of 4,424 sq. ft. The maximum depth of water outside of this dam was 19.9 ft.

The east cofferdam had maximum dimensions of 91.9 ft. by 56.3 ft., inclosing an area of 4,655 sq. ft. The maximum depth of water outside of this dam was 20.9 ft.

The excavation (all soft clay) was carried down to a general elevation of −20.0 (the river being at elevation about +0.8), from which depth four caissons were sunk to bed rock, which lies at an average elevation of −81.1. The sites of the cofferdams were first cleared with dipper dredges, the west cofferdam being dredged from an original *average* depth of 2.3 ft. to an *average* depth of 10.7 ft., and the east cofferdam, from an *average* depth of 4.3 ft. to an *average* depth of 11.7 ft. The excavated material was dumped into scows and towed to dumping grounds in Lake Michigan. The only dredging paid for consisted of that enclosed by the cofferdams, although considerable dredging was done outside of the cofferdam walls. After the site was cleared the foundation piles and the cofferdam sheeting were driven. "Lackawanna" arched web sheeting, weighing 35 lbs. per square foot and having a length of 40 ft., was used in the river and also up to a point about 10 ft. inland where it connected with 6 × 12-in. × 28-ft. "Wakefield" sheet piling. At the east side of the river the steel sheeting was extended along a nine-story reinforced concrete building and a one-story freight house where their foundations appeared to be in danger.

Six brace piles were also driven in each cofferdam to support temporarily the system of bracing. The waling timbers were of 12 × 12-in. pine and were suspended by cables which passed through holes in the top of the steel sheeting. A 12 × 12-in. post was set on top of the upper tier of waling and bolted to the steel sheeting, the cables and posts preventing any movement of the waling due to the changing elevation of the water level within the cofferdam. The remaining timbers were either 12 × 12-in. pine or waste pieces of piles. Where timbers butted against waling pieces a 4 × 12-in. × 3 ft. oak block was used. Corner braces were used in the cofferdam pockets over the caissons. Four sets of bracing were placed in each dam—at elevations +0.5, −6.0. −10.0 and −14.0, the bottom of the main excavation being at elevation −20.0. The tiers of bracing were separated by 12 × 12-in. posts and were tied together with double ¾-in. tie rods. They were also bolted to the brace piles where convenient.

One 12-in. and three 8-in. centrifugal pumps were required to pump the first 6 ft. of water from the west cofferdam, this pumping requiring about two hours. From this level a 6-in., or an 8-in. pump, operated from time to time, was sufficient to remove the water from the cofferdam. When the pumping began, fine ashes were distributed along the outside of the steel sheeting, which proved very effective in stopping leaks. No other means were employed to make the sheeting watertight.

At the completion of the work all the material composing the cofferdams and bracing was recovered except the "Wakefield" sheeting and 43 pieces of the "Lackawanna" steel sheeting.

The high cost of pumping given in Table X was due to the fact that it was necessary to pump part of the time both day and night, which necessitated the employment of hoisting engineers as pumping engineers for 24 hours each day.

Tables X and XI give cost data, for the west and east cofferdams, on the driving of wood and steel sheet piling, the pumping of water from the cofferdams, the bracing of the cofferdams, and removing them.

Table XII gives a summary of the labor costs of constructing and removing the two cofferdams.

TABLE X.—FORCE ACCOUNT AND LABOR COST DATA FOR WEST COFFERDAM

Item	Total hours	Rate, cts. per hr.	Total cost	Remarks
Driving Wood Piles and Wood Sheeting				
Sorting old piles and lumber	140.8	..	$ 65.71	
Driving 11 22-ft. piles at back and side of dam.	200	..	109.40	Rate, 4.4 piles per 8-hr. day.

Burning off 43 pieces steel sheeting at ground	32	..	16.66	Burn about 7 per hr. The 32 hrs. includes helpers' time.
Pulling 138 pieces steel sheeting = 113½ tons	558	..	357.23	Rate 20 pieces per 8-hr. day. $2.59 each = $3.14 per ton.
Prorated charge	96	..	52.10	
Total	1,264	59	$ 742.70	
Superintendence, etc., 12.1 per cent	152.9	..	89.87	
Grand total	1,416.9	59	$ 832.57	

TABLE XII.—SUMMARY OF LABOR COSTS OF EAST AND WEST COFFERDAMS

	West dam		East dam		Both dams	
Item	Total cost	Per cent of total	Total cost	Per cent of total	Total cost	Per cent of total
Driving piles and sheeting for cofferdam	$1,272.25	16.4	$1,323.17	20.3	$ 2,595.42	18
Pumping water from cofferdam	4,586.38	59.2	3,278.20	50.2	7,864.58	55.4
Bracing cofferdam	926.33	11.95	1,091.48	16.7	2,017.81	14
Removing cofferdam	959.32	12.45	832.57	12.8	1,791.89	12.6
Total	$7,744.28	100	$6,525.42	100	$14,269.70	100

"*C*"—*Miscellaneous Work.*—The miscellaneous work included the following items: Making preliminary borings; furnishing scows and other supports for steel tapes during the taking of measurements across the river; making temporary sewer diversions; building and removing shed for storage of cement; protecting, supporting, maintaining, and restoring adjacent buildings affected by the construction of the cofferdams and substructure (no work required as buildings were not damaged); providing office space and temporary telephone service during construction. The lump sum bid for this work was $910. The borings were made by the city. One of the offices given below was 12 × 20 × 10 ft. high and the other, 10 × 20 × 9 ft. high.

The actual labor cost for this work was divided as follows:

Item	Total hours	Total cost
Twice diverting 5-ft. east sewer into 140-ft. wooden flume	1,522.8	$ 759.32
Diverting 4-ft. west sewer into 146-ft. wooden flume	427.1	186.59
Constructing two offices, 3,100 ft. B. M. lumber used	170.39	102.91
Miscellaneous work	973.59	439.49
Total (average wage rate, 48 cts. per hour)	3,093.88	$1,488.31

"*D*"—*Excavation.*—The price bid for excavating the site of the piers, tail pits and abutments, including the necessary back-fill, was $1.29 per cubic yard.

The excavation naturally divides itself into three classes: that removed by dredging; the excavation outside of the cofferdams; and the excavation within the cofferdams. Before excavation was commenced soundings were taken so that the river bottom at the bridge site could be accurately plotted. The sites of the cofferdams were then dredged and the dams constructed. Later, another set of soundings was taken, and the actual quantity of material removed from the cofferdams by dredging was computed to be 2,651.5 cu. yds., which was about 39 per cent of the total excavation. The material within the cofferdams was soft, blue clay and this was excavated by hand, the material being handled in buckets by derricks into dump scows and towed to the dumping grounds in Lake Michigan. The excavation outside of the cofferdams, principally at the site of the abutments, was also clay. The labor of cutting off the foundation piles was included in that classified under excavation. The total and unit labor costs of excavation are given in Table XIII.

TABLE XIII.—LABOR COST OF EXCAVATION

Item	Total hours	Rate, cts. per hr.	Total cost
Dredging Within Cofferdams			
Dredging, 2,651.5 cu. yds..................	2,168	..	$ 712.43
Prorated charge..........................	95	..	37.31
Total..................................	2,263	33	$ 749.74
Cost per cu. yd. (0.815 hrs.) = $0.268			
Superintendence, etc., 12.1 per cent......	273.8	..	90.72
Grand total............................	2,536.8	33	$ 840.46
Cost per cu. yd. (0.96 hrs.) = $0.32			
Excavation Outside of Cofferdams			
Excavation for east and west abutments, 1,389.7 cu. yds..........................	1,660	48	$ 800.03
Prorated charge..........................	75	..	42.00
Cost per cu. yd. (1.2 hrs.) = $0.58			
Total..................................	1,735	..	$ 842.03
Superintendence, etc., 12.1 per cent	209.9	..	101.89
Grand total............................	1,944.9	48	$ 943.92
Cost per cu. yd. (1.4 hrs.) = $0.68			
Excavation Outside of Cofferdams			
Excavation, 2,949 cu. yds................	6,258	..	$3,136.53
Prorated charge..........................	280	..	166.31
Total..................................	6,538	51	$3,302.84
Cost per cu. yd. (2.2) hrs. = $1.065			
Superintendence, etc., 12.1 per cent.......	791.1	..	399.64
Grand total............................	7,329.1	51	$3,702.48
Cost per cu. yd. (2.5 hrs.) = $1.25			
Back-fill			
Back-fill................................	667	43	$ 289.55
Prorated charge..........................	30	..	14.50
Total..................................	697	..	$ 304.05
Superintendence, etc., 12.1 per cent.......	84.3	..	36.67
Grand total............................	781.3	43	$ 340.72
Grand total, all items, 6,990.2 cu. yds...	12,592.1	46	$5,826.58
Cost per cu. yd. (1.8 hrs.) = $0.83			

"*E"—Oak Timber in Place.*—The price bid for the oak timber used in constructing docks and pier protection, bumping timbers in tail pits and permanent sheet piling, including all labor, timber, tools, bolts, nuts, washers, spikes and other appurtenances, was $62.40 per M. ft. B. M. in place. The quantity of oak lumber placed was 5,564 ft. B. M.

TABLE XIV.—LABOR COST OF PLACING OAK TIMBER

Item	Total hours	Rate, cts. per hr.	Total cost	Per 1,000 ft. B. M. Hours	Per 1,000 ft. B. M. Cost
Placing 5,564 ft. B. M. oak.......	375	63	$236.17	68	$42.50
Prorated charge................	11	..	4.66	..	......
Total..........................	386	..	$240.83	69	$43.00
Superintendence, etc., 12.1 per cent..........................	46.7	..	29.14	..	......
Grand total....................	432.7	63	$269.97	78	$48.50

The high cost of this work, given in Table XIV, is mainly due to the small quantity of timber used and to the large amount of cutting and fitting required. The excavation required for a part of the sheeting also increased the cost considerably.

"F"—Pine Timber in Place.—The price bid for the pine timber used in constructing docks, pier protections, etc., including all labor, timber, tools, bolts, nuts, washers, spikes and appurtenances, was $39.00 per M. ft. B. M. The amount of pine timber placed was 5,128 ft. B. M

The high cost of placing this timber, given in Table XV, was due to the same causes as were given for placing the oak timber.

TABLE XV.—LABOR COST OF PLACING PINE TIMBER

Item	Total hours	Rate, cts. per hr.	Total cost	Per 1,000 ft. B. M. Hours	Per 1,000 ft. B. M. Cost
Placing 5,128 ft. B. M. pine......	496	57	$284.48	97	$55.50
Prorated charge................	41	..	22.30	....	......
Total......................	537	..	$306.78	105	$60.00
Superintendence, etc., 12.1 per cent......................	65	..	37.12	....	......
Grand total.................	602	57	$343.90	117	$67.00

"G"—Test Piles.—The price bid for furnishing and driving four 60-ft. test piles was $120. These piles were located so as to be used later as protection and foundation piles. The plant used was one pile driver. The actual labor cost for this work was divided as follows:

Item	Total hours	Total cost
For driving four 60-ft. test piles (cost per foot, 11½ cts.; rate per 8-hour day, 6.4 piles)........................	50	$27.35
Prorated charge....................................	11	4.55
Total..	61	$31.90
Superintendence, etc., 12.1 per cent..................	7.38	3.86
Grand total....................................	68.38	$35.76

Average labor cost, 52 ct. per hour; rate per 8-hour day, 4.7 piles.

"H" and "I"—Furnishing Oak and Norway Pine Piles.—The piles under the abutments were only about 25 ft. long, this short length being used so as not to interfere with the future subway construction at this location. The remaining foundation and protection piles were about 45 ft. long. The cost of these piles delivered was as follows:

Oak piles, 7,182 lin. ft. at 18 cts......................	$1,292.76
Norway pine piles, 5,100 lin. ft. at 16 cts..............	816.00
Total..	$2,108.76

"J"—Driving Piles.—The bidding price below cut-off for driving piles in foundations, piers, pier protections, abutments, outside walls and dock lines was 11½ cts. per linear foot. There were 320 piles, 9,902 lin. ft., actually used, the bidding price for this item being $1,138.73.

The actual labor cost of driving these piles was divided as follows:

Item	Total hours	Total cost
Driving piles (320 piles, 9,902 lin. ft., below cut-off)....	1,466	$ 799.90
Prorated charge..................................	266	144.00
Total..	1,732	$ 943.90
Superintendence, etc., 12.1 per cent..................	209.45	114.21
Grand total..	1,940.45	$1,058.11

Cost (exclusive of prorated charge and superintendence), 8 cts. per linear foot below cut-off; rate, 17.4 piles per 8-hour day.

Cost (including prorated charge and superintendence), 11 cts. per linear foot below cut-off; rate, 13 piles per 8-hour day.

"K"—Concrete in Tail Pits, Outside Walls, Sewers, Abutments and Footings.—The price bid for the concrete in the piers, tail pits, outside walls, sewers and sewer outlets, abutments, footings, etc., including all labor, materials, forms, etc., was $7.25 per cubic yard. This concrete work did not include that in the caissons, which was let under a separate item. The quantity of concrete placed was 3,604 cu. yds.

The concrete used for this work and also for the caissons was a 1:3:5 mix. Part of the sand used was bank torpedo, hauled in by cars and teamed to the site; the remainder was Lake Michigan torpedo sand, brought to the site by a sand sucker and unloaded by two clam-shell buckets onto a moving belt attached to a 60-ft. boom. By this arrangement the sand was placed practically where it was wanted. The crushed stone used was brought in by teams and boats; that delivered in boats being loaded on skips at the quarry and unloaded at the site by a derrick.

The mixer on the west side of the river was set on top of the approach and the concrete chuted into place. The materials were measured in wheelbarrows, a batch being about ¼ cu. yd. The capacity of the mixer was ½ cu. yd. Most of the chutes were built of 2 × 12-in. plank and were unlined. At the east side of the river an 85-ft wooden tower was used. The sand was delivered by boat. The tower was 4 ft. 9 ins. by 6 ft. 3 ins., and was built of 6 × 6-in. posts and 2 × 6-in. braces. The main distributing chute was set at an angle of about 30° with the horizontal. The same mixer was used as for the west side.

The forms were built of 2 × 8-in. planks and 4 × 6-in. studs placed about 3 ft. apart. The forms on the inside of the pit and on the outside above the water line were *D* and *M* lumber.

Table XVI gives the labor costs for the concrete work under item "K."

"L"—Cement Mortar for Facing and Waterproofing.—The price bid for furnishing and placing the Portland cement mortar used for facing and for waterproofing the courses in the tail pits was $11.00 per cubic yard. The quantity of mortar placed was 357 cu. yds.

The mortar used for this work was a 1:2 mix. A 6-in. horizontal mortar course was placed at elevation −18, or about in the center of the tail pit floor, and extended from this course on the outside of the tail pit walls to elevation −2, where the thickness was reduced to 4 ins. From elevation +2 to the tops of these walls the thickness of the mortar course was 2 ins. The inside of the pit had a 3-in. mortar finish on the floor and a 2-in. course on the sides. The small walls on the outside of the main piers were merely spaded, as were the abutments.

TABLE XVI.—LABOR COSTS OF CONCRETE UNDER ITEM "K"

Item	Total hrs.	Rate, cts. per hr.	Total cost	Unit-costs Per cu. yd. Hrs.	Cost
	Mixing and Placing Concrete, 3,604 Cu. Yds.				
Labor	7,228.5	46	$3,343.71	2.00	$0.93
Prorated charge	570.5	..	258.00	....	.....
Total	7,799	46	$3,601.71	2.16	$1.00
Supt., etc., 12.1 %	943.7	..	435.81	....	.....
Grand total	8,742.7	46	$4,037.52	2.44	$1.20
	Building Forms, 38,340 sq. ft.*				
Labor	3,929	60	$2,337.49	1.09	$0.65
Prorated charge	303	..	186.00	....	.....
Total	4,232	60	$2,523.49	1.17	$0.70
Supt., etc., 12.1 %	512.1	..	305.34	....	.....
Grand total (38,340 sq. ft., 3,604 cu. yds.)	4,744.1	60	$2,828.83	1.32	$0.73
	Stripping Forms				
Labor	1,004.5	50	$ 505.28	0.28	$0.14
Prorated charge	77.3	..	39.06	....	.....
Total	1,081.8	50	$ 544.34	0.30	$0.15
Supt., etc., 12.1 per cent	130.9	..	65.87	....	.....
Grand total	1,212.7	50	$ 610.21	0.34	$0.17
Grand total, all items	14,699.5	51	$7,476.56	2.9	$2.10

* The unit costs per sq. ft. of forms were about one tenth of the cost per cu. yd. being $0.061, 0.066 and 0.075.

The same plant was used for this work as for the concrete work. The mortar was held in place by 1-ft. mortar boards. These boards were set up against the forms, and the concrete was placed up to their tops. The mortar was then placed in the space between the forms and the mortar boards. The boards were then raised, and the operation was repeated. The concrete was thus placed in 1-ft. horizontal layers and the mortar placed against the concrete while the latter was still green.

Table XVII gives the labor costs of mixing and placing the mortar courses.

TABLE XVII.—LABOR COSTS OF MIXING AND PLACING MORTAR COURSES

Item	Total hrs.	Rate, cts. per hr.	Total cost	Per cu. yd. Hrs.	Cost
Mixing and placing mortar, 357 cu. yds.	1,612	44	$ 706.92	4.5	$1.98
Prorated charge	411.6	..	212.40	...	.....
Total	2,023.6	45	$ 919.32	...	.....
Superintendence, etc., 12.1 per cent	244.9	..	111.24	...	.....
Grand total	2,268.5	45	$1,030.56	6.3	$2.90

"M"—Concrete Shaft Foundations from Elevation −20 *to Elevation* −45. The price bid for completed concrete shaft foundations below elevation −20 and above elevation −45 was 39¼ cts. per cubic foot (net volume). This price included cost of excavation, removal of water, removal of boulders of less than 20 cu. ft. each, and furnishing of all labor, materials, tools, ma-

chinery, etc., necessary to do the work (except steel sheeting and reinforcing bars). The quantity of concrete placed was 18,648 cu. ft., making the price bid for this item $7,319.34.

The concrete caisson foundations were divided into two parts, the rectangular portion from elevation −20 to elevation −45 and the circular portion from elevation −45 to bed rock. The upper was already lined with steel sheeting; therefore it was only necessary to place the bracing, which consisted of 6 × 12-in. and 12 × 12-in. pine spaced about 5 ft. apart, as the excavation proceeded. The material encountered, down to elevation −45 was blue clay and could be removed with shovels. It was first hoisted by means of tripods and windlasses and later with the derrick, the latter being more economical. The waste material was towed in dump scow to Lake Michigan for disposal. The price bid, 39¼ cts. per cubic foot, included the concrete work. The concrete plant is described under item "K."

Table XVIII gives the labor costs for the concrete shaft foundations between elevation −20 and elevation −45.

TABLE XVIII.—LABOR COSTS OF CONCRETE SHAFTS BETWEEN ELEVATIONS −20 AND −45

Item	Total hrs.	Rate, cts. per hr.	Total cost	Per cu. yd.* Hrs.	Per cu. yd.* Cost
Preliminary Work and Excavation					
Loading and unloading from scow the lumber for bracing.	32	....	$ 16.88	....	.....
Excavating and bracing caissons from El. −20 to El. −45............	2,470.5	50	1,244.28	3.58	$1.80
Prorated charge................	320	....	174.57	....	.....
Total..........................	2,822.5	51	$1,435.73	4.1	$2.08
Superintendence, etc., 12.1 per cent	341.5	....	173.72	....	.....
Grand total....................	3,164.0	51	$1,609.45	4.6	$2.32
Concreting between Elevation −20 and Elevation −45					
Concreting of upper part of caisson.	1,392.3	47	$ 649.41	2.0	$0.94
Prorated charge................	60.1	....	26.90	....	.....

Grand total....................	1,628.1	47	$ 758.14	2.36	$1.10
Grand total, excavating and concreting....................	4,792.1	49.5	$2,367.59	6.96	$3.43

* Per cubic foot; 0.258 hrs.; $0.127.

"*O*"—*Steel Sheeting for Concrete Shafts.*—The price bid for the steel sheeting used for the shaft foundations, including furnishing of same, driving and leaving in place was 2.5 cts. per pound. It was specified that the sheeting must weigh at least 35 lbs. per square foot. The length of the steel sheeting was 25 ft. its top being at elevation −20.5 and its bottom at elevation −45.5. "Lackawanna" arched web sheeting, weighing 35 lbs. per square foot was used. The size and shape of the top portions of the sub-foundation piers were changed to 10.5 ft. square for the river caissons and 8 ft. 2 ins. by 9 ft. 4 ins. for the anchor pier shafts, to accommodate the sheeting and at the same time give the same area as called for in the original plans. The sheeting was all driven with a floating pile driver, before the cofferdams were closed, so as not to blockade the river. The method of procedure was as follows:

A corner sheet was first placed. This sheet was then plumbed very carefully in one direction with a transit and in the other by a hand level. It was driven into the mud far enough so that its top was just above the water. The remaining sheets on this side of the shaft were then placed, particular attention being given to the other corner to insure its being vertical. The two adjacent sides of the caissons were set simultaneously, care being taken to keep the correct distance between them. The opposite wall was then set. (It should be noted that the sheets were merely set in place in the mud, all their tops being above water.) The sheeting was then driven by using another 25-ft. steel sheet as a follower. Two steel lugs were bolted to the sides of the follower at the bottom, to keep it in place on the first sheet. The "Worthington" steam hammer used for this work was an additional help in keeping the follower in place. A total of 264 pieces, weighing 139.74 tons, was used. Table XIX gives the labor cost for this work.

TABLE XIX.—LABOR COST OF DRIVING STEEL SHEETING FOR SHAFTS

Item	Total hrs.	Rate, cts. per hr.	Total cost
Preliminary handling of sheeting	125	..	$ 66.89
Placing lugs on followers	50.5	...	21.14
Total	175.5	50	$ 88.03
Superintendence, etc., 12.1 per cent	21.2	..	10.65
Grand total	196.7	50	$ 98.68
Driving Steel sheeting			
Driving steel sheeting	2,560.5	..	$1,675.08*
Prorated charge	454	..	245.00
Total	3,014.5	64	$1,920.08
Superintendence, etc., 12.1 per cent	364.8	..	232.33
Grand total	3,379.3	64	$2,152.41†
Grand total, preliminary and driving	3,576	63	$2,251.09‡

* Av. 8.2 pieces per 8-hr. day; 18.3 hrs. per ton; $11.99 per ton.
† 24.2 hrs. per ton, or $15.50 per ton.
‡ Av. 5.6 pieces per 8-hr. day; 26.9 hrs. per ton; $16.80 per ton.

"P"—Reinforcing Bars for Concrete.—The price bid for furnishing and placing the steel reinforcement in the concrete cylinders, shafts, foundations, piers, pit constructions, outside walls, and abutments was 2 cts. The amount placed was 72.85 tons.

The labor costs of this work are given in Table XX.

TABLE XX.—LABOR COSTS OF PLACING REINFORCING BARS

Item	Total hrs.	Rate, cts. per hr.	Total cost	—Per ton— Hrs.	Cost
Unloading, sorting and miscellaneous handling of bars	160	..	$ 78.53	.....	.....
Placing bars, 72.85 tons	927.5	..	437.68	.....	.....
Total	1,087.5	47	$516.21	14.9	$7.07
Superintendence, etc., 12.1 per cent	131.6	..	62.46	.....	.....
Grand total	1,219.1	47	$578.67	16.8	$7.95

"*Q*"—*Handling and Setting Substructure Steel.*—The price bid for handling and setting substructure steel (furnished by contractor for the superstructure) was 3 cts. per pound. The amount of steel set was 102.27 tons.

The steel set consisted principally of four "knocked down" trusses spanning the caissons, two anchor columns, one floorbeam connecting these columns, and four large anchor bolts for each side of the river. The cofferdam bracing was designed so as to avoid interfering with the erection of these substructure trusses. The pieces were all handled by the derrick, being fastened together with turned bolts. These trusses were set in place before any part of the main piers was concreted. When the concrete reached the proper height the anchor columns and floorbeam were set, particular care being taken to set them accurately.

Table XXI gives the labor costs of handling and setting the substructure steel.

TABLE XXI.—LABOR COSTS OF PLACING SUBSTRUCTURE STEEL

Item	Total hrs.	Rate, cts. per hr.	Total cost	—Per ton— Hrs.	Cost
Handling steel from cars to site	177	..	$ 93.76	1.7	$ 0.92
Bolting and erecting	1,154	..	803.83	11.3	7.90
Total	1,331	..	$ 897.59	13.0	$ 8.80
Prorated charge	133	..	73.78	....	......
Total	1,464	..	$ 971.37	....	......
Superintendence, etc., 12.1 per cent	177.1	..	117.54	....	......
Grand total	1,641.1	67	$1,088.91	16.0	$10.65

Note.—Derrick and derrick scow were used about 10 days each.

"*R*"—*Furnishing and Erecting Structural Steel.*—The price bid for furnishing and erecting structural steel was 2.5 cts. per pound. The quantity placed was 9,136 lbs.

This steel was principally chains for the pile clumps, and the work was so closely allied to the pile driving that its labor cost was merged with the cost of pile driving.

"*S*"—*Diverting and Extending Sewer.*—The price bid for diverting and extending the 5-ft. sewer (two-ring brick construction), including excavation, was $9.60 per linear foot.

As the sewers on each side of the river were located in the center of the street, it was necessary to make a temporary diversion to the side while construction was being carried on. The above price, $9.60 per linear foot, included the connection from the original sewers to the new outlets. The cost of the temporary diversion was included in item "C." On the west side of the river 50.1 ft. of new sewer were built, and on the east side 19.5 ft. were constructed. Practically all of this construction was on a curve and through a 15-ft. cut. The cost of this work is given in Table XXII.

TABLE XXII.—LABOR COST OF CONSTRUCTING 5-FT. SEWER

Item	Total hrs.	Rate, cts. per hr.	Total cost	Per linear ft. Hrs.	Cost
Excavating in clay, bracing trench, pumping, laying 2-ring, 5-ft. sewer, and backfilling	1,498	52.5	$787.41	22	$11.31
Superintendence, etc., 12.1 per cent	181.3	....	95.28	..	......
Total	1,679.3	52.5	$882.69	24	$12.70

"U"—Concrete Shafts Below Elevation −45.—The price bid for completed concrete shafts below elevation −45 was 47½ cts. per cubic foot. This price included the cost of excavation, removal of water, removal of boulders of less than 20 cu. ft. each, furnishing and placing all lagging and iron or steel rings, and all equipment for doing this work. This price did not include reinforcing bars. The total quantity of concrete placed was 14,601 cu. ft., the concrete being a 1:3:5 mix.

The part included in this item is the circular portion of the shaft foundation, the river pier and the anchor pier cylinders being 8 ft. and 7 ft. in diameter, respectively. These diameters were adhered to as closely as possible. The material down to elevation −60 could be removed with shovels; but from this elevation to bed-rock, at an average elevation of −81, it first had to be loosened with grubs. The clay overlying the rock was impregnated with gravel and small boulders, and directly above the rock there was a thin layer black sand, slightly water-bearing. The excavated material was disposed of in the same manner as in the upper part of the shaft, tripods and windlasses being first tried only to be discarded for the derrick, which hoisted the material from the four caissons. The lagging used was 3 × 6-in. tongue-and-groove lumber, in 3-ft. and 6-ft. lengths. The lagging was held in place by ¾-in. by 4 and 5-in. iron rings spaced about 3 ft. apart.

Table XXIII gives the labor costs for constructing the concrete shaft foundations below elevation −45.

TABLE XXIII.—LABOR COSTS OF CONCRETE SHAFTS BELOW ELEVATION −45

Item	Total hrs.	Rate, cts. per hr.	Total cost	Per cu. yd.* Hrs.	Per cu. yd.* Cost

Cost of Abutment Masonry and Slope Paving for Highway Bridge Foundations Illinois and Mississippi Canal.—The following matter, compiled from data collected by Fred W. Honens, U. S. Engineer's Office, Kansas City, Mo., is given in Engineering and Contracting, April 20, 1910.

To carry highways across the Illinois & Mississippi Canal required 67 bridges. Except for one swing bridge, three lift bridges and two special bridges at locks, these bridges are fixed truss bridges on concrete abutments. Three types of structure were employed.

1. On the eastern section generally the abutments were U shaped and the superstructures were pony Warren trusses of 100-ft. spans and 14-ft. clear roadway.

2. On the western section generally the abutments were wing abutments and the superstructures were 110-ft. Pratt trusses. The wing abutments were 23 ft. long and 16 ft. high, with 18-ft. wings at an angle of 30°.

3. On the feeder canal a three-span structure carried on straight abutments and two-tower piers was employed. The main 75-ft. spans were pony Pratt trusses and the two approaches were stringer spans of 21 ft.

On the main canal the bridges had a clearance of 17 ft. over the water. On the feeder canal the clearance was reduced to 12 ft. The following data relate to the structures used on the western section of the main canal.

The wing abutments contain for each bridge (two abutments) 190 cu. yds. of natural cement concrete in the footings and 248 cu. yds. of Portland cement concrete in the abutments proper. The parapets are oak timbers 12 ins. wide and 22 ft. long. The slopes of the canal in front of each abutment for a distance of from 60 to 120 ft. are paved with hand laid rubble for the first bridges built and with concrete about 10 ins. thick for the bridges built later.

The steel superstructures were designed to carry a live load of 100 lbs. per sq. ft. or an engine load of 8 tons on axles 7 ft. c. to c. The trusses are 110-ft. spans, 20 ft. high and spaced 19 ft. 1 in. c. to c., having a clearance of 16½ ft. between guards. These guards are 6 × 8 in. pine raised 3 ins. above the floor and having on the wearing side 3 × 3 × ¼-in. angles.

The embankment approaches are 21 ft. wide on top, with side slopes of 1 on 1½ and with grades running from 3 to 6 per cent. The roadways are surfaced with gravel or crushed rock and have board railings extending from bridges to foot of slope.

The costs given here relate to the substructure, that is, the concrete abutments and footings and the adjacent slope paving. The forms for the abutments were simple, consisting of opposite posts tied through the walls at bottom and mid height with bolts and at the top above the wall with 3 × 12-in. plank with short knee braces. The concrete was mixed in a Smith mixer charged by one-horse dump carts and was hauled to the work in cars and hoisted by horse elevator and dumped into the forms.

The following is the detailed cost of the substructure for highway bridge No. 34. Excavation and back fill cost as follows:

	Total	Per cu. yd.
Excavation (576.6 cu. yds.):		
Labor	$ 151.52	......
Stakes	3.00	......
Total	$ 154.52	$0.268
Back fill (256.4 cu. yds.):		
Labor	$ 55.88	$0.220

There were 190 cu. yds. of natural cement concrete in the footings which cost as follows:

	Total	Per cu. yd.
Concrete Materials:		
Cement	$ 208.80	$1.099
Crushed stone	289.02	1.521
Sand	113.00	0.594
Total	$ 610.82	$3.214

Receiving Concrete Materials:		
Hauling cement	$ 23.50	$0.214
Unloading cement	2.65	0.014
Hauling crushed stone	94.98	0.499
Freight on gravel	7.50	0.039
Total	$ 128.58	$0.676
Labor mixing and placing	218.39	1.149
Grand total	$ 955.79	$5.039
Form Materials:		
Lumber	$ 28.50	$0.150
Stakes	3.00	0.016
Hardware	1.65	0.008
Total	$ 33.15	$0.174
Form Labor:		
Hauling and unloading lumber	$ 3.70	$0.019
Labor constructing	17.16	0.090
Labor wrecking	2.00	0.011
Total	$ 22.86	$0.120
Grand total	56.01	0.294
Miscellaneous:		
Labor receiving materials	$ 15.48	$0.081
Miscellaneous labor	8.72	0.046
Total	$ 24.20	$0.127
Grand total	1,038.00	5.460

The cost of 248 cu. yds. of Portland cement concrete in the abutments proper was as follows:

	Total	Per cu. yd.
Concrete Materials:		
Cement	$ 496.32	$2.001
Crushed stone	378.00	1.524
Sand	135.52	0.546
Total	$1,009.84	$4.071
Receiving Concrete Materials:		
Hauling cement	$ 23.87	$0.096
Unloading cement	3.40	0.013
Testing cement	29.50	0.118
Hauling crushed stone	114.78	0.462
Freight on gravel	9.50	0.038
Total	$ 181.05	$0.727
Concrete labor	265.67	1.071
Running mixer labor	22.00	0.081
Total	$ 287.67	$1.152
Grand total	$1,478.56	$5,952
Form Materials:		
Lumber	$ 59.50	$0.239
Hardware	11.35	0.045
Total	$ 70.58	$0.284
Form Labor:		
Hauling and unloading lumber	$ 50.82	$0.205
Labor constructing	119.86	0.483
Labor wrecking	15.75	0.063
Total	$ 186.43	$0.751
Grand total, forms	257.28	1.035

Miscellaneous:		
Labor receiving materials	$ 19.39	$0.078
Miscellaneous labor	15.42	0.062
Coal	19.19	0.076
Total	$54.00	$0.216
Grand total	$1,789.84	$7.217

The cost of 313 sq. yds. of rubble stone paving was as follows:

Item	Total	Per sq. yd.
Rubble stone	$406.78	$1.299
Hauling rubble stone	83.44	0.266
Labor paving	180.32	0.576
Labor receiving material	13.94	0.044
Miscellaneous labor	7.86	0.025
Total	$692.34	$2.210

The following expenses were charged against the whole work:

Engineering and inspection	$153.43
Traveling	4.08
Chicago office expenses	69.84
Total	$227.35

The grand total cost of the whole work was $3,957.93.

The work described was done by day labor and the wages paid were about as follows:

Carpenters, per day	$2.50
Laborers, per day	1.75
Teamsters with team	3.00

An 8-hour day was worked.

In Table XXIV are given the masonry and slope paving costs of 20 other bridges of the same type as that described.

TABLE XXIV.

	National cement, concrete		Portland cement, concrete		Slope paving

Cost of Dismantling an Old Highway Bridge and Erecting New Truss and Girder Spans.—George Harper gives the following data in Engineering and Contracting, Dec. 24, 1913.

The following data apply to the dismantling of an old highway steel truss bridge, with roadway and sidewalks, and to the erection in its place of a new structure with a 60-ft. roadway and an 8-ft. sidewalk. The new bridge consists of a deck truss span over the Mahoning River and two through girder spans over six railroad tracks of three different trunk lines, at Youngstown, Ohio. The work was done in 1910.

The span across the river has a length of about 180 ft. and that across the railroad tracks has a length of about 84 ft. The old structure was used by the sub-contractor as falsework during the erection of the new bridge; and as it was taken down after the completion of the connection, its weight is included in the tonnage given in Table I, being about 35 per cent of the total for this span. The dismantling and removal of it cost about 35 per cent of the total cost shown in the table for the river span.

The sub-contractor for the work was a first-class bridgeman, who took personal charge of the work and who had gathered an efficient crew of skilled men. He was, however, subjected to many delays, which were due to no fault of his and which served seriously to hinder the progress of the work.

The weight of steel in the two girder spans over the railroad tracks is about 198 tons. The erection cost for these spans is higher than that for the river span, as it was necessary to use a Lucius erector to set them. One span was set in about five minutes and the other in about eight minutes, without any delay to traffic.

The total erection cost of $8,136, shown in Table XXV, was within three per cent of the actual erection and other costs to the sub-contractor. The painting of the structure, the railing, roadway paving, and the cement sidewalks were let under separate contracts. The data shown in the table are only for the dismantling of the old highway bridge, the erection of the new structure, and the placing and riveting of the buckle plates for the roadway. The best type of hoisting engines and general apparatus were used on this work. The dismantling of the old structure was hindered somewhat and the cost of the

TABLE XXV.—DATA ON DISMANTLING OLD TRUSS BRIDGE AND ERECTING NEW SPANS

	Time, days	Rate per day	Labor cost	Total* cost	Cost per ton (560 tons†)	Erection cost per ton on girder spans (198 tons)

* Total cost is made up of labor cost plus 15 per cent to cover plant cost.
† The 560 tons consisted of 374 tons of new steel erected and 186 tons of old steel taken down and used as falsework.

work was increased due to the difficulty of removing the old piers, which were in bad condition. The time required, the rate of wage, and the cost of the work, exclusive of materials, are shown in Table XXV.

The work on the river span was done during May and August and that on the span over the railroad tracks during October and November, 1910.

Cost of Erecting the St. Paul, Neb., State Aid Bridge.—Geo. K. Leonard gives the following data in Engineering and Contracting, Feb. 28, 1917.

The contract for this bridge was let in September, 1915. It is located one mile from the town of St. Paul, Neb., and extends over the Middle Loup River. The right of way adjoins that of the Union Pacific R. R. and the same length of spans was used so that the piers in the two bridges would fall in the same line. The entire bed of the river at this point is composed of fine sand with

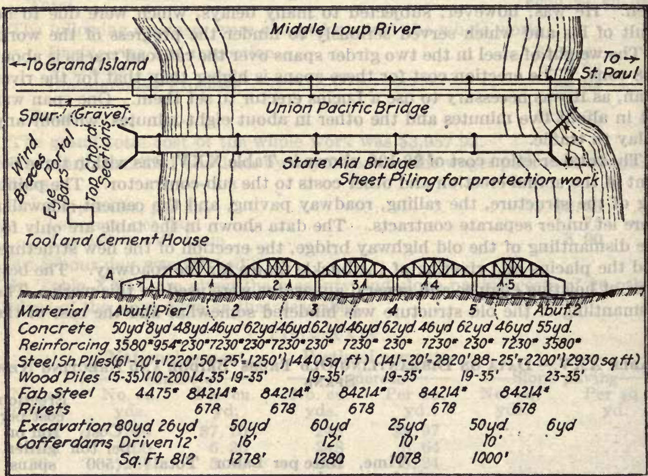

FIG. 7.—General layout of St. Paul, Neb., state aid bridge and material quantities involved.

some gravel too deep to excavate economically for concrete. During the summer the river is practically dry with the exception of one channel under Span No. 5. The general layout of the structure is shown in Fig. 1. The material quantities also are shown in this cut.

The superstructure is composed of five 8-panel 145-ft. pin-connected curved chord trusses and one 20-ft. I-beam span, all with a 16-ft. roadway, carrying a 6-in. concrete floor. It was designed to carry a live load of 75 lb. per square foot, or a 15-ton traction engine.

The substructure includes five mass concrete piers and two reinforced concrete abutments resting on 35-ft. cypress piles. A row of 7-in. Lackawanna steel sheet piling 20 ft. long is driven under the whole length of each abutment and adjoining these on Abutment No. 2 additional piling are driven for protecting the approach. The concrete extends to a depth of 3 ft. below the low water level and the piles are embedded in the footings 2 ft.

At the start of the work the contractor made arrangements with the Union Pacific R. R. for the construction of a spur to the end of the highway bridge. All material with the exception of the form lumber, which was hauled from St. Paul, was delivered to the bridge site on this spur. The cost of the spur was charged to the various materials according to their tonnage as follows:

Material	Amount	Tonnage	Amount charged
Steel Sheet piles	7,490 lin. ft.	47.00	$ 15.32
Wood piles	4,330 lin. ft.	64.95	21.25
Falsework piles	4,315 lin. ft.	64.73	21.20
Cement	977 bbls.	195.40	64.00
Gravel		1,096.00	358.60
Reinforcing steel		22.71	7.43
Fabricated steel		212.77	69.60
Coal		166.20	54.40
Plant		25.00	8.20
Total tonnage		1,894.76	
Total cost spur			$620.00

Total cost spur ton of material 32.7 cts.

These amounts which are charged to the material from the spur will hereafter be charged to hauling, since the spur did away with the hauling costs.

Labor Organization.—The labor organization was as follows:

	Per hour, cents
Pile driving:	
1 foreman	40
1 engineer	40
1 niggerhead man	35
1 fireman	30
1 jet man	30
3 laborers	30
Concrete:	
1 mixer man	35
5 cart pushers	30
2 tampers	35
1 cement man	30
4 gravel wheelers	25
Steel erection:	
1 foreman	40
1 engineer	40
1 niggerhead man	35
1 fireman	30
2 laborers	40
2 laborers	35
4 laborers	30
Riveting (two gangs):	
1 foreman	42½
1 compressor man	35
1 fireman	30
2 rivet heaters	42½
1 gun man	42½
1 gun man	40
2 buckers	35
2 rivet catchers	35
2 fitting-up men	35
1 supply man	25
General foreman	45
Night watchman	20
Water boy	15

Plant.—Piles were driven and a platform built from the spur to the end of the bridge. On this the plant was erected and part of the material unloaded. For the pile driving a traveler carrying a stiff-leg derrick and a steam hoisting engine, operating a 1,600-lb. hammer in swinging leads, was used. A small jet pump assisted greatly in all the pile driving.

The cofferdam at Pier No. 1 was first driven, using the sheet piling, which were afterward driven under the abutments. The excavation was done with an orange-peel after which the wood piles were driven. Next the falsework of Span No. 1 was driven, the floor beams being placed on each successive bent and enough joists to carry the traveler bolted to the beams. The work progressed in like manner across the bridge.

Concreting followed the pile driving and after the footings were poured the traveler returned and pulled the cofferdam.

In Abutment No. 2 the sheet piling served for both cofferdam, and forms around the face and wood forms had to be sunk around the rear. Abutment No. 1 was finished last.

At the start a ¼-yd. mixer was used, being run by a gas engine. Later a steam engine and boiler were used. In mixing for Piers Nos. 1 and 2 the mixer was set over the forms, but it was then moved to the end of the bridge and the rest of the concrete was mixed there and hauled to the forms in Koppel cars.

The cost of the plant and its distribution is as follows:

Making working platform	$ 85.00
Making tool and cement house	30.00
Unloading and erecting derrick	88.00
Erecting and moving concrete plant	164.90
Repairs on derrick	194.89
Wrecking and loading out plant	178.75
Hauling	8.20
Total	$749.74

This was charged to the various branches of the work according to the time spent on same. If the unit costs are desired without the plant included it is very easily found.

Following is the distribution of the plant cost to the various branches:

Kind of work		Repairs	Total charged
Driving falsework	$ 53.52	$ 27.35	$ 80.87
Driving sheet piling	12.05	....	12.05
Driving wood piling	165.56	80.47	246.03
Driving cofferdam piling	74.00	78.32	152.32
Steel erection	84.82	8.75	93.57
Concreting	164.90	....	164.90
Totaling	$554.85	$194.89	$749.74

Coal:	Cost per ton	Total cost
166.2 tons	$6.43	$1,068.66
Unloading	.185	30.74
Hauling	3.27	54.40
Total	$6.942	$1,153.80

Construction Costs

SUPERSTRUCTURE

Falsework:	
Labor driving	$ 711.55
Labor removing	112.15
Coal (18 tons)	125.00

SUMMARY SUBSTRUCTURE

Wood piles	$ 1,964.85
Steel sheet piles	2,508.78
Concrete	8,597.55
Reinforcing	1,488.28
Total	$14,559.46

TOTAL COST OF BRIDGE

Superstructure	$18,103.71
Substructure	14,559.46
Miscellaneous material	535.00
General foreman	810.00
Night watchman	260.00
Water boy	47.75
Total	$34,315.92

Cost of a Steel Highway Bridge in Texas.—William C. Davidson gives the following costs in Engineering and Contracting, Oct. 25, 1916.

The bridge was built in McLennan County, Texas, about 10 miles from Waco. It spans Aquilla Creek, one of the larger tributary streams of the Brazos River. The structure has a total length of 273 ft., consisting of 120 ft. of main span and 153 ft of timber trestle approaches.

The work was handled under direct supervision of the county engineer. An experienced steel bridge foreman was employed to superintend the construction work, which was in direct charge of the writer as assistant engineer. Foundation excavation was commenced about July 1, 1915, and two months later the road and bridge were opened to traffic. To obtain a more direct alignment the site of the new bridge was moved several feet upstream from the site of the old structure.

Labor for handling the work was obtained locally with the exception of a form-builder who was obtained from Waco. Common labor was obtained at $1.50 to $1.75 per day of eight hours each. The form builder was paid at the rate of $3 per day. Practically all the hauling was done under contract. Miscellaneous teaming was paid for at the rate of $0.40 per hour. The foreman was employed at $4 per day straight time, no overtime being allowed for more than an eight-hour day. Laborers were paid overtime for all work exceeding eight hours per day. It was necessary to haul a part of the material, such as form lumber, tools, equipment for camp outfit and other miscellaneous supplies, from Waco. This teaming was done by one of the county maintenance outfits, at a cost of $3 per day.

The nearest railroad spur was situated a distance of five miles from the site of the bridge. Cement, structural steel, bridge lumber, piling and wood preserver for treating certain portions of the wood work, were shipped to this point. The hauling of this material to the site was contracted to a local teamster at the following prices: Cement, 6⅔ ct. per sack; bridge lumber, 25 ct. per 100 ft. B. M.; structural steel, $1 per ton. The piling and wood preserver were hauled to the site at a cost of $0.40 per hour for man and team. Gravel for the pile footings and concrete piers was also hauled under contract, from local pits situated two and five miles from the site, respectively. From the pit located two miles distant, 130 cu. yd. were obtained at a cost of $0.50 per yard for the hauling and $0.10 per yard for the gravel. Added to the above cost was that of stripping the pit which amounted to $0.11 per yard, making a total cost per yard at the site of $0.71. Owing to the fact that the above pit would not supply sufficient gravel to construct the piers and footings, it became necessary to haul 39½ cu. yd. from another local pit situated five miles from the site. This gravel was contracted at $1.15 per cubic yard for loading and hauling and $0.10 per cubic yard for the gravel, making a total cost at the site of $1.25 per cubic yard. No stripping was necessary at this pit. Tickets were issued to the teamsters by the foreman for each load of gravel as it was received at the site, and payment was made upon the basis of these tickets, The invoices of the material companies were taken as the basis of payment for the haul of cement, steel and lumber.

The concrete used in the construction of the piers was mixed in the proportion of one part of cement to six parts of pit run gravel. A form finish was given the outer surface of the piers. Vertical and horizontal reinforcing rods were used as shown on the pier detail. The steel was designed for what was designated in the standard specifications as a "Class B Loading." This consisted of a load of 80 lb. per square foot of total floor surface, being the equivalent of a 10-ton traction engine having axles 8 ft. on centers and a 6-ft. gage, two-thirds of the load to be carried on the rear axles and distributed over 12 ft. in width.

The following is an itemized statement of the cost of the bridge, including all material and labor:

Material:	
Structural steel, f. o. b. cars at factory, 42,770 lb. @ \$3.14 per 100 lb.	\$1,325.87
Freight on steel, 42,770 lb. @ 55c per 100 lb.	235.24
Bridge lumber, 25,335 ft. B. M.	426.56
Cement, 425 sacks @ 32c per sack net	178.50
Reinforcing steel, 4,455 lb. @ \$2.75 per 100 lb.	122.51
Form lumber, 3,900 ft. B. M.	104.39
Piling, 454 lin. ft. @ 7½c per foot	34.05
Nails, 2 kegs 60d and 1 keg 6d	7.85
2 rolls, No. 9 wire for forms	4.90
Gravel, 169½ cu. yd. @ 10c	16.95
Paint, 14 gal. @ \$1.95	27.30
Linseed oil, 4 gal. @ 85c	3.40
Machine bolts	19.64
Misc. tools and hardware	29.98
Paint brushes	1.15
Wood preserver	5.00
Total	\$2,643.29
Labor:	
Clearing of bridge site	\$ 8.90
Foundation excavation	57.35
Mixing and placing concrete	78.40
Building of forms	165.05
Removal of forms	16.75
Hauling form lumber	12.00
Hauling cement, 425 sacks @ 6⅔c	28.33
Hauling gravel, 169½ cu. yd. (130 cu. yd. @ 50c, 39½ cu. yd. @ \$1.15)	110.43
Hauling reinforcing steel	8.00
Extra cutting of steel	.75
Hauling bridge lumber	65.42
Erection of steel, including decking of main span and approaches	207.20
Construction and removal of false work	51.50
Building approaches (not decking)	42.55
Painting steel span (one coat)	14.90
Rent on storage house	3.00
Miscellaneous hauling:	
Moving concrete mixer from R. R. to site	2.00
Stripping gravel pits	14.80
Hauling cement from storage house to site	3.60
Hauling piling from R. R. to site	8.00
Unloading piling at R. R.	4.80
Unloading bridge lumber at R. R.	3.75
Moving lumber at bridge	.40
Foreman's time (60 days @ \$4.00 per day)	240.00
Structural steel workman (connecting span)	25.00
Total	\$1,172.68
Cost of material	2,643.29
Grand total cost, material and labor	\$3,815.97

Unit Costs.—On the basis of the foregoing cost data, unit costs on the several items of material have been computed. The foundation excavation was entirely pick and shovel work and consisted of alluvial deposits and a firm clay. The depth of the excavation was 12 ft. and a double handling of material was required near the bottom of the piers. There was a total of 85.7 cu. yd. of material taken from both piers, at a total cost of \$57.35 or a unit cost of $0.67. Mixing and placing of concrete cost $78.30. The total cubic yardage of concrete in the piers and pile footings amounted to 125.7, from which is deduced a cost of $0.62 per cubic yard. Water used in mixing the concrete was obtained from the creek at the site by means of a hand pump. It was pumped into barrels to an elavation of about 20 ft. above the creek, from which it was conveyed by means of buckets to the mixer. The piers were poured to an elevation slightly above the ground, then the approaches were built and the mixer placed upon them, from which the remainder was poured without difficulty.

The piers being of rather unusual design, involved expensive form work from the standpoint of labor, the total cost being $165.05, or a unit cost per yard of concrete, of $1.33. The lumber, wire, nails, removal of forms and the hauling of form lumber amounted to $140.79, with a resultant unit cost for material of $1.12 per cubic yard. Therefore the total unit cost for forms was $2.45 per cubic yard, which is somewhat higher than is to be expected for form work on piers.

The total cost of the cement at the site, including first cost, hauling and storage, was $215.43, from which it is estimated that the cost for cement per cubic yard of concrete amounts to $1.70. The concrete gravel cost at the site $142.18, including first cost, hauling and stripping of pits. This results in a unit cost of $1.13 per cubic yard. The cost of water for the concrete was included in the item "mixing and placing" and the cost of placing reinforcing steel was not separated from that of building forms. From the foregoing a summary of cost per cubic yard of concrete is as follows:

Cement	$1.70
Gravel	1.13
Forms	2.45
Mixing and placing	.62
Supplies for mixer	.02
Foreman	.38
Total	$6.30

The bridge was erected at a total cost for labor on superstructure and false work of $258.50, which cost included the erection of steel and the decking of main span and approaches. A cost of $0.95 per linear foot of bridge is deduced from the foregoing. It required material amounting to $31.85 to paint the steel work, with a corresponding cost per ton of steel of $1.49. Labor required amounted to $14.90 or a cost per ton of steel of $0.70. The total cost, therefore, per ton of steel for labor and material was $2.19.

Unit Costs of Constructing Plate-Girder Bridges with Concrete Substructures in Chicago.—The following data are taken from an article in Engineering News, Aug. 27, 1914, by Harry J. McDargh.

In erecting seven plate girder bridges on west fork of the North Branch of the Chicago River the work was carried out by the use of day labor. The field organization consisted of an engineer (Mr. McDargh) acting as general superintendent; an instrument man as time-keeper and material clerk; a foreman of carpenters, cement mixers and laborers and in charge of substructure construction, and a foreman of bridge and structural-iron workers in charge of erection of the superstructure. The rates of wages (union scale) were as follows:

Foremen	80 cts. per hour.
Engineman (for hoisting)	72½ cts. per hour.
Carpenters	65 cts. per hour.
Laborers	40 cts. per hour.

Material costs under contracts made by the city were as follows:

Material:	Cost
Cement	$ 1.20 per bbl. net.
Torpedo sand	1.70 per cu. yd.
Stone and gravel	1.65 per cu. yd.
Lumber (average)	$29.00 per M. ft. B. M.
Superstructure steel	2.61 cts. per lb.

The plant consisted of a 10-ton stiff-leg derrick with a 42-ft. boom, a 16-hp. steam-hoisting engine, four 1-yd. self-dumping steel buckets, a steam pump, a gasoline-driven concrete mixer of 8-ft. batch capacity, and the other necessary smaller equipment.

The superstructure design is shown in Fig. 8. The main girders are 75 ft. 8 in. long, with the floor system designed to carry the heaviest city traffic. The roadway is 24 ft. between curbs, paved with 4-in. creosoted-wood blocks on 2-in. creosoted subplanking laid tight on 4 × 6-in. creosoted sleepers spaced 9 in. c. to c. The two 8-ft. walks are of reinforced-concrete flat-slab construction. The sidewalk railing on the bridge is of ornamental iron construction, and joins the concrete parapet walls carried on the wing walls of the substructure.

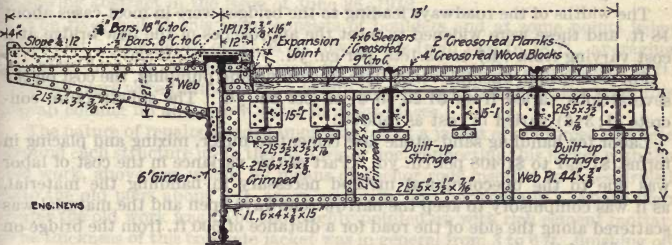

FIG. 8.—Half cross-section of plate-girder bridges over the west fork of the North Branch of the Chicago River.

The wing walls of the substructure end in a circular return and come to within 2 ft. of the property line. All streets are 66 ft. wide. The esthetic treatment of both the substructure and superstructure was recommended by the Chicago Plan Commission, and the resulting structure is quite effective in appearance. Excavation for the substructure was made through loam. gravel and stiff blue clay to a depth of at least 8½ ft. below low water to allow for a possible future dredging of this stream.

The average depth of excavation was 26 ft. below the curb grade, and each pit was sheathed tight to blue clay, due to the water-bearing gravel and the proximity to the river. No extraordinary conditions were encountered. Excavation of the blue clay was laborious, however, as it could only be loosened in small chunks by the use of mattocks. Keeping the clay water-soaked was found advisable.

Cost and Progress of Work.—The substructures at N. 40th Ave. and N. 48th Ave. were started during the fall of 1912, but all work was suspended before the end of the year. Work was again started May 9, 1913, and three other substructures (at Central Park Ave., Kedzie Ave. and 56th Ave.) were completed during the year. The substructure at Forest Glen Ave. was 90 per cent completed on Dec. 31, and was entirely completed Jan. 29, 1914.

The superstructure steel for N. 40th Ave. was delivered on the site July 2, the erection completed Aug. 12 and the roadway opened to traffic Sept 1. Erection of 48th Ave. superstructure was started July 31, completed Sept. 3, and the roadway opened to traffic on Oct. 1.

The next superstructure steel arrived Oct. 21, and was erected at Central Park Ave. and this bridge opened to traffic on Dec. 20.

The steel for the Kedzie Ave. superstructure arrived on Dec. 4, erection was completed Dec. 27, and the roadway opened to traffic Feb. 14, 1914. Erection of the superstructure at 56th Ave. was started Dec. 29, completed Jan. 28, and the roadway opened to traffic Feb. 26. At Forest Glen Ave. the delivery of the steel was started Feb. 9, but was tied up until Feb. 20 by a strike on the company furnishing the material. Erection was completed Mar. 12, and the roadway opened to traffic on Apr. 7, 1914.

The erection of the steelwork was done without the aid of power machinery and all riveting was by hand. The cost varied from 0.75 to 0.77c. per lb.

The creosoted wood-block pavement with sub-planking and sleepers cost for material $4 per sq. yd.; the labor for placing averaged 81½c per sq. yd. for roadways without car tracks and $1.40 on the roadway with car tracks.

The widths of the roadways leading to the bridges were in most cases about 18 ft. and these were widened to meet the approaches of the new bridge at a cost varying from 74.7 to 95.1cts. per cu. yd.

For excavation, backfill, coffer-dam, sheathing and pumping, the cost on the several jobs varied from $1.23 to $1.55 per cu. yd. The substructure concrete (1:3:6) varied in cost as follows:

Labor for handling sand, stone and cement to mixer, mixing and placing in forms, $1.291 to $1.408 per cu. yd. Part of this variance in the cost of labor was due to the uneconomical method necessary in handling the material, as it was compulsory to keep the narrow roadways open and the material was scattered along the side of the road for a distance of 600 ft. from the bridge on each side of the river.

Material cost $3.778 to $4.558 per cu. yd. of concrete. This variance was due to difference in length of haul for delivery.

Forms, including labor and material, cost $1.580 to $1.986 per cu. yd. of concrete.

Cost of Moving Small Highway Bridge in Chicago.—In replacing a bridge at Kedzie Ave. over the west fork of the North Branch of the Chicago River in 1914, it was decided that the bridge could be moved to Foster Ave., an unimportant thoroughfare, and that it would serve 10 yrs. or more at this, its third place of usefulness. Harry J. McDargh in Engineering News, Aug. 27, 1914 gives the cost of moving the bridge as follows:

The old structure was a wrought-iron through-truss bridge, 63 ft. long and 36 ft. wide over all and weighed 35 tons. The truss while being "house moved" was carried on two sets of 12 × 12-in. timbers 6 ft. c. to c., placed symmetrically to the center of the bridge. Using wood rollers on a timber runway and a crab, the truss was moved 4,300 ft. and set upon bents for $383.50. The rates of wages (union scale) were as follows:

Foreman	80 cts. per hour
Carpenters	65 cts. per hour
Laborers	40 cts. per hour

Cost of 105-Ft. Strauss Bascule Bridge over the Sabine Neches Canal at Port Arthur, Texas.—According to Engineering Record, Aug. 19, 1916, this bridge was completed by the contractor in 1913 at a cost of $35,000, the steel being fabricated at Beaver Falls, Pa.

The main span of the bridge is 105 ft. center to center of channel piers; six-panel through riveted Warren trusses, 24 ft. apart on centers, provide a 21-ft. clear roadway and two 6-ft. clear sidewalks are carried on cantilever brackets. The roadway has 3-in. wooden planking supported on steel stringers and provides for a double-track electric street railway.

Cost of Jacketing with Concrete the Underwater Portions of a Bridge Substructure.—Three masonry piers and an abutment founded on stone-filled cribs were repaired in 1911 by building jackets of concrete around the underwater portions. The old piers had been in use some 65 years. The portions above low water were of squared granite laid in mortar probably of lime or a mixture of lime and natural cement. Below low water the piers were closely framed hewn pine cribs filled with field stone and were well preserved. The strengthening work was considered necessary to fit the piers to carry a steel superstructure being built to replace the original wood spans. The conditions encountered in this work and the method and cost of doing the work are described by E. E. Greenwood, engineer in charge, in the Proceedings, Maine Society of Civil Engineers, from which Engineering and Contracting, gives the following abstract in the issue of June 26, 1912.

The river bed at this point consists of boulders and at some points ledge crops out. The depth of water at low tide is from two to 18 ft., averaging about 12 or 14 ft. at the piers, and the ordinary rise of the tide is about 16 ft. The old piers were protected by a heavy riprap deposited about the base, this riprap coming up above low water in a few places.

The nature of repairs decided upon was to put a jacket of reinforced concrete around each structure up to the high water line, connecting this jacket with the old work, above low water, by means of anchor rods inserted in holes drilled into the old piers about 3 ft. apart vertically and horizontally. Above high water the old work was to be thoroughly pointed up with rich cement mortar. The thickness of this concrete jacket was in general from 3 to 6 ft., finishing off at the top two and one-half feet thick.

On account of the uncertainty of what we should have to contend with as the work should progress it was thought impracticable to make specifications under which a contractor could be expected to make a reasonable bid on the work, either by unit prices or a lump sum. It was therefore decided to do the work by the day under the supervision of a competent foreman.

The first step was to remove a large part of the old riprap about the piers and prepare a foundation for the concrete jacket. As a cofferdam of sufficient depth was impracticable it was decided to do this work with divers. Therefore two divers' outfits were organized and set to work, and the old riprap and debris were removed to such a depth as to secure a suitable foundation.

It was found that the old riprap was so closely packed that it was not necessary to go down to the old river bed in most places. The depth was generally from 3 to 10 ft. below low water, with some points deeper.

Our next step was to devise the most practicable method of building a form for the concrete, and it was decided to build a timber crib 8 ft. wide entirely around the pier, leaving the space between the crib and pier to correspond with the required thickness of concrete, which was generally about 6 ft. below low water.

This crib was built of 8 × 8-in. hemlock timber and divided into checks about 8 ft. square, each alternate check being floored over to contain rocks for sinking it. The crib was built up to 2 or 3 ft. above water at low tide, thus giving something on which to work while the tide was out to build the forms in the ordinary manner above that height. After the crib was grounded all the checks were filled with field stone and a quantity of the larger sized stones was deposited outside the crib as an extra precaution against scour. The inner side of the crib was then lined with vertical matched spruce plank driven as much as possible in the bed and all holes at the bottom thoroughly chinked by divers, thus giving an almost water-tight form for the concrete. The concrete was then deposited in the water, partly by means of the bottom dump bucket and partly by means of the flexible chute method, always endeavoring to deposit the mixture with the least possible wash. After reaching the height of low water the work was mostly done by working a few hours at a time while the tide was out. The concrete in general was a 1:2:4 mixture of Portland cement, sand and crushed rock. In the abutment where the work was all above water a 1:3:6 mixture was used. This piece constituted about one-sixth of the entire job. A Smith mixer of 1 cu. yd. capacity was used on all of the work.

The cement was delivered on the work by the local dealers for $1.73 per barrel. Sand was delivered for $1.50 per load of about 1¼ cu. yds. or at about $1.20 per cubic yard. Crushed rock cost delivered on the work $2.25 per cubic yard. Labor cost $2 per day of nine hours. Hemlock lumber cost $18 per thousand and spruce lumber $22 per thousand delivered.

An accurate account was kept of the total cost but the exact division between the different classes as given below is something of an estimate but is believed to be quite near the facts. The total amount of concrete built assuming that 5 per cent of the total entered the cavities of the old work was 2,190 cu. yds.

Lumber for crib work and forms cost	$ 1,922
Tools bought and hired	800
Field stone for filling cribs	356
Teaming	112
Cement	4,249
Sand	1,059
Crushed rock	3,582
Liability insurance	125
Coal	112
Incidentals and office expenses	575
Labor on cribs, forms and concrete	5,337
Preparing foundations under water	5,100
Making anchor connections with old work	400
Iron for reinforcing and for protecting corners	490
Pointing up old work above concrete jacket	300
Riprapping outside of cribs	200
Engineering	1,350
Total	$26,069
Less estimated salvage on tools and lumber	500
Net cost	$25,569

This gives a cost of $11.68 per cubic yard for the whole job. But if we omit the last six items above mentioned as not usually chargeable to the yard price of concrete, we have $8.32 as the net yard price which includes the cost of all crib work and forms.

The work was done between July 5 and October 13 and was under the direct supervision of Joseph Mullen.

Cost of Forms for Concrete Bridges and Culverts.—The following is taken from Engineering and Contracting, March 26, 1919.

It has been found in bridge and culvert work in Kentucky that a fair approximation of the cost of forms for the different classes of reinforced concrete superstructures or culverts in state work may be estimated per cubic yard of concrete (if the forms are not to be used the second time) by allowing 100 ft. B.M. of lumber per cubic yard and four hours' time each for the carpenter and helper for the erection; and for the substructures of slabs or girder bridges, 2½ hours' carpenter's time and 2½ hours' helper's time for the plain concrete. These figures were given by Charles D. Snead, Bridge Engineer of the State Department of Public Roads, in an address at the Kentucky

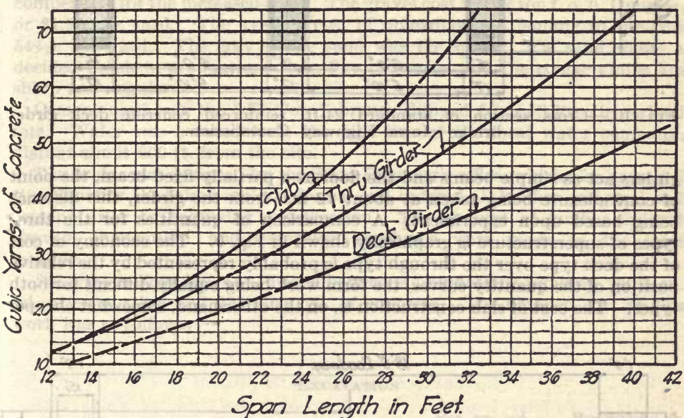

FIG. 9.—Quantities of concrete in three standard types of reinforced concrete superstructures—Iowa Highway Commission.

Road School, and are based upon actual work done with the ordinary type of labor available in the state. Where the forms are used twice it has been found that it requires about one-half the time, estimated for buildings, to re-erect them.

Relative Economy of Slab, Through Girder and Deck Girder Types of Concrete Bridges.—The following matter is taken from an abstract, published in Engineering and Contracting, March 24, 1915 of a paper by C. B. McCullough, presented at the 11th Annual convention of the American Concrete Institute at Philadelphia, Pa.

The slab type of superstructure consists of a simple beam or slab, reinforced for main and diagonal tension by longitudinal rods, and for lateral distribution, shrinkage and temperature stresses by transverse rods.

The deck girder type (see Fig. 10) depends for its economy on the fact that the carrying capacity of a beam varies as the square of the depth but only as the first power of the width. Thus the use of deep narrow girders operates to reduce the amount of material and consequently cuts down the cost. The stresses arising in the superstructure are transmitted into the girders by means of a thin doubly reinforced floor, which acts as a beam partially fixed and partially continuous. The girders themselves are reinforced for main and diagonal tension both by bent up rods and by stirrups.

In the through type of girder construction (see Fig. 11) two main side girders support the floor, which is hung or suspended between them. The main

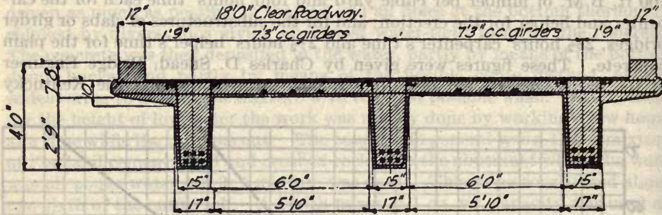

Fig. 10.—Cross section of standard 24-ft. reinforced concrete deck girder bridge—Iowa Highway Commission.

girders act as simple beams and the floor as a partially fixed beam, the point of contraflexure being taken at about 12 ins. from the girder, this distance being based upon experiment. A comparison of quantities for the three types of superstructure is graphically shown in Fig. 9. The economy of cost of the deck type over the through type is probably represented by the relative position of the quantity curves, the form work being equally difficult for both types. The cost of slab construction is, on the other hand, somewhat cheaper

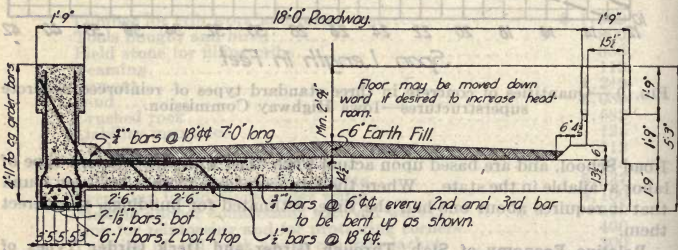

Fig. 11.—Cross section of standard 30-ft. reinforced concrete through girder bridge—Iowa Highway Commission.

than the quantitites would indicate, on account of the simple form work, and this type of construction is probably the economical one for spans below 20 or 22 ft. The economy of the through girder and the slab over the deck type is one of headroom rather than of cost.

Cost of 113-Ft. Reinforced Concrete Girder Bridge Near Douglas, Ariz.—During 1915–1916 the State Highway Department of Arizona constructed a 113-ft. concrete bridge over the Whitewater River near Douglas, Ariz. The structure was of the through girder type, and consisted of two spans 37 ft. 6 in. each and one span 38 ft. It replaced a 90-ft. frame bridge. Very complete cost data on the work are given in the recently issued annual report of Lamar Cobb, State Engineer, from which the matter that follows is given in Engineering and Contracting, Dec. 27, 1916.

The bridge was constructed by day labor under the direction of J. C. Ryan, Division Engineer of the State Highway Department. Laborers were paid $3 per 8-hour day and carpenters $4 per day. Teams and drivers were hired for $5 per day.

Gravel was secured from the Fairbanks beds. A few cars of screened sand were bought, but most of it was run-of-bank gravel and was screened on the ground. This gravel shows a very low voidage content.

Although this gravel was expensive, the superior results secured from it on account of its low voidage content, and general good qualities for mixing, compensate for the increased cost. The gravel cost $1 per ton f. o. b. Douglas, or $1.39 per yard. The average cost of unloading and hauling to site was 54½c per yard. The cost of the sand was the same. The sand shows a decided break in graduations from fine to coarse, and the coarse grains are sharp and angular.

Cement used was the "El Toro" brand, shipped from El Paso in carload lots. Water was secured from the pipe line of the local water company, distant about 600 ft. from the site.

The bridge was designed by the State Engineer's office, which also prepared the plans for the falsework and forms, and ordered all lumber and steel and cement prior to beginning construction. The amount of lumber ordered proved inadequate and extensive purchases were made in the local market.

Subaqueous Foundations.—The subaqueous foundations required 236.5 cu. yd. of excavation and 223.7 cu. yd. of concrete. The detailed cost of this work was as follows:

EXCAVATION

	Total	Per cu. yd. excavation (236.5 cu. yd.)	Per cu. yd. concrete (223.7 cu. yd.)
Foreman	$ 200	$0.85	$0.90

Superaqueous Foundations.—The original design, which called for reinforced concrete walls and columns resting on 24-in. footings at the bottom of the subaqueous excavation, was not followed in the construction. The successful placing of the reinforcing and concrete as in the original design would have required a water-tight sheet-piling, and a concrete seal at the bottom, and a type of sheeting that would stand without bracing. Sheet-steel piling would have served this purpose, but was not obtainable, so the original design was abandoned. Instead, that part of the foundations that were below water level were cast in mass-concrete, and that part of the foundations that were above the water level were put in according to the plans. This required that the reinforcing steel be cut to new lengths. The East abutment did not extend to sufficient depth to establish a firm foundation, and an extra subfooting was put under it, although the plans did not call for that depth. The only difficulty experienced in pouring this part of the foundation was that the forms for the columns were not strong enough to stand the weight of the concrete, and they bulged in spite of all that could be done to tie and brace them in place. The columns were on a skew, and the concentration of pressure on the sharp angles overcame the pressure on the flat angles, so that the columns deformed along the sharp angles. One column skewed so badly it was torn down and replaced, while all of them showed more or less deformation on the sharp angles. It is thought that if a heavy piece of timber had been placed along the sharp angles, and tied in securely, the trouble might have been prevented, but no provision had been made for such timber in the plans of the forms. The parapet placed on the abutments as a continuation of the curb on the girders did not allow sufficient play to take care of the expansion and cracks have developed in the parapet, especially on the east end.

The superaqueous foundations required 810 cu. yd. of excavation and the placing of 87 cu. yd. of concrete.

The yardage as to excavation, represents the dry excavation for the abutments. The excavation on the west end was through clay, while on the east end it was through hard gravel, requiring blasting to loosen it. Both excavations, after loosening, were taken out with scrapers. The yardage as to concrete is for the two abutments only.

Recapitulation—Substructure

Account	Cost	Pctg. of total cost of bridge	Cu. yd.	Cost per yard
Subaqueous foundations	$3,988.44	33.25	223.7	$17.85
Superaqueous foundations	2,470.58	20.55	120.0	20.61
Total substructure	$6,459.02	53.80	343.7	$18.80

Cost per yard subaqueous concrete, $17.85; cost per yard superaqueous concrete, neglecting reinforcements, $16.98. Average mix used in subaqueous concrete: 1 part cement, 3.2 parts sand, 4.8 parts gravel, 1.8 slag. Average mix used in superaqueous concrete: 1 part cement, 2 parts sand, 4 parts gravel.

SUPERSTRUCTURE

Falsework.—The original plans for falsework did not allow of any adjustment between the posts and caps, and it was necessary to make hard-wood wedges, and purchase additional timbers to serve as bottom caps. Twenty piles were also driven over the channel of the creek.

Girder Forms.—The failure of the girder forms to stand up under the strain of the pouring of the concrete caused the resulting girder to have a decidedly wavy appearance. The cause of this lay in the fact that the inside forms had no direct support, but relied on the outside forms to prevent any motion of the inside forms without a corresponding movement of the outside forms, but did not prevent both forms from moving laterally together. Not sufficient lumber was provided to prevent such lateral movement and when the concrete was poured, and the short legs under the inside forms were of necessity removed, the whole girder warped as a result of the unsupported weight on the inside. On the second and third spans, the brackets were left off the cross-pieces since they served no useful purpose. On these spans, the inside forms dropped, as on the first, but without pulling the outside forms so badly out of place. If it had been possible to pour the floor first, and then set the girder forms on the floor, this trouble might have been prevented, but the nature of the reinforcement did not allow casting the floor and curb-line separately from the girders, and that method was impracticable. If sufficient timbers had been provided to allow hanging both the girder forms from cross-timbers supported on posts resting on the falsework, it would again have been possible to avoid the trouble, but such timbers were not available.

An effort was made to put the forms up in sections, in order to save expense, but this plan failed because of the recessed corners at the top and bottom of the inside panels where the panels joined the coping and the curb. The forms caught in these recesses and prevented swinging the forms away after pouring. Because of this, each inside post had to be torn down before the panels could be moved. The same applies to the outside posts, but in a lesser degree, since the outside posts were of one piece, while the inside posts were in three pieces.

Concreting.—The first span was poured by dumping the buggies into a chute and shoveling from the chute to the forms, in an effort to save the forms from vibration as much as possible. Since this did not seem to have any effect, the rest of the bridge was poured by constructing a trestle work level with the tops of the forms and dumping directly into the forms.

Reinforcing.—The reinforcing presented some difficulty on account of its complexity, which ran up the cost of placing. The bars were spaced by small concrete bricks, and every effort was made to conform to the cross-section shown on the plans. In bending, the only trouble encountered was in the stirrups. The Bates Tyer used worked in a satisfactory manner, but the ties furnished were too light for the heavy steel, and broke easily under strain.

Forms—Framing and Erecting

Yardage concrete, 171 cu. yd.; board feet framed, 10.221 M. B. ft.; actual board feet used, 7.679 M. B. ft., $27.65; square feet covered, 5,330 sq. ft.; total cost per M. B. ft. actually used, $110; labor cost only per M. B. ft. actually used, $80; ratio feet framed to feet used, 1.34:1.

Total	$107.00	$0.6274	$10.510	$0.02014

Total Forms—Framing, Erecting and Stripping

Total cost, $952.99; cost per cu. yd. concrete, $5.5744; cost per M. B. ft. framed, $93.29; cost per square foot covered, $0.17894; cost of labor only, per M. B. ft. framed, $70.50; materials per square foot, $0.1350; cost of materials only, per M. B. ft. framed, $22.79; per square foot, $0.04394; first cost of lumber used, $300.10; per M. B. ft., $39.05; less credits for scrap recovered, $88; per M. B. ft., $11.40; net cost of lumber, $212.10 per M. B. ft., $27.65; ratio first cost to credits, 1:0.292.

The above costs are for the costs of framing both the girder, forms and the floor. Complete figures as to cost of the floor were not kept, but an estimate, based on the labor distribution for the first span shows the following costs per square foot:

Floor, 2,500 sq. ft. at $0.07	$175.00
Girders, 2,830 sq. ft. at $0.2330	671.00

From which:

Cost of laying floor, per sq. ft.	$ 0.0700
Cost of forms for plain surfaces	.1535
Cost of forms for paneled surfaces	.2330

These figures are for framing and erecting only, and do not include cost of stripping.

FALSEWORK: FRAMING AND ERECTING: BENTS

Yardage, concrete, 171 cu. yd.; board feet framed, 12.919 M. B. ft.; board feet actually used, 8.902 M. B. ft.

Concreting	2,137.00	12.5040
Total	$5,161.00	$30.1835

Costs of the McKinley Ford Bridge, La Salle County, Illinois.—The following data are from a detailed account of the construction of this bridge published in Engineering and Contracting, Feb. 24, 1915.

The McKinley Ford Bridge is located in Sarena township, La Salle county, Illinois. It consists of two 50-ft. reinforced concrete through girder spans on a concrete pier and abutments. The clear width of roadway is 16 ft., and the height of the pier and abutments, from bottom of footing to bridge seat, is 16 ft. 11 ins. The bridge was designed under the "General Specifications for Bridge Work" of the Illinois State Highway Department. It is a standard type, and was built during the latter part of 1913, at an actual cost of $3,893.

Pier.—The center pier has a thickness of 3 ft. and a width of 23 ft. 1 in., under coping; a thickness of 4 ft. 2 ins.; and a width of 24 ft. 3 ins. at the base; and a height, from bridge seat to bottom of footing of 16 ft. 11 ins. The coping has a width of 3 ft. 8 ins., a length of 23 ft. 9 ins., and a thickness of 15 ins. The footing has a width of 8 ft., a length of 25 ft., and a thickness of 2 ft., and it is reinforced with a layer of ½-in. square bars, spaced 12 ins. on centers. At the top, near each end of the pier, there is a recess 20 × 25 ins. × 15 ins. deep for the cast iron rockers. A concrete mixture consisting of 1 part cement, 3 parts sand, and 5 parts gravel was used. The pier extends 4 ft. 6 ins. below the bed of the stream.

Abutments.—The concrete abutments, which have a height, from bridge seat to bottom of footings, of 16 ft. 11 ins., are reinforced and are of the wing-wall type, the wing-walls being of the cantilever type. The abutments have a thickness of 12 ins., with vertical faces, this thickness being increased to 18 ins. under the girders. The footings have a width of 4 ft. 6 ins., a thickness of 20 ins., and extend to the same depth as the pier.

The wing-walls have a top thickness of 12 ins., and a bottom thickness of 18 ins. Their footings have a width of 6 ft. 3 ins. and a thickness of 20 ins. A concrete mixture consisting of 1 part cement, 2½ parts sand, and 4 parts gravel was used for the abutments and wing-walls.

Girders.—The girders have a depth of 5 ft. 6 ins., a thickness of top flange of 26 ins., and of web of 23 ins., and are paneled as shown in Fig. 1. They are spaced 18 ft. 2 ins. on centers. All exposed edges of the girders are beveled with a ¾-in. triangular molding, and all edges of panels have a 45° bevel. The girders are heavily reinforced, the main reinforcing bars being arranged in four rows, spaced 5 ins. on centers. The concrete mixture for the girders and floor system consists of 1 part cement, 2½ parts sand, and 4 parts gravel.

Floor System.—The bottom of the reinforced concrete floor slab is flush with the bottoms of the girders, while the top is crowned to conform with the finished roadway. The thickness of the floor slab at the crown is 13 ins., and at the curb 10 ins. Drainage of the roadway is secured by placing 3-in. tile drains through the slab and near the curb on 8-ft. centers. The wearing surface (which is not included in this contract) consists of a 6-in. layer of macadam.

Cast Iron Rockers.—Cast iron rockers are used under the ends of the girders which rest on the center pier; they are not used under the abutment ends of the girders. These segmental rockers have a thickness of 3½ ins., a depth of 14 ins., and a length of 2 ft., the top and bottom surfaces of which are turned to a diameter of 7 ins.

Steel bearing plates, 9 ins. wide, 1 in. thick and 2 ft. long, are placed at both the top and bottom of the rockers.

Expansion Joint.—A ¼-in. tar paper expansion joint is provided between the two girder spans. Tar paper is also placed on the top of the piers between the rockers and the edges of the piers. The space around the rockers is filled with asphalt.

SUMMARY OF MATERIALS REQUIRED

Reinforcing steel:	Lbs.
In pier	160
In abutments	6,360
In superstructure	36,080
Total	42,600
8 steel bearing plates	490
4 cast iron rockers	1,190
Concrete:	Cu. yds.
Class B, in pier	60.4
Class A, in abutments	103.8
Class A, in superstructure	140.4
Total Class B	60.4
Total Class A	244.2
Total concrete in bridge	304.6

As actually constructed there were used in the construction of this bridge 308.3 cu. yds. of concrete, the extra 3.7 cu. yds. being placed in the substructure. Square twisted bars were used for reinforcement.

Construction Features.—Construction work was started Sept. 13, 1913, and the bridge was completed Nov. 28, 1913. The bridge is located about four miles from the railroad station, and the materials, with the exception of the sand and gravel, were hauled that distance. The sand was removed from the creek and was transported in wheelbarrows a distance of 150 ft. The gravel was also obtained near the site, being hauled about 400 ft. About 125 cu. yds.

of the total of 187.4 cu. yds. of gravel required were screened. The prices of the materials are given under "Cost Data."

The pier was located in the bed of the stream, and the abutments, one on each bank. About 500 ft. B. M. of sheet piling were required for the coffer-dam of the center pier. Of the 240 cu. yds. of excavation required, about 108 cu yds. were classified as dry excavation and 132 cu. yds. as wet excavation. Foremen were paid 65 cts. per hour and workmen 25 cts. per hour. The rate of pay for teams was 45 cts. per hour.

Cost Data.—The data in Table XXVI give the quantities of materials used, the unit prices, the cost of each item, and the total actual cost of the bridge to the contractor.

TABLE XXVI.—QUANTITIES OF MATERIALS, UNIT PRICES AND TOTAL COSTS

Cement, 416 bbls. at $1.25		$ 520.00
Hauling cement 4 miles		65.84
Sand, in place, 117.2 cu. yds. at 30 cts		35.16
Hauling sand 150 ft. in wheelbarrows from creek		98.40
Gravel, in place, 187.4 cu. yds. at 30 cts		56.22
Screening 125 cu. yds. of gravel		78.20
Hauling gravel 400 ft		187.18
Form lumber, 6,000 ft. B. M. at $22.67		136.00
Falsework lumber, 3,000 ft. B. M. at $15		45.00
Wire, nails, etc., 240 lbs. at 5 cts		12.00
Hauling form lumber 4 miles		15.00
Hauling falsework lumber 4 miles		7.00
Reinforcing steel, 42,600 lbs		816.80
Hauling steel 4 miles		32.00
Rockers and plates, 1,680 lbs. at 2 cts		33.60
Asphalt, 50 gals. at 15 cts		7.50
Hauling rockers and asphalt at $4.50 per day		3.50
Sheet piling, 500 ft. B. M. at $20		10.00
Cost of driving sheet piling		8.00
Cost of removing sheet piling		5.00
Labor on 108 cu. yds. dry excavation:		
Foreman, 40 hrs. at 65 cts	$ 26.00	
Laborers, 344 hrs. at 25 cts	86.00	112.00
Labor on 132 cu. yds. wet excavation:		
Foreman, 130 hrs. at 65 cts	$ 84.50	
Laborers, 1,272 hrs. at 25 cts	318.00	402.50
Cost of pumping during excavation:		
Foreman, 9 hrs. at 65 cts	$ 5.85	
Laborers, 104 hrs. at 25 cts	26.00	31.85
Cost of pumping during concreting:		
Foreman, 4 hrs. at 65 cts	$ 2.60	
Laborers, 34 hrs. at 25 cts	8.50	11.10
Labor, building forms:		
Foreman, 115 hrs. at 65 cts	$ 74.75	
Laborers, 1,146 hrs. at 25 cts	286.50	361.25
Labor, building falsework:		
Foreman, 35 hrs. at 65 cts	$ 22.75	
Laborers, 350.5 hrs. at 25 cts	87.63	110.38
Labor, bending and placing steel:		
Foreman, 36 hrs. at 65 cts	$ 23.40	
Laborers, 361 hrs. at 25 cts	90.25	113.65
Labor, mixing and placing concrete:		
Foreman, 115 hrs. at 65 cts	$ 74.75	
Laborers, 1,142 hrs. at 25 cts	285.50	360.25
Labor, removing forms:		
Foreman, 20 hrs. at 65 cts	$ 13.00	
Laborers, 231 hrs. at 25 cts	57.75	70.75
Traveling expenses of men from Chicago and back		100.00
Gasoline, oil and incidentals		97.00
Total		$3,943.13
Salvage on lumber and falsework		50.00
Total net cost to contractor		$3,893.13

Table XXVII gives the unit costs of the various items of the bridge. There were 308.3 cu. yds. of concrete and 42,600 lbs. of steel placed. There were used on this work 416 bbls. of cement, 117.2 cu. yds. of sand, and 187.4 cu. yds. of gravel. The costs given do not include the cost of removing the old bridge.

The cost of the excavation per cubic yard of substructure concrete was $5.435, and the cost of the falsework per cubic yard of superstructure concrete was $1.278.

TABLE XXVII.—UNIT COSTS OF VARIOUS ITEMS

Item	Cost per cu. yd. of concrete
Cement	$ 1.971
Sand	0.448
Gravel	1.125
Labor on forms	1.525
Form materials	0.315
Labor on falsework	0.421
Falsework materials	0.161
Steel, in place	3.241
Mixing and placing concrete	1.379
Excavation	1.897
Miscellaneous, not included in above	0.145
Total	$12.628

Cost of Concrete Viaduct at Fort Worth, Texas.—The viaduct which carries an extension of North Samuels Ave. across the Trinity River in Fort Worth, Texas consists of nine spans of 50 ft.

The following data are given in a description of the methods and costs of constructing this viaduct by E. W. Robinson, published in Engineering and Contracting, April 29, 1914.

Contractor's Equipment.—The plant used on the job consisted of both new and second-hand machinery, which invoiced at the beginning of the job at $4,852. It consisted of the following: One 5-ton "A"-frame derrick car with a 60-ft. boom, operated by a 7 × 10-in. D. C. D. D. hoisting engine; a concrete chuting plant with an 18-cu. ft. bucket and 121 ft. of steel chutes; a single-drum mine hoist; a 9-cu. ft. gasoline-driven mixer with a self-loader; a 3-cu. ft. gasoline-driven mixer; 25 ft. of swinging leads and a 2,500-lb. drop-hammer which was operated from the boom of the derrick; two 1-cu. yd. turn-over dirt buckets and a 1-cu. yd. clam-shell bucket; and two pumps, one steam-driven and the other gasoline-driven. The small mixer was used to mix the concrete used in the railing at the opposite end of the bridge from the main plant, which made it unnecessary to operate the main plant for the small amounts of concrete required for that work. The chuting plant was moved twice, the second move being back to the first location.

In addition to the above mentioned equipment there were the usual petty tools and supplies for a job of this kind, on which depreciation is not far from 100 per cent. The total amount expended for petty tools and repairs for this job was $1,642, and these tools will likely invoice at about $200, showing a depreciation of 87 per cent, which is 5.9 per cent of the pay roll.

Materials and Proportions.—The concrete for the substructure was mixed in the proportions of 1:2½:5, and for the superstructure, in the proportions of 1:2:4. The top ½ in. of the sidewalks was surfaced with a 1:1 cement mortar, which was floated and troweled to a smooth finish. The sand was bank sand from local pits. It was delivered on the job for $1.20 per cubic yard. The stone used was crushed limestone from a nearby town. It was required to pass a 1-in. ring for the 1:2:4 concrete, and to pass a 2-in. ring for the 1 : 2½ : 5 concrete. The stone cost $1.26 per long ton of 2,240 lbs. f. o. b. cars at a team track located about ¼ mile from the work. It was unloaded by contract for $0.25 per long ton. One-man stone cost practically the same on the job as the crushed stone. About 250 tons of this were used in the abutments and pier shafts, but little saving was effected by its use, owing to the high cost of placing it, as the yardage in each place did not warrant much outlay for hoisting, etc.

Mixing and Placing.—All of the concrete, except a small yardage in a part of the railing, was mixed and placed through the central plant at the tower. The whole superstructure between curbs for one span was poured in one continuous operation, the sidewalk stringer, the curb stringer and the sidewalk slab being poured a few days later. The reason for this was because of the difficulty of supporting the side forms for the curb stringers to line and grade while the concrete on the roadway slab was still green.

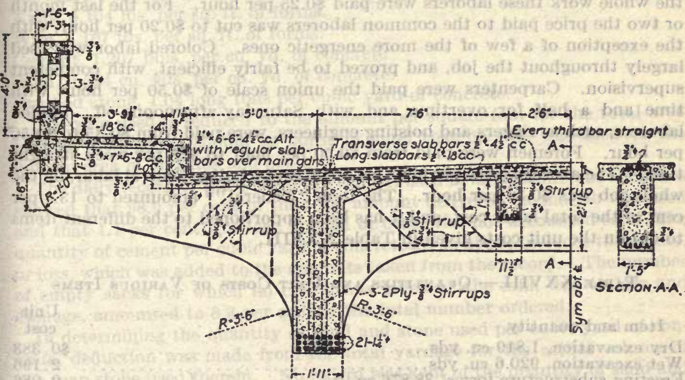

FIG. 12.—Cross-section of roadway—Fort Worth Viaduct.

The main towers, which were approximately 110 ft. high, were so designed that the concrete would reach all points on a grade of not less than 1 in 4. However, the arrangement was not always followed as intended, and occasionally this slope was flattened. The maximum distance which the concrete was chuted was 250 ft., and no trouble was experienced except when a dry batch was run through, which caused the following batch to spill over the sides of the chutes.

The stone and sand were dumped as near as possible to the mixer, and were conveyed from the piles to the hopper of the self-loader in wheelbarrows. Although at times of short duration the concrete was properly mixed and deposited at the rate of 30 or 35 cu. yds. per hour this rate could not be maintained for any great length of time. A good average for the whole day's run was 20 cu. yds. per hour. A high-speed mine hoist was used for raising the bucket in the tower, and there were no delays from that source. The typical organization of the concrete gang for a day's run was 3 men on the sand, 6 men on the stone, 2 men bringing and emptying the cement into the mixer, 1 man each to run the mixer and hoister, and 4 men on top placing and working the concrete around the reinforcement and shifting the chutes. However, the above organization would vary according to the location and condition of the stone and sand piles.

Cost Data.—The general foreman, or timekeeper, was required to make out daily reports showing the number of hours spent each day on each item of work, together with the wage rate. These reports were filed in the office, together with the progress charts and photographs, and constitute a complete record of the progress of the work as well as furnishing a method of determining the cost of the various classes of work done. The man who made out these reports was required to make the totals check with the total time turned in for the pay-roll. In this way the total cost of labor is absolutely correct, although the different items may be in error to some extent.

Eight hours constituted a day's work except in an emergency. For the first week or two common laborers were paid $1.75 per day, but for practically the whole work these laborers were paid $0.25 per hour. For the last month or two the price paid to the common laborers was cut to $0.20 per hour, with the exception of a few of the more energetic ones. Colored labor was used largely throughout the job, and proved to be fairly efficient, with competent supervision. Carpenters were paid the union scale of $0.50 per hour, with time and a half for overtime and with Saturday afternoons off. Skilled laborers, such as riggers and hoisting engineers, were paid from $0.35 to $0.50 per hour. Foremen were paid from $0.50 per hour to $25 per week straight time. The average price per hour for all labor, including general labor, on the whole job was $0.34 per hour. The item "General"* amounted to 13.4 per cent of the total labor cost, and it has been apportioned to the different items to obtain the unit costs given in Table XXVIII.

TABLE XXVIII.— QUANTITIES AND UNIT COSTS OF VARIOUS ITEMS

Item and quantity	Unit cost
Dry excavation, 1,819 cu. yds.	$0.383
Wet excavation, 920.6 cu. yds.	2.196
Erecting substructure forms, 38,876 sq. ft.	0.086
Erecting substructure forms, 3,413.6 cu. yds.	0.971
Wrecking substructure forms, 38,876 sq. ft.	0.017
Wrecking substructure forms, 3,413.6 cu. yds.	0.190
Erecting superstructure forms, 44,460 sq. ft.	0.149
Erecting superstructure forms, 1,237.2 cu. yds.	5.346
Wrecking superstructure forms, 44,460 sq. ft.	0.025
Wrecking superstructure forms, 1,237.2 cu. yds.	0.928
Bending and placing reinforcing steel, 123.9 tons	13.42
Driving foundation piles, 200	2.995
Preparing concrete plant, 4,650.8 cu. yds.	0.302
Mixing and placing concrete, 4,650.8 cu. yds.	0.823
Railing, complete, 906 lin. ft.	1.395
Railing, complete, 76.9 cu. yds.	16.44
Placing rip-rap, 690 cu. yds.	0.129

* The item "General" is intended to cover all labor which is general in its nature and cannot be charged to any particular class of work, such as that of the superintendent, general foreman, night watchman, and water boy. This cost is kept as a separate item, and is distributed to all other items in proportion to their total costs.

Miscellaneous Data.—The following quantities of lumber were delivered and used on the job:

Size	Ft. B. M.
1-in.	60,161
2-in. and 3-in.	98,848
4 × 4-in. to 8 × 12-in.	37,840
Miscellaneous and second-hand	20,800
Total, various sizes	217,649

Of this amount between 7,000 and 8,000 ft. B. M. of the 1-in. lumber had a salvage value of from one-half to two-thirds its cost price. There was also about the same amount of 2-in. and 3-in. lumber which could be used again or sold as second-hand lumber. Practically all of the large timbers were in good shape at the end of the job, but in the smaller sizes the loss approximated 50 per cent or more.

The quantities of materials given below are reduced to the amounts used per cubic yard of concrete or per square foot of forms, as the case may be:

Nails, 0.104 lbs. per sq. ft. of forms.
Wire, 0.107 lbs. per sq. ft. of forms.
Cement, 1.207 bbls. per cu. yd. of concrete
Sand, 0.504 cu. yds. per cu. yd. of concrete.
Crushed stone, 1.04 long tons per cubic yard of concrete.

The wire used is reduced to the amount per square foot for the total area formed, although it should be borne in mind that no wire was used on the bottom area of all slabs and beams.

The daily record of the quantity of cement used in all the different members showed that 98.9 per cent of the total amount delivered on the job was used and that 1.1 per cent was lost, wasted or otherwise not accounted for. The quantity of cement per cubic yard of concrete given above includes this waste, or loss, which was added to the amounts taken from the record. The number of empty sacks for which no credit was given at the mill, due to loss and damage, amounted to 8.3 per cent of the total number ordered.

In determining the quantity of sand and stone used per cubic yard of concrete, deduction was made from the total yardage for the actual volume of one-man stone used therein. No record was kept of the quantity of sand and stone used in the separate members.

Construction was started the latter part of May, 1913, and the work was completed in January, 1914.

The total bidding price of the viaduct was $54,339.63, but owing to increases in the quantities over the engineer's estimate, due to changes in the plans, the final contract price was $57,303.48. Although all of the work never ceased, except during the very heaviest rains, the whole progress was delayed several weeks on account of high water. Some material was lost by floods during September and December. Fortunately, each time the water rose to an unusual height it happened that there were no newly poured spans on the falsework in the channel.

(The cost per sq. ft. was about $3.07, based upon the contract price of $54,339.63 and the total area of the viaduct.)

Cost of Main Street Concrete Viaduct, Fort Worth, Texas.—The contract cost of the Main Street Viaduct, Fort Worth, Tex., given in Engineering and Contracting, March 10, 1915 in an abstract of a paper by S. W. Bowen in Proceedings A. S. C. E., Vol. XL, follows:

The viaduct has a 54-ft. clear roadway and two 8-ft. sidewalks. The general dimensions and type of construction are shown in Fig. 13.

Because of the sudden, large and rapid rises to which the Trinity River is subject it was thought advisable to use, at least for the arch spans, a method of construction that would not require falsework in the stream.

After a careful consideration of various types, it was decided to use, for the main spans of the viaduct, three-hinged, ribbed arches, with structural steel reinforcement designed to support the weight of the forms and the plastic concrete of the ribs and braces during construction. For the approach spans and for the river spans of the smaller viaducts girder spans were adopted.

The three-hinged arch was selected because it would not be strained by unequal settlement, because the stresses are statically determinate, and

TABLE XXIX.—QUANTITIES OF MATERIALS AND COST OF VIADUCT

Item No.	Description	Quantity	Unit price	Cost	Percentage
1	Grading............	4,720 cu. yds.	$ 0.35	$ 1,652.00	0.43
2	Foundation excavation...............	15,227 cu. yds.	1.00	15,227.00	3.96
3	Rock excavation.....	444 cu. yds.	2.00	888.00	0.23
4	(a) Concrete No. 1 (1:2:4)...........	10,611 cu. yds.	10.25	108,762.75	28.16
	(b) Concrete No. 2 (1:2½:5)...........	14,880 cu. yds.	6.85	101,928.00	26.40
	(c) Concrete No. 3 (1:3:6)...........	438 cu. yds.	6.25	2,737.50	0.71
5	Railings...........	3,875 lin. ft.	2.00	7,750.00	2.01
6	Structural steelwork.	1,537,400 lbs.	0.05	76,870.00	19.90
7	Steel reinforcing bars.	1,375,150 lbs.	0.035	48,130.25	12.46
8	Steel castings........	205,460 lbs.	0.07	14,382.20	3.72
9	Iron castings........	11,173 lbs.	0.04	446.92	0.11
10	Anchor-bolts and T. P. casings.........	21,311 lbs.	0.06	1,278.66	0.33
11	Steel dowels.........	98	3.00	294.00	0.08
13	Rip-rap............	836 cu. yds.	1.50	1,254.00	0.32
14	Manholes..........	2	50.00	100.00	0.03
15	Removing old bridge.	....	......	2,500.00	0.65
17	Timber piles........	194	10.00	1,940.00	0.50
	Total..........................		....	$386,141.28	100.00

because the temperature stresses are eliminated. Ribbed construction was adopted as being light and best adapted to the use of hinges, and also because no waterproofing would be required. Structural reinforcement for the ribs and braces was used in order to dispense with falsework, as far as possible.

The cost of the viaduct, per linear foot, was $244.60; the cost, per square foot of horizontal projection, was $3.66; the cost, per square foot of vertical projection, was $6.34; and the cost, per cubic foot of volume, between finished ground line and crown of roadway, was $0.091. The total estimated cost of the viaduct, including paving, lighting and engineers' fees, was $428,882.

The cost per square foot of vertical projection is based on the area of the projection of the viaduct between the finished ground line and the top of the roadway. For the horizontal projection, the extreme width over the copings or stringer moldings was taken. In computing the cost per cubic foot the volume included between vertical planes through the copings and between the finished ground line and the top of the roadway was taken. The total cost on which the above unit costs are based is the cost of the structure based on the contractor's unit prices and the quantities as given in the table, to which has been added the cost of the paving, lighting, and engineers' fees.

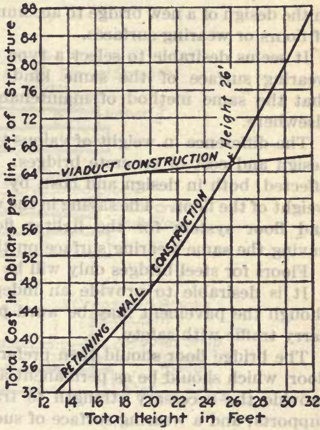

FIG. 13A.—Economic height-limit of retaining wall.

Economic Height-Limit of Retaining Wall as Compared with Viaduct Construction for Hill Side Road.—In constructing the side-hill road called Beardsley St., in Kansas City, comparative cost studies were made to determine at what height (from foundation to grade) viaduct construction would be more economical than retaining walls with fills.

The following cut reproduced from Engineering News-Record, June 13, 1918, shows the general method used. The solution in this particular case gave the economic height-limit of the retaining wall construction as 26 ft. In applying this method to other conditions it would be, of course, necessary to make a new diagram plotted from estimates for those conditions.

Cost of Steel Highway Bridges and Floors.—The following data, given in Engineering and Contracting, Jan. 1, 1915, are taken from a paper by Clifford Older (Bridge Engineer, Illinois Highway Commission) presented at the annual convention of the American Road Builders' Association in Chicago, Dec. 14–18, 1914.

Maintenance of Bridge Floors.—Definite statistics in regard to the number and length of highway bridges for any considerable mileage of highways are difficult to obtain and are not at present available. In some states, however, we are able to ascertain the amount of the total expenditure for bridge work of all kinds. Available information of this kind seems to indicate that approximately one-half of the funds raised for ordinary road and bridge purposes are expended in the renewal and maintenance of bridges.

It is evident, therefore, that if maintenance expenditures are to be reduced to the minimum highway bridges and bridge floors should receive careful consideration.

Judging from conditions in Illinois it is probable that at least 90 per cent of all existing highway bridges are provided with nothing better than plank floors, and that the maintenance of these floors costs approximately 15 per cent of the total expenditure for road and bridge maintenance, or about $10 per mile of road per annum.

Floors for New Bridges.—It is a simple matter to provide sufficient strength in the design of a new bridge to accommodate any of the various modern types of floors or wearing surfaces.

It seems desirable to select a type of floor which will permit the use of a wearing surface of the same kind as that on the adjacent highway, so that the same method of maintenance may be used on the bridge floor as elsewhere.

The difference in weight of vaious types of floors has but little effect on the design and cost of concrete bridges. Steel bridges, however, are materially affected, both in design and cost, by a comparatively small variation in the weight of the floor. The saving in the weight and cost of the steel in the trusses and floor system for the lighter floors may out-weigh the advantage of having the same wearing surface on the bridge as elsewhere on the highway.

Floors for steel bridges only will be considered in this discussion.

It is desirable to provide an independent wearing surface so that even though the pavement may be worn practically through, the bridge will still carry traffic with safety.

The bridge floor should then preferably consist of two elements: The sub-floor, which should be as permanent as the bridge superstructure, and should provide the necessary strength to transmit the highway loads to the floor supports; and a wearing surface of such character as to permit of economical maintenance.

In considering construction materials for both of these elements the matter of weight increases in importance with the length of span. For sub-floors of the more permanent type buckle-plates with concrete covering, reinforced concrete, and creosoted plank cover the field. For wearing surfaces, brick, concrete, creosoted blocks, macadam gravel, mixtures of bituminous materials with sand, gravel or stone, plank, ordinary soil, and practically all other varieties of surfacing materials have been used.

In comparing costs it is necessary to consider, not only the cost of the floor and its maintenance, but also the effect of the weight of floor selected on the design and cost of the remainder of the bridge.

Classification of Floors.—For the purpose of considering the effect of the weight of the floor on the design of the superstructure the various types of floors are herein grouped in four classes, as follows:

Class A Floors.—Floors which weigh approximately 100 lbs. per square foot of roadway surface are included in Class A. Floors consisting of a reinforced concrete sub-floor, assumed to weigh 50 lbs. per square foot, on which is placed a wearing surface of concrete, brick, macadam or gravel, are of this class. The wearing surface is assumed also to weigh 50 lbs. per square foot of roadway surface.

Class B Floors.—Floors which weigh approximately 65 lbs. per square foot of roadway surface are included in Class B. Floors consisting of a concrete sub-floor, with a creosoted block wearing surface, and floors consisting of creosoted plank sub-floors with a brick wearing surface, are of this class.

Class C Floors.—Floors which weigh approximately 32 lbs. per square foot are included in Class C. Floors consisting of a creosoted plank sub-floor, with a creosoted block wearing surface, are included in this class.

Class D Floors.—Floors which weigh approximately 26 lbs. per square foot are included in Class D. Floors consisting of a creosoted plank sub-floor, with a wearing surface about ¾ in. thick and composed of a mixture of gravel and bituminous material, are of this class.

Buckle-plate floors are not considered, as they weigh as much and cost more than concrete sub-floors.

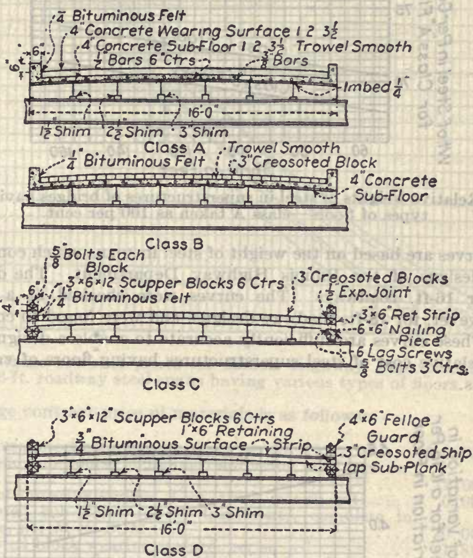

FIG. 14.—Standard types of bridge floors, Illinois Highway Department.

Standard Types of Floors.—Figure 14 shows standard designs used by the Illinois Highway Department for the floors above mentioned.

The creosoted plank sub-floors (Class C and Class D) are crowned by bending the plank over the stringers and anchoring the ends to the nailers by means of lag-screws.

The creosoted blocks (Class B and Class C) are laid on a ¼-in. bituminous felt cushion, which is coated with asphalt immediately before laying the blocks.

Ship-lap sub-plank are used for floors having a bituminous gravel wearing surface. The use of this form of sub-plank has been found to be the cheapest and most effective method of preventing the leakage of the bituminous material.

Explanation of Curves.—The curves shown in Fig. 15 give the weight of the structural steel in bridge superstructures as a percentage of the weight of the steel in superstructures having Class A floors, that is, the weight of superstructure steel in bridges having floors weighing 100 lbs. per square foot is taken as 100 per cent and the weight of steel required for the lighter floors is expressed as a percentage of this weight.

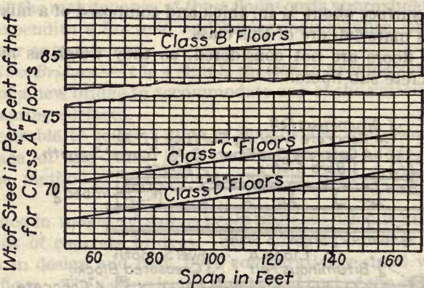

FIG. 15.—Relative weights of steel in superstructures of bridges having different types of floors—class A taken as 100 per cent.

These curves are based on the weight of steel in spans which conform to the standard designs of the Illinois Highway Department. The designs used provide for 16-ft. roadways. The curves were checked at a number of points, however, for 18-ft. roadway designs, and were found to conform very closely. These curves are sufficiently accurate to enable a designer to determine the relative cost of steel superstructures having floors of various types and weights.

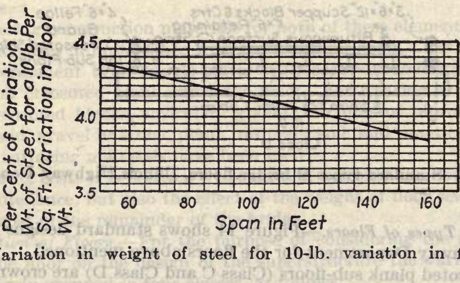

FIG. 16.—Variation in weight of steel for 10-lb. variation in floor weight.

The curve shown in Fig. 16 is based on the curves of Fig. 15, and it shows the average per cent variation in weight of steel for a variation of 10 lbs. per square foot in the weight of the floor.

Figure 17 shows the average contract prices for the Illinois Highway Department standard 15-ft. roadway steel spans with floors complete. For spans up to 80 ft., inclusive, riveted pony trusses are used, and for spans from 90 to 160 ft., riveted Pratt trusses are used. This range of span length covers at least 90 per cent of the highway bridges in Illinois.

"A."—Sub-floor concrete, surface concrete.
"B."—Sub-floor concrete, surface blocks.
"C."—Sub-floor plank, surface blocks.
"D."—Sub-floor plank, surface bituminous.
"D_1."—Sub-floor plank, surface bituminous—includes capitalized maintenance.
"E."—Untreated plank floor—includes capitalized maintenance.

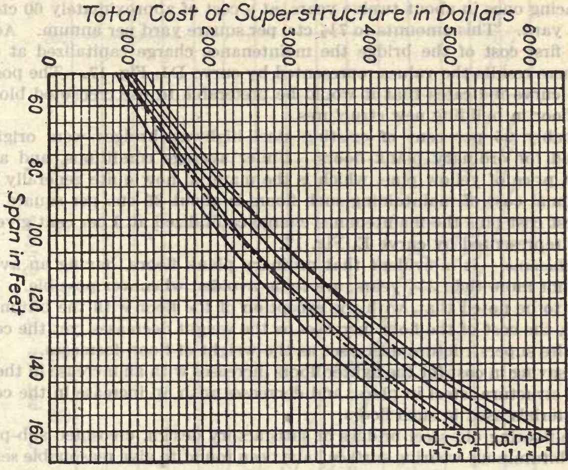

FIG. 17.—Average contract prices for Illinois Highway Department standard 16-ft. roadway steel spans having various types of floors.

The average contract price of materials is as follows:

Structural steel complete in place, per lb.	$ 0.03½
Concrete sub-floors, including reinforcing steel, per cu. yd.	12.00
Concrete wearing surface, 4 ins. thick, per sq. yd.	0.90
Creosoted sub-plank (12-lb. treatment), complete in place, per M ft. B. M.	70.00
Creosoted block wearing surface, per sq. yd.	1.80
Bituminous gravel wearing surface, per sq. yd.	0.60

The average cost of sub-floor and wearing surface per linear foot of 16-ft. wide roadway (1.78 sq. yds. including curbs) is as follows:

	Per lin. ft. of bridge
Concrete sub-floor with concrete wearing surface (wt. 100 lbs. per sq. ft.)	$4.25
Concrete sub-floor with creosoted block wearing surface (wt. 65 lbs. per sq. ft.	5.80
Creosoted plank sub-floor with creosoted block wearing surface (wt. 32 lbs. per sq. ft.)	7.30
Creosoted plank sub-floor with bituminous gravel wearing surface (wt. 26 lbs. per sq. ft.)	5.15

It seems probable that under average conditions the length of life of the floors represented by the upper three full-line curves of Fig. 17 may equal that of the remainder of the superstructure and that the cost of maintenance for this period would be small.

The experience of the Illinois Highway Department seems to indicate that, under average conditions, the bituminous wearing surface requires a light treatment of oil and stone chips or screened gravel at intervals of about four years, at a cost of about 10 cts. per square yard, and a probable complete resurfacing once in about twelve years, at a cost of approximately 60 cts. per square yard. This amounts to 7½ cts. per square yard per annum. Adding to the first cost of the bridge the maintenance charge capitalized at 6 per cent there results the values represented by curve D1, Fig. 17. The position of this curve indicates that it would be preferable to use creosoted block or other floor in building new structures.

Probably 95 per cent of existing steel highway bridges were originally designed for ordinary plank floors. Under average conditions, and at the present price of yellow pine, which is the material now quite generally used, the annual cost of maintaining such floors is about 35 cts. per square yard. The first cost plus the maintenance charge capitalized at 6 per cent gives the results represented by curve E, Fig. 17.

Conclusions.—It is evident that ordinary plank floors, having an average life of not more than 3½ years, are to be avoided whenever possible.

It is to be noted that, with the exception of the floor with the bituminous surface, the cost of the floor increases as the weight decreases, yet the cost of the entire superstructure decreases as the weight of floor decreases.

The saving in cost for the lighter floors increases with an increase in the unit cost of structural steel in place, and decreases with an increase in the cost of the materials used in such floors.

In re-flooring old steel bridges of satisfactory design, creosoted sub-planks with a bituminous wearing surface have been found to give reasonable service. The weight is somewhat greater than that of a plank floor, but the effect of the added weight is probably offset by the reduction of impact, due to the comparatively smooth and yielding surface.

The cost of maintaining the bituminous surface is only about 20 per cent of that of an ordinary plank floor.

There seems to be no place in the economic design of new highway bridges for floors consisting of a creosoted plank sub-floor with a brick wearing surface, as the life of such a floor could hardly be greater than that of Class C, Fig. 14, while the cost of the complete superstructure would be greater than that represented by curves B and C, Fig. 17.

The floors listed under Class A seem hardly to be justifiable, except for short spans, unless other considerations outweigh first cost.

Economic Panel Length for Bridge Floors of Concrete Slabs on Steel Beams.—William Snaith gives the following data in an article "Standard Bridge Floors of Concrete Slabs on Steel Beams" published in Engineering News-Record, July 12, 1917.

The floor systems investigated have been designed to meet the usual standard specifications as to construction. The dead-load D is taken to include the weight of the concrete slab, the supporting steel and two hand-rails each weighing 200 lb. per lin. ft. The live-load L is either a 15-ton road roller or a uniform load of 100 lb. per sq. ft., whichever gives the greatest stresses. The roller is assumed to consist of two back wheels with 20-in. face and 5-ft. center to center and of one front wheel with 40-in. face, the axles being 10 ft. center to center and the load on each of the three wheels being 10,000 pounds.

The effect of impact is calculated from the formula:

$$Impact = \frac{L_2}{2(D + L)}$$

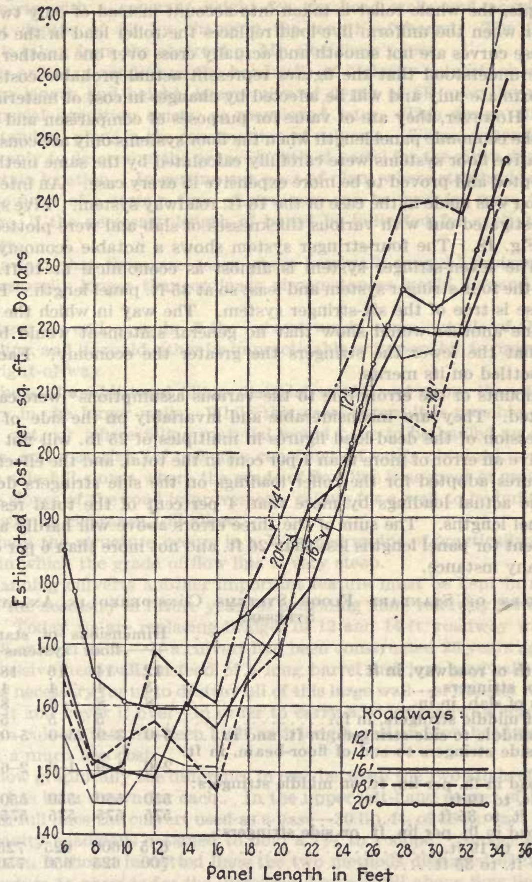

FIG. 18.—Estimated costs of floors per square foot, including floor-beams, stringers, slab and curb.

This impact formula will give uniformly better results than a straight percentage of the live-load or a formula based only on live-load and panel length.

Average prices for steel beams in place in bridge floors and for concrete in place were assumed, and the total cost of one bay (slab, curb, stringers and floorbeam) was calculated. These values were divided by the area of floor supported (nominal width multiplied by panel length), and the results were expressed in curves, Fig. 18.

Owing to the use of commercial sizes and abrupt changes in loading, when, for example, the whole roller is taken into account instead of only two back wheels, or when the uniform live-load replaces the roller load in the calculations, these curves are not smooth and actually cross over one another. It is not to be understood that the figures represent actual probable costs; they are approximate only and will be affected by changes in cost of materials and locality. However, they are of value for purposes of comparison and clearly indicate the economic panel length when the floor systems only are considered.

Alternative floor systems were carefully calculated by the same methods as those adopted and proved to be more expensive in every case. An interesting comparison was made in the case of the 16-ft. roadway system. Five systems were investigated out with various thicknesses of slab and were plotted similarly to Fig. 18. The four-stringer system shows a notable economy at all spans. The seven-stringer system is almost as economical at 10-ft. panel length as the four-stringer system and least so at 35-ft. panel length. Exactly the reverse is true of the six-stringer system. The way in which the curves crossed one another would show that no general statement would be warranted that the fewer the stringers the greater the economy. Each case must be settled on its merits.

The amounts of the errors due to the various assumptions* were carefully investigated. They are inconsiderable and invariably on the side of safety The expression of the dead-load figures in multiples of 25 lb. will not in any case involve an error of more than 1 per cent in the total, and the effect of the round figures adopted for the roller loadings on the side stringers does not exceed the actual loadings by more than 4 per cent of the total results at 35-ft. panel lengths. The sum of the three errors above will hardly amount to 4 per cent for panel lengths less than 20 ft. and not more than 6 per cent at 35 ft. in any instance.

PARTICULARS OF STANDARD FLOOR SYSTEMS CONSIDERED IN ANALYSIS OF STRESSES

	Dimensions of standard floor systems				
Clear width of roadway, in ft.	12	14	16	18	20
Number of stringers	3	4	4	4	5
Thickness of slab, in in.	8	8	8	8	8
Spacing of middle stringers, in ft.	...	5	5	5	5
Distance middle to side stringers, in ft. and in.	5–0	3–9	5–0	5–0	4–6
Distance side stringers to end of floor-beam, in ft. and in.	2–0	1–9	1–6	2–6	1–6
Dead-load in lb. per lin. ft. on middle stringers:					
Panels 6 ft. to 19 ft.	550	550	550	550	550
Panels 20 ft. to 35 ft.	575	575	575	575	575
Dead-load in lb. per lin. ft. on side stringers:					
Panels 6 ft. to 19 ft.	675	600	625	725	600
Panels 20 ft. to 35 ft.	700	625	650	750	625

* The assumptions were as follows:
1. Max. bending moment equals the sum of the Max. L.L. and D.L. moments.
2. D.L. per lin. ft. per stringer taken in round numbers to nearest multiple of 25 above the actual.
3. L.L. from the roller on side stringers taken in even thousands of pounds.
4. Wt. of each wheel acts at a point (in stringer and floor beam calculations).
5. In stringer calculations the slab is assumed not to be continuous.
6. Length of floor beam (between center line of trusses) is assumed to be 2 ft. greater than width of roadway.

The Economic Design of Culverts for Various Depths of Fill.—In a paper before the Ohio Engineering Society, an abstract of which is published in Engineering and Contracting, March 31, 1915, P. K. Sheidler of the Ohio Highway Department points out the advantages of using a standard design for culverts with a constant height for the head walls and providing for different depths of fill by changing the length of barrel. The following matter is taken from the abstract of Mr. Sheidler's paper.

Under ordinary conditions the headwalls of highway culverts should have the same length and height, irrespective of depth of fill over them—unless some special condition exists, as mentioned later. This design allows the use of standard plans in the construction of culverts To use a standard plan one has only to determine the proper length of barrel for the given depth of fill at a certain location. In getting out a set of plans where standards are used, one blue print of a certain type of structure can be used for more than one structure, if the necessary length of barrel be indicated for each particular structure.

It is a fact that there are cases where headwalls must be designed higher and necessarily longer than ordinary circumstances would demand. These are:

1. Where the end or ends of the culvert would come outside of the right-of-way line, and it would either be impracticable or impossible to procure additional right-of-way.

2. Where the additional filling material would cost more than the extra masonry in the larger walls. While this case is rare it is possible—such as in rock cut, or where filling material would have to be hauled an excessive distance, and materials for masonry construction easily obtained.

3. On side hill slopes where the grade of flow line is as great or greater than the side slopes of the road improvement, calling for a wall to be built as close to roadway as clearanee will allow.

4. Where the structure occurs in a V-shaped ravine of practically constant width, in which the grade of flow line is very steep.

In planning culverts another important feature must be kept in mind. I refer to the necessity in future years of providing more roadway for increased traffic. Today we are replacing bridges of 12 and 14-ft. roadway with those of 16, 18 or even 24 ft. If a culvert had been constructed 25 years ago with a high, massive headwall, instead of a long barrel and low headwall, today it becomes necessary for us to destroy all of this large wall—or at least to remove part of it and cover it over—in order to carry a wider roadway across. Extending a culvert that has been built with long barrel and low headwall can be done at a much less cost.

To show graphically the difference in cost between the two kinds of designs, a curve has been drawn for each. In the upper left-hand corner of Fig. 19 is shown in full lines the culvert used as a base—30 lin. ft. of 18-in. cast iron pipe with gravity headwalls designed to hold a 1½ to 1 slope. Superimposed on this section is shown in dotted lines the two methods discussed of increasing the structure to provide for the increased depth of fill above flow line.

Two tables were computed to obtain data for plotting the curves and are also shown. The table marked "A" gives total costs of culverts whose barrels are kept a constant length of 30 ft. and whose headwalls are raised and lengthened for different depths of fill varying by 1 ft.

Table "B" shows the cost of culverts whose headwalls are kept of constant dimension, and whose barrels vary in length to fit the road section.

TABLE A.—ESTIMATED QUANTITIES AND COSTS OF CULVERTS WITH HIGH HEAD WALLS

H = height above flow line	L = length of head wall	W = width of bottom	Concrete, cu. yds.	C. I. pipe, lin. ft.	Hand rail, lin. ft.	Cost of head wall	Cost of barrel	Cost of hand rail	Total cost
3	5′–0″	1′–9″	2.6	30	..	$ 20.80	$60.00	......	$ 80.80

11	5′–0″	1′–9″	2.6	54	125	20.80	108.00	50.00	178.80
12	5′–0″	1′–9″	2.6	57	175	20.80	114.00	70.00	204.80

The curve "C" was plotted to show the cost of fill that would be necessary to cover the barrel of the long culverts and to occupy the space taken up by the high headwalls, if they were to be removed. The area between the curves "B" and "C" represents this cost—the ordinates being plotted from the curve "B."

The sudden jump in the upper curve is caused by adding the cost of handrail to this type of culvert at the point where top of the wall is five feet above flow line in order to comply with the state law governing this. The assumed prices used are:

Concrete, cu. yd.	$8.00
18-in. cast iron pipe, lin. ft.	2.00
Handrail, lin. ft.	1.00
Earth fill, cu. yd.	.40

In order to show a specific example from these tables, we have selected the two types of culverts that would be necessary for a fill of ten feet above the flow line—the two types are superimposed to make the comparison more striking. This is shown in Fig. 19. The cost of the culvert with the high walls is $607.60, while that of the other is only $162.80, representing a saving of $444.80.

Cost of Concrete Arch and Pipe Culverts, Using Collapsible Steel Forms, Menominee County, Mich.—In extending the Bay Shore Road in 1911 a number of culverts were required. The costs of these culverts as built by force account are given in an article by K. I. Sawyer in Engineering and Contracting, March 13, 1912, from which paper the following data are taken.

Three sizes of concrete culverts were adopted for use on this road, standard sizes being used in batteries when necessary capacity required. The sizes adopted were 24 in. round tile and 48 and 96 in. diameter full arch culverts.

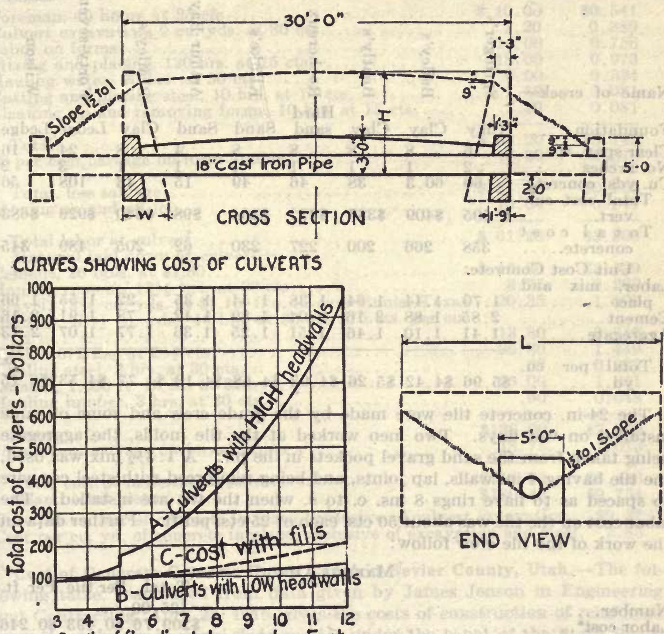

FIG. 19.—Curves showing the difference in cost under various depths of fill of a typical road culvert.

The so-styled culvert crew put in all the 4 and 8 ft. arches on this road and two arches on No. 1 road this season. The crew was equipped with Blaw collapsible steel centering, lumber and miscellaneous tools. The crew lived in tents, taking its own cook with it, and moved from creek to creek. All culverts are designed for 25 ton engine, live load; they are of monolithic pattern and without reinforcement. This latter requirement was not to the satisfaction of the engineer, but was necessary on account of local sentiment. The crew was inexperienced when started and the engineer lived practically on the job for the first two structures. Better success was had, however, than a year previous, when a culvert was installed by a crew of experienced sidewalk and street concrete workers.

Costs and data on culverts are given in Table XXX. The schedule of wages of this culvert crew was:

Foreman, 30 cts. per hour.
Teams, 45 cts. per hour
Labor, 20 cts. per hour.

TABLE XXX.—MASS CONCRETE CULVERTS—NO REINFORCEMENT

Name of creek—	Springer's	Bailey's	Beatly's	Rochereux	Klinke's	Arthur Bay	Brailey's	Forty-seven	Wilson
Foundation......	Clay	Clay	Clay	Hard sand	Sand	Sand	Clay	Ledge	Ledge
Clear span, ft ...	16	8	8	8	8	4	8	24	16
No. arches	2	1	1	1	1	1	1	3	2
Cu. yds. concrete.	60	60.3	38	46	49	15	43	108	56
Total cost culvert.	$ 505	$409	$387	$372	$364	$98	$340	$929	$683
Total cost concrete.....	358	266	200	227	230	62	205	489	345
Unit Cost Concrete:									
Labor, mix and place	1.70	1.44	1.64	1.38	1.54	1.35	1.22	1.55	1.66
Cement.........	2.85	1.88	2.16	2.04	1.89	1.42	1.78	1.91	2.16
Aggregate.......	1.41	1.10	1.46	1.51	1.25	1.36	1.77	1.07	2.13
Total per cu. yd..........	$5.96	$4.42	$5.26	$4.93	$4.68	$4.13	$4.77	$4.53	$6.15

The 24-in. concrete tile were made by the grade crew and some of same installed on wet days. Two men worked at the tile molds, the aggregate being taken from the sand gravel pockets in the pit. A 1:3½ mix was used, the tile having 4-in. walls, lap joints, and being reinforced with steel car wire so spaced as to have rings 8 ins. c. to c. when the tile are installed. The labor cost on the tile was about 50 cts. each or 25 cts. per ft. Further data on the work of the tile crew follow:

MAKING TILE

	Total	Per tile	Per ft.
Number..	425.00		
Labor cost*..	$209.76	$0.493	$0.246
Cement cost..	170.50	0.401	0.201
Total cost..	$380.26	$0.894	$0.447

INSTALLING TILE

	Total	Per tile	Per ft.
Number..	214	....	.....
Cost*..	$331.56	$1.55	$0.775

*Labor rates were the same as for the culvert crew.

Cost of a 4 × 5-Ft. Reinforced Concrete Box Culvert.—The following cost data on the construction of a 4 × 5-ft. concrete box culvert, 26 ft. long, given in Engineering and Contracting, Dec. 4, 1912, are taken from a bulletin on culverts and small bridges issued by the North Carolina Geological and Economic Survey. The culvert was constructed by a regular county concrete gang, composed of a foreman, seven men and two teams and drivers. It was completed in four days of 10 hours each. The excavation was light, but the soil was of a hard, black nature that was hard trimming. Water for mixing had to be hauled two miles. Sand gravel was used for aggregate in the concrete. The gravel contained a slight excess of sand. Mixing was done by hand with negro labor. Twisted square steel bars were used for reinforcing. The quantities were as follows: 14½ cu. yds. of 1:3:5 concrete; 4 cu. yds. of 1:2½:4 concrete; 432 lbs. of ¾-in. steel; 640 lbs. of ½-in. steel; and 1,000 ft. B. M. of lumber. The cost of the culvert was as follows:

	Total	Per cu. yd. concrete
Labor—		
Foreman, 40 hours at 25 cts.	$ 10.00	$0.541
Culvert excavation, 9 cu. yds. at 80 cts.	7.20	0.389
Labor on forms	14.00	0.756
Mixing and placing, 120 hrs. at 15 cts.	18.00	0.973
Hauling water, 20 hrs. at 30 cts.	6.00	0.324
Cutting and placing steel, 10 hrs. at 15 cts.	1.50	0.081
Cleaning up and removing forms, 10 hrs. at 15 cts.	1.50	0.081
Total	$ 58.20	$3.145
50 per cent salvage on form lumber	7.00	0.378
Total, less salvage	$ 51.20	$2.767
Moving on and off job	10.00	0.541
Total labor at culvert	$ 61.20	$3.308
Material laid down at culvert—		
Cement, 26 bbls. at $1.80	$ 46.80	$2.529
Hauling cement, 12½ hrs. at 30 cts.	3.75	0.203
Gravel, 18½ cu. yds. at $1.10, f. o. b. cars Ennis, Texas	20.35	1.100
Hauling, 18½ cu. yds., 46 hrs. at 30 cts. (75 cts. per cu. yd.)	13.80	0.746
Steel, 1,072 lbs. at 2½ cts.	26.80	1.449
Hauling steel, 2 hrs. at 30 cts.	.60	0.032
Lumber, 1,000 ft. B. M. at $25	25.00	1.351
Hauling lumber, 3 hrs. at 30 cts.	.90	0.048
Total	$138.00	$7.459
75 per cent salvage on form lumber	18.75	1.013
Total cost of material on job	$119.25	$6.446
Grand total cost of job	$180.45	$9.754
Cost per cu. yd. of concrete in place, exclusive of culvert excavation		$9.37
Cost per cu. yd. of concrete in place, exclusive of excavation and steel		7.85

Cost of Concrete Culverts Under Canal in Sevier County, Utah.—The following table, rearranged from data given by James Jenson in Engineering and Contracting, April 23, 1913, gives the costs of construction of reinforced concrete culverts to carry flood waters under the canal of the State Board of Land Commissioners, in Sevier county, Utah. The length of canal along which these culverts were distributed is ten miles. No two culverts were constructed from the same setting. On account of the comparatively small units in which this work had to be done, and the ruggedness of the country with reference to the moving of machinery and mixers, all concrete was mixed by hand. Sand and gravel for these structures was hauled by team an average distance of three miles, and constitutes the sole cost in column headed "Sand and Gravel." Water for mixing and camp purposes was also hauled by team a distance of two to three miles, and is included in the column headed "Haulage and Moving," which column also includes the cost of hauling cement, reinforcing steel, and form material from the railroad station, a distance averaging about eight miles. This column also includes the cost of moving apparatus and mixing boards from one setting to another; also moving the construction camp three different times.

The column headed "Hand Excavation" represents the cost of digging the trenches for the footing walls, and leveling the main trench for the culvert after it had been cut down practically to grade by team and scraper work.

The column headed "Form Material" is obtained from taking the total cost of all form material, including timber, wire, nails, etc., and dividing it up in proportion to the number of cubic yards of concrete in each structure. No deductions have been made from these averages on account of any salvage value of form material still on hand.

Two mixing gangs were used, each provided with its own accompaniment of apparatus and teams for hauling purposes. The work was done during the months of February, March and April, 1912, under extremely adverse weather conditions. During the major portion of this time all green concrete had to be covered up to keep it from freezing. No account was kept of this, but is included in the column headed "Mixing and Placing Concrete."

TABLE XXXI.—COST PER CU. YD. OF CULVERT CONSTRUCTION

Cost per cu. yd.:					
Cement	$ 3.200	$ 3.200	$ 3.200	$ 3.200	$ 3.200
Reinforcement at 3 cts. per lb.	0.549	0.526	0.664	0.658	0.461
Sand and gravel	2.240	1.076	1.250	1.353	1.713
Mixing and placing concrete	2.080	4.985	3.062	2.879	3.236
Total concrete	$ 8.069	$ 9.787	$ 8.176	$ 8.040	$ 8.610
Form material	2.023	2.023	2.022	2.022	2.023
Building and moving forms	0.825	0.793	0.602	0.484	0.635
Total forms	$ 2.848	$ 2.816	$ 2.624	$ 2.506	$ 2.658
Haulage and moving	1.333	1.336	1.333	1.333	1.333
Hand excavation	0.447	0.447	0.447	0.448	0.450
Grand total	$12.697	$14.39	$12.584	$12.327	$13.051

The chief item of interest as shown by these cost data, aside from the general value for comparison with other structures of a similar nature and built under like conditions, is the inverse proportion of the labor costs to the size of the unit constructed, which emphasizes the importance of knowing not only total yardage of concrete to be installed, but also its distribution in various units, and the variation of size in these units.

Wages per day paid were as follows: Teams with driver, $4; foreman, $4; laborers, $2.25.

SUMMARY

A total of 3,093 sacks of cement and 22,640 lbs. of reinforcement was used in the 28 culverts, and an automatic spill, waste gate and waste valve. Total concrete, 613.1 cu. yds.

Item	Total	Av. per cu. yd.
Cement	$1,979.06	$ 3.23
Reinforcement at 3 cts. per lb.	679.20	1.11
Sand and gravel	810.51	1.32
Mixing and placing concrete	1,566.20	2.55
Total concrete	$5,034.97	$ 8.21
Form material	1,240.17	2.02
Building and moving forms	270.53	0.51
Total forms	$1,510.70	$ 2.53
Haulage and moving	748.43	1.22
Hand excavation	274.21	0.44
Grand total	$7,568.31	$12.40

Construction Cost of 5-ft. Combination Corrugated Pipe and Concrete Culvert.—The following data are taken from an article in Engineering and Contracting, Jan. 1, 1913, by John N. Eddy.

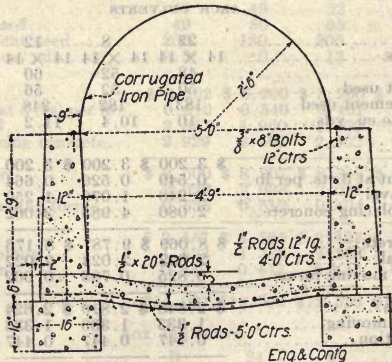

FIG. 20.—Combination corrugated pipe arch and reinforced concrete invert culvert.

Fig. 20 represents a section of a 40-ft. combination iron pipe and concrete culvert built by force account for the City of Billings, Mont. in the summer of 1912. This design assumes the use of a half-section of corrugated pipe for the arch only, which rests on side walls of concrete as shown. While it was found that the concrete portion cost approximately the same as a half-section of pipe, it was possible to secure slightly greater culvert area. The plan was adopted primarily as an experiment, and seems to have possibilities worthy of consideration. The figure showing the details of this design is self-explanatory.

In constructing the combination culvert, the side wall footings were placed first, after which the reinforced concrete floor was laid on a gravel base. Wall forms were then built and concrete poured. The setting and bolting of the iron arch completed the work with the exception of the end walls, which were then built. The cost of this culvert was as follows:

20 lin. ft. of 60-in. No-co-ro culvert pipe, at $5.44 per lin. ft.	$108.80
Cement, 62 bbls., at $2.10, net	130.20
Gravel, 37.5 cu. yds., at $1.25 per cu. yd	46.90
Lumber, 1,024 ft. B. M	28.70
Reinforcement, 183 lbs., at 5 cts. per lb	9.15
Backfilling, 248.5 cu. yds., at 17 cts. per cu. yd	42.25
Foreman, $4 per day of 8 hrs. Labor, $3 per day of 8 hrs.	401.30
Miscellaneous (hardware, power and wiring for pump, drayage, etc.)	27.00
Total cost	$794.30

Cost of Reinforced Concrete and Vitrified Pipe Culvert.—F. M. Balsey gives the following in Engineering News-Record, June 13, 1918.

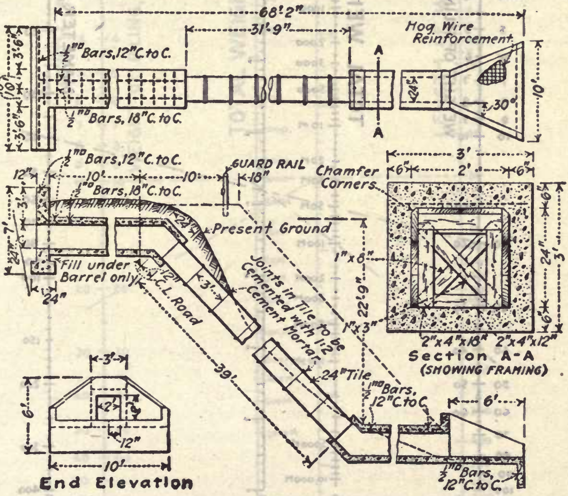

FIG. 21.—Special culvert for roads built in rolling country.

Drop-inlet culverts to convey water from the upper ditch to a point of discharge very much lower on the other side of the road are often necessary on highway work in rolling country. The design shown in Fig. 21, was worked up to meet a condition where the point of discharge was 24 ft. lower than the flow line of the upper ditch.

If a conventional drop-inlet culvert had been installed at this point it would have necessitated the excavation of a well at least 22 ft. deep and the driving of a tunnel from the bottom of this well to the point of discharge. Another alternative would, of course, have been to cut through the entire bank. In either case the excavation would have been difficult and expensive. The special design is considerably cheaper and in other ways much to be preferred.

Reference to the drawing will show that the ditch was cut to a slope of about 1½ to 1, and of a width to take the 24-in. sewer pipe which was used in place of concrete because no economical method could be devised by which the concrete could be poured on so steep a slope. Tile of this size could not be found

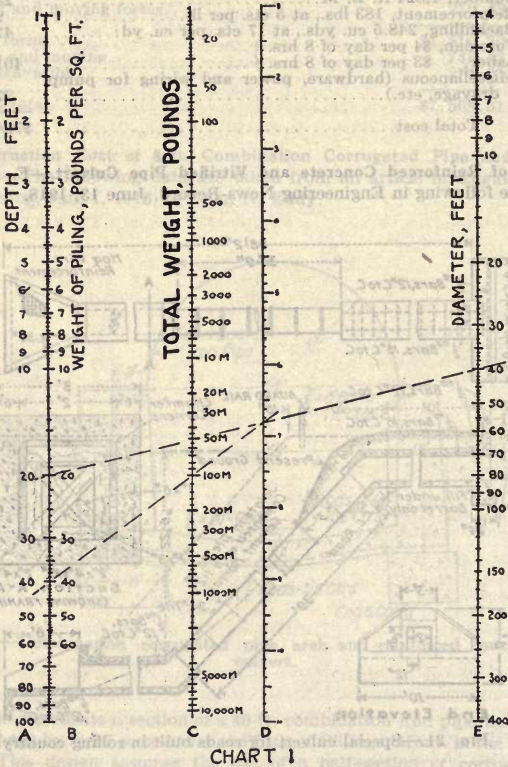

FIG. 22.—Chart for determining weight of steel sheeting required for circular cofferdams.

in stock in the neighborhood, and the necessity for ordering it specially added somewhat to the cost of the work, which was $227.61, distributed as follows:

Reinforced concrete, 10 cu. yd. at $11	$110.00
24-in. sewer pipe, 39 lin. ft.	52.71
Freight on pipe	31.40
Labor installing pipe	15.31
Contractor's fee, at 15 %	15.34

A total of 146 lb. of steel was required for the reinforcement exclusive of the "hog-wire" used in the apron. A complete bill of material follows:

Steel,
2½ in. sq. bars 16 ft. long
22½ in. sq. bars 2½ ft. long
6½ in. sq. bars 9½ ft. long
3½ in. sq. bars 14 ft. long
Cement, 15.5 bbl.
Sand, 4.3 cu. yd.
Stone, 8.6 cu. yd.

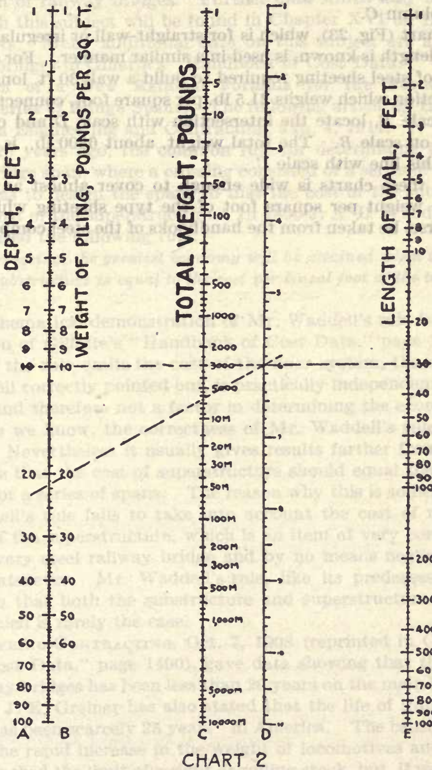

FIG. 23.—Chart for determining weight of steel sheeting required for straight-wall or irregular cofferdams.

The design can easily be modified in dimension or in slope of barrel to fit almost any condition found in the field. In many cases it will be found that considerable saving will result.

Weight of Steel Sheeting for Round or Box Cofferdams.—In Engineering Record, Oct. 7, 1916, N. G. Near gives the following nomographic charts which save considerable time in calculating the quantity of steel sheeting required for a given wall or cofferdam, especially in the case of a circular structure. Chart No. 1 (Fig. 22) is for computing the weight of such cofferdams, and its use may be illustrated by supposing that it is desired to find the weight of steel sheet piling required to construct a cofferdam 40 ft. in diameter and 20 ft. deep, assuming that a section weighing 40 lb. to the square foot is used. To solve this problem, connect 20 on scale *A* with 40 on scale *E* and locate the intersection with scale *D*. Connect the point thus found with 40 on column *B*. The weight, 100,000 lb., is then read at the intersection of this last line with column *C*.

The second chart (Fig. 23), which is for straight-wall or irregular structures where the total length is known, is used in a similar manner. For example, to find the weight of steel sheeting required to build a wall 30 ft. long and 10 ft. deep, using a section which weighs 21.5 lb. per square foot, connect 10 on scale *A* with 30 on scale *E*, locate the intersection with scale *D* and connect this point with 21.5 on scale *B*. The total weight, about 6500 lb., is read at the intersection of this line with scale *C*.

The range of these charts is wide enough to cover almost any sheet-pile structure. The weight per square foot of the type sheeting which is to be used can, of course, be taken from the handbooks of the steel companies which make piling.

CHAPTER XVII

RAILWAY BRIDGES

This chapter is made up of cost and other economic data relative to the construction of railway bridges. Further data which may be useful in connection with this subject will be found in Chapter XVI on Highway Bridges and Culverts. Many additional data on this subject are also given in the section on bridges in Gillette's "Handbook of Cost Data."

Deduction of a New Rational Formula for the Economic Length of Each of a Series of Bridge Spans.—The following article by H. P. Gillette was published in Engineering and Contracting, Jan. 4, 1911.

Up till 20 years ago, the common rule for determining the approximate length of bridge span, where a crossing consisted of a series of spans supported by piers, was to design the spans so that the cost of the substructure would equal the cost of the superstructure. In 1890 J. A. L. Waddell, M. Am. Soc. C. E., deduced the following rule:

For any crossing, the greatest economy will be attained when the cost per lineal foot of the substructure is equal to the cost per lineal foot of the trusses and lateral system.

The mathematical demonstration of Mr. Waddell's rule is reprinted in the 1910 edition of Gillette's "Handbook of Cost Data," page 1489. It will be noted that the rule omits the cost of the floor system, the cost of which, as Mr. Waddell correctly pointed out, is practically independent of the length of the span, and therefore not a factor in determining the economic span.

So far as we know, the correctness of Mr. Waddell's rule has never been disputed. Nevertheless it usually gives results farther from the truth than the old rule that the cost of superstructure should equal the cost of the substructure for a series of spans. The reason why this is so lies in the fact that Mr. Waddell's rule fails to take into account the cost of maintenance and renewals of the superstructure, which is an item of very considerable importance in every steel railway bridge and by no means negligible in any steel bridge whatsoever. Mr. Waddell's rule, like its predecessor, involves the assumption that both the substructure and superstructure are equally permanent which is rarely the case.

Engineering-Contracting, Oct. 7, 1908 (reprinted in Gillette's "Handbook of Cost Data," page 1490), gave data showing that the average life of steel railway bridges has been less than 20 years on the main lines of American railways. J. E. Greiner has also stated that the life of iron or steel railway bridges "has been scarcely 25 years" in America. The cause of this short life has been the rapid increase in the weight of locomotives and cars. Perhaps we have reached the limit of weight or rolling stock, but, if we are to judge the future by the past, we certainly have not reached the limit; and, if we have not, the life of steel bridges built today will probably be little if any greater than was the life of steel bridges built 20 years ago—at the time that Mr. Waddell deduced the rule above quoted.

Our object is to present a rational formula for determining the economic pan of each of a series of bridges, taking into consideration not only first cost but maintenance and depreciation. We shall show that, when these important factors are considered, a correct rule (= equation 17 deduced below) to be applied is as follows:

For the economic span, where a series of spans rest on piers, the length of span must be such that the first cost plus the capitalized cost of annual maintenance and depreciation of the longitudinal trusses (or girders) and the lateral system must equal the first cost plus the capitalized cost of annual maintenance and depreciation of the piers and other substructure.

We shall also deduce a general formula (eq. 16) that will give the economic length of span, for any class of bridge, upon substitution of proper values for the constants.

Proceeding now to the demonstration the following symbols will be used:

L = length, in feet, of span.
K = cost, in dollars, of each pier.
S = cost of substructure, in dollars, per lineal foot of bridge.
T = cost of trusses, in dollars, per lineal foot of bridge.
y = cost of entire bridge (piers and superstructure) per lineal foot.
p = price, in dollars, per pound of steel trusses in place.
w = weight of steel, in pounds, per lineal foot of entire superstructure.
C = a constant in the straight line formula for bridge weight ($w = CL + F$), the value of C depending on the type of bridge and the loading.
F = weight of steel floor system, in pounds, per lineal foot of bridge.
M = capitalized cost of annual repairs and renewals of steel trusses, expressed as a percentage of the first cost of the trusses.
N = capitalized cost of annual repairs and renewals of the pier, expressed as a percentage of the first cost of the pier.
B = width, in feet, of floor of a highway bridge.

The weight per lineal foot of a steel bridge, whether plate girder or truss bridge, may be expressed by the following general formula:

$$w = CL + F \qquad (1)$$

Hence the cost of the steel per lineal foot of bridge is

$$I = wp = pCL + pF \qquad (2)$$

When the cost of a pier is not affected by increasing or decreasing the length of bridge span, as is usually the case, then

$$S = \frac{K}{L} \qquad (3)$$

But

$$y = I + S \qquad (4)$$

$$y = pCL + pF + \frac{K}{L} \qquad (5)$$

To determine the minimum value of y (= cost per lineal foot of entire bridge), differentiate eq. (5), remembering that L and y are the only variables.

$$dy = pCdL - \frac{KdL}{L^2} \qquad (6)$$

Placing the first differential coefficient $\frac{dy}{dL} = 0$, we have

$$pC = \frac{K}{L^2} \qquad (7)$$

Substituting for $\frac{K}{L}$ its value in eq. (3), we have

$$pC = \frac{S}{L} \qquad (8)$$

$$pCL = S \qquad (9)$$

But pCL is the cost of the trusses per lineal foot of bridge, hence

$$T = pCL \qquad (10)$$

$$T = S \qquad (11)$$

Hence, for the economic span, the cost of the trusses per lineal foot of bridge must equal the cost of the pier per lineal foot of bridge, provided there is no annual expense for maintenance and depreciation.

If eq. (7) be solved for L, we have

$$L = \sqrt{\frac{K}{pC}} \qquad (12)$$

If eq. (7) be solved for K, we have

$$K = pCL^2 \qquad (13)$$

Equation (12) is to be used only where there is no annual expense for repairs or renewals of either substructure or superstructure, which is rarely the case.

If a steel bridge has a life of 20 years, and if money is worth 5 per cent per annum to the investor, a sinking fund table shows that \$3 must be put in the fund annually to amount to \$100 at the end of 20 years. This \$3 is the annual cost of renewals. Capitalizing it at 5 per cent, we have \$3 ÷ 0.05 = \$60, which is the capitalized cost of renewals on every \$100 of first cost of bridge steel in place. Hence the value of M in this case is 60 per cent, or 0.60. In other words the total cost of the steel per pound is $p + Mp$, or $(1 + M)p$, or $1.6p$ in this case, if we include not only the first cost but the capitalized cost of renewal.

In addition there is the annual cost of painting the steel. If it costs \$2 a ton to scrape and paint the steel, and if this is done every 5 years, we have \$0.40 as the annual cost of painting, which capitalized at 5 per cent is \$8 per ton. If steel costs \$80 per ton in place, the capitalized cost of painting the steel is 10 per cent, or 0.10, of its first cost. This 0.10 also is a part of M, hence the total value of M in this case is $0.6 + 0.1 = 0.7$. Hence in this case the entire cost of the steel per pound is its first cost plus its capitalized cost of renewal and painting, or $1.7p$. Therefore, if the steel in a bridge has a limited life, we must substitute for p, in eqs. (9) and (12) its entire cost, namely $1.7p$ in the particular case just discussed, or $(1 + M)p$ in any case. This gives us, instead of eqs. (9) and (12),

$$(1 + M)pCL = S, \text{ or } (1 + M)T = S \qquad (14)$$

$$L = \sqrt{\frac{K}{(1 + M)pC}} \qquad (15)$$

Assuming money to be worth 5 per cent per year, we can readily derive the capitalized cost of steel renewals for any given life of steel bridge, by the method above indicated, and adding 0.10, or 10 per cent, as the capitalized cost of painting, we have the total value of M as in Table I.

TABLE I

Life in years	Value of M
20	0.60
25	0.52
30	0.40
35	0.32
40	0.27
50	0.20

Values of C may be derived from formulas giving the weight of steel per lineal foot of bridge. Using the formulas given on pages 1471, 1474 and 1478 of Gillette's "Handbook of Cost Data," 2nd edition, we have Table II.

TABLE II

C = 7, for single track railway truss bridges, Cooper's E-50 loading.
C = 12, for plate girder bridges, ditto.
C = 1½, for single track electric railway truss bridges, loaded with 30-ton cars, or 2,000 lbs. per lin. ft.
C = 5, for plate girder bridges, ditto.

$C = \frac{B}{11.3} = 0.09\ B$, for highway riveted steel truss bridges, with sidewalks, wooden floor system, loaded 80 lbs. per sq. ft., with sidewalks (B being width in feet of floor, including width of sidewalk).

$C = \frac{B}{9.5} = 0.11\ B$, for ditto without sidewalks.

$C = \frac{B}{4.25} = 0.24\ B$, for through plate girders, ditto.

$C = \frac{B}{5} = 0.20\ B$, for deck plate girders, ditto.

$C = \frac{B}{4} = 0.25$, for truss highway bridge with solid floors (assumed dead weight being 150 lbs. per sq. ft. of floor).

$C = \frac{B}{2.4} = 0.42\ B$, for through plate girders, ditto.

$C = \frac{B}{2.6} = 0.38$ for deck plate girders, ditto.

There are some rivers and river beds of a character that necessitate considerable expenditures for riprap and other pier protection at frequent intervals. In such cases, the annual cost of pier protection should be capitalized and added to the first cost. Thus, if \$50 is the average annual expenditure for pier protection and maintenance, we have \$50 ÷ 5 per cent = \$1,000, which is the capitalized cost of pier maintenance. If the first cost of the pier is \$2,500, this \$1,000 is 40 per cent, or 0.40, of the first cost. Hence $N = 0.4$, and in eq. (15) we must substitute $(1 + N)K$ for the value of K there given, if we are to take into consideration the capitalized maintenance cost of the pier as well as its first cost. Then we have

$$L = \sqrt{\frac{(1 + N)K}{(1 + M)pC}} \qquad (16)$$

In like manner, eq. (14) becomes

$$(1 + M)T = (1 + N)S \qquad (17)$$

Eq. (17) is the rule printed above in italics.

EXAMPLES

Example I.—Assume a first cost for a bridge pier of \$2,500, a first cost of \$0.04 per lb. for steel in place, a life of 30 years for the steel, of a single track railway truss bridge, Cooper E-50 loading. What is the economic span when there are a series of spans?

In eq. (15) substitute the above values, and we have

$$L = \sqrt{\frac{K}{(1+M)pC}} = \sqrt{\frac{2{,}500}{(1+M)\times 0.04C}} \quad \text{(16)}$$

Table I gives $M = 0.4$ for a life of 30 years.

Table II gives $C = 7$ for a truss railway bridge.

Therefore,

$$L = \sqrt{\frac{2{,}500}{1.4 \times 0.04 \times 7}} = 80 \text{ ft.} \quad \text{(17)}$$

Hence the economic span is 80 ft.

Example II.—Assume a solid floor highway truss bridge with floor width (B) of 24 ft., a cost of each pier of \$3,600, a first cost of \$0.04 per lb. for steel in place, a life of 40 years for the steel. What is the economic span?

$$L = \sqrt{\frac{K}{(1+M)pC}} = \sqrt{\frac{3{,}600}{(1+0.27)\times 0.04 \times 6}} = 109 \quad \text{(16)}$$

Hence the economic span is 109 ft.

Example III.—A series of railway truss bridge spans consists of 150 ft. spans; the loading is Cooper E-50; steel costs 4 cts. per lb. in place. What should be the cost of each pier to justify such a span, even assuming that the steel requires no repairs and renewals?

Eq. (13) gives the desired value for K, hence

$$K = pCL^2 = 0.04 \times 7 \times 150 \times 150 = \$5{,}300 \quad \text{(17)}$$

A concrete pier containing 200 cu. yds. and costing \$12.50 per cu. yd. including cost of cofferdam, excavation and foundation piles, costs \$2,500. Such a \$2,500 pier is fairly typical, and railway spans of 150 ft. may be frequently seen on piers of no greater size and cost, showing that a much shorter span than 150 ft. should have been used. In fact, as was shown in Example I, a span of 80 ft. is the economic where piers cost \$2,500 each, and where the life of the steel bridge is 30 years, money being worth 5 per cent.

Discussion.—It will be noted that Mr. Waddell's rule (eq. 11), or its equivalent as given in eq. (12), results in a considerably longer span than is obtained by the use of the correct rule (eq. 17), or its equivalent as given in eq. (16).

A study of eq. (16) or (17) shows that an engineer should make the surveys for and designs of the piers of a bridge crossing, and should carefully estimate the cost of piers before attacking the problem of designing the span. The size and cost of a pier are usually not materially affected by the cost of the span, whereas the length and cost of the span are functions of the cost of the pier. Many bridge engineers have attacked such problems wrong end to, selecting span lengths in advance of determining the probable cost of piers. Witness to this may be had by studying published costs of bridge crossings, as well as by even cursory examination of many crossings.

Rules for Designing Bridge Spans, the Cost of Whose Supports Varies with the Span Length.—In the deduction of the preceding formulas it has been assumed that the cost of each pier, K, was not affected by the length of the span. This usually holds true of piers in rivers, for their cross-section is designed to resist the thrust and impact of ice, logs, boats, etc., and is, therefore, far in excess of a cross-section required merely to support the bridge spans and their loads. But when a bridge is built over the land, or in still water where boats do not ply, or wherever the piers (or their equivalent) are given a cross-section sufficient merely to support the load, the preceding formulas can not be used without modification.

When a pier becomes merely a supporting column, its cross-section varies directly with the load. Hence doubling the span doubles the load on the column, and therefore doubles its area of cross-section and approximately doubles its cost. In brief, the total cost of columns is practically a constant for any given length of crossing, regardless of the lengths of individual spans. Such columns are like the floor system in that their cost per lineal foot of bridge is unaffected by changes in the span lengths. Hence, the formulas above given can be applied to a series of spans supported by columns, only upon condition that the cost of the columns be entirely ignored. In the case of an elevated railway, for example, K (in the above formulas), becomes merely the cost of the foundations, or, more correctly, the cost of that part of the foundation not appreciably affected by the load upon the column. The same holds true of viaducts.

A study of the detailed cost of a number of steel viaducts, given in Gillette's "Handbook of Cost Data," page 1620 et seq., shows that several viaducts approximate closely to eq. (17), but that many of them fall wide of the economic mark, so wide, in fact, that it is quite clear that the designers made little or no advance study of the cost of the foundation and pedestals.

Cost of elevated railways, in the same book, page 1376 et seq., show similar errors of economic design, if no account is taken of the fact that close spacing of columns on city streets is often prohibitory, because of damage, or alleged damage, to property. This last factor, however, is one that frequently operates to produce longer spans of elevated railway girders than would otherwise be economically permissible.

It is evident that in applying eq. (17), the designer must bear in mind that no part of the cost of the substructure which is a function of the load of the span and its live load should be regarded as being a part of K. When this provision is held clearly in mind, eq. (17) furnishes a correct solution not only for bridge spans on masonry piers, but for viaducts and elevated railways.

Deduction of a Formula for the Most Economic Span of Timber Trestles.—The following is an article by H. P. Gillette in Engineering and Contracting, April 17, 1912.

The calculation for timber trestle spans differs mainly from that for steel spans in that the masonry piers for steel spans have a much longer life than that of the steel spans, whereas the bents of a trestle usually have a life that is the same as that of the stringers or beams. The economic effect of a life of masonry piers that is longer than the life of the supported steel spans is fully discussed in the preceding pages. In the same article it is shown that the cost of the floor system does not enter as a factor in the problem of most economic steel span. Similarly, of course, the cost of the "deck" of a railway trestle or the cost of the floor plank of a highway trestle does not enter the problem before us.

Let

C = total cost (in dollars) of beams or stringers in a span.

c = cost of beams per lin. ft. of trestle.

K = total cost of a bent.

k = cost of bents per lin. ft. of trestle.

y = combined cost of beams and bents per lin. ft. of trestle.

W = total safe load (dead and live) in lbs. at center of a span

F = constant for any given kind of timber = 70 for southern yellow pine.

b = aggregate breadth, in inches, of beams in a span.

d = depth of beam, in inches.

L = length of span, in feet.

M = number of 1,000 ft. B. M. of beams in a span.

p = price (in place) per M. of timber in beams, in dollars.

(1) $C = pM.$

(2) $c = \dfrac{pM}{L}.$

(3) $k = \dfrac{K}{L}.$

(4) $y = c + k = \dfrac{pM}{L} + \dfrac{K}{L}.$

(5) $W = \dfrac{Fbd^2}{L}.$ (See theoretical mechanics.)

(6) $bd = \dfrac{WL}{Fd}.$

(7) $M = \dfrac{bdL}{12{,}000}.$

(8) $bd = \dfrac{12{,}000M}{L}.$

Combining (6) and (8)

(9) $\dfrac{WL}{Fd} = \dfrac{12{,}000M}{L}.$

(10) $M = \dfrac{WL^2}{12{,}000Fd}.$

Substituting in (4).

(11) $y = \dfrac{pWL}{12{,}000Fd} + \dfrac{K}{L}.$

To solve for a minimum unit cost (y), differentiate and place the first differential coefficient equal to zero.

(12) $dy = \dfrac{pWdL}{12{,}000Fd} - \dfrac{KdL}{L^2}.$

(13) $\dfrac{dy}{dL} = \dfrac{pW}{12{,}000Fd} - \dfrac{K}{L^2} = 0.$

(14) $K = \dfrac{pWL^2}{12{,}000Fd}.$

Substituting value of M (see eq. 10) in eq. (14).

(15) $K = pM$.

But by eq. (1), $pM = C$, hence

(16) $K = C$.

Hence the most economic trestle span is secured when the cost of a single bent equals the cost of all the beams or stringers in a single span.

To arrive at a formula that will give the length of the most economic span directly, solve for L in e. (14). Then:

$$(17)\ L^2 = \frac{12{,}000KFd}{pW}.$$

$$(18)\ L = \sqrt{\frac{12{,}000KFd}{pW}} = 110\sqrt{\frac{KFd}{pW}}.$$

nearly. Equation (18) is the desired formula by which to determine the most economic span for a timber trestle.

It will be observed that the first step in solving for L in eq. (18) is the determination of the cost (K) of a bent. It will also be noted that K is assumed not to be affected by the length of the spans between bents, which is essentially true in all ordinary railway and wagon trestles, for the posts are commonly made of some standard cross-section (as 12 × 12 ins.) regardless of the height of the bents, and so large a factor of safety is used for the posts that the number of posts in a bent is not altered by ordinary changes in the spacing of the bents; that is, in the span of the beams. If, however, change is made in the amount of timber in the bents because of increased live load per bent due to longer spans, then, although there is an increase of material in the posts per bent, there is no increase in the total material of all the posts in the whole trestle. In other words, changes in the amount of material in posts of a bent resulting from increased spans cause no change in the material in all the posts per lin. ft. of bridge; hence we must confine our attention, in solving for K, to such costs of a bent as remain unaffected by changes in spacing of bents.

For any given type of trestle and loading, the cost per bent (K) is mainly a function of the height of the bent and the price of timber in place. Hence the economic span L varies approximately as the square root of the height of average bent in the trestle. This is a point that is seldom given enough consideration by designers of trestles.

The ordinary limitations as to commercial length (L) and depths (d) of timber beams do not permit any great refinement in solving for the most economic span in trestles. But on the Pacific coast, where very long and large timbers are available at low cost, trestle designers can use eq. (18) to great advantage. The writer has seen any number of wagon road and railway trestles on the Pacific coast that were uneconomically designed, apparently because "standard designs" worked out for eastern conditions had been adopted. Highway trestles with bents spaced 16 ft. apart are far from being economic in a country where timbers 30 ft. long are available and cheap; yet a 16 ft. spacing of bents is often used for wagon road trestles, merely because it is "standard." Standard designs are money savers when standard conditions exist, but otherwise standard designs are frequently causes of great waste of money.

Equation (18) makes it evident that before the spacing of bents is decided upon, the average height of bents should be determined. It also shows that the unit price (p) of timber is an important factor when the unit price of timber in the beams exceeds that in the bents, as often happens where very long beams are required.

The safe center load (W) should of course include the load of the beams and deck, and this is readily allowed for by remembering that a uniformly distributed load is equal in effect to half as great a center load on a beam.

Equation (18) contains the element d, or depth of beam; d is usually made as great as possible, having regard to commercial sizes of timber and the effect of d upon the unit price of timber (p). In any given market the relation

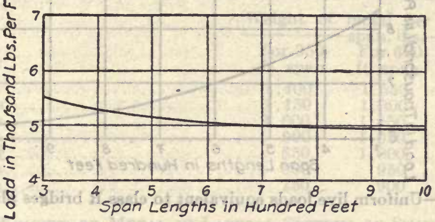

FIG. 1.—Uniform live load equivalent to class R bridges.

of p to d (the depth) and L (the length) of beams can be determined and expressed in the form of an equation, so that the value of p thus determined can be substituted in eq. (18), thus permitting a direct solution of the problem without resorting to the clumsier method of successive approximations.

A Comparison of Carbon Steel and High-alloy Steels for Bridges.—The following data on "High-alloy Steels for Bridges," abstracted and rearranged from a paper by J. A. L. Waddell, in Proceedings, American Society of Civil Engineers, Vol. XL, p 669, and from the discussion of this paper on p. 1613 of

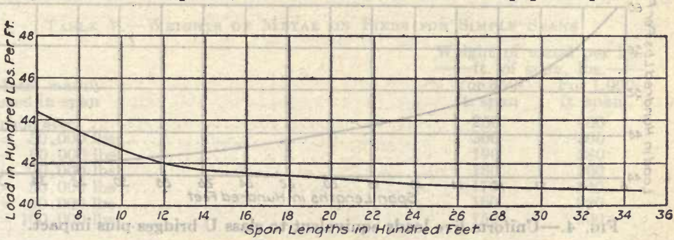

FIG. 2.—Uniform live load equivalent to class U bridges.

the Proceedings, were published in Engineering and Contracting, June 17, 1914.

A condition which at present militates seriously against the use of nickel steel in bridge building is that the manufacturers ask for it an additional price of about 2 cts. per pound, as compared with ordinary carbon steel, although but little more than one-half that would be a sufficient excess price. As the future development of America will necessitate the construction of many long-span bridges it is almost a necessity that there be found an alloy of steel of great strength, high elastic limit, workable under all necessary manipulations in the shops, and of moderate cost. It is realized that the discovery of such an alloy will require much study and exhaustive experiments, but the saving in cost of a single large bridge might easily exceed the entire expenditure for such experiments.

The basis of the following investigation is a mass of diagrammed and tabulated data on the weights of metal in simple spans and cantilever bridges of carbon steel, up to a limit of 600-ft spans for the former and 1,800-ft. main openings for the latter, accumulated by the writer and his firm during the last

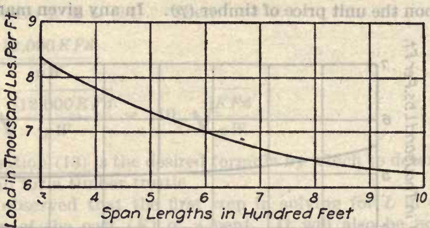

Fig. 3.—Uniform live loads equivalent to class R bridges plus impact.

25 years, together with the weights of nickel-steel bridges and of mixed nickel-steel and carbon-steel bridges computed by the writer in the preparation of a previous paper on "Nickel-Steel for Bridges." As the weights of metal per linear foot in simple truss bridges were limited to lengths of 600 ft. in the former paper they have here been extended to 1,000 ft. by making actual calculations of stresses, sections, and weights of metal for several long spans, using the various kinds of steel assumed. The weights for bridges of carbon steel are based on the standard specifications given in the writer's "De Pontibus." They are quite accurate up to the limits of 1,000 ft. for

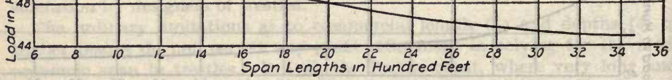

Fig. 4.—Uniform live loads equivalent to class U bridges plus impact.

simple spans and 1,800 for the main openings of cantilever bridges. Figs. 1 and 2 give the equivalent uniform live load per linear foot of single track assumed in computing the weights of trusses. The impact percentages were obtained from the writer's formula.

$I = \dfrac{40,000}{L + 500}$, where I is the percentage of impact, and L is the loaded length, in feet, required to give the maximum stress. Figs. 3 and 4 give a combination of the equivalent uniform live loads and the impact loads. The loads obtained from these curves added to the dead loads give the total loads per linear foot used for the bridges.

Tables III to VIII, inclusive, give the approximate weights of metal, in pounds per linear foot of span, for the floor system, lateral system and on piers for simple and cantilever bridges, for various spans and elastic limits, *E*. From these tables and the diagrams shown in Figs. 5 and 6 (which will be explained later) there can be determined the weights for the trusses.

(The author develops reduction formulas for determining the weights of floor systems, lateral systems and on piers of alloy-steel bridges from the known weights of carbon-steel bridges, but we have omitted these in our abstract.)

TABLE III.—WEIGHTS OF METAL IN FLOOR SYSTEMS OF SIMPLE SPANS

Metal mainly used in span	Weight of metal per lin. ft. of span, lbs. For 350-ft. span	For 600-ft. span	For 1,000-ft. span
Carbon steel	1,400	1,550	2,000
E = 50,000 lbs.	1,150	1,300	1,750
E = 60,000 lbs.	1,000	1,150	1,600
E = 70,000 lbs.	900	1,050	1,500
E = 80,000 lbs.	850	1,000	1,400
E = 90,000 lbs.	800	950	1,300
E = 100,000 lbs.	750	900	1,200

TABLE IV.—WEIGHTS OF METAL IN LATERAL SYSTEMS OF SIMPLE SPANS

TABLE VIII.—WEIGHTS OF METAL ON PIERS FOR CANTILEVER BRIDGES

Metal mainly used in span	Weight of metal per lin. ft. of span, lbs. 600-ft. span	1,200-ft. span	1,800-ft. span	2,400-ft. span	3,000-ft. span	3600-ft. span
Carbon steel	700	1,100	2,100	.....	.....	.....
E = 50,000 lbs.	600	900	1,700	.....	.....	.....
E = 60,000 lbs.	580	860	1,600	2,200	.....	.....
E = 70,000 lbs.	560	820	1,500	2,100	3,500	.....
E = 80,000 lbs.	540	780	1,400	2,000	3,200	.....
E = 90,000 lbs.	520	740	1,300	1,900	2,900	3,900
E = 100,000 lbs.	500	700	1,200	1,800	2,600	3,600

The weight in pounds per linear foot of the trusses of simple carbon steel spans may be expressed by the formula,

$$T = K + T_1 + C_c + C_w,$$

where K is the part of the total truss weight per linear foot which is independent of the quality of the metal and of the stresses; T_1 is the weight of the main portions of the tension members and of their details which are directly affected by the stresses; C_c is the weight of the main portions of the compression chords and inclined end posts and their details which are directly affected by the stresses; and C_w is that of the main portions of the compression web members which are directly affected by the stresses. From experience in designing large bridges it may be stated that, as an average, $K = 0.2T$; $T_1 = 0.3T$; $C_c = 0.3T$; and $C_w = 0.2T$.

It is well known that in trusses with parallel chords and of economic depths the weight of the chords is equal to the weight of the web; but in trusses with polygonal chords, having center depths less than the theoretically economic ones, as do those of all long-span bridges, the weight of the chords is much greater than that of the web. As a general average for long spans the ratio of weight of chords to that of webs is about 6 to 4.

Fig. 5 gives the total weight of metal per linear foot of span in simple-truss bridges for "Class R" live load, for carbon steel and for alloy steels having various elastic limits. An inspection of these curves shows the great saving in weight of metal which may be obtained by using alloy steels instead of carbon steel. This difference is most apparent between the weights for alloy steel having an elastic limit of 50,000 lbs. (the nickel steel which the manufacturers are willing to furnish) and that having an elastic limit of 60,000 lbs. The gradual reduction in the saving of metal with the increase of elastic limit is strikingly noticeable; and the conclusion may be drawn that, unless the extremely high-alloy steels can be obtained with only a moderate increase in cost, there will be no economy in using them for simple-span bridges.

Fig. 6 gives the average total weights of metal per linear foot of span for

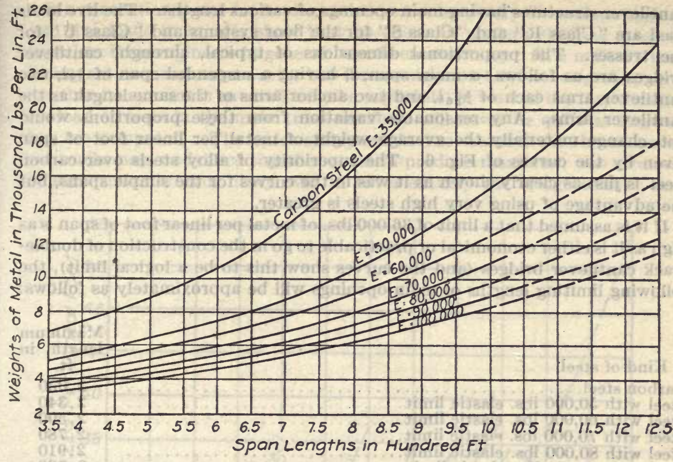

Fig. 5.—Total weights of metal per linear foot of span for double-track, simple-span bridges of carbon steel and alloy steels of various elastic limits.

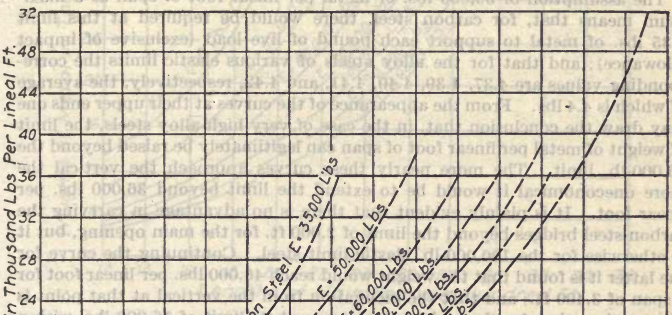

Fig. 6.—Total weights of metal per linear foot of span for double-track, cantilever bridges of carbon steel and alloy steels of various elastic limits.

cantilever structures having main openings of various lengths. The live loads used are "Class R" and "Class S" for the floor systems and "Class U" for the trusses. The proportional dimensions of typical, through, cantilever bridges are as follows: a main span, l, having a suspended span of $\frac{3}{8}l$, two cantilever arms each of $\frac{5}{16}l$, and two anchor arms of the same length as the cantilever arms. Any reasonable variation from these proportions would not change materially the average weight of metal per linear foot of span given by the curves of Fig. 6. The superiority of alloy steels over carbon steel is just as clearly shown as it was in the curves for the simple spans, but the advantage of using very high steels is greater.

If it is assumed that a limit of 36,000 lbs. of metal per linear foot of span is as high as it is either economical or practicable to go in the construction of double-track cantilever bridges (and the curves show this to be a logical limit), the following limiting lengths of main openings will be approximately as follows:

Kind of steel	Maximum length, in ft.
Carbon steel	2,030
Steel with 50,000 lbs. elastic limit	2,340
Steel with 60,000 lbs. elastic limit	2,590
Steel with 70,000 lbs. elastic limit	2,780
Steel with 80,000 lbs. elastic limit	2,910
Steel with 90,000 lbs. elastic limit	3,030
Steel with 100,000 lbs. elastic limit	3,140

The assumption of 36,000 lbs. of metal per linear foot of span as a maximum means that, for carbon steel, there would be required at this limit 4.35 lbs. of metal to support each pound of live load (exclusive of impact allowance); and that for the alloy steels of various elastic limits the corresponding values are 4.37, 4.39, 4.40, 4.41, and 4.42, respectively, the average of which is 4.4 lbs. From the appearance of the curves at their upper ends one may draw the conclusion that, in the case of very high-alloy steels, the limit of weight of metal per linear foot of span can legitimately be raised beyond the 36,000-lb. limit. The more nearly these curves approach the vertical the more uneconomical it would be to extend the limit beyond 36,000 lbs. per linear foot. It is plainly evident that there is no advantage in carrying the carbon-steel bridges beyond the limit of 2,000 ft. for the main opening, but it is otherwise for the 100,000-lb. elastic limit steel. Continuing the curve for the latter it is found that the weight would reach 46,000 lbs. per linear foot for a span of 3,400 ft.; and that the inclination from the vertical at that point is greater than that for the carbon-steel curve at its limit of 36,000 lbs. with a main opening of 2,030 ft. Perhaps therefore it would be more correct to assume the extreme economic limit of main opening to be 3,400 ft. or even 3,500 ft. For this last length the average weight of metal per linear foot of bridge shown by the 100,000-lb. elastic limit curve would be 52,000 lbs, which means that it would require 6.38 lbs. of metal to support each pound of live load, exclusive of the effect of impact. Although this is an excessive quantity, it is nevertheless conceivable that conditions might exist which would render it advisable to adopt this extreme limit of main opening, although at such a length a suspension bridge would undoubtedly be cheaper. If it is admitted (as is maintained by some bridge engineers) that the impact of the live load on the main members of long-span trusses is immaterial, the practical limit of length of the main opening will be somewhat increased. Moreover, such a contention is not far from correct, as the latest experiments on impact from live loads in bridges show that its effect on moderately long spans is much less than engineers in general have been assuming. It is unlikely that the impact ever reduces to zero, but for openings of 1,200 ft. or greater it is true that its amount is so small as to be negligible, in view of the fact that the live load stresses in the main truss members will never be quite as large as they are computed. The latter statement is true, because (a) the trains on two tracks never advance together so as to produce maximum web stresses; (b) such trains are not likely ever to cover entirely the bridge or even any

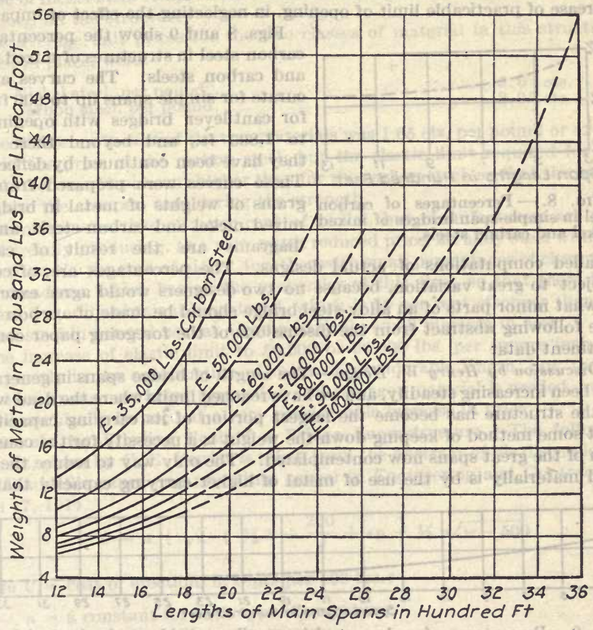

FIG. 7.—Total weights of metal per linear foot of span for double-track, cantilever bridges of carbon steel and alloy steels of various elastic limits when impacts are assumed as zero.

individual part of it, except, perhaps, the central span; and (c) it is improbable that any load of cars—unless they are ore or coal cars—will ever be uniformly full or loaded to the assumed limit.

Fig. 7 shows the curves of weights for cantilever bridges of the same type and loading as those used in preparing the curves in Fig. 8 except that the impact on main members of trusses is assumed to be zero. These curves begin at main openings of 1,200 ft. and extend to the greatest practicable limiting lengths of such openings. A comparison of the curves of Figs. 6 and 7 shows that by neglecting impact on trusses there is an average saving of about 700 lbs. of metal per linear foot of span, for all spans and all kinds of steels. With a few exceptions this difference is comparatively uniform for all the curves, over their entire lengths.

Under the assumption that the limit of weight of metal is 36,000 lbs. per linear foot the greatest practicable span lengths have been increased on the average only about 20 ft. by neglecting impact on trusses. By comparing the extensions of the curves for steel having an elastic limit of 100,000 lbs. it is found that, for an assumed limit of 52,000 lbs. of metal per linear foot of span, the extreme practicable length of main opening has been increased only 25 ft. These comparisons indicate that there is little gain, either in economy or increase of practicable limit of opening, in neglecting the effect of impact.

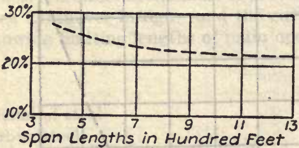

FIG. 8. — Percentages of carbon steel in simple-span bridges of mixed nickel and carbon steels.

Figs. 8 and 9 show the percentages of carbon steel in structures of mixed nickel and carbon steels. The curves are accurate for simple spans up to 600 ft. and for cantilever bridges with openings up to 1,800 ft., and beyond these limits they have been continued by deflections. These curves were prepared from diagrams of weights of metal in bridges of mixed nickel and carbon steels, and the diagrams are the result of careful, detailed computations of actual designs. The percentages are, of course, subject to great variation, because no two designers would agree exactly as to what minor parts of an alloy-steel bridge should be made of carbon steel. The following abstract from the discussions of the foregoing paper contains pertinent data:

Discussion by Henry W. Hodge.—The length of bridge spans in general use has been increasing steadily, and we have reached limits where the dead weight of the structure has become the largest portion of its carrying capacity, so that some method of keeping down the weight is a necessity for the construction of the great spans now contemplated. The only way to reduce the dead load materially is by the use of metal of higher carrying capacity than our

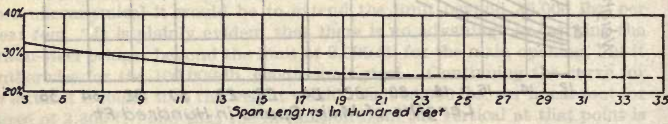

FIG. 9.—Percentages of carbon steel in cantilever bridges of mixed nickel and carbon steels.

present materials, and an important step has been made in this direction by the use of nickel steel, which has 50 per cent greater carrying capacity than the carbon steel in general use.

The trusses of the three 668-ft. spans of the St. Louis Municipal Bridge were designed for nickel steel throughout, except certain minor sub-members. Nickel-steel eye-bars and carbon-steel compression members were also used, the floor system and bracing being of carbon steel in each case.

The weights of each span were:

With complete nickel-steel trusses, lbs.	9,200,000
With nickel-steel bars, and the rest of carbon steel, lbs.	10,900,000

As the dead load of railways, tracks, etc., was 5,500 lbs. per linear foot, the total average dead load was:

With nickel-steel trusses, lbs. per linear foot	19,300
With nickel-steel bars, and the rest of carbon steel, lbs. per linear foot	21,800

Thus, the nickel-steel compression members in the trusses made a difference in weight of 2,500 lbs. per linear foot, or 13 per cent.

The average live load on the two decks was 16,600 lbs. per linear foot, thus the use of nickel-steel compression members made a saving of 7 per cent in the total load on the structure.

The average unit prices for the two classes of material in this structure, erected in place, were:

Nickel steel, per pound	5.6 cts.
Carbon steel, per pound	3.95 cts.

The difference in cost of the two materials was 1.65 cts. per pound or 42 per cent of the price of the carbon steel; but the elastic limit required for the nickel steel was 50 per cent higher than for the carbon steel, so that the nickel steel was the cheaper, considering the strength.

The nickel steel had 3¼ per cent of nickel, but manufacturers are now commercially producing, at a very much reduced price, an alloy steel with not more than 1½ per cent of nickel, together with small percentages of chromium and vanadium, which has all the properties of this steel, so that there is at present a readily obtainable material, which is 50 per cent stronger than the carbon steel in general use, at a comparatively small increase in cost.

The increase of elastic limit to 50,000 or 60,000 lbs. per square inch will help greatly in the construction of spans of considerable length; but, for the very long spans now being planned, a still stronger material is needed, and it can economically be used at a very considerable increase in price.

Formula for Erection Cost of a Bridge Superstructure.—The following formula, given by C. E. Fowler is taken from the abstract of his discussion of Mr. Waddell's paper (see preceding pages) in Engineering and Contracting, June 17, 1914.

$$C = a + \sqrt{l} + \tfrac{3}{4} h + \frac{200}{d} + sp - \tfrac{1}{5}\sqrt{w - 500}$$

where C = cost of erection, in cents per 100 lbs.;

a = a constant for each type of structure;
= 15 cts. for railway pin trusses;
= 25 cts. for railway riveted trusses;
= 20 cts. for railway girders;
= 20 cts. for highway pin trusses;
= 30 cts. for highway riveted trusses;
= 15 cts. for highway girders;
l = span length, in feet;
h = height of falsework, in feet;
d = daytime temperature, average, in degrees Fahrenheit.
p = number of coats of paint;
w = weight in lbs. per lin. ft.

Taking the case of a riveted railway span 225 ft. long, height of falsework 48 ft., average temperature 40°, 2 coats of paint, and weighing 2,100 lbs. per linear foot, we find the probable erection cost to be 83 cts. per 100 lbs., or $16.60 per ton.

A railway pin span of 144 ft., height of falsework 36 ft., average temperature 50°, 2 coats of paint, and weighing 1,400 lbs. per linear foot, would have an erection cost of 62 cts. per 100 lbs., or $12.40 per. ton.

These two examples show what an influence a change in any one of the factors will have on the unit erection cost. The formula was deduced to fit certain conditions, which to a large extent were due to the personal equations of the designer and the erector; and, with plans prepared by some designers, the cost of erection would exceed very greatly the values found from the formula, it being only too common on the part of many designers to forget that structures must be erected at a reasonable cost, and still others seem to forget the process of erection entirely. Many erection costs, of course, will exceed greatly what they should, due to unforeseen causes.

Cost of Concrete Abutments and Pedestals on Track Elevation Work.—Charles G. Huestis gives the following data in Engineering and Contracting, Feb. 21, 1912.

At the point where the following described work took place two streets intersect at the exact place crossed by four tracks of the railroad proposed to be elevated. On one of these streets are two tracks of a very busy street car line and steam tracks on both streets. On account of heavy traffic the railroad company was obliged to use at least two of its tracks during construction and at least one of the trolley tracks had to be kept in service. Team traffic also had to be maintained on at least one side of the street. Overhead along the railroad line were twenty or more telegraph and telephone wires and along the streets were electric light wires and trolley wires.

The masonry consisted of a heavy concrete abutment on each side of the street and 23 pedestals in the street. It was impossible to find place in the street for machinery so that all the working room allowed was the space of two tracks and outside the outer track about 20 ft. in width and back as far as required.

The railroad company abandoned two of its tracks, and the stub end on each side of the street was allowed the contractor for construction sidings. A stiff-leg derrick with a 40-ft. boom was set up, with one leg parallel to the face of the abutment and in such a position that the boom would reach pedestals in the center of the street. One track of the street railway company with its trolley wire was taken out of service and by working a low boom the derrick was able to avoid other wires almost entirely. The stiff-leg parallel to the abutment necessarily crossed the siding track but was high enough to allow cars to move under it so that excavated material from the pedestal pits might be loaded by derrick and taken away by the railroad company.

A ½-cu. yd. Smith mixer was set up near the end of the siding and far enough ahead of the derrick to allow the boom to reach the mixer when very high. When the siding was not in use for cars to remove excavated material the cars containing materials for concrete were placed alongside and back of the mixer and derrick. Plank staging was built alongside the cars and to the mixer, so that wheelbarrows might be loaded over the sides of cars and wheeled to the mixer. The excavated material as well as the concrete were handled in 1-cu. yd. dump buckets by the derrick. When several pedestals had been built the excavated material from others was used as backfilling for the ones completed.

The derrick was first erected near the face of the abutment and when the pedestals in the street were completed it was necessary to move the entire rig, derrick and mixer, backward about 40 ft. in order to build the abutment. This was accomplished by drawing the engine on rollers by its own power, and sliding the derrick on plank, still erect, using the engine for power.

Exactly the same method was followed on the opposite side of the street, two derricks and two mixers being used on the entire work.

Excavation.—The excavation for the abutments was about 16 ft. in depth and for the pedestals from 16 to 22 ft. The material, beside the street paving and sidewalk on top, was about 5 ft. of clay and the remainder gravel, all perfectly dry. Excavaton, as covered by the contract, was measured only to the foundation lines of the concrete footings though as a matter of fact much more was necessarily excavated in deep pits. The entire payroll for excavating, sheathing and bracing, backfilling to original ground or loading on cars was the sum of $2,292.58 for 2,832 cu. yds., engineer's measurement. (This gives a unit cost of slightly over 80 cts. per cubic yard.—Editors.)

Concrete.—The concrete materials were crushed stone and gravel taken from cars direct as described above. Water was piped to the mixers from a nearby hydrant, and cement was carried from box cars back of gravel and stone cars. The cost of unloading materials as described and wheeling them to the mixer, together with mixing and placing them and the finishing of the face after the forms were removed, was as follows for a total of 1,598 cu. yds.:

46½	hrs. foreman at 40 cts.	$ 18.60
20	hrs. foreman at 37 cts.	7.40
52	hrs. foreman at 38½ cts.	20.02
138	hrs. foreman at 32½ cts.	44.85
144	hrs. hoist runner at 30 cts.	43.20
3	hrs. carpenter at 27½ cts.	.73
54½	hrs. straw boss at 25 cts.	13.63
2,186½	hrs. labor at 20 cts.	437.30
781	hrs. labor at 17½ cts.	136.67
51	hrs. labor at 15 cts.	7.65
	Total	$730.05

(This total gives a cost per cubic yard of concrete of 45.7 cts., say 46 cts.—Editors.)

Forms.—The concrete forms were extremely easy to build and set. There were no sloping wings and nothing but straight work except that one end of each abutment was turned at an angle of about 30°. The other ends of the abutments were left for future extension. There were three expansion joints in one abutment and two in the other, where a full stop in each case was made and key ways put in for bonding. It took 30,500 ft. B. M. of lumber to form the neat work of abutments and the formed part of pedestals, if all had been formed at once. Two-inch yellow pine boards were used and 4 × 6-in. yellow pine for uprights. The total payroll for building forms, oiling with paraffine oil, removing forms and cleaning lumber was as follows:

23½	hrs. foreman at 40 cts.	$ 9.40
58½	hrs. foreman at 38½ cts.	22.52
7	hrs. foreman at 37 cts.	2.59
18	hrs. foreman at 32½ cts.	5.85
56	hrs. hoist engineer at 30 cts.	16.80
451½	hrs. carpenters at 27½ cts.	124.16
479½	hrs. carpenters at 25 cts.	119.88
69½	hrs. carpenters at 22½ cts.	15.63
463½	hrs. labor at 20 cts.	92.70
25½	hrs. labor at 17½ cts.	4.46
4	hrs. labor at 17½ cts.	.60
	Total	$ 414.59

(On a basis of 1,598 cu. yds. of concrete the cost of forms per cubic yard was 25.9 cts. or say 26 cts. As a matter of fact not all of the concrete work required built forming, so that this unit cost is indicative only —Editors.)

Rigging.—The total payroll for setting up and taking down, together with moving each plant once as described above, also the building and moving of stagings alongside of cars, for two derricks and two mixers, was as follows:

40 hrs. foreman at 38½ cts.	$ 15.40
31 hrs. foreman at 40 cts.	12.40
119 hrs. rigger at 32½ cts.	38.68
57 hrs. hoist engineer at 30 cts.	17.10
45½ hrs. carpenter at 27½ cts.	12.43
157½ hrs. carpenter at 25 cts.	39.38
41 hrs. carpenter at 22½ cts.	9.23
3 hrs. carpenter at 23 cts.	.69
479½ hrs. labor at 20 cts.	95.90
149½ hrs. labor at 17½ cts.	26.16
30½ hrs. labor at 15 cts.	4.57
Total	$271.94

The payroll for setting up one derrick only, unloading and setting one mixer, together with building platform and stagings once only, was as follows:

8 hrs. foreman at 40 cts.	$ 3.20
10 hrs. foreman at 38½ cts.	3.85
30 hrs. rigger at 32½ cts.	9.75
20 hrs. hoist engineer at 30 cts.	6.00
100 hrs. carpenter at 25 cts.	25.00
3 hrs. carpenter at 23 cts.	.69
30 hrs. carpenter at 22½ cts.	6.75
29 hrs. labor at 20 cts.	5.80
35 hrs. labor at 17½ cts.	6.12
Total	$67.16

The other items of payroll not mentioned in the above were as follows:

Building and repairing tool house	$ 28.71
Loading and unloading tools and lumber	133.87
Night watch, Sunday watch and other general expense	158.97
Repairs to machinery	12.66
Total	$334.21

Total payroll for the work $4,043.36.

The ledger accounts for this work show other expenses as follows:

Premium on bond	$ 20.00
Liability insurance	98.72
General and sundry expenses	48.65
Office and timekeeper	275.00
Materials for repairs	11.29
Small tools	34.49
Lumber for foundations	274.04
Form lumber	267.70
Wire and nails for forms	40.20
Paraffine oil for forms	3.70
Oil waste, etc	37.70
47.04 tons of coal	141.13
Water, lump sum	75.00
Paid railroad company for unloading cars of excavated material	76.80
Total ledger accounts	$1,404.42

The coal consumption amounted to about ⅓ ton per day per boiler. Only 20 h.p. upright boilers were used.

Fig. 10 shows the character of the masonry. In constructing the abutment 2 × 2-in. molding was used to bevel top and bottom edges of the coping and to mark expansion joints. There were eleven square pedestals of the dimensions shown; ten pedestals 18 ins. less in height and 9 × 8 ft. on the bottom, and two pedestals irregular in shape on account of being set close to the sidewalk. These were five courses in height.

Labor Cost of Piers and Abutments for Viaduct of the Fort Dodge, Des Moines & Southern (Electric) Ry.—In Engineering and Contracting, March 19, 1913, C. J. Steigleder describes the methods of constructing the piers and abutments for the steel deck plate girder viaduct, 784 ft. long and 156 high, which replaced a wooden trestle. The following data are taken from Mr. Steigleder's article.

Fig. 11 shows the general arrangement of the work.

Specifications called for a concrete mixture of 1:3:6, except for the coping course. The coping course was considered the top foot of the pedestal and was made of 1:2:4 concrete. The stone used with the 1:3:6 measure was from 1 to 2 ins. in the largest dimensions, and for the 1:2:4 mixture not more

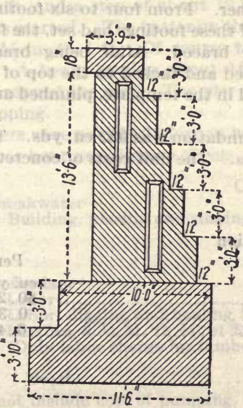

FIG. 10.—Section of concrete abutment.

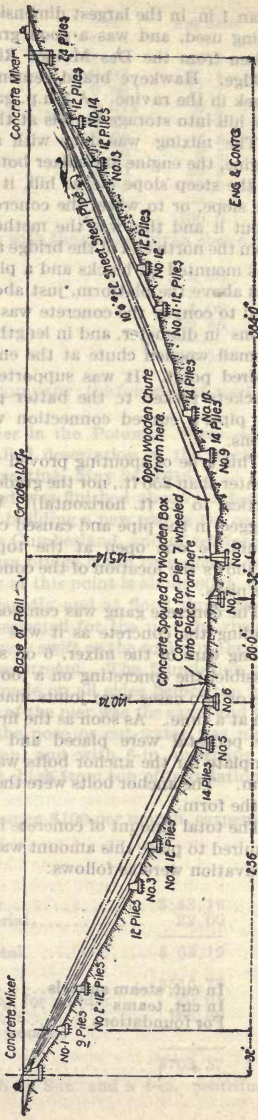

FIG. 11.—Diagram showing arrangement of chutes for concreting viaduct piers.

than 1 in. in the largest dimensions. All stone was screened, no crusher run being used, and was a good grade of limestone rock. The sand used was taken from the Des Moines River, about five miles above the site of the bridge. Hawkeye brand cement was used, and water was secured from a creek in the ravine. A 7-h.p. gasoline pump was used to force the water up the hill into storage barrels at the mixer.

The mixing was done with a Ransom mixer, driven by a 6-h.p. Stover engine, the engine and mixer both being mounted on the same frame. Owing to the steep slope of the hill, it was impracticable to move the mixer down the slope, or to wheel the concrete to place. The most efficient way was to spout it and this was the method used One-half of the piers were poured from the north end of the bridge and the other half from the south. The mixer was mounted on blocks and a platform built up around it so that the hopper was above the platform, just about the height of a wheelbarrow The chute used to convey the concrete was made of No. 23 sheet steel, circular in form, 10 ins in diameter, and in lengths of 10 and 12 ft. The pipe was attached to a small wooden chute at the end of the hopper, and from here run to any desired point. It was supported at joints by wooden cross-frames, or by brackets tacked tc the batter posts on the existing bridge. At the end of the pipe, a curved connection was used to turn the concrete down into the forms.

This type of spouting proved very satisfactory where the distance was not greater than 250 ft., nor the grade less than 24° with the horizontal (about 1 ft. vertical to 2.3 ft. horizontal). When on a less grade than this, the concrete clogged in the pipe and caused considerable trouble. A better type of chute would be one open at the top so as to give access to the concrete. Fig. 11 shows the location of the concrete mixer and how the piping was carried to the piers.

The concrete gang was composed of 12 men and a foreman; 2 were used in spading the concrete as it was placed, 1 on water and dumping cement, 1 taking care of the mixer, 6 on sand and rock, and 2 carpenters. As far as possible, the concreting on a footing or pedestal was continuous, and only in one or two cases were joints made in either. From four to six footings were run at a time. As soon as the first two of these footings had set, the forms for the pedestal were placed and securely braced. After being braced, the template for the anchor bolts was centered and tacked to the top of the pier form. The anchor bolts were then placed in the template, plumbed and wired to the form.

The total amount of concrete in the foundation was 932 cu. yds. The time required to place this amount was 40 days. The unit costs of concrete and of excavation were as follows:

Excavation

	Per cu. yd.
In cut, steam shovels	$0.22
In cut, teams	0.36
For foundations	0.48

Concrete

	Per cu. yd.	Per cent
Cement	$1.16	21.3
Rock	0.93	17.1
Sand	0.80	14.7
Water	0.014	0.3
Lumber	0.40	7.3
Pipe for spouting	0.25	4.6
Train service	0.19	3.5
Labor*	1.65	30.3
Incidentals	0.05	0.9
Total	$5.44	100.0

* The average daily output was 23.3 cu. yds.; with the gang as given above, the rates of pay would be about as follows:

1 Foreman	$ 5.00
2 Carpenters @ $4.00	8.00
1 Engineman	3.00
9 Laborers @ $2.50	22.50
	$38.50

The excavation was done by the railroad company; the foundation work by contract.

Cost of Cofferdam for a Small Bridge Pier in the Potomac River.—The following data are taken from a more detailed description of the work by Elliott Vandevater in Engineering and Contracting, May 24, 1916.

The work was begun in October, 1910, and was finished about the last of December of the same year. It consisted of building a new pier in the center of the Potomac River about ten miles above Cumberland, and of reinforcing the old stone abutments, so that the old truss bridge could be replaced with plate girders of one-half the span. The river at this point is about 80 ft. wide in times of ordinary flow but it rises very rapidly and at flood times covers more than twice this width. At the point selected for the pier the river is about 8 ft. deep normally and the current is very swift as the rocks on the east bank throw the current to the center of the stream. The foundation was 30 × 14 ft. and a step of about 18 in. was made on all sides before the neat work was started. The batter on three sides of the pier was the same and was about 1½ in. to 1 ft. Of course that on the nose or cut-water was much greater. A heavy coping about 1½ ft. deep, and with 6-in. overhang all around, capped the pier. The pier was 20 ft. high from top of foundation to top of coping.

Laborers were paid $1.75 for ten hours, foremen $100 per month, carpenters 35 cts. per hour and firemen 25 cts. per hour.

Costs*

Breakwater—	
Building, placing and sinking—Labor	$ 43.19
Material	22.00
Total	$ 65.19
Cofferdam—	
Labor	$516.76
Labor, digging and hauling 55 yd. clay for puddle	20.01
Lumber, 8.34 M. B. M. at $20	166.80
(Only labor charge for lumber cut in woods.)	
Total	$703.57

* Do not include cost of pumping, for which an 8-in. and a 4-in. centrifugal pump were used.

Trestle for Unloading Materials—	
Labor	$ 45.83
Lumber, .5 M. B. M	10.00
Total	$ 55.83
Concrete Trestle—	
Labor	$ 75.62
Material, 2 M. B. M. at $20	40.00
Total	$115.62
Excavating Cofferdam—	
Labor	$196.97
Coal, oil, etc	15.00
Total	$211.97
Two Mixing Boards, 10 × 14 Ft.—	
Labor	$ 7.71
Material	12.00
Total	$ 19.71

Unloading stone cost 12 cts. per ton.
Unloading sand cost 3 cts. per ton.
Unloading 15,000 bd. ft. lumber cost 65 cts. per 1,000 ft. B. M.
Unloading cement (carried about 50 ft.) cost 2.5 cts. per bbl.
Mixing, hauling and placing concrete cost $1.05 per cu. yd.
Forms, including material, building, erecting and stripping, cost $1.74 per cu. yd.

The breakwater consisted of a V-shaped crib which was sunk about 10 ft. above the nose of the location of the foundation and was so placed to make it possible to examine the bottom of the river at the pier site.

The cofferdam consisted of a crib 3 ft. wide and with dimensions about 2 ft. larger than those of the foundations. The crib was built out of 6 × 6-in. timber with cross pieces of the same size about 4 ft. apart. On top of the bottom course of 6 × 6-in. timbers a 2-in. flooring was laid to hold the stone used in sinking the crib. Sheet piles of 2-in. lumber were driven on the outside and inside of the crib and the bottoms were cut to conform as closely as possible to the rock underlying the river bed. It was found necessary to drive an additional row of sheet piles 4 ft. outside of the crib and fill the space between the crib and this outer row of piles with clay.

The railroad approached the bridge from the east on a 15-ft. fill about 100 ft. long. A switch for unloading materials had been put in at the end of the fill. A one-legged trestle was built on the side of the fill and the track from the siding extended out on it, so that cars could be run out there and dumped by gravity. The bents were 7 ft. apart, the caps 10 × 10 in. and the stringers were two pieces of 6 × 6 in. laid symmetrically with respect to the rail. The legs and battered braces were cut in the adjoining woods and were at least 8 in. in diameter and not over 7 ft. long. The cement was unloaded on a level with the switch and stored in a tent. From here it was dropped through a chute directly onto the mixing board. Two mixing boards were placed together. Five men were kept mixing, four turning and one attending to cement and water. After mixing a batch on one board they changed to the other while four men loaded the mixed batch into a car and hauled it out to the foundation and dumped it. One man was kept busy loading wheelbarrows with stone and sand. As the distance was very short the mixing gang wheeled the material onto the board, dumped it and returned the wheelbarrows to place. This was found to work very satisfactorily, as the mixing gang mixed the concrete a little faster than it could be hauled away. When they had both boards full the mixing gang was put to work getting out cement until the hauling gang had caught up with them.

The concrete was deposited in the forms, built inside of the crib, from a light track supported by a trestle hanging from the bottom chords of the existing bridge.

Erection Costs for a Double-track Railway Bridge.—In Engineering News, Feb. 20, 1913, M. A. O. Stilson gives the erection costs of a bridge consisting of three double-track through spans, each 154 ft. 6 in. long c. to c. The trusses are of lattice type. The piers are square to the track and trusses.

There were in place two old spans (single-track), which were taken out as the work progressed. For cutting apart they were blocked up on the falsework put in for the new spans. The grade of the new track was that of the old, the pier height above high-water allowing for the extra depth of the new floor-beams. The use of a derrick car enabled this work to go forward while the first new span was erected.

An overhead traveler (see Fig. 12) was used for the erection. It was assembled and raised from the old truss. The raising of a traveler becomes a simple and rapid task when old spans are in place to erect from, as the assembling can be in a position not far from the vertical, letting the upper frame of the traveler rest on the top chord of the old spans and finally pulling the small distance to a perpendicular with tackle just prior to joining the bents of the traveler. The traveler could also be raised from the flat floor of the falsework, by means of a jack-frame erected at the foot of the traveler legs. This takes nearly twice the time of the other method, and costs (a gang of 12 men can have a traveler framed and ready for use in three days with the help of a hoisting engine) about $300.

The piers of the new three-span bridge were so located that the masonry could be all completed, with the exception of a few bridge-seat stones to carry track stringers, before the arrival of the bridge steel, thus allowing the new shoes to be placed at once. A temporary trestle at the upstream side of the main line cared for the train movement, allowing the erection to proceed undisturbed by the traffic. Therefore, the falsework had to be proportioned for the trusses alone.

The height of the piers above mean low water was about 27 ft. The river bottom was a well washed gravel, into which a pile could be driven to a penetration of 5 ft. only with difficulty.

The sequence of operations in the erection of the bridge was as follows: (1) Ship equipment and materials to bridge site; (2) unload; (3) place hoister and compressor and house them; (4) put in falsework; (5) erect traveler and wreck old spans; (6) place and block floor-system and bottom chord, cambered; (7) erect web-members; (8) place end posts; (9) place top chord; (10) place bottom and top laterals, with portals and other small members, or release traveler to second span; (11) rivet up; (12) strike falsework and traveler; (13) load material and equipment.

Cost of Shipment.—The cost of shipment of equipment and material to the bridge site is an item varying in each case, and also depending on the terms of the contract with the company owning the bridge. If a railway company, the contract may include transportation and work-train service during erection, though these items are properly a part of the cost, no matter by whom paid. It is not unusual, however, for a charge of $25 per day to be incurred for a locomotive, flat-cars and crew, especially where the bridge members have had to be unloaded at a distance. The economy effected through the use of a derrick car capable of propelling itself and loaded flat-cars thus becomes apparent.

Cost of Unloading.—The unloading of the material and bridge members at the site or some adjacent point, while variable, will generally be covered by the expense of a derrick and hoister, its erection and a possible shift, if the ground available makes this necessary. In the present case the material for the three spans was unloaded in about three weeks, including delays, by a gang of eight men, one engineer and one foreman, about $200 per week for labor cost.

Hoist.—Placing the hoister, compressor and their boilers is comparatively a small item unless considerable falsework be necessary for support. In this case three bents of six piles each, capped and braced, with plank floor, were placed, and the power set, by 12 men and one foreman in four days, costing $200.

Falsework.—The erection of the falsework, consisting of pile bents, capped and braced, floored with timbers parallel with the bridge and some plank, can go forward during the same period. The equipment of scow, pile hammer and hoister engine was able to drive 15 bents of 10 piles each (150 piles) in four days. The piles were delivered into the water above; they were of 25 to 27 ft. lengths, and were driven to a penetration of 5 ft. This gang consisted of one foreman, one engineer and four men, a labor cost of about $23 per day, according to rate of wages paid. The cost was, therefore, $92, or practically 62cts. per pile in place. The piles cost 10c. per lin. ft. delivered above the work, or $2.50 to $2.70 apiece, making $482 the total cost of piles in place. (This figuring assumes that the equipment can leave the work in good condition, so as to be available at full value for other work.) Cutting off the piles, capping, boring and bracing, was completed in eight days by a gang consisting of one foreman and eight carpenters, at a cost for labor of $23.50 per day, or $188 total. This includes placing the timbers to carry the trusses, drifting them in place, and laying floor-plank and traveler track.

The labor cost of one span of falsework in place is thus $280. The cost of piling is $390, and of timber as follows:

30 caps 12 × 12 in. × 25 ft.	9,000 ft. B. M.	
12 saddles 12 × 12 in. × 8 ft.	1,152	
50 stringers 12 × 12 in. × 25 ft.	15,000	
120 braces 3 × 12 in. × 30 ft.	10,800	
80 blocks 8 × 8 in. × 8 ft.	3,411	
240 plank 2 × 12 in. × 12 ft.	5,760	
Cost:		
40 M at $30	$1200	
6 M at 25	150	
		$1350
Total Cost of Falsework:		
Lumber	$1350	
Piles	390	
Labor	280	
	$2020	

This gives $2020 cost of falsework of one span in place ready for setting steel. In the three-span bridge in question, the riveting of Span No. 1 was completed early enough to release the falsework for use under Span No. 3, except for piling.

Traveler.—The traveler, as shown in Fig. 12 consisted of two bents suitably braced, supporting four timbers 12 × 16 in. by 30 ft., two over each truss, to carry the blocks of the main falls and smaller tackles. The erection of the traveler has been stated to cost about $150. It followed the placing of the falsework, using the old spans to erect from. The cost of the traveler itself was as follows:

1 foreman, $4	4	
6 carpenters, $3	$ 18	
4 days at	$22	$ 88
4 legs 12 × 12 in. × 48 ft	2,304 ft. B. M.	
4 batters 12 × 12 in. × 40 ft	1,920	
2 bott. chords 12 × 12 in. × 36 ft	862	
4 top chords 12 × 12 in. × 30 ft	1,440	
4 top timbers 12 × 16 in. × 30 ft	1,920	
16 braces 3 × 12 in. × 20 ft	960	
24 braces 3 × 12 in. × 12 ft	864	
4 diagonals 3 × 12 in. × 36 ft	432	
4 sills 8 × 16 in. × 30 ft	1,280	
12 doz. ¾-in. bolts, etc., at 60 lb	.05,	$36
4 flanged wheels, at 100 lb	.03,	12
4 sets axles, bearings, etc., at 40 lb	.03,	5
Cost of traveler:		
Lumber, 10 M at $35	$350	
Lumber, 3 M. at $25	75	
Hardware	54	
Labor	88	
		$567

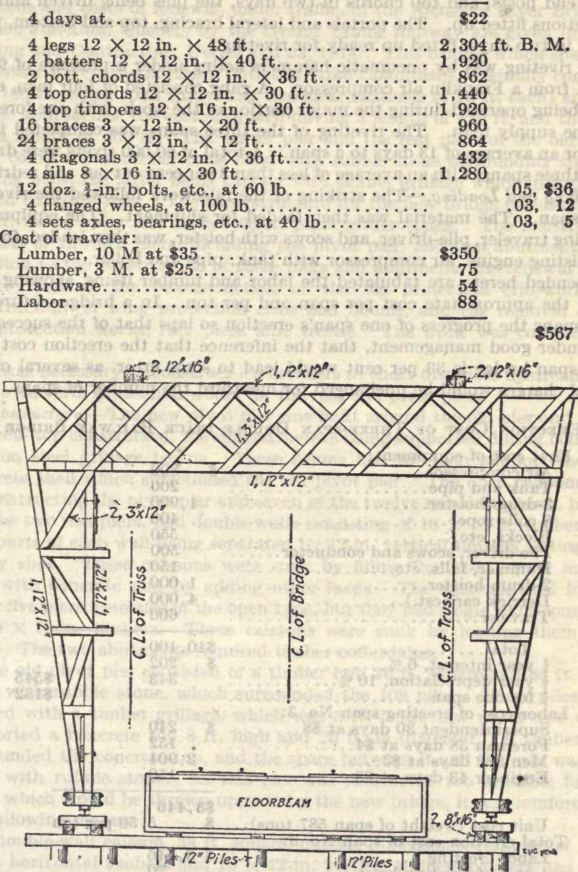

FIG. 12.—Sketch of bent of wooden traveler.

Removing Old Spans.—The wrecking of the two old spans occupied one foreman with 12 men two weeks, the pieces of the members being taken away by the derrick car.

Erecting New Trusses.—The floor-system of one span, including bottom chords, was put in place, blocked up, and bolted, by a gang consisting of two foremen, 18 men and one engineer in five days, assisted by a derrick car with one engineer, one foreman and eight men, who brought the bridge members from the storage yard in proper order.

The truss members and hanger posts were placed in two days, and the shoes, end posts, and top chords in two days, the pins being driven and the connections fitted up. The portals and lateral bracing, top and bottom, were placed in two days, fitted up ready for riveting.

The riveting was by pneumatic hammers acting under a pressure of 90 to 100 lb. from a Franklin air compressor. A gang consisted of four men, eight gangs being operated during the major portion of the work, with one foreman and one supply man. The riveting of the three spans was completed in 39 days, or an average of 13 days to a span. A total of 60,000 rivets were driven in the three spans, with an average of less than 3 per cent cut out and redriven.

Striking and Loading.—The striking of the falsework followed the riveting of its span. The material was then loaded for shipment. The equipment, including traveler, pile-driver, and scows with hoister, was then loaded, freeing the hoisting engine, air compressor with tank, pipe and boiler.

Appended hereto are tabulated the labor and lumber items, showing at a glance the approximate cost per span and per ton. In a bridge of three or more spans the progress of one span's erection so laps that of the succeeding one, under good management, that the inference that the erection cost of a single-span bridge is 33 per cent would lead to some error, as several of the general charges would be unchanged for one-third the number of spans.

Erection Cost of Three-span Double-track Railway Bridge

First cost of equipment:		
Air compressor	$ 800	
Tank and pipe	200	
3-drum hoister	1,900	
8 coils rope	400	
Blocks, etc.	550	
Pile driver, scows and conductor	500	
Hammer, falls, etc.	150	
2-drum hoister	1,000	
Derrick car (est.)	4,000	
Traveler	600	
Total	$10,100	
$\frac{1}{3}$ year interest, 6 %	$ 202	
$\frac{1}{3}$ year depreciation, 10 %	343	$545
$\frac{1}{3}$ for one span		$182
Labor cost of erecting span No. 3:		
Superintendent 30 days at $8	$ 240	
Foreman 38 days at $4	152	
Men 832 days at $3	2,904	
Engineer 43 days at $3	150	
	$3,446	
Unit cost (weight of span 587 tons)	$ 5.50 per ton	
Total erection cost of span No. 3:		
Labor erecting	$ 3,446	
$\frac{1}{3}$ cost of erecting hoist	70	
$\frac{1}{3}$ cost of erecting traveler	50	
$\frac{1}{3}$ cost unloading material, etc.	200	
$\frac{1}{3}$ interest and depreciation	182	
Total erection cost for 587 tons	$ 3,948	
	6.72 per ton	

The assumption has been made that an equipment such as has been described was in the hands of the erection company. But since it would be proper to add a charge not only for depreciation, but for interest on the invested funds, a value on which to base such is also given, the items of which are mostly estimated, although some are actual costs.

Costs of the Richelieu River Bridge, Lacolle Junction, Quebec.—The methods and costs of renewal, under traffic, of the Richelieu River Bridge at Lacolle Junction, Quebec, by the Grand Trunk Railway are given in Engineering and Contracting, Dec. 9 and 23, 1914. This bridge, which spans the Richelieu River, the northern outlet of Lake Champlain, originally consisted of a 180-ft. swing span (providing two clear channels of 73 ft. each) and pile trestle approaches, the east approach having a length of 350 ft. and the west one a length of 500 ft. The center pier and the rest piers of the old swing span consisted of timber cribs filled with rubble stone surrounding the supporting piles, the latter being capped with timber grillage which in turn supported concrete tops. The superstructure for the new bridge consists of one 250-ft. swing span and twelve 60-ft. plate girder spans. The substructure consists of thirteen piers, including the pivot pier, and two abutments. In addition to the construction of these piers and abutments the renewal of the bridge required the reconstruction of the old protection crib-work, the construction of wing protection cribs and booms, and the removal of the old protection works, rest piers and trestle. The work was completed in 1913.

It was necessary to construct ice breakers at short distances upstream, and to provide crib protection works for the rest and pivot piers.

Substructure.—The new pivot pier was built around the old pier and a new concrete top constructed, the superstructure being supported during construction on steel grillage beams. These beams had for their support the new concrete shell which surrounded the old pivot pier. The open caissons used in constructing the pivot pier and seven of the twelve remaining piers, including the two rest piers, had double walls consisting of 10 × 10-in. timbers, the two parts of each wall being separated by 12-in. vertical timbers resting on a heavy shoe. These caissons were sunk by filling the 12-in. space in each wall with concrete and by adding other loads. The caissons used for the other five piers were also of the open type, but they had single walls consisting of 10 × 10-in. timbers. These caissons were sunk by loading them with rails. The two abutments required timber cofferdams.

The old pivot pier consisted of a timber crib 26 ft. square and 33 ft. high, filled with rubble stone, which surrounded the 108 piles. These piles were capped with a timber grillage, which was 3 ft. below low water and which supported a concrete top 8 ft. high and 20 ft. in diameter. A timber wall surrounded the concrete top, and the space between it and the crib was also filled with rubble stone. As this pier was considered too unstable for the loads which would be thrown upon it by the new bridge, it was reinforced in the following manner:

A double-wall caisson, 38 ft. square, outside dimensions, built up of 10 × 10-in. horizontal timbers and 12 × 12-in. vertical timbers between the walls at intervals, was sunk around the old pier, leaving a 3-ft. space between it and the old crib. After this space was filled up to approximately 6 ft. below low water with plain concrete, reinforced concrete walls were carried up to the required level to receive the eleven 26-in., 166-lb. I-beams, on which the swing span was erected and operated during the completion of the piers.

Fig. 13 gives a half section showing the caisson and the old pivot pier before alteration, and a half section of the complete pivot pier.

It was originally intended to remove the rubble stone filling from the old crib one pocket at a time, but this was found to be impracticable owing to the existence of fissures in the slate-rock foundation, which made unwatering impossible. The stone was, however, taken out to a level 2 ft. below the old timber grillage. The old piles, the timber grillage and the concrete top were left in place, except the upper 18 ins. of the latter, which were removed by blasting. Instead of unwatering the pier, water was pumped into it until a 3-ft. head was produced, this head being utilized in forcing a 1:2 grout into the voids of the rubble stone. After the voids were filled the water was

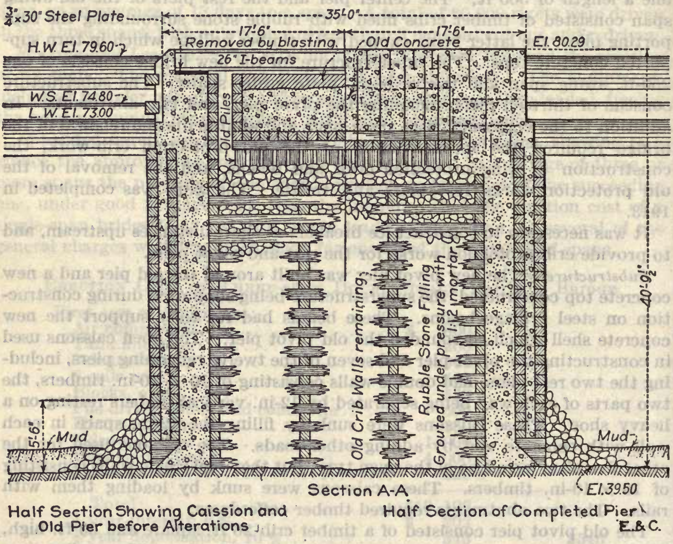

FIG. 13.—Half section of old pivot pier and half section of completed pivot pier of Richelieu River Bridge.

pumped out, and the concrete work was completed in the dry, grillage beams being embedded in the coping to distribute the loads from the swing span.

Seven of the intermediate piers (Nos. 4, 5, 6, 7, 9, 10 and 11) have caisson foundations, which are of similar construction to that used for the pivot pier and which differ only in shape. These piers are pointed, both on the upstream and downstream ends. Fig. 14 (a) shows a half cross section and a half end elevation of a typical intermediate pier and caisson in which the double-wall type of caisson was used; Fig. 14 (b) shows a side elevation of the pier and caisson; and Fig. 14 (c) shows a plan of the caisson. Above elevation 70 (the top of the permanent caisson) the construction for all of these piers is alike.

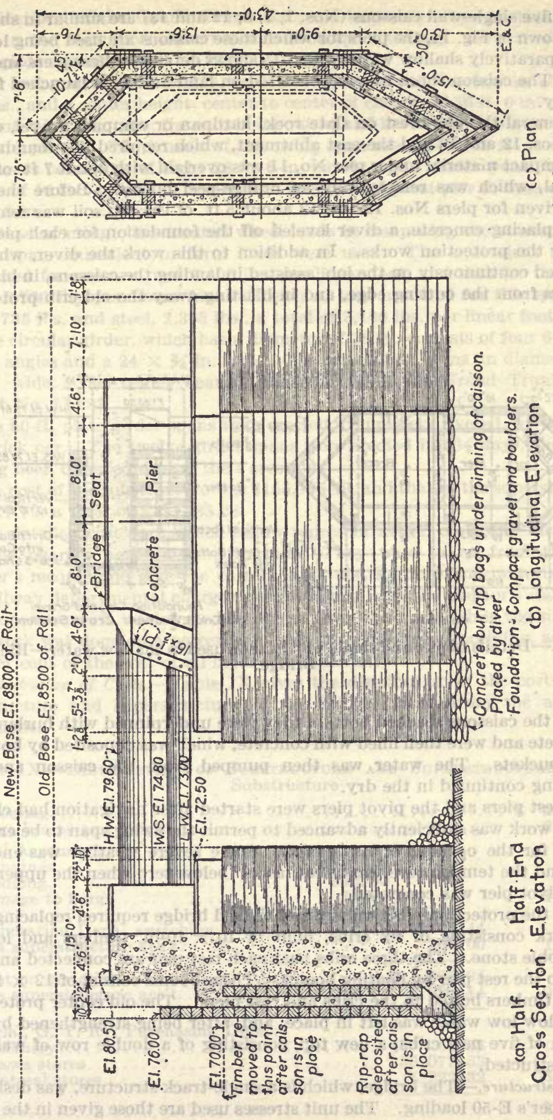

FIG. 14.—Details of typical intermediate pier and double-wall caisson of Richelieu River Bridge.

The five single-wall caissons (Nos. 1, 2, 3, 12 and 13) are similar in shape to that shown in Fig. 14, the piers for which these caissons are used being located in comparatively shallow water. Fig. 15 shows details of these piers and caissons. The caisson shoes were constructed on land and were launched from a skidway.

In general the piers rest on slate rock, hardpan or compact gravel, except piers Nos. 12 and 13 and the east abutment, which required pile foundations. The compact material under pier No. 11 was overlaid with about 7 ft. of loose material, which was removed by an orange-peel bucket. Before the piles were driven for piers Nos. 12 and 13 about 5 ft. of the top soil was removed. Before placing concrete, a diver leveled off the foundation for each pier and also for the protection works. In addition to this work the diver, who was employed continuously on the job, assisted in landing the caissons, in blasting boulders from the cutting edge, and in blasting away the old crib protection works.

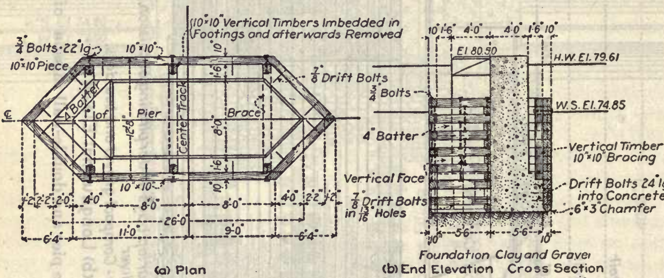

FIG. 15.—Details of pier and single wall caisson used in shallow water—Richelieu Bridge.

After the caissons reached bottom they were underpinned with burlap bags of concrete and were then filled with concrete, which was deposited by bottom-dump buckets. The water was then pumped from the caisson and the concreting continued in the dry.

The rest piers and the pivot piers were started after navigation had closed, and the work was sufficiently advanced to permit the swing span to be erected in time for the opening of navigation. Some severe weather was encountered, and the temperature was as low as 28° below zero when the upper part of the pivot pier was concreted.

All of the protection piles and cribs of the old bridge required replacing, the new work consisting of six cribs, built of 10 × 10-in. timbers and loaded with rubble stone. The three cribs near each rest pier are connected and are joined to the rest pier by floating booms. These booms consist of 12 × 12-in. vertical timbers bolted to the cribs and rest piers. The old center protection work below low water was left in place, and, after being strengthened by the addition of five new cribs, a new top, consisting of a double row of walings, was constructed.

Superstructure.—The bridge, which is a single-track structure, was designed for Cooper's E-50 loading. The unit stresses used are those given in the 1910 specifications of the Grand Trunk Ry., the impact allowances being those given in the Dominion Government's 1908 specifications. The twelve deck plate girder spans possess no unusual features.

The swing span has a length, center to center of end floorbeams, of 244 ft. 7½ ins., and a center height, center to center of chords, of 36 ft. 0 in. It is of the center-bearing type, the ends being raised and lowered by wedges operated by hand power. The trusses of the swing span are spaced 18 ft. on centers, each truss consisting of eight 28-ft. 6-in. panels and a center panel having a length of 16 ft. 7½ ins. The distance from top of pivot pier to base of rail is 11 ft. 0 in.

Instead of using concentrated wheel loads in computing the stresses in the swing span equivalent uniform loads were used. The equivalent uniform load used for one arm was 6,400 lbs. per linear foot, and that for the entire span, 5,700 lbs. per linear foot. The dead load assumed for this span was: floor, 735 lbs. and steel, 2,365 lbs., a total of 3,100 lbs. per linear foot.

The circular girder, which has a diameter of 18 ft., consists of four 6 × 4 × ⅝-in. angles and a 24 × ¾-in. web. The wheels are 12 ins. in diameter and 8 ins. wide. The center bearing steel casting is the Grand Trunk Ry.'s patent No. 11,283.

The 60-ft. plate girder spans were erected, completely riveted, by means of a derrick car. The twelve girder spans were erected in 5½ days, the traffic having been diverted during their erection.

The cost of the substructure was $155,955.49, and that of the superstructure $77,877.79, a total of $233,833.28.

The detailed cost data which follow represent actual costs and include all possible charges against the structure. They were taken from the contractor's records and give the correct labor distributions and material costs. All railway departmental charges were obtained from the auditor's statement. The superstructure was erected by the railway company, while the substructure work was done on a percentage basis, the contractor receiving, as profit, 6½ per cent of the cost of all labor and materials.

Distribution of Costs.—Table IX gives the distribution of the costs of the substructure and superstructure of the bridge, taken from the auditor's statement.

TABLE IX.—DISTRIBUTION OF SUBSTRUCTURE AND SUPERSTRUCTURE COSTS

Substructure

Engineering			$ 2,705.85
Grillage beams and freight			2,460.59
Special Accounts:			
Soundings	$ 81.00

Scale of Wages.—The prices paid for the various classes of labor were as follows:

	Cts. per hr.
Common laborers	22½
Handymen	25
Carpenters	35 to 40
Labor foreman	35
Carpenter foreman	40
General foreman	60
	Per day
Superintendent	$8.00
Driver*	6.50
Helper*	4.50

* Furnished by railway company.

Material Prices.—The following data give the materials used, where they were obtained, and the prices paid for them:

Sand, f. o. b. Swanton, Vt., 32 cts. per ton, duty free.
Crushed stone, f. o. b. Chazy, N. Y., 75 cts. per ton, duty 17½ per cent.
Rubble stone, f. o. b. Chazy, N. Y., 60 cts. per ton, duty free.
Rubble stone, f. o. b. bridge site, by barge from Isle La Motte, Vt., 85 cts. per ton, duty free.
Cement, f. o. b. Belleville, Ont., (Canadian brand), net $1.25 per barrel.
Lumber, McAuliffe-Davis Lumber Co., Chicago:
  2 × 4-in. × 10 to 14-ft. hemlock at $15 per M.
  2 × 6-in. × 10 to 14-ft. hemlock at $15 per M.
  2 × 8-in. × 10 to 14-ft. hemlock at $15 per M.
  1 × 6 to 8-in. × 10 to 18-ft. hemlock at $15 per M.
  1 × 6-in. × 12 to 16-ft. pine form lumber at $19.50 per M.
Lumber, E. Hines Lumber Co., Chicago:
  12 × 12-in. × 26-ft. l. l. y. p. at $28.50 per M
  12 × 12-in. × 18-ft. l. l. y. p. at $26.50 per M.
  12 × 12-in. × 22 to 24-ft. l. l. y. p. at $27.50 per M.
  10 × 10-in. × 22-ft. l. l. y. p. at $25.50 per M.
  10 × 14-in. × 14 to 25-ft. l. l. y. p. at $34.00 per M.
Lumber, John Harrison & Sons, Owen Sound, Canada:
  10 × 10-in. × 10 to 20-ft. hemlock at $20 per M.
  12 × 12-in. × 10 to 20-ft. hemlock at $20 per M.
Lumber, A. J. Martin, Sherbrooke, Canada:
  10 × 10-in. × 14-ft. hemlock at $18 per M.
  10 × 10-in. × 20-ft. hemlock at $20 per M.
  10 × 10-in. × 22-ft. hemlock at $22 per M.
Lumber, Marsh & Bingham, Chicago:
  10 × 10-in. × 10 to 14-ft., l. l. y. p., at $28 per M.
  10 × 10-in. × 16 to 20-ft., l. l. y. p., at $32 per M.
  12 × 12-in. × 10 to 14-ft., l. l. y. p., at $30 per M.
  12 × 12-in. × 16 to 20-ft., l. l. y. p., at $31 per M.
  12 × 12-in. × 26-ft., l. l. y. p., at $33 per M.
Lumber, W. H. Bromley, Canada:
  12 × 12-in. × 12 to 20-ft. red pine, at $25 per M.
Lumber, Colonial Lumber Co., Canada:
  12 × 12-in. × 12 to 20-ft. red pine, at $25 per M.
Lumber, Long Lumber Co., Hamilton, Ontario:
  10 × 10-in. × 12 to 18-ft. hemlock, at $16 per M.
  12 × 12-in. × 16 to 18-ft. hemlock, at $20 per M.
Lumber, R. Laidlaw & Co., Canada:
  12 × 12-in. × 16-ft. Georgia pine, at $35 per M.
  12 × 12-in. × 18-ft. Georgia pine, at $37 per M.
Lumber, W. B. Crane & Co., Chicago:
  12 × 14-in. × 14 to 16-ft. white oak, at $38 per M.

Prices of Miscellaneous Materials.—The following prices were paid for the miscellaneous materials listed in the accompanying table:

Reinforcing steel, per 100 lbs	$ 1.45
Drifts, sheared points without head, per 100 lbs	1.90
Ship spikes, per 100 lbs	2.90
Anchor straps, each	4.80
Machine bolts:	
7/8 × 15-in., per 100	29.40
7/8 × 24-in., per 100	42.00
1/2 × 15-in., per 100	10.62
Nose plates, each	7.15
1 10-in. sheave block	14.00
1 10-in. sheave snatch block	7.50
1 8-in. triple wood block	1.95
Steam hose, per lin. ft	.93
Suction hose, per lin. ft	1.33
1 3-ton M. J. duplex block	72.00
1 1-ton M. J. differential block	7.00
1 3-ton Harrington block	67.50
Dynamite, f. o. b. factory, per lb	.19
Amazon 3-ply roofing paper, per square	2.25
1 motor boat, 18-HP	600.00

Equipment Furnished by Substructure Contractor.—The accompanying table gives the equipment, and its value, furnished by the J. S. Metcalfe Co., the substructure contractor:

6 Hudson, V-shaped, 1-cu. yd. cars	$ 390
Track	40
1 No. 3 Gould trench pump	25
1 1/2-cu. yd. Cube mixer	1,600
1 1/2-cu. yd. Smith mixer (old)	400
1 Pulsometer pump	100
1 Emerson Jr. B. pump	120
1 No. 2 Emerson steam pump	368
2 No. 2 Wood electric drills	250
Motor and fittings	600
2 locomotive boilers	800
1 vertical boiler	300
12 wheelbarrows	45
Total	$5,038

Work Done by Bridge and Building Department.—The data given in Table X refer to materials furnished and work done by the Bridge and Building Department of the Grand Trunk Ry.

TABLE X.—COST DATA ON WORK DONE BY BRIDGE AND BUILDING DEPARTMENT

Piles and Pile Driving	
117 40-ft. piles (4,670 lin. ft. at 15 cts. per ft.)	$ 700.00
Motive Power Department	329.61
14½ days' pile driving at $8 per day, labor $16	232.00
*Labor, cutting piles—east abutment	20.00
Labor, cutting piles by driver, average about 8 piles per day at $17 per day; total, 62 piles in 8 days	136.00
Freight	80.00
Overhead charges	79.00
Total cost (per ft., 33.8 cts.)	$1,576.61
Supporting Track by Bridge Dept.	
Labor	$ 415.20
Material	500.00
Freight	120.00
Overhead charges	71.00
Total	$1,106.20

TABLE X.—(*Continued*)

Work Done by J. S. Metcalfe Co. as Part of B. & B. Dept.'s Work
This work consisted of changing trestle bents, supporting track and removing old trestle piles.

Labor	$1,411.57
Material	200.00
Transportation	23.44
Freight	70.00
Overhead charges	159.00
Total	*$1,864.01

*$1,864.01 − $20.00 = $1,844.01.

Table XI gives cost data on work done by the diver, such as cutting off piles and excavation for caissons and protection cribs.

TABLE XI.—COST DATA ON WORK DONE BY DIVER

Cutting off piles in foundation:	
Labor	$ 100.00
Material	20.00
Freight	2.75
Overhead charges	13.25
Total	$ 136.00
Cutting of old trestle piles inside and outside of caissons:	
Labor	$ 100.00
Material	20.00
Freight	2.76
Overhead charges	13.75
Total	$ 136.51
Excavation by diver:	
This account was for excavation work for caissons (area, 6,400 sq. ft.; cost, $1,975), and for protection cribs (area, 2,000 sq. ft.; cost, $851).	
Labor	$2,400.00
Material	130.00
Freight	10.00
Overhead charges	286.00
*Total	$2,826.00
*Cost per square foot (8,400 sq. ft.) =	34 cts.
Grand total	$3,098.51

Data on Open Timber Caissons.—Table XII* gives the quantity of timber required for the caissons of the piers and abutments, the various labor and material costs, the cost of miscellaneous items and the total and unit cost. The contractor's percentage and the engineering costs are not included (for contractor's percentage of the total cost of each pier and abutment see Table XV). The overhead charges given include: construction buildings, timekeeper, tool boys, watchman, shoveling snow, superintendence, general expense, equipment, labor and material.

Concrete Work.—Table XIII* gives the quantity of concrete placed in the piers, the various labor and material costs for piers and abutments, the cost of miscellaneous items, the total cost of the concrete in piers and abutments, and its unit cost. The contractor's percentage and the engineering costs are not included. (For contractor's percentage of the total cost of each pier and abutment see Table XV.) The overhead charges given in Table XIII include: construction buildings, shoveling snow, timekeeper, tool boys, watchman, superintendence and general expenses. The concrete was deposited under water by bucket, the average depth of water being about two-thirds of the height of the pier. In connection with the concrete work the pumping account amounted to $1,676.92, divided as follows: labor, $797.92; fuel, $530; miscellaneous material, $200; and overhead charges, $149; this amounts to 31.2 cts. per cubic yard of concrete in the piers and abutments.

* Tables XII and XIII have been greatly reduced from those given in article in which the details are given separately for each pier and abutment.

Crib Protection Works, Booms and Waling.—Table XIV gives the quantities of materials used in the cribs, booms and waling, the labor and material costs of various items, the cost of miscellaneous items, the total costs of the cribs. booms and waling, and their unit costs. The engineering costs are not included, The cribs were filled with stone from barges, the rip-rap being unloaded from trains. The total cost of the wing cribs and booms was $15,594, and that of removing the old protection work $1,190.98 (for details see Table XVI).

Summary of Pier Costs.—Table XV gives a summary of the cost of the various items of each pier and abutment, the total cost of each pier, and the total cost of all piers and abutments. The engineering costs are not included. Cofferdams were constructed for the two abutments and for pier No. 1. The cofferdam used for pier No. 1 consisted of 2-in. sheeting driven flush with the outside of the caisson and banked with clay on the outside. The cost given for this cofferdam, $306.98, includes the cost of excavating for the pier and that of puddling. The excavation work for the two abutments (cost, $300) was done by ordinary labor; that for pier No. 11 (cost, $600) was done by a dredge; and that for the remaining piers (cost, $1,975), by divers. The cost given for the caisson of the west abutment ($448) was for rip-rap only. The distance from the top of masonry to the base of rail is 8 ft. 6 ins.

The itemized costs of the pivot pier (No. 8) are shown in Table XV. These costs do not include engineering nor removal of old pier, the costs of which were $416 and $900, respectively. If these items are included, the total cost of the pivot pier is $24,517.96. The total cost of the concrete work for this pier was $11,827.45, which was divided as follows:

12-in. wall, 140 cu. yds. at $9.00	$ 1,260.00
Encasing walls and concrete burlap bags, 650 cu. yds. at $8.46	5,500.00
Rubble grouting, 450 cu. yds. = 150 cu. yds. grout at $12.00	1,800.00
Pier top, 360 cu. yds. at $8.22	2,969.45
Forms	298.00
Total	$11,827.45

The estimated cost of the pivot pier, including its proportion of the general charges, freight, interest and depreciation of plant, contingencies, engineering and superintendence, was $31,250. The difference between this and the actual cost of about $24,500 is due mainly to: (a) Grouting the rubble filling instead of removing it and replacing with concrete (approximate saving, $3,500); (b) lower cost of concrete than estimated (approximate saving, $2,500); and (c) lower cost of caisson (approximate saving, $750).

Table XVI gives a general summary of the costs of the bridge, the tabulation being made in such manner as to show the costs of labor and superintendence, material, transportation, fuel, freight, overhead charges and totals for each item of the work. It will be noted that the cost of labor and superintendence was about $9,600 in excess of that of materials.

In Fig. 16 the heights of the piers have been platted as ordinates and their total costs as abscissas. Excluding the rest piers, which are special cases, it is seen that the height-cost curve is practically a straight line.

Unit Costs.—The following unit costs include, in addition to the items noted, train service and freight, but do not include contractor's percentage nor engineering charges:

Timber in Caissons.—The average cost of the timber in the caissons, framed, erected and in place, including materials, tools, equipment and labor, was $69.02 per M ft. B. M.

Timber in Protection Crib Work.—The average cost of the timber in the crib protection work framed, erected and in place, including materials, tools, equipment and labor, was $60.87 per M ft. B. M. The prices of the various kinds of timber, per M ft. B. M., were: hemlock and spruce, $20; red pine, $25; long leaf yellow pine, $26 to $34.

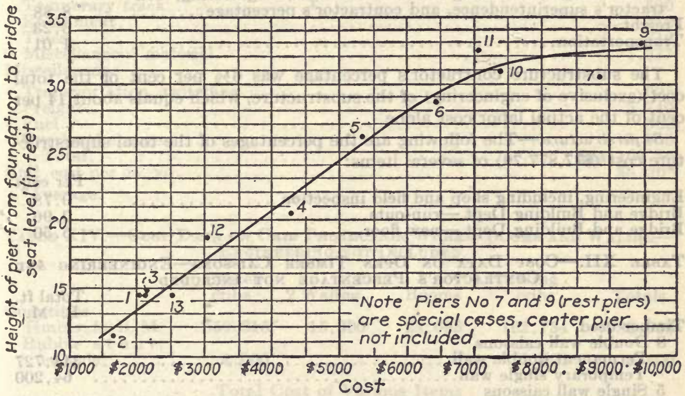

FIG. 16.—Curve showing relation between height and cost of intermediate piers of Richelieu River Bridge.

Concrete.—The average cost of the concrete, including materials, equipment, tools and labor, was $8.20 per cubic yard. The prices of the materials were: crushed stone, $1.10 per cubic yard ($0.75 per ton); sand, $0.32 per cubic yard; and cement, $1.25 per barrel, net.

Excavation.—The cost of the excavation, including equipment and labor, for the three classes of work as follows:

By diver, preparing bottom, 8,400 sq. ft., $0.34 per square foot.

By orange-peel bucket, 200 cu. yds., $4.22 per cubic yaid.

By ordinary labor, 200 cu. yds., $1.50 per cubic yard.

Rip-rap.—The cost of the 1,300 cu. yds. of rip-rap, including equipment and labor, was $2.25 per cubic yard.

Stone Filling.—The 5,400 cu. yds. of stone filling, including equipment and labor, cost $1.69 per cubic yard.

Piles.—The 40-ft. hardwood piles cost, in place, $13.48 each, or $0.34 per linear foot. This cost includes material, equipment, driving, cutting off and all other labor.

Superstructure.—The weight of the 250-ft. swing span was 737,062 lbs., and its cost, erected, was 5.34 cts. per pound.

The weight of the twelve 60-ft. deck plate girders was 710,370 lbs., and their cost, erected, was 3.27 cts. per pound.

The power plant and machinery cost $5,167.

PERCENTAGES OF TOTAL COST OF VARIOUS ITEMS

Substructure.—The following are the percentages of the total substructure cost ($155,955.49) of some of the principal items:

	Per cent
Engineering, including preliminary surveys, plans and field inspection	1.73
Bridge and Building Dept., including changing of trestle bents, re-supporting track, etc	1.90
Soundings	0.23
Contractor's superintendent	1.66
General charges, including overhead charges, engineering, contractor's superintendence, and contractor's percentage	8.88
Freight	6.23
Transportation	1.01

The substructure contractor's percentage was 6½ per cent of the total cost (exclusive of engineering) of the substructure, which equals about 14 per cent of the actual labor cost alone.

Superstructure.—The following are the percentages of the total superstructure cost ($77,877.79) of several items:

	Per cent
Engineering, including shop and field inspection	0.78
Bridge and Building Dept.—run-outs	0.96
Bridge and Building Dept.—new floor	6.50

TABLE XII.—COST DATA ON OPEN TIMBER CAISSONS—ENGINEERING AND CONTRACTOR'S PERCENTAGE NOT INCLUDED

	Total ft. B. M.
Timber used	
8 Double wall caissons	
Permanent double wall	344,727
Temporary single wall	64,200
5 Single wall caissons	
Permanent single wall	28,760
Temporary single wall	18,400

COSTS

	Total
Labor	
Framing	$13,881
Tearing down, single wall	459

Cost of Converting a Pin-Connected Bridge into a Riveted Structure.—The following matter is taken from an article published in Engineering News, Oct. 8, 1914.

The conversion of a pin-connected bridge span into a riveted span is an interesting and very exceptional piece of bridge work recently carried out. The bridge is a single-track swing span on a branch of the Pennsylvania Lines, crossing the Grand Calumet River, at Burnham, Ill., and was built by A. Gottlieb & Co., in 1886. It is 183 ft. long, c. to c., having two 81-ft. arms and a central 21-ft. panel. It was necessary to adapt the bridge to carry heavy loading (Cooper's E-60), and investigation showed that this could be done much more rapidly and at much less cost by strengthening the old structure than by replacing it by a new bridge. The work in general was as follows:

(1) Reinforcing the main trusses; (2) adding an additional row of stringers for each rail; (3) placing new top and bottom cover plates and additional end hanger plates on the floor-beams; (4) strengthening the circular girder of the turntable drum.

Execution of Work.—One arm of the bridge is over shallow water and the other over the navigable channel. The plan of reconstruction adopted was to build falsework under the former arm and make all the alterations to it, such truss pins being removed from it as were necessary to make way for the new parts. The bridge was then revolved, and the other arm treated in the same way. The traffic averaged 20 trains daily.

As the work was done before the navigation season opened, the bridge was not required to be swung for river traffic. When reversed for the reconstruction work, it was swung by means of its hand-operated machinery in the regular manner. A locomotive crane standing on the bridge was used to take out the old members and put the new members in place, while the use of oxyacetylene torches in cutting away old material considerably reduced the time and cost of the work.

In all, about 20 tons of metal were removed and 80 tons of new metal placed, the bridge as now completed having a weight of about 170 tons.

The necessary alterations to the bridge and the methods of carrying them out were planned under the direction of J. C. Bland, Engineer of Bridges of the Pennsylvania Lines. The contract for the execution of the work was awarded Dec. 2, 1913. Work was commenced Jan. 20, 1914, and completed May 13, 1914. The cost was approximately $16,500, while it is estimated that a new bridge to meet the same conditions would have cost about $75,000.

The Cost of a Cable-Lift Drawbridge of the Pennsylvania Lines is given in Engineering News, Nov. 13, 1913. The bridge in question being one of two parallel double-track bridges built in 1913 across the Calumet River at South Chicago. The bridges are on skew, each having an extreme length (including approach spans) of about 340 ft., and a length of 210 ft. c. to c. of end pins of the lift span. The distribution of cost for one span is as follows:

Substructure	$110,000
Towers, including approach spans	88,000
Lift span	70,000
Electrical apparatus	16,500
Operating machinery	45,000
Rail latches	3,000
Cables	13,000
Concrete counterweights	3,400
	$348,900

TABLE XVI.—GENERAL SUMMARY AND CLASSIFICATION OF COSTS

Items	Superintendence and labor	Material	Miscellaneous*	Overhead charges	Total
Overhead charges:					
Construction buildings	$ 1,660.53	$ 1,562.80	650.00	....	....
Timekeeper, tool boys, watchman	2,500.00	....	....	....	....
Shoveling snow	64.00	....	....	....	....
Equipment (handling and repairing)	2,922.00	1,300.00	....	....	....
General expense	....	593.00	....	....	....
Superintendence	2,585.12	....	....	....	....
Caissons	14,800.00	9,770.00	1,524.40	$2,701.00	$ 28.795.40
Crib protection work, etc.:					
Waling	813.72	585.00	94.00	169.00	1,661.72
Booms	1,253.00	780.00	136.00	248.00	2,417.00
Wing protection	3,795.00	4,850.00	660.00	1,000.00	10,305.00
Center protection	7,465.00	12,330.00	1,490.00	2,490.00	23,775.00
Concrete:					
Concrete	11,792.56	17,281.00	6,820.00	4,036.00	39,929.56
Forms	2,941.00	550.00	345.00	344.00	4,180.00
Rubble stone:					
Riprap	960.09	1,127.00	500.00	332.00	2,919.09
Filling cribs	2,543.15	4,713.00	350.00	832.00	8,438.15
Removing old structure:					
Old rest piers	1,010.00				
Old center pier	600.00				
Old wing protection	576.00	1,041.29	....	432.00	4,518.27
Old center protection	614.98				
Old wharf	244.00				
Removing under water by diver	2,148.38	130.00	20.00	258.00	2,556.38
Cutting trestle piles inside caisson	100.00	20.00	2.76	13.75	136.51
Cleaning bottom of piers and cribs by diver	2,400.00	130.00	10.00	286.00	2,826.00
Excavation and cofferdams—E. & W. Abut. and Pier No. 1	1,232.98	235.00	20.00	169.00	1,656.98
Unwatering all piers	797.92	200.00	530.00	149.00	1,676.92
Sounding	256.00	50.00	....	55.45	361.45

Engineering	....	....	2,705.85	....	2,705.85
Contractor's percentage	....	....	9,188.80	....	9,188.80
Total	$68,234.20	$58,668.09	$29,053.20	....	$155,955.49

* Miscellaneous includes Transportation—$1,573.44, Fuel—$2,159.40, Freight—$9,715.51 and miscellaneous—$15,604.85

The cost of the lift span covers furnishing and erecting the steelwork complete, the machinery and operator's houses, wood walkways and platform sand their railings. The cost for the counterweights includes furnishing and placing the concrete. The cost of dismantling the old span, providing temporary supports for tracks during erection, royalty, extras in erection, and various other items will make the total cost of each double-track bridge about $400,000. To this must be added the proportional share of the cost of the power plant.

Cost of Erecting Structural Steel for Manhattan Elevated Railway Improvements.—Early in 1916 work was completed on the addition of single continuous express track to the Manhattan elevated railway in New York City. The work included the building of 23 miles of single track elevated structure, the erection of 50,000 tons of steel, the building of 638 foundations, and the construction or reconstruction of 29 stations. Most of the work was on city streets often congested with traffic. Traffic on the elevated railway lines was maintained according to the regular schedule throughout the period of reconstruction. In a paper published in the Dec. 1917 Proceedings, Am. Soc. C. E., F. W. Gardiner and S. Johannesson describe the design and construction features of this improvement. The following notes, on the cost of the work, taken from the above-mentioned paper are given in Engineering and Contracting, Jan. 23, 1918.

The work was performed under a contract, dated Feb. 13, 1914, with the Terry & Tench Co., Inc., The Snare & Triest Co., and the T. A. Gillespie Co., which last company acted as executive. The work was distributed as follows;

All foundation work was done by the T. A. Gillespie Co.; the Snare & Triest Co. carried out all work, including steel erection, station finish, and track-laying on Sections Nos. 6-C and 7; the Terry & Tench Co. completed all steel erection and track work on the remaining sections, and the station finish work on these sections was partly carried out by the Terry & Tench Co. and partly by the T. A. Gillespie Co. The contractor's work was in executive charge of a vice-president of the T. A. Gillespie Co.

The sub-contractors for the manufacture and delivery of the steelwork, the tonnage delivered, and the prices per pound of the material delivered, are given in Table XVII.

TABLE XVII.—STEEL WORK FOR "MANHATTAN ELEVATED IMPROVEMENTS"

Section	Sub-contractor	Tons	Price per lb.
1	Milliken Brothers	5,963	$0.0288
2-A	American Bridge Co	4,562	0.0293
2-B	American Bridge Co	3,820	0.0262
3	Phoenix Bridge Co	3,929	0.0239
4-A	McClintic-Marshall Co	5,544	0.0215
5-A	Pennsylvania Steel Co	1,732	0.0290
5-B	Pennsylvania Steel Co	1,440	0.0275
5-C (Structural steel)	Pennsylvania Steel Co	1,100	0.0290
5-C (Machinery)	Pennsylvania Steel Co	163	0.1045
5-D	Pennsylvania Steel Co	1,113	0.0320
6-A	L. F. Shoemaker & Co	2,926	0.0250
6-C	McClintic-Marshall Co	8,075	0.0243
7	L. F. Shoemaker & Co	1,487	0.0254
8-A	American Bridge Co	5,041	0.0245
8-B	Milliken Brothers	1,302	0.0270
8-C	Milliken Brothers	547	0.0254
10-B	Belmont Iron Work	1,200	0.0285

The contracts for the manufacture and delivery of rails were made with the following companies:

Bethlehem Steel Co., Standard rails, 2,961,520 lb., at $0.014 per pound.

Lackawanna Steel Co., standard rails, 2,916,940 lb., at $0.014 per pound.

Illinois Steel Co., manganese rails, 564,060 lb., at $0.0905 per pound.

The track lumber, which was all yellow pine and amounted to about 8,000,000 ft. B. M., was obtained from the D. L. Gillespie Co., of Pittsburgh, Pa., and cost $30.50 per 1,000 ft. B. M.

Other lumber, for shoring, forms, etc., was bought for $23.50 per 1,000 ft. B. M.

The prices paid for materials for concrete delivered were as follows:

Cement, per bbl.	$1.70
Sand, per cu. yd.	1.00
Stone, per cu. yd.	1.70

Cost of Labor.—The wages paid to the men engaged on the work were at the prevailing rates, and were as follows, for an 8-hour day:

Bricklayers	$ 6.00
Iron workers	5.00
Iron workers apprentices	3.00 to $4.00
Carpenters	5.00
Carpenter foreman	7.00 to 8.00
Dock builders	4.00
Water-proofers	4.25
Rock drillers	3.75
Timber men	2.50
Timber men or foreman	3.00 to 3.50
Painters (structural)	2.25 to 2.50
Painters foreman	4.00 to 5.00
Blacksmiths	4.50 to 6.00
Blacksmiths' helpers	3.20
Machinists	3.50
Lead caulkers	4.50
Labor foreman	3.50 to 4.00
Handy man	2.50 to 3.00
Laborers	2.00 to 2.25
Painters for timber work	4.00
General foreman	8.00 to 10.00, straight time
Compressor men	125.00 per month
Hoisting engineers	30.25 to 33.00 per week
Watchmen	12.00 to 14.00 per week

The total cost of the work done by the contractors was $10,273,636. The contractors' expenses for engineering and superintendence amounted to $559,340, or about 5½ per cent of the total cost.

The cost of steel erection varied greatly for the different sections, on account of the varying difficulties connected with the erection. Table XVIII gives for each section the cost of erecting 1 ton of steel and the cost of shoring per ton of steel erected.

As an example of the cost of riveting, etc., it may be stated that, on Section No. 6-C, 365,000 rivets were driven at the cost of 14.2 cts. per rivet, including overhead charges. There were four men in a gang, and each gang averaged 172 good rivets for an 8-hour day. This work was interfered with, on account of the train traffic. About 325,000 holes were drilled from the solid, mostly 15/16 in. in diameter, at a cost of 15.1 cts. per hole; about 40 per cent of these holes were drilled in new steel on the street surface, the remainder in the structure. About 115,000 old rivets and bolts were cut out of the existing structure at a cost of 9.6 cts. each, including replacing the rivets cut out with temporary bolts.

Table XVIII.—Cost of Erection

Section No.	Cost of erection, per ton	Cost of shoring, per ton
1	$ 30.42	$12.57
2-A	21.27	5.41
2-B	13.80	1.50
3	43.71	20.18
4-A	14.22	0.88
5-A	50.85	20.61
5-B	39.62	26.53
5-C	85.76	......
5-D	32.49	6.49
6-A	28.70	17.06
6-C	39.82	10.30
7	93.94	7.34
8-A	33.41	15.33
8-B	.....	.....
8-C	57.80	13.90
10-B	105.24	2.68

The labor charges for the construction of the foundations varied considerably, according to whether the new foundations were at new locations or replaced existing foundations, and also according to the sub-surface structures encountered. On Section No. 2-A, for example, 49 foundations, each containing, as an average, 15.8 cu. yd. of concrete, were placed at new locations at $24.50 per cubic yard, including all excavation, placing of sheathing, forms and concrete, back-filling, and repaving. Seventeen foundations under existing columns were placed at a cost of $37 per cubic yard, and, in addition, the cost of shoring the structure amounted to $210.36 for each foundation.

On Section No. 5-A, 23 foundations, each containing, as an average, 20 cu. yd., under existing columns, were placed at a cost for labor of $18.93 per cubic yard, and the charges for shoring the structure amounted to $255.77 for each foundation.

On Section No. 5-B, 24 foundations, each containing 7.5 cu. yd. of concrete, at new locations, were completed at a cost of $22.47 per cubic yard, or a total of $168.50 per pier, distributed as follows:

Superintendence: Timekeeping, storekeeping, material checking, general foreman		$ 21.02
Carpenter work	Protections	$ 4.00
	Sheathing	20.00
	Making forms	4.00
	Placing forms	7.00
	Stripping forms	3.40
	Repairing forms	6.00
Labor	Excavating	50.80
	Concreting	9.90
	Back-filling	10.16
	Cleaning up	5.00
Watching		12.10
Hauling materials		15.12
		$168.50

Cost of Reinforcing a Steel Bridge with Concrete.—The following is given in Engineering and Contracting, Feb. 22, 1911.

The use of concrete for stiffening the columns of steel trestles and for making old steel trestles permanent, has been successfully accomplished by the Wabash R. R. On one of the bridges, thus reinforced, the St. Charles Bridge over the Missouri River, the saving has been about $140,000 as compared with the cost of a new trestle. The saving per lineal foot is about $32.20 for this trestle which averages about 40 ft. in height.

Before the work was started, estimates were made of the probable cost of a new trestle to replace the present one and also of the probable cost of doing the work as it has now been carried out. Assuming the concrete to cost $6 per cu. yd. and the steel, 4 cts. per lb. in place, it was found that the cheapest new structure that could be built was one consisting of 45-ft. deck girder spans on concrete piers, and the cost of such a structure would be $50 per lin. ft. With the same unit prices, the cost of a new trestle composed entirely of steel with towers 30 ft. in length and intermediate spans of 60 ft., was found to be $53 per lin. ft., and if the intermediate spans were made 30 ft. instead of 60 ft., the cost would be $56 per lin. ft., but if the intermediate spans were made 15 ft. instead of 60 ft., the cost would be $51 per lin. ft.

By way of comparison with the above estimate, the steel columns of the St. Charles bridge approaches have been reinforced with concrete at a cost of $7.30 per lin. ft. of trestle. It is estimated that the cost of steel stringers to replace the old wooden ones will be $10.50 per lin. ft. in place, making the total cost of strengthening the trestle $17.80 per lin. ft. The saving, therefore, over a structure costing $50 per lin. ft. is $32.20 per lin. ft., and as this trestle is 4,342 ft. long, the total saving amounts to about $140,000.

It must be noted that there will be an additional saving, as the amount of salvage that would accrue from the sale of materials in the old trestle would be much less than the cost of removing the trestle. Another fact worth noting is that this kind of work can be done gradually at a cost which would be but little more than the present maintenance expenses. The trestle as now reinforced, as estimated from previous column tests, and inspection of the completed work, will carry any engine that it is possible to build.

Construction Work.—The contractor for the work on both bridges was furnished with materials f.o.b. cars at the site, with "dead-head" freight on all lumber, tools and equipment, and free transportation of laborers, all of which materially reduced the cost of construction to the contractor.

In the two approaches to the St. Charles Bridge there are 300 columns, 40 to 50 ft. high, tied in groups of four, with transverse and longitudinal struts, to form towers. These columns, with the exception of the built-up shapes at the strut crossings, are of the Phoenix section. An 18-in. octagonal section for the Phoenix columns was adopted and a 24-in. square section was used for the sections at the street crossings.

With the exception of the bases, which were poured by hand, each tower was poured monolithically, using a 1:3 mortar reinforced with No. 6 spiral hooping for the Phoenix columns and with 1 in. square bars for those at the street crossings. Despite the excessive length of the columns, the troublesome connecting struts with their knee braces, and the frequent vibrations due to the regular traffic, a remarkably smooth job was obtained, with faces true to line and free from honeycomb or cracks. In placing the reinforcement and the forms, hanging scaffolds were used; the steel gang on one scaffold being closely followed by the carpenter force on another. The scaffolds were used again in the wrecking.

The ⅞-in. forms were cut, in sections of approximately 14 ft. so that they could be used six times, thus reducing the carpenter cost, necessarily high, because of the cutting and framing around the struts and lateral braces. The spiral reinforcement although very effective, was comparatively expensive because of the "cork screw" fashion in which it had to be applied. The experiment of using wire mesh with equivalent cross sectional area of steel, was made and proved less expensive, in labor. This test was made near the close of the job after all the spirals were on hand, and was intended only for the general information of the contractors.

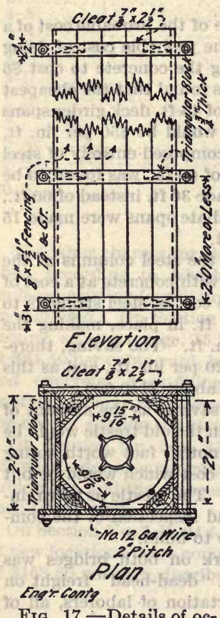

FIG. 17.—Details of octagonal forms for encasing steel columns.

The concrete was made with a mixer mounted on a work train and the materials were carried in bins upon the car with the mixer. The concrete was poured into the forms through spouts leading from the mixer to the column caps. The work train was frequently interrupted and sidetracked for passing traffic, but this lost time was used, as far as possible, in refilling the material bins.

The cost of the work to the contractor, allowing 90 cts. per bbl. of cement and 50 cts. per cu. yd. for sand, was $12.45 per cu. yd. of concrete or an average of $165 per tower. This cost includes the following items: Material for concrete; material for forms; labor building, placing, repairing and removing forms; labor placing reinforcement; labor mixing and placing mortar; labor unloading and rigging; equipment; administration and miscellaneous labor. The contract was let on a percentage basis with a guaranteed maximum which closely approximated the actual cost. The structure was completed in 5 months.

Cost of Constructing Three Single-Track Concrete Arch Bridges, Lake Champlain & Moriah Railroad.—The following costs, given in Engineering and Contracting, June 15, 1910, by Eugene Klapp, are for constructing three reinforced concrete arch railway bridges in the northern part of New York by company forces. The prices of labor and materials were as follows:

Common labor, per day	$1.30
Carpenter foreman, per day	3.00
Boss carpenter, per day	2.25
Common carpenters, per day	1.75
Stationary engineer, per day	2.00
Foreman reinforcement, per day	2.00

A 10-hour day was worked for five days and a nine-hour day on Saturday. Tailings were used for concrete aggregate and cost only the freight and labor for loading, both of which are included in the labor costs given.

Lumber for forms cost $18 per M. ft. B. M. unplaned; the planing was done on the job and is included in the labor costs for forms. Cement cost $1.20 per bbl. after deducting credit for return of bags.

Bridge 1.—This bridge consists of an arch 18-ft. wide, 20 ft. long and 24 ft. high. It was founded on earth and required a spread footing 12 ft. wide.

The bridge contained 560.7 cu. yds. of concrete and was estimated to cost $7,000. The actual itemized cost was as follows:

Item	Total	Per cu. yd. concrete
Temporary constructions—		
Materials	$ 10.51	$ 0.019
Labor	255.42	0.455
Miscellaneous	525.27	0.936
Total	$ 791.20	$ 1.410
Excavation—		
Materials	$ 4.12	$ 0.001
Labor	374.94	0.668
Total	$ 379.06	$ 0.669
Forms—		
Materials	$ 923.95	$ 1.647
Labor	1,228.92	2.191
Total	$2,152.47	$ 3.838
Mixing Concrete—		
Materials	$ 55.19	$ 0.098
Labor	251.73	0.449
Total	$ 306.92	$ 0.547
Placing Concrete—		
Materials	$ 135.20	$ 0.241
Labor	$ 242.51	0.432
Total	$ 377.71	$ 0.673
Reinforcing—		
Materials	$ 397.37	$ 0.708
Labor	198.34	0.354
Total	$ 595.71	$ 1.062
Cement	$ 780.75	$ 1.392
Superintendence	312.50	0.557
A round total	$5,696.72	$10.146

The concrete work proper, therefore, cost as follows per cubic yard:

Forms	$3.838
Mixing	0.547
Placing	0.673
Reinforcement	1.062
Cement	1.392
Total	$7.512
Superintendence prorated say	$0.445
Grand total	$7.957

In comment on these figures it may be noted that the item "materials" for forms includes the lumber used in trestles. Referring to "miscellaneous" charges under "preliminary construction," $262.23 of the total were paid for specifications and plans, or 4.6 per cent of the total cost. Superintendence cost 5½ per cent of the total.

Bridge 2.—This bridge, a much simpler structure than Bridge 1, being founded on rock and having plain abutment and wing walls, is a simple arch 34 ft. wide, with footings 9 ft. wide. A feature of the design is the expansion joint placed across the barrel of the arch about mid length. The bridge contained 1,804 cu. yds. of concrete and its estimated cost was $10,500. The actual itemized cost was as follows:

Item	Total	Per cu. yd. concrete
Temporary construction—		
Materials	$ 60.07	$0.033
Labor	915.73	0.508
Miscellaneous	796.10	0.441
Total	$1,771.90	$0.982
Excavation—		
Materials	$ 27.20	$0.015
Labor	411.84	0.228
Total	$ 439.04	$0.243
Forms—		
Materials	$ 965.91	$0.535
Labor	1,568.76	0.869
Total	$2,534.67	$1.404
Mixing concrete—		
Materials	$ 514.10	$0.285
Labor	572.12	0.316
Total	$1,086.22	$0.601
Placing Concrete—		
Materials	$ 31.25	0.017
Labor	834.09	0.462
Total	$ 865.34	$0.479
Reinforcing—		
Materials	$ 210.12	$0.116
Labor	56.70	0.031
Total	$ 266.82	$0.147
Cement—		
Materials	$1,675.40	$0.928
Labor	19.91	0.011
Total	$1,695.31	$0.939
Superintendence	$ 538.49	$0.299
Grand total	$9,197.79	$4.094

The concrete work proper, therefore, cost as follows per cubic yard:

Forms	$1.404
Mixing	0.601
Placing	0.479
Reinforcing	0.147
Cement	0.939
Total	3.570
Superintendence prorated say	0.225
Grand total	$3.795

In the above items "materials" for forms include trestle lumber and "miscellaneous" charges include $262.23 for plans and specifications. The charge for plans and specifications was 2.85 per cent and the cost of superintendence was 5.85 per cent of the toal cost. The influence of complexity of forms on form costs and cost of placing concrete is indicated by comparing these costs for Bridges 1 and 2.

Bridge 3.—This bridge, founded on rock just below the surface is a simple arch 34 ft. wide and 104 ft. long and has plain abutments and wing walls. A notable feature of the design is the extension upward of the abutment walls to form a cross wall between spandrel walls and the bracing together of the spandrel walls by two intermediate diaphragm walls. There is an expansion joint across the spandrel walls over the center pier. This bridge contained 1320.7 cu. yds. of concrete and was estimated to cost $7,500. The actual itemized cost was as follows:

Item	Total	Per cu. yd. concrete
Temporary construction—		
Materials	$ 34.71	$0.026
Labor	186.38	0.141
Miscellaneous	538.66	0.408
Total	$ 759.75	$0.575
Excavation—		
Materials	$ 3.77	$0.003
Labor	797.57	0.603
Total	$ 800.84	$0.606
Forms—		
Materials	$ 912.51	$0.691
Labor	1,036.49	$0.785
Total	$1,949.00	$1.476
Mixing concrete—		
Materials	$ 487.50	$0.369
Labor	678.04	0.513
Total	$1,165.54	$0.882
Placing concrete—		
Materials	$ 1.05	$0.001
Labor	510.19	0.386
Total	$ 511.24	$0.387
Reinforcing—		
Materials	$ 396.83	$0.300
Labor	45.88	0.035
Total	$ 442.71	$0.335
Cement	$1,221.20	$0.924
Superintendence	$ 176.78	$0.134
Grand total	$7,027.06	$5.319

The concrete work proper, therefore, cost as follows per cubic yard:

Forms	$1.476
Mixing	0.882
Placing	0.387
Reinforcing	0.335
Cement	0.924
Total	$4.004
Superintendence prorated say	0.100
Grand total	$4.104

As with bridges 1 and 2, materials for forms include lumber used for trestles. The cost for plans and specifications was $262.23, and is included under "miscellaneous" preliminary construction charges. Plans and specifications cost 3.7 per cent and superintendence cost 2.5 per cent of the total cost.

Cost of Concreting Bridges of C., M. & St. P. Ry.—The Chicago, Milwaukee & St. Paul Ry., in 1915, completed two single track reinforced concrete viaducts near Rosalia, Wash., thereby replacing a 60-ft. high, 2,100-ft. long frame trestle. The two bridges are separated by 334 ft. of embankment. The easterly structure is composed of a 107½-ft. reinforced concrete trestle abutment, a 100-ft. spandrel arch span and a 79½-ft. reinforced concrete trestle abutment. The westerly structure consists of a 77-ft. reinforced concrete abutment, three 77½-ft. and one 68⅛-ft. spandrel arches, one 58½-ft. encased steel girder and a combination trestle and U-abutment. The following description of the concreting plant used on this work is published in

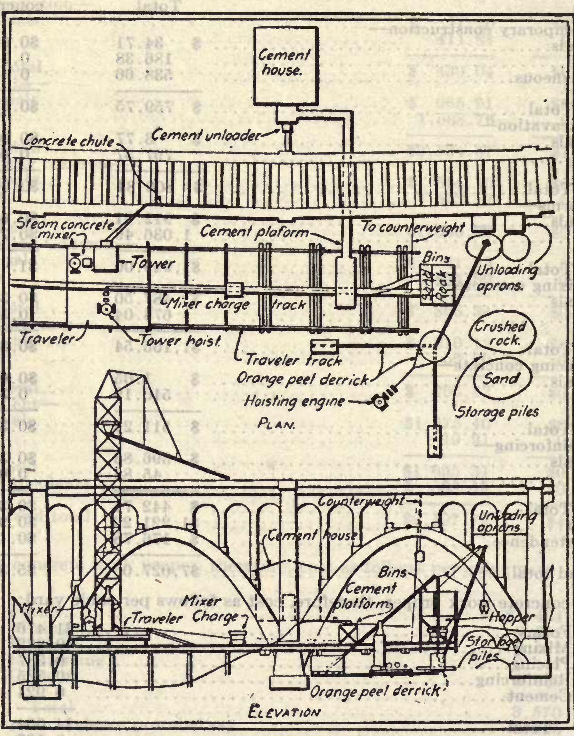

FIG. 18.—Layout of Rosalia, Wash., concreting plant.

Engineering and Contracting, Nov. 22, 1916 and is taken from the report "Efficient Methods of Handling Work and Men," submitted on Oct. 17, 1916, at the annual meeting of the American Railway Bridge and Building Association:

It was impracticable to place the plant on the track grade, and, accordingly, it was located under the westerly bridge, the layout being as shown in Fig. 18. The crushed rock and sand were delivered in hopper bottom cars and unloaded through chutes to the ground below, and then placed in storage piles by a stiff-leg derrick fitted with 60-ft. boom and orange peel bucket. This derrick was so located as to handle the materials to the storage piles and from there to hoppers for loading in small cars for transportation to the mixer. The derrick was operated by a double drum engine fitted with a Dake swinging gear connected to a bullwheel on the base of the mast.

The mixer and tower were placed on a traveling platform that could be moved along the north side of the bridge. Most of the concrete was spouted in this way directly into the forms. The concrete was elevated and the cars containing the dry material were hauled by a hoisting engine on the traveling platform. The empty cars were pulled back to the loading hoppers by a counterweight fastened to the bridge. The cement was unloaded into a storage house immediately underneath the south of the bridge by means of an endless belt with a friction brake which enabled the lowering of the cement at slow speed to prevent damage to sacks by tearing or burning. The cement was then wheeled directly to the cars as they left the loading hoppers.

The same plant was used to mix the concrete for the easterly bridge. In this case, however, the concrete was hoisted into small cars on a narrow-gage track on the north side of the main line and hauled by a gasoline locomotive. Concrete was mixed and placed in the easterly bridge for as low as 34 cts. per cu. yd. in this way, although the average was considerably above this on account of the inability to make continuous runs while concreting.

The steel reinforcement was all cut and bent on the platform at the west end of the westerly bridge and lowered into place from the track level. Portable forms were also built at the same point and handled in the same way. Water was obtained from city mains and in this way the necessity of installing a pump was avoided.

The organization of the forces was as follows:

	Per mo.
One general foreman	$150.00
One timekeeper	75.00
	Per 10 hours
One carpenter foreman	$ 3.50
One blacksmith	3.25
One labor-foreman	3.00
Two sub-foremen	3.25
Twenty-six carpenters	3.00
Two engineers	3.00
One engineer (gasoline)	2.50
One fireman	2.50
Ten carpenter helpers	2.25
Twenty-four laborers	2.00

The size of the crew varied considerably on account of the difficulty in obtaining men and on account of some delay in obtaining material at various times. During the progress of the work the average traffic was eight passenger and about twelve freight trains per 24 hours. There was an average of four passenger and four freight trains on the Northern Pacific track under the easterly bridge; eight passenger and four freight trains on the Spokane & Inland Empire tracks under the westerly bridge and heavy team and automobile travel on the state highway, so that it was necessary to provide special falsework in each case to avoid blocking traffic.

The total amount of concrete placed was 5,924 cu. yd., the average cost per cubic yard for labor and material being $7.56. The total amount of reinforcing placed was 960,000 lb. at $1.80 per 100 lb.

CHAPTER XVIII

STEAM RAILWAYS

This chapter deals mainly with the construction and maintenance costs of steam railways. Costs of bridges and tunnels are given in Chapters XVII and XX respectively.

Further data on steam railway construction, maintenance and operation are given in Gillette's "Handbook of Cost Data."

The "Handbook of Mechanical and Electrical Cost Data" by Gillette and Dana gives costs of electric railway construction and other operating cost data of use to either or both steam and electric railways.

Approximate Costs of Rapid-Transit Lines.—The following relative costs of producing rapid-transit structures, contained in a paper entitled "Provisions for Future Rapid Transit," presented by John Vipond Davies, consulting engineer, of New York City, before the National Conference on City Planning at Toronto, May 25 to 27, are given in Engineering Record, June 6, 1914.

The figures are given as average costs for construction of structures and the installation of structural equipment, but without power or rolling stock. They do not include the value of property for rights of way or easement and are given on the basis of constructing a double track railroad in each case, although reduced to the cost per mile of single track:

Types of Structure
For Double Railway Tracks

	Cost per mile of single track
Trolley railroad in suburban district, either on public roads or private right of way where no paving is required, complete with overhead trolley construction, track bonded; all in operating condition	$ 25,000
Trolley railroad on city streets, including asphalt or granite block pavement for width of tracks and 2 feet outside of tracks; complete with overhead trolley construction, track bonded; all in operating condition	$ 42,000
Underground trolley railroad in congested streets of a city, including necessary pavements, conduits, etc., and with reasonable allowance for changes of subsurface improvements:	
New York	$ 126,000
Washington	49,500
Elevated railroad of a type and for the loading permissible to meet requirements of Public Service Commission of New York; complete with stations, contact rail, ties and track; averages	$ 125,000
Railroad in open cut similar to Sea Beach Railroad of Brooklyn Rapid Transit Company in Brooklyn, where work is executed with steam shovel and with concrete walls; averaging cost of bridges and stations as part of the cost; complete with contact rail, ties and track; averages	$ 225,000
Railroad on masonry viaduct filled in with stone ballast, similar to structure erected on Queens Boulevard from Queensboro Bridge to Greenpoint, on Long Island, New York; complete with stations, contact rail, ties and track; averages	$ 330,000

Subway such as the Fourth Avenue Subway in Brooklyn, where work is unaffected by subsurface improvements, where the digging is easy and can be done with steam shovel and under typical, ideal conditions; complete with structural and track equipment; averages	$ 402,000
Subway such as the Broadway Subway constructed in New York City, where the work is very difficult and involves extreme interference with subsurface improvements of all kinds, the support of street surface, trolley car tracks, underground trolley construction, etc.; complete with structural and track equipment; averages	$1,190,000
Iron lined tube tunnels under waterways or below water level; complete with structural equipment and track; averages	$2,700,000

In connection with these costs, the difference in the first cost of constructing improvements in a city like Washington, where the soil is advantageous to excavate, where the streets are broad and where there is no difficulty in changing subsurface improvements, is in marked contrast to the cost of executing similar work in a city like New York, where the material to be excavated is most difficult, where the streets are congested and where there are numerous and extensive subsurface improvements to be cared for.

Cost of Elevated Railways and Subways.—The following notes are taken from an article by Maurice E. Griest published in Engineering News, May 20, 1915.

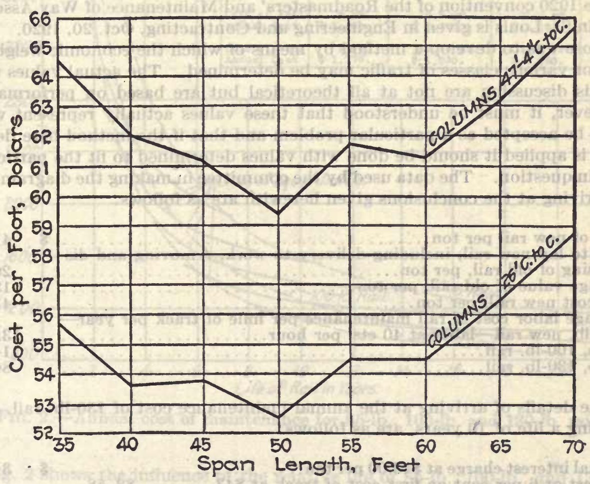

FIG. 1.—Effect of span-length on cost of three-track elevated railway.

Relative Cost of Subway and Elevated Lines with ballasted floor and with open floor are as follows:

COST OF SUBWAY AND ELEVATED STRUCTURE

		Per lin. ft. of structure
Three-track subway		$300 to $500
Three-track elevated	Solid floor	$200
	Open floor	$125

Economic Span Length for Elevated Railway.—Fig. 1 is based on the design of the 3-track elevated structure as used by the N. Y. Rapid Transit System. The costs exclude track, stations and ducts and are based on average prices of recent (1914–15) contracts as follows:

Steel	$54.00 per ton*
Cast iron	48.00 per ton
Concrete	7.00 per cu. yd.
Excavation	2.00 per cu. yd.
Paving	3.00 per sq. yd.

* The cost of steel makes up about 80 per cent of the cost of an elevated structure exclusive of track, signals and station finish.

Plate Girders vs. Latticed Stringers.—Latticed stringers are from 10 to 15% lighter than plate-girder stringers of the same span. The cost of fabrication of the latter, however, particularly without cover-plates, is about 10% less than of a latticed girder without connection plates and 15% less than of a latticed girder with connection plates. The first cost, therefore, is practically the same in either case. Depreciation and maintenance costs of plate-girder construction are less than for latticed girders; details are simpler and the structure is more rigid. Plate-girder stringers were therefore adopted.

Economic Weights of Rail.—The following abstract of a committee report at the 1920 convention of the Roadmasters' and Maintenance of Way Association in St. Louis is given in Engineering and Contracting, Oct. 20, 1920. The purpose was to develop a method by means of which the economic weight of rail for various classes of traffic may be determined. The actual values used in this discussion are not at all theoretical but are based on performance. However, it must be understood that these values actually represent what must be accepted as a particular problem and that if the method here developed is applied it should be done with values determined to fit the particular case in question. The data used by the committee in making the diagram and in arriving at the conclusions given herewith are as follows:

Cost of new rail per ton	$ 41.00
Cost to lay new rail, including delivery to work, removing and disposing of old rail, per ton	20.00
Salvage value of old rail, per ton	18.00
Net cost new rail, per ton	43.00
Average labor cost of rail maintenance per mile of track per year—85-lb. new rail—labor at 40 cts. per hour	135.00
Ditto, 100-lb. rail	114.00
Ditto, 130-lb. rail	86.00

The details of arriving at the annual maintenance cost of 130-lb. rail, considering a life of 10 years, are as follows:

Annual interest charge at $43.00 per ton		$ 3.077
Interest at 6 per cent on first cost of track at $43	$2.58	
Taxes at 1 per cent on first cost of track at $43	0.43	3.010
Interest at 6 per cent and taxes at 1 per cent on $18 salvage per ton when removed		1.260
First cost (10-year life) per ton		$ 7.347
Tons of rail per mile of track (130-lb. rail)		204.29
Annual charge per mile of track based on 10-year life		1,501.00
Annual cost (labor 40 cts. per hour) of maintaining 130-lb. rail in 1 mile of track		86.00
Annual cost of maintenance, including interest, taxes, depreciation and labor		1,587.00

The committee concludes that under similar conditions of traffic, the life of 100-lb. rail is 1¾ times that of 85-lb. rail, and that the life of 130-lb. rail is double that of 100-lb. rail. The relative life of over 100,000 tons of 130-lb. rail compared to the life of 100-lb. rail in the same tracks was actually determined, based on four years' experience with the heavy rail, during which time over 4,300 tons of the heavy rail were actually removed from tracks on account of being worn out.

To allow for the comparatively short period of time for which the data concerning heavy sections were taken, the relationship between the average life of heavy section rail and 100-lb. rail was taken to be 2 to 1. The data concerning the relative life of 100-lb. and 85-lb. rail were of a more extended and broader nature, but had not been kept in as detailed a manner.

	85-lb. Rail	100-lb. Rail	130-lb. Rail
Life of Rail	2 yr.	3.50 yr.	7.00 yr.
Annual Cost	$ 3,327.	$ 2,490.	$ 1,945.
Life of Rail	3 yr.	5.25 yr.	10.5 yr.
Annual Cost	$ 2,407.	$ 1,860.	$ 1,360.
Life of Rail	4 yr.	7.0 yr.	14.0 yr.
Annual Cost	$ 1,942.	$ 1,540.	$ 1,353.
Life of Rail	6 yr.	10.5 yr.	21.0 yr.
Annual Cost	$ 1,481.	$ 1,240.	$ 1,165.
Life of Rail	9 yr.	15.75 yr.	31.5 yr.
Annual Cost	$ 1,176.	$ 1,030.	$ 1,050.

Fig. 2.—Annual cost of maintenance for 85-lb., 100-lb. and 130-lb. rail.

Fig. 2 shows the influence of the relative life of 85-lb., 100-lb , and 130-lb. rail under similar conditions of traffic; that is, lines representing the life of various sections of rails under similar conditions of traffic, from which can be determined the difference in the annual cost of maintenance due to different rail sections. For example, suppose 85-lb. rail gave a life of two years—the average maintenance cost is $3,327—then 100-lb. rail should give a life of 3½ years, with an average maintenance cost of $2,490, while 130-lb. rail should give a life of 7 years with an average maintenance cost of but $1,945—clearly a case where heavy section rail could be used economically from a maintenance point of view.

As a measure for the wear of rail under various conditions of traffic, the committee decided on the number of cars per day passing over a stretch of track as the measure of traffic conditions. Such a unit closely reflects the locomotive tons and gross tons; the average weight of cars, the average cars per train and average locomotive miles per train mile ordinarily varying

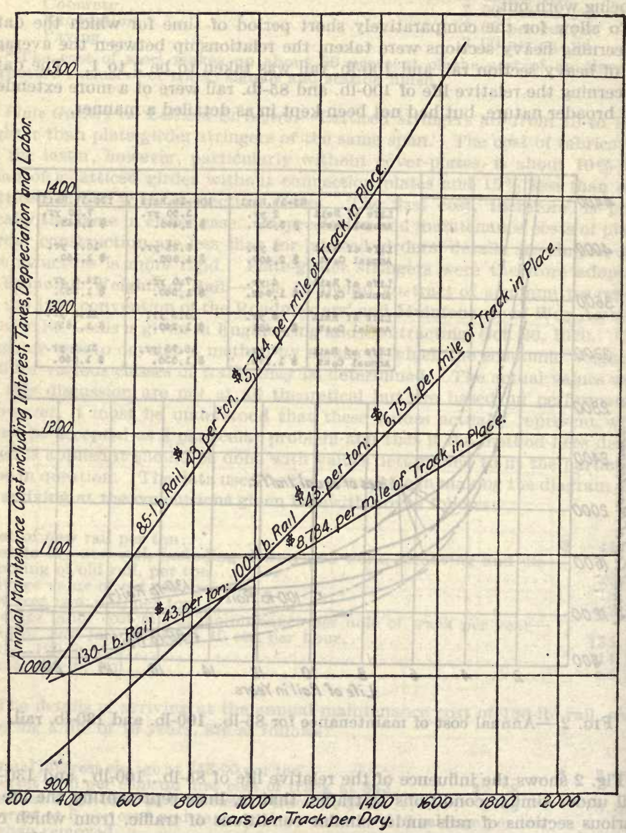

FIG. 3.—Effect of density of traffic on annual maintenance cost.

between narrow limits from month to month. Also the average number of cars passing a particular point over a stretch of track during any period can readily be determined at any time without elaborate machinery or organization.

To determine the proper life to assign to 100-lb. rail under various traffic conditions, 14 stretches of track were selected for which information concerning the car movement and rail renewals was available. From this information was determined the average life of 100-lb. rail in each stretch of track. This data varied from 417 cars per track per day to 1,697 cars per track per day.

The curves in Fig. 3 show that the 100-lb. rail is economical for a traffic of not over 900 cars per track per day and that for a greater car movement the 130-lb. rail is economical. As between the 100-lb. rail and 85-lb. rail, the data would indicate that, on railroads using heavy power and having a wide range of physical characteristics, the 85-lb. rail is no longer economical, but that modern railroading demands a 100-lb. rail. When traffic reaches 1,800 cars per day over a double track railroad, the point is reached to consider increasing the weight of section to about 130 lb.

Equation of Track Values for Equalizing Lengths of Sections for Maintenance Work.—Engineering and Contracting, Oct. 20, 1920, gives the following:

For some years past railway officials have been giving thought to the matter of finding a way to measure, accurately, the different units of work so as to be able to equalize the sections, instead of making the track sections of standard length, as has been so generally the custom.

A committee report to the Roadmasters' and Maintenance of Way Association at St. Louis, Sept., 1920 gives the results of two questionnaires sent out Jan., 1920. The answers represent the opinion of practical track men, engineers and others and as averages are believed to be as near a proper conclusion as it is practicable to arrive at. The committee states that in the main it compares favorably with the findings of several of the large railroad systems which recently made an exhaustive study for their own information.

The questionnaires follow.

Questionnaire No. 1

Subjects	Replies	Average
How many miles average passing siding equal to one mile of main line?	57	2.75
How many average miles of storage, industrial, or commercial siding equal to one mile main line?	57	3.84
How many average main line turnouts equal to one mile main line?	56	15.3
How many average siding, yard or other inside turnouts equal one mile of main line?	56	16.77
How many average main line railroad crossings equal one mile of main line?	56	10.95
How many average siding railroad crossings equal one mile of main line?	55	19.18
How many heavy traffic, important city street crossings equal one mile of main line?	56	9.20
How many (medium) important city street crossings equal one mile of main line?	57	14.00
How many light traffic street crossings or outlying highway crossings equal one mile main line?	57	20.90
How many average farm crossings or other unimportant crossings equal one mile of main line?	57	46.58
How many average stock chutes and pens equal one mile of main line?	45	17.00
How many average re-icing stations equal one mile of main line?	37	4.15
How many average watering stations equal one mile of main line?	46	5.50

How many average interlocking plants equal one mile of main line?	51	3.40
How many average cattle guards equal one mile of main line?	48	48.00
How many average feet of track in tunnels equal one mile of main line outside?	38	2,848
How many average coaling stations equal one mile of main line?	47	3.82
How many average fire or cinder cleaning stations equal one mile of main line,	47	2.47
How many average station grounds equal to one mile of main line?	52	5.68
How many average automatic signals and incidental fixtures equal one mile of main line?	27	20.74
How many miles of average fencing equal one mile of main line?	48	15.07
How many feet of ordinary average ditching will equal one mile of main line?	42	10,160

QUESTIONNAIRE No. 2

Subject	Replies	Average
Assuming a double track railroad having an average normal gross tonnage of 100,000 per day or 40 freight trains, 20 in each direction, with an average normal number of 12 passenger trains, using a maximum speed of 60 miles per hour; grade generally level, 3 per cent maximum; line 3 per cent curvature 6 degree maximum. What length of section should be established at outlying points if no such conditions prevail as are listed in above questions?	54	3.68
What length of section should be established on a single track railroad, having same curvature and gradient, with one-half the gross tonnage and one-half the number of passenger trains listed above?	52	6.0
How much should such sections be lengthened or shortened for each 25,000 gross tons and two passenger trains daily that might be added or taken off on such double track sections?	35	.914
How much for a single track section for each 12,000 gross tons or one passenger train?	30	.867
What difference should be made in the mileage of a double track section having motor cars as compared with hand cars?	28	1.17
What on single track sections?	35	1.20

Cost of Railway Track Reconstruction.—In Engineering and Contracting, Sept. 7, 1910, D. A. Wallace publishes the following records which give the cost per 100 ft. and per mile for reconstructing track on two jobs, one in 1906 and the other in 1908.

1. The work consisted in putting up dirt track on crushed stones, replacing 58-lb. rail with 85-lb. rail and renewing 15 ties per 100 ft. The itemized cost was as follows, using negro labor at $1.25 per day and foreman at $60 per month:

Materials:	Per 100 ft.	Per mile
2,784 cu. yds. stone at 45 cts	$ 23.71	$1,252.80
Ties at 35 cts. f. o. b	5.25	277.20
133,577 tons rails at $30	75.32	3,977.13
Angle bars at 64 cts	3.87	204.80
Bolts at $4.90	1.21	63.70
Spikes at $3.20	2.06	108.80
Total materials	$111.42	$5,884.43

Labor:	Per 100 ft.	Per mile
Unloading stone	$ 3.11	$ 164.25
Raising grade 7 ins	5.53	292.00
Unloading ties at 0.9 cts	0.14	7.13
Applying ties at 10.4 cts	1.56	82.37
Unloading rails	0.18	9.60
Unloading fastenings	0.01	0.53
Laying rails	3.46	184.00
Stone surfacing, 3 ins., 2 ins., raise	7.50	396.00
Unbolting old rails	0.18	9.75
Loading old rails	0.44	23.25
Stripping track	1.25	66.00
Total labor	$ 23.36	$1,234.88
Grand total	$134.78	7,119.31
Credit 9.15 tons old rails at $16	$ 27.33	$1,464.32
Net cost	$107.45	$5,654.99

2. The work comprised 5 miles of track, 21 years old, 50 per cent of which consisted of 6° curves. The track had about 4 ins. napped stone under the ties and spaces between the ties filled in with enough coarse rock to prevent bunching of the ties. The rail was 30-ft., 56-lb. and had been in service 21 years. Approximately 7 ties per rail were broken off or decayed. The rails were replaced with 33-ft., 70-lb. rails, joint ties spaced, and 8 months later the track was raised, 6 ins. in gravel unloaded from hopper bottom coal cars at a cost of 15 cts. per cu. yd. on cars at pit and 15 cts. per cu. yd. for a haul of 80 miles, making a total cost of 30 cts. per cu. yd. on the ground. About 25 ties per 100 ft. were renewed. Negro labor at $1.25 per day and foreman at $75 per month were employed. The cost of the work was as follows:

Materials:	Per 100 ft.	Per mile
110 tons 70-lb. rail	$66.66	$3,520.00
Angle bars at 70 cts. per pair	4.85	256.00
4¼-in. bolts at $5	0.05	30.00
Spikes at $4	1.13	60.00
1,000 cu. yds. ballast at 30 cts	5.68	300.00
1,320 ties at 31 cts	7.75	409.20
Total materials	$86.12	$4,575.20
Labor:	**Per 100 ft.**	**Per mile**
Unloading rail	$ 0.40	$ 26.05
Unloading fastenings	......	0.25
Curving rail	0.55	28.66
Distributing by push car	0.27	14.59
Laying rail	2.83	149.80
Surfacing first raise 4 ins	1.94	102.50
Smoothing second raise	1.37	72.50
Dressing ballast	2.27	119.85
Unloading ties at 1.6 cts	0.40	21.12
Applying ties at 10.7 cts	2.67	141.24
Loading and unloading old rails	0.75	39.77
Total labor	$13.45	$ 716.33
Grand total	$99.57	$5,291.53
Credit 88 tons old rail at $24	$ 4.00	$2,112.00
Net cost	$95.57	$3,179.53

Prices Used in the Valuation of Railways in Nebraska.—E. C. Hurd, Engineer of Valuation, Nebraska State Railway Commission gives the following data in Engineering and Contracting, July 31, 1912.

Table 1 shows the unit prices which were very largely used for reproduction. The unit prices for all material arriving from the east includes commercial freight charges to the Missouri River gateways. The western products, namely that of lumber, were delivered to any point of the state on a flat commercial rate, while rail material from Colorado is estimated delivery at Denver commercial rates.

The Nebraska timber and soil conditions to be met in railroad construction admit of a nearly uniform treatment for the 150 miles in the east part of the state, while some variance is found in the westerly portion. Within the easterly portion certain allowance was made necessary for clearing and grubbing, whereas in the westerly section no allowance was made. The soil conditions are similar throughout, when cost of excavation is considered, and only in the westerly portion is there any rock of consequence.

TABLE I.—ROADWAY ITEMS—UNIT PRICES FOR 1909
Only Including Freight to Gateways

Grading:	
Earthwork, ordinary, per cu. yd	24 and 26 cts.
Overhaul 600 feet, per cu. yd	1½ cts.
Earthwork, terminal, yards, etc., no overhaul	30 to 47½ cts.
Loose rock	65 cts.
Solid rock	$1.00
Rip rap, rough or dumped stone in place	$ 1.80 to $ 2.20
Rip rap, laid up (dry)	4.30
Retaining walls, coursed rubble, per cu. yd	6.00 to 11.00
Retaining walls, concrete, per cu. yd	7.75 to 9.00
Retaining walls, brick, per cu. yd	8.00
Dykes, pile, brush or stone, per lin. ft	10.00 to 13.00
Dykes, earth, per cu. yd	.40
Clearing, per acre	20.00
Grubbing, per acre	50.00
Drain for wet cuts, per lin. ft	.43
Indemnity insurance on rock and extra hazardous	6 % of labor
Tunnels:	
Average basic cost per lin. ft. unlined	$125.00
Rock excavation, per cu. yd	4.50
Earth (Brule clay), per cu. yd	3.50
Shaft excavation, per cu. yd. (additional)	3.00
Timber lining, per M. B. M. in place	45.00
Indemnity insurance	9 % of labor

NOTE.—But one tunnel owned by the Burlington Railroad and located at Belmont lies within the state, excavated almost entirely through Brule clay, length being 694 feet.

Bridging:	
Piling, ordinary foundation and trestle, per lin. ft. in place	$ .45
Piling, 34 feet and longer, per lin. ft. in place	.65 and .70
Piling, sheet, 3-in. plank, per lin. ft	.08
Timber, Douglas fir, per M. B. M. in place	38.50
Timber in Howe truss, per M. B. M. in place	$43.50–48.00
Timber in piers, per M. B. M. in place	41.00
Timber, creosoted, per M. B. M. in place	45.00
Masonry:	
Stone, Ashlar, per cu. yd. in place	$ 12.00
Stone, coursed rubble, per cu. yd. in place	10.00
Stone, broken, per cu. yd. in place	8.00
Stone, dry, per cu. yd. in place	6.00
Stone, Missouri River bridge, per cu. yd. in place	25.00
Stone, arch culverts, per cu. yd. in place	12.00
Concrete, includes forms, foundations and substructures	9.00
Concrete, reinforced, foundation and substructures	11.00
Concrete, Missouri River bridge, foundation and substructures	27.00
Concrete, culvert end walls, per cu. yd	7.50

TABLE 1.—*Continued*

Masonry:	
Concrete, arch culverts, per cu. yd	12.00
Foundation excavation, per cu. yd	1.00
Steel girders, per net ton in place	75.00
I beams, per net ton in place	68.00
Truss towers or bents, per net ton in place	80.00
Railroad viaducts, per net ton in place	90.00
Missouri River bridges, per net ton in place	115.00
Wooden bridge hardware, per lb	.03
Reinforcing bars, per lb	.03
False work, ordinary, per lin. ft	10.00
Vitrified clay pipe, size 6 × 36-in., per lin. ft. in place	37 to 4.00
Wooden Howe truss, excluding foundation, 72-ft. spans in place, per ft.	25.00
Wooden Howe truss, excluding foundation, 116-ft. spans in place, per ft.	36.00
Wooden Howe truss, excluding foundation, 160-ft. spans in place, per ft., covered	52.00
Inside guard rails, two ends, complete	$35.00 to $ 40.00
Cast Iron Pipe Culverts, without end walls, cost per net ton—	
Sizes, in place	$ 36.00
18-in. diameter, per lin. ft. in place	3.00
24-in. diameter, per lin. ft. in place	4.75
36-in. diameter, per lin. ft. in place	8.75
48-in. diameter, per lin. ft. in place	13.50
Cast Iron Pipe Syphons, concrete ends—	
18-in. diam., per lin. ft. in place	$ 5.75 to $ 6.00
24-in. diam., per lin. ft. in place	7.00 to 7.50
36-in. diam., per lin. ft. in place	12.00 to 12.50
Concrete and Stone Arch Culverts (semicircular) complete, including excavation, foundation piling, wings, forms, etc.—	
4 ft. wide at spring line, per lin. ft. of barrel	$ 42.00
6 ft. wide at spring line, per lin. ft. of barrel	50.00
8 ft. wide at spring line, per lin. ft. of barrel	60.00
10 ft. wide at spring line, per lin. ft. of barrel	80.00
16 ft. wide at spring line, per lin. ft. of barrel	140.00
20 ft. wide at spring line, per lin. ft. of barrel	180.00
Timber Box Culverts (12 × 12-in. with 2-in. floor)—	
1 × 2½-ft., per lin. ft	$ 3.75
2 × 2-ft., per lin. ft	4.50
2 × 3-ft., per lin. ft	5.00
3 × 3-ft., per lin. ft	6.00
3 × 4-ft., per lin. ft	6.75
4 × 4-ft., per lin. ft	7.75
4 × 5-ft., per lin. ft	8.50
Ties:	
Missouri white oak, standard, each	.70
Missouri oak, mixed, each	62½ and .65
Northern white oak (6 × 8 × 8), each	.80
Northern white oak (7 × 9 × 8), each	1.00
Northern cedar, each	.74
Southern cedar, each	.70
Southern pine, each	.80
Southern pine, treated, each	90 and .95
Black Hills and Wyoming pine, each	.50
Black Hills and Wyoming pine, treated, each	.65
Douglas fir, sawed, 7 × 9 × 8, each	1.05
Douglas fir, sawed, 7 × 9 × 8, treated, each	1.20
Hemlock, each	.61
Hemlock, treated, each	.76
Switch ties, oak, per M. B. M	31.00
Switch ties, fir or pine, per M. B. M	28.00
Switch ties, fir or pine, treated, per M. B. M	30.00
Bridge ties, fir, per M. B. M	26.00
Bridge ties, oak, per M. B. M	32.00
Labor framing and placing bridge ties, per M. B. M	16.00

TABLE 1.—*Continued*

Rail:

At eastern gateways, per gross ton	30.75
At Denver, gateway, per gross ton	29.00
Relayers, f.o.b. Omaha, per gross ton	25.00
Scrap rail, per gross ton	10.00 to 14.00

Frogs and Switches:

Rigid frogs, material only, per cwt	2.75
Spring frogs, material only, per cwt	2.95
Switch points (15′), material only, per cwt	4.28
Crossing frogs, material only, per cwt	3.75
Derails, each	12.50

Average cost per complete turnout in place:

Weight of rail	60 lbs.	70 lbs.	75 lbs.	85 lbs.
No. 7 frog	$ 94	$103.00	$111.50	$117.00
No. 9 frog	100	107.00	113.00	120.50
No. 10 frog	101	109.00	116.00	122.00
No. 12 frog	....	109.50	117.00	125.00
No. 14 frog	....	114.50	122.00	130.50

Crossings placed at an average of $65.00 each.

Track fastenings and other material:

Angle bars and base plates, per cwt	$ 1.96
Continuous joints ($1.30 to $1.90 per pair), per cwt	2.125
Track bolts, per keg, 200 lbs	5.05
Tie plates, ordinary rigged or corrugated, per cwt	.125
Tie plates, heavy flat, per cwt	....
Average cost, first mention, 7½ cts.; second mention, 12 cts. each.	
Nut locks, ¾-in., per. 1,000	6.00
Nut locks, ⅞-in., per 1,000	6.25
Rail braces, rolled, each	10 to .12
Rail braces, cast, each	12 to .14
Spikes, standard, per keg, 200 lbs	3.75
Screw spikes, per cwt	2.93
Bumping posts, for freight yards, each	55.00
Bumping posts, for passenger yards, each	80.00

Ballast:

Gravel, Sherman Hill, Wyoming, f.o.b. pit, per cu. yd	$ 0.11
Gravel, Atkinson and Eureka, Neb., f.o.b. pit, per cu. yd	.15
Gravel, Chillicothe, Ill., f.o.b. pit, per cu. yd	.12
Gravel, Oral, S. D., f. o. b. pit, per cu. yd	.16
Gravel, Grand Junction, Ia., f. o. b. pit, per cu. yd	.15
Gravel, Cheyenne River and Guernsey, Wyo., f. o. b. pit, per cu. yd	.12
Crushed stone, Louisville and Meadow, Neb., also Blue Springs, Neb., f. o. b. quarry, per cu. yd	.65
Stone quarry screenings, f. o. b. pit, per cu. yd	.20¼
Slag, f. o. b. Omaha, per cu. yd	.20
Cinders, f. o. b. any division point, per cu. yd	.22
Sand, f. o. b. any pit, per cu. yd	.12
Burnt clay, f. o. b. pit, per cu. yd	.48

Average weight of ballast material per cu. yd.:

Gravel, Sherman Hill, lbs. per cu. yd	2,950
Gravel, all others, lbs. per cu. yd	3,200
Crushed stone, lbs. per cu. yd	2,400
Cinders, lbs. per cu. yd	1,680
Burnt clay, lbs. per cu. yd	1,700
Slag, lbs. per cu. yd	3,360
Sand, lbs. per cu. yd	3,300

Track laying and surfacing:

Laying track on main line, 70 to 90-lb. rail, including sidings, per mile	$375.00
Laying track on branch lines, 52 to 70-lb. rail, including sidings, per mile	310.00
Placing additional switches, main line, each	20.00
Placing additional switches, branch line, each	15.00

Above price in track laying contemplates average ½ switch per mile.
Indemnity insurance, 3⅓ per cent of labor.

TABLE 1.—*Continued*

Surfacing	Per track mile Main Line	Based on avg. 6-in. ballast under tie Branch Line
Earth	$335	$300
Cinders & gravel	380	345
Burnt clay	553	516
Crushed stone	620	590
Additional to above allowance on up-keep of track during construction, per mile		$90.00 to 120.00

Roadway tools:	
Average allowance per section gang per set	$120.00
Average allowance per extra gang per set	600.00
Average allowance per bridge gang per set	600.00
Average allowance per roadmaster's inspection car, etc., each	125.00
Average allowance per bridge supervisor car, etc., each	125.00
Average allowance per signal supervisor car, etc., each	125.00
Average allowance per signal maintainer car, etc., each	150.00
Fencing—Right of way:	
4 barbed wires, 32-ft. panels, wood or wire sag lath, per fence mile	128.00
4 barbed wires, 16-ft. panels, wood or wire sag, per fence mile	160.00
For each additional wire to above add	12.50
Cattle guards, single, wood strips, each	15.40
Cattle guards, single, iron strips, each	17.50
Farm gates, wire, each	2.50
Farm gates, wood, each	4.30
Farm gates, iron, each	7.00
Crossings and signs:	
Oak crossing planks in place, per M. B. M.	34.00
Walks, board, per sq. ft	10 to .25
Walks, cinder, per sq. ft	.06¼
Walks, cinder with curb, per sq. ft	.125
Walks, concrete, per sq. ft	12 to .14
Walks, brick, per sq. ft	.125
Wood curbing, per lin. ft	.16⅔
Crossing alarms (electric automatic), per crossing, each	$200.00 to 325.00
Crossing gates, per crossing, each	255.00
Gate towers, per crossing, each	250.00
Highway crossing signs (post and 2 crossboards), each	4.50 to 7.00
Bridge, railroad crossing or station 1 mile signs, each	2.40 to 3.75
Yard Limit, Slow, etc., each	3.50
Post signs, ordinary, each	1.50 to 1.90
Bridge warning, each	19.00
Bridge and culvert numbers, each	.50 to 1.75

Interlocking and other signals:

This item is too varied to undertake to express an average, but some of the costs herewith are typical:

Interlocking plant, single track, wood tower, 16 lever, mechanical	$4,800.00
Crossing gate, with signals and torpedo attachment	650.00
Electrical block signals, single track, per mile	1,150.00
Electrical block signals, double track, per mile	1,500.00
Electric-gas signals, single track, per mile	1,210.00
Interlocking outlying switches with home and distance signals, per switch, each	500.00
Train order signal, high mast, each	120.00
Train order signal, box and board on depot building, each	35.00 to 60.00

Telegraph and telephone lines:

Only a few of the simpler telegraph lines will here be mentioned.

6-in. 30-ft. poles, 30 per mile, with cross arms, 4 No. 10 wires	$194.00
6-in. 30-ft. poles, 30 per mile, with cross arms, 6 No. 10 wires	240.00
6-in. 30-ft. poles, 30 per mile, with cross arms, 8 No. 10 wires	292.00
Station sets, ordinary, each	25.00 to 35.00
Station sets, complete quads, each	135.00

TABLE 1.—*Continued*

Station buildings and fixtures:		
Depots, one story, frame, averages, per sq. ft.		$1.37½ to 1.90
In typical buildings, 16 × 40 ft.		$ 880 to 1,000
In typical buildings, 18 × 56 ft.		1,500 to 1,700
In typical buildings, 20 × 40 ft.		1,100 to 1,350
In typical buildings, 20 × 56 ft.		1,500 to 1,770
In typical buildings, 20 × 80 ft.		2,240 to 2,700
In typical buildings, 24 × 60 ft.		2,100 to 2,500
In typical buildings, 24 × 80 ft.		2,800 to 3,500
In typical buildings, 24 × 100 ft.		3,000 to 3,850
Depots, two story, frame, averages per sq. ft.		$2. 20 to 2. 63
In typical buildings, 20 × 40 ft.		1,600 to 1,900
In typical buildings, 22 × 56 ft.		2,500 to 3,300
In typical buildings, 22 × 80 ft.		3,800 to 4,800
In typical buildings, 24 × 56 ft.		2,800 to 3,200
In typical buildings, 24 × 70 ft.		3,100 to 3,800
In typical buildings, 24 × 90 ft.		4,400 to 5,400
Depot furniture and fixtures—		
Small stations		$100 to 140
Medium stations		250 to 350
Larger stations		400 to 600
Section dwelling houses—		
1 story, frame, per sq. ft.		$1.00 to 1.375
1½ story, frame, per sq. ft.		1.25 to 1.50
2 story, frame, per sq. ft.		1.75 to 2.25
Water closets, coal houses, etc., per sq. ft.		1.25
Section tool houses, per sq. ft.		.52 to .75
Freight houses, frame, averages per sq. ft.		1.25 to 1.50
In typical buildings, 22 × 64 ft.		$1,600
In typical buildings, 24 × 50 ft.		1,800
In typical buildings, 24 × 100 ft.		3,000
In typical buildings (brick), 40 × 80 ft.		$8,000 to 8,800
Shops, engine houses and turntables:		
Shop buildings for ordinary division points containing 3,000 to 8,000 sq. ft.		
Brick and frame, per sq. ft.		$2.10 to 3.50
Brick and steel, per sq. ft.		2.50 to 4.50
Shop buildings for terminals containing 30,000 to 60,000 sq. ft		
Brick and frame, per sq. ft.		$ 2.05
Brick and steel, per sq. ft.		2.50
Engine house, wood, 65 to 70 ft. long, 1 stall		2,200.00
Engine house, wood, 65 to 70 ft. long, 2 stalls		3,100.00
Engine house, wood, 65 to 70 ft. long, 3 stalls		4,250.00
Engine house, wood, 65 to 70 ft. long, 6 stalls		7,800.00
Engine house, wood, brick lined—		
	65 to 70 ft.	80 to 90 ft.
1 stall	$ 2,800.00	....
2 stalls	3,500.00	$ 4,700.00
3 stalls	4,350.00	....
5 stalls	8,600.00	11,700.00
8 stalls	13,200.00	17,000.00
Engine house, brick—		
5 stalls	12,600.00	15,000.00
10 stalls	19,600.00	24,100.00
20 stalls	44,500.00	48,500.00
30 stalls	65,400.00	78,500.00
Turntables, wood, Gallows type, length 50 ft., each		$ 1,250.00
Turntables, steel, permanent center, 60 ft. each		3,950.00
Turntables, steel, permanent center, 70 ft., each		5,760.00
Turntables, steel, permanent center, 80 ft., each		6,950.00
Water stations: Average cost found		
32,000-gal. tank, wooden tub and tower, in place		$ 1,500.00
50,000-gal. tank, wooden tub and tower, in place		1,800.00
65,000-gal. tank, steel tub and tower, in place		3,750.00
Water crane, 10 and 12 in., with piping and pit in place, each		700.00
Pumping plant, machinery and house, in place, each		595.00
Windmills, 20-ft. wheel, 50-ft. tower, in place, each	$400 to	550.00

TABLE 1.—*Continued*

Water stations: Average cost found	
Windmills, 20-ft. wheel, 70-ft. tower, in place, each........650 to	770.00
Typical plant, 50,000-gal. wood tank, 1 track outlet, ordinary steam or gasoline pumping plant, well and piping...........	4,200.00
Typical plant, 65,000-gal. steel tank, 2 standpipes, steam or gasoline pumping plant, well and piping..................	6,900.00
Fuel stations: Average cost found	
Wooden coal shed, hand derrick and buckets, in place, each.......	$ 1,740.00
Coal chute (Williams, White, Clifton, Kerr, etc.).	
5 to 10 pockets, 40 to 50-ton capacity..........................	4,860.00
10 pockets, 80-ton capacity......................................	8,330.00
20 pockets, 100 to 200-ton capacity..........................	12,800.00
Conveyor, bucket type, single, 2 pockets, 100-ton capacity	7,690.00
Conveyor, bucket type, double, 4 pockets, 200-ton capacity.....	11,880.00
Link belt type with scale hopper, single, 2 pockets, 100-ton capacity..	11,880.00
Tipple car type, 35 to 50-ton capacity.........................	9,130.00
Tipple car type, 150-ton capacity..............................	10,580.00
Cable hoist type, 4 pockets, 200-ton capacity.................	12,060.00
Miscellaneous structures:	
Stock yards, average prices found in place—	
Fence, per lin. ft..	$ 0.5
Gates, each..	12.00
Shelter sheds, per sq. ft..	.24
Hog sprinklers, each...	25.00
Feed troughs, each..	5.00
Chutes, single, each..	112.50
Chutes, double, each...	148.00
Scale and rack, 4-ton capacity, each........................	160.00
Scale and rack, 6-ton capacity, each........................	190.00
Scale and rack, 10-ton capacity, each......................	240.00
Windmills, small tank and pipe............................$500 to	750.00
Typical stock yard, 2 pens, 1 chute, each...................	400.00
Additional pens, each...	125.00
Snow fence, portable, 12-ft. panels, each......................	7.50
Snow fence, fixed, 5 ft. high, 10-ft. panels, per lin. ft..............	.245
Snow fence, fixed, 7 ft. high, 10-ft. panels, per lin. ft..............	.315
Snow fence, fixed, 12 ft. high, 10-ft. panels, per lin. ft.............	.375
Mail cranes, Barker and similar types, each, in place..............	22.00
Park fence, 2 and 3 flues, in place, per lin. ft.............. $0.42 to	.45
Adaptation and solidification of roadway:	
Method of determining cost of this item—	
a. Cost of labor spread over a period of three years.	
For main lines—	
First class—single line roadway, including all appertaining tracks, per roadway mile per annum..............................	$312.00
Second class—ditto as above..	240.00
For branch lines—	
First class—ditto as above...	204.00
Second class—ditto as above..	180.00
b. Cost of material account of shrinkage and subsidence.	
For main lines—	
1st class—add to the cost of grading....................................	3 to 8 %
2d class—add to the cost of grading....................................	2½ to 6 %
For branch lines—	
1st class—add to the cost of grading....................................	3 to 6 %
2d class—add to the cost of grading....................................	2 to 4 %
For two or more main line tracks and for each track additional to the first track 75 per cent of the first track.	
Engineering and superintendence:	
Entire as found within the state, per roadway mile...............	$1,034.67
Entire as found within the state, per track mile....................	810.15
Per cent of total value, roadway, equipment, etc....................	2.16 %

Net ton units were adopted for locomotives considering the weight of the engine loaded and the tender light. This plan was adopted primarily for the reason that the information could in that form be most readily obtained from the railroad companies' records. As the appraisal progressed, a further convenience developed in finding that the engine loaded increases in a very direct proportion to its net weight. In assembling the locomotive costs, further development indicated three general classes by weight, the first those exceeding 100 tons, the second those from 60 to 100 tons, and the third all those under 60 tons. Drawing finer lines, further subdivisions have been found in service and utilized in some cases. Tables were prepared showing in detail the methods used in arriving at the cost per ton, and which were adopted in the appraisal. One table shows the average cost per ton for each of the three classes and for each year, in which these classes of locomotives were built. In some cases, however, not sufficient data was obtainable to give a true average. In the year 1909, $2,000,000 actual expenditures for locomotives was deemed sufficient for determining an average, and the result was a cost of $115.81 per ton for engines over 100 tons in weight. For those 60 to 100 tons in weight only about 25 instances were found, the resultant costs represented thereby being $122.70 per ton, but after careful perusal this was not adopted as an accurate average. A seemingly more perfect average was reached by considering a much larger survey for engines in the first and second mentioned classes for five-year periods, ending 1903 and 1909. From this the average cost of the second mentioned class of engines was determined to be $120.26 per ton. The average cost of engines of the third class was determined as $125.93 per ton. The type of locomotive, whether for passenger, freight or switching, seems to evidence little difference in the results of cost per ton. Commercial freight rates were allowed from the eastern manufacturers to the Missouri River, but not within the state, and the freight east of the river was added in addition to the units. The first outfit of tools was a further charge in addition to the units, but extra tools and apparatus not embraced under the classification was excluded.

For passenger cars the units adopted provided for the general items of construction and equipment. Type and size of the car gave no correct results when the finish and equipment for the vehicle influenced the cost to a very large extent. The main items on which unit costs were based are as follows:

1. Car bodies, not including trucks, air brakes and signals; heating and lighting, seats, vestibules, mail racks, dining car equipment, oak finish for passenger cars, painted for baggage and mail or express. These were divided into different types, such as baggage, postal, combination, passenger, dining, etc., and costs were ascertained on the different lengths of each class and type of construction.

2. Trucks, four and six-wheel, with cast and steel-tired wheels, and for each three main sizes of journals.

3. Automatic air signal and brake apparatus per car, with 12-inch, 14-inch and 16-inch cylinders.

4. Vestibules, extra per end for wide or dummy vestibule over open platform.

5. Heating apparatus, cost per car, with various types of equipment.

6. Lighting, cost per car for various types, and cost each for the various kinds of oil, gas and electric light fixtures.

7. Seating, cost with various types used.

8. Mail racks, cost each for various types, in 15, 20, 30 and 60-foot apartments.

9. Smoking apartment, cost where such is installed.

10. Dining car equipment, average cost per car, including stoves, ranges, refrigerators, china, glassware, linen, etc.

11. Finish, including extra for mahogany over oak.

12. Steel under frame, extra over wood under frame, for various lengths of cars.

Additional to the above percentages were obtained, showing the average cost of observation-parlor and parlor cars over coaches of the same description.

Table II gives the cost of the reproduction of passenger cars used for the 1909 appraisal, although circumstances demanded in various instances specific treatment.

TABLE II.—UNIT PRICES ON PASSENGER CARS AND EQUIPMENT

Car bodies exclusive of trucks, air brakes, signals, lights, heating and seats, but having monitor roofs, canvas covered and painted Pullman, wood construction except as specified.

Length of body over end sills	Baggage cars Standard heavy construction; no windows or platforms	Cheaper design	Postal cars Standard heavy construction; no platforms	Cheaper design	Comb. pass., baggage, mail; no vestibules	Pass. cars oak finish, open platform; toilets
75 ft.	......	......	......	......	$5,647	......

LENGTH OF APARTMENTS FOUND IN COMBINATION CARS

Length of car	Baggage	Mail	Passenger
75 ft.	15 ft.	30 ft.	25 ft.
60 ft.	20 ft.	15 ft.	25 ft.
54 ft.	16 ft.	15 ft.	22 ft.

Other sizes relatively in proportion.

Truck per car—composite wood-plated frames

Size of journals	33-in. cast iron wheels: 4-wheel trucks	33-in. cast iron wheels: 6-wheel trucks	37-in. steel tired wheels: 4-wheel trucks	37-in. steel tired wheels: 6-wheel trucks
$4\frac{1}{4} \times 8$	$731	$1,226	$1,103	$1,789
5×9	833	1,373	1,204	1,935
$5\frac{1}{2} \times 10$	928	1,457	1,300	2,020

High speed automatic air brake and signal—complete per car

12-inch cylinder....................................	$ 81.00
14-inch cylinder....................................	90.00
16-inch cylinder....................................	108.00

Vestibules extra, per end	
Wide Pullman	$ 333.00
Dummy	54.00
Heating arrangement	
Direct steam heat equipment only	$ 149.00
Steam heat with Baker heater	360.00
Passenger car wood or coal stove, each	41.00
Passenger car stove, each	18.00
Lighting apparatus	
Oil center lamps, each	$ 32.00
Acetylene gas light equipment, per car	360.00
Acetylene gas center lamp, each	32.00
Acetylene gas bracket lamp, each	2.50
Pintsch gas equipment, 1 tank	167.00
Pintsch gas, each additional tank	81.00
Pintsch coach center lamps, each	36.00
Pintsch baggage car center lamps, each	32.00
Pintsch bracket lamps, each	4.50
Electric wiring only, with axle light system, per baggage car	171.00
Electric wiring only, with axle light system, per coach	230.00
Electric wiring only, with axle light system, per dining car	270.00
Head end dynamo, train line in conduit and train connection—	
Per baggage car	306.00
Per coach	365.00
Per dining car	405.00
Axle light system and batteries	1,325.00
Single pendants, fixtures, each, up	1.10
Combination gas and electric center lamps, over 1 gas lamp, each	16.00
Elaborate designs for parlor and cafe cars	63.00
Seating	
Low back reversible coach seat, rattan	$ 20.00
Low back stationary coach seat, rattan	12.60
Low back reversible coach seat, plush	22.50
Low back stationary coach seat, plush	14.40
High back reversible coach seat, plush	26.10
High back stationary coach seat, plush	16.20
High back reclining chairs, per chair	38.25
Harrison mail racks	
For 15-ft. compartment	$ 68.50
For 20-ft. compartment	100.00
For 30-ft. compartment	135.00
For 60-ft. compartment	293.00
Smoking compartment	
To seat nine, leather upholstered, extra	$ 257.00
Dining car equipment	
Includes refrigerators, ranges, chairs, tables, china, silver, glassware, linen and kitchen utensils, average per car	$3,047.00
Finish, extra for mahogany over oak	
For dining car, add	$ 225.00
For 60-ft. coach, add	144.00
Steel underframe over wood underframe	
60-ft. car, extra per car	$ 787.00
70-ft. car, extra per car	845.00
Observation parlor cars	
Extra above all steel coaches	12%
Parlor cars	
Extra above all steel coaches	10%

Table III gives the reproduction cost of freight equipment for one of the principal properties operating in the state.

TABLE III.—C. & N. W. RY. CO.'S FREIGHT CARS

Class	Size	Date built	Reproduction cost
Box	36′ × 80 Cap.	1907–1903	$ 693
Box	40′ × 80 Cap.	1909–1908	668
Furniture	40′ × 60 Cap.	1905	717
Furniture	50′ × 60 Cap.	1905	747
Flats	40′ × 80 Cap.	1907–1905	520
Flats	40′ × 100 Cap.	1901	700
Flats	40′ × 70 Cap.	1902	427
Gondola	35′ × 80 Cap.	1907–1902	623
Gondola	40′ × 100 Cap.	1909	908
Stock	36′ × 60 Cap.	1907–1905	638
Ore	22′ × 80 Cap.	1907	659
Ore	21′ × 80 Cap.	1902–1903	659
Ore	21′ × 80 Cap.	1909	808
Ballast	36′ × 80 Cap.	1907	927
Ballast	38′ × 80 Cap.	1905	626
Refrigerator	34′ × 60 Cap.	1904	871
Refrigerator	34′ × 60 Cap.	1905	900
Caboose, standard	....	1904–1901	834
Caboose	....	1909–1905	834
Caboose, drovers	....	1909–1901	1,280

Rebuilt work equipment, as an average for all properties, was determined as follows:

Box, bunk and outfit cars, depreciated value per car	$ 106.25
For re-building	160.00
	$ 266.25
Cinder cars, self dumping, converted from old flats or stock, depreciated value per car	$ 89.00
For re-building	280.00
	$ 369.00
Wooden pile drivers, built on old flats, depreciated value per car	$ 287.00
For re-building	3,713.00
	$4,000.00

On one of the principal lines, as a fair example, the statement (Table IV), showing the *value of tools and special equipment*, was determined for the various kinds of rolling stock and allowed in addition to the units heretofore mentioned:

TABLE IV.—VALUE OF TOOLS AND SPECIAL EQUIPMENT

Item	Total
For 573 road locomotives, each	$ 87.27
For 87 switch locomotives, each	53.67
For 268 cabooses, each	268.28
For 10 business cars, first class, each	1,094.29
For 6 business cars, second class, each	656.57
For 9 observation electric lighted cars, each	97.33
For 30 diners, each	1,626.98
For 33 postal, wood, each	207.01
For 14 postal, steel, each	225.32
For 49 chair, each	41.76
For 112 coach, each	41.76
For 66 baggage, each	98.50
For 36 baggage and mail, each	138.55
For 19 baggage and passenger, each	98.98
For 4 baggage, mail and passenger, each	139.03
For 5 mail and passenger, each	114.12
For 7 composite, each	51.78
For 17 motor cars, each	141.69

For the expenditure of inspection and purchase of equipment there was added to each class 1 per cent of the cost in total, not including the freight charges. This amount was fixed after having made considerable investigation as to the proper measure to be allowed, and was based upon a number of instances of actual experience.

Additional to the above averages there was allowed commercial freight to the state.

Prices Used in the Valuation of the New York, New Haven & Hartford R. R.—In the valuation of the physical property of the New York, New Haven & Hartford R. R., under the direction of George F. Swain, the unit prices adopted were based upon the average ruling prices for the various elements during the last few years previous to the appraisal and upon prices actually paid by the railway company. From the report on the valuation, Engineering and Contracting, Feb. 21, 1912, gives the following.

Grading:	
Clearing, per acre	$ 40.00
Grubbing, per acre	160.00
Earth excavation, per cu. yd	0.32
Solid rock excavation, per cu. yd	1.30
Solid rock excavation, per cu. yd	1.15
Loose rock excavation, per cu. yd	0.65
Borrowed excavation	0.32
1st class retaining wall, per cu. yd	15.00
2nd class retaining wall, per cu. yd	8.00
3rd class retaining wall, per cu. yd	6.00
Sodding, per sq. yd	0.30
Riprap, per cu. yd	2.50
Piling, per lin. ft	0.40
Timber, per M. ft. B. M	50.00
Tunnels:	
Excavation, per cu. yd	$ 5.00
2nd class masonry, per cu. yd	8.00
Brick lining, per cu. yd	15.00
Bridges, trestles and culverts:	
1st class deck girders, per ton	$ 70.00
2nd class deck girders, per ton	60.00
1st class through girders, per ton	75.00
2nd class through girders, per ton	65.00
1st class trussed bridges, per ton	80.00
Draw and lift bridges, per ton	120.00
Counterweight bridges, per ton	50.00
Viaducts, per ton	75.00
Howe truss bridges, per lin. ft	90.00
Timber trestles, per lin. ft	10.00
Solid floor, per lin. ft	12.00
Stringers, per M. ft. B. M	50.00
I-beam stringers, per ton	50.00
1st class masonry, per cu. yd	15.00
2nd class masonry, per cu. yd	8.00
3rd class masonry, per cu. yd	6.00
Riprap, per cu. yd	2.50
Paving, per sq. yd	1.75
Wet excavation, per cu. yd	1.00
Dry excavation, per cu. yd	0.50
Timber, per M. ft. B. M	50.00
Piling, per lin. ft	0.40
Bolts, per lb	0.05
Cast iron pipe culvert to 24 ins., per lin. ft	3.65
Cast iron pipe culvert over 24 ins., per lin. ft	11.00
Sewer pipe culvert to 24 ins., per lin. ft	0.85
Sewer pipe culvert over 24 ins., per lin. ft	3.57

Ties:	
Main track, per tie	$ 0.60
Sidings, per tie	0.45
Switches, per M. ft. B. M.	22.00
Bridge floor, per lin. ft.	3.00
Rails:	
Main track, 100-lb. per mile	$4,790.00
Main track, 79-80-lb. per mile	3,830.00
Main track, 74-78-lb. per mile	3,590.00
Main track, 66-72-lb. per mile	3,210.00
Main track, 50-65-lb. per mile	2,880.00
Siding, over 75-lb. per mile	3,590.00
Siding, 65-75-lb. per mile	3,210.00
Siding, 50-65-lb. per mile	2,880.00
Frogs and switches:	
100-lb. rail turnouts	$ 223.00
79–80-lb. rail turnouts	196.00
74–78-lb. rail turnouts	178.00
66-72-lb. rail turnouts	147.00
56-65-lb. rail turnouts	140.00
100-lb. rail derails	18.00
66-80-lb. rail derails	15.00
50-65-lb. rail derails	12.00
100-lb. rail slip	500.00
74-80-lb. rail slip	300.00
50-72-lb. rail slip	300.00
Track fastenings, etc.:	
100-lb. rail per mile (main track)	$ 680.00
74-80-lb. rail per mile (main track)	430.00
66-72-lb. rail per mile (main track)	397.00
50-65-lb. rail per mile (main track)	344.00
75-lb. rail per mile (sidings)	430.00
66-75–lb. rail per mile (sidings)	397.00
50-65-lb. rail per mile (sidings)	344.00
Ballast:	
Stone, per mile	$2,900.00
Gravel, per mile	1,450.00
Other ballast, per mile	1,000.00
Track laying and surveying:	
Main line, per mile	800.00
Sidings, per mile	600.00
Fencing:	
Wire, per mile	300.00
Tight board, per mile	1,800.00
Open, per mile	1,000.00
Stone, per mile	3,000.00
Crossings and signs:	
Cattle guards, per pair	$ 30.00
Timber, piling, excavation, etc., as previously given.	

Cost of Grading, Watauga & Yadkin River R. R.—The following data are taken from an article by H. C. Landon published in Engineering and Contracting, April 1, 1914.

The Watauga & Yadkin River R. R. is a standard-gage line from North Wilkesboro, N. C., where connection is made with the Southern Ry. to Boone, N. C., a distance of 52 miles.

The methods followed in construction were rather unusual, as the company was its own contractor. In other words, the grading was done largely by its own forces under the direction of the Chief Engineer. One small six-mile section was constructed by contract.

The profile of the first 30 miles of projected line, indicated generally light work. There were some heavy cuts and fills, but it was not practicable, on account of poor roads and lack of bridges to entertain any steam shovel proposition, and generally the cuts and fills were too light to make steam shovel operation economical. Labor was scarce, and at a premium everywhere. The plan was to do the work with the aid of teams, machines and powder as far as practicable.

Equipment.—After a careful study of the projected profile, it was decided to purchase the following equipment:

12	1½ cu. yd. Troy wagons at $112.50	$1,350.00
24	drag scrapers at $5.56	133.44
36	No. 2½ wheel scrapers at $36.75	1,323.00
1	elevating grader at $920.00	920.00
4	2,500 lb. wagons at $55.00	220.00
8	16 ft. by 24 ft. tents at $38.63	309.04
2	32½ ft. by 65 ft. mule tents at $149.30	298.60
2	Ingersoll rock drills at $312.50	625.00
1	16 hp. boiler on wheels, 2d hand, at $300	300.00
10	1 yd. dump carts with harness at $46	460.00
4	2 yd. dump carts with harness at $30	120.00
100	steel wheel barrows, 3 and 4 cu. ft. at $3.00	300.00
12	doz. round Pt. D handle shovels at $5.25	63.00
4	blacksmith outfits, including a forge, anvil and other tools, at $40.00	160.00
12	doz. picks with handles at $400	48.00
	Total	$6,630.08

The dump wagons and grader were only used about two months and did fair work in the territory where they were used. They were not used for a longer period on account of inability to get sufficient mules and teams to operate them.

Teams.—Before the company started work, we were advised that all the teams we would require could be secured in the community, but although we paid $3 per day or 50 cts. more than the ruling price, we could only secure 15 to 18 teams and they were not all of the best type. It was then decided to purchase our own mules and 45 teams were purchased in the St. Louis market. These were mules that could pull, the average weight of the animals being over 1,225 lbs. These teams were in almost continuous daily service from Aug. 1, 1912, to June, 1913. Only two mules were lost and it is estimated that there was not over 5 per cent lost time for the mules in service. Our cost of feeding the mules averaged 95 cts. per team per day. For all camps hay averaged $25 per ton and oats 57½ cts. per bushel delivered at the camps.

On June 1, 1913, the work was shut down for short time. At that time had our mules gone on the market they would have brought more than they cost, as their condition was excellent, due to their excellent care. It was the theory of the company that only from well fed and well kept teams could satisfactory efficiency be secured. The teams were taken care of by a competent stable boss. A supply of necessary remedies and an emergency case were kept at each camp. The fact that there was not over 5 per cent lost time for the teams explains the low price and rapid progress.

EARTH EXCAVATION

Organization of Forces.—It was realized that in order to secure efficiency, the organization of the various forces should be fixed. These forces were called "Standard" and only varied when it was shown that the nature of the work demanded it. Thus the Standard wheel scraper force was as follows for hauls not exceeding 300 ft.: 6 wheel scrapers with teams and drivers, 2 teams to plows, 1 snatch team, 1 man dumping, 1 loader, 1 wheeler, 1 waterboy, when required, and 1 foreman.

When the haul increased the number of wheel scrapers was increased, in order to keep the snatch team and other laborers busy. This was very closely watched by the foremen of the various gangs, in order to keep up their records, as every dumper was supplied with a counter and the day's work reported. In this way, a very close estimate could be made of the yardage moved.

The "Standard" drag scraper force consisted of 6 scrapers, with teams and drivers, 2 teams to plow, 1 dumper, 1 loader, who acted as foreman, and 1 waterboy.

The drag scraper work and the wheel scraper work were watched with great care to determine the economical haul. The drag scraper is very efficient and very useful for very short hauls only. Observation of the various hauls up to 200 ft., fully demonstrated the fact that for a distance of over 100 ft. the drag scraper was an expensive implement. Under 100 ft. it will do efficient work. Wheel scrapers ordinarily can be used where the drags can, and had the advantage in making about the same speed with about five times the load. As a general proposition, only a few drags should be used on work of this character. Their advantage is in their cheapness and for a small amount of work with short hauls the drag scraper might be desirable equipment. A gang of wheelbarrow men properly handled will do work about as cheap as a drag and in some instances at less expense.

Cost of Drag Scraper Excavation.—Assuming the haul for a drag scraper to be 100 ft., a lively mule team to a scraper will not make over 1.3 miles per hour on account of the frequent turns and loading, or about 6,900 ft. per hour. This will be at the rate of 3.45 cu. yds. per hour or 34½ cu. yds. per 10-hour day per team. With a "Standard" drag scraper force and teams at $3 per day, 8 drags will handle 27.6 cu. yds. each per 10-hour day, at a total labor cost of $37.50, or nearly 14 cts. per cubic yard. With a haul of from 50 to 75 ft. the cost will not exceed 12 cts. per cubic yard. Seventy-five ft., therefore, should be the maximum haul with drag scrapers. Six drag scrapers with the shorter haul were therefore established as the maximum to use with the minimum haul.

Actual observation on a 110-ft. haul with country teams, indicated that under the best conditions only 25½ trips were made per hour, or a speed of 5,000 ft. per hour. The company teams which were all well fed Missouri mules, made as high as 7,200 ft. per hour with drag scrapers on a haul of 150 ft.

These results were obtained under the best possible conditions where the dumper man counted and reported every load and in addition the teams were under my personal observation.

A few drag scrapers on every job of similar character are a good investment, but their number and use should be limited. An injudicious foreman will often use them at the company's expense.

Our standard forces were modified as the hauls increased, the number of wheelers increased to eight, and, possibly, with very long haul ten or even twelve wheelers could be used to advantage.

Cost of Wheel Scraper Excavation.—In only one instance did the haul with wheelers much exceed 600 ft. and in this instance the haul averaged 1,350 ft.; ten wheelers only were available, but we were able to handle 225 cu. yds. at a cost of 23½ cts. per yard, figuring teams at $3.50 per 10-hour day, although all the teams which we used actually only cost us approximately $3 per day.

With a haul of 415 ft. a careful timing of the teams indicated that they were making four trips in 20 min. The average of twelve trips per hour was made for the entire day. The wheelers were loaded to their capacity, and therefore, an average of nearly 60 cu. yds. per wheeler was secured. The wheeler force using only six wheelers cost $30 per day. The labor cost in this case did not much exceed 10 cts. per yard.

Wheelbarrow Excavation.—The wheelbarrow when properly used is a most useful, necessary, convenient and economical tool. Three types of barrows were purchased: the ordinary railroad wooden barrow, the wooden frame contractors barrow, with steel tray, and the all steel wheelbarrow with one piece tubular bent handles. Barrows of 3 and 4 cu. ft. capacity were bought. The barrow holding 4 cu. ft. in general seemed to suit our work and could be handled about as easy as the barrow holding only 3 cu. ft. The ordinary wooden wheelbarrow gave very poor service. We had a few of the barrows with wooden frames go out of service, but the all steel wheelbarrows are practically as good as new after 8 months fairly good service. The barrows are painted when out of service any length of time.

For side-hill work and to open grade points the barrow is giving very efficient service. Observation on side-hill work with a gang of 25 men handled dirt at the rate of eight wheelbarrows per minute for an hour with a haul of 21 ft. This would mean that they moved over 500 cu. yds. per day in wheelbarrows holding 4 cu. ft. Good runways were always provided, so that the loads could be moved with the least possible waste of energy.

The gangs were placed in the hands of efficient foremen, who taught the men how to handle the most dirt with the least possible loss of time. It was endeavored at all times to have a standard gang of not less than 25 men under each foreman. The work varied as the conditions necessitated. In some cases much drilling was required, in others none at all.

Cost of Dump Car and Cart Excavation.—Four small dump cars with revolving bodies were found to be convenient and useful in short cuts and at the approaches to the one tunnel that has been built. These cars run on a track of 30-in. gage and had a capacity of 2 cu. yds. The cars were particularly useful in small cuts and where the haul was long. The revolving body would permit the car to be dumped in building the fill ahead of it and could be dumped on the side to widen the fill or waste the material. Light rails not being available these cars were run on a track made of 4 × 4 oak timbers. The wooden rails only required a few renewals during their six months of service.

Dump carts can only be used economically upon hauls about 100 ft. long, but two of the cars moved by mules would keep a gang of 10 to 12 shovelers continuously busy—where the haul was from 600 to 700 ft.

In one cut alone, it is estimated two of these cars handled 15,000 cu. yds. of earth and rock, with a maximum haul of 650 ft., at a cost not to exceed 20 cts. per cubic yard. The average gang, including drillers, was about 14 men and a foreman. This number of men loaded about 150 cu. yds. per day at a labor cost of about $25 per day. It took nearly three months to remove the cut.

While dump carts should be used for short hauls of from 100 to 125 ft., yet they have been used to advantage where the maximum haul was 250 ft., provided the roadway was kept in good order and several carts were used to keep a good sized gang moving. In one instance, six carts were used in completing a fill and did the work very rapidly where the haul was approximately 150 ft. Six carts and 30 laborers moved 325 cu. yds. per day, at an expense of approximately $47 or about 15 cts. per cubic yard. As a general proposition our cost of handling earth and rock with dump carts and men is about 26 cts. per cubic yard, exclusive of explosives.

ROCK EXCAVATION

Methods of Using Explosives.—The line as located and the material afforded a splendid opportunity for the use of explosives. Much of the line was located in the side hills in locations where heavy blasts would be made without endangering life or property. The proper using of explosives, however, for moving earth has been given, as a general thing, very little attention. The experienced men that we employed had only used explosives to shatter and break up the rock or hard soil, so that it could be handled by either hand or steam shovels, and the old powder men at first tried to continue the use of that method. Much valuable time and good powder were wasted before we could so improve the use of powder that the blast would move the maximum amount of rock and earth out of or off from the railroad grade.

In all cases where there were over five holes, the battery was tested with a Rheostat and every fuse and finally the line was tested with a galvanometer, so that no misfires occurred. It is not rare that a faulty fuse is found, and when they do occur they can cause annoyance if they are used.

Methods of Spacing, Drilling and Loading Blast Holes.—It was difficult at first to get the desired results as all the old-time powder men rather believed in the single shot or two or three shots plan, the result being that a poor showing was made. I finally made arrangements with the general foreman to lay out or plan the blasts in the other cuts and for some time no heavy blasting was done except under personal direction. The cuts were usually of a length where 30 or less than 30 holes would cover the portion of the cut to be moved, so that a No. 3 blasting machine would explode the blast.

The holes were spaced on lines that have since entered into our general instructions for use of powder and other explosives. In general where the cut at the center line was over 4 ft., and the material earth or soft rock, the first line of holes was placed not more than 2 ft. above the center line. All holes were driven to a point 2 ft. below grade and usually about the same distance apart as the depth of the hole to grade, except when depth was greater than 15 ft. The maximum distance apart was about 15 ft. If the hillside was steep and the lower side of the road bed at grade, one set of holes was sufficient. If the cut under ordinary circumstances was a through cut with the depth of cut 2 ft. or more on the lower side, then a lower set of holes was drilled parallel to the first at the lower ditch line at points midway between the upper holes, so that there would be no question about moving the material out of way. This will not change materially the amount of powder used, as one yard of soft rock should be moved with about 2 lbs. of powder. The soft rock usually was decomposed granite or a Carolina gneiss which was not hard to drill.

The hard rock encountered was usually a mica schist. This was very hard, and in these cases the upper line of holes was placed on the upper ditch line and a distance apart equal to the depth up to 10 ft. No holes were placed farther apart than this. The lower holes were placed on the lower ditch line at the same distance apart but intermediate to the upper line of holes.

The arrangement had to be modified according to the rock, as hard and soft rock would be found in the same cut that was to be demolished by a single blast. The arrangement of the strata changed our plans, although generally the strata we encountered was nearly vertical or leaned slightly to the northwest.

The general tendency was to use too much powder in the soft rock or earth and too little in the hard rock. A careful estimate was made of the quantity in the cut. If soft rock, 2 lbs. or less were used per yard; if hard rock, 3 lbs. per yard or more. The general foreman in charge followed instructions carefully and used good judgment in his large blasts and usually wasted very little or no powder. After he became acquainted with the rock and the mistakes, mistakes were rare.

In all the smaller shots that are being made, the foremen are instructed to use powder judiciously, and they are getting good results with a minimum amount of powder. The holes are made on the center line to a point about 2 ft. below the grade line and are spaced a distance apart equal to the depth of the holes. It is found that the holes drilled on the center line and to this depth below the grade will ordinarily pull down the grade about the amount desired, and will not move the earth too far back of the slope line where soft rock is handled.

Drilling Outfit.—Steam drills are used with hard rock, while a large percentage of the other holes are put down by hand and churn drills. In many places churn drills were successful in soft rock. In all hard rock, steam drills are used when possible. The two drills used were the Ingersoll P-24 type with 3-in. cylinders 6½-in. stroke. One 12 h.p. boiler supplied the two drills.

Cost of Excavating a Rock Sidehill Cut.—Several large blasts have been successfully made along the route in sidehill cuts on different sections of the line, moving almost ½ cu. yd. of material for every pound of powder used. In one cut, estimated at 8,000 cu. yds., 95 per cent of which was solid rock, 33 holes

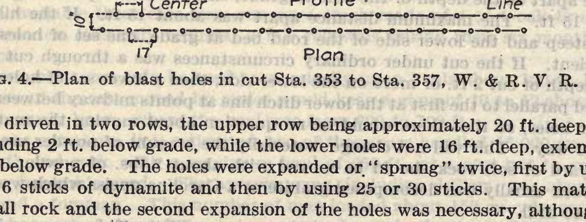

FIG. 4.—Plan of blast holes in cut Sta. 353 to Sta. 357, W. & R. V. R. R.

were driven in two rows, the upper row being approximately 20 ft. deep and extending 2 ft. below grade, while the lower holes were 16 ft. deep, extending 6 in. below grade. The holes were expanded or "sprung" twice, first by using 5 or 6 sticks of dynamite and then by using 25 or 30 sticks. This material was all rock and the second expansion of the holes was necessary, although it is believed that one expansion of the holes, using 10 or 12 sticks of dynamite, would have given better results, as the second expansion tended to fill the holes rather than open them up to sufficient size. An average of 11 kegs of powder was used in the upper holes and 13 in the lower holes. The results of this blast were very satisfactory, 378 kegs of powder being used, moving fully 7,000 cu. yds. of rock. A No. 3 push down battery was used in this explosion, although this was overloading the battery slightly.

Fig. 4 shows the profile of the cut where this blast was made and a plan showing the location, spacing and arrangement of the 33 blast holes.

Fig. 5 shows a typical cross-section of the cut before and after the blast and as completed. A wagon road was shifted farther back from the river after the grading was done.

On a small sidehill rock cut at Sta. 926, holes were drilled by hand for a blast made June 16, 1913. Six lower holes were drilled approximately 4 ft. down hill from the center line having depths of from 7 to 11 ft. Three holes were drilled along the center line, and 17 holes having depths of from 11 to 18 ft. were drilled at an average distance of 7 ft. above the center line. All holes were drilled about 2 ft. below sub-grade. The rock was of hard grey character, and eight cans of powder were placed in most of the deepest holes, although one hole required eleven cans. Three cans were loaded into the shallow holes. The cost of making the blast and cleaning out the cut, which contained a total of 1,300 cu. yds., was as follows, (the item of $126 being for labor in cleaning out the loose material left by the blast and in dressing up the cut):

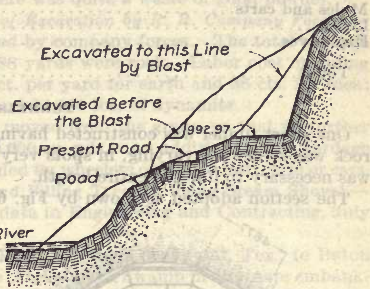

FIG. 5.—Cross section of cut at Sta. 355 + 34, W. & Y. R. R. R.

		Per cu. yd.
121 cans powder at $1.30	$157.30	$0.121
150 lbs. dynamite at $0.15	22.50	0.017
50 20-ft. fuses	3.40	0.003
58 16-ft. fuses	2.78	0.002
Labor drilling and loading holes	135.00	0.104
Labor, 84 men at $1.50	126.00	0.096
Total	$446.98	$0.343

About 320 ft. of holes were drilled at a cost of approximately 40 cts. per lineal foot for drilling labor, which was only 0.24 ft. of hole per cubic yard of rock blasted. Powder was used at the rate of 2.3 lbs. per cubic yard of rock blasted, the springing of the holes requiring 0.12 lbs. of dynamite per cubic yard of rock. It was estimated that 900 cu. yds. of rock were shot out of the cut, so the unit cost for clearing out and dressing the cut was $126 ÷ 400 = $0.31 per cubic yard of rock left in the cut after the blast. The cut was ready for track three days after the blast was fired.

Cost of Excavating a Through Rock Cut.—For the purpose of comparison the cost of excavating a through rock cut between Sta. 1038 + 50 and Sta. 1041 is here given. The material in the cut was medium hard rock, much of it being mica schist, and amounted to 2,200 cu. yds. Thirty-seven holes were drilled and fired in eleven blasts. About 28 pop shots and small shots were required for breaking up rock and removing rock to a point below grade. Some of the material was removed by wheelbarrows to the side of the cut, but the greater portion was moved by carts into a nearby fill, the haul being about 250 ft. The mules were owned by the company but the cost was estimated at $1.50 per 10-hour day. The total cost of excavating the cut was as follows:

Item		
Mules and carts	$ 47.00	$0.021
Labor	1,018.25	0.463
Explosives	174.45	0.079
Totals	$1,239.70	$0.563

TUNNELS

One short tunnel was constructed having a total length of 194 ft. As the rock was somewhat varying, in spots very hard and at other points loose, it was necessary to line the entire length.

The section adopted as shown by Fig. 6 is rather narrow, had it been the intention to maintain a permanent tunnel, but as it is the purpose to make an open cut at this point, the smallest safe section was adopted. The track has a summit about half way through the tunnel which provides for draining track ditches to both ends.

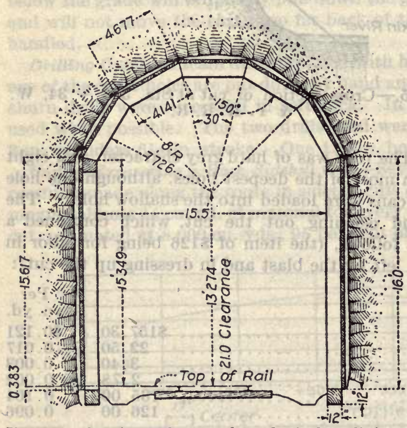

FIG. 6.—Section of tunnel and timber lining, W. & Y. R. R. R.

Cost. — The tunnel was driven by hand, the entire cost being $6,730.74, or $34.69 per foot. This is very reasonable, taking into account the fact that very little experienced labor could be found. No accidents in the tunnel proper occurred. The above cost includes all material, explosives and labor in any way connected with the tunnel. It required 39 days to drive the headings, and about the same time to drive the benches. Labor was scarce and difficult to get.

Method of Using Powder Tunnels for Excavating Rock.—The tunnel approaches contained approximately 40,000 cu. yds. of earth and rock, 75 per cent of which was earth. Nearly 50 per cent of this was moved by two blasts, one on each approach; 30,000 lbs. of powder were used. The powder in these later instances was placed in powder tunnels running about on the ditch line with branch tunnels leading from the main. The powder was emptied into paper flour sacks and then compacted as closely as possible in the extreme end of the main tunnel and branches. After the powder was placed, the balance of the tunnel was filled with earth compacted as well as possible. The fusees and lead lines in these blasts were tested at every step in the wiring of the blasts.

While effective and satisfactory work was done by these two blasts yet it is believed that by the use of more powder somewhat differently placed, had the dirt been better compacted at the tunnel mouth or had there been a solid stone or concrete wall built across the mouth of the tunnel, or in the tunnel next to the powder, better results would have been obtained. The powder tunnels were very dry and it is not believed the powder would have deteriorated very much during 48 hours necessary to give a concrete wall time to set. The fact that there was evidence of considerable force wasted at the mouth of the tunnel was evidence that there was quite a waste of good powder.

Total Amount and Average Cost of Excavation by R. R. Company Forces.— Approximately 24 miles were graded by company forces. The total yardage moved was 475,052, of which 99,688 yards were rock. Labor cost including explosives was approximately .12 ct. per yard for earth and 36 cts. for rock; 213,250 lbs. of powder were used and 24,000 lbs. of dynamite.

It is estimated that the powder moved from the grade, so that no further handling was necessary, at least 80,000 cu. yds. An additional large yardage of material was shaken up to be loaded by wheelers or loaded into carts or cars.

Cost of Raising Embankment and Filling Trestles Using Steam Shovel.— D. A. Wallace gives the following data in Engineering and Contracting, July 20, 1910.

The Frisco line (C. S. N. O. & P. R. R.) from Beaumont, Tex., to Baton Rouge, La., was built through the Atchafalaya Swamp in alternate embankment and temporary trestle. The original plans were made for continuous embankment of station work, but continued high water in the swamp prohibited 50 per cent of the station work and temporary trestling was resorted to for filling in the gaps between the embankment which had been started or completed. The greater portion of the grade was 8 ft. high. The material in the embankment was the black gumbo commonly encountered in Southern Louisiana swamps. The work described consisted of raising the embankment and filling in the temporary trestling. The conditions were difficult.

The track was laid following closely behind the trestle gang, and frequent use of the track by the bridge material train put the track into a very poor condition. A great portion of the embankment built by station work was partially washed out by high water leaving holes 4 ft. deep for 15 or 20 ft. of track. The temporary trestles stood 12 or 18 ins. higher than the approaches. This condition was due to the excessive settlement of the swamp soil when put up by station work and also to heavy rains. The worst holes were cribbed up with ties and tree branches but even then a great amount of delay was caused the unloading trains by derailment and trains breaking in two in attempting to get over the bad places. It was necessary to unload dirt at these places before the track could be surfaced, as the gumbo would not hold a surface under one trainload of dirt. In many instances cars were unloaded standing on track 18 ins. out of level and 3 ft. out of surface in a distance of 10 ft. along the rail.

Hart convertible cars were used and were unloaded by Lidgerwood and plow. Before dirt was unloaded on the fills it was necessary to jack the track up out of the gumbo. It was impossible to move the track with No. 6 Barrett jacks after the dirt was unloaded. In many instances it was found necessary to strip out the track before it could be lifted from the gumbo with 12 No. 6 Barrett jacks, resting on boards, per rail length. The grade on embankment was raised not less than 12 ins. at any point.

The unloading was planned so that when the front gangs were unable to get the track in shape ahead of the unloading or when they were not able to care for the dirt as fast as it came, the unloading was done on the trestles, and as they were being filled a gang was kept busy tamping the dirt in under the caps and stringers. Following a rain, the dirt packed hard and the caps and stringers were removed by the Lidgerwood and cable.

The shovel pits from which the dirt for filling was taken, averaged a 15-ft. face and 1,600 ft. in length. The dirt was a sandy clay compacting very quickly in embankment. The pit was opened up along one side of the main line and track laid behind the shovel in the first cut and used as a loading track for the next cut of the shovel. More difficulty than usual was experienced in keeping the pit properly drained. Good drainage was very necessary to take care of the frequent and heavy rains common to the country. Three trains were used, 1 loading train, which also handled the water cars for the shovel, 1 swing train which made the run of 12 miles to the front in 40 minutes and 1 unloading train. The unloading was started 12 miles from the pit. A siding and water tank were located there affording water to the swing and unloading trains. About 25 minutes were generally consumed there in switching empties and locals.

The work recorded was done from Sept. 12 to Oct. 16, 1907. The daily expenses were as follows:

Loading, transporting and unloading:	
1 Trainmaster at $150 per mo.	$ 5.00
3 Conductors at $100 per mo.	10.00
3 Brakemen at $75 per mo.	7.50
3 Brakemen at $60 per mo.	6.00
3 Engineers at $100 per mo.	10.00
3 Firemen at $75 per mo.	7.50
3 Engine watchmen at $60 per mo.	6.00
1 Hostler at $75 per mo.	2.50
1 Hostler helper at $1.80 per day	1.80
1 Steamshovel engineer at $150 per mo.	5.00
1 Steamshovel craneman at $90 per mo.	3.00
1 Steamshovel fireman at $75 per mo.	2.50
1 Steamshovel watchman at $60 per mo.	2.00
1 Machinist at $0.35 per hour	3.50
1 Machinist helper at $1.80 per day	1.80
1 Blacksmith at $0.35 per hour	3.50
1 Blacksmith helper at $0.20 per hour	2.00
1 Car repairer at $0.25 per hour	2.50
1 Car repairer at $0.225 per hour	2.25
1 Carpenter at $0.275 per hour	2.75
1 Pumper at $60 per mo.	2.00
1 Lidgerwood engineer at $90 per mo.	3.00
6 Pit men at $2 per day	12.00
6 Cablemen at $2 per day	12.00
Total wages	$116.10
20 tons coal at $4	$ 80.00
Supplies	2.56
Ice	1.00
Water at 50 cts. per tank from city	2.00
10 gals. gasoline at 10 cts.	1.00
Total supplies	$ 86.56
1 Steam shovel rent	$ 10.00
3 Engines rent at $5.53 per day	16.59
62 Cars rent at 50 cts. per day	31.00
1 Water car rent at 50 cts. per day	0.50
1 Spreader rent at $2 per day	2.00
1 Lidgerwood rent at $5 per day	5.00
Total plant rental	$ 65.09
Add 10 % super. and 5 % misc.	$ 40.15
Grand total	$307.90

NOTE.—The 5 % misc. includes overtime, etc.

During the total period of 35 days, the total time lost due to Sundays, rain, etc. was as follows:

Sundays	5.0 days
Rain or mud	2.18 days
Moving	1.6 days
Shovel breaking down bank	0.25 days
Failure of transportation	0.22 days
Total	9.25 days

Of this total of 9.25 days, 6 days are accounted for by 5 Sundays and 1 day moving from job.

The total cost of the work, $14,178, was made up as follows:

Pitmen at $75 per mo. and $1.75 per day	$ 727
Labor at the front at same rates as pitmen	3,519
Steam shovel 29 days at $308	8,932
5 days at 200	1,000
	$14,178

Pit cross-section showed a yardage of 35,445 removed thus making the cost 40 cts. per cu. yd.

Dragline Bucket Eliminates Maintenance of Track in Cuts.—The following note is taken from Engineering and Contracting, Jan. 16, 1918.

In planning methods of excavating railway or canal cuts, sight should not be lost of the cost of laying and maintaining tracks over which the spoil is hauled away. This cost mounts rapidly where the bottom of a cut is wet and difficult to drain. In such cases it is frequently economic to use a dragline excavator instead of a steam shovel, for both the track for the excavator and for the muck train can be laid on the surface of the ground instead of in the bottom of a wet cut.

In making a cut for the Nickel Plate Ry. in Cleveland, the contractor, Walsh Construction Co. of Davenport, used a 175-ton Marion dragline with a 100-ft. boom and a 5-yd. Page bucket. Working two 11-hr. shifts daily the dragline averaged 3,600 cu. yd. every 24 hrs. where there were no delays. The earth, a sandy clay, was loaded into 12-yd. Western cars. The bottom width of the cut was 72 ft. and the maximum depth was 24 ft. The dragline dug on both sides of itself as well as behind, and then moved back 30 ft., repeating this operation again and again.

Costs of Railway Ditching by Various Methods.—An interesting comparison of costs at 1918 prices of cleaning railway ditches by different methods was given in a committee report at the 1919 annual meeting of the Roadmasters' and Maintenance of Way Association in Chicago. The following data given in Engineering and Contracting, Dec. 17, 1919, are from this report and are for single track lines with six trains during working hours; roadbed in soft clay; ditches 7 ft. from rails, 3 ft. wide and 2 ft. deep.

Method	Output per day, cu. yd.	Cost per cu. yd.
Ditcher of steam-shovel type, on cars	224	$0.4130
Steam ditcher of drag-scraper type	252	.4034
Push cars and laborers	38½	.5862
Car barrows and laborers	13	.7670
Wheelbarrows and laborers	19	.7142
Casting or shoveling	38½	.3525

The unit costs for the various methods follow:

	Per day
Ditcher of steam shovel type on cars:	
Ditch labor	$ 18.90
Work train labor	23.86
Rental of equipment	31.00
Maintenance of equipment	1.45
Supplies	12.80
Total (224 cu. yd. at 41.3 cts.)	$ 92.51
Steam ditcher of drag scraper type:	
Ditch labor	$ 31.75
Work train labor	28.36
Rental of equipment	30.00
Maintenance of equipment	.93
Supplies	10.62
Total (252 cu. yd. at 40.3 cts.)	$101.66
Two push cars and hand labor:	
1 foreman at $83	$ 2.77
11 laborers at $2.25	19.80
Total (38½ cu. yd. at 58.6 cts.)	$ 22.57
Car barrows and hand labor:	
1 foreman	$ 2.77
4 laborers at $1.80	7.20
Total (13 cu. yd. at 76.7 cts.)	$ 9.97
Wheelbarrows and hand labor:	
1 foreman	$ 2.77
6 laborers at $1.80	10.80
Total (19 cu. yd. at 71.4 cts.)	$ 13.57
Casting or shoveling:	
1 foremen	$ 2.77
6 laborers at $1.80	10.80
Total (38½ cu. yd. at 35.2 cts.)	$ 13.57

Cost of Steam Shovel Work Loading Into Cars for Railway Ballasting and Grading.—D. A. Wallace gives the following data in Engineering and Contracting, July 27, 1910.

Slag for Ballasting.—This slag was loaded by a 45-ton shovel working against a 20-ft. face, into cars placed on a spur track on a 3 per cent grade. The grade permitted the spotting of cars by hand while the engine was unloading the loaded cars. The greatest haul was 4 miles. There was no delay to the slag train due to meeting revenue trains. The slag was in alternate vitrified and spongy layers. The use of the light shovel necessitated some use of powder but not more than the ground gang could drill the necessary holes for and handle. Holes were drilled on an average 9 ft. horizontally into the face 3 ft. from the ground line and about 10 ft. centers. Rodgers ballast cars were used. The size of the slag permitted easy unloading. The train crew with the help of one of the gang did the unloading and sweeping off.

The daily expense was as follows:

Engineer @ $125.00 per month	$ 4.80
Craneman @ $40.00 per month	3.46
Fireman @ $60.00 per month	2.31
Foreman @ $65.00 per month	2.50
6 ground men @ $1.25 per day	7.50
2 tons coal at $2	4.00
Waste and oil	0.50
Dynamite	0.93
Work train	25.00
Total	$51.00

The slag cost $2 per car load of 40 cu. yds. or 5 cts. per cu. yd. Including this the cost of loading, hauling and unloading was as follows per cubic yard:

6 cars, 240 cu. yds	$0.262
7 cars, 280 cu. yds	0.232
8 cars, 320 cu. yds	0.209
9 cars, 360 cu. yds	0.191
12 cars, 480 cu. yds	0.156

Earth for Grade Raising.—Loose earth was loaded into Hart convertible cars spotted on the main line. The shovel was cut in on both sides of the main line and cuts were widened. A 12-ft. face was worked. The dirt was unloaded by the railway company in widening fills or grade raising just as was most convenient, depending on the progress of the gangs and the time of revenue trains. The contractor was paid 7 cts. per cu. yd. pit measure for dirt loaded on cars and the following costs were for loading alone. The shovel used was a 70-ton Giant with a 2-cu. yd. dipper.

About 1½ gals. of cylinder oil at 40 cts. per gallon were used per day and 2 gals. of black oil at 10 cts. per gallon. The daily expenses were as follows:

Engineer @ $150.00 per month	$ 6.00
Craneman @ $90.00 per month	3.60
Fireman	2.00
Watchman	1.85
6-ground hands @ $1.50 per day	9.00
Total labor	$22.45
Cylinder oil	$ 0.60
Black oil	0.20
Waste	0.10
1 ton coal	1.50
Int. at 6 % on $10,000	2.00
Total	$26.85
Grand total	49.30

The shovel loaded 45 cars of 24 cu. yds. per car or 1080 cu. yds. per day, giving a cost of 4½ cts. per cu. yd.

Sand for Ballast.—Two sand pits were opened up, one on each side of the main line, and the lead track to each pit was used as a loading track. A 60-ton Marion shovel was cut into one pit and a 45-ton Vulcan shovel into the other pit. Three work trains were used for spotting cars, hauling and unloading. Each crew handled different parts of the work depending on the arrival of the unloading trains and the speed of loading. One crew usually spotted cars for both shovels. This was done very easily because of the frequent moves of the shovels due to the shallow face of the cut. The sand was a white sand containing about 20 per cent loam. It made a very satisfactory ballast for light traffic. Hart convertible cars were used and were unloaded by Lidgerwood and plow on new track. A large amount of time was lost due to the slow running necessitated by the very rough track.

The following was the total output of the 60-ton Marion for 22 working days in July, 1,075 cars or 29,008 cu. yds.

The number of days worked was 22 or 220 hours, during which time there were 91 hrs. 45 mins. delays distributed as follows:

Cause	Hrs.	Mins.
Moving shovel	23	55
Waiting for cars	53	10
Closing car doors	4	35
Coal and water	5	50
Derailments	3	20
Shovel repairs	0	55
Total	91	45

The following was the output of the 45-ton Vulcan shovel for 7 day's work, 235 cars or 7,570 cu. yds.

The number of days worked was 7 or 70 hours during which time the delays amounted to 49 hrs. 43 mins. distributed as follows:

Cause	Hrs.	Mins.
Moving shovel	7	8
Waiting for cars	28	20
Tank repairs	7	0
Shovel repairs	7	0
Derailments	0	15
Total	49	43

Summarizing the work of the two shovels we have:

Item	60-Ton	45-Ton
No. cars loaded	1,075	235
Cu. yds. loaded	29,008	7,570
Av. no. cars per day	43¾	33½
Av. cu. yds. per day	1,318.5	1,081.4
Av. cu. yds. per car	27.2	32.2

The face worked averaged 10 ft. and the haul was 10 miles.

In August the two shovels worked more nearly the same amount of time. The total working time of the 60-ton shovel was 26 days or 310 hours during which time there were the following delays:

60-ton Marion

Item	Hrs.	Mins.
Moving shovel	43	0
Waiting for cars	82	30
Waiting for laborers	29	0
Waiting on track work	6	25
Miscellaneous	10	0
Total	170	55

45-ton Vulcan

Item	Hrs.	Mins.
Moving shovel	35	0
Waiting for cars	45	30
Waiting for laborers	20	0
Waiting on track work	15	0
Waiting for power	20	0
Repairing shovel	27	0
Miscellaneous	12	0
Total	174	30

Summarizing the work of the two shovels we have:

Item	60-ton	45-ton
No. cars loaded	1,268	1,046
No. cu. yds. loaded	33,486	30,710
Av. cu. yds. per day	1,272	1,121
Av. cars per day	48⅘	40
Av. cu. yds. per car	26½	28⅔

The total yardage for the month for both shovels was 63,196 cu. yds. The cost of loading, transporting and placing this material in the track was as follows:

Item	Total	Per cu. yd.
Loading	$ 1,207.65	$0.019
Transporting	2,973.74	0.0464
Surfacing	9,504.71	0.1504
Fuel and supplies	4,761.56	0.0753
Rental equipment	3,422.07	0.0541
Supervision	1,116.30	0.0183
Total	$23,031.03	$0.3635

The face averaged 8 ft. and the haul was 10 miles.

Cost of Unloading, Spacing and Renewing Ties.—D. A. Wallace gives the following data in Engineering and Contracting, Aug. 10, 1910.

Unloading Ties.—(1) Ties were unloaded from work train while running, with negro labor at $1.10 per day and foreman at $50 per month. Work train cost $25 per day. Six men unloaded 250 ties from a coal car in 30 mins. at the following cost:

Train service, 30 mins	$1.04
Labor, 30 mins	0.45
Total	$1.49

This gives a cost per tie of 0.6 cts.

Thirteen men unloaded 970 ties from 3 box cars in 2 hours. Four men per car were worked with one to follow. The cost was as follows:

Train service, 2 hrs	$ 6.24
Labor, 2 hrs	5.35
Total	$11.59

This gives a cost per tie of 1.2 ct. It will be seen that it cost twice as much to unload from box cars as from coal cars.

2. Work train unloaded 9 cars carrying 2100 ties on a run of 106 miles, picking up section gangs and unloading in spots. Cars were coal cars and train was called at 6:15 a. m. and tied up at 6:15 p. m. Negro labor at $1.10 per day and foreman at $50 per month were employed. The expense per day was as follows:

Work train, including coal, oil, etc	$28.80
Labor	4.40
Foremen	1.00
Total	$34.20

The train was in service 12 hours as follows:

	Hrs.	Mins.	Fraction of day
Delays	3	35	0.300
Unloading time	2	13	0.184
Running time	6	12	0.516
Total	12	00	1.00

The cost of unloading per tie was, therefore, as follows:

Delays	0.48 ct.
Unloading time	0.29 ct.
Running time	0.83 ct.
Total	1.60 cts.

Tie Renewals.—When track is being surfaced out of face in two raises the renewal of ties during the first raise consumes too much time and should be done during the second raise. The following gang organizations were employed in the work for which the records are given.

Good Surface; Foreman and 4 Men; Not more than 2 Ties to Be Removed at a Place.—Foreman will loosen up the spikes on 4 ties on each side of the tie that is to be removed; 2 men can be used in thoroughly cleaning the ballast from around the tie that is to be removed; the other 2 men should each have a jack to raise the rail, so as to let the tie come out easily, without disturbing the general surface. The 4 men should then slip in the new ties, working in pairs. The foreman should drive the spikes home as soon as possible in order to keep the track safe, and should dress up the track.

Foreman and 6 Men; Smoothing Track; 7 or 8 Ties per Rail Length.—Gang as follows: 2 men with jacks, 2 men with claw bars, 2 men pulling ties out of track. Where 3 or 4 ties together come out the foreman should put in the middle tie and spike it to keep the track safe. When about 20 ties are removed the gang should go back and full-tie the track, care being taken not to disturb ties that are not to be taken out of the track, even if it is necessary to loosen up the spikes on 3 or 4 ties on each side of the tie to be removed. Spikes should not be pulled all the way out, and ties left in track should not be raised more than ¼ in. Only 20 ties should be removed at a time before new ties are put in, for the reason that the gang may be picked up by a work train or called away suddenly for some reason and the work be left in bad shape for the regular trains. As the new ties are being put in place the gang can smooth up.

The following are records of tie renewals:

1. An average of 4 ties per rail renewed during a 7-in. raise in rock ballast, with Italian labor at $1.25 per day and foreman at $60 per month. The ties were 7 × 9 ins. × 8½ ft. The average was 11 ties per man day; the best day's work was 20 ties per man day.

The cost of renewing 1 tie was $0.104.

2. Ties put in during a 3-in. raise in rock ballast by section gangs, with negro labor at $1.10 per day and foreman at $50 per month. Ties were 6 × 8 ins. × 8 ft. The best record was 19½ ties per man day; the average was 14 ties per man day.

The cost of renewing 1 tie was $0.08.

3. Ties renewed in rock ballast during a 2-in. raise by section gangs working negroes at $1.10 per day and foreman at $50 per month. The ties were 6 × 8 in. × 8 ft. The best record was 17.5 ties per man day; the average was 13.3 ties per man day.

The cost of renewing 1 tie was $0.082.

4. Ties renewed during a 7-in. raise in rock screenings, working Italians at $1.25 per day and foreman at $60 per month. Ties were 7 × 9 ins. × 8½ ft. The best record was 16 ties per man day, the average was 12.7 ties per man day.

The cost of renewing 1 tie was $0.098.

5. Ties renewed in 2-in. slag by section gangs working white labor at $1.10 per day and foreman at $50 per month. Ties 6 × 8 ins. × 8 ft. The best record was 17.9 ties per man per day, the average was 13.1 ties per man day.

The cost of renewing 1 tie was $0.083.

6. Ties renewed in 2-in. surface gravel working white labor at $1.10 per day and foreman at $50 per month. Ties 6 × 8 ins. × 8 ft.

The best record was 18.2 ties per man day, the average was 13.5 ties per man day.

The cost of renewing 1 tie was $0.08.

7. Ties renewed during rock smoothing working negroes at $1.10 per day and foreman at $50 per month. Ties 6 × 8 ins. × 8 ft. The best record was 17.8 ties per man day, the average was 12.5 ties per man day.

The cost of renewing 1 tie was $0.088.

Spacing Ties.—The spacing of ties in rock ballast in the following record was a good average of the work done on several miles. The ties were special following the first raise and just before the ballast for the second raise was unloaded. The tie spacing in stripped track was done just before the unloading of the ballast for the first raise. Negro labor at $1.10 per day and foreman at $50 per month were worked. The record is as follows:

No. ft. track	No. days worked	Kind of ballast	Feet per man per day
430	15	Rock	28½
495	12	Rock	40
430	9½	Stripped	45
365	6	Stripped	60½
330	5	Stripped	66

One man spaced 6 joints per day in rock ballasted track, no raise, and rail laid broken jointed.

Amounts of Creosote and Zinc Chloride for Cross Ties.—The following table, reprinted in Engineering and Contracting, Dec. 15, 1920, from the Nov. 20, 1920, Cross Tie Bulletin of the National Association of Railroad Tie Producers shows the board feet and cubic feet per tie, number of ties per 1,000 board feet, gallons of creosote and pounds of zinc chloride per 1,000 ties under specified treatments for the more common sized sawed ties. The table was compiled by E. M. Blake:

Dimension	Board ft. per tie	Cu. ft. per tie	No. of ties per 1,000 board ft.	Gals. of creosote per 1,000 ties, sp. grav. 1.0436, or 8.7 lb. per gal. treated under Rueping process 5.5 lb. per cu. ft.	6.0 lb. per cu. ft.	Lbs. of zinc chloride per 1,000 ties at ½ lb. per cu. ft.
LENGTH, 8 FT.						
6″ × 8″	32.00	2.66	31.25	1,686	1,839	1,333
7″ × 8″	37.33	3.11	26.80	1,967	2,146	1,555
7″ × 9″	42.00	3.50	23.80	2,212	2,414	1,750
7″ × 10″	46.66	3.88	21.43	2,459	2,682	1,944
LENGTH 8 FT. 6 IN.						
6″ × 8″	34.00	2.83	29.41	1,791	1,954	1,417
7″ × 8″	39.66	3.31	25.21	2,091	2,281	1,654
7″ × 9″	44.62	3.73	22.41	2,351	2,565	1,860
7″ × 10″	49.58	4.13	20.17	2,612	2,850	2,066

Treated Ties Reduce Maintenance Expense.—C. A. Morse, Chief Engineer of the Chicago, Rock Island & Pacific Ry., speaking on maintenance of way labor before the Roadmasters and Maintenance of Way Association at Chicago, Sept. 17, 1919, made the following statement, which is given in Engineering and Contracting, Oct. 15, 1919.

Today the railroads that began using treated ties 10 years ago are reaping the benefit of the investment in big figures. They are averaging about 200 ties to the mile of all tracks, while the average number of ties used on a road where treatment has not been used is over 300 per mile of all tracks.

This means that a railroad that is using 2,000,000 treated ties per year would have to buy 3,000,000 ties had they not adopted tie treatment ten years before. This means $1,000,000, at the price that ties cost today, for the ties alone, and much more than that—it means saving the cost of transportation, the cost of unloading and the cost of the insertion of a million ties; and the saving on insertion alone, which at this time is from 32 to 40 cts. per tie, is a saving of from $320,000 to $400,000 of expense. There is yet another saving: one has disturbed his track in only two-thirds as many spots, and there is the saving of much retamping required later to get the track as solid as it was before the new tie was inserted.

Treated ties should be adzed and bored by adzing and boring machine before treating. This insures the seat for both rails being in the same plane and gives a full bearing for the tie plates, as tie plates should always be used on both treated and untreated soft wood ties, and on all treated hardwood ties.

The Most Economical Tie for Different Conditions of Track and Traffic.—Much information on the length of life, first cost and annual cost of railroad crossties of various classes under various conditions is contained in a circular and key of instructions on the use of crossties issued by the Baltimore & Ohio Railroad. The following notes published in Engineering Record, May 27, 1916, are taken from the April-June issue of *Wood-Preserving*, which devotes three pages to the circular. The circular is based on an extended investigation, in which the experiences and opinions of both engineers and trackmen were utilized. The instructions were prepared, it is stated, to define the most economical tie for every condition of track and traffic, and to assist in the most economical distribution of ties.

The circular divides ties into five classes according to kind of wood. Class A embraces white, burr and chestnut or rock oak, cherry, mulberry, black walnut and locust (except honey locust). Class B includes chestnut only. Class C includes red, black, scarlet, Spanish, pin and shingle or laurel oak, also honey locust, beech and hard or sugar maple. Silver, soft or white maple, red, soft or swamp maple, red or river birch, sweet or black birch and white, rock and red elm make up class D, while pines—short leaf, loblolly and sap long leaf—form class E. Classes A and B are used without, classes C, D and E with preservative treatment.

As to size, class A has three grades, 7 or 6 × 8 in., 6 × 7 or 6 × 6. The other classes have two grades only, 7 or 6 × 8 and 6 × 7. (Class E ties are respectively 7 × 9 and 7 × 8.) Attention has also been given to length, as this has an important bearing.

Table V gives estimated life lengths for all classes, grades and lengths under various conditions of traffic. It also shows where these classes and grades are and are not used. It will be noted that the use of tieplates adds materially to the life length. The instructions stipulate that all treated ties should be tieplated.

Table VI gives the detailed first cost to the Baltimore & Ohio for the various 8½ ft. classes of ties, and derived therefrom, the annual costs, with interest figured at 6 per cent.

TABLE V.—ESTIMATED LIFE OF TIES IN YEARS UNDER VARYING CONDITIONS OF TRAFFIC

† Not tieplated.

Organization for and Progress of Laying Rail with Locomotive Cranes.— The Lehigh Valley R. R. has developed a rail laying method, in which has been incorporated the use of such labor saving equipment as locomotive cranes, air compressors and drills, etc., which has resulted in increased output and reduced costs. With this method daily averages are being made of from 80 to 110 rail length per hour, all completely bolted, spiked, etc., and ready for service, while in special instances as many as 159 rails have been laid in one hour. The following, is from a description of the method given in Railway Age, as abstracted in Engineering and Contracting, Jan. 19, 1921.

In conducting this work the necessary labor has been secured by assembling the section forces employed in the locality where the rail is to be laid. The work in then so planned as to be carried on in a series of progressive stages or steps, such as, pulling spikes, throwing out old rail, etc., each step being assigned to a required number of men. In practically all but a few cases the individual gangs or sub-divisions of the forces are composed of section gangs complete with their foremen or multiples thereof. The foremen work with their men as well as supervise them. This feature in itself has been found to speed up the work materially.

With the forces and equipment assembled and all assignments understood the track upon which rail is to be laid is taken over completely and operations commenced. During the period of laying the remaining track is operated as a single track section. Through the close co-operation of the operating department little delay has been caused by the adoption of this method, even under comparatively heavy traffic. It is a question whether or not the delays caused by laying rail under traffic do not equal or exceed the delays when the track is given over entirely.

As stated before, the method is based on progressive steps with all new materials distributed previously along the section to be laid. The old track is not disturbed under any circumstances until the time when it is taken over. The sequence of the various stages is in general as follows: Joints are broken every 10 rail lengths, spikes pulled, one rail thrown out, old tie plates removed, creosoted wood plugs placed in old spike holes, ties adzed, new tie plates placed, new rail laid with locomotive crane, rail center spiked and gaged, joints placed and bolted, holes drilled and bond wires installed, track gaged and full spiked, signal connected up and work generally finished up.

Where one crane is used a force of about 200 men are required to keep the crane working to its capacity and the work proceeds one rail at a time, the crane being moved back to the point of starting at the completion of laying of the first line of rail and starting on the second rail. With two cranes a duplicate organization follows the first crane preparing the other rail for the second crane, both of which are followed by a finishing gang of about double the size.

Rail bonding is carried on by means of portable units of air compressors and their drills. One compressor generally handles four drills requiring a crew of six men. The saving of labor in this item has been very marked and a much greater output has been obtained in addition to increasing the life of the drills from five to eight times. In connection with this class of equipment several pneumatic wrenches were tried out recently for the purpose of running up the nuts on the track bolts. The average time consumed for running up one 6-bolt splice and moving to the next was about 30 seconds.

Figuring on a one-crane basis, as any multiple up to four can be used efficiently on one set of tracks provided there are sufficient men available, the following is a typical organization in detail: The men comprising this organization are listed in the exact sequence under which they pass over the track.

A TYPICAL ONE-CRANE ORGANIZATION
ADVANCE WORK

3 men removing every tenth joint on the old rail.
24 men pulling spikes. This includes 2 foremen.
14 men swinging out old rail. Two foremen with section gangs.
3 men throwing out old tie plate.
3 men placing creosoted tie plugs in spike holes.
2 men driving creosoted tie plugs in spike holes.
12 men adzing ties. One section foreman included.
2 men sweeping off ties after adzing.
5 men placing new tie plates. One foreman included.

This covers the preparatory work for the crane, which has the following organization:

4 men on rail, two on each end to steady and guide it into place.
1 man on crane hook. The foreman in charge of crane forces.
1 man on expansion template.
2 men driving spikes on inside of new rail.
2 men driving spikes on outside of rail after laid.
1 man with lining bar to bar rail to place as laid.
2 men operating crane. The operator and fireman.

The locomotive crane was followed by the following gang:

1 man adzing joint ties for a 1 to 20 cant.
10 men placing new joints. Two foremen included.
5 men removing rail anchors from old rail.
1 man placing insulated joints.
12 men gaging new rail.
34 men full spiking.
30 men bolting up joints.

This was followed by the bonding layout and the finishing gangs:

4 men operating air drills.
2 men operating motor cars and distributing bond wires.
1 man operating air compressor.
2 men bonding new rail.
5 men clearing out for rail anchors. One foreman included.
5 men placing new rail anchors. One foreman included.
2 men operating motor cars, two trailers with extra tools, etc.
3 men checking up on tie plates, spiking and joints, etc. One foreman included.
3 men carrying drinking water.
1 man charging wire at signal connections.
1 man soldering signal connections.

With the experimental introduction of the pneumatic wrenches the organization was changed slightly from that shown above, the 30 men assigned to bolting being removed and the following substituted for them:

2 men on pneumatic wrenches.
1 man tapping joints into place.
1 man on air hose.
1 man operating motor car.
1 man operating air compressor.

In the particular instance mentioned above a stretch of track between two switches located nearly 2½ miles apart was laid with 136-lb. rail in a total elapsed time of 7 hours 10 minutes, or at the rate of 107 rail lengths per hour for a total of 770 rails. The force shown totals up to 205 men in the first case and 180 men with the introduction of the wrenches.

Cost of Unloading Railway Rails.—D. A. Wallace gives the following data in Engineering and Contracting, Aug. 10, 1910.

For short jobs of rail unloading with men not used to the work and where the ground is smooth, there is no objection to unloading from the sides of the car, provided, of course, that both ends of the rails are released together.

The following are records of unloading rails:

1. The 70-lb., 33-ft. rail was unloaded from the sides of gondola and flat cars by section gangs which had no experience in handling new rail. Two rails were dropped at a place, then the train moved ahead one rail length and the operation repeated.

When unloading gondola cars, one man followed the train to straighten out an occasional rail lying too close to the track; the remainder of the gang unloaded the rails by hand with the assistance of 2 men at each end of the car with lining bars.

Rail unloaded from flat cars was rolled off the sides, using lining bars and shovels. Two men at each end had lining bars and the remainder had shovels. As soon as the bar men had started the rail they were assisted by the shovelers, one bar man at each end always using his bar as a skid, keeping the rail up from the floor, thus giving leverage to the shovel men. One man followed the train to straighten out rails lying in a dangerous position.

Negro labor at $1.10 per day was employed, with foreman at $50 per month. The work train cost $25 per day. The cars unloaded were as follows:

	Rails
Gondola car	84
Gondola car	84
Gondola car	113
Flat car	113
Total	394

The time required for unloading was 3 hrs. 50 mins., and the cost was as follows:

18 men at $1.10 per day	$ 7.59
3 foremen at $50 per month	1.84
Work train	25.00
Total	$34.43

This gives a cost of 8.7 cts. per rail and of $27.84 per mile of track.

2. In the record which follows no charge was made against the Road Department by the Transportation Department for roadway work performed by revenue trains other than overtime made by trains doing the work and in this case the revenue business was light and no overtime was made. The cars unloaded were:

	Rails
One gondola car	84
One gondola car	113
One flat car	113
Total	310

The working time was 1 hr. 30 mins. and the cost was as follows:

13 men	$2.14
4 foremen	0.96
Total	$3.10

This gives a cost of 1 ct. per rail and of $3.20 per mile of track.

3. In the following record a comparison is made between the time of unloading gondola and flat cars. The time of unloading the gondola cars was as follows:

1 car	113 rails	1 hr. 0 mins.
1 car	113 rails	1 hr. 0 mins.
1 car	84 rails	2 hrs. 14 mins.
3 cars	310 rails	4 hrs. 14 mins.

The time for unloading 5 flat cars was:

1 car	141 rails	35 mins.
1 car	114 rails	30 mins.
1 car	78 rails	20 mins.
1 car	73 rails	20 mins.
1 car	76 rails	25 mins.
5 cars	482 rails	2 hrs. 10 mins.
Grand total unloading time		6 hrs. 24 mins.
Delays		1 hr. 42 mins.

In comparison the time per rail and per mile of track was as follows:

1 car 113 rails.. 1 hr. 0 mins.

Item	Gondola	Flat
1 rail, time required	.81 min.	.27 min.
1 mile, time req'd	4 hrs. 20 mins.	1 hr. 25 mins.

Therefore it costs three times as much to unload rails from a gondola car as it does from a flat car.

Where rail was unloaded from flat cars it was customary for half of the gang to unload from one side and half to unload from the other. This was a very good method, as there was always a rivalry between the two gangs, each to unload its half first so that the few bottom rails in the center of the car would be left for the slower gang to unload. The cost of unloading the eight cars, 792 rails, was as follows: The wages for labor were $1.10 per day and for foreman $50 per month, but as the work was done on Sunday time-and-a-half was paid the men. The cost was therefore:

17 men at $1.65 per day	$28.05
4 foremen at $50 per month	6.66
Work train	25.00
Total	$59.71

This gives a cost of 7.5 cts. per rail and of $24 per mile of track.

Summarizing the costs of records 1, 2 and 3 given above, we have:

(1)	394 rails unloaded at	$34.43
(2)	310 rails unloaded at	3.10
(3)	792 rails unloaded at	59.71
	1,496 rails unloaded at	$97.24

This gives a cost of 6.5 cts. per rail and of $20.80 per mile of track.

4. Generally rails are piled on a car in layers. In each layer the rails are placed alternately head up and head down, the head of one rail being always overlapped by the base of the adjacent rail. In this case the rails were loaded loosely on a flat car, with just enough straightening around to put them parallel with the sides of the car. In unloading these rails no difficulty was experienced in loosening up a rail such as is oftentimes the case when rails are piled tightly in layers.

Negro labor at $1.10 per day and foreman at $50 per month were worked. A gang of 10 men unloaded 90 85-lb. rails in 45 mins. The cost of the work was as follows:

Train service	$1.56
Labor	1.05
Total for 90 rails	$2.61

This gives a cost of 2.9 cts. per rail or of $9.30 per mile of track.

Time Tests of Loading 65-lb. Rail on Flat Car by Hand.—A. M. Van Auken gives the following data in Engineering and Contracting, Dec. 17, 1919.

The work was done near Ypsilanti, Mich., on the Michigan Central R. R. on April 12, 1917, the gang consisting of the following:

1 foreman at	$90.00 per month
1 timekeeper at	75.00 per month
1 cook at	2.10 per day
1 water boy at	2.10 per day
15 laborers at	2.10 per day

The equipment consisted of two hand cars.

The gang was surfacing tracks near Milepost 29 until 11:30 a. m. It then knocked off for ½ hour for dinner. The transporting of the men consumed 40 minutes for a distance of 3 miles to a point (Milepost 32) on the main track opposite the pile of rails to be loaded.

The material loaded consisted of 102 odd lengths of used rail including 2,756 ft. of 65-lb. rail and 20 ft. of 80-lb. rail.

The labor time distribution was as follows:

Left mile post 29 at 12:00.
Arrived mile post 32 at 12:40.
Loaded rail and lumber from 12:40 to 3:45; this includes delays.
Left mile post 32 at 3:45.
Arrived mile post 29 at 4:10.

Delays in loading the rails were as follows:

	Mins.
Stopped at Ypsilanti station for foreman to receive reports of trains	8
Removing hand cars from track	2
Walking from hand cars to where rails lay	5
Waiting for rails to be measured before placing on flat car	9½
Moving flat car about 10 ft.	3
Moving flat car about 2,000 ft. (rails were in two piles about 2,000 ft. apart)	22
Loading lumber	35

The latter item involved the loading of 42 pieces of 3 in. × 10 in. × 16 ft. planks in a box car. The lumber lay opposite the pile of rails so no time was lost in moving from rail to lumber. The results of a test made to determine the time required to lift and throw 10 rails on flat car follow:

15 sec.	27 sec.
38 sec.	40 sec.
65 sec.	35 sec.
18 sec.	20 sec.
22 sec.	27 sec.

It will be noted that it took 307 seconds to load the 10 rails (25 to 33 ft. long). This gives an average of ½ minute for loading each rail.

The average time of loading each of the 102 lengths, delays deducted, was 59 seconds. In other words, while under direct time observation, men doubled their output.

Loading Rails with Ditcher at Cost of 2 Cents per Rail.—Engineering and Contracting, Oct. 16, 1918, publishes the following:

By using a railroad ditcher the Crowell Spencer Lumber Co., of Longfileaf, La., was able to load 60-lb. rails from piles onto flat cars at a cost of about 2 cts. per rail. The crew consisted of the ditcher operator, fireman, and a section crew of 3 men and foreman. Its duties were:

One man operating ditcher.

One fireman. As wood was burned, it was his duty to keep a supply of it on the ditcher.

One man to put stakes in pockets, carry water and load spikes and angle bars.

One man on car to keep rails straight and unhook tongs. Frequently entire cars were loaded without it being necessary to unhook the tongs even once. When the operator dropped the rail 1 or 2 feet the tongs usually let go themselves.

One man on the ground to hook the tongs.

One foreman, who kept the rails turned ball up.

This crew with the American ditcher loaded 2,083 rails in 3 days, the actual working time being 4½, 5½ and 6 hours. The ditcher was on its own flat car and loaded onto empties set in front and behind it. The daily cost of the rail loading, according to the American Ditcher Scoopings, was as follows:

Ditcher operator	$ 5.00
Ditcher fireman	2.50
3 laborers at $2.50 each	7.50
Gang foreman	3.25
Fuel (wood)	1.00
Oil, waste, etc	.50
Total	$19.75

Cost of Loading Rail from Roadbed to Cars.—D. A. Wallace gives the following data in Engineering and Contracting. Aug. 3, 1910.

1. The rail was lying on the shoulder of the grade, just as it had been thrown out from the track and disconnected. One pair of angle bars was fastened to each rail by two bolts. Two men with lining bars kept the rails straightened out on the flat car as they were loaded. The train was followed by two men who picked up any loose scrap that might have been left behind. A work train and a gang of 40 men were used; the labor was negro, at $1.25 per day, and foreman at $60 per month. A total of 429 rails was loaded in 3 hrs. 2 mins. at the following cost:

Train service	$25.00
Labor	20.00
Foreman	0.66
Total	$45.66

This gives in round figures a cost of 10 cts. per rail loaded. The work was costly, due to the fact that the banks were very narrow, permitting the rail in many instances to slip down to the bottom of the fill. The work was also hindered by a growth of high weeds.

2. The rail was disconnected with angle bars lying alongside. One man loaded the angle bars and scrap bolts on the rear car; 2 men with lining bars

kept the rail straightened on the flat car as it was being loaded; 11 men loaded the rail on one side of the car until half the load was placed, then the train was backed up while the other side of the car was loaded. The rail was 56-lb. rail left lying along the shoulder; 6 flat cars with a capacity of 100 rails each were loaded. A total of 800 rails was loaded at the following cost:

Train service	$25.00
Labor	20.00
Total	$45.00

This gives a cost of 5.6 cts. per rail or of $19.71 per mile of track. This same crew loaded and unloaded 400 rails with the same shipment. In unloading the rail two greased rails were used as skids. Six men were on the car to start the rails, and 8 men were on the ground to straighten them up in piles. The cost of the work was 11.3 cts. per rail or $39.77 per mile of track.

3. The rails were lying on the shoulder of the grade, disconnected, as taken from the track. A force of 22 men, 18 per rail, and 4 on the car, loaded 160 58-lb. rails in 2 hrs. 45 mins. The rate of wages was negro labor at $1.20 per day and foreman at $60 per month. The cost was as follows

Train service	$ 5.53
Labor	5.12
Total	$10.65

This gives a cost of 6.6 cts. per rail or of $20.25 per mile of track.

4. A gang of 24 men loaded rails into end of gondola car from pile 15 ft. from the track; 16 men to a rail and 8 men on the car. A total of 100 rails were loaded in 1 hour 40 mins. or 1 rail per minute. The labor was negro at $1.25 per day, and foreman at $60 per month. It cost to load the 100 rails $5.30 or 5.3 cts. per rail.

Cost of Tracklaying with Tracklaying Machine.—D. A. Wallace gives the following in Engineering and Contracting, Aug. 3, 1910.

The work was done by contract in June, 1907, on the Frisco line in Louisiana. The record is a poor one, due to faulty working organization. The average day's work was 6,000 ft., full teed, bolted and spiked. Work was greatly delayed on account of the poor handling of material in material yard. A 35-mile run was necessary for the night crew to bring the angle bars and spikes to the front for the next day's work.

The outfit equipped for each half-day's work consisted of a pioneer car, 5 flat cars loaded with 300 ties each and 2 flat cars loaded with 90 rails each.

Two train crews were used. The day crew came on duty at 6 a. m. and was released at 6 p. m. by the night crew, which had had supper when the day crew returned with the gang from the front. The night crew then ran to Eunice, 15 miles, filled up the tank car, left flat cars spotted for loading ties and rails and ran to Opelousas, 20 miles further, for angle bars and spikes, returning to camp with train made up for first half-day's work at 6 a. m. The day crew returned to camp at 12 noon for dinner, getting back to the front at 1 p. m. During the noon hour the night crew switched out the empty tie and rail cars and picked up the loaded tie and rail cars ready for the afternoon's tracklaying. Lining gang handled the back switch work.

The force itemized in the following table was needed to lay 6,000 ft. of track. This force may be reduced to 90 men by half bolting and spiking the track, the track work being done on days when there is delay to the material. The gang required was as follows:

Item	Per day
1 general foreman at $150 per mo.	
1 timekeeper at $75 per mo.	
1 commissary clerk at $90 per mo.	
Total	$ 10.50
Front Gang:	
1 straw boss at $2.25	$ 2.25
1 rope man at $1.75	1.75
1 chain and puddle man at $1.75	1.75
18 men (9 on a side) at $2	36.00
1 spike puller at $2	2.00
1 bolt puller at $2	2.00
23 men. Total	$ 45.75
Machine Gang:	
1 foreman and board at $3	$ 3.00
1 rail feeder at $2	2.00
1 angle bar man at $2	2.00
2 rail pullers at $2	4.00
4 tie buggy men at $2	8.00
6 laborers (3 on side) at $2	12.00
15 men. Total	$ 31.00
Ground Gang:	
1 foreman and board at $3	$ 3.00
1 bolt puller at $1.75	1.75
1 spike puller at $1.75	1.75
2 bridle rod men at $1.75	3.50
2 wrench men at $1.75	3.50
2 jack men at $2	4.00
8 tie spacers at $1.75	14.00
6 gage men at $1.75	10.50
1 maul man at $1.75	1.75
1 bar man at $1.75	1.75
16 spikers at $2	32.00
8 nippers at $1.75	14.00
2 water boys at $1.50	3.00
51 men. Total	$ 94.50
Lining Gang:	
1 foreman and board at $3	$ 3.00
8 liners at $1.75	14.00
1 water boy at $1.50	1.50
10 Men	18.50
Night Loading Gang:	
12 laborers at $1.75	$ 21.00
Camp help:	
1 head cook at $100 per mo	$ 3.30
1 second cook at $35 per mo	1.15
1 flunkey at $30 per mo	1.00
3 flunkeys at $25 per mo	2.50
1 yard man at $40 per mo	1.35
1 camp woman at $40 per mo	1.35
8 Total	$ 10.65
Train Crew:	
2 engineers and board at $100 per mo	$ 6.70
2 firemen and board at $60 per mo	4.00
1 conductor and board at $100 per mo	3.30
2 brakemen at $60	4.00
7 men. Total	$ 18.00
Miscellaneous expenses:	
1 pioneer car, rent $25 per mile	$ 23.40
Rent, equipment, coal, waste	10.00

Summarizing, we have the following:

Item	Per day
Pioneer car	$ 23.40
Gen. foreman, timekeepr and clerk	10.50
Front gang	45.75
Machine gang	31.00
Ground gang	94.50
Lining gang	18.50
Night loading gang	21.00
Camp help	10.65
Train crew	18.00
Equipment, coal, etc	10.00
Total	$283.30

To be deducted from this total are the following amounts:

Item	Per day
Receipts from board	$ 50.00
Commissary profits	12.00
Total	$ 62.00
Net daily expenses (283.30—$62)	$221.30

The contractor received $275 per mile for tracklaying, or for 6,000 ft. of track laid per day, $312.40. His net income per day was $312.40—$221.30 = $81.10. On the basis of a net daily expense of $221.30 the cost per mile of track laid was closely $200.

Cost of Laying Track With Machine.—The following matter is taken from Engineering and Contracting, April 1, 1914.

The conditions affecting track laying are numerous and varying, and it would be practically impossible for anyone except an experienced contractor with well organized forces to attain the results shown by the data below. Forces which have been employed for years in as narrow or specialized a field as track laying, are bound to attain a high degree of efficiency, provided the management is the best, for a body of most able overseers is gradually collected, which assures wide, efficient and progressive supervision. If, in addition to the above, a concern builds up a reputation for paying the best wages and giving absolutely the best treatment possible, consistent with the work required, an asset of no small importance is added.

The track laying described herein was done by a force which showed the results of all the advantages mentioned above.

Make-up of Track Laying Machine Train.—When laying track, the train carrying the machine is made up as follows, beginning with the "pioneer car," which always remains at the "front," and is not changed out as are the other cars in the train. Immediately behind the "pioneer" are four cars of rails, then the locomotive, and behind that eight cars of ties; next comes a car of tie plates, when they are used, the "trailer," which is a car carrying spikes, bolts and base plates, a car of plank for crossings, a car of cattle guards, a tool car and the way car. This makes twenty cars, and all are flat cars except the two last mentioned.

The first car of rail behind the pioneer is "trimmed," that is, on it is loaded angle bars enough to lay the amount of steel carried on the train. The angle bars are carried forward over the pioneer car and delivered as needed to the "strap hangers" in front. The rails underneath the angle bars are the last ones laid from the train, in order that the angle bars may be cleared off by the time rails are needed.

A system of trams is used to carry the ties and rails to the front. The trams are made in sections, each 33 ft. long, the sides consisting of $2\frac{1}{2} \times 10$ in. planks. Tie trams are 14 ins. wide, and rail trams are 12 ins. wide. The trams are held together by bolts on which are pipe separators to hold the sides the proper distance apart. Near the bottom of the trams are live rollers, which complete a trough-shaped way for ties or rails.

On the pioneer car is installed a 20-h. p. upright engine for driving the live rollers in the trams; this is done by means of a tumbling shaft and gear or cog wheels. Steam for the stationary engine is piped from the locomotive. The shaft is fitted with "patent couplings," that is, on one end of each section is a casting containing a square socket into which the end of the next rod fits. Each length of tram has a section of the shaft bolted to it and as the trams are hung the rods are fitted together, thus forming a continuous shaft. The trams are "hung" on iron brackets or trusses which hook into the stake pockets on the cars. The trusses are made with flange rollers on which the trams are placed, thus taking care of the slack of the train in starting and stopping. The trams have a coupling device which holds them together, the ones on the pioneer being permanently fastened to the car.

The tie trams, 660 ft. long, are operated on the right hand side of the train. Those for the rail, 240 ft. long, are on the left. The movement of ties and rail is controlled by the "dinkey skinner," *i. e.*, the stationary engineer, so as to deliver them in front of the train as needed. A tie chute 53 ft. long provided with dead rollers is attached at the front end of the tie tram on the pioneer and through this chute the ties are pushed by the ones coming forward over the live rollers. And as fast as they are delivered at the end of the chute they are taken by the "tie buckers" (laborers) and are placed across the grade ready for the rails.

A similar chute attached to the rail tram provides a way for delivering the rail in front of the pioneer. These chutes are supported at the outer end by cables attached to the rear end of the pioneer car and carried up over a high frame work or "gallows" on the front end. A boom, also attached to the front end of the pioneer car, extends far enough ahead to have the cable attached to it reach the middle of the rail when placing it in position in track. This cable is operated by hand with an ordinary crab. Instead of cranks, a small, light buggy wheel is used by the operator to wind up the cable, which lifts the rail and holds it while the "heeler" and his assistants place it in position on the track. (A newer device handles the cable with compressed air). The rails are placed in the trams by three men, and are handled in front by six more. One man on each car places the ties in the trams. The spikes, bolts and base plates are peddled from the trailer as the train proceeds.

(The rails are held to gage by bridle rods until the train passes over, all spiking being done in the rear. The train moves ahead one rail length at a time when laying square joints, and half a rail length when laying broken joints. The trams are taken down when cars are empty and replaced on the loaded cars when a new train arrives; from 100 to 125 men are required for a full crew.

Material for the track machine is loaded by railway company forces, and great care is taken to have the material loaded, not only in correct proportion but in correct order and position on cars. A train, called the swing train, is then made up of sufficient material for a half day's work, and is transported to the front, or rather to the camp of the contractor, where it is placed in the most convenient place available for the track machine crew to pick up. The swing train crew then takes a train of empties and returns to the material yard. The track machine is served regularly by the same locomotive and train crew. As the track machine does not move ahead by its own power, a locomotive and train crew are required to remain with the machine onstantly.

Briefly, the movement of the machine is as follows in laying square jointed track: ties are trammed and carried ahead constantly and laid on the grade; the machine moves ahead, and a rail is chuted out and heeled in by the rail gang, and the angle bars bolted on loosely with two bolts only; a second rail is placed and held to gage by bridle rods; the machine is then moved ahead a rail length by the locomotive, and the operation repeated. When laying broken jointed track, the machine is moved ahead a half rail length at a time, thus requiring twice as many moves.

Back of the machine the bridle rods are removed, and enough ties are spiked to hold the rails from spreading. Spacing ties, bolt tightening and full bolting are all done behind the machine, and cause it no delay.

Organization of Gang.—A gang of 125 men will easily lay two miles of track per day, provided no unusual difficulties, such as soft grade, etc., are encountered. A gang of this size would be placed about as follows:

1 general foreman at, per day	$ 5.00
1 ass't foreman, with rail gang, at, per day	3.50
1 ass't foreman, watching trams, at, per day	3.50
1 ass't foreman, with spikers, at, per day	3.50
1 ass't foreman, lining track, at, per day	3.50
1 stationary engineer at, per month	75.00
1 pole man at, per month	75.00
1 oiler at, per day	2.50
1 line man at, per day	2.25
16 "tie buckers" at, per day $2.25 and	2.50
2 tie spacers ahead of machine, at, per day	2.25
1 man fiddling ties, at, per day	2.25
6 "rust eaters," handling rail, at, per day	2.50
1 bridle man at, per day	2.25
1 heel nipper at, per day	2.25
2 strap hangers at, per day	2.25
1 man, carrying angle bars from "trimmed" car to pioneer car, at, per day	2.25
3 steel rollers, rolling rails into trams, at, per day	2.50
8 tie trammers rolling ties into trams, at, per day	2.25
2 spike peddlers, distributing spikes, at, per day	2.25
2 bolt and joint plate pedlers at, per day	2.25
2 "bridle men," carrying bridle rods from rear, at, per day	2.25
4 rear bolters at, per day	2.25
2 water boys at, per day	2.25
8 men spacing ties at, per day	2.25
1 gage man at, per day	2.25
32 spikers at, per day	2.50
16 nippers at, per day $2.25 and	2.50
8 liners at, per day	2.25

When the gang is smaller, the force behind the machine is cut down, and 70 men would be organized about as follows:

1 general foreman at, per day	$ 5.00
1 ass't foreman, with rail gang, at, per day	3.50
1 ass't foreman, watching trams, at, per day	3.50
1 ass't foreman, with rail gang, at. per day	3.50
1 ass't foreman on general work, at per day	3.50
1 stationary engineer at, per month	75.00
1 pole man at, per month	75.00
1 oiler at, per day	2.50
1 line man at, pe day	2.25
10 "tie buckets" at, per day	$2.25 and 2.50
2 tie spacers at, per day	2.25
6 rail handlers at, per day	2.50
1 bridle man at, per day	2.25
1 heel nipper at, per day	2.25
2 strap hangers at per day	2.25
1 man carrying angle bars at, per day	2.25
3 steel rollers at, per day	2.50
8 tie trammers at, per day	2.25
2 spike peddlers at per day	2.25
2 bolt and joint plate peddlers at, per day	2.25
1 bridle rod man at, per day	2.25
2 rear bolters at, per day	2.25
1 water boy at, per day	2.25
1 gage man at, per day	2.25
4 men spacing ties at, per day	2.25
12 spikers at, per day	2.50
6 nippers at, per day	2.50

During the work from which the cost data were obtained, the gang varied from about 50 to 100 men. The $2.50 laborers (spikers, nippers, and tie buckers) averaged about 40 per cent of the entire gang. During the 65 days the following expenses were chargeable against track laying:

Overhead charge on machine (interest at 6 per cent, depreciation at 10 per cent)	$ 100.00
Dinkey skinner, 2½ mos., at $100	210.00
Timekeeper, 2½ mos., at $85	177.00
Locomotive and crew, 65 days, at $40	2,600.00
Supervision and labor	8,710.00
	$11,797.00
Force account, or extras allowed	578.00
	$11,219.00
Average cost per mile	$ 280.50

This cost represents the cost to the contractor, plus the cost of the locomotive and crew at $40 per day. The latter charge should be added, however, as it represents a real part of the operation expense of the track machine.

The rail was a 90-lb. section. It was laid on white oak ties, spaced 18 to 21 under a 33 ft. rail on tangent, and 19 to 22 ties per 33 ft. on curves. The joints were made with ordinary angle bars with four bolts, and spring nut locks. The heads of the bolts were staggered, that is, alternate bolt heads were respectively on the inside and outside of rail. The number of ties per rail length were varied to suit their sizes—18 broad faced ties being used, or 21 narrow faced ties, on tangents.

The cost of transporting the machine and the men to the work is not included herein, the data given representing the costs after the machinery and the laborers were on the work.

An inspector was employed by the company, but although his expenses represent a charge against the track by the railway, it is not chargeable against the contractor's expenses.

Grading and Tracklaying with a Ditcher.—By using a railroad ditcher for grubbing, grading and for tracklaying, the Potlatch Lumber Co. materially reduced its construction costs and at the same time dispensed with a considerable force of laborers. The methods employed on this work are described by the Railway Review, from which Engineering and Contracting, July 17, 1918, gives the following abstract.

The main idea in building logging roads is to get the logs to the mill at the lowest possible cost and since the railroad is only temporary in character, considerable latitude is allowed in the construction methods used, the lines being laid out to tap the desired timber land and the ditcher put to work preparing the subgrade.

Where a small amount of filling is necessary the ditcher scoops up the earth alongside the line and dumps it ahead, where it is leveled off by laborers. As the work proceeds the ditcher is moved ahead under its own steam on a portable track built in short sections. Three short sections of track are used, the ditcher standing on two while the third is picked up from behind and swung around to the front with the boom. Ties 10 × 11 in. × 10 ft. long, and closely spaced, are used, and the sections are braced with diagonal pieces of ½ by 1½-in. strap iron held in place by ¾-in. wood screws and extending from corner to corner of the sections. In case a deep fill is required, to prevent too much of a sag in the track where sufficient earth cannot be reached alongside with the regular dipper, logs are pulled in with the boom to form a portion of the fill, and earth is then placed on the logs to build up the desired grade. In localities where the grading required is slight the timber is logged off the right-of-way, the stumps pulled and the necessary clearing done by the ditcher in addition to making the fill.

Side-hill cuts are made with equal facility, the Potlatch Lumber Co. having recently made an 8-ft. cut 300 ft. long on a 6 per cent grade. Fills as deep as 8 to 10 ft. on 4 per cent grades have also been made.

After the grade is completed the machine is run back over the line and mounted on a flat car with steel rails fastened to the deck to permit the necessary amount of shifting of the machine to pick up and handle materials from two cars in rear and place them in the track. In this manner the ditcher is used as a tracklaying machine. The 60-lb. rails, 33 ft. long, are loaded on the car next to the ditcher and the ties piled high on the second car. The dipper boom is removed, so as to allow the use of the machine as a crane, the only extra equipment required being two tie slings made from short lengths of cable with a hook at each end, and a pair of rail tongs.

Two men on the tie car make up bundles of ties which are picked up and swung around onto the grade ahead, where they are distributed, 17 ties to the rail, by a gang of six men. After placing the ties the rails are picked up from the car by center tongs of a special, non-teetering type, a man on the rail car hooking them to the rail. They are then swung around in front and heeled into the angle bars. Two men also put on the bridles to hold the rails in line and to gage until spiked. One man brings the angle bars forward from the front of the rail car and places them on the rails and another man bolts up the joints. One man is employed to carry the bridles ahead, to be used as fast as the rail is laid up to them. These, together with the operator and fireman of the ditcher, make a crew of 16 men required for laying track, the gang being made up as follows:

2 men on tie car.
6 men distributing ties.
1 man attaching rail hooks.
2 men heeling in rails and putting on bridles.
1 man carrying bridles.
1 man placing angle bars on rails.
1 bolter.
2 men to operate the ditcher.

In placing rails the ditcher, after swinging the rail around to the front, is run out to the end of the flat car on which it operates, so as to swing the near end of the rail slightly beyond the joint. The machine then backs up until the line that holds the rail hangs at a considerable angle, in which position the rail is easily heeled into the joint. The rail tongs are so constructed that they release as soon as the rail rests on the ties.

The spiking crew, working behind the machine, consisted of 2 boilers, 15 spikers and 1 spike peddler, a total of 18 men. Thus the total crew required to complete the tracklaying work numbers 34 men. As much as 3,000 ft. of track have been laid in a day by this crew on heavy grades and where trees on the right-of-way must be cleared off. On straight work, without clearing, it is estimated that one mile of track a day can be laid. By the use of the ditcher in this way the company saves the wages of 25 men at $3.50 a day that would otherwise have been required.

Cost of Making 2-In. Lift on Main Line Track.—A. M. Van Auken gives the following data in Engineering and Contracting, Nov. 19, 1919.

This work was done on April 9, 1917, on the Michigan Central R. R. The weather was clear and the temperature was about 50° F. A total length of 1,221 ft. of 3° curved track was lifted. In addition 62 ties were placed in track. The force was as follows:

1 foreman	$90.00 per month
1 assistant foreman	77.50 per month
1 cook	2.10 per day
1 timekeeper	75.00 per month
22 laborers	2.10 per day
1 water boy	2.10 per day
2 flagmen	2.10 per day

Of the above force the timekeeper, cook, water boy and the two flagmen are classed as "dead" labor.

The men left the bunk cars at 6:30 a. m., and began work at 7. They lifted track from 7 to 11:30, took half hour for lunch, and were engaged again from 12 to 4:30 p. m. in lifting track. They left the work at 4:30 and arrived at bunk cars at 5 p. m. It will thus be noted that the working time was 9 hours. However, there was a total delay of 40 minutes due to passing trains, which makes the actual working time 8 hours and 20 minutes.

The equipment used consisted of track tools and three hand cars.

The cost of the work was as follows:

	Per lin. ft. of track
Superintendency	$0.0038
Active labor	.0314
Dead labor	.0074
Delays to entire gang	.0077
Total, cost of 2-in. lift and replacing .05 of a tie	$0.0503

Cost of Renewing Rail.—The following data given by D. A. Wallace in Engineering and Contracting, Aug. 31, 1910, include various items of work besides rail renewal proper but all come within the same general classification.

Job 1.—Relaying 58-lb. with 85-lb. rail, full bolted, full spiked and gaged, with negro labor at $1.25 and foreman at $60 per month, in May, 1906. The work was done by a gang averaging 1 foreman, 31 men and 1 water boy. Delays include delays by trains and time spent in trucking badly distributed rail, etc. The angle bars were 6-hole, 4-in. bars. The work was full bolted, full spiked and completed each day. Connection for trains was made by using a short piece of old rail cut to fit and connected with the new rail by a compromise joint The average number of feet of rail laid per day with the gang of 33, as noted above, was 1305 ft. with an average of 3.5 hrs. delay.

The cost was $3.33 per 100 ft. of track or $176 per mile of track.

Job 2.—Owing to the narrow fills at some places, and to the amount of rock at others, it was occasionally necessary in unloading the rail to skid it off in piles and then redistribute it from the piles with the steel gang thus causing delays. There were also a few delays by trains. The rail was 56-lb. changed to 70-lb. and all rail was curved for curves of 5° and over. About one-fourth of the time was consumed in curving and tracking rail. One-half the entire distance was curves of 5° and over. The average for 24 days showed that a gang of 19.5 men (varying from 2 to 53) laid 945 ft. of rail per day with delays averaging 3.28 hrs.

Negro labor was employed at $1.15 and $1.25 per day and foreman at $75 per month. For the first nine days' work the rate was $1.15 and for the remainder of the time it was $1.25 per day. The cost of the work was as follows:

Item	Per ft.	Per rail	Per mile	Per cent
Unloading	$0.004	$0.13	$ 21.05	9.8
Curving	0.0054	0.179	28.66	13.4
Distributing	0.003	0.097	14.59	6.8
Laying	0.0283	0.936	149.80	70.0
Total	$0.0407	$1.342	$214.10	100.0

Applying Tie Plates.—The tie plates were applied to white oak ties on track in service. These plates were placed under the rail and settled with a sledge. After three or four days they were settled completely with a sledge. During this work, there were an average of 6 braces to a rail to remove. White labor was employed at $1.10 per day and foreman at $50. The best record was 140 plates per man per day, the average was 93 plates per man per day.

The cost of applying each plate was 1.1 ct.

Gaging Track.—(1) This record is of work done by season gangs. The track was in very poor gage due to sharp curvature and rotten white oak ties. In the majority of cases the rail was gaged on each tie. All old spike holes were plugged. Ties were adzed when necessary. The foreman made a hand in every case. There was an average of 6 braces per rail. Negro labor at $1.25 and foreman at $50 per month were employed. The best record was 275 ft. per man per day, the average was 205.4 ft. per man per day.

The total cost of gaging one mile was $28.30.

2. This record was made by a picked gang. Every tie was gaged and holes plugged. No rail braces were used as the track was on tangent. The gang consisted of 1 foreman at $50 per month and 4 laborers at $1.10 per day. On this work 2 men were placed drawing spikes and 2 men spiking, the fore-

man assisting in lining the rail, etc. This gang gaged 1,440 ft. in 10 hours, at a cost of $22 per mile.

Disconnecting Rail.—The work consisted in unbolting 30-ft., 4-bolt rail and in fastening loosely one pair of angle bars to each rail with two bolts. Negro labor at $1.25 and foreman at $75 per month were employed. The average record was 45 rails per man per day, the maximum was 50.

The cost was as follows:

One rail	$0.027
One mile of rail	4.45
One mile of track	8.90

Tightening Spikes.—This work was done by regular gangs on regular maintenance work. Each spike was driven home; each man took one rail length. Negro labor at $1.25 per day and foreman at $60 per month were employed. The average record was 14 rails per man per day, the maximum was 15.

The cost of tightening was 9 cts. per rail length or $14.40 per mile of track.

Applying Rail Braces.—The rail braces were applied by small gangs and track walkers on curves which had been put up to gage. The labor was white at $1.10 per day with foreman at $50 per month. The average record was 183 braces per man per day, the maximum was 200.

The cost to apply one brace was 0.6 ct.

Curving Rail.—Rail 33 ft., 70-lb. was curved to 5°. Rail curved from side and placed in a roller Jim Crow in the center of the track and curved by 8 men. Six men could do the work, but 8 were needed to move the rail.

8 men 10 mins. at $1.15 per day	$ 0.153
1 foreman 5 mins. at $75 per mo	0.020
Total, one rail	$ 0.173

This gives a cost of $55.36 per mile.

Wrenching.—(1) This work was on 4-bolt joints on 56-lb., 30-ft. rail; the bolts had not been tightened in 5 years. At each joint one bolt was broken out and replaced. Negro labor at $1.10 and foreman at $50 per month were employed. The average record was 61 joints per man per day, the maximum was 87.

The cost of tightening was as follows:

1 bolt	$ 0.0045
1 joint	0.018
1 mile of track	6.35

2. On this job the bolts were in good shape in 6-bolt joints on 33-ft. rail. Negro labor at $1.25 per day and foreman at $60 per month were employed. The average record was 80 joints per man per day, the maximum was 85.

The cost was as follows:

One bolt	$0.0025
One joint	0.015
One mile of track	5.00

Time Tests in Relaying 105-lb. Rail.—A. M. Van Auken gives the following data in Engineering and Contracting, Nov. 19, 1919.

In connection with the relaying of 104 pieces of 105-lb., 33-ft. new rail in the yards of the Michigan Central R. R. at Jackson, Mich., on March 2, 1917, several tests were made of different operations to determine the average amount of time used and lost during a day's work on this kind of construction. On the day this work was done the weather was clear and cold with a temperature of + 12° F.

The force engaged was as follows:

	Total daily cost
1 foreman drilling at $87.50	$ 3.40*
1 assistant foreman at $75	2.90*
1 timekeeper at $75	2.90*
2 cooks at $2	4.00
40 laborers at $2	80.00
1 water boy at $2	2.00
2 men drilling at $2.50	5.00
1 man wiring at $2.25	2.25
Total daily cost	$102.45

* On the basis of 26 working days per month. It should be borne in mind, however, that the men on a monthly scale receive pay regardless of whether or not the rest of the gang is working.

The men drilling and wiring were engaged in bonding. With the exception of this bonding crew and the timekeeper, the entire labor force were Turks.

The material used in the work was as follows:

104 pieces of 105-lb., 33-ft. new rail.
103 pieces of 105-lb., 38-in. angle splices.
4 kegs of track spikes.
624 bolts with nuts.
212 pieces of 52-in. copper plated bonding wires.
424 pieces copper plated bonding lugs.
1 pair 105-lb. continuous insulated joint.
2,580 wooden tie plugs.

The labor force left the bunk houses at 6 a. m., on hand cars for Jackson Yards, 3 miles distant. They arrived at the yards at 6:20 a. m. Unloading hand cars and preparing for work took from 6:20 a. m. to 7:00 a. m. From the latter hour to 12:30 they were engaged in laying rail. The dinner hour was from 12:30 to 1:30 and from 1:30 to 5:00 the gang worked relaying rail. They left the yards for the bunk houses at 5 p. m., arriving there at 6 p. m. The above time includes delays from various causes but does not include the time taken for cutting bolts and taking apart old rail.

Waiting for material to be distributed along the track and for a train to pass so track could be broken made 22 laborers idle from 7 a. m. to 7:30 a. m., and 36 laborers from 7:30 a. m. to 7:50 a. m. Breaking and closing track for continuous traffic amounted to 3 hours for the various trains. While this operation does not make the men idle, it delays the progress of the work. The men are kept busy spiking and fastening the rail which had not been completely finished as the work proceeded. An accident to one of the men caused the gang to be idle for 10 minutes.

The time tests of the various operations gave the following results:

Driving Spikes.—It took one man 15 minutes to drive 20 spikes. With a unit of one spike for the same man the following time was used for each spike drive: 1 minute; 45 seconds; 30 seconds; 30 seconds; 25 seconds; 30 seconds; 15 seconds; 30 seconds.

Bonding.—One man drilling four holes in each 105-lb. rail with drilling machine:

Delay in starting	Time from start to finish	Time to move to next joint
	4 min. 15 sec.	35 sec.
15 sec.	5 min. 40 sec.	40 sec.
0 sec.	4 min. 25 sec.	35 sec.
5 sec.	4 min. 20 sec.	40 sec.
25 sec.	3 min. 55 sec.	....

With one man wiring and two men bonding wires to each joint the following records were obtained:

Time from start to finish	Time to move to next joint
1 min., 00 sec.	10 sec.
1 min., 15 sec.	12 sec.
1 min., 18 sec.	15 sec.
1 min., 20 sec.	10 sec.
1 min., 50 sec.	20 sec.
1 min., 20 sec.	10 sec.
1 min., 19 sec.	12 sec.

In addition to this 15 minutes were used to bend 125 bonding wires at one end and distribute them over 2,000 ft. of track.

Pulling Spikes.—One test showed that 18 laborers pulled 700 spikes, in a distance of 1,155 ft., in 30 minutes. At a unit of one 33-ft. rail length, 20 ties to the rail, spikes pulled on both sides of one rail only, it took 7 laborers 12 minutes to pull the 40 spikes. At a unit of one man for 20 spikes (one side of 33-ft. rail) the two records varied greatly as will be seen from the following table:

	Time
1st man	14 min.
2nd man	3 min.,
3rd man	3 min., 30 sec.
4th man	6 min., 25 sec.
5th man	5 min., 20 sec.
6th man	3 min., 50 sec.

Lifting Old Rail and Throwing Off Ties.—Four laborers handled 254 ft. in 14 minutes, and 3 laborers handled 990 ft. in 43 minutes. These entire lengths were in one piece, and on one side of the tracks the rail was lifted over the outside line of spikes, as these were left in to set and line new rail.

Plugging Old Spike Holes and Adzing Ties.—In this work 7 laborers covered 264 ft. in 25 minutes; and 9 laborers covered 990 ft. in 50 minutes. This includes sweeping and removing dirt from the ties.

Placing New Rail.—Ten laborers placed 30 lengths of 105-lb. 33-ft. new rail in 56 minutes, despite the fact they were held up 15 minutes waiting for the adzing gang to clear ties.

Placing Splices.—In this work two bolts were first fastened in the splice after the rail had been placed for passing trains. The remaining bolts were fastened later during spare time of men. The time for placing two bolts and splice was as follows:

Time from start to finish	Time moving to next joint
3 min.	30 sec.
3 min., 30 sec.	30 sec.
3 min.	1 min.
11 min. for insulated joint	1 min.

Small Turntable Cuts Cost of Handling Relay Rails.—John H. Sawkins gives the following helpful suggestion in Engineering News-Record, May 24, 1917.

The turntable shown in the accompanying sketch proved a big labor and time saver in handling rails for the car-repair yard of the Pennsylvania R. R. at Greenville, New Jersey.

The 85-lb. rails used were second-hand, and the ball of each was badly worn on one side. It was therefore necessary to place the unworn side on the inside of the track being laid and it happened that many of the rails had to be turned end for end before placing them. Previous to building the turntable it required considerable maneuvering by a gang of at least six men to turn one rail. With the turntable, however, which is set up about 18 ft. from the track being laid, two men can turn a rail with ease. The device was made complete for $8.

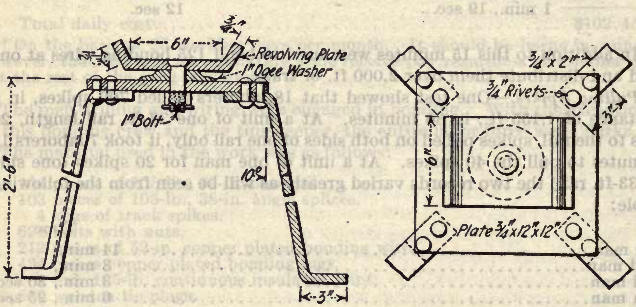

Fig. 7.—Device saves much time in handling old rails.

Unit Costs for Railway Switches.—The following data, relating to switch installations in Detroit, Mich., for the Michigan Central R. R., are given by A. M. Van Auken in Engineering and Contracting, Dec. 17, 1919.

Cost of material in switches from ledger account.

90-lb. rail:	
Number of switches installed	2
Highest cost per switch	$197.28
Lowest cost per switch	195.82
Average cost per switch	196.55
80-lb. rail:	
Number of switches installed	32
Highest cost per switch	$274.90
Lowest cost per switch	142.02
Average cost per switch	178.17
65-lb. rail:	
Number of switches installed	24
Highest cost per switch	$222.19
Lowest cost per switch	131.70
Average cost per switch	163.74
70-lb. rail:	
1 installed, cost	$155.54

Cost of material in industry tracks. Exclusive of switch material.

Number of jobs	35
Total length of track laid, ft.	30.933
Highest cost per foot	$ 1.3094
Lowest cost per foot	.5578
Average cost per foot	.7950

Installing switches, laying switches and setting concrete dumping posts.

Installing switches:	
Number installed	59
Lowest cost of installation	$ 16.06
Highest cost of installation	79.96
Average cost of installation	45.50
Laying track:	
Number of jobs	35
Total length of track, ft.*	30.281
Average length per job, ft	865
Lowest cost per lin. ft	$ 0.0577
Highest cost per lin. ft	.2545
Average cost per lin. ft	.1488
* Exclusive of switches.	
Setting bumping posts:	
Number set	17
Largest number on one job	7
Smallest number on one job	1
Average number on one job	1.7
Highest cost per post	$ 6.40
Lowest cost per post	2.01
Average cost per post	4.21

Cost of Replacing Three Crossing Diamonds.—A. M. Van Auken gives the following data in Engineering and Contracting, Jan. 21, 1920.

This work was done on May 7–9, 1917, by the Michigan Central R. R. It involved the replacing of crossing diamonds at East Main St., Jackson, Mich. One of them was in the westbound main track, another in the eastbound main track, and the third in a sidetrack. The track was crossed by one street railway track of the Michigan Ry. The electric cars averaged 1 per minute during the greater part of the day. Vehicle and pedestrian traffic also was heavy. The weather during the three days was variable, the temperature ranging from 45 to 55°.

The three crossing diamonds were of the Ajax type, 22 ft. 11 in. by 22 ft. 11 in. in size. They consisted of 100-lb. manganese built up. The angle of crossing was 34° 48′. The cost of the three was $2,302.50.

The materials required for the three crossings were as follows:

	Crossing No. 1 West-bound main track	Crossing No. 2 East-bound main track	Crossing No. 3 side track
Ties	19	16	15
Rails, 100-lb., 33 ft	4	4	..
Splices, 100-lb., 23-in. continuous, non-insulated, pairs	8	8	10
Bolts with nut locks	32	32	40
Tie plates, Sellers	14	9	8
Spikes, kegs	2	2	.6

In addition five 12-ft. ties were divided among the three crossings. Crossings Nos. 1 and 3 each had two pairs of special compromise joints furnished by electric railway.

Two roadmasters were on the work part of the day. The laborers included 10 Poles and 3 Americans. Work was started at 7:30 a. m. and continued to 5:30 p. m., with 1 hour off for lunch. Except as noted below the 17 laborers worked full time in removing bricks and planking and excavating at crossings Nos. 2 and 3. Two men worked 2 hours removing bolts from 14 joints—2 bolts to the joint—and 1 foreman and 6 laborers worked 1 hour and 15 minutes in hauling ties. Work was carried on during the night of May 7–8 in changing the sidetrack diamond. Four laborers worked from 6:30 to 9:30 p. m., and 23 laborers, 5 foremen and 1 assistant foreman worked from 9 p.m. to 6:15 a. m. Three oil and two carbide lights furnished illumination. A work train, consisting of engine, crane, 1 flat car and 1 box car, was in service from 10 p. m. to 6 a. m. The charges for this service were:

Train crew and engine crew	$ 4.00 per hour
Engine rental	10.00 per day
Crane rental	20.00 per day
Crane engineer	3.95
Crane machinist	4.44
Box car	.50 per day
Flat car	.50 per day

The day force on May 8 consisted of 5 foremen, 1 assistant foreman and 23 laborers, who worked from 7:30 a. m. to 3 p. m. with pay for 1 day, and 2 foremen, and 12 laborers, working from 2 to 5:30 p. m. In addition there was one team and driver employed from 10 a. m. to 5:30 p. m. with pay for 1 day.

The equipment consisted of track tools and push car.

Work during the night of May 8–9 was carried on at the eastbound main track crossing and westbound main track crossing.

The force consisted of 7 foremen, 1 assistant foreman and 35 laborers, who worked from 10:45 p. m. to 5:45 a. m., and were credited with pay for 1 day.

The force employed on May 9 consisted of three foremen and six laborers, working from 8 a. m. to 11:30 a. m.; two laborers, working from 9 a. m. to 11:30 a. m., and 3 foremen and 12 laborers, working from 12:30 to 5:30 p. m.

In the following summary of the cost of installing the three crossing diamonds, with the exception of foremen, where rate of pay shown is for the month, and train and engine crews where the rate is per hour, the rates shown are the daily wage.

West-bound Main Track Crossing

	Total
Labor:	
Day of May 8—	
1 yard foreman, ¾ day at $90	$ 2.60
1 assistant yard foreman, ¾ day at $75	2.16
4 section foremen, ¾ day at $77.50	8.94
2 section foremen, ⅜ day at $77.50	2.24
20 laborers, ¾ day at $2.25	33.75
12 laborers, ⅜ day at $2.25	10.13
Night of May 8—	
35 laborers, ½ day at $2.25	39.38
Day of May 9—	
1 yard foreman, ⅓ day at $90	1.15
2 section foremen, ⅓ day at $77.50	1.99
9 laborers, ½ day at $2.25	10.13
1 laborer, ⅓ day at $2.25	.75
1 team and driver, ¾ day at $6	4.50
Total labor*	$117.72
Equipment and Service:	
Engine rental, ½ day at $10	$ 5.00
Crane rental, ½ day at $20	10.00
Flat car, ½ day at 50 ct	.25
Box car, ½ day at 50 ct	.25
Train and engine crews, 4 hours at $4	16.00
Crane crew	4.60
Total equipment and service	$ 36.10
Grand total†	153.82

East-bound Main Track Crossing

Labor:	
Day May 7—	
1 yard foreman, ½ day at $90	$ 1.73
2 section foremen, ½ day at $77.50	2.98
1 assistant yard foreman, ½ day at $75	1.44
17 laborers, ½ day at $2.25	19.13
1 team and driver, ½ day at $6	3.00
Day May 8—	
1 yard foreman, ¼ day at $90	.87
1 assistant yard foreman, ¼ day at $75	.72
4 section foremen, ¼ day at $77.50	2.98
2 section foremen, ⅛ day at $77.50	.75
20 laborers, ¼ day at $2.25	11.25
12 laborers, ⅛ day at $2.25	3.38
Night May 8—	
35 laborers, ½ day at $2.25	39.38
Day May 9—	
1 yard foreman, ⅓ day at $90	$ 1.15
2 section foremen, ⅓ day at $77.50	1.99
7 laborers, ½ day at $2.25	7.88
1 laborer, ⅓ day at $2.25	.75
1 team and driver, ¼ day at $6	1.50
Total labor*	$100.88
Equipment and rental same as West-bound Main Track Crossing	36.10
Grand total†	$136.98

Sidetrack Crossing

Labor:	
Day May 7—	
1 yard foreman, ½ day at $90	$ 1.73
2 section foremen, ½ day at $77.50	2.98
1 assistant yard foreman, ½ day at $75	1.44
17 laborers, ½ day at $2.25	19.13
Team and driver, ½ day at $6	3.00
Night May 7—	
23 laborers, 1 day at $2.25	51.75
Day May 8—	
3 laborers, 1 day at $2.25	6.75
1 yard foreman, ⅓ day at $90	1.15
Day May 9—	
2 section foremen, ⅓ day at $77.50	1.99
2 laborers, ½ day at $2.25	2.25
1 laborer, ⅓ day at $2.25	.75
Total labor*	$ 92.92
Equipment and service:	
Engine rental, 1 day at $10	$ 10.00
Crane rental, 1 day at $20	20.00
Flat car rental, 1 day	.50
Box car rental, 1 day	.50
Train and engine crews, 8 hours at $4	32.00
Crane crew	8.39
Total equipment and service	$ 71.39
Grand total†	164.31

* Seven Foremen worked night of May 8 without additional pay.
† This total does not include complete cost of surfacing.

Cost of Maintaining Anchored and Unanchored Track.—The relative cost of maintenance of unanchored track and track anchored to prevent creeping of ties is shown in an article in the Railway Age Gazette, from which Engineering and Contracting, March 27, 1912, gives the following abstract.

The data are taken from records made on the maintenance of 3½ miles of double tangent track of level grade, light gravel ballast, 85 lb. rail and broken joints. The heavy traffic was north bound and consequently all data are based on the north bound track, as the creeping tendency here was decided. This track had been put in service 14 months before, and one mile in the center of the stretch was anchored, leaving 1½ miles on the north and one mile on the south end not anchored. Where the track was anchored, 640 anti-creepers were applied, two per rail length, opposite joints against opposite end of joint ties. The anti-creepers have received no maintenance and have shown no failure, although they had been in service 14 months at the time of inspection.

The character of the work done on the two pieces of track in 14 months is stated in the columns below:

Anchored track—
Track resurfaced once.
Unanchored track—
Track resurfaced twice.
Ties spaced twice.
Rail driven back twice.

The total maintenance cost for the mile where the anti-creepers were applied, including the cost of anti-creepers, is as follows:

Cost of anti-creepers, 640 at 17½ cts. each	$112.00
Applying 640 anti-creepers at ½ ct. each	3.20
Resurfacing, 10 men working 16 days, at $1.55 per day	248.00
Total	$363.20

The total cost of the next mile north of the mile where the anti-creepers were applied, subject to the same conditions of traffic, roadbed, etc., but unanchored, is given below:

Cost of resurfacing twice, each time 10 men, 16 days, at $1.55 per day, $248	$ 496.00
Cost of respacing ties twice, each time 10 men, 17 days, at $1.55 per day, $263.50	527.00
Cost of driving back rail twice, each time 10 men, 2 foremen, 6 days, at $1.55 per day, $111.60	223.20
Total	$1,246.20

This shows a saving in 14 months of $883 in favor of the anchored track.

It will be noted that the original cost of the anti-creepers and of their application have been included in the first 14 months. These costs are properly chargeable over the total number of years anchors are in service, which in all cases is at least as long as the life of the rail on which they are applied. This would make the saving considerably greater than has been estimated. Furthermore, this maintenance cost does not include injury done to ties, spikes and joints, which was considerable where anchors were not applied as the creeping had pulled the ties badly askew, bending or completely destroying the spikes and often causing broken joints. Where the anti-creepers were applied, this wear and tear were hardly worth considering.

The above figures were obtained directly from the railway, and the roadmaster stated that he could have maintained this 3½ miles of track in better shape with three men less per year had he been allowed to anchor the balance.

Railway Maintenance Cost is Increased by Fast Passenger Trains.—The following note is taken from the Engineering News-Record, April 25, 1918.

Speed of trains affects the cost of maintenance of way and structures to the extent that the higher the proportion of passenger traffic, which may be assumed as high-speed traffic, the greater the cost of maintenance. This is the conclusion arrived at in a preliminary report presented by the track committee at the 1918 annual meeting of the American Railway Engineering Association.

In the accompanying diagram, the curved lines represent traffic of which the passenger-car miles constitute 7.5, 12.5 and 20.3% of the total car mileage.

It is recognized by the committee that the assumption of high-speed and low-speed traffic as synonymous with passenger and freight traffic is not entirely correct, but this, the committee says, offers the only opportunity for classifying expenses in accordance with differences of speed. The car-mile was taken as the unit for comparison on the ground that it gives the best measure of the facilities required by each class of traffic.

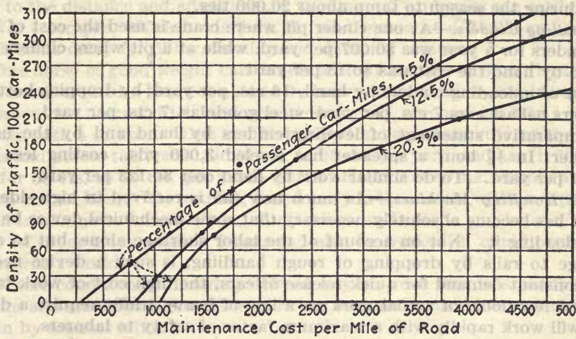

FIG. 8.—Effect of percentage of passenger-car-miles on maintenance cost.

Labor Saving Devices in Maintenance of Way Work.—Much useful information on labor-saving devices for track work was given in a committee report adopted at the 1920 annual meeting of the Roadmasters and Maintenance of Way Association. The following data are taken from an abstract of the report, published in Engineering and Contracting, Feb. 18, 1920.

Mechanical Tie Tampers.—The great majority of those who have used a tamping machine and given it a fair trial will testify to its wonderful value as a labor-saving device. It is the committee's observation that the machine work is more uniform and better than track tamped by hand. It has been proved that a tamping machine is of particular value around frogs and switches, water pans, tunnels, etc., as it is possible to tamp with it in places which cannot be reached by a tamping bar or pick.

Carefully compiled figures for hand and machine tamping from several railways covering a period of three seasons follow:

For a 2-tool machine: 1 foreman, 10 hours at 32 cts., $3.20; 4 men, 10 hours at 22 cts., $8.80; 12 gal. gasoline at 24 cts., $2.88; total, $14.88.

Without machine: 1 foreman, 10 hours at 32 cts., $3.20; 4 men, 10 hours at 22 cts., $8.80; total $12.

Cost per mile of track without machine, 32 days at $12, $384.00; cost per mile of track with machine, 16 days at $14.88, $238.08; balance in favor of machine, $145.92.

For a 4-tool machine the comparison between hand tamping and mechanical tamping was as follows:

Hand gang and foreman, 16 men, 8 hours, tamped 500 ft. of track; machine gang and foreman, 6 men, 8 hours, tamped 528 ft. of track; saving of 10 men and 80 hours for machine.

Expense: Hand gang and foreman, 16 men, $43.50; machine gang and foreman, 6 men, $18.50 (cost to run $6.95); $24.45; saving by machine, $18.05.

Fixed charges are given as follows as near as it is possible to get them: Depreciation at 10 per cent, interest 5 per cent, repairs 5 per cent, total fixed charges 20 per cent.

Experience during the four years this machine has been in use teaches that, under normal conditions in the northern states, each machine will be used during the season to tamp about 20,000 ties.

Handling Cinders.—At one cinder pit where crane is used the cost of loading cinders for a year was $0.007 per yard, while at a pit where cinders were loaded by hand the cost was $0.13 per yard.

Cost of unloading cinders by hand, 16 cts. per yard; by dropping bottoms, Rodgers ballast cars 7 cts. per yard; steel gondolas, 7 cts. per yard.

Comparative statement of leveling cinders by hand and by the use of spreader: In ½ hour a spreader has leveled 3,000 yds., costing less than $0.001 per yard. To do similar work by hand cost $0.123 per yard.

Rail Handling Machines.—As much new rail is received in high-side coal cars it has become absolutely necessary that some mechanical device be used for unloading it. Not on account of the labor shortage alone, but to avoid damage to rails by dropping or rough handling, is such a device needed. The constant demand for quick release of cars, the high cost of work trains, and the few hours of actual work on a line of heavy traffic require a device that will work rapidly with a maximum factor of safety to laborers.

There are rail-handling machines in use which are capable of loading or unloading two cars of rail at the same time. For the operation of these machines nine men are required, one man to operate hoists and four men to each car of rails. The machine is operated by air from the train line. Such machines will unload rails more quickly and without damage to rails or injury to men than could be accomplished by 40 men by hand, thus a saving of 31 men a day is made possible. This machine can also be equipped with tongs to load or unload as many ties with three men as can be loaded or unloaded by 20 men by hand.

Snow Melting Devices.—The committee is not unanimous in its views as to the benefits to be derived from snow melting devices. The following results were submitted by one of the members:

Two laborers at $3.80 per day, $7.60; royalty on cars, $5 per year (used about 5½ months, 2 cars), 6 cts. per day; 6 gal. hydro-carbon fluid at 11 cts. per gallon, 66 cts.; total cost with melting device, $832.

If done by hand: Foreman at $3.35 and 10 laborers at $2.80, total $31.35; 6 rattan brooms at 28 cts., $1.68; total cost by hand, $33.03. Saving by use of device, $24.71.

Another device which can be used successfully for the same purpose is the Hauck snow melting torch.

Motor Cars.—The majority of the committee is in favor of the more general use of motor cars, particularly on lines of light traffic, where the length of sections are such as to warrant their use. Therefore it is the committee's opinion that the economy in the use of motor cars decreases in proportion to the additional number of main tracks, which in turn shortens the length of sections. It has obtained the following figures showing the economy effected by the use of motor cars:

Time spent in carrying 14 men and foreman by motor car 14 miles, 30 minutes; for round trip, 1 hour, or total of 15 hours. Time spent for round trip by hand car, 3 hours, or a total of 45 hours, showing a saving of 30 hours in favor of motor cars. There is still a larger saving in the increased energy of the men when they arrive on the job, in the better class of labor attached, and in the time saved on emergency jobs.

The Horse as a Labor-saver.—On divisions where much ditching must be done by work trains or wheelbarrows, teams with scrapers have been tried, with the following results: One laborer can fill scrapers for 2 to 4 teams, according to the distance and advantage of working. Two horses can easily handle a No. 1 scraper, which holds 7 cu. ft., and moves at a 2-mile-an-hour rate, with some delay for filling, turning and dumping scrapers.

One horse of good weight can handle a No. 2 scraper of 5 cu. ft., and after teams are trained a boy not able to do heavy manual labor can drive a team, or when in a narrow ditch, and one horse is used, one boy can take two single horses with a scraper. Dirt can be handled in very short cuts, at the ends of cuts and across the track, for 20 cts. to 25 cts. per yard, and haul it 500 to 600 ft. for 50 cts. to 60 cts. per yard—this with teams at 80 cts. an hour and labor at 35 cts. an hour. By starting teams early in the season, with an experienced man in charge to handle them, all ditching can be done and balance of gang left on other track work. Teams can also be worked in muddy cuts where men won't work.

Where conditions of mowing right of way are such that it is possible to use teams and mowing machines the work can be done by machinery much cheaper than by manual labor.

Ditching Machines, Dump Cars and Spreaders.—When heavy ditching has to be done the use of steam ditchers is recommended, together with the use of at least two 16 to 20 yd. side-dump cars and a spreader car for short hauls. For a longer haul from 4 to 6 side-dumps should be used. A light locomotive can be assigned to handle this outfit, and with an outfit of this kind, which includes a train crew, ditcher engineer and fireman, dirt can be handled for 10 cts. to 25 cts. per yard, according to the length of haul.

Through long usage the steam ditcher and spreader, especially when the latter is operated by air, has reached such a high state of efficiency that they are practically indispensable, and the fact that they can be used for many different varieties of work places them among the most important labor-saving devices.

A saving of at least 60 per cent over that of manual labor is obtained by using a No. 3 crane for removing ballast from between tracks, in preparing for stone ballast, digging drains under tracks, unloading old ballast on fills, to strengthen shoulder and fill up holes, load and unload rails, and for various other purposes.

The magnet is used very successfully to load and unload scrap of various kinds. This machine is capable of picking up six or eight 33-ft. rails as rapidly as it will one, and eliminates handling the rails by hand, and reduces to a minimum the liability of injuring men.

Labor Saving Equipment Employed in Track Maintenance by B. &. O. R. R.—The following data are taken from an abstract of a paper presented before the New England Railroad Club by E. Stimson and published in Engineering and Contracting, Jan. 15, 1919.

Ditching machines of the "American and Barnhart" types are well adapted to the uses of a steam derrick within the limits of their lifting capacity, and are of great use in unloading and loading rail, ties, timbers, etc. With a clam shell bucket substituted for the dipper arm their uses are still further extended.

Each of these various uses of this machine results in a great saving in man-power, the best example being that of ditching. The loading capacity is about 60 cu. yd. per hour in ordinary material. It would require 100 men to load this amount by hand. As it requires but 5 men to operate the ditcher, the large saving is evident. In handling rail 6 men and the machine will readily do the work of 40 men.

The Use of Horses.—We have found that, including plowing, a 1-horse scoop and driver working in a clay cut averaging 4 ft. in height, and wasting the material on top of the cut, can handle 45 cu. yd. in 9 hours. Another man is required for dressing up the ditch. The two men and one horse, therefore, do the work of at least 10 men. Up to a 300-ft. haul the wheelbarrow is a good proposition as compared with other methods. While these methods may not show great economies over the steam ditcher and work train, and do require much greater time for completion, they are to be recommended where the matter of quick completion is not vital. They require but a small number of men and give steady employment, which promotes efficiency. With the intense traffic conditions prevailing and the great demand for train crews and engines to handle the business it is most desirable to release all the work train service possible. The cost of this service has increased about 40 per cent during the past year and nearly 100 per cent in the past 10 years. These considerations make it desirable, both from necessity and from the standpoint of economy, to adopt methods to reduce work train service.

Rail Handler.—A home-made device which has proven a great labor-saver is an air-operated rail handler. With it a gang of six men and a foreman will load one rail per minute. By hand methods 20 men will load 1 rail every 2 minutes on to flat cars and one rail every 5½ minutes on gondolas. The machine is also used for handling frogs, switches, ties, scrap and other maintenance materials with proportionate labor savings.

Pneumatic Tie Tamping Machines on Track Work.—More labor is used in surfacing and lining of track than on any other item of track work. Normally this will amount to about 35 per cent of the total track payroll. This offers an attractive field for labor saving. About four years ago pneumatic tie tamping machines were introduced for this work. The earlier machines were limited to two tampers, but the later ones have the necessary power to operate four tampers with a consequent reduction in overhead and operating expenses. Our experience indicates that with a 2-tool machine 5 men do the work of 9 men tamping with picks and with a 4-tool machine 7 men will do the work of 17 men without them. There is also an indirect saving made by the more uniform and permanent work done by the tamper, requiring less frequent re-tamping than when the work is done by hand.

Ballast Cleaning Appliances.—Stone ballast, to be fully effective, must be kept clean and the voids unclogged. Where traffic is heavy, particularly on grades, stone ballast will require cleaning at least once in three years and in many places much oftener. To raise the track on dirt ballast and dress off with clean stone is poor practice, and to clean it by forking it over is slow, expensive, and requires a large number of men. A number of methods for cleaning ballast have been considered, even to a gigantic vacuum cleaner which, on account of cost, is out of the reach of most of us. The most practical is the ballast screen. The standard performance with 3 screens and 12 men and a foreman is 200 ft. of double track per 10-hour day. To clean with forks, this length of track would take the same number of men 2.8 days or 36 men with forks to do the work of 13 men with the screens.

Removal of Grass and Weeds.—Much labor is applied each year to the cleaning of grass and weeds from the track and roadbed. Two methods have been more or less effective as "weed killers," burning, and spraying with a solution of arsenite of soda.

About 10 years ago a western railroad designed a weed-burning machine. A strip 7 ft. on each side of center line of track was burned at an average cost of $9.46 per mile. Two burnings were necessary, so that to destroy the weeds the cost would be $18.92. As compared with hand labor it was claimed to save 14 men per day.

The spraying method has been extensively used. In 1916 the cost of spraying 744 miles of single track averaged $18.11 per mile. Including the train crew the work was done by 10 men, averaging 21 miles per day. To do a like day's work by hand where the growth was medium heavy in soft ballast 273 men would be required at an average cost of $23.25 per mile. A large saving in men is thus effected, though not so much in money.

Cost of Cleaning Weeds and Grass From Track.—D. A. Wallace gives the following records in Engineering and Contracting, Sept. 17, 1910.

The cleaning of weeds and grass from track was done by section gangs, the men getting $1.10 per day and foreman $45 per month. In the first two cases the weeds were removed only from end to end of ties. One or two men went ahead with picks and loosened the gravel and 2 men followed pulling weeds and grass by hand, each man working a strip 4 ft. wide. There was considerable crab and Bermuda grass. In the third case the cleaning was done from edge to edge of the ballast, giving an additional width of about 18 ins. While the record is of one man's work only it was selected as an average of several days' work of a gang. The records are as follows:

1. Rock ballast, weeds, medium thick:

Number of feet	Number of days	Feet per man per day
5,280	8	660
5,000	9	555
5,280	9	586
Average		600

The cost per mile was $11.15.

2. Slag ballast, weeds medium thick:

Number of feet	Number of days	Feet per man per day
18,500	12½	1,480
1,400	9½	147
3,200	7	457
390	1	390
3,360	4½	946
8,600	8	1,075
6,100	20½	300
2,640	3½	754
Average		693

The cost per mile was $9.80.

3. This work was in gravel ballast and the weeds were very thick. One man cleaned 210 ft. in one day. The cost per mile was $19.40.

4. Gravel ballast, weeds medium thick:

Number of feet	Number of days	Feet per man per day
1,740	10	174
4,410	14	315
2,760	5	552
7,560	12	630
Average		417

The cost per mile was $15.30.

Records of Work in Surfacing and Smoothing Track.—The following data are given by D. A. Wallace in Engineering and Contracting, July 27, 1910.

1. In this work dirt surface track was stripped and stone ballast unloaded from Rodgers bottom dump ballast cars. The raising was done with a spotboard and four or five days later the second raise of a 3 or 4-in. surface was made with tamping picks. The record for 20 days—first raise 7 ins. in rock from stripped dirt track shovel tamped with Italian labor—was as follows:

	Ft. per man per day
Max	30
Min	18
Average	25

2. This work consisted of surfacing track 4 ins. in rock on top of a 6-in. raise where ties had been renewed at the rate of about 7 per rail length. The work included spacing and gaging. The record for 7 days with negro labor was as follows:

	Ft. per man per day
Max	33
Min	15
Average	22

3. This work consisted of surfacing track 3 ins. in rock on top of a 7-in. raise where ties had been renewed at the rate of about 7 to the rail length. The record for 7 days with negro labor was as follows:

	Ft. per man per day
Max	26
Min	12
Average	20

4. On this work new rail had been laid on track which was in very poor surface. In order to keep the new rail in good condition, a 3-in. stone surface was necessary. Sufficient stone for the raise was taken from the shoulders of the ballast then in place. The surfacing was done immediately after rail renewal. The record for 8 days with negro labor was as follows:

	Ft. per man per day
Max	31.5
Min	21.1
Average	24.8

5. This work was the first raise of 7 ins. in screenings for stripped track, shovel tamped. The record for 4 days with Italian labor was as follows:

	Ft. per man per day
Max.	33
Min.	29
Average	30

6. This work was the second raise of 3 ins. in screenings on a 7-in. raise track lined and dressed, pick tamped. The record for 3 days with Italian labor was as follows:

	Ft. per man per day
Max.	150
Min.	100
Average	116

7. This work was the first raise of 7 ins. on cinders from dirt stripped track, shovel tamped. The record for 2 days with Italian labor was as follows:

	Ft. per man per day
Max.	43
Min.	30
Average	36

8. These records were taken from work of three sections and one extra gang. The track was poorly ballasted with hand napped stone and was raised 4 ins. on gravel consisting of pebbles and non-cementing sand. The rail was laid with broken joints. Gravel was unloaded from bottom dump coal cars at a cost of 30 cts. per cu. yd. on the ground. These records were kept in order to determine the most economical method of making a raise of 4 ins. under these conditions. The track put up by Sec. No. 1 stood 1st. The track put up by Ex gang No. 1 stood 2d. The track put up by Sec. No. 2 stood 3d. The track put up by Sec. No. 3 stood 4th. Negro labor at $1.10 per day and foreman at $50 per month were worked.

Section 1.—Made one raise and pick-tamped the length of the tie except 14 ins. in the middle; raised track one day and dressed up on the following day. The record of 11 days' work at raising track was as follows:

	Ft. per man per day
Max.	40
Min.	31
Average	36

With a gang of 6 men 1 mile is surfaced in 24 days.

The record for 5 days work for dressing was as follows:

	Ft. per man per day
Max.	100
Min.	71
Average	84

With a gang of 6 men 1 mile of track is dressed in 10 days.

Section 2.—Made one raise, pick-tamping heads of ties and shovel-tamping insides except 14 ins. at centers. The track surfaced on one day was dressed the next day. The record of 17 days for surfacing was as follows:

	Ft. per man per day
Max.	54
Min.	37
Average	48

With a gang of 6 men 1 mile is surfaced in 18 days.

The record of 7 days for dressing, working a gang of 7 men, was as follows:

	Ft. per man per day
Max.	100
Min.	77
Average	89

With a gang of 7 men 1 mile was dressed in 8 days.

Section 3.—The track surfaced by this gang was shovel tamped heads and inside. After an interval of 3 days the gang went back over the raised track and caught up low joints with picks and put up the track complete. The record of 10 days for surfacing was as follows:

	Ft. per man per day
Max.	110
Min.	55
Average	74

With a gang averaging 4½ men 1 mile was surfaced in 16 days.

The record of smoothing for 10 days was as follows:

	Ft. per man per day
Max.	83
Min.	45
Average	59.5

With a gang averaging 5½ men 1 mile was smoothed in 16 days.

In dressing the foreman sent 3 men back to work alone; the record for 8 days was as follows:

	Ft. per man per day
Max.	250
Min.	75
Average	133

This gang of 3 men dressed 1 mile in 15 days.

Extra Gang.—This gang made a 5-in. raise shovel tamped ties on first raise and after 3 or 4 days went back over the work picking up low places with the pick. The gang made an average of 70 ft. per man per day on the first raise. With a gang of 25 men 1 mile of track was raised in 3 days.

A gang of 17 men averaged 100 ft. per man per day smoothing up first raise, smoothing up 1 mile in 3 days.

A gang of 10 men dressed an average of 55 ft. per man per day or at a rate of 1 mile in 10 days. The work was slow on account of uneven distribution of ballast unloaded from bottom dump cars.

The surfacing done by these four gangs consumed more time than a 4-in. rise in gravel on account of using a good portion of the stone in the track in tamping with gravel.

9. The following records were secured from the work performed by section gangs. By running surface is meant the work done in bringing track to an easy riding surface, by tamping up the low places, not much attention being given to the general surface as far as appearances go. Surfacing refers to the raising of the track out of face to a uniform grade line. Smoothing up refers to the picking up of low joints and centers to the general level. Negro labor at $1.10 per day and foreman at $50 per month were worked.

Record 1.—Covers 18 days, running surface in slag ballast.

	Ft. per man per day
Max	93
Min	45
Average	66

Record 2.—Covers 31 days running surface in rock ballast.

	Ft. per man per day
Max	86
Min	30
Average	55

Record 3.—Covers 12 days running surface in gravel ballast.

	Ft. per man per day
Max	120
Min	60
Average	87

Record 4.—Covers 20 days smoothing up in slag ballast.

	Ft. per man per day
Max	161
Min	60
Average	116

Record 5.—Covers 75 days smoothing up on rock ballast.

	Ft. per man per day
Max	225
Min	51
Average	120

10. This work was done on the Frisco lines in Louisiana working "Cadian" labor at $1.75 per day and foreman at $75 per month. The dirt was a good solid black loam. The shoulders of the grade were skinned off to a slope of 1 in. to 1 ft. outward from the ends of the ties by a plow constructed on the order of a dirt spreading machine. The dirt was cast up against the ties by the cutting edges of the wings. The amount of dirt, however, was insufficient for the raise, and the remainder was secured by shoveling up from the berm

to the shoulder after having been loosened by plows. The embankment averaged 4 ft. in height.

The average for a 4.1 in. raise was 22.7 ft. per man per day.

Cost of Stopping Trains—When it is Cheaper to Install Interlocking Signals.—(Engineering and Contracting, Nov. 16, 1910.)

Under the laws of Canada, all trains are required to come to a full stop before crossing another railway at grade. C. L. Hackett, in an article on railway signaling in the *Canadian Engineer*, shows that the installation of interlocking signals is an actual saving in operating expenses when trains reach a certain number. The following figures are based on the results secured by Mr. Peabody, signal engineer of C. & N. W. Ry., who having experimented with different trains, concluded that the cost of stopping and again accelerating a train to its original speed average 45 cts. per train. The interlocking plant considered is for a single track crossing, where 16 levers would be required. A day and night towerman would be required, and the following is the estimated annual cost:

Cost of interlocking, complete	$4,800.00
Interest at 4 %	192.00
Depreciation at 7 %	336.00
Maintenance, per year	240.00
Operation, per year	1,200.00
Total cost per year	$1,968.00

The following table shows the saving brought about by such a plant as compared with stopping trains for 14, 20 and 25 trains per day:

Trains Per day	Cost of stopping, per year	Cost of interlocking, per year	Net saving, per year	Years required to pay for installation from savings
14	$1,971	$1,968	$ 3.00	...
20	2,817	1,968	849.00	5½
25	3,521	1,968	1,553.00	5

It is apparent, from this table, that 14 trains a day in this case would justify the installation of the plant, aside from the savings due to increased safety.

Cost of Turntables.—Table VII is complied from data taken from a committee report to the American Railway Bridge and Building Association and published in Engineering and Contracting, Nov. 6, 1912.

The total cost of turntables varies greatly with the type of construction and kind of excavation and to a lesser degree with the weight of engines for which the table is designed.

The cost of excavation and foundations for the through girder type is less than for the deck type. However the steel for the through type is more expensive than the deck type.

A fair average cost of turntable complete with foundations, including pit with concrete wall and paved floor (in 1912) was $100 per lin. ft. of diameter. Thus a 75 ft. turntable cost $7500, an 80 ft. table cost $8,000 and a 100 ft. table cost $10,000.

The cost of the table with center cost about $40 to $50 per lin. ft. of radius.

The cost of mechanical tractor of electric, compressed air or gasoline motor type averaged about $1,150 per installation.

The above costs have about doubled in 1920.

TABLE VII.—COST OF TURNTABLE CONSTRUCTION

Railroad	Type	Loading (wt. of eng. tons)	Power for turning	Length, ft.	Cost: Excav. and foundation	Cost: Table with center	Cost: Tractor	Cost: Misc.	Cost: Total
A., T. & S. F.	Through	243.0	E.M.	85	$5,500	.....	$1,400	.....	$11,000
B. & O.	Through	137.5	E.T.	80	......	.....	......	.....	7,500
B. & L. E.	Deck	Coopers E. 60	E.T.	80	3,000	3,000	1,500	1,000	8,500
B. & A.	Deck	Coopers E. 60	E.T.	85	......	3,500	......	.....	9,000
C. of G.	Deck	Coopers E. 55	Hand	80	2,280	2,100	......	.....	5,100
C. of N. J.	Deck	Coopers E. 55	A.M. E.T.	80	5,000	2,677	......	.....	8,277
C. & O.	Deck	311.5	A.T.	100	....	.....	......	.....	10,000

The Cost of Railroad Signal Protection.—James B. Latimer, Signal Engineer, C. B. & Q. R. R. gives the following data in Engineering and Contracting, June 14, 1911.

Mechanical Interlocking.—The generally accepted unit for rough estimating is the working lever, and very substantial plants can be constructed for, roughly speaking, $400 per lever. This includes the tower and "power" (electric) distant signals, but does not include electric route locking, which adds considerably to the expense.

The accompanying tables (Tables VIII and IX) give the actual cost in detail of 2 interlocking plants installed within the last year, one a plant to protect a grade crossing of 2 single track lines, almost at right angles to each other, with power distant signals on both lines and quite elaborate electric route locking. This machine contained 14 working levers and two spare spaces, and as there was apparently no immediate likelihood of enlargement the tower was made simply large enough for a 16 lever machine. Details of the cost of this plant are given in Table VIII.

The other was a plant to protect a junction of a single and double track line, with a number of switches, one of which was 1,600 ft. from the tower. The machine had 47 working levers and 5 spare spaces—a 52 lever frame. This plant had two power distant signals and two mechanical time locks, but no electric locking. Details of cost are given in Table IX.

In both cases the tower buildings were contracted for and were built by the same contractor. He furnished all material and built the towers complete, including the foundations and service building. The towers are heated by hot water heaters which were installed by the railroad company's forces.

The reader will note that his attention was called to the fact that in the first case the railroad lines were nearly at right angles. This sort of a track layout usually adds to the cost of a plant, and in close estimating should be allowed for. The reason being that pipe lines to the signals and derails each side of the crossing on each line must be run on a separate set of foundations, which require more labor to set; besides which the concrete blocks which carry the pipe carriers cost about 30 cts. each. They are set every 7 ft. and as they will carry 6 lines of pipe as easily as they will 1, there is always a slight economic waste when they are not worked to their limit.

TABLE VIII.—DETAIL COST OF 16-LEVER INTERLOCKING PLANT WITH 14 WORKING LEVERS

1 16-lever frame interlocking tower with concrete foundation and storm sash complete. Cost by contract		$ 925.00
1 hot water heater and necessary piping for same		101.69
Labor section men unloading material—putting in ties and derails		34.20
Labor linemen stringing wires for distant signals		22.80
Labor signalmen installing interlocking and heater		1,608.22
1 interlocking machine with 14 levers and 2 spaces at $22.50 per working lever and $9.00 per space		333.00
10 vertical 90° deflecting bars	$ 6.40	64.00
10 horizontal 90° deflecting bars	4.40	44.00
24 11¾" cranks R. S. A. standard	1.60	38.40
14 compensators R. S. A. standard	4.75	66.50
25 one way pipe carriers	.25	6.25
260 three way pipe carriers	.73	189.80
8 eight way pipe carriers	1.81	12.67
10 one way transverse pipe carriers	.95	9.50
4 two way transverse pipe carriers	1.12	4.48
6 three way transverse pipe carriers	1.35	8.10

1 lb. soldering compound	.50	.50
6 lbs. solder	.20	1.20
25 lbs. 8d nails (C)	2.30	.58
30 lbs. 20d nails (C)	2.20	.60
15 lightning arrestors	1.25	18.75
24 porcelain cleats		.45
1 operator's table		9.00
1 rubber mat, 3 ft. by 22 ft		7.70
1 tower lamp		3.50
1 clock		12.50
2 tower indicators	15.00	30.00
4 electric locks for back locks of distant signals	21.00	84.00
2 mechanical time locks with attachments	60.00	120.00
7 circuit breakers for machine	9.00	63.00
Total		$16,290.25

The Railroad Signal Association has adopted a table of so-called "operated units" which is designed to be used as a unit by which to divide the cost of construction and maintenance of joint interlocking plants. These units are shown in Table X.

TABLE X.—"OPERATED UNITS" OF THE RAILWAY SIGNAL ASSOCIATION

Name of operated unit	Value units
Each mechanical signal arm working in two or three positions	1
Each power signal arm working in two or three position on mechanical plants, normal indication locking included	2
Each pair of switch points	1
Each single slip switch (2 pairs of switch points)	2
Each double slip switch (4 pairs of switch points)	4
Each set of movable point frogs (2 pairs of frog points)	2
Each derail	1
Each 55 ft. of detector bar with or without locks	1
Each torpedo placer	1
Each drawbridge coupler	1
Each drawbridge rail surface and alignment lock for one pair of rails	1
Each drawbridge leveling and operating apparatus lock	1
Each track circuit	1

This table works out very evenly as to cost, both of installation and maintenance, and might with advantage be used in place of the levers for estimating. For instance, in the first plant described above there were 24 operated units and in the second 68, which averages $272 per operated unit, which will be found a very fair figure for rough estimates.

The lever basis does well enough where no power signals or electric locking is introduced, but when, as is now pretty generally the case, either or both of these factors come in, the unit basis will be found to give more satisfactory results.

It should be noted also that the labor for both of the interlocking plants described, approximates $65 per unit. These figures are actual and show that the work can be done for that money. Many signal engineers estimate and spend much more than these amounts. All the writer can say is that when the labor exceeds $70 per unit, the person who is to pay the bill had better analyze the figures and discover, if possible, the causes for the excess.

The foregoing are, of course, "Railroad Company's" figures and do not include any charges for transportation of men, tools and materials, or any overhead charges.

Power Interlocking.—The cost of power interlocking (i. e., that in which the signals, switches, etc., are operated by electricity or compressed air), varies much more than does that of mechanical interlocking, and as none of the signal companies publishes a complete price list of the apparatus of this nature manufactured or furnished by it, really reliable estimating figures are hard to obtain. Six hundred dollars a function is a fairly safe figure, including tower and power plant; but as this sort of interlocking is rarely used except in large terminal work, so that the question does not come up often, the signal company whose apparatus is to be used had best be consulted if a very close estimate is desired.

Manual Signals.—The cost of a manual block, train order or station signal is about $100.00 per station. The items are as follows:

One 2-bladed station signal complete with lamp, table levers and connections	$ 74.00
Concrete for foundation	6.00
Labor	20.00
Total	$100.00

If such a signal has to be placed across the track or any distance away from the station, allowance must be made for such fact.

Automatic Block Signals.—The cost of automatic block signals varies with the number of signals used, the type of signal and the number of switches to be insulated.

Straight track circuit (i.e., for unbroken track) may be considered as a constant and costs $256.00 per mile. This cost is shown in detail in Table XI.

TABLE XI.—DETAIL COST OF 1-MILE TRACK CIRCUIT.

700 bond wires	$ .01½	$ 10.50
1,500 channel pins (M)	6.50	9.75
2 battery chutes	10.50	21.00
6 cells gravity battery	.85	5.10
105 ft. trunking	.05	5.25
28 stakes	.16	4.48
150 ft. No. 8 rubber covered wire (M)	30.00	4.50
16 ft. No. 6 bare copper wire		.48
2 relay boxes and posts		28.00
2 relays		37.00
½ yard concrete (for foundations of relay boxes)		3.50
4 insulated joints (each)	5.25	21.00
Paint, tape, solder and nails		2.80
Labor bonding, 350 joints (each)	.06	21.00
Labor putting in insulated joints		4.50
Labor setting batter chutes, trunking and wiring for same		32.50
Labor setting relay boxes and relays and wiring same to track		45.00
Total		$256.36

Each switch in the circuit must be insulated and equipped with a switch indicator. The itemized cost of 1 switch indicator is shown in Table XII and that of 1 signal in Table XIII.

TABLE XII.—DETAIL COST OF 1 SWITCH INDICATOR

4 insulating joints	$ 21.00
2 insulated switch rods	11.00
1 switch box	15.00
1 switch indicator	16.50
155 ft. trunking	7.75
20 stakes	3.20
¼ yard concrete	1.75
Nails, tape, solder and paint	6.00
300 ft. No. 12 rubber covered wire	7.20
100 ft. No. 8 rubber covered wire	3.00
15 ft. No. 6 bare copper wire	.18
4 lightning arrestors	5.00
Channel pins and galvanized bond wires	.80
Total	$ 98.38
Less value of non-insulated switch rods taken off	3.00
Total	$ 95.38
Labor	58.00
Total	$153.38

Table XIII.—Detail Cost of 1 Signal

1 1-blade signal (2 position signal)	$187.50
1 semaphore lamp	3.60
2 red roundels	1.80
1 green roundel	.70
1 relay (500 ohms)	19.00
1 yard concrete for foundation	7.00
4 1″ × 36″ hook bolts	1.40
75 ft. trunking	3.75
15 stakes	2.40
500 ft. No. 12 rubber covered wire	12.00
1 battery well	40.00
5 lightning arrestors	6.25
18 cells caustic soda battery	35.00
Nails, paint, tape, solder	8.00
Total	$328.40
Labor	80.00
Total	$408.40

The usual practice in automatic signal work is to make the sections just about half a mile long. This means in each mile of circuited track there will be 4 insulated joints, 2 sets of track battery and 2 relays. Besides which the rails must be bonded together.

A one-blade, three-position signal costs $245 and requires an additional relay so that in estimating they should be valued at $485 each.

A two-blade signal costs $260 and also requires two relays, and in addition thereto an extra lamp and three extra roundels so that in estimating they should be valued at $505 each.

An average of five line wires all the way is about right, though if a very close estimate is required it would be necessary to have a circuit plan drawn up, as almost every signal engineer or signal company uses a different circuit, and the location of switches has some bearing.

Bare copper wire in place at present prices is worth about $40 per mile per wire, or an average of $200 per mile for line wire.

Insulated copper line wire in place is worth about $70 per mile.

Galvanized iron or copper clad wire, either bare or insulated, is worth less than the above figures.

To summarize, therefore, automatic block signals may be figured as follows:

Track circuit per mile	$256
Each switch in circuit extra	153
Each one-blade two-position signal	408
Each two-blade two-position signal	505
Each three-position signal	485
Line wire, per mile	200

Cost of Changing 17 miles of Railroad Track from Narrow Gage to Standard Gage.—The following data are taken from an article by Henry R. Somes, published in Engineering and Contracting, May 16, 1917.

The railroad on which the work was done was built during the 1880's as a narrow gage road. It runs from Wilmington, Vt., to Hoosac Tunnel Station at the east end of the Hoosac Tunnel on the Fitchburg Division of the Boston & Maine R. R. The length is about 25 miles, and as it runs along a narrow valley bordering the Deerfield River it is a line of sharp curvature and short, steep grades.

The old rails being much worn, enough second-hand rails, 56 lb. to the yard, were purchased of the Ulster & Delaware R. R. to relay the line. About 8½ miles of the line from the Wilmington end were relaid to standard gage outside the narrow gage iron. On the rest of the line the old iron was replaced by these rails, they being laid narrow gage as the ties and roadbed were not in condition to carry standard gage equipment.

In 1913, after some negotiations, a contract was let for changing the 17 miles northerly from Hoosac Tunnel Station. This portion of the line followed the winding of the Deerfield River and lay in a narrow valley with high hills on each side. There were many long, sharp curves, the map of the road showing about 120 curves of 6° or over in the 17 miles. The track was laid with 4-bolt angle bar splices except about 1½ miles where Fisher joints had been used. The first 5 miles had been re-tied where needed.

The work was carried out during July, 1913; the contractor lost money on the job, which loss was due to several factors, some of which were: Labor was scarce and hard to get, and very inefficient. Experienced men could not be obtained and the job was so short that green men could not be properly broken in. The method employed (which was specified by the railroad company) did not allow time to familiarize the men with their work, or allow the work to be started with a small force and gradually increased. There was no labor to be had in the territory tributary to the line and the contractor was obliged to pick up green men in the cities and use them. The weather was excessively hot, and the road lying in a narrow winding valley, the wind could not cool the air; this reduced the output of the men to a marked degree. When men were hired it was with the understanding that experienced spikers were to be paid 25 cts. per hour, and other laborers 20 cts. per hour, but during the first afternoon about two-thirds of the men (inexperienced) struck for 25 cts. per hour. Four passenger trains and two freights per day were being operated over the line at the time the work was done.

The method employed was to divide the men into two gangs and work each gang on a separate line of rails, pull the spikes on one line of rails, throw them out 10¼ in., and respike, while another gang followed at a reasonable working distance, pulling spikes on the opposite line of rails, throw it to standard gage and respike. Of course on the long, sharp curves the outside line of rails would soon stretch so that it would be necessary to break open a joint and start spreading again at the break; the inside of the curve would crowd so that it would have to be broken open and another start made there. As there were many of these breaks, three or four to each long curve, a separate gang was organized to connect up the track at these points.

The short ends of the rails on the inside of the curves were sawed off with the hack saws, and additional holes drilled in the ends of the rails for the angle bars. On the outside of the curves where the rails were too short, a rail was unbolted, cut in two with cold chisels and a longer piece cut from an extra rail and inserted in the line, making a better job than by putting in a short piece. The spiking gangs followed immediately behind the gangs that were spreading rails, leaving gaps where joints were broken open; the gang repairing breaks spiked the track at these points.

	Per mile	Total
Pulling spikes—		
2,001 hours @ $0.25	......	$500.25
Per mile 117.7 hours	$27.42	....
Foremen, 2* (1 @ $10 per day) (1 @ $3 per day)	......	71.50
Foremen, per mile	4.21	....
Average gang, 14.73 men	$33.63	$571.75

* Includes extra payments to 4 men that acted as working foremen. These payments are added to this foreman's pay for simplicity in figuring.

The claw bars had heels and worked satisfactorily. The spikes pulled much easier from the new ties than from the old. In the latter they were rusted in and in many cases where the ties were checked and splintered, the splinters raised up even with or above the spike heads and make it difficult to get the claw bars under the spike heads.

Throwing rails—	Per mile	Total
762 hours @ $0.25	......	$190.50
Per mile, 44.82 hours	$11.20	....
Foremen, 2 (1 @ $10 per day) (1 @ $3 per day)	......	17.00
Foremen, per mile	1.00	....
Average gang, 6 men	$12.20	$207.50

Ordinary lining bars were used for throwing the rails. Owing to the splintered condition of the old ties, causing the rails to catch, it took longer on that part of the track than on the section that had been re-tied. Broken stubs of spikes also caused delay. A special gage bar was made for getting the gage of the first line of rails thrown. This was made of wood shod with iron as shown in the sketch.

Spiking—	Per mile	Total
6,438 hours @ $0.25	......	$1,609.50
Per mile, 378.7 hours	$94.68	....
Foremen, 2 (1 @ $10 per day) (1 @ $3 per day)	......	146.50
Foremen, per mile	8.62	....
Average gang, 48 men	$103.00	$1,756.00

When the old section of the track was reached much trouble was experienced with spiking. The hard shell on the ties made it difficult to enter the spike, and if the tie was at all splintered spikes would rebound so that at times it was necessary to have one man hold a spike while another started it. On this section the spikes were old, and many bent in pulling. These had to be straightened before using, as the railroad was very economical with spikes. Ties averaged 21 per rail.

Adzing ties—	Per mile	Total
249 hours @ $0.25	......	$62.25
Per mile adzed (9 miles)	$6.92	.....
Foremen included in spikers.		
Average gang, 3 men.		

It was necessary to adz only an occasional tie, and this was done by a small gang that worked ahead of the spike pullers.

Cutting Curves, Drilling, Bolting, and Setting Over Frogs and Switches

Cutting curves—	Per mile	Total
978 hours @ $0.25	......	$244.50
Per mile, 57.53 hours @ $0.25	$14.38	......
Foreman @ $4 per day	......	60.00
Foreman, per mile	3.53	....
Average gang, 7 men	$17.91	$304.50

The short ends of the rails were cut with hack saws, the long rails with cold chisels. Gang would cut and connect up from 6 to 13 breaks per single line of rails with the saw, and the same amount with the chisel, each day. The number of breaks taken care of per day depended on the amount of curvature encountered. Days when few cuts were made the gang spent a large part of their time moving from curve to curve or helping the rear spiking gang. This gang had a push car to carry their tools and usually carried one extra rail. This gang made the cuts, drilled one hole on each side of the cut, put on angle bars and spiked the rails at the breaks. The balance of the work was done by another gang that finished drilling the required number of holes, put in the bolts, and completed any other necessary work. Each break on a curve necessitated a cut with the chisel and one with the saw. The hack saws were 14-in. blades in a high frame, and 2 men would make a cut in 20 to 30 minutes.

Each break cost, average of 10 per day—		
Labor, 7 hours @ $0.25		$ 1.75
Foreman, 1 hour @ $0.40		.40
		$ 2.15
Drilling rails at breaks and bolting—		
883 hours @ $0.25		$220.75
Per mile, 52 hours @ $0.25	$13.00	....

Gang—6 men in 2 gangs who worked without foremen. Each gang averaged drilling and bolting 25 holes per day.

Paulus track drills were used. The drills were sharpened in the railroad shop and sent out to the men by the passenger trains.

Frogs and switches were merely set over and spiked. This work was carried out by the gang cutting curves. Balance of switch work and yard work was done by the railroad forces. There were 30 switches on the line and the average cost of setting them over was:

Labor, 4 hours @ $0.25	$1.00
Foreman, ½ hour @ $0.40	.20
	$1.20

The railroad had a small gang following about 2 days behind that put rail braces on some of the curves.

Miscellaneous expenses—	Per mile	Total
Water boy	......	$ 48.85
Labor, 8 hours @ $0.15; 8 hours @ $0.20, per mile	$2.80	....
Superintendence—		
16 days @ $8.00		$128.00
Per mile	$7.53	....

TABLE XIV.—COST OF CHANGING GAGE OF 17 MILES OF TRACK

Development expenses—			
Fees of men, employment bureau			$ 18.00
Fares of men			92.52
Freight on tools and supplies			$ 21.92
Traveling, superintendent			20.00
Rent of camp			25.00
Liability insurance			120.00
Tool charges			50.00
Superintendent's time; looking over job; finding men, making preparatory arrangements, hiring camp site, etc., 8 days @ $8.00			64.00
Per mile		$ 24.21	$ 411.44
Camp outfit for taking care of 65 men—			
Blankets	$ 62.15		
Mattresses	131.50		
Cooking and eating outfit	85.61		
	$279.26		
Less salvage	40.00		239.26
Per mile		14.08	
Development and camp expense		$ 38.28	$ 650.70
Total costs			$3,946.30
Total costs, per mile		$235.58	
Total costs less development expense		$197.29	$3,295.60

The railroad furnished a work train made up of an old passenger coach and two flat cars. This train carried the gangs to and from the camp and carried a few rails, ties, several kegs of spikes, and tool boxes. This train remained at the head of the work all day, just ahead of the spike pullers.

The working time for the 17 miles was 14.3 days, making a speed of 1.19 miles per day, and as the ties averaged 21 to the rail against 17 on some other roads, it would have meant a speed of about 1.5 miles on the latter. There was considerable delay due to transferring passengers, express and mail from the narrow gage to standard gage trains and vice versa. About one-half hour before the train was due at the working point it was necessary to stop pulling spikes and set these men at other work. When the trains arrived nearly all the gangs would help transfer mail, baggage and express. This operation could not be hurried, as neither train could move until the passengers had left the one and boarded the other. Passengers did not take kindly to the operation and showed no desire for speed. Of course after the gang stopped pulling spikes, the other gangs would gain on them and the entire force would be bunched together and working inefficiently until the spike pullers had gained a proper lead again. This delay amounted to about one-half hour for the entire gang for each train, and as there were four of these transfers per day, the delay from this cause amounted to two hours per day, so the gang was only working effectively about 80 per cent of the time.

Life and Cost of Timber Snowsheds of the Southern Pacific R. R.—Engineering News-Record, Jan. 3, 1918, gives the following.

As built on the Southern Pacific, the sheds are constructed of "Shasta pine" cut near the site, which costs the company only about $10 to $15 per 1000 ft. B. M. to cut and deliver on the work. This wood has an average life in these sheds of about 20 or 22 years, which might be divided into three periods, as follows: During the first 10 years virtually no repairs are required. The next 5 or 10 years require increasing repairs, particularly the renewal of footings and sections where dampness has access to the wood. In the third period, from the fifteenth year on, according to conditions, the items requiring replacement include braces, caps, joists and in fact all parts up to the point where it is considered cheaper to renew the shed entirely. In 1918 there was renewed a section of shed which had been in service 27 years—probably the longest life on record for this division.

As renewed under 1918 prices the cost varies, according to the design of the section, from $12 to $14 per lin. ft., this figure being a rough average of single and double-track construction. The average maintenance per foot per annum is figured at about $1.60. This includes renewal made necessary by fire, slides and decay, and also the cost of fire patrols and interest on the first cost.

Tests of snow taken from shed roofs, frequently show a weight of 40 lb. per cu. ft. Based on a safe margin for the 15-ft. snow load likely in this region, all sheds have been designed for a uniformly distributed load of 300 lb. per sq. ft. This loading is approximately the same as would result if the sheds carried a train of consolidation locomotives.

Cost of Locomotive Repairs, Renewals and Depreciation.—Table XV published in Engineering and Contracting, April 17, 1912, is extended from one given in "Railway and Engineering Review" and is of interest as it gives the comparative costs of repairs, renewals and depreciation for locomotives. The figures, except the totals, are calculated by slide rule and are accurate to within a tenth of 1 cent per mile run.

TABLE XV.—SHOWING COST PER MILE RUN OF LOCOMOTIVE REPAIRS, RENEWALS AND DEPRECIATION ON 30 RAILROADS FOR 1911

Name of road	Total miles run	Repairs per mile, cents	Renewals per mile, cents	Depreciation per mile, cents	Total, cents
A., T. & S. F.	47,060,848	13.44	.01	1.50	14.95
Atl. Coast Line	20,980,390	6.44	.01	.60	7.11

Life of Railway Rolling Stock.—In the valuation work of the Nebraska State Railway Commission an extensive investigation was made and a large number of data were collected from the records of service of equipment of a number of the large western systems. The following matter is taken from an article by E. C. Hurd published in Engineering and Contracting, Aug. 21, 1912.

The study embraced the following up of each locomotive through its life in type, and also of each car of a kind and series. The final disposition of the article was found. The salvage value was also carefully inquired into at the time of vacation. From this tabulations were made setting out straight lines of depreciation, in combination with the non-depreciating factors of salvage, from which were derived a value per cent of expectancy. These graphic illustrations also developed other interesting features even beyond that of valuation, having reference to the durability of the several classes of equipment and the points at which the life begins to break and vacations from age occur. Further there was demonstrated that liability to accidental destruction in the first few years was practically the same in all classes of cars. In more detail setting out the determination of plans for depreciation for locomotives, passenger cars and freight cars, which plans were made up in an identical manner, that having reference to freight cars will be further mentioned. The average value at the time of vacation expressed in a per cent of reproduction cost was found to be 22.4 per cent and which became the non-depreciating factor for freight cars. From a resume of the study of all classes of freight cars and considering all factors of elimination, 19.92 years, or practically 20 years, was established as the average life. From this information the following formula was obtained as covering all classes of freight cars:

$$\frac{100\% - 22.4\%}{20 \text{ years}} = 3.88 \text{ per cent as the value depreciating per cent per annum.}$$

After having utilized such formula, the result would still be affected in limited measure by recognizing a minimum value if still found in service beyond its expectancy. This minimum value for freight equipment was determined from considerable evidence in hand at 25 per cent of the value new. The present change in material utilized into the construction of cars—namely: that from wood to steel—may show a modification in more or less degree of the results hereabove set out, but the length of life for this class of equipment for study, not over ten years, does not admit of any accurate figures except the factor of

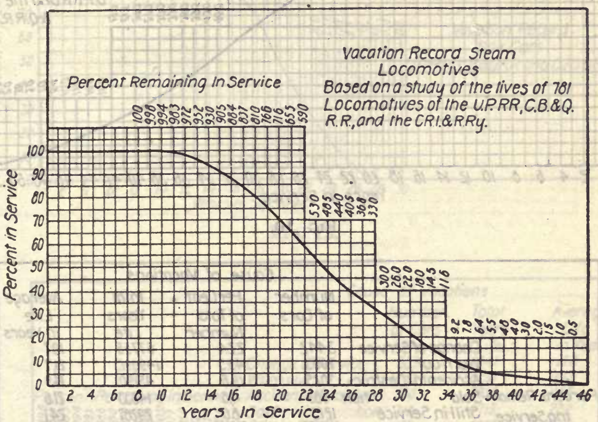

FIG. 9.

accidental destruction seems to remain the same as of the earlier equipment. A very good opinion seems to obtain in that the increase in the strength of design and materials has improved closely in accordance with the demands for increased capacity and service ability, and therefore the history of destruction will be in close accordance to that of the older.

The data described briefly relative to locomotives are shown graphically in Fig. 9, that for passenger cars in Fig. 10, that composite for freight cars. Fig. 11, that for box cars Fig. 12, that for stock cars Fig. 13, that for coal flats Fig. 14, and that for refrigerator cars Fig. 15 herewith. (Vacation record of Ry. rolling stock, Figs. 9 to 15.)

Cost of Locomotives and Freight Cars in 1918.—Engineering and Contracting, June 19, 1918, gives the following note:

The Railroad Administration has ordered 1,025 locomotives to cost \$60,000,000 and 100,000 freight cars of 50 tons each to cost \$300,000,000. This is equivalent to \$60,000 per locomotive and \$3,000 per 50-ton car. Half the cars are gondola coal and half box. The prices of the locomotives range from \$90,000 for the heavy Mallets to \$35,000 for switching engines.

The builders, both of cars and locomotives, will receive a profit of 5 per cent on the estimated minimum cost. The Government guarantees the estimated

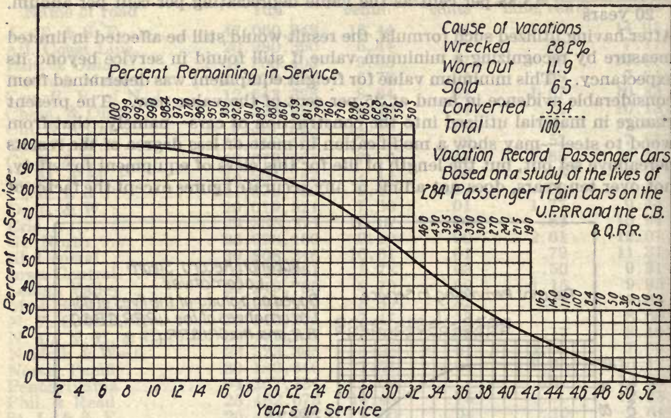

FIG. 10.

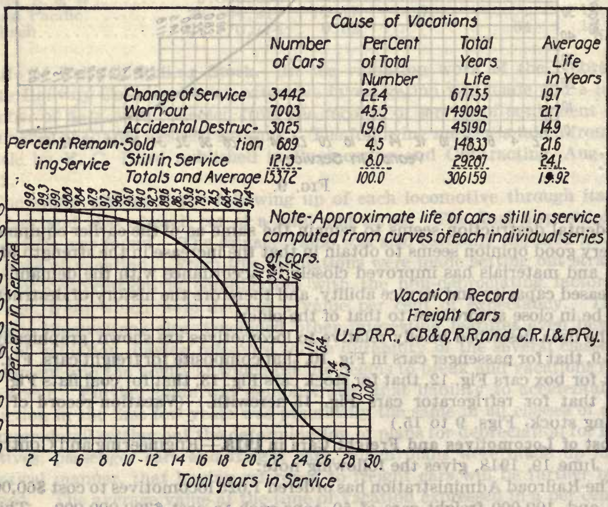

FIG. 11.

cost of the materials, but, if the actual cost is less than the estimate, the Government shares the saving equally with the builders.

The locomotives average 338,000 lb. each; hence the price is almost 18 ct. per pound, or double the price in 1905. The heaviest weighs 540,000 lb.

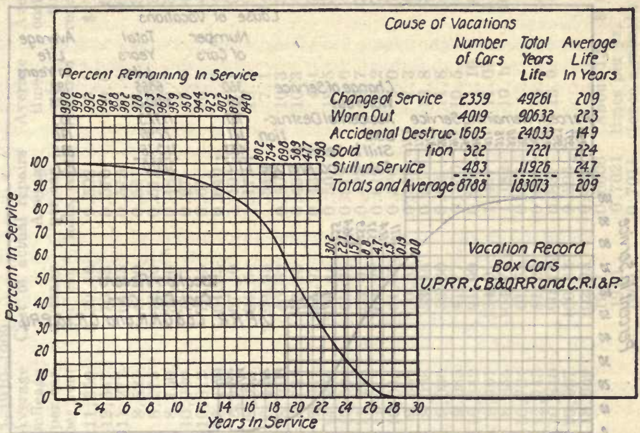

FIG. 12.

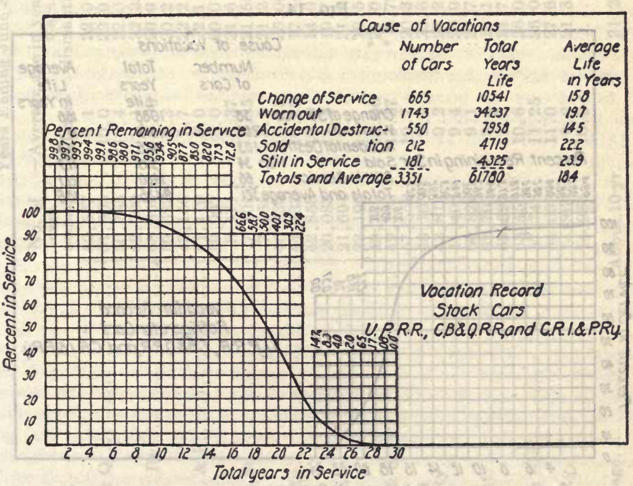

FIG. 13.

Life and Cost of Maintenance of Freight Cars.—Table XVI, reprinted in Engineering News, March 7, 1912, is from the Feb. 10 issue of the *Railway* *and Engineering Review*, which credits it to a Mechanical Engineer of one of the railway companies mentioned.

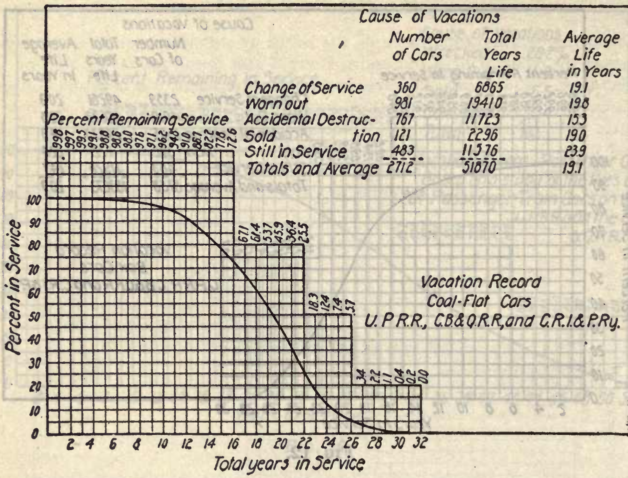

FIG. 14.

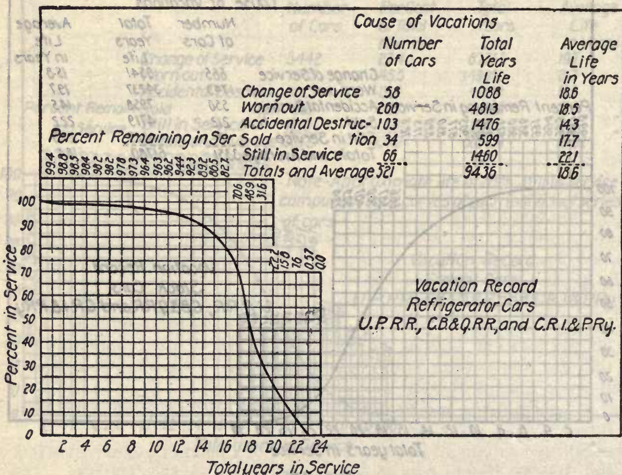

FIG. 15.

The average age of all freight cars in service, according to these figures, is a little less than 10 years; omitting destruction by wrecks the average life is

TABLE XVI.—FREIGHT CARS, AGE, MILEAGE AND REPAIRS

Years Ending June 30, 1911–1910–1909

lengthened to 21.24 years. During its life each car is repaired on an average of once a month, at an average cost of $6.26 each time, and therefore, each car requires a total expenditure for repairs of about $1600, or twice the first cost of the car.

The Life of Steel Freight Cars.—Steel freight cars have been long enough in use to make it possible to estimate their average natural life and Engineering and Contracting, April 26, 1916 quotes M. K. Barnum, who states in a recent issue of the Railway Age Gazette, that the oldest steel freight car of which he has knowledge was built in 1896. Two years ago it received a new floor, beside other extensive repairs, and appearances indicate that it may be good for at least 10 years more. However, this car seems to be an exception, and Mr. Barnum puts the average life of steel gondola and hopper cars at about 16 years.

The short life of steel cars is largely due to corrosion of the steel plates. Cars in service near salt water corrode more rapidly than elsewhere. Idle cars corrode much more rapidly than those in use, two months of idleness being equivalent to about two years of use. Frequent painting—every three to five years—prolongs the life 25 to 50 per cent, but relatively few steel cars have been painted.

Natural and Functional Life of Freight Cars.—The following note is given in Engineering and Contracting, May 15, 1918.

Freight cars have heretofore shown an average life of nearly 28 years, about 3.6 per cent of the total number being "vacated" annually (See Gillette's "Handbook of Cost Data"). However, as is well known, though often overlooked in estimates, most of the cars are not retired because they are worn out or too expensive to maintain; but because it is more profitable to substitute cars of greater capacity. The war has brought about conditions that enable us roughly to segregate natural depreciation (wear and tear) from functional depreciation (inadequacy and obsolescence) of cars; for the demand for freight cars has become so great that none are being retired because of functional depreciation.

During 1917 about 119,000 new freight cars were manufactured. The net gain in cars at the end of 1917 was about 72,000 over 1916, indicating a retirement of some 47,000 cars because of wear and tear, or about 2 per cent of the total number in use. This would indicate a natural life of 50 years, as compared with a composite natural and functional life of 28 years. While this estimate is not conclusive, it is very significant, and it has more than academic interest at this time.

Cost of Water Softening for Railroads.—The following data are taken from an abstract, published in Engineering and Contracting, April 8, 1914, of a paper presented before the Illinois Water Supply Association by R. C. Bardwell, chemist of the Missouri Pacific Ry.

On the Missouri Pacific there are at present 45 complete water softening plants in operation, the majority being on the hard waters west of the Missouri River. The average amount of water treated per year, reducing the hardness so that it will form practically no scale, is 1,692,000,000 gals. The total average amount of scale removed from this water is 5,537,000 lbs., which would make over 110 carloads at 50,000 lbs. each; a considerable amount when it is remembered that but for treatment this scale would have to go through the engine boilers and most of it would have to be removed by hand. The total annual cost for the above treatment, interest and depreciation on plants is about $65,000. Conservative figures show, however, that with this expenditure there is a net saving of about $105,000 from cutting down the following losses alone:

1. Frequent renewal of flues and other parts of boiler account of scale accumulation and injury to flue ends from repeated caulking. 2. Labor caulking flues and other engine house boiler repairs. 3. Loss of engine time during boiler and firebox repairs. 4. Loss of fuel due to insulating effect of the scale on the flues and other heating surfaces.

Besides the foregoing there are the indeterminate benefits in the road performance of locomotives by reducing failures and interruptions to traffic with the reduction of the number of locomotives required for a given traffic.

At one terminal approximately 18,000,000 gals. of water are treated monthly, eliminating 5 lbs. of scale per 1,000 gals. or a total of about 80,000 lbs. per month. The cost of chemicals for this is about 4 cts. per 1,000 gals. or a total monthly bill of about $720. The length of life of flues using straight raw water before the installation of the softening plant was from eight to twelve months with serious trouble on account of frequent leaks. The locomotives now using the straight treated water average 18 months between shopping, and the trouble with leaky flues is practically eliminated.

At another terminal shop about 30,000,000 gals. of water are treated monthly, removing 3 lbs. of scale per 1,000 gals. for a total of 90,000 lbs. Prior to the installation of the softener, five boilermaker days and four boilermaker nights were required caulking flues. After the treating plant was put in operation this was reduced to one-man days and one-man nights. The saving in this one item alone is reported to be $5,712 per year on an $8,000 investment. The life of flues was increased from 8 to 15 months.

In most cases where softening plants are installed, the foaming conditions are increased, especially for the first few days after the treatment is started due to the fact that the old scale in boilers is loosened and, falling off, increases the amount of suspended matter making a dirty boiler which seems to be the most important of the contributory causes of foaming.

To soften a water to three grains per gallon, or less, of incrusting salts, which is the object in most cases, demands a purity in this respect of 3 parts in 58,341 or 99.995 per cent. This merely shows the deceptiveness of reporting water softening on the percentage basis, for although sounding complex it is a comparatively simple matter. However, each individual water has its peculiarities such as the temperature at different seasons and the difference in content of magnesium salts which slow up the reaction and without due allowance for same leave a milky water for a final product. Creek waters of course change with the precipitation and I have also found that in some parts of the country well waters become softer in winter while others get harder.

So far the development of water softening on a large scale has centered around lime and soda ash as being the chemicals which produce the results for the least cost. However, barium hydrate is the ideal reagent on account of its leaving no detrimental by-products as in the case of soda ash. So far the expense has retarded its development. Numerous boiler compounds through the high degree of exploitation obtained have been tried by a few railroads but investigation would show that even where the work desired was done the cost greatly exceeds that of the recognized methods. Inert powdered graphite is now being largely exploited as a cure-all for scale troubles, but its economical merits are yet to be proven. The "sunlight on corrugated aluminum" patent, which was supposed to render the scale inert in the water without removing it chemically has been tried at several points in this section

and seems to have proven unworthy. The Permutitt water softener, the artificial zeolite, will never be a universal success in railroad work on account of the replacing of incrusting carbonates with sodium carbonate, that is, waters which are sufficiently hard to warrant the expense of treatment, as a rule contain sufficient incrusting carbonates, which if replaced by sodium carbonate could not be used on account of foaming properties. Therefore it would seem that common lime and soda ash will continue to remain in service.

CHAPTER XIX

SMALL TUNNELS

Notes on management and organization for constructing small tunnels as well as cost and progress data for both earth and rock tunneling are given in this chapter. Further notes of interest and applicable, in a degree, to small tunnels are given in Chapter XX.

Additional data on the methods and costs of driving small tunnels in rock are given in Gillette's Handbook of Rock Excavation.

Costs of 20 Tunnels.—A compilation of tunnel costs, from data personally collected and given in Bureau of Mines Bulletin 57 by D. W. Brunton and J. A. Davis, are published in Engineering and Contracting, June 24, 1914.

There are set forth in the following pages as complete and accurate data as could be obtained, showing the cost of various phases of tunnel work at a number of different tunnels. Although the writers have not had the advantage of auditing the books from which these figures were taken and hence can not vouch personally for the absolute accuracy of the figures, the data were in all cases procured from persons in charge or who were in a position to know what the work actually cost. Accompanying the figures is a brief list of the more important features of the tunnel, without which it is impossible to make even an approximate comparison between any two pieces of tunnel work.

GUNNISON TUNNEL

Important Details.—Location: Montrose, Colo. Purpose: Irrigation and reclamation. Shape of cross section: Horseshoe. Size: 10 ft. wide at the bottom, 10 ft. 6 ins. wide at the spring line, 10 ft. high at the spring line, 12 ft. 4 ins. high at the center of the arch. Length: 30,645 ft. Character of rock penetrated: Chiefly metamorphosed granite with some water-bearing clay and gravel, some hard black shale, and a zone of faulted and broken rock. Type of power: Steam. Ventilator: Pressure blower. Size of ventilating pipe: 17 ins. Drills: At first, pneumatic hammer, 4 drills in the heading; afterwards, pneumatic, piston, 4 drills in the heading. Mounting of drills: Horizontal bar for the hammer drills, vertical columns for the piston drills. Number of holes per round: 20 to 24 in the heading (approximately one-half of the tunnel). Average depth of round: 6 to 7 ft. Number of drillers and helpers per shift: 4 drillers and 2 helpers. Number of drill shifts per day: 3. Explosive: 60 per cent gelatin dynamite, with some 40 per cent. Number of muckers per shift: 5 to 8. Number of mucking shifts per day: 3. Type of haulage: Electric. Wages: Drillers, \$3.50 and \$4; helpers, \$3 and \$3.50; muckers, \$2.50 and \$3; blacksmiths, \$3.50 and \$4; motormen, \$3; brakemen, \$2.50 and \$3; power engineers, \$4. Maximum progress in any calendar month: 449 ft. Average monthly progress: 250 ft., approximately

Cost of Driving

	Cost per foot of tunnel
10,019 feet driven by undercut heading and subsequent enlargement	$87.23
20,626 feet driven by top heading and bench	62.18
Average cost of excavation of entire tunnel	70.66

These costs include all labor, all materials, all repairs, all power, depreciation figured as 100 per cent on all equipment, with a proportionate charge for general (supervisory) and miscellaneous expenses of the entire reclamation project.

Laramie-Poudre Tunnel

Important Details.—Location: Home, Colo. Purpose: Irrigation. Cross section: Rectangular. Size: 9½ ft. wide by 7½ ft. high. Length: 11,306 ft. Character of rock penetrated: Closegrained red and gray granite. Type of power: Hydraulic at the east end, electric at the west. Ventilator: Pressure blower. Size of ventilating pipe: 14 and 15 ins. Drills: 3 pneumatic hammer. Mounting of drills: Horizontal bar. Number of holes per round: 21 to 23. Average depth of round: 10 ft. at first, 7 to 8 ft. later. Number of drillers and helpers per shift: 3 drillers, 2 helpers. Number of drill shifts per day: 3. Explosive: 60 per cent gelatin dynamite, with some 100 per cent in the cut holes. Number of muckers per shift: 6. Number of mucking shifts per day: 3. Type of haulage: Mules. Wages: Drillers, $4.50; helpers, $4; muckers, $3.50; blacksmiths, $5; drivers, $4.50; dumpmen, $3.50. Maximum progress in any calendar month: 653 ft., March, 1911. Average monthly progress: 509 ft. (for the 16 months when complete plant operated). Special feature: Inacces sibility; the tunnel was located about 60 miles from the nearest railroad siding, and the roads were mountainous and very steep in places.

Cost of Driving Tunnel 11,306 Ft

	Cost per foot of tunnel
Superintendents and foremen	$1.50
Drilling	4.47
Mucking and loading	4.92
Tramming and dumping	4.63
Track and pipe	.47
Power house	.35
Blacksmithing	.84
Repairs	.47
Bonus to workmen	1.75
Maintenance of camps, buildings, and fuel	.62
Machinery repairs	.12
Air drills and parts	1.33
Picks, shovels and steel	.84
Explosives	4.50
Lamps and candles	.42
Oil and waste	.38
Blacksmith supplies	.53
Liability insurance	.81
Office supplies, telephone and bookkeeping	.86
	$29.81
Permanent equipment (less approximately 10 per cent salvage)	9.73
	$39.54

The permanent equipment included power plant, camp buildings and furnishings, pipes, rails, etc.

LOS ANGELES AQUEDUCT

Little Lake Division, Tunnels 1 to 10A

Important Details.—Location: Inyo County, Cal. Purpose: Water supply, power, and irrigation. Cross section: See Fig. 1. Size: See Fig. 1. Type of power: Electric power purchased at a nominal cost per kilowatt-hour from a hydraulic plant constructed and owned by the aqueduct. Ventilators: Pressure blowers. Size of ventilating pipe: 12 ins. Drills: Pneumatic hammer, usually 2 in each heading. Mounting of drills: Horizontal bar. Number of holes per round: Usually 14 to 16. Average depth of round: 6 to 10 ft. Number of drillers and helpers per shift: 2 drillers and 2 helpers. Number of drill shifts per day: Usually 1, but sometimes 2. Explosive: 40 per cent gelatin dynamite, with some 20 per cent and some 60 per cent; ammonia dynamite also tried. Number of muckers per shift: Usually 5. Number of mucking shifts per day: Usually 1, but 2 when 2 drill shifts were employed. Type of haulage: Tunnels 1 to 3-N, mules; tunnels 3-S, to 10A-N, electric; tunnel 10A-S, mules. Wages: Drillers and helpers, $3; muckers, $2.50; blacksmiths, $4; helpers, $2.50; motormen, $2.75; dumpmen, $2.50.

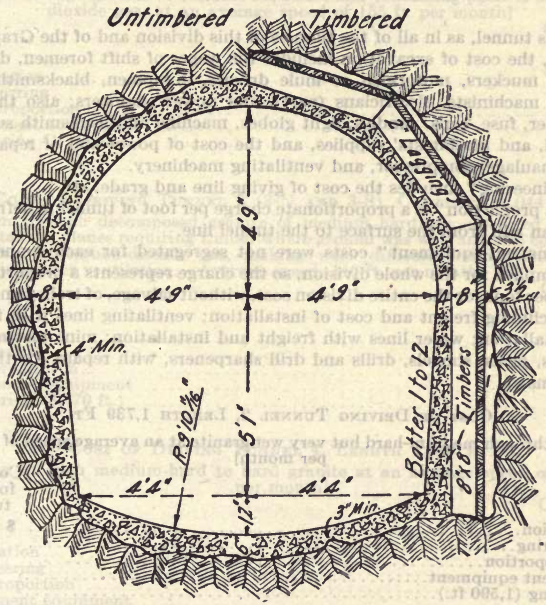

FIG. 1.—Typical cross-section of tunnel, Los Angeles Aqueduct.

Cost of Driving Tunnel 1B-S for 1,341 Ft.

[Driven through medium-hard granite at an average speed of 225 ft. per month*]

	Cost per foot of tunnel
Excavation	$ 9.15
Engineering	.18
Adit proportion	.28
Permanent equipment (estimated)	2.35
Timbering (857 ft.)	1.02
	$12.98

* The average speed given is computed on the basis of one heading per month.

In this tunnel, as in all of the tunnels of this division and of the Grapevine division, the cost of excavation includes the wages of shift foremen, drillers, helpers, muckers, motormen or mule drivers, dumpmen, blacksmiths and helpers, machinists, electricians (part), and power engineers; also the cost of powder, fuse, caps, candles, light globes, machine oil, blacksmith supplies and fuel, and machinists' supplies, and the cost of power and of repairs for power, haulage, compressor, and ventilating machinery.

"Engineering" includes the cost of giving line and grade, etc.

"Adit proportion" is a proportionate charge per foot of tunnel to defray the cost of an adit from the surface to the tunnel line.

"Permanent-equipment" costs were not segregated for each tunnel, but were compiled for the whole division, so the charge represents a proportionate charge per foot for the entire division cost, without salvage, of trolley and light lines, including freight and cost of installation; ventilating lines with freight and installation; water lines with freight and installation; mine locomotives and cars, picks, shovels, drills and drill sharpeners, with repairs for the last four items.

Cost of Driving Tunnel 2, Length 1,739 Ft.

[Driven through medium-hard but very wet granite at an average speed of 170 ft. per month]

	Cost per foot of tunnel
Excavation	$ 8.81
Engineering	.19
Adit proportion	.34
Permanent equipment	2.35
Timbering (1,590 ft.)	3.28
	$14.97

Cost of Driving Tunnel 2A, Length 1,322 Ft.

[Driven through medium-hard granite at an average speed of 150 ft. per month]

	Cost per foot of tunnel
Excavation	$8.05
Engineering	.16
Adit proportion	.34
Permanent equipment	2.35
Timbering (1,322 ft.)	2.51
	$13.41

Cost of Driving Tunnel 3-N for 1,148 Ft.

[Driven through medium-hard granite at an average speed of 150 ft. per month]

	Cost per foot of tunnel
Excavation	$10.10
Engineering	.23
Adit proportion	.51
Permanent equipment	2.35
Timbering (956 ft.)	2.44
	$15.63

Cost of Driving Tunnel 3-S for 1,358 Ft.

[Driven through granite of variable hardness, and containing pockets of carbon-dioxide gas, at an average speed of 155 ft. per month]

	Cost per foot of tunnel
Excavation	$12.38
Engineering	.28
Adit proportion	.16
Permanent equipment	2.35
Timbering (1,244 ft.)	3.28
	$18.45

Cost of Driving Tunnel 3 (3-N and 3-S), Complete, 4,044 Ft.

[Driven through decomposed granite of medium hardness, dissected by slips and talcose planes requiring timber where ground was wet, and also containing pockets of carbon-dioxide gas, making work difficult and requiring extra provisions for ventilation. Average speed, 140 ft. per month]

	Cost per foot of tunnel
Excavation	$12.67
Engineering	.24
Adit proportion	.35
Permanent equipment	2.35
Timbering (3,570 ft.)	2.71
	$18.32

Cost of Driving Tunnel 4, Length 2,033 Ft.

[Driven through medium-hard to hard granite at an average speed of 145 ft. per month]

	Cost per foot of tunnel
Excavation	$12.00
Engineering	.24
Adit proportion	.16
Permanent equipment	2.35
Timbering (1,705 ft.)	2.16
	$17.01

Cost of Driving Tunnel 5, Length 1,178 Ft.

[Driven through medium-hard to very hard granite at an average speed of 120 ft. per month]

	Cost per foot of tunnel
Excavation	$11.10
Engineering	.21
Adit proportion	.08
Permanent equipment	2.35
Timbering (916 ft.)	1.83
	$15.57

Cost of Driving Tunnel 7, Length 3,596 Ft.

[Driven through biotite granite of variable hardness at an average speed of 140 ft. per month]

	Cost per foot of tunnel
Excavation	$13.55
Engineering	.27
Adit proportion	.13
Permanent equipment	2.35
Timbering (2,609 ft.)	3.60
	$19.90

Cost of Driving Tunnel 8-S for 1,334 Ft.

Driven through medium-hard to hard granite at an average speed of 135 ft. per month]

	Cost per foot of tunnel
Excavation	$12.82
Engineering	.19
Adit proportion	.18
Permanent equipment	2.35
Timbering (126 ft.)	.39
	$15.93

Cost of Driving Tunnel 9 for 3,506 Ft.

[Driven through medium-hard to hard granite at an average speed of 195 ft. per month]

	Cost per foot of tunnel
Excavation	$12.19
Engineering	.18
Adit proportion	.07
Permanent equipment	2.35
Timbering (305 ft.)	.29
	$15.08

Cost of Driving Tunnel 10 for 5,657 Ft.

[Driven through medium-hard to hard granite at an average speed of 200 ft. per month]

	Cost per foot of tunnel
Excavation	$13.50
Engineering	.19
Permanent equipment	2.35
Timbering (194 ft.)	.11
	$16.15

Cost of Driving Tunnel 10A–N for 1,496 Ft.

[Driven through medium-hard to hard granite at an average speed of 165 ft. per month]

	Cost per foot of tunnel
Excavation	$13.02
Engineering	.13
Permanent equipment	2.35
Timbering (24 ft.)	.78
	$16.28

COST OF DRIVING TUNNEL 10A-S FOR 2,200 FT.

[Driven through medium-hard to hard granite at average speed of 200 ft. per month]

	Cost per foot of tunnel
Excavation	$12.37
Engineering	.20
Permanent equipment	2.35
Timbering (215 ft.)	1.15
	$16.07

GRAPE VINE DIVISION, TUNNELS 12 TO 17B

Important Details.—Location: Kern County, Cal. Purpose: Water supply, power, and irrigation. Cross section: See Fig. 1. Size: See Fig. 1. Type of power: Electric power purchased from aqueduct plant. Ventilators: Pressure blowers. Size of ventilation pipe: 12 ins. Drills: Pneumatic hammer, usually 2 in. each heading. Mounting of drills: Horizontal bar. Number of holes per round: Usually 18 to 20. Average depth of round: 6 to 8 ft. Number of drillers and helpers per shift: 2 drillers and 2 helpers. Number of drill shifts per day: Usually 2. Explosive: 40 per cent ammonia dynamite, but 60 per cent and 75 per cent gelatin dynamite were employed in hard ground. Number of muckers per shift: 4 or 5. Number of mucking shifts per day: Usually 2. Type of haulage: Electric after the first 400 to 500 ft. Wages: Drillers and helpers, $3; muckers, $2.50; blacksmiths, $4; helpers, $2.50; motormen, $2.75; dumpmen, $2.50.

COST OF DRIVING TUNNEL 12, LENGTH 4,900 FT.

[Driven through hard granite at an average speed of 185 ft. per month]

	Cost per foot of tunnel
Excavation*	$22.10
Engineering*	.32
Permanent equipment*	2.35
Timbering (90 ft.)	.08
	$24.75

* These items include the same costs as for the Little Lake division.

COST OF DRIVING TUNNEL 13 FOR 1,525 FT.

[Driven through hard granite at an average speed of 130 ft. per month]

	Cost per foot of tunnel
Excavation	$20.60
Engineering	.10
Permanent equipment	2.25
Adit proportion	.37
	$23.32

COST OF DRIVING TUNNEL 14, LENGTH 859 FT.

	Cost per foot of tunnel
Excavation	$22.70
Engineering	.13
Permanent equipment	2.25
Adit proportion	.72
Timbering (22 ft.)	.16
	$25.96

Cost of Driving Tunnel 15, Length 895 Ft.

	Cost per foot of tunnel
Excavation	$23.28
Engineering	.11
Permanent equipment	2.25
Adit proportion	2.42
	$28.06

Cost of Driving Tunnel 16, Length 2,723 Ft.

[Driven through hard granite at an average speed of 145 feet per month]

	Cost per foot of tunnel
Excavation	$20.07
Engineering	.17
Permanent equipment	2.25
Adit proportion	.55
Timbering (18 ft.)	.04
	$23.08

Cost of Driving Tunnel 17, Length 3,024 Ft.

	Cost per foot of tunnel
Excavation	$20.47
Engineering	.21
Permanent equipment	2.25
Timbering (142 ft.)	.22
	$23.15

Cost of Driving Tunnel 17½ for 1,345 Ft.

[Driven through medium-hard to hard granite at an average speed of 225 feet per month]

	Cost per foot of tunnel
Excavation	$19.56
Engineering	.31
Permanent equipment	2.25
	$22.12

Cost of Driving Tunnel 17A for 3,275 Ft.

	Cost per foot of tunnel
Excavation	$18.70
Engineering	.17
Permanent equipment	2.25
Timbering (441 ft.)	1.18
	$22.30

Cost of Driving Tunnel 17B for 4,915 Ft.

	Cost per foot of tunnel
Excavation	$2.109
Engineering	.21
Permanent equipment	2.25
Timbering (163 ft.)	1.90
	$25.45

ELIZABETH DIVISION, ELIZABETH LAKE TUNNEL

Important Details.—Location: Los Angeles County, Cal. Purpose: Water supply, power and irrigation. Cross section: Rectangular, with arched roof. Size: 12 by 12 ft. Length: 26,870 ft. Type of power: Electric power purchased from aqueduct plant. Ventilator: Pressure blower. Size of ventilating pipe: 18 ins. Drills: Pneumatic hammer, 3 in the south heading and 2 in the north. Mounting of drills: Horizontal bar. Number of holes per round: 25 in the south heading, 16 in the north heading. Average depth of round: 8 to 10 ft. Number of drillers and helpers per shift: 2 drillers and 2 helpers at the north end, 3 drillers and 3 helpers at the south end. Number of drill shifts per day: 3. Explosive: 40 per cent and 60 per cent gelatin dynamite. Number of muckers per shift: 6. Number of mucking shifts per day: 3. Type of haulage: Electric. Wages: Drillers and helpers, $3; muckers, $2.50; blacksmiths, $4; helpers, $2.50; motormen, $2.75; dumpmen, $2.50. Maximum progress in any calendar month: 604 ft., April, 1910. Average monthly progress per heading: 350 ft. per month.

COST OF DRIVING THE NORTH HEADING, ELIZABETH LAKE TUNNEL

[Driven through altered granite, requiring much timbering, 13,370 ft.]

	Cost per foot of tunnel
Drilling and blasting	$11.25
Mucking and tramming	11.70
Engineering and superintendence	1.27
Drainage	.45
Ventilation	.22
Light and power	5.55
Timbering (13,031 ft.)	8.48
Cost of auxiliary shaft	.93
Permanent equipment (full charge, no salvage; estimated)	3.70
	$43.55

COST OF DRIVING THE SOUTH HEADING, ELIZABETH LAKE TUNNEL

[Driven through medium-hard to hard granite, requiring but little timbering, 13,500 ft.]

	Cost per foot of tunnel
Drilling and blasting	$14.65
Mucking and tramming	11.10
Engineering and superintendence	.86
Drainage	.17
Ventilation	.41
Light and power	4.93
Permanent equipment (without salvage; estimated)	3.70
Timbering (3,424 ft.)	2.19
	$38.01

LUCANIA TUNNEL

Important Details.—Location: Idaho Springs, Colo. Purpose: Mine development and transportation. Cross section: Square. Size: 8 by 8 ft. Length: 12,000 ft. projected; 6,385 ft. driven December 1, 1911. Character of rock penetrated: Hard granite. Type of power: Purchased electric

Current. Ventilator: Pressure blower. Size of ventilating pipe: 18 and 19 ins. Drills: Pneumatic hammer, 3 in the heading. Mounting of drills: Vertical columns. Number of holes per round: 25. Average depth of round: 8 to 9 ft. Number of drillers and helpers per shift: 3 drillers and 2 helpers. Number of drilling shifts per day: 1. Explosive: 50 per cent gelatin dynamite. Number of muckers per shift: 3. Number of mucking shifts per day: 1. Type of haulage: Horses. Wages: Head driller, $5; drillers, $4; nipper, $3.50; boss mucker, $5; muckers, $4; drivers, $4; power engineers, $4; blacksmith, $5. Maximum progress in any calendar month: 263 ft., September, 1911. Average monthly progress: 125 ft. per month for the first 4,800 ft., 240 ft. per month for the last 1,575 ft.

AVERAGE COST OF DRIVING FIRST 4,800 FT.

	Cost per foot of tunnel
Labor	$ 8.86
Powder	7.86
Fuse and caps	.17
Candles and oil	.21
Horse feed and shoeing	.18
Power	1.64
Repairs	.14
Tunnel equipment	2.75
Surface plant	1.25
	$23.06

"Tunnel equipment" includes the cost of materials and installation of the pressure air line, the ventilating line, rails, ties and fittings, and the drainage ditch. "Surface plant" includes buildings, compressor blower, transformers, motors and drill sharpener.

Cost of driving next 1,575 ft.: The contractor received $21.50 per foot to cover the cost of labor, powder, fuse, caps, candles, oil, horse feed and shoeing, power and repairs, and the installation of the tunnel equipment.

MARSHALL-RUSSELL TUNNEL

Important Details.—Location: Empire, Colo. Purpose: Mine drainage, development and transportation. Cross section: Rectangular. Size: 8 ft. wide by 9 ft. high. Length: 11,000 ft. projected; 6,700 ft. driven January 1, 1913. Character of rock penetrated: Granite and gneiss. Type of power: Purchased electric current; also a small auxiliary hydraulic plant. Ventilator: Fan. Size of ventilating pipe: 12 and 13 ins. Drills: 2, pneumatic hammer. Mounting of drills: Vertical columns. Number of holes per round: 18 to 20. Average depth of round: 9 to 10 ft. Number of drillers and helpers per shift: 2 drillers and 2 helpers. Number of drill shifts per day: 1. Explosive: 40 per cent gelatin dynamite; with some, 80 per cent. Number of muckers per shift: 4. Number of mucking shifts per day: 1. Type of haulage: Horses. Wages: Drillers, $4; helpers, $3; blacksmith, $4; helpers, $3; muckers, $3.25; trammers, $3.75; dumpmen, $3.25; power engineer, $3.50; shooters, $3.25. Maximum progress for any calendar month: 187 ft., June, 1909. Average monthly progress: 125 ft.

Cost of Driving Tunnel 6,700 Ft.

	Cost per foot of tunnel
Labor	$ 9.37
Powder, fuse, caps and blacksmith coal	3.35
Drills, steel and repairs (less 30 per cent salvage)	1.34
Power	1.41
Permanent equipment and general expense (less 30 per cent salvage on permanent equipment)	3.41
	$18.88

MISSION TUNNEL

Important Details.—Location: Santa Barbara, Cal. Purpose: Water supply. Cross section: Trapezoid. Size: 6 ft. wide at the base, 4½ ft. wide at the top, 7 ft. high. Length: 19,560 ft. Character of rock penetrated: Shale, slate, and hard sandstone. Ventilator: Pressure blower. Size of ventilating pipe: 10 ins. Drills: 1 pneumatic hammer. Mounting of drills: Horizontal bar. Number of holes per round: 12 to 14. Average depth of round: 7 to 8 ft. Number of drillers and helpers per shift: 1. Number of drilling shifts per day: 3. Explosive: 40 per cent and 60 per cent gelatin dynamite. Number of muckers per shift: 4. Number of mucking shifts per day: 3. Type of haulage: Electric. Wages: Drillers, $3.50; helpers, $3; muckers, $2.75; blacksmiths, $4; helpers, $3; motormen, $2.75; dumpmen, $2.50; power engineers, $2.75. Maximum progress in any calendar month: 414 ft., February, 1911. Average monthly progress: 210 ft.

Cost of Driving the South Portal, Mission Tunnel, May, 1909, to September, 1911, 5,515 Ft.

	Cost per foot of tunnel
Administration	$ 1.14
Labor	9.20
Power	2.12
Explosives	1.97
Timbering (563 ft.)	.30
Track and pipe	1.22
Miscellaneous supplies	2.46
Drill parts (including steel)	1.02
Bonus	.48
	$19.91

"Administration" includes superintendence, office supplies, and general charges. "Miscellaneous supplies" includes candles, light globes, shovels, picks, blacksmiths' supplies and fuel, and machinists' supplies.

NEWHOUSE TUNNEL

Important Details.—Location: Idaho Springs, Colo. Purpose: Drainage and transportation. Cross section: Square. Size: 8 by 8 ft. Length: 22,000 ft. Character of rock penetrated: Idaho Spring gneiss. Type of power: Purchased electric current. Ventilator Pressure blower. Size of ventilating pipe: 18 ins. Drills: Pneumatic hammer. Mounting of drills: Vertical column. Number of holes per round: 14 to 22. Number of drill shifts per day: 1 and 2. Explosive: 40 per cent gelatin dynamite, with some 100 per cent in the cut holes. Number of muckers per shift: 3. Number of mucking shifts per day: 1 and 2. Type of haulage: Electric. Wages:

Drillers, $4 to $4.50; helpers, $3.25 to $4; muckers, $3.50; motormen, $3.50; dumpmen, $3; blacksmiths, $3.50 to $4.50; helpers, $3.

COST OF DRIVING THE NEWHOUSE TUNNEL

	Jan. to Aug. 1909, 2,233 ft.	Sept. to Dec. 1909, 1,098 ft.	Apr. to Aug. 1910, 693 ft.
Labor	$ 6.72	$ 6.98	$11.73
Explosives	4.15	3.52	4.57
Fuse and caps	.39	.36	.44
Transportation of materials broken	1.49	1.47	2.22
Power	1.99	2.16	2.82
Blacksmithing	1.57	2.61	2.00
Use of drills, repairs and steel	1.50	2.74	2.86
Equipment, ties, rails, pipe, etc.	1.74	1.78	2.19
Sundries	.79	.80	1.85
	$20.34	$22.42	$30.68

RAWLEY TUNNEL

Important Details.—Location: Bonanza, Colo. Purpose: Mine drainage and development. Cross section: Trapezoidal. Size: 8 ft. wide at the base, 7 ft. wide at the top, 7 ft. high. Length: 6,235 ft. Character of rock penetrated: Tough, hard andesite. Type of power: Steam with wood for fuel. Ventilator: Pressure blower. Size of ventilating pipe: 12 and 13 ins. Drills: 2, pneumatic hammer. Mounting of drills: Horizontal bar. Number of holes per round: 23 to 25. Average depth of round: 8 to 9 ft. at first, 5 to 6 ft. later. Number of drillers and helpers per shift: 2 drillers and 2 helpers. Number of drill shifts per day: 2 at first, 3 later. Explosive: 40 per cent and 60 per cent gelatin dyanmite (in the proportion of about 2 to 1). Number of muckers per shift: 4. Number of mucking shifts per day: 2 and 3. Type of haulage: Horses and mules. Wages: Drillers, $4.50; helpers, $3.75; muckers, $3.50; blacksmiths, $4.50; drivers $3.50; power engineers, $4. Maximum progress in any calendar month: 585 ft., July, 1912. Average monthly progress: Approximately 350 ft.

COST OF DRIVING THE TUNNEL, 6,235 FT.*

	Cost per foot of tunnel
Drilling and firing	$ 5.25
Mucking	2.16
Tramming	1.13
Track and pipe	.44
Miscellaneous underground expenses	1.44
Power plant	2.50
Blacksmithing	.73
Miscellaneous surface work	.83
General expenses	1.98
Permanent plant	3.24
Timbering (1,618 ft.)	1.18
Boarding house, debit balance	.04
	$20.98
Credit by salvage on permanent plant	1.11
	$19.87

* A more detailed statement of the cost of this tunnel may be found in an article entitled "A Problem in Mining, Together with Some Data on Tunnel Driving," by F. M. Simmons and E. Z. Burns, Bull. Am. Inst. Min. Eng., March, 1913, p. 369.

"Drilling and firing" includes labor, powder, fuse, caps, supplies, and repairs. "Mucking," "Tramming," and "Track and pipe" include labor and supplies. "Miscellaneous underground expenses" include wages of foremen, underground telephone, etc. "Power plant" includes labor, supplies, and fuel. "Blacksmithing" and "Miscellaneous surface work" include labor and supplies. "General Expenses" include salaries, office supplies, telephone, etc. "Permanent plant" includes machinery and buildings, with labor of installation, steel rails, permanent supplies, and repairs. "Timbering" includes labor and supplies. The salvage of the permanent plant is approximately 50 per cent on salable articles, such as machinery, rails, cars, etc.

ROOSEVELT TUNNEL

Important Details.—Location: Cripple Creek, Colo. Purpose: Mine drainage. Cross section: Rectangular, with large ditch at the side. Size: 10 ft. wide by 6 ft. high. Length: 15,700 ft. Character of rock penetrated: Pikes Peak granite, chiefly. Type of power: Purchased electric current. Ventilator: Purchased electric current. Ventilator: Pressure blower. Size of ventilating pipe: 16 and 17 ins. Drills: 3, pneumatic hammer. Mounting of drills: Horizontal bar. Number of holes per round: 24, usually. Average depth of round: 6 to 7 ft. Number of drillers and helpers per shift: 3 drillers, 2 helpers. Number of drill shifts per day: 3. Explosive: 40 per cent, 60 per cent, and some 100 per cent gelatin dynamite. Number of muckers per shift: 4, usually. Number of mucking shifts per day: 3. Type of haulage: Horses and mules. Wages: Drillers, $5; helpers, $4; muckers, $3.50; power engineer, $4; blacksmith, $5; helper, $3.50; dumpman, $3.50; drivers, inside, $5; outside, $4. Maximum progress in any calendar month: 435 ft., portal heading, January, 1909. Average monthly progress: Portal heading, 300 ft.; shaft headings, 270 ft.; all headings, 285 ft.

Cost of Driving Tunnel

Total cost of portal work	$111,980.06
Contractor's percentage	11,404.88
Cost of shaft heading	262,126.55
Total cost of tunnel	$386,421.49
Number of feet driven	14,167
Average cost per foot	$ 27.27

Cost of Driving the Portal Heading

	Feet	Cost per foot
1908—		
February and March	514	$22.690
April	262	30.970
May	268	26.760
June	187	35.010
July	203	29.600
August	300	21.760
September	351	19.600
October	287	23.000
November	360	21.120
December	334	18.350
1909—		
January	435	16.410
February	290	22.206
March	340	21.745
April	316	21.266
May	402	18,762
June (8 days)	62	40.600

Cost of Driving Shaft Headings

	Feet	Cost per foot
1908—		
October (2 headings)	49	$105.52
November (2 headings)	141	44.38
December (2 headings)	177	40.11
1909—

November (1 heading)	192	27.786

Typical Distribution of Expenses, Portal Heading, July, 1908, 203 Ft

	Cost per foot of tunnel
Machinery and repairs	$ 0.61
Air drills and parts	.99
Picks, shovels and steel	1.90
Ditch men	1.09
Explosives	6.90
Candles	.36
Oil and waste	.09
Electric power	2.06
Blacksmith supplies	.09
General expense	.16
Liability insurance	.17
Lumber, ties and wedges	.01
Horses and feed	.01
Compressor men	1.79
Drillers and helpers	4.21
Blacksmiths and helpers	3.43
Muckers and drivers	4.11
Foremen	1.50
Bookkeeper	.12
	$29.60

TYPICAL DISTRIBUTION OF EXPENSES, SHAFT HEADING, FEBRUARY, 1910, 259 FT.

	Cost per foot of tunnel
Maintenance of buildings, tents, etc	$0.096
Machinery and repairs	1.158
Air drills and parts	1.930
Shovels, picks and steel	1.930
Pipe and fittings	.193
Ditch men	1.480
Explosives	5.032
Lamps and candles	.217
Oil and waste	.252
Electric power	2.440
Blacksmith supplies	.150
Liability insurance	.213
General expense	.342
Lumber, ties and wedges	.119
Horses and feed	.324
Machine men and helpers	4.050
Muckers	3.065
Blacksmiths and helpers	1.362
Engineers	1.300
Pipe and track men	.675
Drivers and dump men	2.355
Foremen	1.752
Mine telephone	.008
Bookkeeper	.193
	$30.636

STILWELL TUNNEL

Important Details.—Location: Telluride, Colo. Purpose: Mine drainage and development. Cross section: Square, with ditch at side. Size: 7 by 7 ft. Length: 2,950 ft. Character of rock penetrated: Conglomerate and andesite. Type of power: Purchased electric current. Ventilator: Fan. Size of ventilating pipe: 10 ins. Drills: Started with electric drills, finished with pneumatic piston drills, using 2 in the heading. Mounting of drills: Vertical columns. Number of holes per round: 16. Average depth of round: 6 to 6½ ft. Number of drillers and helpers per shift: 2 drillers and 2 helpers. Number of drill shifts per day: 1. Explosive: 40 per cent gelatin dynamite. Number of muckers per shift: 3. Number of mucking shifts per day: 1. Type of haulage: Horses. Wages: Drillers, $4.50; helpers, $4; muckers and trammers, $3.50; blacksmith, $4.50. Maximum progress in any calendar month: 170 ft., August, 1904. Average monthly progress: 150 ft. (last 10 months.)

COST OF DRIVING THE TUNNEL

	Feet	Cost per foot of tunnel
1901	12	$23.88
1901–2	490	22.98
1902–3	377	27.94
1903–4	702	21.69
1904–5	1,077	21.19
1905	292	30.37
Average for	2,950	$23.38

These costs include all labor, supplies, repairs, powder, fuse, caps, candles, tools, lubricants, and general expenses, and the total value on the electric-drill plant with which the tunnel was started, and the total value of the air-drill plant which succeeded it, together with tunnel buildings, pipe, rails, and the ventilator, with no credit for salvage on any of this permanent equipment. The fiscal year dated from Sept. 30. The tunnel was driven in 1901–3 with electric drills, and the high cost for 1905: 292 ft., $30.37.

STRAWBERRY TUNNEL

Important Details.—Location: Utah and Wasatch Counties, Utah. Purpose: Irrigation and reclamation. Cross section: Straight bottom and walls, with arched roof. Size: 8 ft. wide by 9½ ft. high. Length: 19,100 ft. Character of rock penetrated: Limestone with interbedded sandstone, and sandstone with interbedded shale. Type of power: Electric power generated in a hydraulic plant operated in connection with the tunnel. Distance of transmission from west portal to power house approximately 23 miles. Ventilator: Pressure blower. Size of ventilating pipe: 14 ins. Drills: Piston pneumatic, usually 2 in the heading. Mounting of drills: Vertical columns. Number of holes per round: 16 to 18. Number of drillers and helpers per shift: 2 drillers and 2 helpers. Number of drill shifts per day: 3. Explosive: 40 per cent gelatin dynamite. Number of muckers per shift: 6. Number of mucking shifts per day: 3. Type of haulage: Electric after first 2,000 ft. Wages: Drillers, $3.50; helpers, $3.25; muckers, $2.75; motormen, $3.25; brakemen, $2.75; blacksmiths, $4; helpers, $2.75. Maximum progress in any calendar month: 500 ft., November, 1910. Average monthly progress: 320 ft. per heading.

COST OF DRIVING THE TUNNEL

	Feet	Cost per foot of tunnel
West heading—		
Previous to 1909	1,613	$60.05
During 1909	3,892	33.58
During 1910	5,021	30.56
During 1911	3,491	41.52
January to July, 1912	2,382	36.79
East heading, October, 1911, to July, 1912	2,682	33.04
Average for	19,081	$36.78

DETAILED COST OF DRIVING THE WEST HEADING FOR THE YEAR 1909, 3,892 FT.

	Cost per foot of tunnel
Labor—	
Engineering	$ 0.49
Superintendence	.73
Shift bosses	1.22
Timekeepers	.36
Drillmen and helpers	3.15
Miners (for handwork, trimming, etc.)	.23
Muckers	2.96
Track and dump men	.74
Mule drivers	.39
Motormen and brakemen	.44
Electricians and blower men	.07
Disabled employes	.19
Timbermen	.22
Miscellaneous	.40
	$11.59

	Cost per foot of tunnel
Materials—	
Powder, fuse, caps, etc	3.08
Lumber	.29
Oils, candles, etc	.22
Ventilating pipe	.64
Track, including ties	.68
Pressure air pipe	.40
Drill repair parts (including hose)	.18
Miscellaneous	.19
	$ 5.68
Repairs—	
Machine shop expense (including labor and supplies)	.93
Blacksmith shop expense (including labor and supplies)	1.22
	$ 2.15
Power (all purposes)	7.65
Depreciation—	
Haulage equipment	.09
General equipment	1.00
	$ 1.09
General expense	3.96
Camp expense	1.21
Corral expense	.25
	$ 5.42
Total	$33.58

"General expense" includes a proportionate charge for the expenses of the Provo office, such as salaries, stationery, telephone, and supplies; also a proportionate charge for the expenses of the Washington, the Chicago, and the supervising engineer's offices. The Provo office covers approximately 68 per cent of this charge, the Washington office 23 per cent, the Chicago office 2 per cent, and the supervising engineer's office 7 per cent.

Total	$33.04

Labor Costs of Constructing Six Small Tunnels and Shafts in Earth and Rock, Chicago.—The following data are abstracted and greatly condensed from the original given by Myron B. Reynolds in Engineering and Contracting, July 3, 1912.

There were constructed during the year 1906–7 six water pipe tunnels for the city of Chicago, three in clay and three in limestone. During construction inspectors were kept on the work for the full 24 hours. From the inspectors' reports which classified the different labor the costs given further on have been compiled. These costs are believed to be fairly accurate for the actual labor on the work. No costs are given for materials, office expenses, interest or depreciation, or for capital put into plant or into financing the work. No costs of teams or scows or other charges for the disposal of spoil are included other than the actual labor required to remove it out of the way of the work or say within a radius of 200 ft. from the shafts. In the rock tunnels the stone excavated was crushed and removed for use in the concrete and no cost of this is given. It is doubtful whether any money can be saved by so using the excavated stone unless the work is so large that a plant for screening can be installed.

The data common to all tunnels were as follows:

Inside diameter all shafts	10	ft.
Outside diameter of shafts in earth	12	ft.
Outside diameter of Ashland Ave. shaft in rock	10	ft. 8 ins.
Outside diameter of other shafts in rock	12	ft.
Inside dimensions of egg-shaped tunnels . . 7 ft. ×	8	ft. 2 ins.
Concrete lining Ashland Ave. tunnel	4	ins.
Concrete lining all other tunnels	12	ins.
Excavation per foot depth shafts in earth	4.2	cu. yds.
Excavation per foot depth shafts in rock	4.2	cu. yds.
Excavation per foot Ashland Ave. shaft in rock	3.33	cu. yds.
Excavation per foot Ashland Ave. Tunnel	2	cu. yds.
Excavation per foot all other tunnels	2.8	cu. yds.
Lining per foot Ashland Ave., shaft in rock	0.42	cu. yd.
Lining per foot all other shafts	1.3	cu. yds.
Lining per foot Ashland Ave. tunnel	0.31	cu. yd.
Lining per foot all other tunnels	1.1	cu. yds.

ASHLAND AVE. WATER PIPE TUNNEL

The shafts of this tunnel were through clay and solid rock, and the tunnel was entirely in rock requiring no timbering. The shafts in earth were excavated and lined with concrete and the shafts in rock and tunnel were excavated complete before concreting was begun.

The work was started under one foreman but he was soon discharged and the work placed in charge of a first-class man, who, as is shown by the table of excavation cost, reduced the cost per foot.

An average of eighteen holes were drilled, six cut, four helpers and eight rim holes. The cut holes were finished with a 6-ft. steel and the other holes with a 5½-ft. steel. A round comprised generally three shots, the cut first. The guns left from the cut were reloaded and again fired together with the helpers and side rim holes. The top and bottom holes were fired last. About 5 ft. were broken down per round.

For the purpose of ballast for track from 2 to 3 ft. of muck was left in the bottom, and upon removing was found to be very expensive, being very compact on account of trampling, water and blasting. Men would not work very hard at it with a pick because occasionally they would find a quarter of a stick of dynamite or live cap.

The cost of the different classes of work in the construction of the Ashland Ave. tunnel are based upon the following rates of wages.

	Per shift
Foreman	$8.00
Assistant foreman	$5.00–$6.00
Miners	$3.75
Miner's helpers	3.00
Laborers, top	2.75
Laborers, bottom	2.75
Engineers	4.80
Firemen	2.40
Carpenters	4.20
Blacksmiths	4.80
Blacksmith's helper	3.00
Teams and drivers	5.50
Timekeeper	2.50
Watchman	2.50

The above rates of wage are also applicable to the other tunnels described in this article.

Preliminary and General Work.—The cost of unloading coal, sand, cement, etc., from cars; clearing shaft and tunnel; sharpening and maintaining tools, placing ladders and general work; was $5,479.35 divided as follows.

Cost per ft. charged to shaft	$ 5.20
Cost per ft. charge to tunnel	2.60

Installing Plant.—The cost of installing plant was: South Shaft—$724.50; North Shaft—$290.90, divided as follows:

Cost per ft. charged to shaft	$ 1.00
Cost per ft. charged to tunnel	.50

Shaft Sinking in Earth.—The character of ground encountered in the South Shaft was: 1.5 ft. macadam; 14.9 ft. fill; 12.1 ft. blue clay; 7.5 ft. hard clay; 16.7 ft. hardpan and boulders: Total 52.7 ft. Powder was used for lower half. On the North Shaft (60.6 ft. deep) powder was used for the bottom 40 ft. The following costs include lagging up the sides and placing iron rings.

	South shaft	North shaft
Total	$550.95	$496.00
Per lin. ft	10.45	8.20
Per cu. yd	2.45	1.95

Shaft Sinking in Rock.—The time distribution was: Setting up, 5%; drilling, 44%; shooting, 24%; mucking 27%. The costs follow.

Total—South shaft	$ 809.75
North shaft	1422.50
Per lin. ft	44.50
Per cu. yd	13.30

Excavation of Tunnel.—As noted before the change in foreman had a marked effect on the cost. This is shown clearly in the following unit costs

	South end		North end	
	Foreman No. 1	Foreman No. 2	Foreman No. 1	Foreman No. 2
Per lin. ft	$ 17.20	$ 12.40	$ 27.00	$ 10.80
Per cu. yd	8.10	6.20	13.50	4.40
Length excavated, ft	340.5	596.5	61.5	669.

The average unit costs for the total length were $13.30 per lin. ft. or $6.65 per cu. yd.

Trimming and Mucking Bottom.—The mucking consisted of 400 cu. yds. of rock which had been left for ballast. The unit cost of trimming and mucking bottom was $5.00 per lin. ft.

Lining Shafts and Tunnel.—The following are the unit labor costs for lining shafts and tunnel. The costs for concreting the shafts in rock are high due to the fact that the shafts were excavated larger than called for in the specifications, thus necessitating about 3 times as much concrete as should have been used.

Unit Labor Costs of Lining Shafts and Tunnel.—

LINING SHAFTS

	South shaft	North shaft
In earth—		
Depth, ft	50	58
Cost per lin. ft	$5.30	$5.40
Cost per cu. yd	4.10	4.13
Bailing and removing forms—		
Cost per lin. ft	1.65	2.35
Cost per cu. ft	1.27	1.81
Total cost per cu. yd	5.37	5.94
In rock—		
Cost per lin. ft	7.50	7.00
Cost per cu. yd	5.90	6.85

CONCRETING AND PLASTERING TUNNEL

Concreting—per lin. ft	$2.85
per cu. yd	5.70
Plastering—per lin. ft	0.18

DRAINAGE CANAL TUNNEL AT WESTERN AVE.

This tunnel was similar in section to the Ashland Ave. Tunnel except that the lining of the tunnel was 12 ins. instead of 4 ins. of concrete. A great amount of water was encountered in driving the shafts and tunnel. The specifications required the lining to be water-tight. To accomplish this end a large number of 1-in. pipe weepers were inserted as the lining progressed, to which afterward was to be attached a hose to permit grout to be pumped in behind the lining. The grout passed out into crevices in the rock and the scheme was abandoned. Plastering was of no avail. An average of 10 ft. per 24 hours was maintained in the driving of this tunnel, and 3 to 4 ft. in the shafts in rock.

This work was prosecuted under the direction of a competent foreman. An average of 18 holes were drilled and shot in the same manner as in the Ashland Ave. Tunnel.

The cost of the different classes of work in the construction of the Drainage Canal Tunnel follow.

Cost of Preliminary and General Work.—This included: erecting headframe; setting engine and compressor; fitting up pump; building engine house; overhauling plant; installing cage and track; placing ladders in shafts; grouting tunnel; etc. The total cost was $2,524.10 which is charged to shafts and tunnel in the following proportions: cost per ft. shaft $6.60; cost per ft. tunnel $3.30.

Shaft Excavation in Earth.—South Shaft 12 ft. clay, dry; 10 ft. stiff blue clay, wet; 22 ft. hardpan; 19.5 ft. hardpan and boulders, wet. North Shaft 17 ft. clay fill; 23 ft. medium blue clay; 10 ft. hardpan and boulders.

	South shaft	North shaft
Total cost	$837.30	$943.90
Depth, ft	63.5	60.4
Cost per lin. ft	13.20	15.65
Cost per cu. yd	3.15	3.70

Shaft Excavation in Rock

	South shaft	North shaft
Total cost	$744.30	$1,367.95
Progress, ft	26	37.6
Cost per lin ft	28.80	36.50
Cost per cu. yd	6.80	6.70

Tunnel Excavation, Drainage Canal Tunnel

	Three 8-hr. shifts per day	Two 10-hr. shifts per day
Total cost	$1,495.45	$2,980.40
Cost per ft	14.50	10.20
Cost per cu. yd	5.20	3.65
Total per cu. yd	5.75	4.20
Lin. ft	103.2	292

Trimming and Mucking, Drainage Canal Tunnel

	Working two 10-hr. shifts per day
Total cost	$597.20
Cost per ft	1.50
Cost per cu. yd	0.55
Lin. ft	395

Concreting Shafts in Earth, Drainage Canal Tunnel

	South shaft	North shaft
Total cost	$296.50	$232.40
Progress, ft	60	57
Cost per ft	4.95	4.10
Cost per cu. yd	3.80	3.15

Removing Shaft-Forms in Earth, Drainage Canal Tunnel

	South shaft	North shaft
Total cost	$81.80	$157.40
Cost per ft	1.35	*2.80
Cost per cu. yd	1.05	2.10
Cost of concreting and removing forms per cu. yd	4.85	5.25

* Forms under water 60 days.

Concreting Shafts in Rock, Drainage Canal Tunnel

	South shaft	North shaft
Total cost	$296.40	$276.95
Cost per ft	7.90	7.10
Cost per cu. yd	5.30	5.20
Depth, ft	37.6	26 shaft 13 tunnel

Removing Forms, Shafts in Rock, Drainage Canal Tunnel

Total cost	$40.85
Progress, ft	63.6 shaft 13 tunnel
Cost per lin. ft	$ 0.65
Cost per cu. yd	0.15

Total cost of concreting and removing forms per cu. yd.; North Shaft, $5.45; South Shaft, $5.35

Concreting Tunnel, Drainage Canal Tunnel

Total cost	$1,536.95
Cost per ft	4.00
Cost per cu. yd	3.65
Length ft	382

WESTERN AVE. TUNNEL UNDER THE WEST FORK OF THE SOUTH BRANCH OF THE CHICAGO RIVER

This tunnel was similar in all respects to the tunnel under the Drainage Canal. The first 10 or 15 ft. of the north shaft in rock had to be timbered, the rock being of such loose character.

On account of a change in alignment 150 ft. of the bottom varying in depth from 0 to 3 ft. had to be removed in order to obtain the proper grade. The charge of this should not be made directly to the tunnel excavation. The method of blasting was the same as in the Ashland Ave. Tunnel, the work being done under the supervision of the same foreman.

The costs of the different classes of work in the construction of the West Fork Tunnel follow.

Cost of Preliminary and General Work, West Fork Tunnel

This includes erecting head frame, setting machinery, building engine house, installing cage and track, etc.

Total cost	$3,145.35
Cost per ft. charged to shaft	11.00
Cost per ft. charged to tunnel	5.50

Excavation, Shafts in Earth, West Fork Tunnel

	South shaft	North shaft
Total cost	$358.00	$186.20
Depth, ft	37	21
Cost per ft	9.70	8.90
Cost per cu. yd	2.30	2.10

Ground—South Shaft; 5 ft. fill; 11 ft. blue clay; 16 ft. hard dry clay; 5 ft. hardpan and boulders. North Shaft; 6 ft. fill; 10 ft. medium clay; 5 ft. hardpan and boulders.

Shaft Excavation in Rock, West Fork Tunnel

	South shaft	North shaft
Total cost	$439.05	$1,444.65
Depth, ft	19	46
Cost per ft	23.00	31.50
Cost per cu. yd	5.50	7.50

Tunnel Excavation, West Fork Tunnel

Total cost	$5,495.95
Length, ft	350.00
Cost per ft	15.65
Cost per cu. yd	5.60

Excavating Bottom, 150 ft. × 2 ft. Deep

Total cost	$ 841.65
Cost per ft	5.60
Cost per cu. yd	2.50

Trimming Tunnel

Total cost	$ 103.00
Cost per lin. ft	0.30

Concreting Shafts in Earth, West Fork Tunnel

	South shaft	North shaft
Total cost	$244.40	$117.80
Depth, ft	35	19
Cost per ft	7.00	6.15
Cost per cu. yd	5.40	4.70

Concreting Shafts in Rock, West Fork Tunnel

	South shaft	North shaft
Total cost	$237.60	$393.05
Depth, ft	19	46
Cost per ft	12.50	8.55
Cost per cu. yd	9.60	6.00

Concreting Tunnel, West Fork Tunnel

Total cost	$1,670.20
Length, ft	325
Cost per ft	5.15
Cost per cu. yd	4.70

INDIANA ST. WATER PIPE TUNNEL

This tunnel was constructed under favorable circumstances to its completion. But little water (bailing only was necessary at times) was encountered, and in only two places was it necessary to hold up the roof by timbering.

When the full shift was at work 16 ft. were mined and concreted during the three 8-hour shifts. Mining was carried on from 12 o'clock midnight until 3 o'clock P. M., and on the 3-11 shift the concrete linning was placed.

It was first attempted to use 40 per cent dynamite to loosen up the clay, but following the first shot a lump of clay fell on the leg of one man and broke it, after which the ground was grubbed out. The bottom half was hard clay and hardpan and the top half was medium clay.

In the shafts with four miners per shift working 10 ft. were excavated per 24 hours. About 4⅛ cu. yds were averaged per 8 hours for each man digging in both the shafts.

In concreting the shafts the steel rings holding the lagging were removed from the shaft and the lagging taken away from the excavation and placed against centers for forms. A platform was made to fit over the forms and upon it the concrete was dumped and then shoveled into place and tamped.

In concreting the tunnel the bottom was first placed and graded to templet. A board floor was then laid over this concrete, the centers placed and the lagging set in as the concrete came up.

The concrete was hand mixed on a platform at the top of the shaft, loaded into cars and let down on a cage into the tunnel.

The costs in the different classes of the work in the construction of the Indiana Street Tunnel follow.

Preliminary and General Work, Indiana Street Tunnel

Total cost	$1,185.35
Cost to be charged to shaft per ft	3.60
Cost to be charged to tunnel per ft	1.80

Shaft Excavation, Indiana Street Tunnel

	East shaft	West shaft
Total cost	$1,004.30	$775.00
Depth, ft	92	73
Cost per ft	10.90	10.60
Cost per cu. yd	2.60	2.50

Tunnel Excavation, Indiana Street Tunnel

Total cost	$2,080.85
Progress, ft	335
Cost per ft	6.25
Cost per cu. yd	2.25

Excavation was half medium and half hard clay.

Concreting Shafts, Indiana Street Tunnel

	East shaft	West shaft
Total cost	$444.60	$365.90
Lin. ft	90	71
Cost per ft	4.95	5.15
Cost per cu. yd	3.80	3.95

Concreting Tunnel, Indiana Street Tunnel

Total cost	$1,156.40
Lin. ft	335
Cost per ft	$ 3.55
Cost per cu. yd	2.25

ILLINOIS AND MICHIGAN CANAL TUNNEL AT WESTERN AVE.

This tunnel was constructed by the same firm and under the supervision of the same foreman as was the Indiana tunnel. Powder was used in excavating this tunnel, but the clay was too springy for good results.

Some bad cement was delivered and used before testing which did not set up. As a consequence, 60 ft. of the tunnel lining had to be removed and replaced.

The north shaft of this tunnel was excavated and lined by using a windlass for raising and lowering. It appeared as cheap as though a hoisting engine had been used, but the time was much longer.

The costs of the different classes of work in the construction of the Illinois and Michigan canal tunnel follow.

Cost of Tunnel Work, Illinois and Michigan Canal Tunnel

Total cost	$1,138.40
Cost per ft. to be charged to shaft	4.80
Cost per ft. to be charged to tunnel	2.40

Cost of Excavating Shafts, Illinois and Michigan Canal

	North shaft	South shaft
Total cost	$672.60	$830.10
Progress, ft	58	58
Cost per ft	11.60	14.30
Cost per cu. yd	2.75	3.25

Cost of Excavating Tunnel, Illinois and Michigan Tunnel

Total cost	$1,571.30
Progress, ft	225
Cost per ft	7.00
Cost per cu. yd	2.50

Excavation was hard clay. Powder was used.

Cost of Concreting Shafts, Illinois and Michigan Tunne

	North shaft	South shaft
Total cost	$332.30	$365.90
Progress, ft	55	58
Cost per ft	6.05	6.30

Cost of Concreting Tunnel, Illinois and Michigan Tunnel

	Concreting	Replacing condemned lining
Total cost	$793.00	$263.40
Progress, ft	225	60
Cost per ft	3.50	4.40
Cost per cu. yd	3.20	4.00

DIVERSEY BOULEVARD TUNNEL

This tunnel and shafts were shown on the plans to have the same cross section as the other water pipe tunnels in clay. The borings indicated, however, that quicksand would be encountered in the sinking of both shafts and that the tunnel would be in solid rock. Acting on this the contractor elected to use 8 × 8 ft. octagonal bracing instead of the usual circular iron rings. This necessitated placing a much larger amount of concrete in the shaft lining than was actually called for in the specification.

Upon excavating the shafts to about half their depth the method of holding up the excavation was changed from timbering to the use of a steel shield, which was let down in sections and jacked into place as the excavating progressed. Water in large amounts was encountered, a large Nye pump being used in both shafts all the time.

When the elevation was reached for the tunnel grade no rock other than large boulders was found, and a boring 10 ft. deeper did not discover rock. It was presumed that in the original borings large boulders had been struck and mistaken for solid rock. The tunnel was driven through water bearing sand and gravel on top and hard clay on the bottom from the east shaft and through hard clay from the west shaft.

When the eye in the west shaft was cut for the tunnel the ground fell into the shaft and the surface of the ground at the top of the shaft sunk 10 ft., tipping over the hoisting engine and compressor.

No timbering was necessary to hold the ground in the tunnel from the west shaft, but the tunnel sides, roof and face from the east shaft had to be sheeted tight.

In the tunnel from the east shaft one miner worked with two muckers each shift. The miner on one shift was an Assyrian with experience in this class of work. The tunnel was excavated and lined in 4 ft. sections. The excavation was started at the crown, and by removing the upper half the center vertical plank, which had been previously placed to hold up the face, the wet sand and gravel could be removed by hand until there was room to place the crown plank and place a post under it. This method was continued down each side in turn until the springing lines were reached, at which point ground was reached which would stand up. The timbering, except the posts, was left in and the concrete lining placed. The posts were removed as reached by the concrete.

The costs of the different classes of work in the construction of the Diversey Blvd. tunnel follow.

Cost of General Work, Diversey Blvd. Tunnel

Total cost	$2,820.50
Cost per ft. to be charged to shaft	7.80
Cost per ft. to be charged to tunnel	3.90

Cost of Shaft Excavation Diversey Blvd. Tunnel, East Shaft

Cost of Tunnel for the Tallulah Falls Hydro-Electric Development in Georgia.—Charles G. Adsit and Eugene Lauchli give the following data in Engineering and Contracting, May 6, 1914.

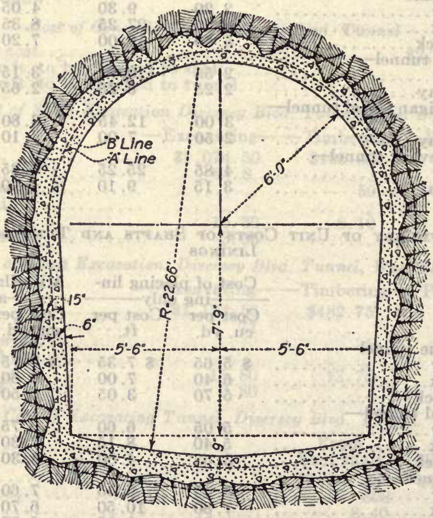

FIG. 2.—Section of tunnel, Tallulah Falls development.

The tunnel 6,665 ft. long and of dimensions indicated in Fig. 2 was driven to convey water from the diverting dam to a forebay or surge reservoir.

The tunnel was driven on a 2 in 1,000 grade, sloping from the intake down to the forebay, through a grey blueish granite, dipping downstream at an angle of 22°, wich occasional mud seams. The ground stood well generally, and only 6 per cent of the tunnel length required timbering during construction.

For the purpose of expediting the work, it was found desirable to drive the tunnel from the intake and forebay ends, as well as from two adits 7 ft. high, 13 ft. wide, 105 and 217 ft. long, respectively, (adits No. 1 and 2) driven on a 1 per cent grade. Before starting work at the intake end, 4,000 cu. yds. of material, mostly rock, had to be excavated. At the forebay, consisting of a shaft 35 ft. wide, 75 ft. long and 70 ft. deep, some 10,800 cu. yds. of rock had to be excavated. Later on, adit No. 3, 150 ft. long, was provided and an 8 × 10-ft. shaft, 112 ft. deep, was sunk between the intake portal and adit No. 1.

The work under consideration involved the following quantities:

	Cu. yds.
Adit excavation	1,250
Main tunnel:	
Heading	23,330
Bench	29,650
Concrete lining within specified lines	15,430
Concrete lining beyond specified lines	3,540

Seventy-five per cent of the tunnel length was driven with a top heading and bench, and the balance with a bottom heading, the overlying material being stoped down on the heading floor. Attention is called here to the fact that, owing to the relatively small section of the tunnel, heading excavation represented about 49 per cent of the total excavation.

Power Plant and Equipment.—The contractor, the Northern Contracting Co., built a temporary power plant housing two 500-HP. S. Morgan Smith hydraulic Francis turbines, operating under an average head of 48 ft. and driving two Laidlaw Dunn Gordon air compressors, each having a capacity of 2,500 cu. ft. of free air per minute, 110 lbs. pressure. A wooden dam, 10 ft. high and 60 ft. long, was thrown across the Tallulah River, at Lador Falls, and a 7.5-ft. steel penstock 80 ft. long served to convey water from a masonry intake located at one end of the dam to the turbines. A 3-ft. diameter steel penstock also diverted water from the intake to 125-HP. Francis turbine driving a 50-KW. generator used for lighting purposes.

The tunnel sub-contractor, Condon, Graham & Millner of Knoxville, Tenn., was furnished, free of charge, with 4,000 cu. ft. of air per minute and also with electric current. Owing to low water conditions, in 1912, it was found necessary to increase the capacity of the air plant, and a steam-driven Sullivan straight line air compressor, with a capacity of 1,875 cu. ft. of free air per minute, and two 200-HP. Scotch Marine type boilers were installed near to the forebay and connected with the main air line, consisting of 10, 8 and 6-in. wrought iron pipe, partly laid along the T. F. Ry. track.

Piston drills were used first, but owing to the hardness of the rock and its abrasive properties, necessitating much sharpening, thus being a serious hindrance to progress, Leyner water core air drills No. 7. were adopted, and their use immediately caused a general improvement in progress. With piston drills, starting holes was found a chief difficulty to overcome, and drilling of dry holes gave little satisfaction.

No. 2 Leyner bit sharpeners were installed at each adit and points of attack. At the shaft the following plant was installed:

1 set 10 × 15-in. Jaw crushers.
1 set sand rolls.
1 60 H.P. steam engine.
1 two-drum 18 H.P. hoist engine operating the shaft cage.
1 set of sand screens.
1 cement house.

Owing to the steepness of the gorge, at the mouth of the adits and intake portal, much of the tunnel muck, necessary for the concrete aggregate was lost, and it was found necessary to open a quarry at adit No. 3.

As a whole, the labor available was extremely poor and unreliable for this class of work. Negro labor was used chiefly. Some Hungarians and Cherokee Indians gave somewhat better results. Rainy weather (annual rainfall varying from 70 to 80 ins.) was a serious hindrance to progress. During holidays a large number of men would leave, thus resulting in onerous transportation charges, and it was no small task to organize and break in two shifts of men for 10 working points. Thus labor conditions account chiefly for the somewhat slow progress in driving the tunnel.

Two shift were worked per day at each heading, a shift consisting of 4 drillers, 4 helpers, 6 muckers, 2 trammers, 1 foreman. Mules were used for haulage. At the adits, forebay and intake, one blacksmith and one helper did the drill sharpening.

The following wages prevailed: Drillers, $2.50; drill helpers, $1.75; muckers, $1.65; foremen, $4.50; blacksmiths, $3.50; helpers, $2.00; carpenters, $3.00; concrete men, $1.75.

Work at the intake heading and driving of adit No. 1 was started during July, 1911, and work at adit No. 2 on the following month. The intake top heading was first excavated for a length of 800 ft.; at this point ground pressure necessitated heavy timbering and in some instances the roof caved in for a height of 10 ft. Progress was very slow and costly; some water was encountered, and as the tunnel was being driven down grade, pumping had to be resorted to in order to keep the heading dry. It was then deemed advisable to carry the bench excavation close to the heading, and work was suspended pending the completion of the bench excavation.

The headings at adit No. 1 and 2 were carried at the top of the tunnel. A top heading was also started in September, 1911, from the bottom of the forebay, the material excavated being handled with a derrick located at the mouth of same. After the heading had been driven some 500 ft., a soft seam was struck, necessitating timbering.

In June, 1912, after the shaft between the intake and adit No. 1 had been sunk to grade, and adit No. 3 had been driven to the main tunnel, headings 8 ft. high were driven at the bottom of the tunnel section, and the overlying material was stoped down on the tunnel floor.

The average progress for heading and bench excavation during the year 1912 was 30 and 38 ft., respectively, per week (6 days). Twice the progress was made in stoping work as in bench excavation, at a less cost of about 50 cts. per cubic yard. During April, 1912, about 1,784 cu. yds. of bench material were excavated at a cost of $4.315 per cubic yard, and during May of the same year 3,807 cu. yds. of rock were stoped down at a cost of $3.789 per cubic yard, or at a lesser cost of $0.526 per cubic yard. The cost of bench and stoping work was as per Table IV.

TABLE IV

	Per cu. yd. stoping work	Per cu. yd. bench work
Labor	$2.415	$2.965
Supt. and walking bosses	.141	.067
General expenses	.036	.101
Office force	.103	.085
Storeroom force	.027	.028
Repairmen	.115	.102
Carpenters	.053	.050

Miscellaneous charges	.066
Depreciation on equipment	.150
Power*	.306
Total	$5.928

* This item represents that part of the original cost and cost of operation of compressor plant No 1 chargeable to tunnel excavation.

Concrete Lining.—Work on the lining was not started until September, 1912, i.e., at a time when the tunnel had been practically completely excavated. About 120 ft. of tunnel invert was concreted first at adit No. 3, and Blaw collapsible steel forms were then erected and concreted. It was soon found out that it would be preferable to concrete the side walls and arch first, and later on the invert, and this procedure was then followed throughout.

A total length of 240 lin. ft. of Blaw forms were used, the lining being carried on simultaneously at three points. Three concreting machines furnished by the Concrete Mixing & Conveying Co. of Chicago were installed and operated by air at 100 lbs. pressure. The best results were obtained when conveying concrete to the steel forms, erected in 20 ft. lengths only, through 6-in. diameter spiral pipes. The concrete was a 1:3:5 mixture, the aggregate being not over 2 ins. in size. In using these concrete conveying machines, great care had to be exercised in order to prevent the formation of voids within the lining, as its thickness was relatively small. In general, it was found that a somewhat better finish would have been obtained had the lining been given a greater thickness, as it was somewhat difficult to clean thoroughly the forms after these had been used. However, the results obtained were satisfactory for the purpose intended; in wet places the concrete was somewhat honeycombed, but this defect was corrected during the grouting process.

In places where the tunnel roof was high, it was found cheaper to use concrete rather than spalls for back filling, inasmuch as all voids were to be grouted.

The average progress of concreting varied from 30 to 60 ft. per week (6 days), the average for the whole tunnel being about 60 ft. The invert was laid without air concreting machines, as it was found that, in order to obtain satisfactory results, the concrete had to be delivered in a confined space. The invert was laid at a rate of about 745 ft. per week.

The cost of the concrete lining is given in Table VII. Cement was sold by the Northern Contracting Co. to the sub-contractor for the sum of $1.80 per barrel.

TABLE VII

Items—	Cost per cu. yd.
Labor	$5.12
Cement	2.995
Miscellaneous materials	0.411
Lumber	0.138
Freight	0.066
Transportation	0.157
Insurance	0.168
Royalty on concreting machine	0.420
Miscellaneous expenses	0.106
Crushing rock	2.02
Quarrying rock	0.87
Plastering concrete	0.206
Cleaning up tunnel	0.382
Total*	$12.041

* Blaw concreting forms and depreciation on equipment not included.

Grouting.—The specifications called for a mixture to be used for this purpose, consisting in 1 to 1½ part sand to 1 part cement. Grout and vent pipes 1½ ins. in diameter were provided in the tunnel arch, or in other places where necessary, 15 ft. apart, more or less. Four grouting machines were used for this purpose, under 40 lbs. pressure. Little trouble was encountered, although in a few places local flaking of the lining occurred where voids had been left. In wet places the grout oozed through the honeycombed concrete, thus making a somewhat rough surface, which was smoothed up later up. The cost of grouting was about $1.10 per cubic yard of concrete placed.

Cost of Driving 8,700 Ft. of Tunnel by Station Men.—In connection with the reconstruction of its canal system the Naches-Selah Irrigation District, comprising some 10,500 acres of orchard lands in the Yakima Valley, Washington, will construct 16 tunnels of an aggregate length of 21,000 ft. Eight of these tunnels, totaling 8,718 ft., were constructed in 1918. The following data are given in Engineering and Contracting, Dec. 17, 1919 by E. M. Chauder who prepared the designs for the work.

The tunnels are 7 ft. wide in the clear, with flat bottoms, side walls from 4 to 5½ ft. high to the spring line of a segmental arch with a 2 ft. rise. The reinforced concrete lining, except in the timbered sections is 6 in. thick, with the exception that in rock the floor thickness is 4 in. The tunnels were driven through soft and dry sand rock and shale, and in all cases but one the drilling was done with coal augers.

The tunnels were driven by station men, who in some instances were paid at the rate of $6 per lineal foot. Three men constituted a shift. The tunnel driving was doubled ended and double shifted. The station men netted from $10 to $15 per day, and at the same time set the pace for speedy, economical tunnel driving.

The holes were bored about 8 ft. deep, usually 9 ft. on a face. No springing was required. The coal auger was held in place by being jacked against the floor and roof. Varying lengths of auger were used as the hole progressed. About an hour usually was required to drill and load the holes. The three men did the mucking, using large scoop shovels for this purpose. One of the three drove the loaded car hauled by a mule to the dump. The haul was short and took only a few minutes. An average of 20 lin. ft. per day was made on some of the tunnels driven in soft shale.

In the tunnels where sandrock was encountered, a little more time for drilling and more powder were required; but there was very little difference in the progress made.

In lining the tunnels, the floor was run in first, contrary to the usual practice, then the sides and then the roof. The mix for the latter was 1:3:5; for the floor and sides it was 1:2:4. The mixing was done outside by machines and carried in by cars on track. Four men in the tunnel, two taking turns shoveling overhead, and two, one on each side, tamping back into place, would ordinarily put in 60 ft. of roof in 8 hours. The maximum run was 70 ft. in 8 hours.

During most of the work labor was paid $4.50 per 8-hour day, and part of the time $5.50.

The following tabulation summarizes the cost of driving and lining the eight tunnels:

Tunnel No.	Length, ft.	Total cost per lin. ft.	Excavation cost per cu. yd.	Lining cost per cu. yd.
1	1,920.0	$21.20	$4.10	$22.20
2	782.5	24.20	5.20	22.80
9	1,363.0	20.00	3.33	23.40
10	1,080.5	19.70	3.39	22.30
11	883.0	18.20	3.89	21.00
12	893.0	18.00	3.51	22.00
13	651.0	18.70	3.32	22.40
14	1,145.0	19.60	3.13	27.20
Total.......	8,718.0	$20.10	$3.73	$23.00

Tunnel No. 1—Sandstone of varying hardness and irregular fracture.
Tunnel No. 2—Cemented gravel and large boulders. Could not use augers or machine drills. Much overbreak.
Tunnel No. 3—Soft sandstone. Concrete run in from one end only.
Tunnel No. 4—Soft sandstone.
Tunnel No. 5—Soft shale with considerable gravel intermixed.
Tunnel No. 6—Soft shale. Lined in winter. Water hauled several miles under bad conditions.
Tunnel No. 7—Soft shale. Concrete material hauled 5.7 miles.
Tunnel No. 8—Soft shale with considerable overbreak. Concrete material hauled 6 miles and water 3 miles in winter over almost impassable roads.

Cost of Cross Cutting, Amador County, California.—Important factors in cross cutting based on actual mining operations are outlined by Edwin Higgins in a bulletin issued on July 1 by the California Metal Producers' Association. The data are the result of an investigation conducted at the mines in Amador County, California. The matter following is taken from an abstract of the bulletin published in Engineering and Contracting, Sept. 19, 1917.

A summary of the data relating to the driving of 10 cross cuts in various California mines is given in Table VIII. In this table costs are figured only on labor and explosives, the following charges being made for labor: Drill men, $3; chuck tenders and muckers, $2.50.

All the cross cuts are in the hard greenstone of Amador County except operation No. 8 (hanging wall slate), operation No. 9 (andesite and schist) and operation No. 10 (slate). Five degrees of hardness were selected, No. 5 being the hardest. Most of the rock encountered was uniformly hard. The strength of the caps used was 6X.

TABLE VIII.—DATA RELATIVE TO THE DRIVING OF TEN CROSS CUTS IN VARIOUS CALIFORNIA MINES

No.	Hardness of rock, 1–5	Distance driven, ft.	Size of cross cut, ft.	Average length of tram, ft.	Type of drill used	Kind of bit	Air pressure at drill, lbs. per sq. in.	Depth of holes, ft.
1	5	94	6 × 8– 7 × 9	Various	Piston	Cross	85–90	5½–6
2	5	346	7 × 9	Various	Water Hammer	Carr	85–90	5½–6
3	4	100	5 × 6½	1000	Water Hammer	Carr	90	5
4	4	500	6 × 9½	275	Stoper Water Hammer	Carr	90–95	5
5	4	427	5½ × 7	1318	Water Hammer	Cross	70–90	5 –6
6	5	172	7 × 9	140	Piston	Cross	75	5 –6
7	4	357	7 × 9	180	Piston	Cross	80	5½–7
8	3–4	450	5 × 6	2190	Piston	Cross	80	6
9	4–5	150	6 × 7½	85	Water Hammer	Cross	90	5 –6
10	3	432	5 × 7	210	Piston	Cross	85	5

No.	No. of holes per round.	Shifts to drill round.	Advance per drill shift, ft.	Shafts worked per 24 hrs.	Days pay, contract	Kind of fuse used.	Kind of powder used	Lbs. powder per round	Cost per ft. labor & explos.
1	15–16	3	1.5–2	2	DP	Comet	30 % Ammo-Gel.	62	$6.12
2	15–16	1–1½	4.0	2	DP	Comet	30 % Ammo-Gel.	62	3.82
3	16	1	4.25	1	DP	Delay Expl.	35 % Gel. Dyn.	50	3.62
4	16	1	4.5	2	DP	Delay Expl.	35 % Gel. Dyn.	50	3.42
5	11–13	1¾	2.60	1	DP	Eclipse Special	40 % Gel. Dyn.	30	4.38
6	15	2	2.0	3	DP	Pacific	40 % Ammo-Gel.	50	5.87
7	12	1	5.0	2	C	Pacific	40 % Ammo-Gel.	62	3.94
8	11	1¼	3.66	3	DP*	Anerold	40 % Nit. Gly.	30	4.07
9	12	⅝ ⅝	5.0	3	DP	Pacific	35 % Ammo-Gel.	38	3.07
10	8–10	⅝	4.5	1	C	Pacific	40 % Ammo-Gel.	30	3.36

* Bonus paid: Machinemen received $3 per day; chuck tenders and muckers $2.50 per day. For every 5 ft. over 50 ft. per week, all men received 25 cts. per day additional.

For fear of creating an erroneous impression regarding the use of some particular drill, it was decided not to mention the make, but simply to divide the drills into two classes, piston drills using solid steel, and hammer drills using water through hollow steel. In practically all of the operations 1-ton, steel, end-dump cars were used, and shoveling was done either from a steel sheet or from planks. Hand-tramming was used in all of the operations except No. 3, in which mules were used. The track gage in all cases was 18 in., and 16-lb. rails were used except in operations Nos. 6 and 10, where 12-lb. rails were used. No. timber was used, except in operations Nos. 5, 6 and 7, which required a few sets each.

Operation No. 1: This work was done in 1915, the cost of the 94 ft. being as follows:

	Cost	Percentage of total cost
Drilling (labor)	$295.25	41.2
Mucking and tramming	192.50	26.8
Supplies	48.50	6.8
Powder (at 11 cts. per lb.)	181.45	25.2
Total	$717.70	
	or $7.63 per ft.	

Operation No. 2: Of the 346 ft., 239 were driven in 1916 and 107 ft. in 1917. The 1916 costs were as follows:

	Cost	Percentage of total cost
Drilling (labor)	$ 785.25	31.4
Mucking and tramming	583.25	23.3
Powder	946.45	37.9
Track, ties and incidentals	186.43	7.4
Total	$2,501.38	
	or $10.46 per ft.	

The costs during 1917 (107 ft.) were as follows:

	Cost	Percentage of total cost
Drilling (labor)	$ 292.00	27.6
Mucking and tramming	327.00	30.9
Supplies	84.20	8.0
Powder (at 17 cts. per lb.)	354.20	33.5
Total	$1,057.40	
	or $9.88 per ft.	

Operation No. 3: Firing was done electrically from a 110-volt line with switch, using delay exploders.

Cycle of Operations: Machineman goes to work at 7:00 a. m., finding clean set-up. He drills and shoots at about 3:00 o'clock. Two muckers go on at 7:30 p. m., muck out, clean up and put in platform for next shift. All drill parts are kept available in duplicate.

Operation No. 4: Practically same cycle of operations as No. 3, except that two shifts are worked. Machineman comes on to a clean set-up, drilling and shooting about 3:30 p. m. Two muckers come on at 4:00 p. m. and muck back for a clean set-up. They muck out their round, machineman coming on at 7:00 p. m. He drills and shoots at about 3:30 a. m. Two muckers come on at 4:00 a. m. and muck back so that a machineman coming on at 7:00 a. m. will have a clean set-up.

Since this work was done a change has been made which has resulted in greater efficiency. The 1¼-in. round, hollow steel, with cross bit, one set of which sufficed to drill only one hole, has been discarded in favor of 1-in. hexagon, hollow steel, with Carr bit. Drilling speed has increased 25 per cent or more and new steel drills from five to eight holes without resharpening. The drill has been equipped with a striking block, or anvil block.

Operation No. 5: Most of this work was done with one drillman on the first shift and one mucker on the second shift. The 426.5 ft. were driven in the period from July, 1916, to February, 1917, at the following cost:

	Cost	Percentage of total cost	Cost per foot
Timbering	$ 51.88	1.8	$0.12*
Drilling	1,084.16	36.9	2.54
Mucking and tramming	521.73	17.8	1.22
Explosives	670.48	22.8	1.59
Candles	18.60	0.6	0.04
Hoisting	591.10	20.1	1.38
Total	$3,937.95	100.0	$6.89

* Not timbered throughout.

163.5 drill-shifts were worked, which gives an average advance of 2.6 ft. per drill shift.

Operation No. 6: The cost for the 172 ft. was $1,255 ($7.30 per ft.), which does not include air, hoisting, drill sharpening or superintendence. The work was done in July, 1916.

Operation No 7: Drillers and muckers made from $4 to $4.50 per foot on contract. Ventilation was by compressed air, with water spray used after shooting.

Cycle of operations: Driller, chuck tender and two muckers came on at 7:00 a. m. Machine was set up for back and breast holes and muckers started mucking. By noon the round was half drilled and the muck was all out. After dinner the round was finished, muckers putting in track and platform. Shot at 3:20, blowing out with compressed air. Next shift comes on at 6:00 p. m. and has the same cycle of operations.

Following is detailed cost per foot:

Drillers (2)	$2.78
Trammers and shovelers	2.22
Timbermen	.30
Powder	2.42
Fuse	.19
Caps	.06
Candles	.10
Timber	.36
Powder	.58
	$9.01

Cost per foot for 1,015 ft. of drifting under all conditions: all timbered and from soft to very heavy ground:

Drillers	$ 3.90
Engineers	.12
Trammers and shovelers	3.81
Timbermen	1.20
Powder	1.19
Fuse	.13
Caps	.05
Candles	.20
Timber	1.90
Power	.60
	$13.10

Operation No. 9: Detailed cost for 150 ft. of cross cut:

Explosives	$ 142.00
Steel	20.00
Timber	37.30
Pipe	22.50
Air	20.00
Labor	993.60
Total	$1,235.40
	or $8.24 per ft.

Track, superintendence, surveying and power bring the total cost up to $10.34 per foot.

Cycle of Operations: Start setting up horizontal bar and machine at 7:00 a. m. Top holes drilled by noon and by the time muckers had the previous round mucked out; would then tear down and set up for the lifters. Round would be ready to shoot by 2:00 p. m. This operation continued for three shifts.

Operation No. 10: The best progress was 53 ft. over a 10 day period, or at the rate of 160 ft. per 30 days. The average rate was about 120 ft. per month. Actual drilling time for a round was 5 hr., setting up and tearing down taking up 2 hr.

Expenses over a distance of 100 ft.:

700 lb. power, at 17 cts	$119.00
220 caps, at $1.30 per 100	2.86
1320 ft. fuse, at $5.20 per 100 ft	6.86
160 lb. steel, at $0.093 cts. per lb	14.90
100 ft. 2-in. pipe, at 16 cts. per ft	16.00
Contract 100 ft., at $4.50 per ft	450.00
Air	20.00
Total	$629.62
	or $6.30 per ft.

Track, superintendence, surveying, assaying, apportionment of power, hoisting, etc., bring the cost up about $3.60 per ft., making the total cost $9.90 per ft.

All drilling and shooting was done on day shift. Mucking and laying planks and track was done on night shift.

378.5 man-shifts were worked, or 153 shifts day and night.

Comments on the Various Operations.—Nos. 1 and 2: These two operations afford a fair comparison of the solid-steel, piston drill, as compared with that of the water hammer drill. The 94 ft. of operation No. 1 were driven with a piston drill, 5 shifts being required to put in a round of holes. At this point (see operation No. 2) a change was made to the water-hammer drill, after which a round of holes was drilled in from 1 to 1½ shifts.

Attention is directed to the greater percentage of total cost chargeable to drilling in operation No. 1, as compared with No. 2. The increased cost of explosives and supplies in operation No. 2 is due largely to the increase in the cost of these materials in 1916 and 1917.

No. 3: This is one of two operations out of the ten in which delay exploders were used. A minimum of misfires occurred and results were reported better than blasting with cap and fuse. This cross cut was run with a hammer stoper and good progress was made. The section of the drift was small compared with the other operations. It was reported that the fact that drilling was done on one shift and mucking on the next made for economy, but not speed. Keeping of drill parts in duplicate was an important factor in lessening delays.

No. 4: This was an efficient operation. Note that the muckers came on three hours ahead of the drillers. A very important bit of information was brought out at this mine, namely: the change from 1¼ in. hollow, round steel, with cross bit, to 1-in. hollow, hexagonal steel, with Carr bit, which greatly increased the drilling speed and the number of holes that could be drilled with one set of steel.

No. 6: The striking feature here is the slow progress made with the solid-steel, piston drill.

No. 7: This is a case in which good progress was made with the piston drill. However, the ground was not of the hardest at all times and the fact that the work was done on contract had some effect on the speed. The detailed costs are interesting.

No. 8: This operation is a striking illustration of what can be done in cross cutting by day's pay plus a bonus. An average of 77 ft. was made every week. A little figuring will show plainly that the company was the gainer by paying the bonus.

No. 9: This operation showed the lowest cost in labor and explosives.

No. 10: The total cost shown for this operation was abnormally high, for the reason that there was no other work being done in the mine and all charges were directed towards this one cross cut. The progress was excellent, but on account of the fact that the ground was not as hard as any of the other operations it is hardly fair to use this operation in comparison with the others.

As indicated previously, it is believed that Operations 1 and 2 afford the best comparison between the solid-steel, piston and the water-hammer drills. However, one such operation cannot be taken as conclusive. While comparisons from the table are by no means accurate, on account of varying conditions, it is of interest to note the following: Omitting operation No. 10, the average number of shifts required to drill one round of holes was 1.81 for solid-steel, piston drills, and 1.14 for the water-hammer drills. The average advance per drill-shift was 3.10 ft. for the piston drills, and 4.07 ft. for the water-hammer drills. The average cost per foot in labor an explosives was $5 for the piston drills, and $3.66 for the water-hammer drills.

Making a further distinction, the average cost per foot in labor and explosives shows $3.62 for the water-hammer drills using the Carr bit; $3.72 for the water-hammer drills using the cross bit, and $5 for solid-steel piston drills, with cross bit.

Important Considerations.—Based on the information secured during this investigation, the following conclusions and suggestions are offered:

In the hard greenstone and slate found in the Amador County mines, the water-hammer type of drill is superior to the solid-steel piston drill.

Apparently the Carr bit does faster work in this rock.

Working by day's pay with a bonus makes for speed and economy.

The use of 1-in. hollow, hexagonal steel, with Carr bit, as against 1¼-in. hollow, round steel, with cross bit, makes for speed and economy.

It was brought out that in an operation the same progress was made by working two shifts as had previously been made working three shifts. This was due chiefly to the fact that the ventilation was very poor. The further fact was brought out that in poorly ventilated headings the efficiency of the men is often impaired, and sometimes they are entirely overcome, by powder gas. It appears that this trouble is more acute where the rock is hard. Best results seem to have been attained by blowing out the heading with a combined air and water spray after blasting. Where water is available the muck pile should be sprayed from time to time, as an aid in keeping down powder gas.

Inasmuch as the prime factor in drilling efficiency is the force and frequency of the blow struck by the drill, it is of importance to keep compressors working up to efficiency and to watch carefully for leaks in the air line so that the proper pressure may be maintained at the drill.

Drilling economy may be secured by conducting experiments on the proper strength and amount of powder to be used, the kind of bit to be used and the proper number, angle and size of drill holes.

Electrical blasting is recommended where current is available.

The keeping of detailed costs on each operation enables the operator to estimate closely the cost of proposed work. It also affords a check on work in progress, the operator at any time being able to locate any item that might be causing an unnecessary increase in cost.

Costly delays may be eliminated by keeping duplicate drill parts close at hand.

Misfires are a most important factor in causing delays. It is recommended that records be kept of misfires so that remedial measures may be taken should they exceed 2 per cent.

A good drill-steel blacksmith is an absolute necessity for efficient work.

Cost of 10 × 12 Ft. Tunnel at Copper Mountain, B. C.—Very rapid progress was made in the driving of the main haulage level at the Copper Mountain Mines of the Canadian Copper Corp., Ltd., near Princeton, B. C. The methods employed in this work were described by Oscar Lachmund, in a paper presented in the fall of 1918 at the Chicago meeting of the A. I. M. E. from which the matter in this article was abstracted in Engineering and Contracting, March 19, 1919.

Conditions were unfavorable for economical operations. The cost of power was high, for the fuel was of poor grade; besides, during the time the work was in progress, very little other power was needed so that most of the power cost was charged against the footage. The transmission line consisted of No. 4 galvanized iron wire with the result that the line loss was considerable. The voltage transmitted was about 30,000. The plant was operated under a lease, which was due to expire about the same time this work was supposed to be completed; an extension was refused; therefore speed was most important.

The plans called for a straight adit 2,900 ft. in length. At a point 2,800 ft. from the portal, two raises were to be put up to the next nearest workings, a difference in elevation of about 800 ft. One of these was to be a 2-compartment hoistway and the other a zigzag ore pass, or muck run. A location for these raises had been determined by a number of diamond-drill holes, but the material to be penetrated by the adit was not known. It seemed imperative to get the tunnel work completed as rapidly as possible, in order to allow for delays in the raising program, which were certain to occur.

The plans called for a tunnel 9 ft. high by 11 ft. wide; but owing to the "blocky" nature of some of the rock a considerable "over break" occurred. This enlarged the tunnel cross-section to 10.4 ft. by 12 ft. indicated by measurements taken at 200-ft. intervals after the work was finished and slowed up the work on account of the extra waste handled, besides increasing the cost per foot of driving. Several regions of geological disturbance were crossed and the heavy ground encountered called for timber supports. More than 350 ft. of heavy timbering was necessary at various points along the course of the tunnel; this also retarded the work to the extent of about 6 ft. per day for each set of timber placed. Once the working force was organized and the work well under way, three shifts were put on, working 8 hours each.

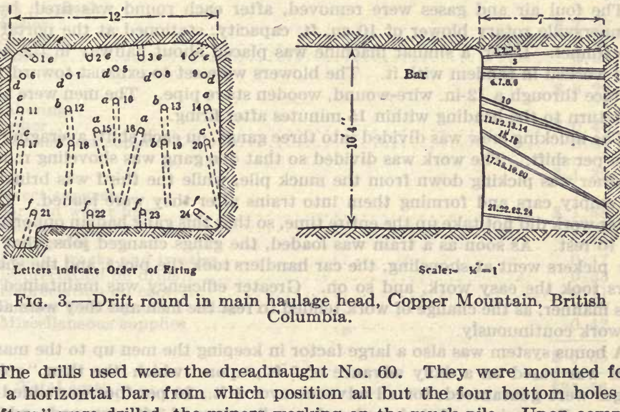

FIG. 3.—Drift round in main haulage head, Copper Mountain, British Columbia.

The drills used were the dreadnaught No. 60. They were mounted four on a horizontal bar, from which position all but the four bottom holes or "lifters" were drilled, the miners working on the muck pile. Upon completion of the upper part of the round, most of the muck had been removed; that which was left was rapidly thrown back from the face, all hands helping on this work. The horizontal bar was then torn down and dropped to the lower position, from which the lifters were drilled. The change of the bar from the upper to the lower position, together with drilling the lifters, loading, and firing the entire round, was frequently made in 50 minutes. The holes were pointed to pull a 7-ft. round and average about 9 ft. in depth. The center, or "cut holes" were fired first, after which followed the side holes, then the back holes, and finally the lifters. The drift round commonly used in this work is illustrated in Fig. 3, which also indicates the firing of the holes in groups. The blasting was done by hand, the fuses being "spit." The timing of the shots was regulated by cutting the fuse in different lengths; the shortest for the center holes, the next longest for the side holes, and so on. The lifters were loaded with extra heavy charges of powder, so as to throw the muck back from the face as much as possible. This was sometimes helped by placing charges of explosive outside and beneath the lifters; these were called muckers, and were set to go off after the rest of the round had been fired.

The powder used was a non-freezing kind, varying in strength from 40 to 60 per cent nitroglycerin, depending on the hardness of the rock at the face.

The rock was handled in small, V-shaped, hand-dump cars of about 1,000-lb. capacity. Tramming was done by hand until the distance from heading to dump became too great, when horse haulage was substituted; later this was replaced by an electric installation. Steel plates were laid on the bottom for a distance of 30 to 40 ft. from the face, to facilitate shoveling, also to permit shunting empty cars past the loaded trains and thereby eliminating the need for double track.

The cars, being light, were easily pulled from the track and, with bodies tilted, were passed on the steel plates, alongside of the loaded cars and then pushed back on to the track at the muck pile and loaded. Temporary track was laid close up to the face before firing a round. The T-rails were laid on their side, allowing the flanges of the car wheels to run on the grooves thus formed.

The foul air and gases were removed, after each round was fired, by a Connersville rotary blower of 10 cu. ft. capacity, stationed at the portal of the tunnel. Later, a similar machine was placed about halfway in the adit and worked in tandem with it. The blowers were set to exhaust toward the surface through a 12-in. wire-wound, wooden stave pipe. The men were able to return to the heading within 15 minutes after firing.

The mucking crew was divided into three gangs, on each shift, averaging 11 men per shift. The work was divided so that one gang was shoveling muck, another was picking down from the muck pile, while the third was bringing up empty cars and forming them into trains after they were loaded. This latter work did not take up the entire time, so that this gang had an opportunity to rest. As soon as a train was loaded, the gangs changed jobs; that is, the pickers went at shoveling, the car handlers took the picks, and the shovelers took the easy work, and so on. Greater efficiency was maintained in this manner, as the change of work tended to rest the men and they were able to work continuously.

A bonus system was also a large factor in keeping the men up to the mark. This was based on a daily advance of 9 ft., upon which the then "going wages were guaranteed; for all advance over 9 ft., $6 per foot was added as bonus. For each set of timber placed, an allowance of 3 ft. was made, which applied on the bonus. Current wages at the time were $4.50 for miners, $4 for helpers, and $3.50 for common labor. The bonus distribution brought these amounts up to $5.91 for miners, $5.25 for helpers, and $4.59 for muckers. The foreman and the shift bosses also shared in the bonus, the distribution being made by pro-rating the bonus in the same ratio as the amount of regular wage received by each man. Everybody seemed satisfied and no difficulties were experienced as far as the labor situation was concerned.

The work was begun on Oct. 9, 1917, and the tunnel was finished March 11, 1918, a total of 154 days. The actual working time was 150 days, four days being lost on account of a break in the power line.

The length of the adit is 2,903 ft. and the daily average progress was 19.3 ft. for each working day. The greatest advance in any one month was in December, 1917, when a total of 645 ft. was driven. The amount of rock handled is estimated at 185 tons per day. The material penetrated was granodiorite, for the greater part of the distance. The total cost of driving the tunnel was $103,242, which brings the cost per foot of tunnel to $35.56. Certain equipment and supplies were charged against the work that should have been carried in a suspense account, as most of these had a certain salvage value because it was intended to use them in the future operation of the mines. For reasons already mentioned, such as expensive power, the cost given does not really represent the actual expense of driving. Had speed not been so important no doubt the work could have been done more cheaply.

The cost items are as follows:

	Per ft
Total driving cost:	
Labor	$ 8.80
Explosives	5.72
Drills, parts and repairs	0.95
Steel, sharpening and replacement	1.37
Miscellaneous supplies	0.66
Power	2.90
	$20.40
Rock disposal:	
Labor	$ 7.52
Supplies	0.57
Power	0.20
	$ 8.29
Timbering:	
Labor	$ 0.46
Timber and supplies	0.86
	$ 1.32
Indirect expense:	
Air and water lines	$ 1.88
Electric lighting	0.35
Ventilation	1.10
Dump, tracks and trestles	0.17
Depreciation on drills	0.33
Depreciation on cars	0.11
Surface hoisting and hauling	1.19
Miscellaneous supplies	0.42
	$ 5.55
Total cost	$35.56
Timbering details:	
53 sets timber installed, cost per set	$72.62
354 ft. of tunnel timbered, cost per foot	10.83
Drilling details:	
Actual drilling hours	8.022
Actual working days	149 11/12
Average drilling hours per day	53.50
Cost of upkeep per drilling hour, in cts	22.53

Organization and Progress in Driving 7 × 12 Ft. Drift, in Hard Gneiss.— Engineering and Contracting, June 16, 1920, abstracts the following data from the Engineering and Mining Journal.

A 7-ft. × 12-ft. drift at the Harmony Mines at Mineville, N. Y., was driven a distance of 213 ft. in 36 8-hour shifts. The gang per shift consisted of two machine men and three men mucking and tramming. No. 248 Ingersoll-

Leyner drills with 1¼-in. round hollow drill steel with crossbits and ¼-in. change were used. The gage of the starter bit is 2¼ in., four changes were made, and the holes drilled according to the V-type cut system. Time fuses, No. 8 caps, and Du Pont gelatin were utilized in blasting. The two machine men drilled, loaded, and fired 26 9-ft. holes per shift, which is 234 ft. of drilling per round. The muckers loaded the dirt in 1½-ton cars and pushed them to the main slope.

Size of drift	7 ft. × 12 ft.
Holes drilled per round	26
Number of feet drilled per round	234
Number of men per shift	5
Advance of heading per shift	5.92 ft.
Advance of heading per man per month	31.93 ft.
Cu. ft. rock removed per man per shift	99.46

Cost of Small Tunnel for Sewer in Very Hard Rock.—In Engineering News Record, May 3, 1917, Charles C. Hopkins gives the cost of a tunnel 410 ft. long driven under his supervision in 1904–5 at Saugerties, N. Y. in very hard rock—Cauda galli formation.

The tunnel was 4 × 6 ft., with no water to contend with, and was to contain a sewer. The mucking was distributed and at a short distance from the tunnel entrance. The contract price for the tunnel was $7 per lin. ft. and the contractor sublet the labor at $6, furnishing the mucking equipment, explosives and hand drills. The equipment consisted of a second-hand car and track. The actual cost of 183 ft. of this tunnel was as follows:

1,500 lb. dynamite @ 10½cts	$ 157.50
2,000 ft. fuse @ ½ct	10.00
1,100 exploders @ 3cts	33.00
800 fuse caps @ 1ct	8.00
Labor @ $6.00 per ft	1,098.00
Total	$1,306.50
Cost per lineal foot	7.14

The use of the plant would be covered by not to exceed 10cts. per ft. No appreciable difference in cost was noticeable in the driving of the remainder of the tunnel. The contractor made no money on this work, but the subcontractor, after paying his helpers, earned $454.55 for the 1110 hours of his time on the 183 ft., or 40cts. per hour. The subcontractor paid his men 20 and 15cts. per hour and made about 2½ ft. per day.

Cost of One-Man-Per-Heading Tunnel Driven Through Shale.—Engineering News-Record, April 12, 1917, gives the following:

A sewer tunnel 3147 ft. long, lined with vitrified-clay segmental blocks to an interior diameter of 36 in., is a feature of the Close's Creek sewer system at Des Moines, Iowa. The tunnel is in hard shale rock that disintegrates on exposure. It is 50 to 60 ft. below the surface. Shafts for manholes were sunk at intervals of 300 ft. and headings driven in both directions from each shaft.

The excavation was sublet to miners, who used coal miners' hand drills as a rule. There was one man to each heading, and he loaded his own car and ran it to and from the shaft. The cars were of wood, with a capacity of 8 cu. ft. and ran on a track of 24-in. gage. The price for excavation was $1.75 per ft., the contractor supplying the dynamite and installing the shaft hoists. No cages were used, the cars being hitched to chain slings. The muck was dumped into wagons for removal. Some gas was encountered, and men were overcome at times, owing to lack of ventilation. No explosions occurred. There was very little water. The progress averaged 2 ft. per heading per 9-hr. day, with six to eight headings under way most of the time.

Cost of Constructing Brick Sewer in Tunnel Under Compressed Air.— Ivan A. Greenwood, gives the following in Engineering and Contracting, Jan. 10, 1912.

The Main Intercepting Sewer of Cleveland extends 13 miles along the lake shore with an outlet about 9 miles east of the center of the city.

The size varies from 5 ft. up to 13 ft. 6 ins. The grade is 2 ft. to the mile, giving a velocity of about 4.3 ft. per second and about 405,000,000 gals. capacity for 24 hours at the outlet.

The contracts for the sections completed between East 61st St. and East 79th St. were let to John Wagner, Bratenahl, Ohio. This section, 12 ft. 3 ins. in diameter, 6,850 ft. long, built by tunneling about 40 ft. under ground, was constructed with three rings of No. 1 shale brick laid with Portland cement mortar mixed in the proportions of 1 to 2. A 6-in. ring of wooden cants extended around the outside of the brickwork. The cants served the double purpose of providing a temporary roof during the mining and also saved the brickwork from damage when the shield was shoved forward by the hydraulic jacks, which braced directly against the cants.

The material encountered for the most part consisted of hard blue clay which was readily knifed. Two pockets of quicksand were encountered one of which necessitated open cutting.

But two shafts were used, one situated at the west end of the work, at East 61st St., operated with one heading; the other, situated at about two-thirds of the way between beginning and end of the work at East 70th St., had two headings. The working plant at the East 70th St. shaft contained a hoisting engine which operated the cage used for conveying material; two hydraulic pumps with a capacity for a pressure of 6,000 lbs. per sq. in., one being used on each heading; two compressors, one for each heading; two 60 h. p. boilers; one dynamo capable of lighting 200 electric lights at 110 volts, and a 30 h. p. engine for operating the dynamo. The cants were made at this plant in a separate shed by sawing sticks of 6 × 8-in. timbers, 3 ft. long, so as to conform to the circumference of the tunnel. The East 61st St. shaft had practically the same machinery, with the exception that only one boiler, one compressor and one hydraulic pump were required. The Lake Shore & Michigan Southern Ry. furnished convenient facilities for receiving material.

The work was carried on day and night. The mining was done during the day and the bricklaying at night. The work was started Oct. 1, 1909, and finished April 1, 1911. Considerable difficulty was encountered due to water and poor roof at each of the shafts when the headings were first started, and before compressed air was used. As soon as about 50 ft. of sewer had been built, brick masonry locks were constructed and the compressors started. About 14 lbs. pressure was all that could be obtained, as beyond that, the air could not be held because of the comparatively shallow depth. The average pressure used was scarcely 6 lbs. and served to keep the face and roof dry. The 3-in. pipe conveying the air was not stopped at the face end of the locks, but was carried along with the construction. Another similar pipe extended from the shaft side of the lock up to the face. This was provided with a valve and was used to take out any water accumulating at the face. It also served as a means of rapidly changing the air at the face.

The shields were of the ordinary variety, consisting of a circular steel shell with a 4-ft. follower for the roof. Two different sizes were used, one only slightly in excess of the required diameter of the tunnel and the other about 4 ins. larger. The larger proved to be much more satisfactory, for the reason that if the shield were tipped slightly in order to go up for grade, the rear end of the follower of course would come down, the result being that the cants were forced downward. This often made it difficult to get in the three full rings of brickwork in the arch. Since the removal and replacement of the cants in the arch was an arduous and sometimes dangerous piece of work, it was found much more satisfactory to have a larger shield and to carry this a little high as the time saved much more than compensated for any slight excess of brickwork required. Each shield was provided with eight hydraulic jacks 4 ins. in diameter. While it was possible to obtain a pressure of 6,000 lbs. to the square inch, as a matter of fact a pressure much over 2,000 lbs. per square inch was seldom used, because the lesser pressure proved sufficient to move the shield. The jacks were the ordinary single action jacks, long enough to shove the shield 2 ft. The jacks were pushed back into their cylinders after a shove by releasing the water and prying them with crowbars. The double acting jacks would have been much more satisfactory for this purpose. The water from the hydraulic pump was carried in a high pressure ¾-in. pipe, especial care being used to secure perfect joints at the coupling. An extension arrangement at the shield fitted with movable joints allowed the shield to progress without uncoupling during a shift.

Progress.—The actual process of mining was carried on by a force of six miners, two muckers, one timber man for the cants, and a boss miner. These men by means of knife and mattocks would dig out the clay about 2 ft. ahead of the shield. The shield would then be forced ahead, and cants set and the process repeated. Each shove would take about five or ten minutes, but the mining for each shove generally took about two hours. As a rule about five shoves a day were made. The greatest distance made for one heading in one day was a little over 17 ft., but the average per heading was about 9 ft. As fast as the material was cut out, it was placed on cars, each holding ½ cu. yd., and hauled by mules to the shaft. The cars ran directly from the tunnel onto the hoist and were raised to a platform, above the street, run out on the platform and dumped into wagons, which carried the clay to the lake shore where it was dumped into the lake. At the East 70th St. shaft the clay was dumped into cars which were hauled on a narrow gage track to the lake about a quarter of a mile away. The brick shift came on at about 7 o'clock in the evening, and stayed until the brickwork was brought up to the face. Two bricklayers with seven helpers could take care of the day's work in eight hours. Steel ribs with wooden lagging 2 ins. square and 12 ft. long were used for the arch, with 2-ft. strips of block lagging for the key.

The contractor employed one superintendent for each shaft. Each superintendent was assisted by a boss miner and mason foreman.

The sawing of the cants was sublet by the contractor. One sawing equipment did the work for both shafts.

The following tables show the make-up of each shift together with the average wage paid for each class of labor:

Mining Shift at East 61st St. Shaft (One Heading)

6	Miners at $4.50 per day	$27.00
1	Timberman at $4.50 per day	4.50
2	Muckers at $2.50 per day	5.00
1	Boss miner at $5.00 per day	5.00
2	Mule drivers at $2.50 per day	5.00
1	Lock tender at $2.50 per day	2.50
1	Cage man at $2.00 per day	2.00
1	Tipple man at $2.00 per day	2.00
2	Yard laborers at $2.00 per day	4.00
2	Dump laborers at $2.00 per day	4.00
2	Teams at $5.00 per day	10.00
1	Engineer at $4.00 per day	4.00
1	Repair man at $4.00 per day	4.00
1	Fireman at $2.00 per day	2.00
1	Superintendent at $6.00 per day	6.00
25	Total	$87.00

Bricklaying Shift at East 61st Street Shaft

2	Bricklayers at $8.00 per day	$16.00
7	Helpers at $2.00 per day	14.00
1	Lock tender at $2.50 per day	2.50
2	Mule drivers at $2.00 per day	4.00
3	Laborers at $2.00 per day	6.00
1	Engineer at $4.00 per day	4.00
1	Foreman at $3.50 per day	3.50
17	Total	$50.00

Mining Shift at East 70th Street Shaft (2 Headings)

12	Miners at $4.50 per day	$ 54.00
4	Muckers at $2.50 per day	10.00
2	Timbermen at $4.50 per day	9.00
2	Boss miners at $5.00 per day	10.00
4	Mule drivers at $2.00 per day	8.00
2	Lock tenders at $2.50 per day	5.00
2	Cage men at $2.00 per day	4.00
1	Tipple man at $2.00 per day	2.00
2	Dump men at $2.00 per day	4.00
4	Yard laborers at $2.00 per day	8.00
1	Engineer at $4.00 per day	4.00
1	Repairman at $4.00 per day	4.00
1	Fireman at $2.00 per day	2.00
1	Superintendent at $6.00 per day	6.00
39	Total	$130.00

Bricklaying Shift at East 70th Street Shaft

4	Bricklayers at $8.00 per day	$32.00
12	Helpers at $2.00 per day	24.00
2	Lock tenders at $2.50 per day	5.00
2	Mule drivers at $2.00 per day	4.00
1	Foreman at $3.50 per day	3.50
1	Cageman at $2.00 per day	2.00
3	Yard laborers at $2.00 per day	6.00
1	Fireman at $2.00 per day	2.00
1	Repairman at $3.00 per day	3.00
1	Engineer at $4.00 per day	4.00
28	Total	$85.50

The tables show clearly the advantage in economy of operating two headings from one shaft. As a matter of fact this did not work out all the time, due to a bad quicksand pocket struck in the heading going east from East 70th St., which delayed that heading until the other two headings came together.

About 750 bricks per running foot were used in construction laid with ½-in. joints. The cement used was Lehigh Portland; between 7 and 8 bags being used with about 0.6 cu. yds. sand per running foot. The cants required about 282 ft. B. M. per running foot. The contract price for the section running between E. 61st St. and E. 67th St. was $35.97 per lin. ft. and for the section running for E. 67th St. to E. 79th St. it was $32.73 per lin. ft.

Cost of Water Works Tunnels Through Waban Hill, Newton, Mass.—William E. Foss* gives the following data in Engineering and Contracting, July 22, 1914.

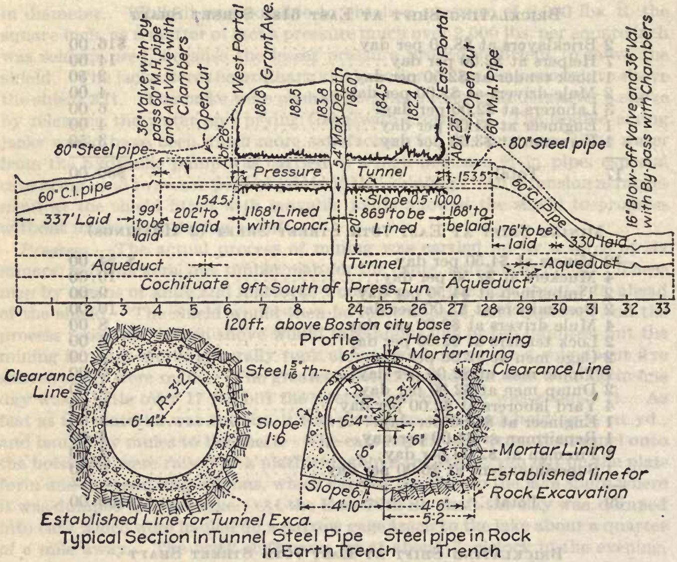

FIG. 4.—Profile and sections of pipe lines and pressure tunnel of Sect. 7 of the Weston Aqueduct supply mains.

The pressure tunnel in rock through Waban Hill in Newton, Mass., profile of which is shown in Fig. 4 was carried on under contract in 1910 and 1911, and included the construction of 2,042 ft. of 76-in. concrete lined pressure tunnel in rock, the laying of 363 ft. of 80-in. steel pipes in deep cut and lining them

*Asst. to the Chief Eng., Metropolitan Water & Sewerage Board, Boston, Mass.

with cement mortar, and the laying of 935 ft. of 60-in. cast-iron water pipe. In this article the item numbers used in the specifications are retained.

The work was begun May 24, 1910, and was suspended for the winter on December 31 of that year. It was resumed on April 1 of the following year and completed on Nov. 25, 1911.

Prior to July 1, 1911, the working day included 9 hours, from 7:30 a. m. to 5 p. m. with ½ hour for lunch, with the exception that during the driving of the tunnel the night shift worked from 7:00 p. m. to such time as the drilling was completed, with one hour for lunch. As blasting was not allowed between 6:30 p. m. and 6:30 a. m., the night shift remained on the work until the blasting was completed after 6:30 a. m. The steam plant was operated continuously through the 24 hours, the engineers working 8-hour shifts.

After July 1, 1911, all work was conducted on an 8-hour per day basis. The work of lining the tunnel with concrete was carried on continuously for six days per week. All wages were substantially the same for the 8-hour day as for the 9-hour day.

Steam plants for driving air compressors, for operating the drills, dynamos, for lighting the tunnel, and the engines for operating the stone crushers were installed at both ends of the tunnel, and the work was carried on from both portals.

Construction Plant.—An approximate estimate of the value of the plant when new is as follows:

Plant at East End of tunnel:	
2 Erie City Iron Works 75 hp. horizontal locomotive type boilers, 54 ins. diameter, 18 ft. long	$1,800.00
1 Buffalo Forge Co. dynamo engine	500.00
1 30 kw. Eddy 120-volt D.C. dynamo, with appurtenances	500.00
1 Rand Drill Co. 110 hp. air compressor	1,650.00
1 Air receiver	45.00
1 No. 3 Austin gyratory stone crusher, conveyor and screens, complete	1,975.00
1 Nagle 55 hp. crusher engine	535.00
1 Blacksmith's outfit, complete	65.00
2 2-in. Canton duplex pumps	120.00
1,200 ft. 2-in. iron pipe	120.00
1,200 ft. ¾-in. iron pipe	40.00
1 wooden water tank, 4 ft. by 5 ft.	25.00
Total cost of plant at East End	$7,375.00
Plant at West End of Tunnel:	
2 Erie City Iron Works 75 hp. horizontal locomotive type boilers, 54 ins. diameter, 18 ft. long	$1,800.00
1 Nagle 32 hp. dynamo engine	500.00
1 110-volt D.C. dynamo, with appurtenances	550.00
1 1890 Model Rand Drill Co. 110-hp. air compressor	1,650.00
1 Air receiver	45.00
1 No. 4 Austin gyratory stone crusher, conveyor and screens, complete	2,365.00
1 Buckeye Engine Co. 50 hp. crusher engine	500.00
1 Friction hoist	400.00
250 ft. ¾-in. cable	45.00
1 Blacksmith's oufit, complete	65.00
1 2-in. Canton duplex pump	60.00
2,800 ft. 2-in., 1-in. and ¾-in. iron pipe	270.00
Total cost of plant at West End	$8,250.00

General plant:

15 tons steel rails	$ 600.00
1 Smith concrete mixer, ½ cu. yd. capacity	700.00
13 3¼-in. Rand rock drills	2,795.00
6 ¾-in. Chicago Tool Co. jap drills	300.00
9 columns, arms, etc., for rock drills	450.00
3 tripods for rock drills	135.00
1 Tidewater Iron Works Cunniff type grout machine	200.00
42 steel dump cars, ⅔ cu. yd. capacity	2,100.00
10 slip scrapers	70.00
2 single dump carts	150.00
1 2-horse wagon	150.00
1 4-ton differential hoist	76.00
1 large vise	5.10
1 pipe vise	4.00
2 2-in. pipe stocks and dies	7.20
1 lead heating outfit	36.50
1 breaking up plough	24.50
6 wheelbarrows	22.50
1 stiff leg pipe derrick	56.00
Total cost of General Plant	$ 7,881.80
Total estimated value of entire plant when new	$23,506.80

Total Cost.—Including an allowance at the rate of 25 per cent per year on this valuation, for interest and depreciation on the plant during the time that it was in use, the total cost of the work exclusive of the expense of the contractor's Chicago office, his personal traveling and other expenses, and his expenses in connection with the litigation and settlement of the claims made by several property owners in the vicinity of the work for alleged damages from the blasting, is as follows:

Interest and depreciation on plant	$ 7,386.81
Labor and teaming, on payrolls	47,821.56
Materials and expenses, on bills	43,744.74
Expenditures for extra work not included above	504.88
Total expenditures	$ 99,457.99
Amount of final estimate	114,472.13
Profit	$ 15,014.14
Profit per cent of expenditures	15.1

Wages.—The prices paid for labor were as follows:

Superintendent, per month		$200.00
Clerk, per month		100.00
Brick mason, per day	$4.00 and	5.60
Blacksmith, per day	$3.50 and	4.00
Calker, per day	$3.00 and	3.60
Carpenter, per day		4.50
Drill runner, per day		3.50
Drill runner's helper, per day		2.50
Engineer, per day	$3.00 to	5.00
Foreman, per day	$4.00 and	5.00
Sub-foreman, per day	$2.50 and	3.00
Laborers (per day);		
Crusher man, lead man, powder man, stableman and teamster		2.50
Tunnel man		2.25
Ordinary		2.00
Teams (per day):		
4-horse hitch, with driver and helper		12.00
2-horse cart and driver		6.00
1-horse cart with one driver for two carts		3.00
Mules, cost of maintenance at contractor's stable, per day		1.03

Materials and Miscellaneous Expenses.—The prices paid for materials and miscellaneous expenses on bills were as follows:

Accidents, damages, etc.		$ 48.64
Blacksmith and jobbing		579.99
Bond premium ($5 per annum per $1,000 on amount of contract, as shown by canvass of bids)		818.14
Bricks, at $9.50 per M		171.50
Brick mason		49.70
Cement, delivered on work $1.72 per bbl., including cost of bags—actual net cost on work, including teaming, storage, loss of bags and cement damaged, 7,308 bbls. at $1.386		10,129.21
Coal—		
1,226 tons bituminous at $3.83 f. o. b. cars per gross ton	$4,694.02	
152 tons at $4.60 delivered on work per gross ton	698.63	
Blacksmith, 8.69 tons at $4.85	42.12	
		5,434.77
Drills and incidentals		2,394.73
Dynamite—		
40 %, 951 lbs. at $0.1225	$ 116.50	
60 %, 25,294 lbs. at $0.1625	4,110.29	
Exploders, 2,000 at $3.43 per 100	68.60	
		4,295.39
Express		294.95
Forms for concrete and mortar lining, rental		1,617.00
Grouting machine, rental		18.00
Hay and grain		1,379.33
Insurance		1,486.03
Jute, 400 lbs. at $0.06		24.00
Lead, 1,050 tons at $95.00, 4.772 tons at $97.50		565.10
Livery		65.93
Lumber—Georgia pine at $35.00; hemlock boards at $25.00; spruce, 8-in, and under, at $28.00; spruce, over 8-in., at $30.00		2,516.95
Oil—Castor at $0.35 per gal. f. o. b. Boston; compressor at $0.20 per gal., f. o. b. Boston; cylinder at $0.215 per gal., gasoline at $0.15 per gal.; kerosene at $0.13 per gal., machine at $0.185 per gal.		502.94
Repairs to plant		1,079.25
Sand—		
Coarse, 1,830.4 cu. yds. at $0.90 delivered on work	$1,647.36	
Fine, 238.3 cu. yds. at $1.25 delivered on work	298.20	
		1,945.56
Sand blasting steel pipe		701.80
Teaming		1,292.32
Telephone		231.19
Tools, hardware and miscellaneous		4,490.28
Transporting plant		1,183.97
Water		428.07
Total for materials and miscellaneous		$43,744.74

Itemized and Unit Construction Costs.—The cost of the various items of work under this contract, in detail, was as follows:

Item 1.—Top Soil Excavation (1412 *cu. yds.*)—Under this item the top soil was excavated from an area of about 0.95 of an acre for an average depth of 11 ins., where other excavations were to be made or embankments were to be built. The material was loosened with plows and transported about 180 ft. to spoil banks and slip scrapers. The cost of the work was as follows:

	Cost per cu. yd.
Superintendence and general labor	$0.04
Labor	0.21
Teaming	0.11
Small tools, etc	0.02
Incidental expenses and insurance	0.014
Plant, interest and depreciation	0.01
Total cost	$0.404
Value of work	0.60
Profit	$0.196

Item 2.—Top Soil Surfacing (1390 *cu. yds.*)—Under this item an area of about 1 acre was covered with loam from spoil banks to an average depth of 6 ins. at the west end of the tunnel, and at the east end an area of about 0.27 acre was covered to an average depth of 1 ft., and another area of about 0.27 acre was covered to an average depth of 3 ins. The entire work was done with teams. The haul averaged about 210 ft. The cost of the work was as follows:

	Cost per cu. yd.
Superintendence and general labor	$0.05
Labor	0.25
Teaming	0.19
Small tools, etc	0.03
Incidental expenses and insurance	0.015
Plant, interest and depreciation	0.001
Total cost	$0.536
Value of work	0.546
Profit	$0.01

Item 3.—Earth Excavation in Open Trench (4184 *cu. yds.*)—Under this item about 480 lin. ft. of trench for the 60-in. pipe line and 350 lin. ft. of trench for 80-in. pipe line was excavated at both ends of the tunnel. The trench for the 60-in. line averaged about 8 ft. in depth, and that for the 80-in. line was made in open cut and varied from 10 to 25 ft. in total depth in earth and rock, the depth of the earth ranging from 5 to 14 feet. The width of the trench was from 20 to 35 ft. at the top and 10 ft. at the bottom, and no attempt was made to brace the sides, which were allowed to take a natural slope. The earth was loosened with picks and shoveled into cars, which were hauled by mules to the spoil banks. The haul averaged about 350 ft. The earth excavated in the 80-in. pipe trench at the east end of the tunnel was a compact binding gravel; so hard that dynamite was used in loosening it. The large percentage of loss on this item was due to the extremely hard material in the 80-in. pipe trench at the east end of the tunnel, and to the nature of the material in the 60-in. pipe trench at this end which was largely a mixture of stone

chips and clay and was hard to excavate and brace. The cost of the work was as follows:

Item	Cost per cu. yd.
Superintendence and general labor	$0.11
Labor	0.64
Teaming	0.05
Lumber for bracing	0.01
Small tools, etc	0.07
Incidental expenses and insurance	0.04
Plant, interest and depreciation	0.02
Total cost	$0.94
Value of work	0.52
Loss	$0.42

Item 4.—Rock Excavation in Open Trench (788 *cu. yds.*)—About two-thirds of the rock excavation under this item was in the deep open cut at the east end of the tunnel, where the rock was extremely hard. On account of the liberal dimensions of the trench and the isolated location, conditions were favorable for excavating the rock cheaply. The rock was loaded on cars and transported by mules to the crusher. The haul averaged about 380 ft. The cost of the work was as follows:

Item	Cost per cu. yd.
Superintendence and general labor	$0.20
Labor	1.11
Teaming	0.10
Explosives	0.19
Drill incidentals	0.25
Small tools, etc	0.16
Incidental expenses and insurance	0.10
Plant—	
Transportation erection, repairs, operation and dismantling	0.94
Interest and depreciation	0.27
Total cost	$3.32
Value of work	3.26
Loss	$0.06

Item 5.—Refilling Open Trenches and Building Embankments (8,569 *cu. yds.)* In refilling the pipe trenches and building embankments selected fine material thoroughly consolidated with rammers and tamping irons was used for bedding the pipe. The remainder of the material was delivered from the spoil bank in cars and was spread in 6-in. layers. About one-fourth of the material paid for under this item was a sharp sandy gravel from the spoil bank of the surplus material from the 60-in. pipe trench on the adjoining section to the west. The remainder of the material was a clayey gravel

excavated from the trenches. The average haul for this work was about 300 ft. The cost of the work was as follows:

Item	Cost per cu. yd.
Superintendence and general labor	\$0.05
Labor	0.33
Teaming	0.03
Small tools, etc	0.03
Incidental expenses and insurance	0.025
Plant, interest and depreciation	0.009
Total cost	\$0.474
Value of work	0.554
Profit	\$0.08

Item 6.—*Tunnel Excavation* (2,042.5 *lin. ft.;* 6,125 *cu. yds.*)—The tunnel was excavated in rock for the entire length of 2042.5 lin. ft. The volume of material excavated was 6,125 cu. yds. which is equivalent to an average excavation of 3 cu. yds. per lineal foot. The average cross-sectional area of 81 sq. ft. is equivalent to the area of a circle 10.15 ft. in diameter, and as the established line for tunnel excavation provided for an excavation 9 ft. in diameter, with a cross-sectional area of 63.62 sq. ft. the actual cross-section exceeded the established section by 17.38 sq. ft., or about 27 per cent. It was provided that the excavation should be trimmed so that the minimum distance from the axis of the tunnel to the rock should be 3 ft. 11 ins., which would leave 9 ins. as a minimum thickness for the concrete lining. Very little trimming was necessary.

For a distance of 600 ft. from the easterly portal the tunnel was excavated in hard trap rock. For the remainder of the distance the excavation was in conglomerate with quartzite pebbles varying from 3 or 4 ins. to ¼ in. in diameter. The felsite cement was very hard in some places and extremely soft at other points, where it had changed to kaolin. About 75 ft. from the west portal a seam of clayey gravel was encountered in the roof of the tunnel, and it was necessary to support the roof on timbers for a distance of about 26 ft. Timbering was also necesssary at five other points to support the side of the tunnel where the excavation broke through into the loosely backfilled shafts of the old Cochituate Aqueduct tunnel, which is located about 9 ft. south of and 20 ft. below the new tunnel. This old tunnel was constructed by the city of Boston in 1848. At one of the old shafts the entire filling caved into the tunnel and had to be removed. Less drilling and explosives were required for the excavation of the trap rock than for the conglomerate, but it frequently broke wide of the desired line and formed an unnecessarily large section, which delayed the progress of the work because of the increased quantity of material to be moved and the caution required to prevent accidents from falling rocks. The work was carried on at both headings with day and night shifts. From 15 to 21 holes from 5 to 6 ft. in depth were drilled and blasted per shift at each heading. The force usually employed included about 12 men and 1 mule. The progress averaged about 5 ft. per shift at each heading. The drilling was done with Ingersoll-Rand drills mounted on vertical columns and operated by compressed air under a pressure of about 100 lbs. per square inch. The following cost of the tunnel excavation includes the cost of loading the excavated material on cars and transporting it to the crusher or dumps by mules. The haul averaged about 750 ft.

Item	Cost per lin. ft.	Cost per cu. yd.
Superintendence and general labor	$1.13	$0.38
Labor	6.40	2.13
Teaming	0.62	0.21
Explosives	2.03	0.68
Lumber	0.05	0.02
Drill repairs	1.08	0.36
Small tools, etc	0.96	0.32
Incidental expenses and insurance	0.78	0.26
Plant—		
Transportation, erection, repairs, operation and dismantling	5.43	1.80
Interest and depreciation	1.85	0.62
Total cost	$20.33	$6.78
Value of work	25.01	8.33
Profit	$4.68	$1.55

Item 7.—Crushing Stone (9,779 *cu. yds.*)—About 80 per cent of all the rock excavated was crushed. At the east portal the rock was delivered directly on the crusher platform and at the west portal the rock was hauled from the tunnel in cars which were left in the open cut at the foot of an incline, up which they were hauled to the crusher platform by a friction hoist operated by the crushing machinery. At both crushers the product was screened and separated into three sizes, one including stones 2 ins. to ¾ in. in diameter, another stones ¾ to ¼ in. in diameter, and the remaining portion included all materials less than ¼ in. in diameter. At the east portal it was necessary to haul about 70 per cent of the product about 100 ft. to storage piles, and at the west portal the entire product was hauled about 125 ft. to storage piles. Most of the rock was delivered to the crusher in convenient size for crushing and very little hand breaking of material was necessary. The large crusher at the west portal was operated during the day only and crushed the 24-hour output from the tunnel easily, as there were ample storage facilities for the muck at this place. At the east portal, on account of the limited storage facilities and smaller size of the crusher, it was necessary to operate the crusher during both shifts. The cost of the work was as follows:

Item	Cost per cu. yd.
Superintendence and general labor	$0.03
Labor	0.17
Teaming	0.02
Small tools, etc	0.03
Incidental expenses and insurance	0.013
Plant—	
Transportation, erection, repairs, operation and dismantling	0.15
Interest and depreciation	0.19
Total cost	$0.603
Value of work	0.75
Profit	$0.147

Item 8.—Portand Cement Concrete Masonry in Tunnel. (2,330 cu. yds. were placed within the line of the established excavation; 144 cu. yds. were placed in old shafts; 1,268 cu. yds. were placed beyond line of established excavation

but only 50 per cent of this last amount was estimated for payment, according to terms of the contract; total, 3,742 cu. yds.)

The 3,742 cu. yds. of concrete placed in lining the tunnel is equivalent to an average of 1.83 cu. yds. per linear foot. The concrete was mixed in the proportion of 380 lbs. of Portland cement, 8 cu. ft. of loosely compacted sand, and 15 cu. ft. of loosely compacted mixture of 2-in. and ¾-in. size crushed stone, giving a 1:2.22:4.17 mixture. The concrete was mixed in a steam-driven Smith mixer of ½-cu. yd. capacity, set on the platform at the tunnel so that the concrete was discharged directly into cars which were run through to the point where the lining was being placed. The concrete was dumped upon a temporary floor of steel plates inside of the circular forms which consisted of channel iron ribs spaced 5 ft. on centers, to which the curved side plates were bolted. The concrete was shoveled from the floor into the space between the forms and the rock walls and was thoroughly spaded and churned. Successive side plates were bolted to the ribs as the work progressed, and this portion of the work was completed by filling the key space at the top, the keying plates being 2.5 ft. in length, so that the concrete could be firmly packed. One hundred and fifty linear feet of forms were used, and as no inside braces were required cars could be run through them. The forms made the mould for the entire cross-section of the tunnel, except the invert strip which was 2.5 ft. wide. In placing the concrete the bottom layer was put in to within 1 ft. of the invert. The side walls and key were then filled and the 2.5 ft. wide invert was placed later.

In the westerly portion of the tunnel the bottom layer was placed on both sides of the track, which was left supported on a central strip of muck which was later removed, just before placing the invert.

In the easterly portion of the tunnel the track was thrown to one side while the bottom layer of concrete was placed on the opposite side. The track was then shifted on to the concrete already placed and concrete was then placed on the other side. The work was carried on in three 8-hour shifts. Forms were removed and set up in one shift and concrete was placed during the remaining 16 hours. The average progress per 24 hours was about 35 lin. ft. of completed section, except for the 2.5 ft. invert strip which was placed and finished to line with a screed after the track and forms were removed.

The concrete was transported an average distance of 620 ft. and the crushed stone an average distance of 240 ft. from the storage pile to the mixer. The sand and cement were usually delivered to within a short distance of the mixing platform.

The cost of this work has been sub-divided to show the cost of forms separate from the cost of mixing and placing the concrete, as follows:

Item	Cost per cu. yd.
Forms:	
Superintendence and general labor	$0.08
Labor	0.45
Teaming	0.06
Lumber	0.03
Small tools, etc	0.07
Incidental expenses and insurance	0.06
Rental and transportation of forms	0.40
Plant—	
Transportation, erection, repairs, operation and dismantling	0.38
Interest and depreciation	0.06
Total cost	$1.59

Item	Cost per cu. yd.
Mixing and placing concrete:	
Superintendence and general labor	$0.20
Labor	1.13
Teaming	0.11
Sand	0.38
Cement	2.11

Plant—	
Transportation, erection, repairs, operation and dismantling	1.35
Interest and depreciation	0.33
Total cost	$7.05
Value of work	8.44
Profit	$1.39

Item 9.—Portland Cement Concrete Masonry in Open Trench (451 *cu. yds.)*—With the exception of a little concrete used for anchorages and backing on the 60-in. cast-iron pipe line, the concrete masonry placed in open trenches was used for covering the 80-in. steel pipe line. The quantity used for this purpose averaged about 0.84 cu. yd. per linear foot of pipe line. This concrete was mixed in the proportion of 380 lbs. of Portland cement to 10 cu. ft. of loosely compacted sand and 18 cu. ft. of a loosely compacted mixture of 2-in. and ¾-in. size crushed stone, making a 1:2.78:5 mixture.

At the west portal the concrete was hand mixed and as the trench was almost entirely in earth, wooden forms were used for the entire section. At the east portal, where the trench was almost entirely in rock, the concrete was placed up to the springing line of the arch, without forms, wooden forms being used for the remainder of the section. At this place the concrete was mixed in a steam-driven Smith mixer and hauled about 100 ft. Before constructing the forms and placing concrete around the steel pipe, it was braced inside to true circular form, and the outside was cleaned to bright iron with a sand blast and then painted with a thick coat of cement paint made by mixing 10 lbs. of cement with 5 lbs. of water. Holes were left in the concrete at the top of the pipe, through which the cement mortar lining was placed later.

The cost of the work has been sub-divided to show the cost of forms separate from the cost of mixing and placing the concrete, as follows:

Item	Cost per cu. yd.
Forms:	
Superintendence and general labor	$0.12
Labor	0.65
Teaming	0.05
Lumber	0.20
Small tools, etc	0.07

Interest and depreciation	0.07
Total cost	$6.96
Value of work	6.43
Loss	$0.53

* Cost per sq. ft. of surface cleaned = 4.6 cts.

Item 10.—*Brick Masonry* (*36 cu. yds.*)—This item included brick masonry used in constructing valve chambers and raising manholes on the Cochituate Aqueduct. The cost of the work was as follows:

Item	Cost per cu. yd.
Superintendence and general labor	$ 0.84
Labor	6.12
Sand, obtained on work	0.14
Cement	2.19
Bricks	4.62
Small tools, etc	0.53
Incidental expenses and insurance	0.34
Plant, interest and depreciation	0.01
Total cost	$14.79
Value of work	15.59
Profit	$ 0.80

Item 11.—*Cement Grout in Tunnel* (292 *cu. yds.*)—When the concrete tunnel lining was placed, 1½-in. steel pipes with couplings on the outer ends, which were temporarily plugged with wood, were run into all seams and cavities which could not be properly filled with concrete. The spacing of the grout pipes was governed to a large extent by the character of the walls of the tunnel at various points. Extra pipes were placed at each of the old shafts on the Cochituate Aqueduct, and in the section where the roof was supported by timbers in the gravel about 75 ft. from the west portal. Under ordinary conditions the average distance between grout pipes was about 20 ft. The pipes and couplings were furnished by the Commonwealth. The specifications provided that grout pipes should be placed so that all voids could be filled without forcing the grout more than 10 ft. in any direction, but it was found that the grout actually traveled much greater distances.

The grouting was not begun until after the lining was entirely completed and the concrete had attained considerable strength and most of the shrinkage cracks had developed. It was required that the sand used for grouting should all pass through a sieve having 64 meshes per square inch, and that at least 40 per cent should pass through a sieve having 1 600 meshes per square inch. In making the grout 4 cu. ft. of sand was mixed dry with 380 lbs. of Portland cement. The mixed material was then divided into nine equal parts and put up in bags in which it was transported to the point where grouting was in progress. Three bags of this material and 1.2 cu. ft. of water were used in charging the grout machine. The machine was a tight steel cylinder about 4 ft. high and 18 ins. in diameter, with a 1-in. connection for admitting the compressed air, and a 2½-in. outlet. It was charged through an opening at the top provided with a heavy cover fitted with a rubber gasket. The compressed air for operating the machine was obtained from the plant at the east portal, which at this time it was necessary to keep in operation solely for this purpose. The pressure averaged about 80 lbs. per square inch. The grout was mixed by turning in compressed air at the bottom, which kept the mixture "boiling" and prevented the sand and cement from settling and choking the outlet pipe. About 0.14 cu. yd. of grout was used per linear foot of tunnel. Three hundred and eighty pounds of cement made about 0.9 cu. yd. of grout. The amount of grout required was probably increased about 25 per cent on account of the amount required at the old Cochituate Aqueduct shafts and at the point where timbering was required near the west portal of the tunnel. The cost of the work was as follows:

Item	Cost per cu. yd.	Cost per lin. ft.
Superintendence and general labor	$ 0.60	$0.09
Labor	3.34	0.48
Teaming	0.01	0.002
Sand	0.76	0.11
Cement	4.58	0.65
Small tools, etc	0.50	0.07
Incidental expenses and insurance	0.30	0.04
Rental, transportation and repairs of grout machine	0.09	0.013
Plant—		
Transportation, erection, repairs, operation and dismantling	2.83	0.40
Interest and depreciation	0.22	0.03
Total cost	$13.23	$1.884
Value of work	12.66	1.810
Loss	$ 0.57	$0.074

Item 12.—*Cement Mortar Lining of* 80-*In. Steel Pipe* (363 *lin. ft.*)—The mortar lining for the 80-in. steel pipe was made 2 ins. thick and was cast in place by pouring a thin mortar into the space between the steel pipe and a central collapsible steel form of the Blaw type, which was held in correct position by means of adjustable bolts, located around the circumference of the form and which were brought to a bearing upon the steel pipe so as to provide the desired 2-in. space for the mortar. The forms were made in sections 7 ft. long, each section consisting of five circular segments bolted together with an adjustable wooden key piece at the top. The mortar was poured through 2-in. holes in the top of the pipe, the lining being cast in sections 14 ft. long, without interruption in the flow of mortar after the pouring of a section was once started.

The end of the section was closed by means of a hose extending around the circumference and expanded by means of water pressure, forming a bulkhead at the end of the annular space between the steel pipe and the form.

Before setting up the forms, the interior of the pipe was cleaned to bright iron with a sand blast and it was then painted with a cement wash in the same manner as the outside of the pipe, described under Item 9. The mortar was mixed in the proportion of 1 part of Portland cement, two parts of sand and water amounting to about 25 per cent of the volume of these materials.

On account of the short length of pipe to be lined, the mortar was mixed by hand in barrels supported on a wooden platform above the top of the pipe. One cubic yard of mortar required four barrels of cement, and was sufficient for lining 7.9 ft. of the pipe.

The cost of the work has been sub-divided to show the cost of forms separate from the cost of mixing and pouring the lining, as shown in Table IX.

TABLE IX.—COST OF PLACING 2-IN. MORTAR LINING OF 80-IN. STEEL PIPE

Item	Cost per lin. ft. of pipe	Cost per sq. ft. surface covered
Forms:		
Superintendence and general labor	$0.13	
Labor	0.74	
Teaming	0.04	
Small tools, etc	0.08	
Incidental expenses and insurance	0.05	
Rental, transportation and repairs of forms	0.77	
Plant, interest and depreciation	0.002	
Total cost	$1.812	$0.086
Mixing and pouring lining:		
Superintendence and general labor	$0.12	
Labor	0.67	
Sand blasting	0.97	
Sand	0.21	
Cement	0.74	
Small tools, etc	0.07	
Incidental expenses and insurance	0.05	
Plant, interest and depreciation	0.002	
Total cost	$2.832	$0.135

TABLE IX.—*Continued*

	Cost per cu. yd.	Cost per lin. ft.	Cost per sq. ft. of surface covered
Total:			
Superintendence and general labor	$ 1.97	$0.25	
Labor	11.10	1.41	
Teaming	0.29	0.04	
Sand blasting	7.62	0.97	
Sand	1.66	0.21	
Cement	5.80	0.74	
Small tools, etc	1.24	0.15	
Incidental expenses and insurance	0.79	0.10	
Rental, transportation and repair of forms	6.03	0.77	
Plant, interest and depreciation	0.03	0.004	
Total cost	$36.53	$4.644	$0.222
Value of work	45.50	5.78	0.276
Profit	$ 8.97	$1.136	$0.054

Items 13 *and* 15.—*Laying* 60-*In. Cast Iron Pipe* (935 *lin. ft.*)—The work of laying the 60-in. cast iron pipes included the teaming of the pipes about two miles, unloading them from the wagons and laying them in trenches, including the furnishing of all materials required. The excavation and refilling of the trenches was paid for under Items 3, 4 and 5. The cost of the portion of the work included under these items was as follows:

Item	Cost per lin. ft.
Superintendence and general labor	$0.23
Labor	1.30
Teaming	0.38
Jute	0.03
Lead	0.60
Blocking and wedges	0.14
Small tools, etc	0.02
Incidental expenses and insurance	0.05
Plant, interest and depreciation	0.003
Total cost	$2.753
Value of work	2.113
Loss	$0.64

The cost of teaming the pipe was $0.38 per ton mile.

Item 14.—*Laying* 80-*In. Steel Pipe* (363 *lin. ft.*)—The 80-in. steel pipe was delivered to the contractor in sections 20 ft. in length and was hauled by him to the work, a distance of about two miles. It was necessary to roll the pipes on skids for an average distance of 100 ft. from the point of delivery to place them in position. The steel pipes were furnished by the Hodge Boiler Works of East Boston, and were placed, riveted together, lined and covered by the contractor for building the tunnel. Each 20-ft. section of the pipe was made of three alternately large and small courses, each course being formed of a single sheet of flange steel 6 ft. 11 ins. wide and 5/16 in. thick. The longitudinal joints were lapped 4⅜ ins. and double-riveted with ¾-in. rivets spaced 2⅞ ins. from center to center. The circular joints were lapped 2½ ins. and single-riveted with ¾-in. rivets spaced about 2⅛ ins. on centers. At intervals of about 40 ins., pads 6 ins. in diameter and ½ in. in thickness were riveted on top of the pipe, through each of which was drilled and tapped a hole for a 2-in.

diameter steel plug. As previously stated these 2-in. holes were used for introducing the Portland cement mortar for lining the steel pipe. At the junction between the 76-in. mortar-lined steel pipes and the 60-in. cast iron pipes, 76 × 60-in. cast iron branches were set and the 60-in. outlet capped for future use when an additional main shall be required. The cost of the work under Item 14 was as follows:

Item	Cost per lin. ft.
Superintendence and general labor	$0.374
Labor, laying pipes	1.08
Labor, riveting	1.03
Teaming	0.20
Small tools, etc	0.234
Incidental expenses and insurance	0.15
Plant, interest and depreciation	0.004
Total cost	$3.072
Value of work	3.376
Profit	$0.304

The cost of teaming the pipe was $0.62 per ton mile.

Item 16.—Extra Work.—The extra work required under the contract included the excavation and timbering of six old shafts on the Cochituate Aqueduct tunnel, where the excavation for the new tunnel broke through into these old shafts, and also some miscellaneous work. For this work the contractor received the actual cost of the work plus 15 per cent, and the total amount paid under this item was $925.89.

Organization and Progress of St. Louis Water Works Tunnel.—C. H. Hollingsworth, superintendent for the contractors, gives some interesting data in regard to the St. Louis Waterworks Tunnel in Engineering and Contracting, May 6, 1914, and Engineering Record, May 9, 1914, from which articles the following data are taken.

The tunnel was driven in both directions from a drainage shaft at the river bank, the shore tunnel being 537 ft. long and the river tunnel 2252 ft.

When the work became well organized it was found that with only one shot in eight hours there was considerable spare time. About 1¾ hours were required to muck out the heading, ½ hour to set up, 3 hours to drill the round of holes, from ½ to ¾ hour to blow out and load and from 50 minutes to 1 hour to shoot. This left from 1 to 1½ hours idle time per shift, part of which was taken up in clearing out the smoke. The smoke was taken care of by a No. 2 Roots reversible blower with 10-in. opening.

Arrangement of Holes.—If it had been possible a longer round would have been drilled to take up the spare time. As it was, however, an 8-ft. round was drilled and would not break the ground to advantage. The trouble was that the tunnel was so narrow that it was impossible to give the cut holes much of an angle with each other. A center cut of six holes, three on each side, was adopted after several other methods had been tried. The arrangement of the holes used through the greater part of the work called for sixteen holes, but occasionally seventeen were drilled. By drilling a 6 or 7-ft. cut and a 4 or 5-ft. side round the ground could be broken with less powder.

Late in December a schedule of four shots in twenty-four hours was started. Working this way the day shift came on at 8 a. m. when the preceding shift had finished shooting. They mucked out the heading, set up, drilled and finished shooting at 2 p. m. Then they mucked out and set up the machines ready for the next shift. The 4-to-12 shift drilled a round and finished shooting it about 8 p. m., and then mucked out, set up and drilled ten or twelve holes on the second round before midnight. The 12-to-8 shift then came on and finished the drilling of the round and shot it about 2 a. m., after which they mucked out, set up, drilled and shot another round before 8 o'clock.

While it was found that after getting this system working the gangs had plenty of time for the various operations, the scheme never worked satisfactorily, for the reason that it is never advisable for one shift to leave work for the next shift to complete. For instance, the way in which the columns were set up by the day shift never suited the 4-to-12 shift and they often tore them down and reset them, while the 12-to-8 shift was always displeased about the way the 4-to-12 shift started the round of holes and claimed that they often had to drill some of them over again.

The time taken for the different operations with four shots per day was about as follows: Mucking out, 1 hour; setting up, 30 minutes; drilling, 3 hours; blowing out and loading, 30 minutes; shooting, 45 minutes; blowing out smoke, 15 minutes.

In order to arrange so that the shifts would each finish their own work I decided to try two shots every shift, and if necessary drill shorter rounds. At first a 6-ft. cut with a 4-ft. side round was drilled, but after the gangs had shaken down to the proper swing 7 and 8-ft. cuts and 5 or 6-ft. side rounds were drilled. The only extra men put on to carry out this schedule were an extra helper in the heading and a foreman and from four to six men on the day shift to fix track and attend to the ditching.

With four shots per day all three shifts used the columns and when the six shots per day started one of the gangs preferred the columns as the heading foreman on that shift was not familiar with the use of the bar. The bar, however, was finally used on all three shifts. A 4½-in. bar 10 ft. long with a single screw was used with four arms on it. The machines were mounted on clamps on these arms, two above and two below the bar. It was necessary even with the bar to muck out the heading to a great extent before setting up the drills, as there was positively no room for even one mucker in the heading after the machines were up and the heading gang working. To help clear the muck away from the face after the four-shot schedule was started two muck shots were placed in the heading and fired with the last holes of the round. These muck shots consisted of from 7 to 10 lb. of powder each, and one was placed on each side of the tunnel close to the face.

When the two-shots-per-shift program was in progress the time was divided about as follows: Mucking out heading, 45 minutes; setting up, 15 minutes; drilling, 2 hours; blowing out and loading holes, 20 minutes; shooting, 30 minutes; clearing out smoke, 10 minutes.

Plant.—The plant used on the tunnel work included three 75-h.p. locomotive-type boilers supplying steam for the compressors for the pumps at the bottom of the shaft and for the hoisting engine for the cages. While sinking the shaft a stiffleg derrick was used and this was later used on the excavation for the screen chamber. The pumps used to take care of the water from the tunnel included a Knowles piston pump and two duplex Worthington plunger pumps. A Norwalk two-stage compressor was used, assisted later on by a single-stage Ingersoll compressor. Current was obtained from the city at 2300 volts, alternating current, and transformed to 220 volts.

Mucking.—A 3-ton General Electric storage-battery locomotive was used to handle the muck cars to and from the shaft after the headings had progressed a few hundred feet from the shaft. The muck cars were specially designed for the work and were wooden box cars, with a door in one side for dumping, and an incline in the bottom of 1 ft. toward the door. The bottom of the car was covered with steel plate and the box itself was built of 2-in. oak well bolted together and fastened at the corners with angle irons. At the ends were eye-bolts running through the frame so that the cars could be coupled in a train. Usually three cars were handled by the locomotive.

In the heading slick sheets of ⅜-in. boiler plate were used to cover the end of the track and to facilitate the shoveling. In working into the muck pile only four men, or occasionally five, could work abreast, and even then it was necessary to select carefully the right and left hand shovelers and keep them on their respective sides. The usual method was to use four men abreast with two more on the muck pile throwing over their heads and loosening up the muck. Two more men worked behind the car picking up bottom, fixing track and helping dump the cars off the track and back on again. On the locomotive there was a motorman and also a switchman, both of whom helped dump off cars.

At the bottom of the shaft were two men who pushed the cars on and off the cages and on top were a top man and three men for pushing cars. One man took care of the pumps which were at the bottom of the shaft and did the pipe fitting. An extra gang consisting of a foreman and from four to six men was employed on the day shift cleaning out the ditch along the tunnel and laying new track. All permanent track was laid on the day shift. The other two shifts put down short sections of rail temporarily. From forty to sixty-five cars of muck were taken out of the one heading on each eight-hour shift, the cars holding about 1 cu. yd. of muck.

Organization and Wages.—In the regular gangs on each shift there were the following men at the rates given:

Force on top: Number and grade	Rate per day
1 compressor engineer at	$7.00
1 hoisting engineer at	7.00
1 fireman at	3.20
1 signal man at	2.80
3 top men or car pushers at	2.40
Force in the tunnel:	
1 pump man and pipe fitter at	4.00
2 cage men at	2.80
1 motor man at	4.00
1 switchman at	2.80
1 muck foreman at	4.80
6 to 8 muckers at	2.80
1 heading foreman at	5.00
4 drill runners at	3.60
4 or 5 helpers at	3.00
1 nipper at	3.00
1 electrician at	4.00
Force of extra men on Day Shift (on top):	
1 blacksmith at	5.00
1 helper at	4.00
1 machinist at	4.00
1 machinist helper at	2.40
In the tunnel:	
1 extra muck foreman at	4.80
4 to 6 extra muckers at	2.80

Rate of Progress.—Taking all things into consideration, the progress was very satisfactory, especially while making the six shots per day.

During the month from 8 a. m. Jan. 21 to 8 a. m. Feb. 21 the progress was 744.7 ft., and for the best week, which was the week ending at 8 a. m. Feb. 20, the progress was 184 ft. This latter was for the full week of seven days or 21 shifts. The month's progress, however, was for 29 days and two shifts, as during the 31 days of the month there were four shifts lost time. The best progress made in one day was 29.1 ft.

The east heading was finished March 4, and a gang on each shift was started immediately cleaning up the bottom and trimming. The gang on each shift consisted of a foreman and ten men mucking, besides one drill runner and three helpers, with the usual cage men, top men, etc. On March 19 a second gang was started on each shift, there being a foreman and ten men in this second gang also. One of these gangs worked from the heading toward the shaft and the other worked from the shaft toward the heading, and on April 1 the trimming was completed and practically all of the bottom had been taken up. In places there were from 50 to 75 ft. that required no trimming at all and less than 200 ft. of the roof required trimming. On the other hand there was less than 100 ft. of the roof that was outside of the 11 ft. circle.

Bonus System.—A bonus system was put in force in the early stages of the work and helped materially in the progress. A minimum of 72 ft. of tunnel per week was set and for all over that the following bonus rates were paid:

	Cts. per ft.
Heading foreman	50
Muck foreman	30
Drill runners	30
Drill helpers	20
Nipper	20
Muckers and cage men	10

From the total weekly progress ending every Friday morning at 8 o'clock 72 ft. was subtracted and each shift received bonus on one-third of the remainder, each shift being credited with one-third of the extra progress.

Cost of Tunnel No. 7 of the Los Angeles Aqueduct.—The following study by C. H. Richards, Division Engineer Little Lake Division, Los Angeles Aqueduct (Engineering News, Nov. 18, 1909) covers the unit costs of driving a timbered tunnel during the 15 day period from Aug. 15 to Aug. 29, 1909. The figures refer to the north heading only.

During this period 90 ft. were driven in 15 8-hour shifts. The tunnel is approximately 10 × 10 ft. in section and contains 3½ cu. yds. in place per lineal foot to pay line. The over-breakage was about 17 per cent, making a total of 6½ cu. yds. of broken material per foot of tunnel.

The heading is 800 ft. in from the portal. It is lighted by electricity in 110 volts, and ventilated by a No. 3 Champion blower through 12-in. pipe, the heading being cleared in fifteen minutes after shooting.

Drilling is done by one No. 7 Leyner drill, water being forced through the hollow steel. This drill used approximately 66 cu. ft. air per minute at 83 lbs. pressure, drilling holes to 10 ft. in depth.

Mucking is facilitated by steel sheets laid down before shooting. The muckers use No. 3 D-handle square-point shovels. Dirt is hauled away in 32 cu. ft. rocker dump cars pulled by a 3½-ton locomotive running on a single 24-in. gage track laid with 25-lb. steel.

The rock is a close-grained hard gray granite, with numerous seams, causing the drill to run from alignment, but it breaks well. The seams and water combined make it necessary to timber all this ground. The ground carries enough water to make disagreeable mucking, and to require pumping.

The timbering comprises sets of 6 × 8-in. Oregon pine, spaced 5 to 8 ft. apart, as ground permits, and 2 × 6 lagging. Each set consists of two vertical posts and a four-segment arch.

The crew consisted of one shift boss at $3.50 per day; four miners at $3 five muckers at $2.50, and one trammer at $2.50. The blacksmith doing the repair work was paid $4 per day.

The four miners worked on day shift, drilling the ground, timbering and shooting. The muckers followed on night shift. This arrangement resulted in a clean heading for the drill crews, and nothing interfered with the mucking crew.

The cost of work during the 15-day period is tabulated below in detail (Table X).

TABLE X.—SHOWING UNIT COSTS OF TUNNELING AND TIMBERING, NORTH HEADING OF TUNNEL NO. 7, LITTLE LAKE DIVISION OF LOS ANGELES AQUEDUCT
For 15-day period, Aug. 15–Aug. 29, 1909; advance 90 ft.

Class of work	Totals for 90 ft. length Labor Hours	Totals for 90 ft. length Labor Cost	Cost lin. ft. tunnel

Total material	$ 480.29	$ 5.433
Live stock:		
Mule, 15 days at 90 cts	$ 13.50	$ 0.15
Total direct and auxiliary field charges	$1,221.45	$13.667

To explain the table further the following particulars are noted as to drilling and powder:

Drilling.—During the 15-day period 150 holes were drilled, aggregating 1,202.3 ft. in length. The average depth of hole therefore was 8 ft. The average speed of drilling was 21.74 ft. hole per hour of actual drilling time, or 15.84 ft. per hr. if lost time is included. This means that the average hole (8 ft.) was drilled in 22 mins. The fastest hole, however, was 9 ft. 6 ins., drilled in 10 mins., while the slowest was 8 ft. 6 ins., drilled in 78 mins. The average cost of drilling per foot of hole was 3.6 cts., as given in the table.

Explosives.—There were used 650 lbs. of 1⅛-in. 40 per cent gelatine; 250 lbs. 1-in. 40 per cent gelatine, and 150 lbs. 1-in. 60 per cent gelatine, a total of 1,050 lbs. This is 11.66 lbs. per lin. ft. of tunnel, or 3.3 lbs. per cu. yd. place measurement. The cost (delivered) was $140.87. Adding the cost of fuse (2,700 ft. $13.85), caps (306 = $2.49), and tamping stick ($0.48), makes the total cost $157.69, which is about $0.50 per cu. yd. place measurement and $0.27 per cu. yd. loose.

The following summarized the above cost, together with the field and office charges assessable to the work. Attention may be called to the fact that the figure $12.165 given as direct charge differs from the previous total of $13.667 by the amount ($1.502) charged for tracks, the latter being included in the previous detail tabulation. In the recapitulation the auxiliary charge is reduced by the estimated amount of salvage on the track material.

RECAPITULATION OF UNIT COSTS

Class of charge		Cost per foot of tunnel
Direct charges:		
Labor	$7.056	
Material and supplies	4.399	
Local administration and engrg	0.56	
Live stock service	0.15	
		$12.165
Auxiliary charges:		
Labor on tracks, etc	$0.468	
Material for tracks, etc	1.034	
	$1.502	
Salvage on material about 66 %	.69	
		0.812
Roads and trails*		1.50
Buildings*		0.20
Water supply*		0.22
Machinery and tools		1.06
Total fixed charges		$15.957
Add 3 % for executive office administration		0.475
Total cost of tunnel, timbered and ready for lining, per lin. ft.		$16.432

* The total cost of these works on the entire division, apportioned to the severa parts of the permanent construction, gives as estimated charges per foot of this tunnel the figures noted.

Deducting from the total of $13.667 of Table X the charges that obviously belong to timbering we get a cost of $11.75 per lin. ft. for excavation, which is equivalent to $3.36 per cu. yd.

Bonus System for Tunnel Work of the Los Angeles Aqueduct.—The following notes are abstracted from the Report on the Los Angeles Aqueduct.

To complete the Los Angeles Aqueduct within a reasonable time limit so as to avoid undue interest charges on the bond issue the controlling factor was recognized by all to be the great length of tunnels, 164 in number, and especially the Elizabeth Tunnel, which is more than 5 miles long. This tunnel, passing through the crest of the Coast Range, more than 20 miles from a railroad base of supplies, had to be driven from two headings only and lined throughout with concrete. A fair rate of progress for tunnels of this size, and in a similar geological formation, has been a mile a year from the two headings, or five years in all.

It was therefore important to devise some method of work which would develop speed and the bonus scheme was adopted. This was modified from time to time, as experience was gained in its application, and the following schedule is the final outcome.

Theory of the Bonus System.—The tunnels were driven for a few months, and the number of men who could work efficiently in the headings, together with their progress, was noted under different conditions. A standard size crew was then authorized, which could not be exceeded. In the Elizabeth tunnel, the number was 16 men for untimbered tunnel and 23 for timbered tunnel. Only those engaged inside on the driving of the heading, trimming, timbering, etc., were included in the bonus crew. The required progress was fixed. At the Elizabeth tunnel it was 8 feet per day, or 2⅔ feet per shift for untimbered tunnel, requiring the excavation of 4.18 cubic yards per lineal foot, and 6 feet per day, or 2 feet per shift for timbered section of the tunnel, requiring the excavation of 5.02 cubic yards per lineal foot, and the placing of 115 feet board measure of lumber. A base wage was paid of $3.00 per day for miners and timbermen, and $2.50 per day for muckers (shovelers). In wet tunnels, 50 cents a day additional was paid. Eight-hour shifts were worked.

For all excess footage over the base rate made by a shift each man on the shift was paid 40 cents a foot in the Elizabeth tunnel. In other tunnels the bonus paid varied from 20 cents to 40 cents per foot, depending on the character of the rock. Each tunnel was inspected by the Chief Engineer or his assistant, and a reasonable rate of progress and bonus pay determined, which when approved by the Board of Public Works, was effective for that tunnel. The superintendent and foremen did not share in the bonus pay, as it was their duty to see that the quality and quantity of the work was up to par. Measurements were made on the 10th, 20th and last day of each month to determine the progress. Any man receiving bonus was required to work continuously through the ten-day bonus period.

The theory of the schedule is to pay the men a fair wage for the day's work, and in addition to give them a share approximating 50 per cent of the estimated saving, in case the base rate of progress is exceeded. It must be kept in mind that the labor charge per day for the driving of a tunnel is a fixed amount, including not only those engaged in the tunnel, but also the outside organization of mechanics, superintendent and clerks. The cost of explosives and power varies with the footage made. Therefore, the greater the rate of progress, the lower the final unit cost of the work will be.

Effect of the Bonus.—The sharing of the benefits with the men by means of the bonus system resulted in an improved relation with them. They became interested in the success of the work. The men in a bonus crew themselves eliminated the drones and did not tolerate loafing. The duties of the foremen and superintendent were almost entirely confined to getting the necessary supplies and equipment. As the bonus profits materialized, the miners not only remained longer on the work, but sent for other workmen whom they knew and who would do their share in increasing the speed.

In fixing the bonus and the base rate, it is important to reach a reasonable balance, which will allow the men a fair share in the saving, giving them a chance to earn from $10.00 to $30.00 a month as a reward for unusual effort. In some places where the bonus has been tried by other organizations, the base rate was placed so high that there was little opportunity for the men to profit by it, resulting in discouragement to them and no benefit to the organization.

In November, 1909, the tunnel work on the Los Angeles Aqueduct was in full swing. This particular month is selected for consideration only because the bonus pay rolls were so large that the City Auditor asked for an investigation of the bonus system to justify its use. A detailed study was made of it, which satisfied the Board of Public Works that it was decidedly beneficial. During this month, 9,131 feet of tunnels were excavated, of which 4,033 feet was excess footage over the base rate as fixed, which is an increase in speed of 72 per cent. Ninety per cent of the crews earned bonus ranging from 12 cents to $1.95 per day for each man. In the 39 tunnel headings, the total wages for that month were $76,837.38, of which $13,133.94 was bonus, or 17 per cent. The average cost per foot of tunnel for labor and bonus was $9.87. If only the base progress, which was the estimated ordinary progress, had been made, the cost per foot for labor would have been $13.80. The footage gained over the estimated base rate cost in bonus pay an average of $3.25 per foot for all tunnels.

In the Elizabeth tunnel, the base progress of 420 feet for the two headings for the month was exceeded 429 feet. In this tunnel, where speed was particularly desired, the muckers, who had the hardest work to do and who largely controlled the rate of advance, worked in relays. A car holding 33 cubic feet would be pushed up to the pile of debris thrown down by the explosion and four of these shovelers would fill it. They would then push it back to the switch, and four fresh men shoved up an empty car and filled it—the first crew meantime doing light work or resting. This process was kept up, so that a fresh crew would come up with each empty car. The result was that the American records for rapid hard rock tunnel work were repeatedly broken, and the world's record for soft rock tunnel driving, (so far as known) was beaten at Tunnel 17 M, in the Jawbone Division, where 1,061 feet were driven at one heading by hand work in August, 1909. The material in Tunnel 17M was a soft sandstone which could be bored with augers.

The entire 26,870 feet of the Elizabeth tunnel was completed on February 28, 1911. The four years and seven months time set for the driving of this tunnel was beaten by 450 days, or 32 per cent. The average progress was 10.8 feet per day for each heading. This includes the time during which the tunnel was driven by hand, while the equipment was being purchased and installed. The rock is granite, favorable for rapid work at the south end, but uneven, full of water, difficult and dangerous at the north end.

The average cost per foot of the Elizabeth tunnel was:

Excavation, including timbering	$41.35
Lining	9.65
Local administration and superintendence	2.10
Equipment	7.92
Buildings, water supply, etc	5.83
Engineering and surveys	1.00
Total	$67.85

This does not include general administration costs, which amounted to 3.55 per cent or $2.35 per foot, making a total cost of $70.20 per foot. The estimate of the Board of Consultng Engineers was $75.33 per foot plus 16.5 per cent for contingencies and water supply, making a total of $87.93 per foot. The saving therefore amounted to approximately $18.00 per foot or about $500,000 for the entire tunnel.

On the Jawbone division, bids were asked for all the construction of this part of the work, excluding siphons, but including 65,000 feet of tunnel. They ranged from $2,294,000 to $4,258,000. After a consideration of the bids received, it was decided that the work would probably cost the City less if it were done by day labor under the Engineering Department. This was done—the bonus system was used in all of the tunnels and the actual field cost of all the work was $700,000.00 less than the lowest price bid.

Rules Governing Payment for Bonus Footage.—1. Ten days shall constitute a period. The first period to be from the 1st to the 10th of the month, inclusive; the second from the 11th to the 20th inclusive; the third from the 21st to the end of the month. Bonus payments shall be allowed upon the basis of measurements made at the close of each ten-day period.

2. The following named classes of employes shall be allowed to participate in bonus payments:

Tunnel Foremen,
Shift Bosses,
Miners,
Muckers

3. The tunnel foreman shall not be considered as one of the crew except when in charge of a single shift, when he shall share in the bonus on the same basis as the men of the crew under his direction. If he is in charge of more than one shift, he shall be allowed bonus based upon the average bonus progress of all headings under his supervision.

4. The shift boss shall be considered as one of the shift crew. He will participate in the bonus on the same basis as the men of the crew under his direction. An exception to this rule is made when a shift boss is placed in charge of two or more shifts in different headings. In this case, he would be placed on the same basis as a foreman—to wit: not to be considered as one of the crew, and would be allowed bonus upon the mean bonus progress.

5. The number of shifts worked in a heading during a day of 24 hours shall be determined by the engineer or superintendent in charge of the work after consultation with the Chief Engineer.

6. All back trimming must be done by the crew sharing the bonus. If the timbers are placed by the miners from the standard crew in a given ten-day period, then the portion of the tunnel shall be considered as a timbered section; otherwise it shall not be so considered.

7. Only men who work continuously through the ten-day period, with the following exceptions, shall be entitled to bonus:

(a) Any employe, entitled to bonus earnings, who is injured or becomes ill during a period from conditions arising directly from tunnel construction, shall participate in bonus in proportion to the number of shifts worked by him during said period.

(b) If an employe, entitled to bonus earnings, is transferred during a period from a heading to another part of the work for reasons other than his own request, he shall participate in bonus in proportion to the number of shifts worked by him on such heading.

8. If the work is interrupted by the failure of power, shortage of material or supplies, floods, cave-ins, or other causes beyond the control of the men, the men shall be entitled to bonus pay in proportion to the number of shifts worked by them during period in which such interruptions occurred.

9. To establish a uniform system of computing bonus earnings in above case, the following formula will be used:

$$\frac{x + y}{\dfrac{x}{a} + \dfrac{y}{b}} = \text{Average base rate per shift.}$$

Let x = Timbered progress = 25 ft.
y = Untimbered progress = 30 ft.
a = Required timbered per shift = 2 ft.
b = Required untimbered per shift = 2.5 ft.
s = Number of shifts during period = 20

Then

$$\frac{x}{a} = \text{shifts required at base rate.}$$

$$\frac{y}{b} = \text{shifts required at base rate.}$$

Or substituting values,

$$\frac{25}{2} = 12.5 \text{ shifts required at base rate.}$$

$$\frac{30}{2.5} = 12.0 \text{ shifts required at base rate.}$$

Total 24.5 shifts required at base rate.

$$\frac{25 + 30}{24.5} = 2.245 \text{ average base rate.}$$

$$20 \times 2.245 = 44.9 = \text{progress required.}$$

$$55 - 44.9 = 10.1 \text{ ft.} = \text{bonus footage.}$$

10. The computation of bonus footage shall be made by dividing the total number of feet run during the period by the total number of shifts worked during the period. From this average footage per shift there shall be deducted the base rate of progress required, and the remainder, if any, will be the bonus footage per shift. The bonus earned per man during the period will be the number of shifts in which he worked, times the average bonus footage, times the bonus price per foot. (Provided all conditions as outlined in these rules are complied with.)

Example 1.—3 shifts working 10 days

Total progress for period — 150 feet.
3 shifts × 10 days = 30 shifts worked.
150 ft. ÷ 30 shifts = 5 ft. per shift.
Base rate of progress 3.5 ft. per shift.
Bonus footage 1.5 ft. per shift.
Bonus earned for per man = 1.5 ft. × 10 shifts × 25 cts. per ft. = $3.75.

Example 2.—1 shift working 10 days

Total progress for period — 50 feet.
1 shift × 10 days = 10 shifts worked.
50 ft. ÷ 10 shifts = 5 ft. per shift.
Base rate of progress 3.5 ft. per shift.
Bonus footage 1.5 per shift.
Bonus earned for period per man = 1.5 ft. × 10 shifts × 25 cts. per ft. = $3.75.

Bonus Schedule for Tunnel Work in the Little Lake Division

Capacity of tunnel	Class of rock	Timbered or untimbered	Class of work	Base rate per shift	No. of men per shift	Rate per man per bonus foot
430 sec. ft.	Soft	Untimbered	Hand	4.5 ft.	9	20 cts.
430 sec. ft.	Soft	Timbered	Hand	4.5 ft.	9	20 cts.
430 sec. ft.	Hard	Untimbered	Hand	2.5 ft.	10	25 cts.
430 sec. ft.	Hard	Timbered	Hand	2.0 ft.	10	25 cts.
430 sec. ft.	Hard	Untimbered	Machine	3.0 ft.	11	30 cts.
430 sec. ft.	Hard	Timbered	Machine	2.3 ft.	11	30 cts.
430 sec. ft.	Hard	Untimbered	Machine	3.0 ft.	11	40 cts
430 sec. ft.	Hard	Timbered	Machine	2.3 ft.	11	40 cts.
430 sec. ft.	Hard	Untimbered	Machine	5.0 ft.	14	30 cts.
430 sec. ft.	Hard	Timbered	Machine	4.3 ft.	14	30 cts.

Bonus Schedule for Tunnel Work in the Elizabeth Tunnel, North and South Portals

Class of rock	Timbered or untimbered	Class of work	Base rate per shift	No. of men per shift	Rate per man per bonus foot
Hard	Untimbered	Machine	2⅔ ft.	16	40 cts.
Soft	Timbered	Machine	2 ft.	23	40 cts.

Noteworthy achievements in tunnel driving by the Aqueduct organization were at Tunnel 17-M, which is in a soft sandstone at the head of the Red Rock Canyon, where a tunnel 10,596 feet in length was excavated in seven months from two headings. As far as known the driving of 1,061.6 feet in the month of August, 1909, is the world's record for fast tunnel driving for one month's run. This tunnel was completely lined in eight months. In other words, this two-mile tunnel was driven and lined in a year and a quarter.

One hundred and sixty-four tunnels were excavated, and practically all of them were driven from two or more headings. There was not an error in instrumental work, either in line or grade, in any of the tunnels, or elsewhere on the work.

Cost of Tunnel in Clay for the Alton, Ill. Sewer Outlet.—Engineering and Contracting, Feb. 10, 1915, publishes the following data given by J. E. Schwaab in a paper before the Thirtieth Annual Meeting of Illinois Society of Engineers and Surveyors.

The outlet necessitated the construction of 1,000 ft. of tunnel through a ridge. The grade of the tunnel varied from 20 ft. to 39 ft. below the natural surface of the ground. Shafts were sunk every 200 ft. These shafts were made 4 ft. by 8 ft. in dimension and were properly braced with oak timbers. Clay was removed from the tunnel by the use of 5 cu. ft. wooden buckets which were raised and lowered into the shafts by the means of an ordinary hoisting engine and swinging boom. This equipment was also used for lowering the 12-in. cast-iron pipe into the shaft and for dragging it along the tunnel. At the bottom of the shaft the heading was driven in both directions for a distance of 100 ft. at the same time. The sides and top were sheeted with 3-in. oak planking as the tunnel was being driven. To operate one shaft there were five men in the tunnel—one man to hook the cable onto the buckets, two men at the headings, and two men wheeling muck to the shaft. On the top there were three men, one man unhooking the bucket and emptying it, and one man with team and scraper to remove the earth from the shaft, and one man to cut timber.

One difficulty experienced was the lack of ventilation. It was impossible to keep a light burning in the tunnel so that the men could see. The air became foul, thus preventing the men from remaining in the tunnel. This obstacle was overcome by the use of an ordinary blower fan operated by a 1½-HP. gasoline engine. To the discharge end of the blower fan 3-in. spouting was connected and run down into the shaft and each way into the headings. This fan furnished sufficient air to enable the men to work in the tunnel without experiencing any discomfort as regards ventilation.

The time required to complete this tunnel was 60 days, average progress being 17½ ft. per day. The maximum progress was 34 ft. per day. The total cost, including labor, material and lumber, was $10,000.

Following are the wages paid for the labor for constructing the tunnel. Each shift consisted of:

One foreman, per month	$75.00
One engineer, per hour	0.25
Two diggers, per hour	0.30
Five laborers, per hour	0.25
One team, per hour	0.50
One water boy, per day	1.00

Eight hours constituted a day's work for each shift; at times there were three shifts working in the 24 hours.

The material through which the tunnel was driven was wet, sandy clay excepting 50 ft. of small gravel and quicksand. The elevation of ground water was 13 ft. below the natural ground surface. The men at the headings used ordinary round pointed spades; picks were used when gravel was encountered.

Cost of a Circular Brick-Lined Water Works Tunnel 8-Ft. in Diameter.—The following data are taken from Engineering and Contracting, April 2, 1913.

The Chicago Avenue Tunnel connection, completed in March, 1913, for the Chicago Water Works, is 8 ft. in diameter; is lined with three rings of brick, and is 1,216 ft. long. It cost $34.82 per lineal foot. This is a moderate figure, considering the quality of the work done; the length of the tunnel; the curves and grades upon which it is built; that air pressure was used, and that engineering and inspection costs are all included. The new tunnel joins the lake section of the 7-ft. Cross Town Tunnel with the 8-ft. Blue Island Avenue Tunnel, which was completed in 1909. The tunnel parallels the curb 10 ft. away on LaFayette Court for a distance of 721 ft. It has a compound curve at the south end consisting of one arc 308.5 ft. long on a radius of 175 ft. and one arc of 55 ft. radius and 141.2 ft. long, which connects with the lake end of the old Cross Town Tunnel. At the north end the main tangent is deflected 30° on a curve of 12 ft. radius, to avoid making a right angle connection with the Blue Island Ave. Tunnel. From this curve the tangent continues about 30 ft. to the juncture with the Blue Island Tunnel with which it makes an angle of 60°.

The grade on which the tunnel is built is level between the construction shaft and the Blue Island Avenue Tunnel, then rises at a rate of 1.3 per cent from the shaft south to the point of curvature whence it dips at a rate of 6 per cent on a curve to the junction with the lake end of the old Cross Town Tunnel. The rising grade is introduced to provide a safe clearance between the new tunnel and three other tunnels which pass under the new bore.

Shaft Construction.—Construction was commenced on May 20, 1912, with the erection of the office building and tool house. The following month was occupied in building a cement shed and men's dressing house; the head house framing; the frames and sheeting for starting the excavation for the shaft; in assembling the 1-cu. yd. tunnel cars, which were built at the city water works shops, and in setting the 100-hp. fire-box boiler, and building under it a foundation and ash pit. The preparations for active work excavating the shaft were continued during the early part of July and the actual excavation was started July 15, 1912, when a hole 15 ft. square was started. This had been carried about 10 ft. below the surface using 2 × 10-in. sheeting held in place by three sets of timber frames spaced 3 ft. apart vertically, when water was encountered. The excavation was then interrupted until the first sections of the steel shell could be placed.

The shell was built by John Mohr & Sons, Chicago, and delivered in place for $930. It consisted of five sections each 11 ft. 5 ins. in diameter and 6 ft. high, made of ⅜-in. boiler plate. The two bottom sections were riveted together in the shop and provided with a beveled cutting edge stiffened around the inside with an additional plate and a 6 × 8 × ½-in. angle 1 ft. above the cutting edge. The total weight of the shell was 21,385 lbs. with the rivets. Its cost delivered was, therefore, 4.35 cts. per pound. Each section was thoroughly calked and all the rivets were countersunk on the outside of the shell. By July 26 the two bottom sections had been placed and another 6-ft. section had been riveted and calked. The shell had also been lined up by vertical guide timbers placed on four sides. The brick lining was then started, the 6 × 8-in. angle serving as a footing; and on July 30 had been carried to a height of 14 ft. With this additional weight the shell was forced down to elevation −4 or 16.6 ft. below the street grade. Preparations were then made to sink the 18 ft. of erected shell deep enough to permit the erection and riveting of the remaining two sections.

All the material removed from the shaft was taken on cars running on a narrow-gage track to a dump on the east side of the street where, by previous arrangement, the city had obtained permission to fill in vacant property to the level of the street. A No. 4 Nye pump was suspended in the bottom of the shaft at this time as the material encountered was a water-bearing stratum of lake sand. This sand was 13 ft. deep, overlying the soft blue clay through which the balance of the shaft was sunk.

By Aug. 8, 1912, the last two sections of the steel shell were erected and the brick lining was then completed to within 6 ins. of the top of the shell. The excavation was next resumed and the shell gradually sank, with the weight of the brick lining, until it reached an elevation of −13 or 25.6 ft. below the street, when it became necessary to add weight to sink it further. About 20 tons of pig iron were loaded on 10 × 10-in. timbers placed across the top of the shell. With this additional weight the cutting edge was sunk 4 ft. or to elevation −17. More weight was added and the shell was finally sunk to elevation −24.20. The total weight used to sink the shell was 163,646 lbs. With the weight of the timbers the entire load amounted to 82 tons.

To estimate the friction between the soil and the shell we have:

	Pounds
Load	184,000
Shell	21,385
Brick lining	126,904
Total weight	312,289

The total area of the shell in contact with the soil when it reached its final position was 970 sq. ft. Dividing the total weight by 970 gives approximately 322 lbs. friction per square foot of contact area. Comparing this figure with the friction indicated when the shell was sunk to elevation −4, we find that at that time the weight of the shell and its brick lining was about 116,000 lbs. and that the area of contact between the shell and the soil was approximately 240 sq. ft. This indicates that a friction of 480 lbs. per square foot existed when the shell ceased to sink at −4. In this case the shell was forcing its way through sand, the area of contact with sand being 145 sq. ft. and with earth fill about 94 sq. ft. In its final position the shell was forcing its way through clay and was in contact with 405 sq. ft. of clay, 471 sq. ft. of sand, and 94 sq. ft. of earth fill. This indicates that the coefficient of friction was reduced as the percentage of area of the shell in contact with clay increased.

The excavation of the shaft was carried 20 ft. below the cutting edge to the top of the tunnel bore and the brick lining from 13 to 18 ins. thick was placed after each day's excavation. The brick lining was suspended by eight 1 in. hanging rods having plate washers. Each rod had an eye at its lower end, which supported the plate and provided for hooking on the next rod below. In the 6 × 8-in. angle which supported the brick work for the steel shell, small eye bolts were placed before any brick work was started, and to these were attached the first set of rods. The shaft was carried down to tunnel grade, and the two tunnel "eyes" excavated 10 ft. each way from the shaft and lined during the last four days of August. A sump also was built, as shown by Fig. 5 with ledge projecting 4 ins. inside the 10 ft. diameter of the shaft to support the cage landing and the floor built over the sump.

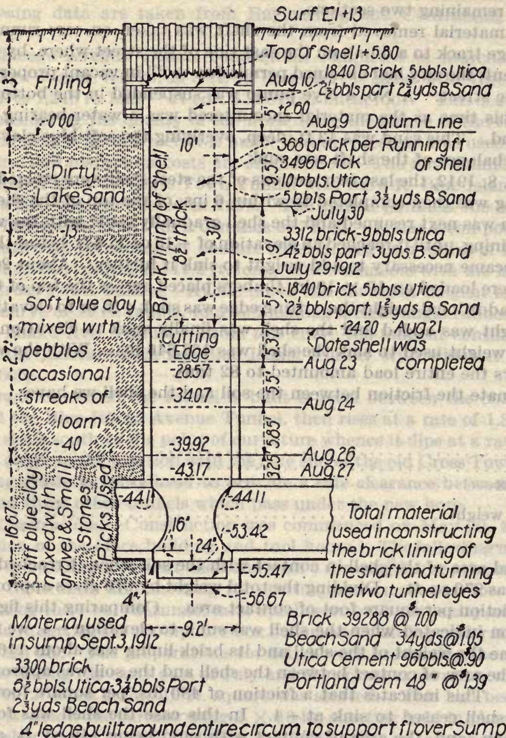

Fig. 5.—Completed shaft.

The total cost of the material and labor for the construction of the shaft including the two tunnel eyes and the brick lining was $4,675, or $66.79 per lin. ft., as follows:

39,288 brick at $7	$ 275.00
34 cu. yds. beach sand at $1.05	35.70
96 bbls. Utica cement at $0.90	86.40
48 bbls. Portland cement at $1.39	66.72
3,000 ft. lumber at $25	75.00
Steel sheet	930.00
Hanging rods	50.00
Labor	2,981.18
Teaming, for pig iron	175.00
Total, 70 lin. ft	$4,675.00
Cost per lin. ft	66.79

The cage, used for the balance of the work, consisted of a light platform suspended in a frame, and was operated by a cable from the hoisting engine in the power house.

Tunnel Construction.—Mining was begun in the south heading on Sept. 5, 1912. The bore of the tunnel was made 10 ft. 2 ins. to accommodate the 13 in. brick lining laid in cement mortar. Labor troubles at this time caused a suspension of mining for four days, during which time a new gang was organized, and an air compressor installed. Air pressure on the tunnel was provided as a precautionary measure to prevent leaks from the four water tunnels over which the new tunnel passed and to prevent damage to the apartment buildings near which the tunnel passed. A Laidlaw-Dunn-Gordon compressor, 12 × 18 × 18 ins. of 626 cu. ft. capacity at 50 lbs. pressure was installed in the power house. It was at first rented for $100 per month, and later was purchased for $800.

The air locks were not installed until Sept. 25, when the mining and lining had proceeded to a point 107 ft. from the shaft. The driving tunnel was then stopped for five days during the installation of the airlock diaphragms. These were placed 21 ft. 7 ins. apart, the nearest one being 63.2 ft. from the shaft. The lock was not quite long enough for the cars on account of the space needed to swing the outer door. The assembling and bricking in of the diaphragms required five days' time.

To insure tightness of the lock, a slot was cut through the tunnel lining about 2 ft. south of the south diaphragm and the soil around the south end of the lock was grouted. The lock walls and the walls of the tunnel for 35 ft. south from the diaphragms were washed with Portalnd cement grout. Tests were made to determine air leakage and the Portland cement grout was put on during a pressure of about 18 lbs. No trouble was had because of leakage throughout the work and the compressor was able to maintain 10 to 15 lbs. pressure running at its lowest speed.

About 135 ft. from the shaft the character of the ground changed from a hard blue clay, that required picking, to a soft clay with a tendency to swell. After this point was reached clay knives were used. This work proceeded without change from this time until the end of the tunnel was reached on February 8, 1913.

The average progress made during October was 7.98 ft. per day, during November 8.25 per day, during December 11.8 per day and during January 13.58 ft. per day. After Dec. 12, to the end of the work, two shifts per day were worked. The progress per shift during this time was 7.8 ft. for December and 6.79 ft. for January. The work slowed up, it will be noted, on the long curve on a −6 per cent grade.

The south end of the tunnel joins the lake end of the old crosstown tunnel at a point midway between two 10 ft. shafts which are about 200 ft. apart. This short section of tunnel was cut out by closing a gate at each shaft. To overcome any leaks around the gate in Shaft *F*, this shaft was filled with soft blue clay to elevation −22.

When the drift was excavated to within a few feet of this tunnel, a hole was drilled through to the old tunnel and a suction pipe connected. The pump was then started and the air pressure run up to from 42 to 48 lbs. to aid the pumping. After the water was pumped out about 10 lbs. air pressure was maintained while the remainder of the excavation was made and the connection bricked up. The material excavated in making the tunnel connections was thrown back into the abandoned tunnel towards Shaft *F*.

The work in the north drift had been extended 12.6 ft. or to 23.6 ft. from the shaft by two days' work during the month of September. It was resumed on Feb. 11, and completed to a point 55.4 ft. from the shaft and 13.8 ft. from the connection with the Blue Island tunnel. A gate shaft about 350 ft. west of the connection permitted the closing of this section of the Blue Island tunnel as the end of this tunnel is about 100 ft. east of the connection. The tunnel was pumped out and the connection made. As the Blue Island tunnel is lined with concrete, this material was used to make the connection and was carried back in the connecting tunnel for a distance of 14.55 ft.

The compressor was shut down on Feb. 9 and the pressure allowed to give out by the working of the air lock during the work of tearing up track. The lock shields were removed and the slots, left in the lining by their removal, were concreted. By Feb. 28 both drifts were entirely cleaned out and a cover of steel beams and concrete was placed on the shaft. The equipment and construction buildings were then removed, leaving the site clear by March 15.

The total itemized labor time in days, and of labor costs are shown in Table XII. This includes the time of all men and teams for the work from the commencement of operations until March 17 when all plant and buildings, with the exception of the office building, had been removed. The total cost as given is $50,556.29.

TABLE XI.—TOTAL AND UNIT COSTS

	Shaft		Tunnel		Grand
	Per lin. ft.	Total	Per lin. ft.	Total	total
Engineering and inspection	$10.12	$ 708.04	$ 2.05	$ 2,434.47	$ 3,142.51
Labor	34.97	2,447.96	24.90	29,529.06	31,977.02
Materials	21.70	1,519.00	7.02	8,320.27	9,839.27
Plant	8.32	582.05	4.23	5,015.44	5,597.49
Total	$75.11	$5,257.05	$38.20	$45,299.24	$50,556.29

Table XI gives the total and unit costs for the work as distributed for the various classes of work on the shaft and on the tunnel. The unit cost for the shaft is given in this table as $75.11 as compared with $66.79 given previously. The difference is due to the addition of a proportionate charge to the shaft work of the total cost of the plant. The plant included in this charge is as follows:

Machinery, cars, etc	$3,757.51
Rails and switches	464.59
Lumber	773.52
Pipe fittings	138.98
Miscellaneous	462.89
Total	$5,597.49

The plant has been charged entirely into the work according to the figures in Table XI and distributed between the shaft and tunnel proportionately to the total costs of those items. This charge is an arbitrary charge and should be reduced by charging only the depreciation of the plant against the work. To do this 2 per cent of its value should be charged against the work each month, or 20 per cent for the ten months. This would reduce the plant charge on the shaft by $6.64 making the total cost of the shaft $68.47 per lin. ft., and would reduce the cost of the tunnel $3.38 per lineal foot making this item $34.82 per lineal foot instead of $38.20. In calculating the unit cost of the tunnel 1,186 lin. ft. was used as the total length, as 30 ft. of the length of the tunnel is included in the construction of the shaft and in the turning of the eyes, and this length was charged to the shaft construction.

The materials used per lineal foot of tunnel are indicated by the following table which is prepared from a record of materials used from Oct. 4 to Jan. 16, during which time 840 lin. ft. of tunnel were built:

Number brick per lin. ft. of tunnel	522.5
Barrels Utica cement per lin. ft.	.92
Barrels Universal cement per lin. ft.	.50
Cu. ft. sand per lin. ft.	1.14

The tunnel was constructed by the City by day labor under the supervision of the construction division of the Bureau of Engineering.

TABLE XII.—TOTAL ITEMIZED LABOR COST OF CHICAGO AVENUE TUNNEL CONNECTION

	Rate per day	Total Time	Total Amt.
Asst. engineer	$ 5.61	227	$ 1,380.69

* Month.

Cost of a Brick Lined Tunnel for 36-In. Water Main Under Chelsea Creek, Boston, Mass.—William E. Foss gives the following data in Engineering and Contracting, Aug. 5, 1914. The work was done by day labor.

For the purpose of guarding against the interruption of the supply of the East Boston low-service district by the breaking of the existing mains, a new 36-in. main was laid in a different location. This new main connects with existing 20-in. and 24-in. mains in Chelsea and extends along the northerly shore of the creek to a point near the Chelsea Street bridge leading to East Boston, where it turns easterly and crosses under the channel through a tunnel 504 ft. long to the East Boston shore. Construction of this brick-lined tunnel, for carrying the 36-in. cast-iron water main under the creek, was carried out by day labor from July, 1910, to January, 1911.

The tunnel is located about 25 ft. down stream from the westerly side line of the Chelsea Street bridge, and includes a vertical shaft at each side of the creek, 9 ft. 4 ins. outside diameter, with top at elevation 14 on the Chelsea shore and at elevation 10 on the East Boston shore. The horizontal section of the tunnel, joining the shafts, is 400 ft. in length, 8 ft. 2 ins. outside diameter with the top 36 ft. below mean low water at the Chelsea end. The shafts were constructed with 12-in. and the horizontal portion of the tunnel with 8-in. brick walls.

The Chelsea shaft rises about 12 ft. above the bed of the creek and is protected by a steel casing which extends about 13 ft. into the silt bottom. The East Boston shaft was sunk through the earth filling, back of the masonry sea wall, and is protected by a steel casing for a distance of 8 ft. below the top.

The axis of the horizontal section of the 36-in. pipe, which was laid in the tunnel, is at elevation − 40. The pipes were laid with ½-in. opening between the end of the spigot and the bottom of the socket, and the joints were run solid with lead and were calked both inside and outside after the pipe was laid. The space between the pipe and the brick wall was filled with Portland cement concrete.

Special 36-in. branches were used at the junction of the horizontal and vertical portions of the pipe line. Thirty-six-inch ¼ curves with manholes were set at the top of the shafts. The pipes used were 1.61 ins. thick.

The steam plant for operating the air compressors, hoists and electric lighting plant was set up on the Chelsea shore of the creek during the latter part of July, and the work of sinking the shaft was begun during the week ending August 13. After August 21, when the air lock was in place, the work was carried on continuously during 24 hours per day, with three shifts. While excavating the mud and silt just below the bed of the creek some inconvenience was experienced on account of gas, which entered the shaft and affected the eyes of the workmen.

The work of excavating and lining the shaft was completed about September 1. An air lock was then built at the entrance to the horizontal portion of the tunnel, and the small lock which had been used for sinking the shaft was removed. The excavation and lining of the horizontal portion of the tunnel progressed at the rate of about 5 ft. per day. The air pressure maintained varied from 14 to 23 lbs. per square inch, according to the stage of the tide in the creek above.

On October 13 a blow-out occurred about 150 ft. from the Chelsea shaft at a point where a pile had been removed. As a result, the tunnel was flooded with water to a depth of about 4 ft. After the hole was stopped the water was pumped out, and the work proceeded without further mishap.

On the East Boston side of the creek the material excavated was hardpan containing boulders, which required some blasting, so that the rate of progress was less than it had been in the sand and clay on the Chelsea side of the creek. A 2½-in. steel pipe was driven, during the week ending November 12, on the center line of the tunnel near the East Boston end, from the surface of the ground to the center of the tunnel, for use in supplying compressed air for sinking the East Boston shaft.

Work in the tunnel was discontinued on November 17, when steel sections of the East Boston shaft and the hoisting engine were set up on the East Boston side of the creek. On November 18 the work of excavating the East Boston shaft was begun, and on November 24 air pressure was applied.

An opening was made from the bottom of the shaft into the tunnel on December 3. All excavation and the brick lining for the tunnel were completed on December 6, and the air pressure was removed on the morning of

December 9. A total of 104 lin. ft. of shaft and 400 ft. of tunnel were built. The tunnel was cleaned out and plastered and, after calking a few small leaks, was substantially watertight.

The force employed on this work while working continuously under air pressure averaged about 15 men for each of the three shifts. After the air pressure was removed the work was carried on with three shifts working six days per week, the force employed averaging about 16 men per shift. The wages paid, price of materials and general expenses were as follows:

PRICES PAID FOR LABOR

	For 8-hour day
Engineer in charge of plant	$5.00
Engineer	4.00
Fireman	2.40
Head miner and foreman	4.00
Miner	2.80
Tunnel laborer	2.40
Laborer	2.00
Calker	3.50
Head mason	7.20
Mason	6.40
Boy	1.60
Double team with driver	5.00

PRICES PAID FOR MATERIALS

Brick, delivered on work, per M	$9.70
Portland cement, delivered on work in bags (credit for empty bags returned, 6½ cts. each), per bbl	1.68
Coal, delivered on work (for 14,700 B.t.u. per pound of dry coal), per gross ton	4.10
Ipswich sand, delivered on wharf, for brickwork, per ton	0.75
Plum Island sand, delivered on wharf, for concrete, per ton	0.75
Bank sand, delivered on cars at bank, per cu. yd	0.35
Freight, additional, per cu. yd	0.35
Teaming, additional, per cu. yd	0.40
Screened gravel for concrete, delivered on cars at bank, per cu. yd	0.75
Freight, additional, per cu. yd	0.35
Teaming, additional, per cu. yd	0.43
Broken stone for concrete, delivered on work, per ton	1.50
Lead, per 100 lbs	4.675

GENERAL EXPENSES

Superintendence and rental of plant		$ 7,700.00
Installing plant:		
Labor	$ 412.90	
Teaming	130.00	
Supplies	121.19	
		664.09
Housing plant:		
Labor	525.85	
Lumber, $743.77; $205.36 received for old lumber	538.41	
Miscellaneous supplies	39.78	
		1,104.04
Operating plant:		
Labor	4,234.40	
Coal	1,947.65	
Water for boilers and compressors	225.35	
Miscellaneous supplies	538.49	
		6,945.89
Removing plant:		
Labor	230.80	
Teaming	106.00	
		336.80
Rental of land		195.00
Miscellaneous expenses		88.35
Total general expenses		$17,034.17

The plant was operated from 7 a. m. Aug. 11, 1910, to 4 p. m. Jan. 11, 1911, a total of 4,017 hours. The cost of general expenses per hour was therefore $4.24.

Earth Excavation.—About 1,040 cu. yds. of earth were excavated under air pressure of 14 to 23 lbs. per square inch. Work was continuous for three shifts per 24 hours. The mud and silt was excavated just below the bed of the creek at the shaft on Chelsea shore. Fine sand and gravel were excavated for 10 ft. below the silt, and the bottom 5 ft. of excavation was in clay.

The shaft on the East Boston shore was excavated through filling of clay and ashes for a depth of 25 ft., coarse gravel for a depth of 15 ft., and below this line the excavation was in hard pan. The horizontal portion of the tunnel was excavated through stratified sand, clay and gravel, the strata dipping about 6° towards the Chelsea shore, so that for the first portion of the work the floor was in clay and the arch in sand. As the work progressed the floor was in gravel and the arch in clay, and at the East Boston end the entire excavation was in hard pan, with some boulders which required blasting. The cost of earth excavation was as follows:

	Cost	Per cent of total
General expenses	$10,190.40	40.0
Steel casings for shaft	833.00	4.1
Roof plates for tunnel	1,387.31	6.8
Lumber	98.96	0.5
Tools	112.36	0.5
Labor	7,778.70	38.1
Total	$20,400.73	
Cost per lin. ft. of tunnel	40.68	
Cost per cu. yd	19.62	

Brick Lining.—Approximately 320 cu. yds. of brick masonry were built under air pressure of 14 to 23 lbs. per square inch. Work was continuous for three shifts per 24 hours.

	Cost	Per cent of total
General expenses	$ 3,078.64	29.2
Brick	1,971.52	18.7
Cement	1,129.00	10.7
Sand	331.39	3.1
Mason	1,210.80	11.5
Labor	2,786.25	26.5
Miscellaneous supplies	36.76	0.3
Total	$10,544.36	
Cost per lin. ft. of tunnel	21.03	
Cost per cu. yd. of tunnel	32.95	

Laying 36-In. Pipe.—Five hundred and three feet of 36-in. pipe were laid. Work was continuous for six days per week with three shifts per 24 hours.

	Cost	Per cent of total
General expenses	$1,708.96	42.2
Lead	382.41	9.4
Calking	252.00	6.2
Labor	1,661.10	41.0
Tools and miscellaneous	50.25	1.2
Total	$4,054.72	
Cost per lin. ft. of tunnel	8.08	

Portland Cement Concrete Protection for Pipe.—Four hundred and seventy-eight yards of concrete were placed. Frost was removed from the sand and gravel for concreting, by steam. The materials were mixed in the following proportions: 380 lbs. of cement, 10 cu. ft. of sand, 18 cu. ft. of gravel. Work was continuous for six days per week with three shifts per 24 hours.

	Cost	Per cent of total
General expenses	$2,056.17	35.8
Cement	917.11	16.0
Sand and gravel	744.15	13.0
Labor	1,994.70	34.8
Miscellaneous expenses	25.00	0.4
Total	$5,737.13	
Cost per lin. ft. of tunnel	11.44	
Cost per cu. yd. of tunnel	12.00	

COST OF CAST IRON PIPE AND SPECIALS

The cost of the cast iron pipe and special castings was as follows:

36-in. cast iron pipe, class H:	
157.348 tons straight pipe, delivered on wharf, at $24.40 per ton	$3,839.29
Cost per lin. ft. of tunnel	7.65
36-in. cast iron specials:	
11,1605 tons, delivered on wharf, at $49	546.86
Cost per lin. ft. of tunnel	1.09

SUMMARY OF COSTS

	Total cost	Cost per lin. ft. of tunnel
Earth excavation	$20,400.73	$40.68
Brick lining	10,544.36	21.03
Laying 36-in. pipe	4,054.72	8.08
Portland cement concrete protection for pipe	5,737.13	11.44
	$40,736.94	$81.23
6-in. cast iron pipe	$3,839.29	$7.65
36-in. special castings	546.86	1.09
Total*	$45,123.09	$89.97

* Exclusive of land damages and engineering and testing and miscellaneous. These items amounted to a sum of $5,687.53 additional, making the total cost $50,810.62.

Construction Plant.—Following is a list of the construction plant units employed and their estimated value when new:

	Est. value when new
1 air compressor, Ingersoll No. 119, 24 × 24¼ × 30 ins	$ 2,700
1 air compressor, Ingersoll No. 82, 18 × 18½ × 24 ins	2,200
2 75 hp. vertical Manning boilers, 60 × 13 ins	2,400
1 60 hp. horizontal Economical boiler, 50 ins. × 10 ft	700
2 air receivers, 4 × 12 ft	200
1 shaft lock, 6 × 6 ft	700
1 tunnel lock, 6 × 12 ft	225
1 4 × 3-in. Worthington duplex pump	200
1 4 × 3-in. Knowles duplex pump	200
1 head house and conveyor	200
1 12 hp. Paine dynamo engine	500
1 Crocker-Wheeler generator, 50 amperes, 110 volts, 12,000 r.p.m.	130
1 two-drum, 20 hp. double cylinder, Floyd Mfg. Co. hoisting engine and boiler	1,200
1 20 hp. double cylinder Kendal & Roberts hoisting engine, without boiler	600
5 tons steel rails	200
3 car trucks, with wheels, axles and boxes	105
Centers, ribs and lagging	100
Pipe and fittings	500
Total	$13,240
6 skips, 5 × 2½ × 2½ ft	180

Cost of Water Pipe Tunnel Under Mystic River, Chelsea, Mass.—The work of widening and deepening the draw at the Mystic River bridge between Charlestown and Chelsea necessitated an extension, in 1912, of the existing tunnel a distance of 273 ft. from the old shaft on the Charlestown side of the former channel. William E. Foss describes this work in Engineering and Contracting, Oct. 14, 1914, from which article the following data are taken.

The work was begun March 8 and was completed Sept. 11, 1912. It was done by the pneumatic process, the pressure varying from 19 to 27.5 lbs. per square inch. The work was carried on continuously with a day labor force working in three 8-hour shifts per 24 hours.

The work of setting up the boilers, air compressors, electric light plant, hoisting engines, pumps, etc., was begun on March 8, and during the week ending March 23 the water was pumped out of the old tunnel, the old pipes removed from the shaft and a brick bulkhead 24 ins. thick built into the tunnel about 12 ft. from the shaft. An air lock was then bolted to the top of the shaft and on April 1 the air pressure was applied. The brick lining was then removed at the bottom of the shaft and the work of driving the tunnel extension began on April 8. While a circular steel shield, and wooden lagging were used in 1900, steel roof plates have been used and the wooden lagging has been omitted in all subaqueous tunnel work since that date.

Rock was encountered in the lower part of the heading and rose as the heading advanced until at a distance of 24 ft. from the center of the old shaft the tunnel was entirely in rock and so continued for a distance of 200 ft. The work of lining the tunnel with brick was commenced on April 13 and both excavation and lining were carried forward at the rate of about 2 ft. in 24 hours until July 17, when the brick lining had been advanced 206.5 ft. beyond the old shaft. A brick bulkhead was then built near the end of the finished brickwork and the lined portion of the tunnel cleaned, plastered with cement mortar and washed with cement grout. A concrete bulkhead reinforced with steel rails was then built into the old shaft, above the tunnel, and on July 25 the removal of the brickwork of the old shaft was commenced.

The tunnel is 6 ft. in interior diameter with a 12-in. wall of brick masonry, except at places in solid rock where the wall is 8 ins. thick. The center line of the tunnel is about 43.5 ft. below mean low water.

The following prices were paid for labor:

Engineer, per week averaging 5¼ days	$25.00
Fireman, per week averaging 5¼ days	17.00
Head miner, per week averaging 7 days	33.60
Miner, per 8-hour day	3.20
Miner, per 8-hour day	2.80
Locktender, per 8-hour day	2.80
Topman, per 8-hour day	2.80
Laborer, per 8-hour day	2.40
Laborer, per 8-hour day	2.25
Blacksmith, per 8-hour day	3.00
Mason (day work), per 8-hour day	6.40
Mason (piece work, tunnel), per linear foot of tunnel	2.00
Mason (piece work, shaft), per linear foot of shaft	3.00

The following prices were paid for materials:

Brick, delivered on work, per M	$ 9.20
Portland cement, delivered on work in bags, per bbl	1.46
Coal, per ton	5.25
Coal, per ton	4.20
Coal, per ton	3.95
Lumber, spruce, per M. ft. B. M	$24 to 29.00
Lumber, hard pine, per M. ft. B. M	35.00
Sand, delivered on work, per cu. yd	1.30
Stone, broken, delivered on work, per ton	1.40
Clay, delivered on work, per cu. yd	2.50
Dynamite, not delivered, per 100 lbs	18.40
Large tunnel plates, each	1.00
Small tunnel plates, each	0.65
Lighter, per day (and lump sum prices for special work)	25.00
Rental of plant and services of assistant per day	30.00

Construction Plant.—The construction plant employed was as follows:

		Estimated value when new
1	Air compressor, Ingersoll-Rand, 18 × 14 × 24-in.	
1	Air compressor, Knowles, 12 × 18 × 18-in.	
2	75-hp. vertical Manning boilers, 60 ins. × 13 ft	$2,400.00
1	Air receiver, 3 ft. × 7 ft.	
1	Shaft lock, 6 ft. × 6 ft	700.00
1	Knowles 4 × 3-in. duplex pump	200.00
1	Worthington 2 × 1-in. duplex pump	200.00
1	Edson pump, 1½-in. discharge.	
1	Head house wheel, 2.75-ft. diameter.	
1	12-hp. Paine dynamo engine	500.00
1	Generator, 50 amperes, 110 volts	130.00
1	Two-drum, 20-hp., double cylinder hoisting engine and boiler	1,200.00
1	Ton steel rails	40.00
3	Car trucks with wheels, axles and boxes	105.00
3	Skips, 5 × 2.4 × 2.1	90.00
6	Cylindrical buckets	180.00
5	3-ft. radius ribs for lagging.	
	Pipe and fittings.	
36	12-in. bracing jacks.	
1	Portable forge	30.00
2	Wheelbarrows	6.00
1	150-lb. medium anvil.	

General Expenses.—The following general expenses were incurred:

Superintendence		$ 2,400.00
Rental of plant and services of assistant		5,520.00
Installing Plant:		
Labor	$ 690.03	
Teams and lighter	135.00	
Supplies	562.76	
		1,387.79
Hoisting plant:		
Labor	$ 797.00	
Lumber	532.92	
Supplies	54.20	
		1,384.12
Operating plant:		
Labor	$7,860.22	
Coal	2,889.60	
Miscellaneous supplies	208.52	
Miscellaneous teaming	48.00	
		11,006.34
Removing plant:		
Labor	$ 421.25	
Teams and lighter	190.00	
		611.25
Preliminary and incidental expenses:		
Pumping water from old tunnel	$ 388.32	
Building and removing bulkheads	382.58	
Cutting brickwork in old tunnel	491.08	
Cleaning out finished tunnel, etc	276.38	
		1,538.36
Total general expenses		$23,847.86

The plant was operated 4,248 hours, from 7:30 a. m., March 13, to 7:30 a. m., Sept. 6, 1912. Cost of general expenses per hour, $5.61.

Earth Excavation.—About 301 cu. yds. of earth was excavated under air pressure of 19 to 27½ lbs. per square inch. Work was continuous for three shifts per 24 hours. Material encountered in the shaft varied from fine silty sand at the bed of the river to sand and coarse gravel, with some boulders, at the elevation of the tunnel. In the horizontal portion of the tunnel the material was largely blue gravel.

		Per cent of total
General expenses	$5,277.34	56.8
Steel casing for shaft	760.00	8.2
Roof plates for tunnel	510.85	5.5
Clay	96.99	1.1
Tools	21.58	0.2
Miscellaneous supplies	23.86	0.3
Labor	2,506.10	26.9
Use of lighter setting steel Casing	93.33	1.0
Total	$9,290.05	
Cost per linear foot		$61.18
Cost per cu. yd. of excavation		30.90

Rock Excavation.—Approximately 302 cu. yds. of rock was excavated in the horizontal portion of the tunnel. The rock was of a hard, though seamy, texture and required blasting. The air pressure used was the same as when the heading was in earth. When the heading was in solid rock, about 2.6 lbs. of dynamite was used per linear foot.

		Per cent of total
General expenses	$12,025.43	59.1
Roof plates for tunnel	493.53	2.4
Blasting supplies	91.38	0.5
Clay	60.45	0.3
Tools	21.56	0.1
Miscellaneous supplies and expenses	47.22	0.2
Labor	7,594.73	37.4
Total	$20,334.30	
Cost per linear foot		$130.85
Cost per cu. yd. of excavation		67.29

Brick Lining.—About 310 cu. yds. of brick masonry (including concrete base at foot of new shaft and concrete plug in old shaft) was built, with an air pressure of 19 to 27½ lbs. per square inch. Brick masons were paid largely by piece work.

		Per cent of total
General expenses	$ 4,368.84	39.7
Brick	1,304.96	11.8
Cement	727.22	6.6
Sand	186.37	1.7
Lumber	53.48	0.5
Miscellaneous supplies	88.52	0.8
Use of lighter placing shaft	121.67	1.1
Brick mason	793.40	7.2
Labor	3,369.08	30.6
Total	$11,013.54	
Cost per linear foot		$33.18
Cost per cubic yard		35.55

Removing Old Shaft.—About 29 cu. yds of brickwork were removed from the old shaft with the use of dynamite and bull pointing. The upper 18 ft. of brickwork were left in the steel casing, which was withdrawn by lighters and transported to the Naval Hospital pier.

General expenses	$2,176.25	
Blasting supplies	19.91	
Clay	30.05	
Miscellaneous	32.37	
Labor	1,155.36	
Use of lighter handling shaft	440.00	
		$ 3,853.94
Credit for steelwork sold as junk		72.00
Total for removing old shaft		$ 3,781.94
Cost per linear foot		$ 74.16

SUMMARY OF COSTS

Earth excavation	$ 9,290.05
Rock excavation	20,334.30
Brick lining	11,013.54
Removing old shaft	3,781.94
	$44,419.83
Engineering	2,200.63
Total cost	$46,620.46
Cost per linear foot of complete tunnel	140.85
The total cost per foot of the original tunnel built in 1900–1901 was	$ 156.00

Cost of Two Tunnels in Rock Under the Erie Canal for the Buffalo, N. Y., Water Works.—In order to run four 60-in. mains from the new pumping station to the main part of the city of Buffalo all four are obliged to cross the Erie Canal a short distance from the pumping station. Two of these mains run up Jersey St. and two up Porter Ave. and it was decided to tunnel under the canal at these two points.

The following data relative to this work are taken from a series of articles by C. H. Hollingsworth, Supt. for the contractors, appearing in Engineering and Contracting, April 17, May 1 and May 8, 1912.

The sections of the Jersey Street and Porter Ave. tunnels were the same in size and length, i.e.—18 ft. wide by 10 ft. high (finished) and 220 ft. c. to c. of shafts. The main difficulties arose in excavating the shafts where large volumes of water had to be pumped. The finished dimensions of the shafts were 10 by 21 ft. in plan and 56 and 65 ft. deep respectively.

Since the work had to be carried on in winter (in order not to block the towpath during the summer months while the canal is in use) the difficulties were greatly intensified. Mr. Hollingsworth gives no data relative to the cost of excavating the shafts but says:

The shaft sinking was one of the hardest propositions in that line that the writer has ever seen. At the dryest shaft (No. 4) the pumpage averaged 300 gals. per minute when the shaft was sunk to grade. At Shaft 3 the leakage was 350 gals. per minute after it had been sunk the full depth, but at times during the sinking the leakage amounted to 1,050 gals. per minute. At shaft 2 the leakage at times during the sinking ran as high as 1,650 gals. per minute and when the shaft was down to grade it was 400 gals. per minute. In Shaft 1 the leakage at times ran as high as 1,300 gals. per minute, and when sunk to grade the leakage ran about 500 gals. per minute. From these figures it can be seen that the pumping was a very considerable item and after drilling a round it was a serious problem to remove the pumps before shooting and replace them after the shot. Oftentimes there was 6 ft. of water in the shaft before the shot could be fired. Added to this was the fact that the severe weather caused everything in the shafts to be coated with ice and it was remarkable that the men stuck so well to the work. Only one shaft pump was used and all the other pumps—of which there were 12 in all, used at different times—were horizontal, duplex plunger pumps of various sizes. These pumps were hung in the shaft, being suspended from the timbering.

Jersey St. Tunnel.—The Jersey St. tunnel was driven from Shaft 4 and was started Feb. 6, but as the first two rounds had to be drilled from tripods, allowing the use of only two machines, the progress was retarded for the first two days. The rock in this tunnel was partly black flint and partly a very hard limestone. The rock being hard, the blasting made considerable concussion, and as the district nearby was thickly populated, a steady stream of complaints began to come in. To make matters worse, the weather, which at the start of the blasting was mild and wet, suddenly turned very cold, freezing the ground so that the slightest shock was transmitted a long way. Windows were broken and crockery was shattered. In order to shut off some of the complaints, the following system was tried: First a round of 8-ft. holes was drilled and fired every eight hours in the heading, the holes being spaced as shown by Fig. 6, and two rounds were drilled on the bench. In shooting, in order to make as little disturbance as possible, the four bottom cut holes were fired first, next the two top cut holes, next the six holes in the side round and lastly the five dry holes. This did not seem to please the public any better than when the entire six holes in the cut were fired in the first shot, so shorter holes were tried. The scheme was to drill a 6-ft. round in the heading and shoot four times in 24 hours, instead of three times. The result showed that about the only way to please the residents in the neighborhood was to stop blasting entirely, and as this could not be done, the writer concluded to try a method of his own, which was to hurry up and get the agony over, so the three

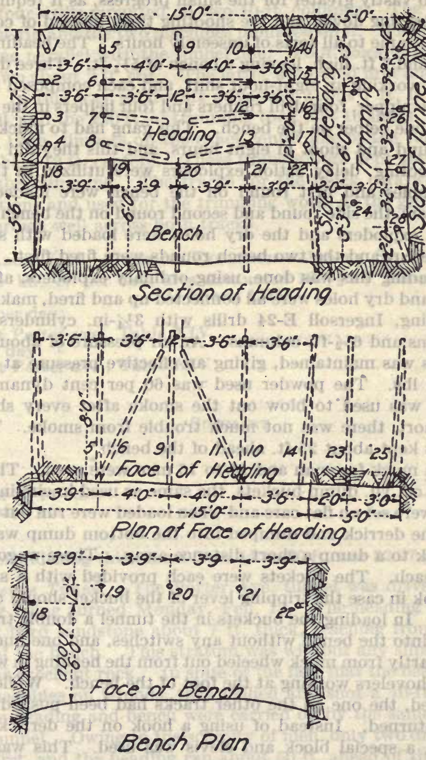

FIG. 6.—Spacing of holes for blasting in tunnels.

Holes 6, 7, 8, 11, 12 and 13 = cut holes, 1st shot in heading—ordinary exploders.
Holes 2, 3, 4, 15, 16 and 17 = side round, 2d shot in heading—1st delay exploders
Holes 1, 5, 9, 10 and 14 = dry holes, 2d shot in heading—2d delay exploders.
Holes 18, 19, 20, 21 and 22 = trench holes, 1st shot in heading—ordinary exploders.
Holes 23 and 24 = 1st shot in trimming—ordinary exploders.
Holes 25, 26, 27 and 28 = 1st shot in trimming—1st delay exploders.

shot schedule was resumed, and 8 ft. rounds were drilled, the entire cut being fired in the first round. As an interesting side light on the question of short holes versus long holes in drilling a heading, it was found that, while the three shots could easily be made in 24 hours, with an average advance of about 5.5 ft. the four 6-ft. rounds could not be drilled and shot in 24 hours. The best that could be done was at the rate of seven shots in two days, averaging 4.1 ft. per shot; so that with the long holes the daily advance was 15.6, while with the short holes the daily progress was 14.3, showing a percentage in favor of the former method. The amount of work required by the short hole method was also vastly greater for the small progress, as it required an extra setting up and tearing down, and the shooting time, instead of coming at the end of the shift, came to all sorts of unseemly hours. The heading was taken out 15 ft. wide and 7 ft. high, leaving a bench of 5½ ft. Three drilling gangs were used, each working an eight-hour shift, and each composed of one heading foreman, one nipper, four drill runners and four helpers in the heading and one runner and one helper on the bench. This gang had to muck out, set up, drill an 8-ft. round and shoot in eight hours, and this they did without any trouble. In shooting, delay action exploders were utilized in the following way: The cut holes and first round on the bench were loaded, using the ordinary exploders, the side round and second round on the bench were loaded with first delay exploders and the dry holes were loaded with second delay exploders. The cut and the two bench rounds were fired first. Then if the cut needed reloading this was done, using ordinary exploders, after which it and side round and dry holes were all connected up and fired, making only two shots. In drilling, Ingersoll E-24 drills with 3¼-in. cylinders were used, mounted on arms and 6½-ft. columns. An air pressure of about 105 lbs. at the compressors was maintained, giving an effective pressure at the drills of about 90 or 95 lbs. The powder used was 60 per cent dynamite and the compressed air was used to blow out the smoke after every shot. As the tunnels were short, there was not much trouble from smoke. The heading was at all times kept about 25 ft. ahead of the bench.

In mucking a muck foreman and 14 to 16 men were used. The muck was loaded into 1½ cu. yd. dump buckets, the same as used in sinking the shafts. These buckets were set on flat cars and when loaded were run out to the shaft, picked up by the derrick and dumped into the bottom dump wagons, which hauled the muck to a dump a short distance away. These wagons took just one bucketful each. The buckets were each provided with a safety chain, with a snap hook in case the tripping lever of the bucket should catch on any of the timbers. In loading the buckets in the tunnel a double track was laid from the shift into the bench without any switches, and one bucket was run in and loaded partly from muck wheeled out from the heading in wheelbarrows and partly by shovelers working at the foot of the bench. While this bucket was being loaded, the one on the other tracks had been pushed out, set up, dumped and returned. Instead of using a hook on the derrick to hook on to the buckets, a special block and clevis was used. This was to prevent accidents from the bucket striking a timber when being lowered and becoming unhooked. The clevis was about as quick to attach and take off as a hook, and was much safer. Owing to the hard and blocky nature of the rock in this tunnel, no extra fast progress was made, although a fair rate was maintained. During the first week a progress of 77.5 ft. was made, but for the first two days of the week only two drills on tripods could be used in starting the heading from the shaft and a shot was lost later on, as the gang had to be taken back to the shaft to drill a sump and some trimming holes. For the second week, ending Monday forenoon, Feb. 20, the progress was 108.2 ft. of both heading and bench. The third week the heading was completed on Wednesday forenoon, Feb. 22, and up to then 35.3 ft. were driven, making the total distance from the south side of shaft 4 to the south side of shaft 3 of 222 ft. in 15 working days (including time of turning the heading), or about 15 ft. per day.

In trimming off the additional 5 ft. to widen the tunnel to 20 ft., it was first trimmed out to full width for a distance of about 20 ft. at a point midway between the two shafts. From this point the trimming was worked both ways, using four drills mounted on two 10-ft. columns. The column was set up close to the rib and the two machines mounted on it. Then 8-ft. holes were drilled running parallel with the tunnel line. Four holes were drilled close to the rib and two about 2 ft. out. The latter were fired first and the other four holes later. In this way each shift advanced about 7 ft. in each direction, or 14 ft. in all, and the 220 ft. of trimming took just 16 shifts, or 5⅓ days. A line of 12 × 12-in. timbers on the exact center line of the tunnel was placed with the timbers 12 ft. centers. These timbers were kept about 12 ft. behind the face of the trimming. The tracks for the muck cars were left in their original locations and used for the trimming work, as the greater part of this muck was thrown well across both tracks.

Table XIII.—Cost of Excavating Jersey St. Tunnel

(Progress 18 lin. ft. per day; area excavated 187½ sq. yds.; cubic yards per 24 hours, 121)

	Cost
Excavation per day:	
Same as at Porter ave., Table XIV	$199.50
Disposal per day:	
Same as at Porter ave., Table XIV	99.00
Total	$298.50

Summary

Item	Per cu yd.
Excavation	$1.65
Disposal	.82
3 lbs. powder at 14 cts	.42
Exploders, wire, etc	.04
Total	$2.93

The cost of widening this tunnel from 15 to 20 ft. was $2.97 per cubic yard.

Porter Avenue Tunnel.—The Porter Ave. tunnel was driven from Shaft 1, the heading being turned Monday, Feb. 13. The heading was in a belt of fine grained hard sandstone about 7 ft. thick, reaching from the roof grade to the top of the bench. This stratum was without any slips or seams whatever and was excellent rock. In spite of the fact that the heading was turned with two machines on tripods, they drilled and shot a 10-ft. round in eight hours. The heading and bench were carried on by the same methods as the Jersey St. tunnel. Owing to the scarcity of men, only two drilling shifts were put on at first, and the heading ran about 50 ft. ahead of the bench the first week, but this was reduced to 25 ft. during the second week. As the rock drilled and broke well, a 10-ft. round could have been drilled and fired every eight hours, but for the fact that the city authorities about this time limited the depth of holes to 8 ft. on account of complaints regarding the jar of the blasting. The progress was much better in this tunnel than at Jersey St. As stated before, only two drilling shifts were worked during the first week, and the progress for that week ending Feb. 20 was 96 ft., including in this, however, two shots made on Sunday, the 19th, or 15 shots in all, averaging 6.4 ft. per shot. On Monday, the 20th, three drilling gangs and three full mucking gangs of 14 to 16 men each were started and the progress for the week ending Monday forenoon, Feb. 27, was 126 ft. of heading and bench. In fact a gain of 25 ft. was made on the bench. This progress was made in the six days and one extra 6-ft. round fired on Sunday to finish up the tunnel to the further side of Shaft 2. The advance made on the 6-ft. round was 5 ft., and deducting this the average advance of the other 18 shots was 6.7 ft. per shot. The only difference between here and the Jersey St. work in the men employed was that at Porter Ave. during this last week an extra muck foreman was used in the heading and this resulted in a much faster handling of the muck with the same number of muckers. The entire distance of 222 ft. was taken out in 34 shots or 11⅓ working days, averaging about 6.5 ft. per shot.

TABLE XIV.—COST OF EXCAVATING PORTER AVE. TUNNEL, ORIGINAL SECTION

(Progress 21 lin. ft. per 24 hours; and of section excavated 187½ sq. ft.; cubic yards per 24 hours 146)

Excavation per shift:	Cost
1 heading foreman	$ 5.00
5 drill runners at $3	15.00
5 helpers at $2.25	11.25
1 nipper	2.25
1 muck foreman	3.00
14 muckers at $2.00	28.00
1 bottom signal man	2.00
Total per shift	$ 66.50
Total per 24 hours (three shifts)	$199.50
Disposal per shift:	
1 top signal man	$ 2.00
2 dumpers at $1.75	3.50
2 men at dump at $1.75	3.50
4 teams at $6	24.00
Total per shift	$ 33.00
Total per 24 hours (three shifts)	$ 99.00
Grand total	$298.50

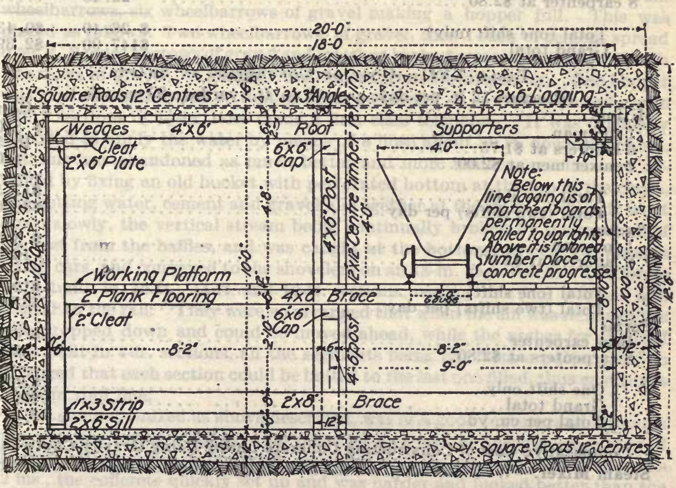

Fig. 8.—Cross section of tunnel showing details of concrete forms.

TABLE XV.—*Continued*

SUMMARY

Item	Per cu. yd.
Excavation	$1.64
Disposal	1.02
Powder 2 lbs. at 14 cts	.28
Exploders, wire, etc	.03
Total	$2.97

In placing the concrete lining of the tunnels and shafts, a Haines mixer was installed in one shaft in each tunnel and all concrete carried from that point in cars as shown in Figs. 7 and 8.

The floor of the tunnel was poured first then the walls and roof. Fig. 8 shows the forms clearly and indicates the general method by which the work was done.

TABLE XVI.—COST OF CONCRETING IN TUNNELS

(Progress 24 lin. ft. per day; and of section 70 sq. ft.; yardage 62 cu. yds.)

	Total	Per cu. yd.
Mixing:		
1 foreman	$ 3.00	......
6 men at $1.75	10.50	......
2 mixer men at $2.00	4.00	......
Total per shift	$ 17.50	......
Total per 24 hours (3 shifts)	$ 52.50	$0.847
Placing:		
1 foreman	$ 3.00	......
8 laborers at $2.00	16.00	......
2 car pushers at $2.00	4.00	......
Total (one shift)	$ 23.00	......
Total per 24 hours (3 shifts)	$ 69.00	$1.113
Forms:		
Boss carpenter	$ 4.00	......
8 carpenter at $2.80	22.40	......
Total (one shift only)	$ 26.40	$0.430

Boss carpenter	$ 4.00
8 carpenters at $2.80	22.40
One shift only	$26.40
Grand total	$99.40
Total per cu. yd	$ 3.43

Comparative Cost of Constructing Concrete Lining Using Gravity Chute and Steam Mixer.—W. D'Rohan gives the following in Engineering and Contracting, July 6, 1910.

In a project to irrigate 12,000 acres of the Mesa lands lying south of the Grand River between Palisades and Grand Junction, Colo, part of the construction consists of a tunnel 6 × 7 ft., 1,740 ft. long, driven through 940 ft. of black shale rock, and 800 ft. of dirt. The dirt section was timbered, roof and sides, in 4-ft. sections, being lined with 2-in. sheeting, supported by 6 × 6-in. posts with caps and sills.

The original intention was to line the timbered section with 9 ins. of concrete and let the shale section go, but as the shale quickly disintegrated in the air, it became necessary to concrete the whole tunnel.

This contingency totally unexpected, found the company in a remote locality with but one steam mixer available and only two months to complete a large amount of concrete work. Extra machinery was immediately wired for, and as it would take from three to four weeks to ship it from Chicago, the writer, as superintendent of construction, suggested the use of a gravity chute through the central air shaft, 82.5 ft. deep. This plan was adopted.

Starting at the bottom, a trestle 7 ft. high was built and arranged so as not to interfere with the form work, and from this was placed a series of platfroms 8 ft. apart, supported by 2 × 8-in. girders sunk into the walls of the shaft which was 4 ft. in diameter, all being connected with short ladders.

The chute proper was simply a trough 10 × 10 ins. with a series of baffles nailed on alternate sides, spaced 2 ft. apart. The baffles were made by cutting 4 × 4s diagonally. The first section rested on the trestle, and the remaining parts were held in place by cleats and so braced that each platform bore the weight of its own section. Three sides were securely nailed, and the fourth, which was cut to suit the platforms, was held in place by clamps made of two pieces of 2 × 4s with two bolts ⅜ in. × 16 ins., two clamps to each section. This made it easy to remove one side for repairs. The top of the chute had two V-shaped hoppers at an angle of 45° with the vertical fitted with a wooden slide door. Into these hoppers the gravel and cement were dumped from wheelbarrows, six wheelbarrows of gravel making a hopper full. This was placed as follows: Two wheelbarrows of gravel, then 1 sack of cement spread over it, 2 more barrows of gravel and another sack of cement, finishing off with 2 barrows of gravel. This kept the cement from blowing away. One hopper was kept continually full so that no delay resulted. A cowbell with some wire and 3 sections of ½-in. hose made a first-class telephone. It was originally intended to apply the water by means of a hose about 30 ft. down the chute, but this was abandoned as much better and more uniform results were obtained by fixing an old bucket with perforated bottom at the top of the chute, and getting water, cement and gravel all together at the start. The mix went down slowly, the vertical stream being continually broken by the rebound of the rest from the baffles, and was caught at the bottom in ½ cu. yd. wooden scoop cars, and conveyed to the shovelers on an 18-in. gage track. The forms were built in 12-ft., 14-ft. and 16-ft. sections, resting on a 2 × 6-in. sill and braced to the rail. They were so arranged that when the sill was removed the side dropped down and could be moved ahead, while the arches for the roof were built in 4-ft. sections, all the segments being cut from a pattern and so arranged that each section could be bolted to the last one filled, thus ensuring a uniform roof line.

The concrete mixed as above described, was of a good texture, and although the weather varied from freezing point to zero and no mechanical means of heating either water or materials was used and the ice formed on the tanks 2 ins., the concrete quickly set up and was harder and looked better than the machine mixed concrete, where water heated by the exhaust steam was used. In handling the steam mixer, 6 men and an engineer were required, while with the chute, 3 men got out twice as much concrete, and so satisfactory to the engineers, promoters and contractors that the new machinery was never used.

A total of 1,500 cu. yds. of concrete were mixed in this manner, and required but one renewal of the baffles, the second set being placed opposite the worn ones to keep the sides from wearing into holes where the concrete hit on the rebound off the baffles. The total cost of chute, renewal of baffles and labor of building in place was $75 or 5 cts. per cu. yd.

Gravel, cement, lumber and water for this work had to be hauled 5 miles over a rough mountain road and were delivered by contract at $1.25 per yard for gravel, cement 75 cts. per ton, and water 10 cts. per barrel. Lumber cost $30 per M. ft. B. M. Ideal Portland cement, a Colorado product, cost $3.25 on the job; labor cost $2.50 for carmen and outside men, $2.75 for overhead shovelers; carpenters 40 cts. per hour, and foremen $4 per day. Two 10-hour shifts were worked and the whole tunnel lining of 2,400 cu. yds. of concrete was completed in 40 working days.

The comparative itemized cost of lining by steam mixing and by the chute were as follows:

STEAM MIXER

1 engineer	$ 4.20
4 men feeding	10.00
1 roustabout	2.50
2 men loading into cars	5.00
4 men placing in forms	11.00
3 carpenters	12.00
3 carpenters' helpers	7.50
2 carmen	5.00
1 trackman	2.50
1 general foreman	6.50
Total labor for 15 yds	$66.20
Labor, per yard	$ 4.41
Gravel, per yard	1.50
Cement, per yard	2.50
Water	0.20
Lumber	0.08
Light	0.10
Coal and oil for mixer	0.25
Wear and tear of mixer	0.25
Total cost per yard	$ 9.29

GRAVITY CHUTE

3 men mixing	$ 7.50
4 carmen	10.00
6 men placing in forms	16.50
4 carpenters	16.00
4 carpenters' helpers	10.00
2 trackmen	5.00
1 general foreman	6.50
Total labor for 35 yds	$71.50
Labor, per yard	2.04
Gravel, per yard	1.50
Cement, per yard	2.50
Water	0.20
Lumber	0.08
Light	0.10
Mixer	0.05
Total cost per yard	$ 6.47

The biggest run with steam mixer was 26 cu. yds. and the smallest 8 cu. yds., due to breakdowns, while the chute made 54 cu. yds. maximum and 21 minimum, due to water giving out.

Cost of Lining Wilson Ave. Water Supply Tunnel Chicago with Pneumatic Mixer.—The following extract, Engineering and Contracting, May 15, 1918, is from a paper by H. B. Kirkland presented before the Western Society of Engineers.

This tunnel is 8 miles long and 12 ft. in finished diameter for 1 mile of its length at the lake end. It is located in solid limestone rock about 150 ft. below datum and has a monolithic concrete lining 1 ft. thick. In lining this tunnel the concreting was carried on simultaneously with the mining, the mine run rock excavated from the heading being used for concrete work.

A pneumatic mixer was mounted on wheels, together with air supply tanks and a measuring hopper above it. In addition a belt conveyor outfit, also mounted on wheels, was used to convey the rock from under the screen to the measuring hopper over the mixer. Upon the framework which held this belt conveyor an electric winch was mounted for hauling 1 cu. yd. cars of mine run up the incline, to be dumped over a flat screen with 4½-in. holes. The rock which passed through the holes fell onto the belt conveyor and was carried up to the measuring hopper. The rejections passed over the screen and fell into an iron plate laid on the floor, from whence they were shoveled into the car to be hauled from the tunnel.

Two Blaw traveling steel forms were used. One of these forms was about 500 ft. away. The 8-in. pipe for conveying the concrete from the mixer to the forms was laid alongside of the tunnel through the first form to the second one, and there it was directed up a 45° angle and into the top of the form. When this form was filled with concrete the pipe was disconnected and arranged for filling the other form and as the concrete set the forms were moved alternately toward the mixer, until about 1,000 ft. of tunnel was completed. The mixer was then moved 1,000 ft. farther and the same cycle of operation was repeated.

One of the new features of placing the concrete at the Lawndale shaft was the use of the pneumatic mixer for placing the concrete in the footing wall. This footing wall is usually built by hand in advance of the regular concrete work and is a wall about 1 ft. high, used as a guide for the forms to follow. In placing this at the Lawndale shaft the concrete was first delivered to the Blaw forms by the pneumatic mixers in the regular manner. But a keyplate was left out of the steel forms and a chute was placed in it, operating so that the concrete being placed by the pneumatic method would overflow through the chute into the car placed beneath the forms under the chute. The car then carried the concrete ahead and dumped it into the forms for the footing wall. In this way the footing wall was placed about three times as fast as it could have been placed by hand.

The number of men required for the operation of the concrete work was as follows:

Screening rock from heading—

3 men pushing up cars to incline, hooking on cable, dumping same on screen and pushing back empty cars to make train bound for heading.
1 man operating motor hoist for pulling cars up incline and operating belt conveyor for carrying screened rock to hopper over mixer.
2 men shoveling rejections from screen into cars to be hauled out of tunnel.

Cement Delivery—
- 2 men unloading cars of cement and storing same on platform above air tanks adjacent to mixer hopper.

Mixing and placing concrete—
- 3 men operating hopper over mixer, feeding cement, water and screen run rock.
- 1 man operating mixer, air valves.
- 1 man at end of pipe in concrete form.

When there was sufficient rock on hand for continuous concreting the forms were filled very rapidly, one form having been filled in 1 hour and 40 minutes. The forms contained from 50 to 70 yd., of concrete, depending upon the excavating section. During January, 1917, one machine at Lincoln Ave. placed 2,707 lin. ft. of tunnel lining.

Working between 16 and 24 hours a day, one machine at the Lincoln shaft put in 2,900 lin. ft. of tunnel in a month, and the yardage of the lining runs 2 cu. yd. per lineal foot. The ultimate capacity of the mixer is 60 cu. yd. per hour.

Quantity of Grout Required for Typical Aqueduct Tunnel.—The following data are taken from an article by James F. Sanborn, published in Engineering Record, April 15, 1916.

The Canniff tank is well adapted for handling grout rapidly. As high as 1,500 batches or 115 cu. yd. of grout have been placed in one day of three shifts by a pair of tanks. A small force operates the tanks and no high-priced men are required for repairs or operation. Either rich or weak grout can be used, and the tank is adapted for low as well as for very high pressure.

A disadvantage of the Canniff tank is shown when used for high pressure work, when the grout is discharged very slowly into fine seams, taking a long time. In such cases the cement has time to settle out of the mixture and clog the openings. However, as very thin grout should be used in such cases, the difficulty is not very serious practically.

The quantity of grout placed in a typical stretch of 12-ft. tunnel of the Catskill Aqueduct was as follows:

	Length of tunnels grouted	No. of connections made	Shifts worked	Cu. yd. liquid grout
Low pressure grouting*	10,113 ft.	170	69	1,744
High pressure grouting†	10,113 ft.	1,670	113	150

* Most of the grout placed in the low pressure operation filled the space above the concrete in the tunnel roof.

† Most of the high pressure grouting was to cut off leaks from seams in the rock, and to fill pans.

The Overbreakage in the Catskill Aqueduct Tunnels.—In building the Catskill aqueduct to New York City careful records were kept of the amount of overbreakage in the different sections of the 49 miles of tunnel. The specifications were so drawn as to encourage the contractors to reduce the overbreakage to a minimum. Engineering and Contracting, Aug. 15, 1917, gives the following brief outline of the specified method of determining the pay yardage both of excavation and of concrete lining and a summary of the data as to overbreakage.

Where the tunnel dipped below the hydraulic grade line and there would consequently be an internal pressure of water on its walls, it was 41 ft. in diameter inside the concrete lining. Let us call this inside concrete line (a circle 14 ft. diam.) "the inside line." Parallel to this line and 10 ins. outside of it is another line within which no rock must project, and this may be called "the clearance line." Parallel thereto and 23 ins. outside of "the inside line" is the "payment line," beyond which neither excavation nor concrete is paid for at the regular contract price. Excavation beyond this "payment line" may be called "overbreakage."

In the Catskill aqueduct specifications it was provided that the contractor should be paid 2.50 or $3 per cu. yd. of overbreakage as compensation for both this extra excavation and the extra concrete lining necessitated by the overbreakage. Since the contractor did not furnish the cement, it was believed by the engineers that this payment for overbreakage would be a fair compensation for any unavoidable overbreakage, but not so large a compensation as to make it profitable to the contractor. Between "the payment line" and "the clearance line" there was another line that may be called "the average line," which was 15 in. outside "the inside line;" and it was specified that the concrete in any cross-section must average 15 in. thick.

The above dimensions relate to the "pressure tunnel" sections, aggregating 35 miles in length. There were 14 miles of "grade tunnels" of horseshoe section that did not dip below the hydraulic grade line, and the inside maximum dimensions of a "grade tunnel" were 13 ft. 4 in. across by 17 ft. high. The "clearance line" of a "grade tunnel" was 5 to 7 in. outside "the inside line;" and the "payment line" was 13 in. outside the "clearance line." These lines relate only to the side walls and roof.

There was considerable variation as to overbreakage, not only because of difference in the kind of rock (which ranged from soft shale to tough granite), but because of the position of the tunnel with respect to the dip of the rock strata, also because of the variation in the managerial skill of the different contractors. In nearly 12 miles of tunnels through shale and slate, there was no overbreakage at all, as the average of 8 contracts; but in fact the average excavation fell half an inch inside of "the payment line." One contractor managed to average a full inch inside "the payment line," but another contractor averaged an overbreakage 2¼ in. outside "the payment line."

In four tunnels through limestone, totaling about 1¼ miles, the overbreakage averaged 1¾ in. outside the payment line.

In 19 tunnels through granite and gneiss, totaling about 8 miles, the overbreakage averaged 3¾ in. outside the "payment line;" but in one 900 ft. tunnel there was an average underbreakage of ¾ in., while in another tunnel (7,330 ft.) the overbreakage averaged 5¾ in. In this last named tunnel the contractor purposely excavated well beyond "the payment line" in order to avoid the expense of trimming projecting rock. Moreover this gneiss was blocky and joints were numerous.

In 10 tunnels through Manhattan schist, totaling about 8½ miles, the average overbreakage was 2½ in., but in one tunnel the overbreakage averaged only ¾ in., whereas in another it averaged 8 in. because the schist was much disintegrated.

Those experienced in tunnel work will see that the overbreakage would have been somewhat less had it not been for the specifying of an average thickness of concrete (see "the average line" above defined). Ordinarily only a "clearance line" (or neat line) and a "payment line" are specified.

In the softer rocks, like shales and limestones, where air-hammer drills can be effectively used in trimming the sides, the overbreakage averages considerably less than in the tough rocks, like granite, gneiss and schist. In tough rocks the contractor drills his blast holes deep enough to insure breakage beyond the "payment line," so as to reduce the trimming. One of the contractors used a large number of horizontal rim holes in excavating the lower half a pressure tunnel through gneiss, and thus secured an underbreakage of ½ in. inside the "payment line."

Cost of Excess Yardage in Tunneling.—The following data are given in the Report on the Los Angeles aqueduct.

Too much care cannot be exercised to avoid overshooting in tunnels, because of the excess yardage that is involved when it comes to lining them with concrete. Some tunnels were driven and trimmed so closely that this excess yardage of concrete did not exceed 15 or 20 per cent of the theoretical yardage of concrete, but the cost of this trimming amounted to as much as $2.00 per lineal foot of tunnel, and probably too much time and care were put upon it. As a rule the excess yardage of concrete was from 40 to 50 per cent of the theoretical, and in some tunnels as much as 100 per cent. Experience indicates that rock tunnels should be driven so that the excess yardage of concrete lining may not be over 30 or 40 per cent. In driving tunnels, frequent measurements should be made of their cross-section to determine what this excess is. Where a yard of concrete to the lineal foot of tunnel is being placed, 100 per cent excess could readily amount to $6.00 or $7.00 per foot, and a 30 per cent excess would represent $1.80 per foot. Tunnels in ordinary rock should be driven with a small amount of trimming; as close as this percentage. It has been found to be the best practice to so excavate the sub-grade at the start that the top of the ties is on the bottom of the theoretical sub-grade, so as to avoid expensive trimming and delays when it comes to concrete lining.

Depth and Number of Drill Holes in Tunnels.—The following tables are taken from Bulletin 57 of the Bureau of Mines prepared by D. W. Brunton and J. A. Davis, as abstracted in Engineering and Contracting, July 8, 1914. The authors in summarizing the discussion of the advantages of shallow and deep holes state that it is, of course, impossible to set any definite standard or guide for the proper depth of hole that will be applicable to all cases. There are too many variables influencing the result. The proper depth must be determined by experiment in each individual case. However, from an extended examination of the results obtained from the methods employed in American practice, from a careful analysis of European practice as outlined in available published accounts, and from a study of all other procurable modern authority, the authors are of the opinion that for the majority of cases the proper depth of drill hole, the one that most equitably balances the advantages and disadvantages inseparable from the problem, is 60 to 80 per cent of the width of the tunnel heading. Table XVIII gives an analysis of American practice in this respect.

TABLE XVIII.—DEPTH OF DRILL HOLES USED IN AMERICAN TUNNELS

Name of tunnel	Type of cut, (wedge, bottom or pyramid)	Height of heading, ft.	Width of heading, ft.	Av. depth of cut holes, ft.	Av. depth of other holes, ft.	Av. depth of round drilled, ft.	Percentage of width of heading of average round	Character of rock penetrated

Determination of the number of holes which secures the best results in driving tunnel headings is affected by too many conditions to permit in any work of precisely following previous experience. Such experience, however, furnishes hints which are of use and for this reason Table XIX is given.

TABLE XIX.—NUMBER OF HOLES USED IN DRIVING TUNNEL HEADINGS IN VARIOUS AMERICAN TUNNELS

Name of tunnel	Number of holes	Character of rock penetrated	Approx. area of heading, sq. ft.	Sq. ft. of heading per hole — Sedimentary rocks	Sq. ft. of heading per hole — Igneous rocks

Comparative Drilling Speeds As Reported at Twenty-Four Tunnels.—The rate of drilling as reported at 24 tunnels is recorded in Table XX, abstracted in Engineering and Contracting, Aug. 5, 1914, from Bureau of Mines, Bulletin 57, by D. W. Brunton and J. A. Davis.

TABLE XX

Name of tunnel	Type of drill, (hammer or piston)	Character of rock penetrated	Drilling speeds per machine per hour, feet	Remarks
Carter	H	Granite	10	Approx.
Catskill aqueduct:				
Rondout	P	Shale	8	Fair average.
Wallkill	P	Shale	10.5	Normal conditions
Central	P	Gneiss	8–16	
Fort William (water)	P	Trap	2	Phenomenally hard rock
Gold Links	H	Gneiss	8–10	Approx.
Joker	H	Breccia	12–15	
Laramie-Poudre	H	Granite	15	Ordinary conditions
Los Angeles aqueduct:				
Little Lake	H	Hard granite	15.84	Av. of 15 accurately timed shifts
Grape Vine	H	Granite	10	Estimated average
Lucania	H	Granite	13	Average of 3 drills
Marshall-Russell	H	Granite	10–20	
Mission	H	†	30	Medium ground
Newhouse	H	Gneiss	10	
Nisqually:				
Headworks end	P	Rhyolite	8–10	
Discharge end	H	Rhyolite	10	Rock is much harder than at other end
Ophelia	P	Granite	8–10	
Rawley	H	Andesite	15–20	Av'ge of 4 accurately timed drill shifts, 19.7 feet
Raymond	H	Granite	8–12	
Siwatch	H	Granite	10–15	
Snake Creek	P	Diabase	*8–12	
Stilwell	P	Andesite	.5–10	
Strawberry	P	Shale	13	Test run
Utah Metals	P	Quartzite	6–8	

Includes time used in setting up and tearing down column or bar, in shifting machine to new holes, and in changing steel, but does not include time used in mucking for set-up or in loading, blasting and clearing smoke.

* During a competition test in which both drills were mounted on the same bar in order to obtain identical conditions of rock, etc, the piston machine drilled 21 feet per hour, whereas a hammer drill made only 20 ft. The conditions were unusual, however, because water under pressure was encountered in practically every hole drilled, and doubtless influenced the results greatly.

† Shale and sandstone.

Air Pressures Used in Tunneling.—Engineering and Contracting, July 1, 1914, gives the pressures of air employed at different tunnels as compiled in Bureau of Mines Bulletin 57 by D. W. Brunton and J. A. Davis as follows:

Tunnel—	Lbs.	Tunnel—	Lbs.
Carter	112	Nisqually	90–95
Central	120	Rawley	100
Gold Links	100	Raymond	90
Gunnison	90	Rondout	100
Laramie-Poudre	120	Roosevelt	110
Mauch Chunk	100	Siwatch	80
Los Angeles Aqueduct	100	Snake Creek	110
Lucania	115	Stilwell	100
Marshall Russell	110	Strawberry	85
Mission	100	Utah Metals	110
Modern	95–100	Wallkill	110
Newhouse	110	Yak	90
Average			102

Cost of Repairs of Drills Employed in Tunneling.—From data collected by personal visits to and special reports from a large number of tunnels, D. W. Brunton and J. A. Davis, in Bulletin 57, Bureau of Mines (reprinted in Engineering and Contracting, July 22, 1914) present the following statement:

From September, 1905, to March, 1906, hammer drills were employed at the Gunnison tunnel with a drill-repair cost per machine of 13 cts. per foot of hole drilled; but when piston drills were substituted the repairs were reduced to 3 cts. per foot. In addition to the cost of materials these figures include also a charge for the labor of the machinist making the repairs, which is not em-

TABLE XXI.—COST OF REPAIRS FOR HAMMER AIR DRILLS, LITTLE LAKE DIVISION, LOS ANGELES AQUEDUCT, JULY, 1909, TO MAY, 1911

Name of tunnel	Distance, excavated, lin. ft.	Cost of drill repairs per foot of tunnel
1B, south	1,030	$0.156
2, north	926	.195
2, south	419	.154
2A, north	460	.100
2A, south	375	.148
3, north	864	.131
3, south	2,149	.235
4, north	448	.149
4, south	725	.297
7, north	1,911	.209

8, north	225	.651
8, south	1,334	.398
9, north	777	.297
9, south	2,479	.163
10, north	2,626	.223
10, south	1,776	.325
10A, north	1,373	.221
10A, south	1,756	.204
Average		$0.24

braced in any of the values which follow. This fact must be considered in making comparisons. Two years later (September, 1907, to August, 1908), in driving the last 3,000 ft. of the Yak Tunnel, the cost of materials only for repairs to the hammer drills employed was only 1¾ cts., approximately, per foot of hole. At the Marshall-Russell tunnel, where hammer drills were employed, the average cost of drill repairs from June, 1908, to June, 1911, was 1½ cts. per foot drilled. Piston machines were used at the Strawberry tunnel from January, 1909, to September, 1911, the cost for repairs being nearly 2½ cts. per foot drilled. On the Little Lake division of the Los Angeles aqueduct, where hammer drills were employed, the average cost of drill-repair materials from July, 1909, to May, 1911, as shown by Table XXI, was only 24 cts. per foot of tunnel excavated. As each of the two machines in the heading drills approximately 8 ft. of hole for every foot of tunnel excavated, the cost per machine per foot of hole is 1½ cts.

For 1910 and the first half of 1911 the repair cost of hammer drills at the Carter tunnel was 2 cts. per foot drilled. At the Lucania tunnel the repairs cost ½ ct. per foot drilled, but the hammer drills had been in use only one month at the time the tunnel was visited. The hammer drills at the Rawley tunnel were new also, the repairs for June and July, 1911, averaging 1 ct. per foot of hole.

Adequate Ventilation Greatly Increases Tunnel and Shaft Progress.—The following note is given in Engineering and Contracting, Oct. 17, 1917.

An interesting example of the effect of poor ventilation on the efficiency of men engaged in underground work was cited by Dr. A. J. Lanza of the Bureau of Mines in a paper presented at the recent meeting of the National Safety Council. A mine, driving a long drift about 3,000 ft. below the surface, was paying $15 per foot, day's pay. The place was hot and moist. A small blower fan was installed at the entrance to the drift, with a canvas pipe leading nearly to the working face, and without any other change the cost was reduced to $8 per foot, day's pay. In shaft sinking this mine had made 50 ft. in one month and 60 ft. in another. A small blower with canvas pipe was installed and the next month 120 ft. was the progress made.

CHAPTER XX

LARGE TUNNELS

References.—In Section XI of the "Handbook of Cost Data" by Gillette, the first 60 pages contain many valuable data on the cost of railway tunnels. Further information on this subject will also be found in Gillette's "Handbook of Rock Excavation."

Cost of Beckwith Pass Tunnel of Western Pacific Ry.—The Beckwith Pass Tunnel of the Western Pacific Ry. at the summit of the Sierra Nevada mountains was constructed between 1906 and 1909. It is a single track bore 6,006 ft. in length. The roof of the tunnel is 24.08 ft. above the top of the foot block; the top of the wall plate is 16.54 ft. above grade, and the width between plumb posts is 17 ft. Cost data on the construction of this tunnel are given by H. Devereux, consulting engineer, San Francisco, Cal., in the Feb., 1917, Western Engineering, from which the matter in this article is abstracted in Engineering and Contracting, Feb. 21, 1917.

The quantities per linear foot of tunnel were as follows:

Excavation, Cu. Yd.

	Heading	Bench
Neat section	3.25	10.39
Enlarged section, side-lagged	4.905	12.351
Enlarged section, lagged	.....	12.04
Enlarged section, increase lagged	.....	1.961
Packing between lagging and 3-in. line	0.267	0.306

Timber, Ft. B. M.

	Heading	Bench
Solid sets	327.4	408.0
2-ft. centers	285.0	210.4
3-ft. centers	234.6	141.6
4-ft. centers	209.4	107.2

For full lagging, add 124 ft. B. M. per linear foot of bench.

Iron, Lb.

	1-bolt	2-bolt	Large washers
Solid sets	10.786	11.571	12.000
2-ft. centers	5.687	6.374	6.750
3-ft. centers	3.944	4.355	4.881
4-ft. centers	3.056	3.607	3.906

Large washers were used after Nov. 1, 1907.

The following scale of wages was in force. As a result of the business depression, the force and in many cases, the wage-rates were reduced on Nov. 25, 1907. Wages are per day unless otherwise noted. Men paid by the month received their board also.

	Before Nov. 25, 1907	After Nov. 25, 1907
Foreman	$ 4.50	$ 4.50
Machine-men	4.00	3.50
Machine-helpers	3.50	3.00
Shovelers	3.00	2.50
Teamsters	3.00	2.50
Cornermen	3.50	2.75
Nippers	3.00	2.50
Carpenters	4.00	3.50
Carpenters' helpers	3.00	2.50
Pump-men	3.00	3.00
Steam-shovel engineer	150.00*	150.00*
Steam-shovel cranesmen	100.00*	100.00*
Dinkey skinners	75.00*	75.00*
Brakemen	50.00*	2.50
Pitmen	3.50	2.75
Dumpmen	2.50	2.25
Timbermen	3.00	2.50
Outside laborers	2.50	2.00
Two-horse teamsters	2.75	2.50
Blacksmiths	100.00*	3.50
Blacksmiths' helpers	2.75	2.50
Electrician	75.00*	75.00*
Compressor engineer (day)	90.00*	90.00*
Compressor engineer (night)	75.00*	75.00*
Master mechanic	125.00*	110.00*
General foreman	150.00*	150.00*
Car repairer	75.00*	75.00*

* Per month.

The following force was employed during December, 1907, when both headings were closed:

OUTSIDE OF TUNNEL

	East end Day	East end Night	West end Day	West end Night
Compressor engineer	1	1	1	1
Compressor fireman	1	1	1	1
Dinkey skinner	1	1	1	1
Brakeman	1	1	1	1
Dumpmen	2	2	3	..
Blacksmiths	2	..	1	..
Blacksmiths' helpers	2	..	1	..
Carpenters	1	..	1	..
Electrician	1	..	..	1
Car repairer	..	..	2	..
General foreman	1	..	1	..
Total	13	6	13	5

IN THE TUNNEL

	East end Day	East end Night	West end Day	West end Night
Foreman	1	1	1	1
Drillers	4	3	3	3
Chuckmen	4	3	3	3
Nipper	1	1	1	1
Shovelers	8	8	16	16
Cornermen	..	..	4	4
Pitmen	4	4	..	..
Teamsters	2	2	1	1
Timbermen	6	..	6	..
"Jumbo" engineer	..	..	1	1
Shovel crew	2	2	..	..
Total	32	24	36	30

When the headings were being driven an additional force of 21 men per shift was required inside the tunnel or 84 men in all. On the outside, seven additional men were required on each shift on the west end, and three additional men on each shift on the east end, or forty in all. On the west end, a traveling platform called a "jumbo" was used to load the material, and on the east end, a model No. 20 Marion shovel operated by air.

The rock at the west end was a decomposed granite. At the east end the granite was hard, "blocky" and "seamy." The cost per cubic yard to the contractor was as follows:

	—Heading—		—Bench—	
	East	West	East	West
Drilling and blasting	$3.65	$2.93	$2.10	$1.20
Shoveling and loading	1.95	2.14	1.15	1.50
Powder	0.80	0.35	0.20	0.12
Outside men	0.63	0.55	0.35	0.30
Plant	0.49	0.33	0.32	0.19

Mount Royal Tunnel—Methods and Progress.—The following data are given in a series of articles published in Engineering Record, Jan. 8, 15, and 22, 1916, by S. P. Brown, Chief Eng'r., Mount Royal Tunnel and Terminal Co., Ltd.

Features of Mount Royal Tunnel.—The Mount Royal tunnel forms the entry into Montreal for the Canadian Northern Railway, the new transcontinental line. The tunnel under Mount Royal, 3.1 miles long between station sites, is double-track, roughly 22 × 30 ft. in excavation, sufficient space being allowed for a central wall and bench between the tracks. In general it will be lined throughout with concrete.

The character of the ground encountered was very diverse and in places extremely complex. The headings were in soft ground in both station sites, and at the city end the tunnel roof was in soft ground for about ¼ mile. Here a roof shield was used with O'Rourke interlocking blocks. The rock at the two ends of the tunnel was Trenton limestone, massive at the west end and somewhat stratified at the city end for the first 1800 ft. Toward the mountain proper the limestone became more crystalline, especially on the west side, where it was unusually hard and dense. The main body of the mountain is an igneous intrusion of Essexite, very hard and tough with a specific gravity of about 3.4. The number of steels dulled per foot of hole in this rock often ran from five to seven, although as a usual thing it required only about 1000 steels sharpened per day in one heading averaging 20 ft. of progress. All the main bodies of rock in the mountain were cut by numerous dikes and sheets of other very hard igneous rock, such as Bostonite, Camptonite, Tinguite, Nepheline Syenite, etc., running up to several feet in thickness. These dikes intersected the tunnel and each other in every direction, sometimes averaging several score in 100 ft. This necessitated drawing the temper of every steel to color suitable for the particular rock encountered. The ordinary method of plunging the steel proved an absolute failure. Of many steels tried, the best was F.J.A.B. (Swedish).

The method of excavation adopted in the Mount Royal tunnel was briefly as follows: First, a bottom heading, 7½ to 10 ft. high by 12 to 14 ft. wide was driven on subgrade along the center line. The points of attack were in the two portal station sites, 3.5 miles apart, and at an intermediate shaft, 234 ft. deep, 1 mile from the west portal. As the headings progressed break-ups were started, at 500 to 800-ft. intervals, along the heading, where the full-sized tunnel was excavated above the grade of the heading roof. At these break-ups, the heading was timbered, so as to give a substantial roof over the tracks, upon which the upper portion of the tunnel excavation could be blasted down safely and through which the muck, thus dislodged, could slide into cars in the gangway below, with a minimum of labor. After the break-up excavation was completed the timbering was removed and the benches, remaining on either side of the heading gangway, were drilled and blasted for air-operated steam shovel excavation. This completed the entire excavation of the tunnel cross-section. Drill carriages were used, first, in the headings, second, on the bench ahead of the steam shovel, and finally for trimming the finished section. In common with all modern drill carriages, these carried the full drilling equipment assembled complete and permanently connected with the manifolds and main hose lines.

The ordinary method of heading excavation was by means of a horizontal bar mounting four drills. The drills were supported on arms similar to those used on the columns common to American tunneling operations, or on special saddle arms particularly designed for this job. Sullivan reciprocating, or percussive, drills were used, so constructed that where the ground made it economically desirable a jet of water and air could be injected through the pistons and steel into the bottom of the holes being drilled. For this reason hollow steel was generally used.

Heading Without Drill Carriage.—Before the rock in the heading became so hard as to require very heavy drills, no drill carriage was used, the drilling equipment being carried and erected by hand. By this method in Trenton Limestone, before the rock had become too crystalline, the maximum progress of 810 ft. was made in an 8 × 12-ft. heading in 31 working days, a record-breaking performance. Six rounds were drilled and fired each day, two each shift. The maximum day's progress was something over 30 ft., while on days when igneous dikes of importance were encountered the progress would sometimes drop below 20 ft., and occasionally a shot would be lost.

Seven muckers were used to handle this excavation, three casting back from the face and four shoveling into the cars. All mucking was done off slick sheets and the cars were designed especially low. Thus the four muckers shoveling into the car handled all the muck made on their shift, which amounted to from 12 to 15 cu. yd. per man per shift. This record is particularly interesting when it is remembered that nearly 2 hours out of each 8-hour shift were lost in blasting.

To break this rock required from 18 to 22 holes and about 500 steels per day for an advance of 26 ft. Four 2⅝-in. Sullivan water drills were used, with the water emulsion through the steel. Each driller averaged about 12.5 ft. per hour, deducting only the time lost in blasting. About 6.8 ft. of hole were drilled per cubic yard of place measurement and about 5.5 lb. of 60 per cent Forcite powder were used per cubic yard with 30-grain detonators.

Headings With Drill Carriages.—As the rock became harder and more complex, requiring more powerful drills, it became imperative to devise some mechanical means of handling the equipment, which had attained a weight of several tons. The common type of European drill carriage, was not suitable in the present case. This was principally because the Mount Royal headings, averaging from 50 to 100 per cent larger than the Alpine tunnel headings, broke so much ground that time could not be spared to muck out the heading before setting up the drills. It was, therefore, necessary to devise a drill carriage with a long cantilever arm by which the drilling equipment could be extended ahead over the muck pile in the heading, without any material delay after the blasting was completed.

In order to bring the carriage near enough the face for an arm of reasonable dimensions to reach the point where the drills were to be set up the track on which the carriage ran was riveted to steel plates, which could act as slick sheets and could be mucked off rapidly. Thus, after the blasting, the muckers cleared this track to within about 25 ft. of the face by throwing the muck that had fallen on it to the sides. As soon as this was done the drill carriage was

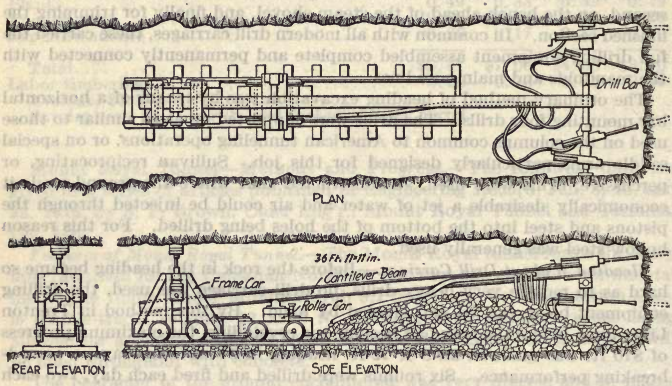

Fig. 1.—Simplest type of carriage, a long adjustable cantilever arm extends drills on horizontal bar over muck pile.

run in, hard up against the muck pile, the cantilever arm carrying the drill bar was extended and the drill bar jacked into place. The drills were thus always in the heading by the time drillers had the roof and sides barred down and sufficient muck thrown back from the face to permit the drill bar to be set. While the drillers were jacking up the bar the pipe-fitter was connecting the two large drill carriage hoses to the ends of the water and air pipes entering the heading. None of the drills was ever dismounted from the bar or disconnected from its manifold. The drillers started work as soon as the bar was tight.

Two types of carriages were designed and built. One (Fig. 1) was very simple, for use in the small 8 × 12-ft. heading; it was merely a carriage proper somewhat similar to the Carter carriage except that the cantilever beam moved with the drill bar instead of having the bar slide on the beam. The other (Fig. 2) had the moving beam, and as it was for use in the large heading, 10 × 13 to 14 ft., it also had a muck-handling attachment for transporting the excavated material from the face to cars in the rear.

Although the muckers lost a few minutes while placing the machine, and only one central track was used at the face, no more muckers were required to clear out the heading with the drill carriage than were used before the drill carriage was installed. This was probably due to having the track cleared down the center of the heading, which permitted all the muckers to work to better advantage while the mucking was actually going on.

Drill Carriage Increases Progress.—The effect of drill carriage work is shown by the results obtained, for instance, in heading 3 E where the muck-handling drill carriage operated for over six months. For the six months prior to the installation of the drill carriage in this heading the average progress was 350 ft. per month in crystalline limestone cut by numerous dikes and in places highly impregnated with various contact minerals. For the six months after the installation of the drill carriage the average progress was 485 ft. per month, almost entirely in Essexite. The hardness of the rock may be realized from the fact that 20 to 24 holes were required to break the ground and about 1,000 steels were used a day for an advance of 19 ft.

Saving Effected.—Four 3⅝-in. Sullivan drills were used. The water attachment was not used, as the length of time required to put down a hole caused the water to freeze and gave trouble in operation. Each driller averaged about 8 ft. per hour, deducting only the time lost in blasting. About 7 ft. of hole were drilled per cubic yard of place measurement, figuring the heading 9½ ft. high by 13 ft. wide. About 7 lb. of 60 per cent powder were used per cubic yard with 30-grain detonators. As the force employed with the drill carriage was practically the same as that employed without it the increase of 38 per cent was made at considerable saving.

It is interesting to note that the progress made with the simple drill carriage was almost identical with that made with the muck-handling drill carriage, the former requiring slightly more muckers per cubic yard.

Muck-Handling Carriage.—The muck-handling drill carriage, which was the first one to be actually built (Fig. 2), was a very heavy machine, having all of its parts operated mechanically, and was designed to remain in the heading while the drilling and mucking were going on. The conveying belt, 16 in. wide by 75 ft. between head and tail pulleys, was driven by a Dake air engine. All other power was electrical. The carriage consisted actually of two separate machines or carriages: First, the drill carriage proper, which supported and operated the cantilever arm carrying the drill bar; and, second, the muck conveyor, which slipped through the lower part of the drill carriage and was supported a few inches above the track on cross shafts. The belt was elevated in order to cantilever out over three muck cars in the rear.

When the tracks were cleared and the drill carriage run in, one man at the electric switches was able to extend the beam over the muck pile, raise or lower it, or swing it to right or left, as the case might be, to fit the heading as it happened to break. Although this machine appears at first glance to be cumbersome and complicated it is an interesting fact that breakdowns of any sort were very rare. In fact, during the six months of its operation the total delays in any way connected with the drill carriage did not aggregate one shift in lost time.

The principal advantages of the muck-handling drill carriage are these: As the carriage remains in the heading after the drills are set up the mass behind the drills is so great as to practically eliminate all vibration during the drilling. Its movements are mechanical, so that the setting up and taking down are more rapid. Since the muck is thrown off the track to the side, the carriage

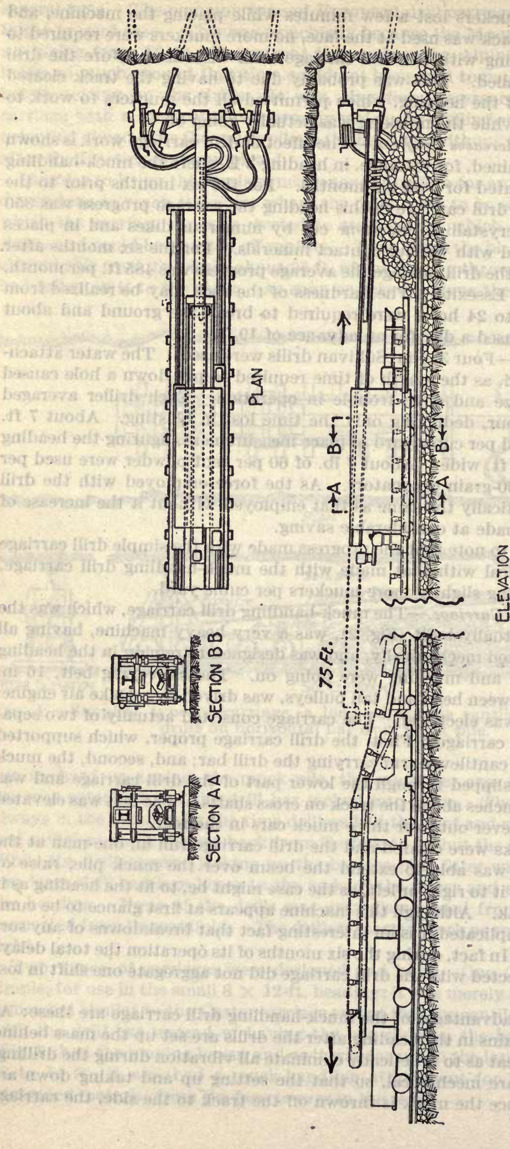

FIG. 2.—More complicated carriage provides for mechanical operation in extending and adjusting bar and equipped with mechanical mucking device.

track being laid at one side of the gangway, the muckers can work with equal efficiency anywhere along the line. As the conveyor is very low, less exertion is required by the men than in shoveling into the higher cars. Three cars are run in at a time by the locomotive so that the muckers lose less time through the shifting of cars.

Heading Carriage Conclusions.—In a heading where the section is large, or the rock reasonably soft, so that the yardage to be handled each day is very considerable, the muck-handling drill carriage is far preferable to the simple carriage. This is especially so where the drilling is rapid, so that a good number of shots per day are obtained, since the time saved in setting up and taking down, as well as the rapidity of mucking, is an important factor. If, however, the rock is hard and the heading small the simple drill carriage will give just as good progress and for a reasonable amount of muck the cost per yard is just as low.

It is the writer's opinion, after having operated both machines under very similar conditions, that the simple carriage is superior to the heavier machine except where a large volume of muck has to be handled or inefficient muckers must be employed. This is principally on account of first cost, since that of the simple carriage is insignificant.

Bench Excavation.—After the heading and break-up work in the tunnel had been completed, two benches remained to be excavated, one on either side of the original heading gangway. These benches aggregated from 8 to 10 cu. yds. of solid excavation per foot of tunnel. The problem of drilling on the benches was a particularly difficult one due to their tendency to slope toward the gangway and the extreme irregularity of their tops. Another complication was the continuous traffic in the gangway since the drilling had to be started long before the completion of the break-up excavation in the central part of the mountain. It was decided therefore to use a drill carriage for this work also and the bench drill carriage as finally designed is quite original both in type and detail. Mr. Brown found this carriage was the greatest money saver in the excavation equipment at Mount Royal.

Bench Drill Carriage.—The carriage proper consisted of a heavy traveler, 30 ft. long, which was moved along the heading gangway as the drilling progressed. The wheels were double-flanged and had very heavy axles, sufficiently long to give lateral play that would enable the wheels to follow the local irregularities of the track horizontally. The vertical play required was given by the spring of the traveler frame itself. The gage of the carriage track was of such a width that the side trusses comfortably cleared the gangway sides in all places and at the same time permitted a single muck track to operate between them. The traveler was fitted at each side with an adjustable outrigger supporting a horizontal quarry bar, which in turn carried from four to six drills mounted on column arms or special saddle arms and connected to the air line through a single manifold thus giving great flexibility in setting up and operating.

The extra width in the tunnel allowed at the haunch for the arch support very much facilitated the drilling. Two parallel lines of bench holes were usually drilled. The outside line next the rib acted as channel or line holes, varying in spacing from about 4 ft. to 8 in., depending on the character of the rock and the accuracy of the line required in the tunnel wall. The second line of breaker holes was spaced farther apart. The line holes were only loaded when the rock was such that it would not break to line from the breaking holes. Thus the sides of the tunnel were not shattered by heavy blasting, and the overbreak was unusually small. This was also true of the break-up excavation, since all the blasting there, being to two faces, required only the lightest kind of shooting. While the headings used 5 to 7 lb. of 60 per cent powder per cubic yard, the break-up and bench excavation averaged less than 1 lb. to the yard.

As the drill carriages kept well ahead of the blasting, and as all the bench muck was handled by steam shovel, only two muckers were required in each drill-carriage crew. These two men cleaned off the top of the bench and extended the drill carriage track, with the aid of the helpers, as the carriage moved ahead. One electrician attended to all the trolley and lighting work connected with both drill carriages, and one mechanic did all the pipe-fitting and drill repairs necessary for both drill carriage outfits. The platform on each carriage above the muck track was mainly used for repairing drills and the storage of extra drills, spare parts, steel and supplies for daily use.

Progress.—The progress obtained with this drill carriage amounted to from 30 to 90 ft. of tunnel per day, depending principally upon the character of the rock and the configuration and condition of the bench. When the ground was particularly irregular and was cut by dikes or when the bench was found to be somewhat shattered from previous blasts the drilling would be slow and uncertain, often several holes being necessary to secure one of the proper depth and direction. Again, when the top of the bench was very irregular or sloped at a steep angle, it was often tedious work to start the holes. Compared with the time required for drilling with columns or tripods, however, the progress was more than merely satisfactory.

It has been found that even under favorable conditions on outside rock the lost time in tripod drilling often amounts to 50 per cent of the time actually spent with the machines. This is due not only to the delay in setting up, but to the time lost in shifting the tripod to "follow the hole." Practically all of this lost time is eliminated in the case of the drill carriage, where the drills supports are rigid and the drills may be shifted accurately and expeditiously with a minimum of labor.

After the drill carriage had got a good start a powder crew was sent in from the west portal and the benches blasted well ahead of the steam shovel. By this method the shovel, a model 41 Marion, never had to back up for shooting, full time being spent in excavation. Five to six hundred cars of muck were usually handled per day of two 10-hr. shifts. This aggregated 1,200 to 1,500 cu. yd. of loose material, or about 700 to 1,000 cu. yd. solid. The linear progress of the shovel sometimes exceeded 600 ft. per week where there was nothing but bench excavation removed.

The Trimming Carriage.—The final trimming of the tunnel section, preparatory to lining, is too often a very measurable percentage of the total cost of any tunnel excavation. There are many cases where the cost of trimming, added to the cost of extra concrete and packing required to fill in cavities left by falls and careless or inaccurate excavation, has exceeded the actual first cost of excavation. For some reason this is an item very often overlooked by a contractor, especially if he is not thoroughly experienced in making up his bids for tunnel work. In the case of the Mount Royal Tunnel however, the actual overbreakage averaged less than 5 per cent and the cost of trimming including squaring up the hitch for the concrete arch and removing the debris ready for the concrete form carriages, added less than 5 cents to the yardage cost of tunnel excavation.

The trimming drill carriage is very similar in construction to the bench carriage except that it is only 20 ft. long instead of 30 ft. In fact, much of the material used in its construction came from one of the bench drill carriages. It consists of two side trusses, 20 ft. long, traveling on six double-flanged wheels. As in the former carriages these trusses are so spaced as to permit the passage of a train of tunnel cars, both for muck and concreting materials. Immediately above the track is a platform for storage and repairs. In this carriage, however, the outriggers with their quarry bars and heavy drilling equipment are at the bottom, where the only heavy drilling occurs. These outriggers mount heavy piston drills and were used in excavating the toe lift in places because the bench was so high that the line holes could not be drilled to sub-grade.

Self-rotating hand hammer drills, operated from extension platforms were used for drilling for the hitches and were also used from the top platform for trimming.

The advantages of this carriage are its lightness and ease of movement. It also eliminated the laborious scaffolds usually required for trimming and also the danger to the workmen from these scaffolds which are hurriedly and too often carelessly erected. Moreover, it is a noteworthy fact that a man works faster and more effectively where he has a sense of security and is entirely familiar with his immediate surroundings.

Cost of Tunnel of the Canadian Pacific Ry.—The Rogers Pass tunnel of the Canadian Pacific Ry. was completed Dec., 1916, 11 months ahead of the contract time. It is a double track tunnel, slightly more than 5 miles in length. One of the most interesting features of the construction was the employment of a pioneer or auxiliary heading. The methods employed in the driving of the tunnel are described by A. C. Dennis, superintendent in charge of the work for the contractors, in a paper presented before the A. S. C. E. and printed in the Jan. Proceedings of the Society, from which the following is abstracted in Engineering and Contracting, March 21, 1917.

The tunnel, except for 1,200 ft. of the east end and 400 ft. of the west end, is all in solid rock, classified as quartzite in the geological reports, but consisting largely of schists.

East Pioneer Heading.—The east pioneer heading was started in September, 1913, about 50 ft. north of the main tunnel, 700 ft. west of the east portal, and about 60 ft. above the main tunnel level. This location was adopted in order to save 700 ft. of pioneer tunneling, to reduce the quantity of soft ground heading, to enable work on the heading to start sooner than that on the approach cut, and to get rid of the muck readily. The power was furnished by the temporary erection of an old compressor along the Canadian Pacific Ry. track above and a pipe line down the hill to the work. This heading was run as nearly level as drainage would permit. The grade of the main heading reached the grade of the pioneer at the third cross-cut, the two former cross-cuts being driven to the dip, and material from the main heading being hoisted up the incline. The heading reached solid rock about 600 ft. in, at which point the first inclined cross-cut was started, at about the beginning of 1914. The pioneer tunnel, in rock, was driven about 2 miles in 1½ years. The maximum progress was 776 ft. The daily average was 20 ft. for the entire drift in rock.

West Pioneer Tunnel.—The west pioneer heading was started by an incline, 300 ft. long, from the rock outcrop, 700 ft. east of the west portal, about 150 ft. above the main heading level, and 50 ft. south of the main tunnel line. This location was selected in order to provide dumping ground, shorten the length of heading to be driven, avoid soft ground tunneling, and permit an earlier beginning than by waiting for the approach cut excavation. This incline was very wet and took 2 months to drive, being finished in the latter part of July, 1914. This pioneer tunnel was driven for a length of more than 1½ miles in less than a year, the maximum monthly progress being 932 ft. The daily average of 24 ft. for nearly a year, largely through very hard quartzite is also unusual.

Pioneer Headings in General.—The pioneer tunnel, in rock, was 7 ft. high and 8 ft. wide. It was driven with light hammer drills, using hollow steel, with water attachments. Three drills, in general, but four in the hardest rock, were used in a heading. Spare drill machines, for the replacement of drills out of order, were kept conveniently at hand in the heading. No repairs were made under ground. The hammer drills are convenient and rapid, the delay and expense of their constant breakage perhaps balancing the advantage of speed under ordinary conditions. The drills are mounted on a light horizontal bar, about 18 in. below the roof line. Air and water are taken over the muck pile, or on hooks in the side, by a single hose line for each, to a manifold from which short individual hose lines supply the drills.

Light cars (½ cu. yd.) were used for muck, and the latter was taken off the track, instead of building sidings for this purpose. Shoveling plates were used at the face and on the side away from the track for some distance back of the face, in order to facilitate the handling of empty muck cars. The ventilating pipe was a 12-in. wooden water pipe connected to the Connersville blowers used for the exhaust. This pipe was hung on the side away from the track, close up to the roof, and was carried to within 20 ft. of the face. Little damage was done to this pipe by blasting. The blowers were started exhausting when the first shot was fired, or a little before, and were run for 20 minutes. The men got back to work in from 5 to 10 minutes. No compressed air was allowed to be blown out for ventilating purposes. After a round was shot, the drillers followed the smoke back, barring down the roof, bringing explosives to reshoot, and wetting down the muck piles, sides, roof and face with water hose. The muckers cleared the track and began loading the muck which was scattered back.

When no further blasting was required, the lights were hung, the foreman sighted the line and grade point in the face, and the drilling gang set up the horizontal bar, placed their drills and proceeded. There was rarely any muck to be handled before the drilling could be started, as it was thrown back from the face by the heavy loading in the bottom holes and the fact that they were shot last, for this purpose. There were two helpers to three drills, who brought up and changed the steel and adjusted the drill machines. When the drilling from the upper set-up was completed, the drillers took down the machines and carried them back, with the hose connections still attached, and oiled them up. After the mucking was done, the bar was dropped to the lower set-up, near the floor, and the drills were set to drill the bottom holes or lifters. The drills were carried forward, put on the bar, and were drilling sometimes in less than 2 minutes after the bar was dropped. While the bottom holes were being drilled, the muckers laid the track, adjusted and covered the mucking sheets with muck, and brought up the explosives. The holes were loaded by the machine men, helpers and foremen.

For the small part of the tunnel where re-shooting was not necessary, an 8-hour shift could do two rounds per shift, or a little better. Two men pick down the muck, and three men load the car and push it out, while three others

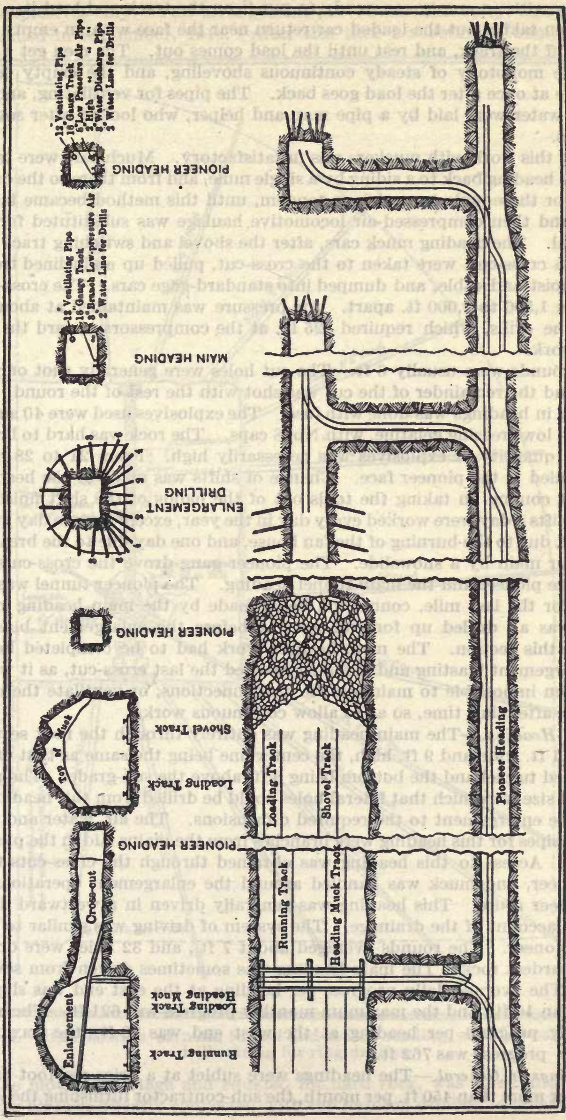

FIG. 3—Details of pioneer heading and its relation to main tunnel.

stand by with an empty car, ready to put it on the track and load it. The three men taking out the loaded car return near the face with an empty car, take it off the track, and rest until the load comes out. The men get a rest from the monotony of steady continuous shoveling, and the empty car is available at once after the load goes back. The pipes for ventilating, and for air and water were laid by a pipe man and helper, who looked after several headings.

Doing this work with muckers was unsatisfactory. Much cars were taken from the heading back to a siding by a single mule, and from there to the dump by two or three-mule team driven tandem, until this method became inadequate, and then compressed-air locomotive haulage was substituted for the long haul. The heading muck cars, after the shovel and switching track had cleared a cross-cut, were taken to the cross-cut, pulled up an inclined trestle by air hoist and cable, and dumped into standard-gage cars. The cross-cuts are from 1,500 to 2,000 ft. apart. Air pressure was maintained at about 90 lb. at the drills, which required 125 lb. at the compressors toward the end of the work.

The rounds were usually 6 ft. The cut holes were generally shot once or twice, and the remainder of the cut was shot with the rest of the round. All shooting in headings was done with fuse. The explosives used were 40 and 60 per cent, low-freezing gelatine, with No. 8 caps. The rock was hard to break, and the quantity of explosives was necessarily high. From 21 to 28 holes were drilled in the pioneer face. Change of shifts was made at the heading, the shift coming on taking the tools out of the hands of the shift finishing. Three shifts a day were worked every day in the year, except for one day at the east end, due to the burning of the fan house, and one day due to the breaking of the air main by a snowslide. The pioneer gang drove the cross-cuts between the pioneer and the main tunnel heading. The pioneer tunnel was not driven for the last mile, connection being made by the main heading only, which was all drilled up for enlargement before the enlargement blasting reached this section. The main heading work had to be completed before the enlargement blasting and mucking reached the last cross-cut, as it would have been impossible to maintain the air connections, or ventilate the main heading, after that time, so as to allow continuous work.

Main Heading.—The main heading was entirely through the rock section. It was 11 ft. wide and 9 ft. high, the center line being the same as that of the completed tunnel and the bottom being 6 ft. above the sub-grade. The position and size were such that lateral holes could be drilled from this heading to break the enlargement to the required dimensions. The air, water and ventilating pipes for this heading were branches from the mains laid in the pioneer heading. Access to this heading was obtained through the cross-cuts from the pioneer, and muck was handled around the enlargement operations by the pioneer route. This heading was generally driven in a westward direction, on account of the drainage. The system of driving was similar to that in the pioneer. The rounds averaged about 7 ft., and 32 holes were drilled in the hardest rock. The main heading was sometimes driven from several faces. The average daily progress per heading at the east end was slightly more than 16 ft., and the maximum monthly progress was 621 ft. The average daily progress per heading at the west end was 20 ft.; the maximum monthly progress was 762 ft.

Headings in General.—The headings were sublet at a price per foot and a bonus for more than 450 ft. per month, the sub-contractor furnishing the labor and explosives only. This arrangement proved unsatisfactory, and was discontinued in September, 1914. After this time a substantial bonus, based

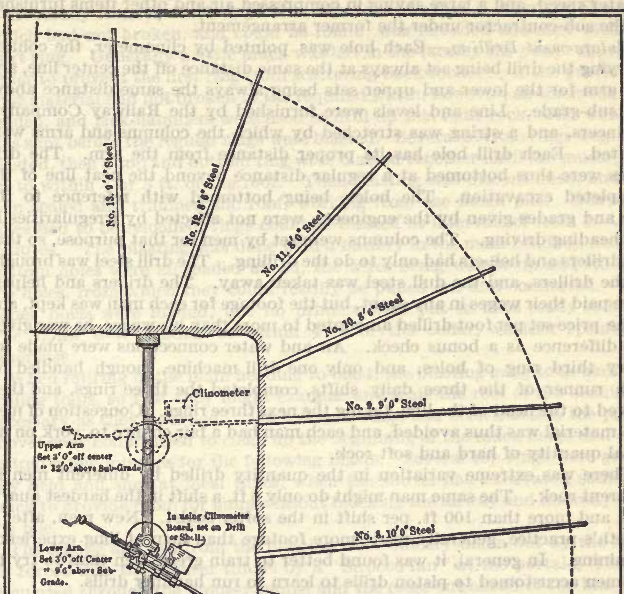

FIG. 4.—Half section of main tunnel and center heading, showing column and drill setting for ring drilling.

on the monthly footage and equated for hard rock, was given and divided among all men directly connected with the heading driving, in proportion to their regular wages earned for the month. It was agreed that the rate of bonus would not be reduced. The latter arrangement resulted in 23 per cent greater speed, and a large saving in compressed air and other items furnished to the sub-contractor under the former arrangement.

Enlargement Drilling.—Each hole was pointed by clinometer, the column carrying the drill being set always at the same distance off the center line, and the arm for the lower and upper sets being always the same distance above the sub-grade. Line and levels were furnished by the Railway Company's engineers, and a string was stretched by which the columns and arms were located. Each drill hole has its proper distance from the arm. The drill holes were thus bottomed at a regular distance beyond the neat line of the completed excavation. The holes, being bottomed with reference to the line and grades given by the engineers, were not affected by irregularities in the heading driving. The columns were set by men for that purpose, so that the drillers and helpers had only to do the drilling. The drill steel was brought to the drillers, and the dull steel was taken away. The drillers and helpers were paid their wages in any event, but the footage for each man was kept, and if the price set per foot drilled amounted to more than his wages, he was given the difference as a bonus check. Air and water connections were made for every third ring of holes, and only one drill machine, though handled by each runner of the three daily shifts, completed the three rings, and then moved to the head of the line, taking the next three rings. Congestion of men and material was thus avoided, and each man had a fair chance to work on an equal quantity of hard and soft rock.

There was extreme variation in the quantity drilled by different men in different rock. The same man might do only 6 ft. a shift in the hardest quartzite, and more than 100 ft. per shift in the softer schist. New men, after a month's practice, generally made more footage than men of long experience in mining. In general, it was found better to train green men than to try to get men accustomed to piston drills to learn to run hammer drills.

Most of the rings were 6 to 6½ ft. apart. When explosives rose in price it was found economical to space the rings 5 ft. apart, as the extra drilling cost was balanced by the saving in explosives, with the added advantage that the muck was broken into smaller pieces and scattered farther back. Where the roof was soft and full of slips, so that trouble was anticipated, the upper set of arms on the column was lowered 1 ft., in order to leave some trimming of the roof to be done by jack-hammer, flat holes and light blasting. The air and water for the enlargement drilling, as well as the supplies, came by the pioneer tunnel and the cross-cuts, so that this drilling was not disturbed by the enlargement blasting. The drilling for the last mile, where no pioneer tunnel was driven, was started at the middle and progressed toward the portal, the track, pipe, etc., being removed as the drilling was finished.

The stopping of the pioneer tunnel was well-timed, as the main heading was driven and the enlargement drilling completed just in time to avoid delaying the enlargement blasting and mucking at the east end.

Enlargement Blasting.—There was considerable difficulty in breaking the bottom to sub-grade when the rock excavation was first started. This was overcome by dropping the floor of the main heading 1 ft. and drilling the holes in the bottom 1 ft. deeper. Difficulty was found also in getting the sides below the springing line to break for the full width. This was overcome by drilling one or two relief holes at this locality in tough breaking rock. In tough rock, two, four, six and sometimes eight holes were sprung. If over-sprung, the ring being shot was likely to break into the next ring and explode it, or shake it up so as to spoil the effect of the blast.

Generally from 10 to 15 rings were kept loaded ahead. Any part of a hole which had not broken, and could be found, was reloaded and shot with the next ring. Generally a little muck was left in the face by the power shovel in order to prevent the first ring from scattering back too far. If the previously shot material had not broken to the required width, however, all the muck was loaded, and jack-hammers were used to drill up this tight rock, after which it was shot before the regular rings were blasted. Several bottom rings were first blasted, then a top and bottom ring were blasted together until the muck piled up to within 4 or 5 ft. of the roof. Then blasting was discontinued, and the men scaled and trimmed the roof, working from the muck pile. Where no holes had to be reloaded, rings could be blasted at intervals of from 15 to 20 minutes. The blasting was done with a battery in the main heading, and the bottom holes were all loaded ahead, the wires being wound up and stuck in the holes, from which they could readily be pulled out and connected. The upper holes were loaded, but no primers were put in until ready to blast. The holes were loaded to within 4 ft. of the collar, whether sprung or otherwise.

When retiring in the main heading to blast, the blasting gang took back the scaling tools, so that they might examine and scale the roof of the heading if necessary as they returned. After several rings had been blasted, the power shovel crew commenced to clean up the beginning of the muck heap, and only retired a few minutes for the following blasts. Several top rings were generally held and shot at meal times, when the shovel had excavated sufficient muck to provide room for more without blocking the airway and manway over the pile.

The smoke and gas from the blasting were quickly taken out by the fresh air forced into the pioneer tunnel by a "Sirocco fan" at the portal. The air circulated through the pioneer tunnel and the cross-cut ahead of the blasting, and then back through the main heading, over the muck pile, and out at the portal of the main tunnel. This circulation was prevented from short circuiting by stopings and doors in the cross-cuts passed by the shovel. The quantity possible to shoot depended on the distance the muck was thrown back, or the quantity of muck for which there was room without interfering with the scaling and trimming of the roof; it varied from 24 to 110 ft. Much time was lost in taking up the track before blasting, in cleaning up the thinly scattered muck directly after a blast, and by other delays incidental to each clean up, which made it desirable to shoot as many rings as possible.

Enlargement of Mucking.—Mucking was done with small steam shovels, with cylinders enlarged so as to be efficient at 100 lb. air pressure, and with the boom sheaves set back so as to shorten the booms and protect the sheaves. The shovels loaded the muck into 12-yd., standard-gage, air-dump cars. The cars were shifted to the shovel by two small compressed-air locomotives, and were taken from a spur near the shovel to the portal by a larger compressed-air locomotive; they were taken by a steam locomotive from the portal to the dump. During the past year the shovels mucked 18,550 ft. throughout 3½ miles of tunnel, or more than 2 ft. per hour. Blasting and trimming took about one-quarter of the time. The best monthly run for one shovel was 946 ft. at the east end, and 1,030 ft. at the west end. The ground between the third and fourth cross-cuts at the west end became so dangerous, owing to the material in the roof and sides falling, that one shift out of three had to be devoted to scaling this section until it was concreted. About 2,500 cu. yd. fell or was scaled in this section, on account of the disintegration of the material on exposure to the air. The scaling car throughout the work was handled by the air locomotive, and the scaling was done by the shovel crew or others during the time the shovel was stopped for enlargement blasting. Any rock not broken to the required dimensions was drilled off the muck pile, or from the floor, as the shovel cleaned up as far as possible, or from a car left at the shovel crew's meal time, and shot before the next rings were blasted. The enlargement drill holes were the general guide as to the trimming required, such points as were missed being marked by the Railway Company's engineer. There was very little over-breakage.

Concreting.—About 1½ miles of the tunnel, including the soft ground at each end, required concreting. This work was sublet. The sub-contractors used wooden forms, and deposited the concrete from a platform near the roof reached by an inclined trestle. The concrete mixer was on the car, and the materials were on other cars back of it. The concrete from the mixer flowed into a small car which was hauled by cable up the trestle incline to the high platform, from which it was shoveled into the forms. Much of the lining required back as well as front forms, and the space behind the back forms was filled with rock or wood. This back form and back-filling work was slow and expensive, especially where there were only a few inches between the back forms and the rock.

Mr. Dennis in Engineering and Contracting, April 18, 1917, states that the cost of the total improvements which includes considerable line outside of the tunnel was approximately $6,500,000.

The tunnel proper for excavation, concreting and so forth, including contractor's profit, was below $150 per foot, which, being a double-track tunnel, compares very favorably with $180 per foot for the Great Northern single-track tunnel.

The general wages paid were 40 cts. per hour to drill runners and 35 ct. per hour to others. The bonus probably averaged 25 per cent in addition to these rates.

Summing up the reasons for the rapid progress and low cost of the Rogers Pass tunnel, they seem to be:

First, the method of tunneling, involving the driving of a pioneer tunnel off the line of the main tunnel.

Second, the excellent administration of the work.

Third, the payment of liberal bonuses to the workmen, which bonuses were adhered to.

Fourth, the use of hammer drills.

In the Aug. (1917) Proceedings of the A. S. C. E., as showing the probable economics of using the pioneer tunnel method, J. G. Sullivan, chief Engineer of the railway, quotes the following from his report of March 13, 1913, to officials of the Canadian Pacific Ry.:

This method, of course, is only applicable where the rock will stand without artificial support, at least during the time of construction. Where the material must be artificially supported, then the top heading is the surest, and I think, the best way. The progress of the work by this method, as I said before, depends only on the speed that the pioneer tunnel can be driven. If rock is self-supporting, I see no reason why from 20 to 25 ft. per day could not be made. Placing the cost of driving the small tunnel at $30 per foot; that is the only part of the work that would be rushed under high pressure, and the heading proper can be taken out at least $5 per foot cheaper than if the work must be done under pressure, then the bench containing 18 cu. yd. per foot (neat section) can, on account of there being no interruptions to wait for drilling or cleaning up to put in breast holes or knocking down material in order to get pipes into the heading, at a low estimate, be taken out 75 cts. per cubic yard cheaper, or $13.50 per foot, which would make a saving in excavation of tunnel proper of $18.50 per foot, leaving $11.50 to be taken care of in interest saved account making greater speed. In my report to you of Oct. 22, 1912, I estimated an annual saving of about $226,000, but all my figures were very conservative, and I took into account only one or two of the larger factors of the extra expense. Mr. Bogue's more accurate figures show a saving of over $370,000. However, his estimate for fuel per hp. hour was 40 per cent higher than the figure I used, and the price of coal was 17 per cent higher than the price I assumed. His price is more accurate than the one I used, but assuming for the sake of being conservative, that the average between the two estimates would be approximately correct, that would mean, say $300,000 per year saving, to say nothing of the interest on the $3,000,000 or $4,000,000 that will be invested in construction, from which we will not be receiving any benefit until the work is completed. Therefore, if this tunnel can be completed one year sooner by using this method, the saving thus made will a great deal more than save the $11.50 additional cost of the pioneer tunnel.

The results, states Mr. Sullivan, proved that these estimates were conservative. The pioneer tunnel, from the most careful studies of the information at hand, cost about $28 per foot instead of $30, as estimated. There was a great deal larger difference than 75 cts. per cubic yard between the actual cost of enlarging the tunnel by this method and the estimated cost of enlarging without the use of the pioneer tunnel; and another item, not taken into account in this estimate, was the fact that the pioneer tunnel only had to be driven less than four-fifths of the total distance.

It has been stated by some that this method is not applicable where there are soft spots in the rock. If the soft rock encountered does not exceed 50 per cent of the total, Mr. Sullivan is confident that this method would still prove more economical than any other which has yet been tried, for the reason that when the soft places are encountered, there is plenty of time to stope out the upper part of the arch and timber it, so that when the steam shovel arrives at those places, there will be no delay whatever, and, instead of having to stope out the entire section by hand, as is necessary in the under-heading method, only about half, or less, of the material in the section requires to be removed in this manner.

Regarding the actual costs Mr. Sullivan quotes further from the report of March 13, 1913:

I figure that by this method the pioneer tunnel can be driven for about $30, the main heading for about $40, and that the bench can be taken out for about $54, making a total of $124. There will be incidentals; contractors' profit should not amount to over $20 per foot. Of course, this method of driving the tunnel, working so many drills at one time, will require a larger plant than if only one heading was driven, and that at a lower speed than we contemplate.

The expectations of the railway company, stated Mr. Sullivan, have been more than realized, as is proved by the speed and the cost of the work. The cost of driving this tunnel through rock, including in this price the cost of driving 19,610 lin. ft. of pioneer tunnel, 12 cross-cuts, each about 40 ft. long, erecting the plant (including freight), the proportionate cost of building about 5 miles of temporary railway tracks, and other overhead charges, plus 10 per cent on all expenditures, will amount to a little less than $5 per cu. yd. for excavation in the tunnel proper.

In his discussion, Mr. Dennis, who was in charge of the work for the contractor, stated that the idea of the pioneer heading originated in the desire to get away from the congestion, smoke, general confusion, and interference of one operation with another, observed in tunnel driving, and to provide muck in large quantities for handling by shovel. His work in coal mines, with air course run with the main entry, suggested the pioneer as a means to the desired end.

Cost of the St. Paul Pass Tunnel.—The following data are taken from an article by K. C. Weedin, in Engineering and Contracting, April 5, 1911.

The St. Paul Pass tunnel is on the line of the Chicago, Milwaukee & Puget Sound Ry. where the latter crosses the Bitter Root range of mountains on the Montana-Idaho state line. It is 8,750 ft. long; 3,412 ft. being in Montana and 5,338 ft. in Idaho. The summit grade in tunnel is elevation 4,169 ft. at a distance of 3,520 ft. west of the east portal and this point is 1,020.7 ft. below the surface. The gradient is 0.2 per cent in both directions from the summit. The location lies in a zone of extremely great snow fall, possibly the greatest in the United States; the actual fall during the winter of 1907–08 being 33 ft. 4 ins. Fortunately there is little wind.

Construction was begun Jan. 18, 1907, and was completed March 4, 1909. The writer assumed charge for the company on Dec. 6, 1907, or about one year after the work was started.

The C., M. & P. S. Ry. practically parallels and lies near the Northern Pacific from Missoula to Taft, Mont.; there they diverge.

Taft being the nearest point to the tunnel on an operated railroad, 2.5 miles distant, it was decided to locate the power house there, generate the electricity and transmit it to substations, one at each end of the tunnel.

A wagon road was constructed from Taft across the range at great expense, over which all supplies, machinery, timber, etc., were transported both for the west end of the tunnel and for the grading and bridge work on the west slope.

This road required a great deal of attention. The average traffic over it was about 100 four-horse teams per day and the maximum about 160 four-horse teams. About 60 men were required in summer to keep the road open, and about twice that number were required in winter and spring. These men were stationed in three camps along the road, one at each portal and one at the summit. The road was about 4½ miles long and the summit was about 1,000 ft. above the portals. Fresh snow was attacked with a steel logging plow pulled by 24 horses, then a 30-horse wooden wedge plow was used and the work was finally finished with shovels. In spite of this work the road bed was steadily elevated during the winter until it was well up to the roofs of the camp houses.

During the winter of 1907–08 a cableway one mile long was built from the east portal to the summit. This cableway was driven by a 30-hp. motor. Supplies, fuel, timber, etc., were teamed from Taft to the lower terminal near east portal, carried on the cableway to the summit, there transferred to wagons and hauled down the west slope. This method obviated the long, heavy team haul up the mountain and greatly lessened the time.

The main power station equipment consisted of the following items:

6 150-hp. Atlas high pressure tubular boilers, set up in batteries of two.
2 Blake 8 × 5 × 10-in. boiler feed pumps.
2 Fairbanks-Morse 5½ × 3½ × 5-in. boiler feed pump.
1 Blake 14 × 7½ × 12-in. underwriters fire pump, normal capacity 500 gals. per minute.
1 Blake 14 × 22 × 24-in. air pump and jet condenser.
2 20 × 48-in. Corliss engines.
1 14 × 28 × 20-in. tandem compound McEwen engine direct connected to a 200-kw. 3-phase, 60-cycle, 2,200-volt generator.
1 17 × 22-in. Atlas engine.
1 10 × 16-in. Atlas engine, driving exciters.
2 200-kw. 3-phase, 2,200-volt, 60-cycle, G. E. generators belted to the Corliss engines.
1 200-kw. 3-phase, 2,200-volt, 60-cycle, engine type, Westinghouse generator, direct connected to McEwen engine. A 17½-kw. 125-volt Westinghouse exciter was belted to this generator.
1 35-kw. 125-volt G. E. direct connected generator, used for exciter.
3 250-kw. 2,200 to 6,600-volt, 60-cycle transformers—oil cooled.
3 Sets of 6,600-volt multigap lightning arresters with choke coils and all necessary switch board panels, connections, volt meters, circuit breakers, etc.

The machine shop equipment was as follows:

1 24-in. × 14-ft. New Haven heavy duty engine lathe.
1 Four-jaw chuck, 16-in. diameter.
1 20-in. Hoefer back geared drill press fitted for No. 3 drill socket.
1 30-in. Wallcott & Wood geared shaper, extended base and counter shaft.
1 No. 96 Forbes belt and hand driven pipe machine with dies from 1 in. to 6 ins. with cutting off attachment.
1 Blacksmith outfit complete.

The power station was protected by a good gravity water system in addition to that afforded by fire pump. The capacity of plant was 750 kw. and the alternating current was carried to the sub-station at each end of the tunnel—2½ miles to the east end and 4½ to the west end.

At each sub-station the current is stepped down from 6,600 volts to 440 volts through three 100 kw., oil cooled transformers.

The east end sub-station equipment comprised the following items:

2 220-hp. 60-cycle, 3-phase, 440-volt, G. E. induction motors, driving compressors.
1 100-hp., 60-cycle, 3-phase, 440-volt, G. E. induction motor.
1 100-kw. 575-volt, G. E., D. C. generator.
1 50 hp. 2-pole Thompson-Houston 500-volt D. C. generator.
1 50-hp. 500-volt Westinghouse D. C. motor.
1 30-hp. 4-pole, 500-volt Westinghouse motor.
2 Westinghouse-Baldwin electric locomotives fitted with 2 No. 64, 500-volt, D. C. motors, 24-in. gage.
2 7½-kw. 500 volt motors.
3 100-kw. 6,600 to 440-volt, 60-cycle, G. E., oil cooled transformers.
3 7½-kw. 440 to $^{110}\!/\!_{220}$-volt Westinghouse oil cooled transformers.
2 1,205 cu. ft. of free air per minute each, running at 135 r.p.m. Ingersoll-Sergeant, belt driven, air compressors, type J-2.
1 Size K Exeter fan with 2,000 ft. 16-in. galvanized iron air pipe.
1 No. 2 Root blower with 5,000 ft. 8-in. galvanized iron air pipe.
1 16-in. swing saw.
1 Numa drill sharpener.
1 No. 1, 20-in. self feed drill press.
1 Walcott engine lathe, 18-in. swing, 12-ft. bed.
1 Model 20 Marion shovel.
25 Ingersoll-Rand 3½-in. air drills.

The equipment at the west end was practically a duplicate of that at the east end except that the air drills used were Wood drills made by the Wood Drill Works, Paterson, N. J.

The compressors at each end furnished power to 13 drills (8 in heading and 5 on bench), the Marion model 20 shovel, the drill sharpening machine, a welding hammer and two forges. The Marion shovels were constructed especially for this character of work, the booms being short to permit swinging between the lining timbers and were equipped with 1¼ cu. yd. dippers. Drill bits were upset, reshaped and sharpened on a Numa, air driven, drill sharpening machine that proved to be a great factor in making rapid progress.

The ventilation of the tunnel was accomplished by the use of an Exeter fan operated as an exhauster, exhausting through a 24-in. galvanized iron pipe made up in 30-ft. lengths with flanged joints and paper gaskets. The end of this pipe was maintained at a distance behind the bench sufficient to prevent the pipe from being dented and perforated by shooting. A No. 2 Root blower was also operated to pump fresh air into the tunnel through an 8-in. galvanized iron pipe. The latter pipe was carried close to the heading face.

The tunnel was driven by the top heading method. The material in general was a laminated quartzite with talc between the strata, but the character changed often, which necessitated changes in the method of conducting the work.

The heading was, when the material permitted, driven with a full face following it as closely as practicable, usually from 50 ft. to 60 ft. with the timber lining, but often it became necessary to drive small side drifts for the wall plates and carry the arch timbers within 2 ft. of the face. Usually 6 drills were operated abreast, driving the full heading face, two on one column about 3 ft. each side of the center line and one on a column in each corner. These were followed by a "trimmer" taking off all points to obtain the correct section. This work was followed by a special timber crew erecting the timber lining.

The packing back of lagging on side walls from the sills to the height a man could shovel is the natural material excavated from the bench; from this elevation to the wall plates and over the arch the packing is cord wood driven tight and wedged. Wood packing was not particularly objectionable here as the tunnel was very wet. The heading material was shoveled into 1 cu. yd. end dump cars, pushed by hand to a chute back of the bench and dumped into a car on a side track on the bench level. The heading track was supported over the bench by timbers spanning the tunnel and resting on the wall plates.

The bench was driven by 4, and at times, 5 drills working on the floor level; occasionally it was necessary to drill "down" holes and also at some places where the material was particularly hard it was necessary to take out a sub bench. In fact, many different tunneling methods were resorted to, as circumstances dictated. The timber lining on the bench was done by the regular bench crew.

The air shovels loaded all bench material into 1½ cu. yd. Peteler cars which were spotted by horses, but hauled out of and into the tunnel by two 15-hp. electric locomotives at each end—from 8 to 11 cars to the train.

The heading muck cars were run out on a platform over the bench workings a distance of 150 ft. to a muck chute leading to the tunnel trains on a track below. This platform was built ahead as the bench progressed and new chutes were added as required. In front of the bench were two narrow gage tracks on the sides of the tunnel with a crossover beyond the chute for the heading muck.

The electric locomotive hauled the cars to the crossover and the cars were hauled by a horse from here to be loaded and returned to the outgoing track. At the east portal the dump began just outside the approach. Here a 60-ft. fill had to be made for the main line. At the west portal there was a haul of about 2,500 ft. to a 70-ft. fill about 600 ft. long. Snow gave trouble on the dumps and 10 or 12 men were required in winter to keep the track open on the west side and on the east side a temporary snow shed was erected over the dinky track.

The overbreak was carefully measured every 8 ft.—oftener when necessary —and averaged 2.94 cu. yds. per lin. ft. of tunnel. The total quantity removed was 21.5 cu. yds. per lin. ft.

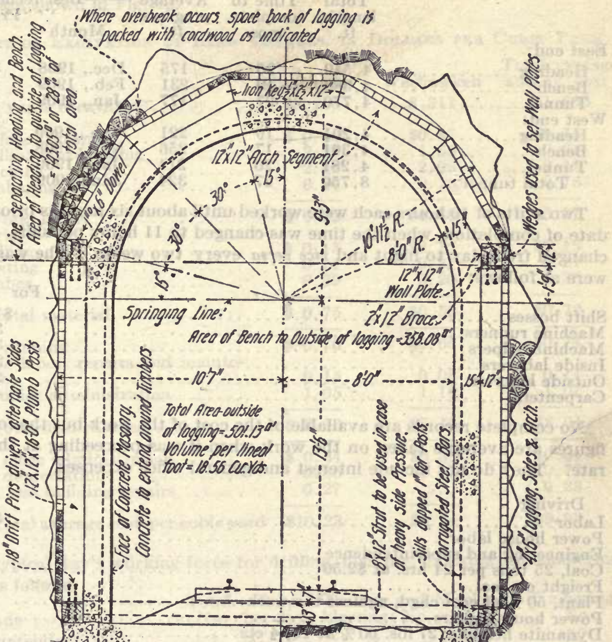

FIG. 5.—Cross section of St. Paul Pass Tunnel, showing type of timbering.

A track incline connecting the heading and bench tracks was utilized for transporting timber and tools to the heading. This incline was so arranged that, as the bench advanced, it could easily be moved forward, and the timbers supporting the heading track could be taken down and used ahead. The incline kept all heading operations away from the bench, and as the work was conducted on the bonus system the bench operations were not interfered with by the carrying of tools, machines and timber into the heading, and consequently the bench operatives could not complain of being discriminated against.

The bonus system consisted in giving $2 to the foreman and $12.50 for distribution among the men for both heading and bench above 3½ ft. per shift based on the monthly average.

The progress record is shown in Table I. The monthly average for the twelve-month 1908, was 544.6 ft.; for 1907, 80.3 ft. The highest records of daily progress were Nov. 17, 18 and 19, 1908, and were, respectively, 23.5 ft., 32.5 ft., and 28.5 ft.

TABLE I.—PROGRESS REPORT OF ST. PAUL PASS TUNNEL

	Total length, ft.	Time to complete, mos.	Average progress, ft.	Best record— Month	Best record— Progress, ft.
East end:					
Heading	4,549	26	175	Dec., 1908	357
Bench	4,389	19	231	Feb., 1909	350
Tunnel	4,770	27	177	Jan., 1909	337
West end:					
Heading	4,201	19	221	Jan., 1909	385
Bench	4,361	17	256	Nov., 1908	527
Tunnel	4,281	20	214	Jan., 1909	416.5
Total tunnel	8,750	27	324	Jan., 1909	753.5

Two shifts of 10 hours each were worked until about six months prior to the date of completion, when the time was changed to 11 hours per shift. Shifts changed from day to night and *vice versa* every two weeks. The wage rates were as follows:

	For 10 hrs.
Shift bosses	$4.75
Machine runners	3.75
Machine helpers	3.25
Inside laborers	2.75
Outside laborers	2.25
Carpenters	4.00

No complete records are available of the cost of the work but the following figures are averages taken on the work when it was proceeding at the usual rate. They do not include interest and general office expenses.

Driving	Per lin. ft.
Labor	$ 84.50
Power house labor	7.00
Engineering and superintendence	3.00
Coal, 25 tons per 24 hrs. at $2.50	4.16
Freight on coal	3.20
Plant, 50% of cost chgd, against the work	15.00
Power house repairs	8.75
Dynamite heading, 27 lbs. 60% at 16½ cts	4.45
Dynamite bench, 23 lbs., 40% at 12 cts	2.76
Caps and fuse	2.10
Rubber clothes	4.62
Drill repairs, small tools, etc	13.65
Water system	.35
Camps	1.10
Total	$154.64

Timbering	Per M. ft. B. M.	Per lin. ft.
Timber delivered at Taft	$18.50	$ 9.25
Timber teaming from Taft, 2½ miles	4.00	2.00
Timber framing	4.50	2.25
Cord wood: cutting $2, teaming $2	4.00	.40
Iron		.40
Erecting on bench		2.00
Erecting in heading		2.35
Total		$ 18.65
Grand total cost of timber lined tunnel		$173.29

Cost of Land Sections of Pennsylvania R. R. North River Tunnels at New York.—The following data are given in an abstract in Engineering and Contracting, May 11, 1910, of a paper by B. H. M. Hewett and W. L. Brown, Proc. A. S. C. E., Vol. XXXVI.

The following summary of the cost of excavating the land tunnels is based on actual records carefully kept throughout the work. Types of tunnel sections are shown in Fig. 12.

COST OF EXCAVATION OF LAND TUNNELS, IN DOLLARS PER CUBIC YARD

	Manhattan	Weehawken	Total yardage and av. cost
Cubic yards excavated	43,289	8,311	51,600
Labor:			
Surface transport	$ 0.49	$0.87	$0.55
Drilling and blasting	2.37	1.55	2.24
Mucking	2.49	2.08	2.42
Timbering	0.87	0.18	0.76
Total labor	$ 6.22	$4.68	$5.97
Material:			
Drilling	$ 0.15	$0.15	$0.15
Blasting	0.21	0.21	0.21
Timber	0.39	0.20	0.36
Total material	$ 0.75	$0.56	$0.72
Plant running	$ 0.76	$0.65	$0.74
Surface labor, repairs and maintenance	0.15	0.08	0.14
Field office administration	1.05	1.18	1.07
Total field charges	$ 8.96	$7.15	$8.64
Chief office administration	$ 0.34	$0.38	$0.34
Plant depreciation	0.66	1.01	0.72
Street and building repairs	0.27	.....	0.23
Total average cost per cubic yard	$10.23	$8.54	$9.93

A typical day's working force for drilling, blasting, mucking and timbering was as follows.

Grade	Total No.	Rate per day	Drilling and blasting: No.	Mucking: No.	Timbering: No.
Superintendent	1	$7.70	½	⅛	⅜
Assistant engineer	1	5.80	½	⅛	⅜
Electrician	1	3.50	½	⅛	⅜
Engineer	1	3.50	....	1	...
Signalman	1	2.00	....	1	...
Foreman	3	4.00	1	1	1
Driller	5	3.00	5	....	...
Driller's helper	5	2.00	5	....	...
Laborers	14	2.00	....	14	...
Timbermen	3	3.00	....	....	3
Timbermen helpers	4	2.00	....	....	4
Machinist	1	4.00	1	....	...
Blacksmith	2	3.50	2	....	...
Blacksmith helper	2	2.00	2	....	...
Nipper	2	2.00	2	....	...
Waterboy	1	2.00	1	....	...
Total	47	.....	20½	17⅜	9⅛

Where there was any large amount of soft ground in the roof, the timber gang was much larger than shown above and was helped by the mucking gang. The drillers did most of the mucking out of their heading before setting up the drills.

The following is an analysis of the cost of drilling.

ANALYZED COST OF DRILLING

Item of cost	Cost per ft. of hole drilled 15 ft. 4 in.	19 ft. 6 in.	24 ft. 6 in.	Average
Drilling labor	$0.25	$0.28	$0.31	$0.28
Sharpening	0.02	0.02	0.01	0.016
Drill steel (5 in. per drill shift)	0.007	0.007	0.006	0.007
Drill repairs	0.02	0.02	0.02	0.02
High pressure air	*0.05	0.04	0.07	0.07
Totals	$0.35	$0.38	$0.41	$0.385

* This is an estimated figure, ascertained by taking a proportion of the whole charge for plant running.

Based on the records of 5 months, in which 12,900 cu. yds. were excavated, the following data were derived.

Portion of excavation	Feet of hole drilled per cubic yard of excavation 15′ 4″ span—twin tunnel	19′ 6″ span—twin tunnel	24′ 6″ span—twin tunnel	Lbs. of powder used per cubic yard of excavation 15 ft. 4 in.	19 ft. 6 in.	24 ft. 6 in.
Wall-plate heading*	13.0	10.97	10.97	3.77	2.85	2.85
Total heading*	7.87	8.17	7.81	2.31	2.02	1.78
Bench and raker bench*	5.97	6.15	7.56	0.94	0.93	1.13
Trench*	9.82	15.96	18.10	1.84	2.48	2.73
Average for section*	6.69	7.43	8.95	1.28	1.30	1.45
Actual amount†	6.82	7.27	8.95	1.22	1.24	1.27

* Figures taken from typical cross-sections.

† This gives the actual amount of drilling done and powder used per cubic yard for the whole period of 5 months of observation, but as this length included 280 ft. of heading and only 220 ft. of bench, the average figures (for powder especially) are too low.

Comparative Cost of Tunnelling in Soft Earth Using Poling Board Method and Hydraulic Roof Shields.—The following data are given in Engineering Record, Feb. 27, 1915.

A pair of hydraulic roof shields, designed and built for the job, was used to complete the Point Defiance tunnel of the Northern Pacific Railway, near Tacoma, Wash. When this work was commenced, a high rate of progress was expected with ordinary timbering methods, owing to the apparently firm and well drained condition of the earth to be encountered, and to the known absence of rock. However, when the bore had been driven through the outer crust, which was comparatively dry, a wet, sandy formation was encountered, which called for heavy timbering and made progress by the poling-board method very difficult. The west heading was advanced at an average of only 126 ft. per month for four months, and at the end of this time the contractors faced the necessity of finding some new method of handling the work, or losing heavily on the contract.

A New Shield Developed.—The material encountered was very heavy and had a tendency to "flow" around the breast boards into the heading. It was decided that some means must be provided for carrying the weight of this material and protecting the workmen while handling muck and placing timber. Accordingly a steel shield of semi-cylindrical shape was built, designed to be thrust forward by hydraulic jacks, and just large enough to clear timbers and lagging placed beneath it. The weight of this shield and its load was carried on the wall plates at the forward end, and upon the timber segments at the rear.

A segmental I-beam rib, projecting on the inner side of the shield and forming part of it, 4½ ft. behind the cutting edge, served as a shoulder against which the jacks could thrust. Twelve 120-ton hydraulic jacks were used, these being set between this I-beam shoulder and the last segment placed. The width of the shield between wall plates was 31 ft., the rise of arch 14 ft. 10 in., and the overall length 14 ft. In addition to the rib for taking the thrust, the frame had a 4 × 6-in. channel-iron brace in four segments, and a 2½-in. steel tie-rod with turnbuckle. The shell was built of two thicknesses of steel plates ¾ in. thick for the inside and ⅝ in. for the outside. All bolt and rivet heads on the outside of the shield were countersunk. The cutting edge consisted of 1-in. plates, bolted to the shield to facilitate easy renewal. Their forward edges were bent upward slightly to prevent wedging. The shoes on which the weight of the shield was carried at the forward end were steel castings arranged to slide on angles laid on the wall plates.

Equipment.—A bench, 24 to 28 ft. long, and of convenient height, was left in the middle of the heading, on which to handle muck and timbers, and as a safeguard against overbreak. The jacks were fed from a hydraulic pump, and driven by an electric motor, set on this bench. This motor also operated a conveyor belt which delivered muck from the heading across the bench to a Marion 40-ton steam shovel running on the tunnel floor. The shovel, which ran with compressed air, loaded this material into 4-cu. yd. cars and also excavated the bench. These cars, of 3-ft. gage, were handled, in trains of two to six at a time, by a 6½-ton electric locomotive. Motor-driven belt conveyors were also used to remove muck from the two wall-plate drifts. These conveyors were arranged so that they could be reversed and used to carry timber into the drifts.

The timber was sawed into standard lengths outside the tunnel and sent in as needed. In order to maintain easy access and thus facilitate the handling of timber, a "high-car" was constructed, whose platform cleared the top of the shovel. A bridge was used to connect this platform with the bench, and the car was thus kept back of the sweep of the shovel boom. The car ran on rails placed on either side of the track provided for the shovel.

Operation.—The normal working pressure on the hydraulic jacks was about 10 to 13 tons, although the initial pressure at starting sometimes rose to 30 tons. The maximum pressure was 50 tons, or a total of 600 tons on the entire shield. After each advance of 4 ft., timbers for a new segment were set. The rate of advance through sandy formation was usually 1 in. per minute, which was found to be about as fast as miners and muckers could handle the material. In order to measure and control the movement of the shield, three measuring rods graduated in inches were attached to it, parallel to the tunnel, one at the top and one at each of the wall-plate shoes. The man who controlled the operation of the jacks stood where he could watch the advance of the top rod, and assistants at each of the other rods called to him the advance of the shield on each side. By closing or opening one or more jacks on either side, the direction of the shield was easily controlled. Curves were successfully driven

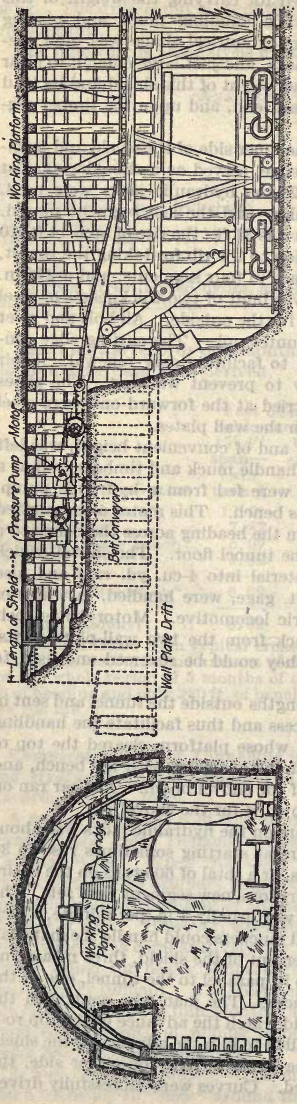

FIG. 6.—Top heading of tunnel worked under roof shield—spoil handled with belt conveyors and steam shovel.

by maintaining different rates of progress on the two sides.

In soft ground the workmen excavating at the cutting edge stood on the turnbuckle thrust-rod which afforded a good footing while they leaned against the face of the heading. Four shovel men cut away the material a few inches ahead of the cutting edge, or took it out through holes in the I-beam ring when it packed up ahead of this projection. About eight muckers were usually required to shovel into the conveyor and keep the bench clear.

The wall-plate drifts were so worked that their headings were always 18 or 20 ft. in advance of the cutting edge. As the shield advanced the earth at the sides of the bench was cut away below the wall plates to the tunnel floor, and plumb posts put in place in the usual way. The wall-plates were placed by the engineer in charge of the work and securely blocked.

Cost and Progress.—With the poling board method the progress with a shift of thirty men had been only 4 to 6 ft. a day, but with the shield in full operation the same number of men advanced the heading 12 to 16 ft. a day, and eliminated all the false timber work required by the former method. The first shield built was tried out near the west portal. Progress with it was very satisfactory, and it was decided to build a second shield. The shields were fabricated by the Seattle Drydock & Construction Company at a cost of about $3500 each. They were made in five sections, and after being assembled in the shop were taken apart for shipment and re-erected in the tunnel. The shield was designed and patented by W. M. McDowell, of Tacoma, and the work done with it in the Point Defiance tunnel was carried out under his personal supervision.

Total for night shift	$2,299.50
Total	$4,715.00
Credit (226,156 board feet of permanent timber furnished by Northern Pacific Railroad and put in place by contractor at $11 per M)	2,487.71
Net total for the month	$2,227.29
Distance tunneled for month, 394 lin. ft.	
Cost per linear foot	$5.65

Cost of Tunnel Lining By Compressed Air Mixing and Placing.—The following data are taken from an article in Engineering and Contracting, Jan. 12, 1916.

Location of Mixer.—Generally speaking the location of the mixer should be as near the place of concreting as possible, having due regard to suitable length of discharge pipe. A part of the mixing process takes place in the discharge pipe and the length of this pipe must therefore be sufficient to complete the mixing process. It is assumed as an approximation that 50 ft. of discharge pipe are necessary. At Sandy Ridge tunnel 40 ft. of discharge pipe was employed at times and no defect of mixture was observed. These lengths of discharge may then be accepted tentatively as necessary. The upper limit of length of discharge pipe is determined by relative costs. Practice records lengths up to nearly 2,800 ft. Generally speaking, length of discharge should be kept well under 1,000 ft. to obtain the best results in comparative output and costs.

In level, the location may (within limits) be, without detriment to results, considerably either above or below the point of depositing. A rise of pipe of 15 to 20 ft. above mixer level is common experience. There are frequent examples of rises of 20 to 30 ft. In experiments concrete has been deposited 100 ft. above the mixer. Probably these are not the extremes, but they indicate generally the limits of location of mixer below the point of deposit. Location above the point of deposit is rare in practice. At Tallulah Falls tunnel, however, one mixer was located at the shaft top and operated successfully.

The ideal location of mixer for tunnel lining, and particularly for lining railway tunnel, would seem to be on a car as at Sandy Ridge and Arminto tunnels. With an air main through the tunnel supplied from an outside compressor plant, a car mounted mixer gives a remarkable flexibility of lining placing operations.

Discharge Pipe.—Size of discharge pipe in relation to capacity of mixer has an important bearing on rapid and economic operation, but ordinarily this is a problem that need not concern the user. As made by the companies controlling the process, mixers are given the discharge openings suited to their capacities. Wear of pipe, pipe alinement and pipe handling are however distinctly users' problems and the troubles they may cause unless their solution is known are many.

Pipe wear is a serious problem. Driving a batch of concrete through a closed pipe under crowding pressure at a speed of a mile a minute is a severe abrasive test. Practice furnishes rather erratic records of pipe wear, because in the past no uniform practice existed in quality and make of pipe used or in the character of the joints. Naturally, alinement varied and especially the amount of curvature and the number of curves. At Tallulah Falls tunnel spiral riveted pipe was first tried, but the lines of rivets caused rapid wear and frequent ruptures. On the Stockton and Twin Peaks tunnels in San Francisco studies of pipe wear gave the following facts: An 8-in. steel pipe was used and 16 cu. ft. charges were shot under 120 lb. air pressure with velocities of 75 to 100 ft. per second. On level straight line ordinary 8-in. flanged connection steel pipe not quite new had a life of about 6,000 cu. yd. of concrete conveyed. The same pipe on an up-grade of 7 per cent wore through first on top. Threaded connections proved least durable; the thinning of the section by threading resulted in rapid cutting through at the joints. At bends, 4 ft. radius, ½-in. steel pipe cut through in instances in 12 hours continuous conveying and averaged only 60 hours' life. As a remedy cast manganese steel elbows were adopted and despite their greater expense proved more economical than ordinary steel elbows. (Note experience in the Mount Royal Tunnel which shows a different result.) Another influencing factor is the character of the coarse aggregate. Pit run gravel causes least wear, broken stone causes more rapid wear and slag causes extremely rapid wear.

The causes for excessive wear indicate the remedies to be adopted. A straight alinement is the first remedy. Such alinement is also desirable because it reduces friction and so saves air. Instead of even upgrade rises use elbows; this confines unusually rapid wear in short sections. When the amount of concrete to be handled is considerable substitute manganese steel for elbows. Have no projections inside the pipe; it should be absolutely smooth. Use a form of connection that makes the joint inside smooth and even and does not reduce the thickness of the shell. For convenience in handling the joint connection or coupling should be one that can be quickly and easily made in restricted space.

Air Consumption.—The amount of air consumed depends upon the specific gravity of the aggregate, size of pipe used, size of storage tank, horizontal and vertical distances of discharge, kind of pipe, number of bends in the discharge pipe and principally upon the operator. Table II gives the theoretical capacities for continuous operation at various horizontal distances.

The figures in Table II are based on observation for the shorter distances of discharge and are computed for the longer distances. At the St. Louis

Average time per shot, 23.1 seconds. Length of conveyor pipe, 102 feet. Vertical rise of pipe, 37 feet. Bends in pipe line, 205 degrees.

measuring hopper; two laborers controlled the sand and stone gates and one laborer operated the gate to the measuring hopper and also the air valves, and another laborer operated the water valve and assisted the mixer operator, making five men at the mixer.

Note that a 600-ft. compressor was used and that the average time of waiting for the air pressure to come up was 17.2 seconds in time study No. 1, where the distance was 350 ft. In study No. 2 where the distance was only 102 ft. there was no wait for air pressure.

Lining Mount Royal Tunnel by Pneumatic Mixer.—The following data are taken from an article, by F. C. K. Stuart, published in Engineering News-Record, Jan. 24, 1918.

In placing the lining of the Mount Royal tunnel several experimental pneumatic mixing plants were tried out before determining the best arrangement for carrying on the work.

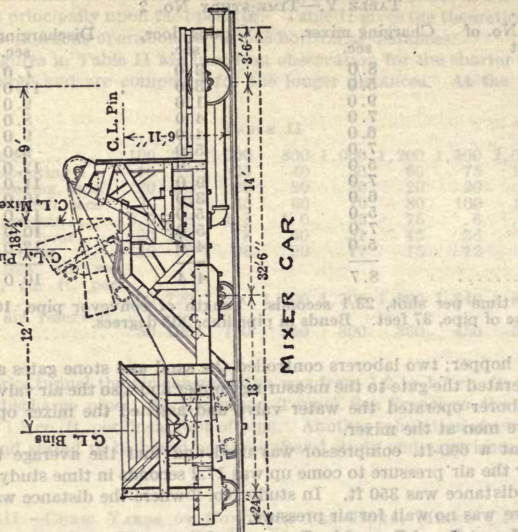
[a] When air pressure got below 70 lb. plugs in line were frequent.

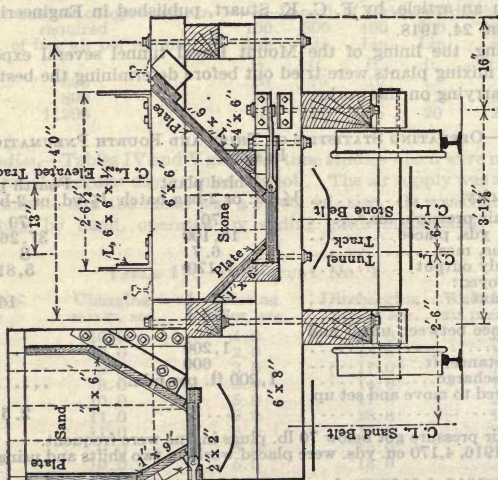
[b] March 1916, 4,170 cu. yds. were placed working two shifts and using five sets of forms.

[c] October, 1916, 5,811 cu. yds. were placed working two shifts and using seven sets of forms.

[d] The average force for one shift in the tunnel on concrete work was a foreman, a mixer operator, a hoist runner, thirteen laborers, three dinky runners, three brakemen, a pipe fitter and a handy man. The carpenters worked one shift.



MIXER CAR



SECTION A-B

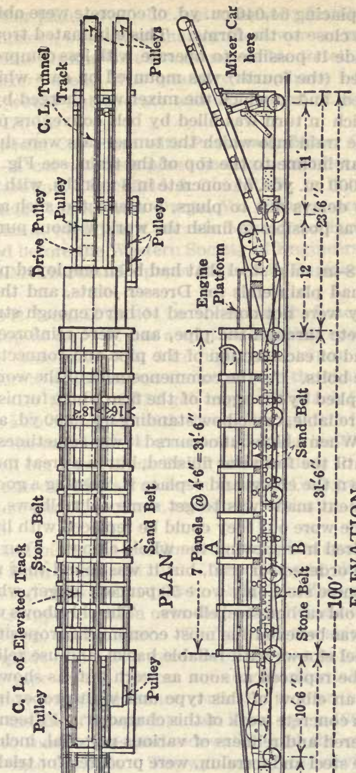


FIG. 8.—Cars ran up on elevated track, side dump discharging sand and bottom dump stone into bins from which two conveyors took material to hopper of mixer car which loaded charging skip.

The best results in placing 64,040 cu. yd. of concrete were obtained by keeping the mixing plant close to the forms. This eliminated trouble with plugging the line and made it possible to operate with less compressed air. The plant finally developed (the fourth) was mounted on cars which could move as the work progressed, and in which the mixer was charged by a skip loaded from a small bin, which in turn was filled by belt conveyors passing beneath bins, mounted on the train into which the tunnel cars were dumped. These cars were hauled up an incline to the top of the train, see Fig. 8. This plant placed more than 37,000 cu. yds. of concrete in 8 months. with 7 sets of forms, not only reduced the delays due to plugs, but effected such a saving in wear on the pipe that it was possible to finish the work without purchasing a large extra quantity.

The pipe used was 8-in. mild steel that had been employed previously as an air line. This pipe had plain ends for Dresser joints, and these joints were used. However, they were not considered to have enough strength to resist the pull of the concrete through the pipe, and were reinforced by fastening two angles to each end of each section of the pipe and connecting angles by a pair of ¾-in. machine bolts. At the commencement of the work ordinary cast steel elbows were supplied by the agent of the firm which furnished the mixers. They proved very unreliable, one elbow standing up 1,000 yd. and another one for less than 100 yd. When a blowout occurred it was sometimes possible to put on a patch to last until the form was finished, but in a great many cases it was necessary to take down the elbow and replace it, wasting a good deal of time.

The first improvement made was to get some split elbows, the idea being that as the backs alone wore out they could be replaced with little more than half the trouble required in removing the whole elbow. Four split elbows of manganese steel were ordered for trial, but it was found that under the same conditions the manganese steel only wore 50 per cent longer, while the cost was four times that of the old carbon steel elbows. The old elbows wore out only in one place, so that it was believed the most economical proposition would be to split a few carbon steel elbows with reliable backs, and use reliners consisting of blocks that could be replaced as soon as worn out, as shown in one of the photographs. With an elbow of this type and with proper inspection there should be no delays in concrete work of this character. Fifteen 45-deg. elbows of this type were ordered and reliners of various material, including cast iron, icast steel, manganese steel and ferralun, were procured for trial. Pure rubber in the shape of old sections of motor truck tires was tried, but could not be held in place in the elbow. The most economical lining was found to be cast iron, though ferralun outlasted all the other materials.

This elbow was a great improvement and was used for the rest of the job. It gave very satisfactory service, though after being relined several times the block reliners had a tendency to blow out owing to wear of the elbow itself alongside the liners. When the elbow reached this stage a forged reliner in one piece was put in to fill up all the worn spots. This type of elbow has since been patented and considerably improved.

The pipe wear was considerable, but no figures are available as to the amount actually destroyed. Most of the wear occurred at the ends, and when a length was worn through the ends were cut off and the pipe used again until entirely worn out. The reinforced Dresser joints gave satisfactory service, but there were occasional blowouts due to bad plugs. Where the end of the horizontal pipe connected to the mixer elbow and to the elbow at the bottom of the vertical pipe, a flange was screwed on the pipe.

The compressor plants available had a capacity far above the rated requirements for the mixers, but unfortunately there were so many drills and pumps run from the same air line that it was impossible to tell exactly the amount of air that the mixers used. The quantity was above 1,100-cu. ft. per minute, and the mixer would not operate without danger of plugging if the pressure dropped below 70 lb.

Output of Special Car Plant with Pneumatic Mixer Outfit for Lining Railroad Tunnel.—A car concrete plant having a number of novel features was used by the Carolina, Clinchfield & Ohio R. R. in lining the 7,804-ft. single track Sandy Ridge tunnel near Dante, Va. The arrangement was described by H. B. Kirkland, president Concrete Mixing & Placing Co., Chicago, in a paper presented before the Western Society of Engineers. The matter following taken from Mr. Kirkland's paper is given in Engineering and Contracting, May 5, 1918.

The car is 40 ft. long, 10 ft. 4½ in. wide near the braces and 17 ft. 9 in. from top of rail to top of car. It has a central chamber open on the sides, 8½ ft. long, 9 ft. 8 in. wide and 10 ft. 3 in. high, in which on one side is located the pneumatic concrete mixer and on the other side the charging skip. Over this chamber is a water tank of 1,850 gal. capacity, which furnishes water for the concrete and is also connected with the cooling system for the gasoline engine. On one end of the car, facing the central chamber, is a stone bin of 30 cu. yd. capacity. Each bin has a chute 20 in. wide leading to the charging skip and each chute is controlled by an under-cut gate. Under the stone bin is a space occupied by a 96-cu. ft. receiver, standing vertically, and the storage of the cement in bags.

Under the sand bin is the gasoline engine and its auxiliary equipment, completely housed from water and dust. The charging skip in its lower position stands with its top rim about 1 ft. 3 in. above the floor and travels on inclined guide rails to its upper position over the mixer, being hoisted by a compressed air cylinder 9¼ in. in diameter. The gate of the skip works automatically by means of a guide rail. The mixer is for a 2-bag batch (0.4 cu. yd.) and has an 8-in. outlet pipe at the bottom running horizontally and curving to the outside of the rear truck and thence vertically to near the top of the car, where it branches by means of a wye into two lines, one a 180° bend to the rear for "shooting" into foundations and sidewalks, and the other going to the roof for "shooting" into the arch. The wye is a special device with a sliding plate controlling the movement of material into either arm. The arrangement of the pipe, traveling with the car and being in position at all times for "shooting" concrete, results in a material saving of time and expense.

Along one side of the car, level with the main floors, is a folding platform 2 ft. wide used by the men carrying cement and to gain access to the engine room. During the ordinary work of the car this platform remains down. The arrangement is compact and arranged with a view to save manual labor. One man controls the hoisting of the skip, the injection of water and the mixing and discharge of the batch. One man is placed at each chute and two men carry, open and empty the cement bags.

The gasoline engine is of the 6-cylinder, 4-cycle tee-head type and is rated 200 hp. at 350 r.p.m. It can be throttled to 125 r.p.m. The motor and its frame constitute one of the trucks of the car. The cylinders stand in a row at right angles to the track and the whole construction is compact but accessible. The engine is started by admitting compressed air into three cylinders, then the explosion of the gasoline takes place in the other cylinders and continues the motion. The transmission is by means of a Morse chain on the driven axle (one only being used) and the control is through a friction clutch of special design.

The loading and storage trestle is so arranged that the concrete car goes under it and receives crusher-run stone, sand, bag cement and water by gravity. The sand and stone are drawn from overhead bins by means of under-cut gates. Cement is conveyed into the car by a chute. The trestle has a track over its deck upon which stone and sand in hopper cars are stored or unloaded into the bins below. There is a continuous row of 27 bins with an aggregate capacity of 324 cu. yd. and a total length of 162 ft., and 5 loaded cars can be stored over these bins to give an additional storage capacity of 200 cu. yd.

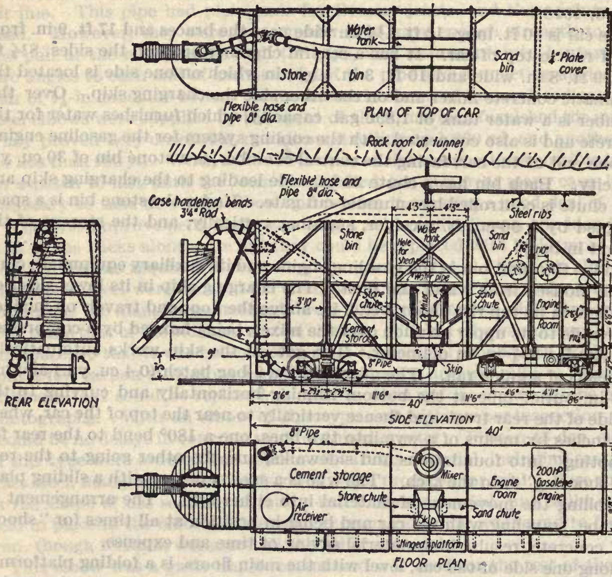

FIG. 9.—Plan and elevation of mixer car.

The compressor plant was exceptional for a temporary outfit. To save money on foundations and at the same time to increase the space, the floor level of the boilers and compressors was fixed 4½ ft. above sub-grade, the concrete foundations and walls were built up to this height and the cellular space underneath was utilized for water tanks and ash pit. The building was built of 1-in. boards covered with tar paper. The arrangement chosen permitted coal to be dumped from cars on the trestle to a pile in front of the boilers. There were two boilers, both locomotive type, one new one of 150 hp., and one old one of 70 hp. The piping connections were such that either one could be cut in or out of service for cleaning or repairs. Two compressors are installed, but an extra foundation for another unit was provided, for reasons which appear elsewhere. The compressors were alike and of the Ingersoll-Rand F. R. I. Rogler valve class, a high speed, single stage type with a steam cylinder 12 in. by 12 in., an air cylinder 12 in. by 14 in., a piston displacement at 250 r.p.m. equal to 528 cu. ft., an actual output of about 375 cu. ft. of free air per minute each. This worked under 125 lb. steam pressure and compressed air to 115 lb. They were cooled by water brought by gravity from the mouth of an old coal mine. From the compressors a 6-in. pipe leads

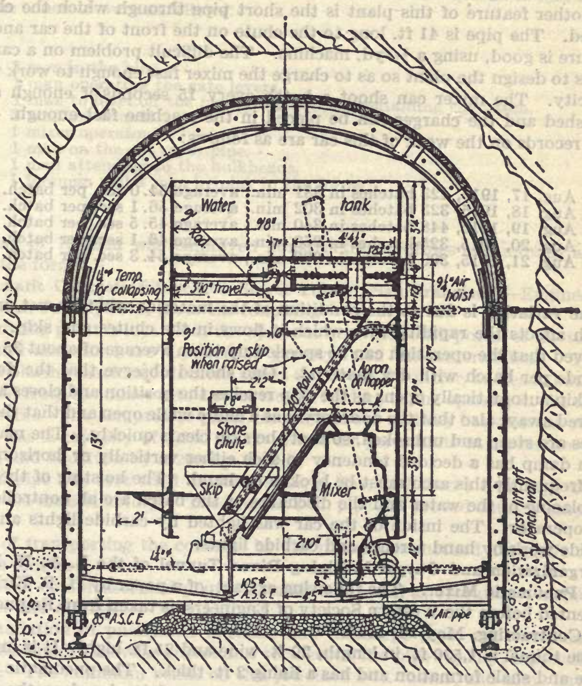

FIG. 10.—Cross-section through tunnel and car.

to a 150-cu. ft. air receiver, from which a 4-in. pipe line led on a steady 0.5 per cent down grade entirely through the tunnel. At the lower end was a pet cock to draw off any water. In order to provide for expansion and contraction, the pipe line was laid alternately on the east and west sides of the track in lengths of about 1,000 ft., connected by curves of 2 ft. radius. The bottom of the pipe was at the level of the bottom of the ties and 1 ft. out from their end. About every 100 ft. a long radius tee was placed and about 20 mine cocks of 4-in. size were provided; these could be shifted to the various tees as the progress of the work demanded. From the mine cock a 3-in. hose 60-ft. long connects with the 96 cu. ft. air receiver on the car which can thus be connected to the 4-in. pipe line from any position in the tunnel.

Several runs of 180 cu. yd. per day and one run of 201 cu. yd. were made. The work consisted of putting in the foundation and the initial lift of bench wall 4 ft. 4 in. high, which involved moving the car more than was necessary when "shooting" into the arch form.

Another feature of this plant is the short pipe through which the charge moved. The pipe is 41 ft. long to the chute on the front of the car and the mixture is good, using a ½-yd. machine. The difficult problem on a car like this is to design the plant so as to charge the mixer fast enough to work to its capacity. The mixer can shoot a batch every 15 seconds if enough air is furnished and the charges can be placed in the machine fast enough. The time records on the work of this car are as follows:

Aug. 17, 1915, 423 batches in 381 min., average 54.0 sec. per batch.
Aug. 18, 1915, 323 batches in 302 min., average 56.1 sec. per batch.
Aug. 19, 1915, 448 batches in 340 min., average 45.5 sec. per batch.
Aug. 20, 1915, 325 batches in 250 min., average 46.1 sec. per batch.
Aug. 21, 1915, 309 batches in 309 min., average 54.3 sec. per batch.

The variation is due to the condition of the material, whether wet or dry, which affects the rapidity with which it flows in the chutes and skip. It is believed that the operation can be speeded up to an average of about 35 to 40 seconds per batch with dry material. One should observe that the door of the skip automatically opens as the skip reaches the position and closes as it is lowered away; also that the door serves as a chute while open and that the side slopes are steep and unbroken, so that the skip clears quickly. The material when damp has a decided tendency to arch either vertically or horizontally, and frequently this arch must be broken by hand. The hoisting of the skip, the placing of the water and the discharge of the batch are all controlled by one operator. The inside of the car was lighted by carbide lights and the outside work by hand torches and carbide lights.

Organization and Output in Lining Diana Tunnel of the L. & N. R. R. with Pneumatic Mixer.—The following extract, of a paper by H. B. Kirkland presented before the Western Society of Engineers, is taken from Engineering and Contracting, May 15, 1918.

The tunnel is 1,520 ft. in length, 29 ft. wide and 25 ft. high. It is in limestone and shale formation and has a lining 2 ft. thick. The pneumatic mixer with storage bins and measuring hopper, etc., was first placed on the south end of the tunnel. One set of Blaw traveling forms was started at the south portal and the second set was started 400 ft. in the tunnel. These forms progressed away from the mixer until the first form had reached the work started by the second form and the second form had reached approximately the center of the tunnel. Then the mixer was moved from the south end of the tunnel to the north end and the forms moved up so that the first form would start at the center of the tunnel and the second form half way between that point and the end of the tunnel. The forms then progressed toward the mixer until the tunnel was completed.

The compressor plant consisted of two Ingersoll-Rand steam-driven compressors, which delivered about 960 ft. of free air per minute at the mixing plant.

At the beginning of the work the engineers permitted the moving of the forms after 6 days, but after a time this period was reduced to 4 days. In all there were 41 form sections, each of approximately 35 ft. and containing about 250 cu. yd. in each section. The longest distance which concrete was transported was 925 ft. and the average distance was about 400 ft. The average time required to concrete one 35-ft. section was approximately 24 hours, although some forms were filled in 15 hours. The men required to mix and place the concrete were as follows:

3 men in the bins.
1 man operating the gate levers.
1 man to level off the measuring hopper containing the batch.
1 man on cement.
1 mixer operator.
1 man on the conveyor pipe.
1 man attending to the bulkheads.
1 foreman and 4 men helping in the forms.

A gang of 10 men was employed constructing footings and moving and setting the forms.

Pneumatic Concreting Stockton Street Tunnel, San Francisco.—Engineering Record, July 4, 1914, gives the following:

The mixing plant is located in the open cut near the south portal of the tunnel. Sand and stone are supplied by gravity from the material bins. The concrete placing machine is located about 8 ft. from the mixer, and each batch is dumped from the mixer into a steel trough leading to the opening in the top of the drum. The compressor plant, situated about midway between the two portals, has a capacity of 1,250 cu. ft. of free air per minute at a pressure of 115 lbs., and is driven by a 200-hp. motor.

A 4-in. pipe was first tried on the discharge line, and then a 6-in. pipe but both proved unsatisfactory. The present 8-in. pipe has proved entirely ample in size.

Costs of transporting the concrete by the pneumatic method are made up chiefly as follows:

1. Cost of compressor and plant (installation as well as operation), including power and air lines.

2. Installation of pneumatic machine and discharge pipe, and wear and tear. The rapidly moving gravel and rock scour the pipe rapidly, especially at bends. The minimum bends on this job have 3-ft. radius, and some have been worn out in two days. A more durable metal, as manganese steel, is considered best for these sharper bends.

3. Royalty on use of system.

The material travels through the discharge pipe at an estimated velocity varying from 3 to 8 ft. per second. The impact of the discharging concrete mass against fresh concrete or against the steel reinforcement was found to erode the concrete rapidly and to displace the reinforcing steel. To remedy this trouble the pipe was raised so that the discharge end is about 1 ft. above the tunnel arch. The concrete then drops without damage into the forms at the crown and then runs downward on either side to fill up the arch ring.

OPERATING FORCE REQUIRED

1 Man operating gate on chute from rock bin.
1 Man operating gate on chute from sand bin.
2 Cement men.
1 Mixer operator.
1 Man at pneumatic machine.
2 Concrete tampers inside tunnel.
1 Concrete foreman, who also watches the pipe line to guard against clogging.
1 Man operating the air compressor.
2 Laborers in the dumping platform above the material bins.

The total concrete crew required is as shown above. Under the most favorable conditions, a batch of 16 cu. ft. can be mixed and placed in a minute. A rate of forty batches per hour or about 190 cu. yd. per 8-hr. day is a fair average when running steadily.

Relining Brick Lined Tunnel with Steam Jetted Concrete.—The brick lining of the Chicago Great Western single track R. R. tunnel 2,600 ft. long at Winston, Ill. was badly disintegrated by the action of water, coal gases and by freezing caused by the cold air forced into the tunnel by a Diesel engine driven ventilating fan. Harold P. Brown describes the situation, his recommendations and the work done in a paper, read at the Feb., 1916 meeting of the American Concrete Institute, and published in Engineering and Contracting, Feb. 23, 1916, from which the following is taken.

About a year ago the writer was called upon to examine the tunnel and suggest a method of relining which would meet the very difficult and unusual conditions. It was evident that the foundation was in satisfactory shape and that the side walls were but little injured. The roof, however, was in dangerous condition and required a lining which would take its proper share of the load.

My report advised a slight lowering of the track level; the drilling of a large number of weep holes 3 in. in diameter; the washing out of the clay between the upper brick and the old timber lining and filling the space with grout under pressure, and the removal of the cracked bricks. These should at once be replaced by an adhering layer of steam-jetted concrete, sufficiently reinforced, if necessary, to take its share of the load and continued 2 in. below the old surface.

In August, 1915, a work train was equipped for the job. The engine was provided with an extra air compressor, a steam pump and a dynamo for electric lighting. A pressure reducing valve set at 90 lb. was connected from an extry heavy nipple on the dome and a 2-in. steam connection carried with Franklin ball and socket joints and suitable couplings to a flat car on which was placed the concrete atomizer. The same car carried the cement, sand and gravel. As it would be difficult to control by hand a nozzle for jetting the concrete on to the roof, I designed for this purpose a nozzle car and trowelling machine which would place the concrete, would indicate the depth applied and would trowel or finish the final layer. The second flat car in the train carried this machine which was mounted on a platform capable of vertical or lateral adjustment, so that it could be made to swing from center line of arch. The nozzle was secured to a shaft mounted on suitable journals and was moved from side to side by a reversible two-cylinder steam engine. The same shaft carried the distance indicator and the trowelling devices. The nozzle car was mounted on wheels running on channel irons and could be moved back and forth 10 ft. by means of a stationary windlass. Steam connections to the engine and to the nozzle were made by means of suspended lengths of wire protected rubber hose. Beyond the second flat car was a box car provided with a railed platform on the roof. Here three men operated a water jet to clean the soot and dirt from the walls, and light pneumatic hammers for removing the defective brick. A signal whistle mounted on the engine which could be sounded from any part of the train was used to control the flow of air, water, steam and concrete. Two acetylene headlights as well as a number of incandescent lamps were used for general illumination.

When the work was started on Sept. 4, I found that the pneumatic drills provided were not heavy enough to penetrate the brickwork for the necessary 3-in. weep holes. Rather than delay until the proper drills could be obtained, I started operations at the eastern portal where water was pouring in streams through the roof. A mixture of 1 part cement, 3 parts of sand and 2 parts of pebbles were used with 10 per cent of water. These were mixed in the concrete atomizer at 90 lb. pressure, with the superheat obtained by dropping from engine working pressure through reducing valve. The concrete was carried through 2-in. hose and shot on to the brick by a steam jet. Although the pebbles at first dropped away, they nevertheless forced the mortar into all the interstices of the brickwork and checked the flow of water. But very little material bounded off and this was collected and used.

Before shooting a load, steam was jetted through the nozzle to complete the cleaning of the brickwork and heat it to the temperature of the concrete. In some places a layer of concrete 7 in. thick was jetted on to the roof and it set up so quickly that the work train could be immediately followed by an east bound freight without trouble from the engine exhaust.

In the final layer lime hydrate was added and the pebbles were omitted. The proportions were 1 part of hydrate to 10 parts of cement and 30 parts of sand. This gave a smooth flowing mixture and delayed the setting so that when the steam jet from the nozzle car was passed over the surface a second time without concrete, a smooth finish was obtained and trowelling was unnecessary.

The work was in charge of my superintendent while the men composing the crew were employes of the railway. Three men cleaned the roof, one man operated the nozzle car, one worked the windlass, one ran the atomizer and two men measured and loaded the materials. The improved machine is arranged so that but one man is needed to work the nozzle car and the windlass. It required about 5 minutes for the gang to clean 10 ft. of roof, load the atomizer, steam the roof and treat and apply the load. As it was important not to interfere with train service upon a double track road through a single track tunnel, only about 6 working hours per day were available in the tunnel. An average of 262 ft. of lining 12 ft. wide and 3 to 4 in. thick was applied in 6 hours, using 35 bags of cement. The concrete was found to be so strong that no reinforcement was needed, nor was it necessary to fill with grout the space above the arch. The work was finished in 41 days, and C. G. Delo, Chief Engineer, pronounced it entirely satisfactory.

Cost Data on Lining Two Tunnels, One with Brick and One with Concrete and Brick.—In Engineering and Contracting, Jan. 14, 1914, George Harper publishes the accompanying data which give the cost of lining two tunnels, exclusive of the portals. The figures for the West Virginia tunnel are for brick arching and packing alone. On the Pennsylvania tunnel the entire lining from footings up is concrete exclusive of one course of fire brick lining in arch area affected by gas and smoke. This single course lining was tied into the concrete with headers every fourth course.

The West Virginia work was put up by thoroughly experienced tunnel contractors, whose system, organization and general methods were of the best and had been evolved from the result of years of experience. The work on the tunnel in Pennsylvania was done by another firm with not so much experience in this line of work, and whose methods were somewhat more expensive, cumbersome and inexperienced. The costs are from private notes and from close contact with both of these undertakings. The brick lining cost in the tunnel in West Virginia is $26.15 per lin. ft., for the arching and packing, and with the concrete walls and footings added it will approximate in all about $40.15 per lin. ft.

West Virginia Tunnel.—The length of this tunnel is 4,211 ft. The tunnel width is 31 ft. The radius of the arch is 15 ft. 6 ins. The arch consists of five rings of brick laid up in five courses with 1 to 3 mortar. An individual brick measured 3 × 4 × 9 ins. The bricklayers worked 167 shifts. Only one shift was worked by others than bricklayers. The time lost due to moving, delays, etc., amounted to 28 shifts. The number of shifts as calendar days amounted to 196. The average length of tunnel lined per shift for the 168 shifts of actual working time was 25 ft. The tunnel lining was carried on simultaneously at different points along the length of the tunnel and for this reason four closures were made. For each lin. ft. of arch 1,227 bricks were required, making in all 5,166,897 bricks in the arch. In each spandrel wall, spacing 5 ft. 4 ins., there were 1,564 bricks; 156,400 bricks in all were used for the spandrel walls. For extra work including portals, bad ground, etc., 31,825 bricks were used. The number of culls, bats, etc., amounting to ¾ of 1 per cent, were 40,878, making the total number of bricks used for the lining 5,396,000. The packing averaged 2 cu. yds. and 4 cu. ft. to each lineal foot of tunnel. The cost data on the West Virginia work are given in Tables VII to X, inclusive. The cost data on the Pennsylvania tunnel are given in Tables XI to XIV, inclusive. The former work was done in 1911 and 1912, while the latter was done in 1912, from July to December.

TABLE VII.—COST OF BRICK ARCH TUNNEL LINING (4,211 LIN. FT.) IN WEST VIRGINIA TUNNEL

	Total shifts	Total cost	Cost per lin. ft.
Bricklaying	7,392	$ 20,580	$ 4.84
Moving centers	672	1,806	0.43
Lagging	504	1,176	0.26
Packing	2,520	4,410	1.05
Key	840	1,075	0.26

Propn. timekeeper and office	10.00	0.38

TABLE X.—COST OF MATERIAL FOR ARCH AND PACKING OF WEST VIRGINIA TUNNEL, F. O. B. PORTAL

	Rate	Cost per lin. ft.
Brick (5,396,000 M.)	$8.25	$10.57
Cement (6,600 bbls.)	1.40	2.20
Sand (3,500 cu. yds.)	.80	0.66
Packing stone (9,050 cu. yds.)	.75	1.61
		$26.14

TABLE XI.—COST DATA ON LINING AND ARCHING ON 4,000 LIN. FT., AND WITHOUT PORTALS, PENNSYLVANIA TUNNEL

Cost, walls, footings and arches	Cost per cu. yd.	Cost per lin. ft.	Basis of figures
Arches, walls with footings and brick	$7.74	$54.20	154.02 cu. yds. concrete in walls.
Arches, walls with brick and without footings	7.43	51.98	
Arches, walls with footings and without brick	7.00	49.01	120.24 cu. yds. concrete in arch.
Arches, walls without brick and footings	6.68	46.79	
Footings:			
Material and labor, 8,000 ft.—1,777 cu. yds.—at $5	.....	2.22	11.08 cu. yds. concrete in footings.
Bricklaying and labor:			
On 4,000 ft. arch only		5.19	286.07 cu. yds. concrete in sec. of 40 ft.
			28,000 cu. yds. concrete, cement and brick used as concrete unit, and without footings.

ESTIMATED QUANTITIES OF MATERIAL

Cement, bbls., 34,500 "Alphia,"	@ $ 1.10 per bbl.	Does not include footings
Sand, cu. yds., 12,160	@ 1.40 per c. y.	
Gravel, cu. yds., 14,560	@ 1.20 per c. y.	
Stone, cu. yds., 7,280	@ 1.30 per c. y.	
Fire brick, M.'s, 900	@ 11.60 per M.	

Work consumed 163 days, an average of 24.50 ft. per day, inclusive of all delays.
Proportion used mortar, 1 and 3.
Proportion used concrete, 1-3 and 5.

TABLE XII.—COST OF PENNSYLVANIA TUNNEL LINING, CONCRETE WALLS AND ARCHING, FOR ENGINES, CARS AND LABOR ONLY

(4,000 lin. ft.)

Walls, bricklaying and arching	Av. No. of men, basis of 13-hour shift	Unit of time for each 40′ sect. 39 hours	Rate per hour	Cost per lin. ft.
Arching—bricklayers	1	39	$1.00	$0.98

Mixer fireman	1	39	0.25	0.24
Pump fireman	1	39	0.25	0.24
				$5.84

Comparative Cost of Excavating and Lining Tunnel With and Without Compressed Air.—The Detroit River Tunnel built for the Michigan Central

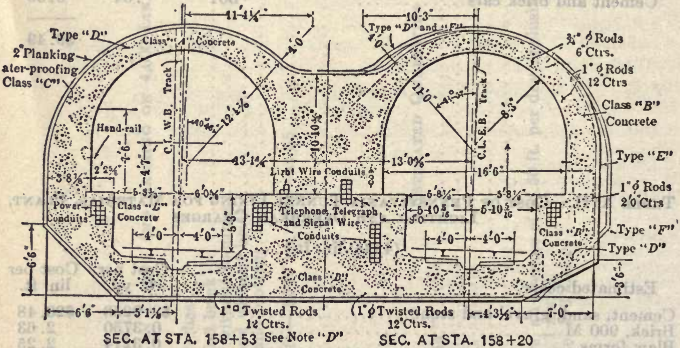

FIG. 11.—Typical section of westerly approach tunnel, Detroit River.

R. R. is a twin tube structure comprising a subaqueous section 2,668 ft. long, a westerly approach tunnel 3,669 ft. long, including 1,510.5 ft. of open cut approach, and an easterly approach tunnel 6,449.2 ft. long, including 2,900 ft. of open cut.

Fig. 11 gives, at a glance, the general type of construction.

According to W. S. Kinnear, (Proc. Am. Soc. C. E., Vol., XXXVII) Engineering and Contracting, Sept. 27, 1911, the rate of progress of excavation at Windsor, with the shields and in the drifts, under favorable conditions, was about the same as at Detroit, being approximately 10 ft. per day of 24 hours with the shields and 12 ft. per day in the drifts. The maximum distance covered by one of the shields in a single day was 19 ft. 10 ins.

The cost of excavating in drifts without compressed air averaged about $2.40 per cu. yd. under favorable conditions; with compressed air, the cost was about $3.50 per cu. yd., except for the work near old Shaft No. 1, where the cost ran as high as $16 per cu. yd. With the shields the fair average cost was $4.90 per cu. yd. These costs include timbering, compressed air, and incidentals. The cost of the compressor plant for supplying air to two side-shield headings and two center-wall headings was a trifle more than $80 per day.

Concrete.—In the easterly approach tunnel the concrete was placed in the same manner as for the westerly approach, except that all concrete was delivered in dump-cars in the tunnel. Arches were filled by shoveling the concrete into the form from the end, as the form for a 12-ft. section was set up complete before concreting was started. Concrete for the center wall, back of the center shield, was delivered in cars up to a level just below the water-proofing course, and above that through chute holes put down from the surface at intervals of about 30 ft. All concrete for the portion of the center wall built under compressed air was delivered in the drifts in cars, as previously stated. The average cost of the 1:2:4 concrete was about $8.25 per cu. yd. in the side-shield headings, and a little more than $6 per cu. yd. in the center wall, where it was deposited through chutes; in the drifts, under fompressed air, the cost was about $10.70 per cu. yd.

Cost of Concrete and Brick Linings of the Land Sections of the Hudson River Tunnels of the Pennsylvania Railroad.—The following matter, published in Engineering and Contracting. May 4. 1910, is extracted from a paper by B. H. M. Hewett and W. L. Brown, Proceedings A. S. C. E., Vol. XXXVI.

The land tunnels of the North River Tunnels of the Pennsylvania R. R. at New York city consist of 1,207 lin. ft. of double tunnel, 977 ft. on the New York side and 230 ft. on the New Jersey side.

The general design of the cross-section consists of a semi-circular arch, vertical side-walls and a flat invert, as shown in diagram by Fig. 1. The tunnel is adapted for two lines of track, each being contained in its compartment or tunnel. The span of the arch is wider than is absolutely necessary to take the rolling stock, and the extra space is utilized by the provision of a sidewalk or "bench" forming by its upper surface a gangway, out of the way of traffic, for persons walking in the tunnels, while embedded in its masss are a number of vitrified earthenware ducts, for high and low-tension electric cables. The provision of this bench enables its vertical wall to be brought much nearer to the side of the rolling stock than is usually possible, thus minimizing the effects of a derailment or other accident. Refuge niches for trackmen, and ladders to the top of the bench, are provided at frequent intervals. In cases where a narrow street limits the width of the structure, as on the New York side, the two tunnels are separated by a medial wall of masonry, thus involving excavation over the entire width of both tunnels, and in such case the tunnels are spoken of as "Twin Tunnels;" where the exigencies of width are not so severe, the two tunnels are entirely distinct, and are separated by a wall of rock. This type is found on the Weehawken side. The arches are of brick, the remainder of the tunnel lining being of concrete.

The general sequence of building the masonry lining is shown in Fig. 12. The operations were as follows:

1. Laying concrete for the whole height of the sand-walls, and for the floor and foundations for walls and benches up to the level of the base of the conduits.

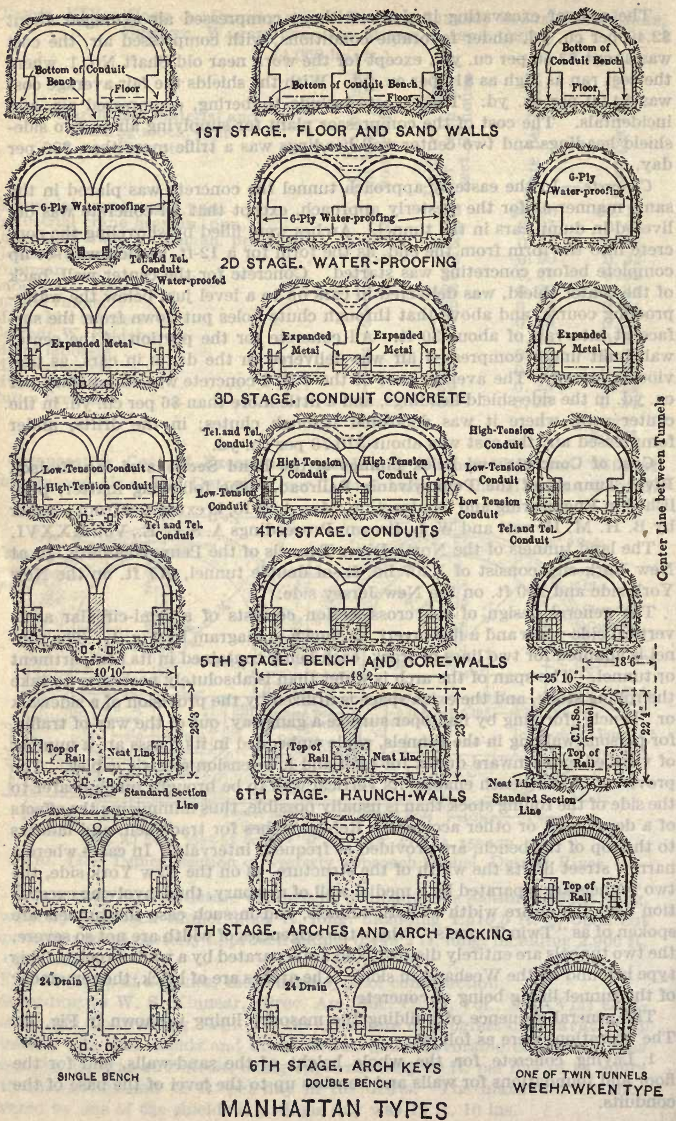

FIG. 12.—Sections showing sequence of operations in placing concrete tunnel lining.

2. Water-proofing the side-walls, and, where there was a middle trench containing subgrade conduits, laying and water-proofing these conduits.

3. Building concrete wall for conduits to be laid against, and where there was a middle trench, filling up with concrete between the conduits.

4 Laying conduits.

5. Laying concrete for benches and middle-wall.

6. Building haunches from top of bench to springing of brick arch.

7. Building brick arch and part of concrete back-filling.

8. Finishing back-filling.

The whole work will be generally described under the headings of Concrete, Brickwork, Water-proofing and Electric Conduits.

Concrete.—The number of types and the obstructions caused by the heavy posting of the timbering made it inadvisable to use built-up traveling forms at the Manhattan side, though they were used in the Weehawken Rock Tunnels.

The specifications required a facing mixture of mortar to be deposited against the forms simultaneously with the placing of the concrete. This facing mixture was dry, about 2 ins. thick, and was kept separate from the concrete during the placing by a steel diaphragm. The diaphragm was removed when the concrete reached the top of each successive layer, and the facing mixture and concrete were then tamped down together. This method was at first followed and gave good results, which was indeed a foregone conclusion, as the Weehawken shaft had been built in this way. However, it was found that as good results, in the way of smooth finish, were to be obtained without the facing mixture by spading the concrete back from the forms, so that the stone was forced back and the finer portion of the mixture came against the forms; this method was followed for the rest of the work. All corners were rounded off on a 1-in. radius by moldings tacked to the forms. The forms were used about four times, and were carefully scraped, planed, filled at open joints and oiled with soap grease each time they were set up. When too rough for face work they were used for sand-wall and other rough work.

The mixing was done by a No. 4 Ransome mixer, driven by 30-hp. electric motors. The mixer at Manhattan was set on an elevated platform at the north end of the intercepting arch; that at Weehawken was placed at the entrance to the tunnels. The sand and stone were stored in bins above the mixers, and were led to the hoppers of the mixers through chutes. The hoppers were divided into two sections, which gave the correct quantities of sand and stone, respectively, for one batch. The water was measured in a small tank alongside. A "four-bag" batch was the amount mixed at one time, that is, it consisted of 4 bags of cement, 8¾ cu. ft. of sand, and 17½ cu. ft. of broken stone, and was called a 1:2½:5 mixture. It measured when mixed about ¾ cu. yd.

The cement was furnished to the contractor by the railroad company, which undertook all the purchasing from the manufacturer, as well as the sampling, testing and storing until the contractor needed it. The railroad company charged the contractor $2 a barrel for this material.

The sand was required by the specifications to be coarse, sharp, and silicious, and to contain not more than 0.5 per cent of mica, loam, dirt or clay. All sand was carefully tested before being used. The stone was to be a sound trap or limestone, passing a 1½-in. mesh and being retained on 2⅜-in. mesh. The contractor was allowed to use a coarser stone than this, namely, one that had passed a 2-in. and was retained on a 1½-in. mesh.

The concrete was to be machine-mixed, except in cases of local necessity. The quantity of water used in the mixture was to be such that the concrete would quake on being deposited, but the engineer was to use his discretion on this point. Concrete was to be deposited in such a manner that the aggregates would not separate. It was to be laid in layers, not exceeding 9 ins. in thickness and thoroughly rammed. When placing was suspended a joint was to be formed in a manner satisfactory to the engineer. Before depositing fresh concrete, the entire surface on which it was to be laid was to be cleaned, washed and brushed, and slushed over with neat cement grout. Concrete which had begun to set was not to be used, and retempering was not to be allowed The forms were to be substantial and hold their shape until the concrete had set. The face forms were to be of matched and dressed planking, finished to true line and surfaces; adequate measures were to be taken to prevent concrete from adhering to the forms. Warped or distorted forms were to be replaced. Plastering the face was not allowed. Rock surfaces were to be thoroughly washed and cleaned before the concrete was deposited. These specifications were followed quite closely.

A typical working gang, as divided among the various operations, is shown below:

	Per month
Superintendence:	
½ superintendent at	$250
½ assistant engineer at	150
1 assistant superintendent at	150
Surface transport:	Per day
1 foreman at	$2.50
1 engineer at	3.00
1 signalman at	2.00
16 laborers at	1.75
3 teams at	7.50
Laying:	
1 foreman at	$4.00
8 laborers at	2.00
Forms:	
1 foreman at	$4.50
4 carpenters at	3.25
5 helpers at	2.25
Tunnel transport:	
¼ foreman at	$3.25
¼ engineer at	3.00
¼ signalman at	2.00
4 laborers at	1.75
Mixers:	
¼ foreman at	$3.25
2 laborers at	1.75

The superintendent and assistant engineer looked after the brickwork and other work as well as the concrete. The surface transport gang handled all the materials on the surface, including the fetching of the cement from the cement warehouses.

The tunnel transport gang handled all materials in the tunnel, but, when the haul became too long, the gang was reinforced with laborers from the laying gang. Of the laying gang, two generally did the spading, two the spreading and tamping, and the remaining force dumped the concrete. The general cost of this part of the work is shown in Table XV.

The figures in Table XV include the various items built into the concrete and some that are certificate extras in connection with the concrete, such as drains, ironwork and iron materials, rods and bars, expanded metal, doors, frames and fittings, etc.

Water-Proofing.—According to the specifications, the water-proofing was to consist of seven layers of pitch and six layers of felt on the side-walls and a ½-in. layer of mastic, composed of coal-tar and Portland cement, to be plastered over the outside of the arches.

By the time the work was in hand, some distrust had arisen as to the efficiency of this mastic coating, and a great deal of study was devoted to the problem of how to apply a felt and pitch water-proofing to the arches. The difficulty was that there was no room between the rock and the arch or between the timber and the arch (as the case might be) in which to work. Several ingenious schemes of putting the felt on in layers, or in small pieces like shingles, were proposed and discussed, and a full-sized model of the tunnel arch was even built on which to try experiments, but it was finally decided to overcome the difficulty by leaving out the arch water-proofing altogether and simply building in pipes for grouting through under pressure, in case it was found that the arch was wet.

As to the arch built through the length excavated by cut-and-cover on the New York side, it was resolved to water-proof that with felt and pitch exactly as the side-walls were done, the spandrel filling between the arches being raised in a slight ridge along the concrete line between tunnels in order to throw the water over to the sides. The portions of arch not water-proofed were rather wet, and grouting with a 1:1 mixture was done, but only with the effect of stopping large local leaks and distributing a general dampness over the whole surface of the arch.

TABLE XV.—COST OF CONCRETE IN LAND TUNNELS, IN DOLLARS PER CUBIC YARD

	Manhattan	Weehawken	Total yardage
Cubic yards placed	14,706½	3,723	18,429½
Labor:			
Surface transport	$ 0.31	$ 1.43	$ 0.54
Superintendence and general labor at point of work	0.31	1.31	0.51
Mixing	0.52	0.56	0.53
Laying	1.38	1.45	1.39
Tunnel transport	1.30	1.47	1.34
Cleaning	0.21	....	0.17
Forms, erecting and removal	1.58	1.51	1.56
Total labor	$ 5.61	$ 7.73	$ 6.04
Material:			
Cement	$ 2.30	$ 2.22	$ 2.28
Sand	0.34	0.40	0.36
Stone	0.91	0.61	0.85
Lumber for forms	0.47	0.45	0.47
Sundry tunnel supplies	0.16	0.17	0.16
Total materials	$ 4.18	$ 3.85	$ 4.12
Plant running	$ 0.44	$ 0.44	$ 0.44
Surface labor, repairs and maintenance	0.25	1.24	0.44
Field office administration	0.50	1.72	0.75
Total field charges	$ 10.98	$ 14.98	$ 11.79
Plant depreciation	$ 0.62	$ 1.57	$ 0.81
Chief office administration	0.24	0.31	0.25
Total average cost per cubic yard	$ 11.84	$ 16.86	$ 12.85
Cost of miscellaneous items in concrete:			
Amount, in dollars	$6,184.83	$1,756.79	$7,941.62
Unit cost	0.42	0.47	0.43

The 24-ft. 6-in. tunnel adjoining the Terminal Station-West was water-proofed by a surface-rendering method which, up to the present time, has been satisfactory. Generally speaking, the arches of the land tunnels, though not dripping with water, are the dampest parts of the whole structure from Tenth Ave. to Weehawken, and it would seem as if some form of water-proofing over these arches would have been a distinct advantage.

There was no difficulty in applying the water-proofing on the side-walls, after a little experience had been gained as to the best methods. The specifications required the sand-wall to be covered with alternate layers of coal-tar pitch and felt, seven layers of the former and six layers of the latter, the felt to be of Hydrex brand or other equally satisfactory to the engineer. The pitch was to be straight-run, coal-tar pitch which would soften at 60°F., and melt at 100°F., being a grade in which distillate oils, distilled from it, should have a specified gravity of 1.105. The pitch was to be mopped on the surface to a uniform thickness of 1–16 in., and a covering of felt, previously mopped with pitch, was to be applied immediately. The sheets were to lap not less than 4 ins. on cross-joints and 12 ins. on longitudinal joints, and had to adhere firmly to the pitch-covered surface. This layer was then to be mopped, and another layer placed, and so on until all the layers were in place. This water-proofing was to extend from the bottom of the cable conduits to the springing of the brick arch. Where sub-track conduits were used, these were to be surrounded with their own water-proofing. The work was carried out as specified; the sand-walls were not rendered, but were built smooth enough to apply the water-proofing directly to them. They were dried with gasoline torches before the application of the pitch, and in very wet sections grooves were cut to lead the water away.

The first attempts were with the felt laid in horizontal strips. This ended very disastrously, as the pitch could not sustain the weight of the felt, and the whole arrangement slipped down the wall. The felt was then laid vertically, being tacked to a piece of horizontal scantling at the top of the sand-wall and also held by a row of planks braced against it at about half its height. A layer of porous brick was laid as a drain along the base of the water-proofing, covered by a single layer of felt to prevent it from becoming choked with concrete.

The water-proofing of the sub-track conduits was troublesome, as the numerous layers and the necessity for preserving the proper laps in both directions between adjacent layers made the whole thing a kind of Chinese puzzle. Various modifications to suit local conditions, were made from time to time. Conduits outside the general outline of the tunnel are difficult to excavate, to lay, and to water-proof, and should be avoided wherever possible.

TABLE XVI.—COST OF WATER-PROOFING, IN DOLLARS PER SQUARE FOOT

	Manhattan	Weehawken	Total
Square feet covered	47,042	13,964	60,736
Labor	$0.07	$0.07	$0.07
Material	0.12	0.09	0.11
Total field charges	$0.19	$0.16	$0.18
Chief office and plant depreciation	0.01	0.03	0.02
Total average cost	$0.20	$0.19	$0.20

The usual force in water-proofing consisted of a foreman, at $3.50 per day, and nine laborers at $1.75 per day. These men not only laid the water-proofing, but transported the materials, heated the pitch, and cut up the rolls of felt. In general, two men transported material, one tended the heater, and the other six worked in pairs, two preparing the surface of the concrete sand-wall, two laying pitch, and two laying felt.

The cost of the water-proofing operation was about as shown in Table XVI.

Brickwork in Arches.—Owing to the heavy timbering, the brickwork at Manhattan was interfered with to a considerable extent, and the gang was always kept at work at two or more places. The work was carried up to a point where it was necessary to back-fill, or prop or cut away encroaching timbers, and then the men were moved to another place while this was being done.

The centers were set up in sets of seven, spaced 4 ft. apart. Two 14-ft. lengths of 3 by 4-in. yellow pine lagging were used with each set of ribs, with 24 × 8-in. block lagging in the crown.

All centers were set ¼ in. high, to allow for settlement, except in the 24-ft. 6-in. span, in which they were set ½ in. high. This proved ample, the average settlement of the ribs being 0.01 ft. and of the masonry 0.003 ft. In the 24-ft. 6-in. span the ribs were strengthened with 6 × 6-in. blocking and 12 × 12-in. posts to subgrade. Great trouble was here encountered with encroaching timbering, due to the settlement of the wide flat span. Grout pipes were built in, as previously mentioned.

Each mason laid an average of 0.535 cu. yd. of brickwork per hour, or 4.28 cu. yds. per day. The number of bricks laid per mason per hour was 218, or 1,744 per day.

The bricks were of the best quality of vitrified paving brick, and were obtained from the Jamestown Brick Co., of Jamestown, N. Y. The average size was 8¾ × 3 15–16 × 2 7–16 ins.; the average number per cubic yard of masonry was 408, the arches being from 19 ft. to 24 ft. 6 ins. in span and from 22 to 27 ins. thick. The joints were 3–16 in. at the face and averaged 9–16 in. through the arch.

The proportions for mortar were 1 of cement and 2½ of sand. One cubic yard of masonry was composed of 73.5 per cent brick and 26.5 per cent mortar. The volume of the ingredients in a four-bag batch was 12.12 cu. ft. and the resulting mixture was 9.54 cu. ft. The number of barrels of cement was 0.915 per cu. yd. of masonry, and about 17.7 per cent of the mortar made was wasted. The average force employed was:

	Per day
Laying:	
1 foreman at	$8.00
4 layers at	6.00
8 tenders at	2.00
2 mixers at	2.00
Forms:	
1 foreman at	$4.50
4 carpenters at	3.50
5 helpers at	2.25
Transport:	
¼ hoist engineer at	$3.00
¼ signalman at	2.00
4 laborers at	2.00

For materials, the following prices prevailed: Cement, $2.00 per bbl.; Sand, $0.90 to $1.00 per cu. yd.; Brick $16 per thousand, delivered at yard; Centers, $26 each; Lagging, $45 per 1,000 ft. B. M. The cost of the brickwork is given in Table III.

TABLE XVII.—COST OF BRICKWORK

	Manhattan	Weehawken	Total
Cubic yards placed	4,137	790	4,927
Labor:			
Surface transport	$ 0.35	$ 1.19	$ 0.48
Superintendent and general labor at point of work	0.17	0.04	0.16
Laying and mixing	2.58	3.20	2.60
Forms: erection and removal	2.62	0.32	2.25
Tunnel transport	1.19	1.12	1.18
Total labor	$ 6.91	$ 5.87	$ 6.75
Material:			
Brick	$ 6.56	$ 6.56	$ 6.56
Cement	1.76	1.75	1.76
Sand	0.20	0.28	0.22
Forms	0.92	0.98	0.93
Overhead conductor pockets	0.15	0.09	0.11
Total material	$ 9.59	$ 9.66	$ 9.60
Plant running	$ 0.55	$ 0.30	$ 0.51
Surface labor, repairs and maintenance	0.36	1.30	0.51
Field office administration	0.55	0.88	0.60
Total field charges	$17.96	$18.01	$17.97
Chief office administration	$ 0.60	$ 0.66	$ 0.61
Plant depreciation	0.35	0.64	0.39
Total average cost per cubic yard	$18.91	$19.31	$18.97

In Table XVIII the cost of grout is expressed in terms of barrels of cement used, because that was in the schedule of prices attached to the contract as the unit of payment for grout.

TABLE XVIII.—COST OF GROUT OVER ARCHES IN LAND TUNNELS, IN DOLLARS PER BARREL OF CEMENT USED

	Manhattan (Gy- East only)	Weehawken	Total
Barrels used	3,000½	261½	3,262
Labor	$0.55	$0.46	$0.53

Field office administration	0.08	0.06	0.08
Plant and supplies	0.10	0.07	0.09
Total field charges	$3.03	$2.84	$2.98
Chief office and plant depreciation	0.21	0.22	0.22
Total average cost	$3.24	$3.06	$3.20

Vitrified Earthenware Conduits for Electric Cables.—The general drawings will show how the ducts were arranged, and that manholes were provided at intervals. They were water-proofed, in the case of those embedded in the bench, by the general water-proofing of the tunnels, which was carried down to the level of the bottom of the banks of ducts; and in the case of those below subgrade, by a special water-proofing of felt and pitch wrapped around the ducts themselves.

The portion of wall in front of the ducts was bonded to that behind by bonds, mostly of expanded metal, passing between the ducts. Examples of the bonding will be seen in the drawings.

The joints between successive lengths of 4-way and 2-way ducts were wrapped with two thicknesses of cotton duck, 6 in. wide, those of single-way ducts were not wrapped, but plastered with cement mortar. The ducts were laid on bed of mortar, and were made to break joints at top and bottom, and side to side with the adjacent ducts. They were laid with a wooden mandrel; a square leather washer at the near end acted as a cleanser when the mandrel was pulled through.

The specifications required the ducts to be laid at the same time as the concrete and be carried up with it, but this was found to be a very awkward operation, as the tamping of the concrete and the walking of men disturbed the ducts, especially as the bonds lay across them. It was resolved, therefore, to build the portion of the wall behind the ducts first, with the bonds embedded in it at the proper heights and projecting from it, then to lay up the banks of ducts against this wall, bending the bonds down as they were reached, and finally, after all the ducts were in, to lay the concrete in front of and over the top of the ducts. Several detailed modifications of this general scheme were followed at one time or another when necessary or advisable.

The laying of ducts below subgrade was not complicated by the presence of bonds; the water-proofing caused the trouble here, as before described.

The specifications called for a final rodding after completion. Ordinary ¾-in. gas pipe was used for the rod, and a cutter with rectangular cross-section and rounded corners was run through ahead of the mandrel; following the cutter came a scraper consisting of several square leather was ers, of the size of the ducts, spaced at intervals on a short rod. The mandrel itself was next put through, three or four men being used on the rods. All the ducts in a bank were thus rodded from manhole to manhole. When a duct was rodded it was plugged at each end with a wooden plug. A solid wooden paraffined plug was used at first, but afterward an expansion plug was used.

Very little trouble was met in rodding the power conduits, except for a few misplaced ducts, or a small mound of mortar or a laying mandrel left in. At such points a cut was made in the concrete and the duct replaced.

In the subgrade telephone and telegraph ducts east of the Manhattan Shaft, much trouble was caused by grout in the ducts. The mandrel and cutters were deflected and broke through the web of the ducts rather than remove this hard grout. Trenches had to be cut from the floor to the top of the water-proofing, the latter was then cut and folded back, and the ducts replaced. To do this, a number of ducts had to be taken out to replace the broken ones and get the proper laps. The water-proofing was then patched and the concrete replaced. This grout had not penetrated the water-proofing, but had got in through the ends of the ducts where they had not been properly plugged and protected. The duct gang, both for laying and rodding, generally consisted of 1 foreman, at $3.50 per day, and 9 laborers, at $1.75 per day. When laying: 4 men were laying, 2 men mixing and carrying mortar, and 3 were transporting material. When rodding: 4 men were rodding, 2 men at adjacent manholes were connecting and disconnecting cutters and mandrels, 1 was joining up rods, and 2 men assisting generally.

The cost of this work is shown in Table V.

TABLE XIX.—COST OF CONDUIT WORK

	Manhattan	Weehawken	Total
Duct feet	115,962	35,155	151,117
Labor	$0.035	$0.032	$0.034
Material	0.043	0.052	0.045
Total field charges	$0.078	$0.084	$0.079

Total average cost	$0.083	$0.092	$0.085

Economy Effected by the Rogers Pass Tunnel.—The following article, reprinted in Engineering and Contracting, Nov. 17, 1915, from the Cornell Civil Engineer for December, 1914 was written by J. G. Sullivan, Chief Engineer of the Western Lines of the Canadian Pacific Ry.

The calculations showing the economy to be attained over the present alignment by constructing the Rogers Pass Tunnel of the Canadian Pacific Railway are here given.

The data to be taken into account are as follows: Present location, total distance 23.1 miles, revised location 18.68 miles. Grades consist on the present location, of 16.65 miles up hill for westbound traffic on maximum grade of 2.2 per cent, 6.45 miles down grade same maximum with a total rise of 1,726 ft. and a drop of 692.1 ft. with 1,860° of curvature on the up-hill and 1,288° on the downhill portion of the line. The revised location consists of 16.77 miles up hill with about 5 miles of 2.2 per cent pusher grade, the balance 1 per cent and a down-hill run of 1.91 miles with a maximum of 2.2 per cent grade; a total rise of 1,178.2 ft. and a drop of 144.3 ft., with 635° of curvature on the up-hill grade and 66° on the down-hill. The average traffic for the years 1912 and 1913, which is made the basis of calculation, was 1,342½ passenger trains in each direction; the average weight of the passenger trains, exclusive of locomotives, was 443 tons; 980 of the passenger trains required pusher engines; the weight of the passenger and pusher engines for passenger trains was 175 tons each; there were 1,738½ freight trains in each direction per year; the average weight of the freight trains eastbound, exclusive of locomotives, was 950 tons; the average weight of freight trains westbound was 898 tons; all freight trains had to be pushed in both directions; weight of freight locomotives and pushers, 181 tons each. The tonnage eastbound and westbound was as follows:

Eastbound

	Tons
1,342½ trains @ 443 tons each	594,727.5
2,322 locomotives @ 175 tons each	406,350.0
1,738½ freight trains @ 950 tons each	1,651.575.0
3,477 locomotives @ 181 tons each	629,237.0
Total	3,281,889.5

Westbound

	Tons
1,342½ trains @ 443 tons each	594,727.5
2,322 locomotives @ 175 tons each	406,350.0
1,738½ freight trains @ 898 tons each	1,561,173.0
3,477 locomotives @ 181 tons each	629,237.0
Total	3,191,487.5

Comparison of Comparable Factors Affecting the Cost of Operating Over Rogers Pass, Via Present Line and Via Tunnel Line, Now Under Construction, Average Traffic for the Years 1912 and 1913

E. B. tonnage per year, including weight of engines, 3,281,890 tons
Resistance to Overcome, on Present Line

	Ft.	Ft.
Actual rise, 692.1 ft	692.1	
Curve resistance, 1,288° × .04 ft	51.5	
Friction resistance, 6.45 mls. × 15 ft	96.7	
Total		840.3

Resistance to Overcome, Tunnel Line

	Ft.	Ft.
Actual rise, 144.3 ft.	144.3

	1,898,935,360
Total	4,080,735.832

One thousand foot-tons equals approximately 1 horsepower hour. Assuming that 5 lbs. of coal is consumed in doing 1 horsepower hour's work and that coal on locomotive costs $4.60 per ton, the saving in fuel will amount to

$$\frac{4{,}080{,}736 \times 5 \text{ lbs.} \times \$4.60}{2{,}000 \text{ lbs. (one ton)}} = \$\,46{,}928.46$$

Extra Wages Train and Engine Crews

Present Line

6,162 trains for 23.1 miles	142,342.2 train miles
5,437 push. engs. for 23.1 miles	125,594.7 push. eng. miles

Tunnel Line

6,162 trains for 18.68 miles	115,106.2 train miles
5,437 push. engs. for 13 miles	70,681.0 push. eng. miles
Amount saved	27,236.0 train miles
	54,913.7 push. eng. miles

27,236 train miles at 22 cts.	$ 5,991.92
54,913.7 pusher miles at 25 cts.	13,728.40

Note.—25 cts. to cover engine crew wages, cost of repairs to pusher locomotives and extra cost of maintenance account of running pushers.

Extra cost maintenance of way, 4.42 miles at $200 plus 27,236 train miles at 20 cts.	$ 6,331.20
Extra cost, maintenance of way, account of extra number of degrees of curvature, assuming that 400° of curvature per mile would increase rate at 20 cts. per train mile for maintenance by 30 per cent—	
6,162 trains × 2,447° × $\frac{1}{40}$ ct.	3,769.60
Special maintenance, account 4½ miles snow sheds	85,000.00
Extra cost, maintenance of equipment, 27,236 train miles at 21 cts.	5,719.56
Extra cost, maintenance of equipment, account of extra number of degrees of curvature, assuming that 400° of curvature per mile would increase rate of 21 cts. per train mile by 40 per cent—	
6,162 trains × 2,447° × $\frac{21}{1,000}$ ct.	3,166.47
Total annual saving in cost of operation	$170,635.61

The rate at which traffic has been increasing would indicate that shortly after the work of constructing the tunnel was completed the traffic would have doubled. In this case, if no further economies were made in methods of operating this section of track, the annual saving on account of operating over tunnel line would be—

$$\$85,635.61 \times 2 + \$85,000.00 = \$256,271.22$$

In arriving at the above figure no account is taken of whether line was single or double track and for comparative figures it was assumed that methods of operation would be the same. Now, as a matter of fact, the present single track line with double the present traffic would make the business too congested for economical single-track operation. Therefore, it was apparent that it was time to study the question of double tracking the present line or seeking a new line for double track. It was decided to double track on the 5-mile tunnel location. Now to operate successfully a 5-mile tunnel we will require the installation of an electric plant and the purchase of electric locomotives. All the details of the proposed electrification have not as yet been worked out, but even if they were, the reader is not interested in the details of cost. He can see at once that the problem was to find out if the cost of operating and maintaining the tunnel line, taking into account the extra costs of operating on account of having a short section of electric operation and extra cost of maintaining tracks in the tunnel, plus the interest on the cost of building the new double track line, including the cost of electrifying the tunnel, would be less than the cost of operating and maintaining a double track line on the present location plus the interest on the cost of building the second track. The figures would not have been very decisive one way or the other if not for the fact that there is now 4½ miles of wooden snow sheds on the present location which will be all done away with on the new location. The maintenance and cost of renewals of these sheds cost between $85,000 and $100,000 per year. To maintain and renew a double-track wooden shed would probably cost at least 50 per cent more than the above, so that with a saving of about $125,000 per year in maintenance and renewals of snow sheds and a calculated saving in operation and maintenance of $171,271.22 on a traffic that surely will be reached in the near future, there was no doubt as to the proper course to pursue.

As to the details of figuring economics of railway location, the writer is well aware that it is impossible to devise any method that will show absolutely the saving in cost of operating one line over another, but he believes that the method herein followed, namely, that of comparing cost of fuel on the basis of work done rather than on a train-mile or any other unit, is much more logical and will give more reliable results than other methods that have been followed. The train mile is possibly the best unit for comparison in cost of wages and for cost of maintenance of equipment. In figuring maintenance of way a fixed sum should be taken plus a rate per daily train rather than a fixed rate alone per train mile, for the reason that a certain amount of expense must be incurred regardless of whether trains are run or not. The fixed sum of $200 per mile taken in this problem is probably about one-half the actual sum that would be assumed if the entire cost of maintenance was to be included in this fixed sum per mile plus the rate per train mile for the reason that cost of maintenance of terminals and other items are not affected by the details of location between fixed terminals.

Frictional resistance, normal conditions, warm weather, modern freight equipment, speed between 7 and 35 miles an hour,

$$R = 2.2T + 121.6\ C.$$

R = total resistance on level tangent.
T = total weight cars and contents in tons.
C = total number of cars in train.

This amounts to 4 lbs. per ton to 8 lbs. per ton, depending on whether cars are fully loaded or empty. This is equivalent to a rise of from 10 ft. to 20 ft. per mile. For mixed traffic a conservative estimate is train resistance equals rise of 15 ft. per mile.

It may appear that the rate of 25 cts. per actual pusher mile covering the cost of repairs and engine crew wages and extra cost of maintenance is too high, but as a matter of fact it is very conservative for the repairs, maintenance and renewals of the locomotives alone will run somewhere between 7 cts. and 10 cts. per mile and we have had cases where the engine crew wages alone averaged 25 cts. per mile for the actual mileage run, on account of delays to the pusher.

Reference to Subaqueous Shield Driven Tunnel Costs.—Many valuable data are given in the paper of B. H. M. Hewett and W. L. Brown on the Pennsylvania R. R. Tunnels under the North River, New York. Proceedings of the A. S. C. E., Vol. XXXVI. Certain parts of this paper may be found in abstract form in Engineering and Contracting as follows.

Methods and Cost of Placing Concrete Lining—issue of May 11, 1910.

Labor Required and Average Progress in Constructing Shield Driven Tunnels—issue of May 18, 1910.

First Cost and Cost of Operating Power Plants—issue of May 25, 1910.

Methods and Cost of Calking and Grummeting Joints in Cast Iron Lining—issue of June 15, 1910.

CHAPTER XXI

BANK AND SHORE PROTECTION

In this chapter are given the methods and costs of constructing certain structures for preventing erosion to river banks and also similar data in regard to the construction of breakwaters of various types. Further references, giving costs of bank and shore protection may be found in Gillette's Handbook of Cost Data.

Costs of Brush Mattresses.—The following statements of methods and costs are compiled from various portions of the Report of the Chief of Engineers, U. S. A. for 1910–11 and are printed in Engineering and Contracting, Nov. 13, 1912.

Hopefield Bend, Ark.—The work done during the year comprised 3,505 squares of mattress and 11,332 sq. yds. of paving. The cost of the mattress work was as follows:

Strand ½ in., 1,654 lbs	$ 46.80
Strand 5/16 in., 6,311 lbs	160.30
Strand ¼ in., 19,027 lbs	523.24
Wire No. 12, 8,896 lbs	195.71
Staples, 950 lbs	19.95
Clips ½ in., 156	3.92
Clips 5/16 in., 1,894	136.37
Brush, 5,632 cords	9,287.82
Stone, 4,009 cu. yds	5,482.82
Steamboat expense	1,836.00
Labor, subsistence and supervision	11,824.66
	$29,517.59
No. of squares	3,505.0
Cost per square	$ 8.42
Cords of brush and poles per square	1.60
Cu. yds. of stone per square	1.14
Cu. yds. of stone per cord of brush and poles	0.712

The cost of grading 2,265 lin. ft. of bank involving 33,200 cu. yds. was as follows:

Coal, etc	$ 281.00
Labor, subsistence and supervision	1,736.00
Total	$2,017.00
Cost per lin. ft	$ 0.89
Cost per cu. yd	0.061

The cost of paving 2,265 lin. ft. of bank or 11,332 sq. yds. of paving was as follows:

Stone, 3,342 cu. yds	$4,162.99
Labor, subsistence and supervision	3,170.00
	$7,332.99
Cost per lin. ft	$ 3.83
Cost per sq. yd	0.647
Cu. yd. stone per sq. yd. paving	0.29

A summary of the total cost of the work is as follows:

Total field cost	$38,867.42
Office expense	1,419.53
Surveys	1,392.07
Care of plant	475.18
Repairs to plant	2,267.93
Depreciation to plant	2,135.33
Total cost	$46,557.46

Walnut Bend, Ark.—During the first part of the season no unusual difficulties were encountered. During the latter part of the season, however, rapid rises in the river gave considerable trouble on account of the flooding of the dead-men holes. The paving consists of the usual form of rip-rap except 500 lin. ft. which is concrete 4 in. thick.

The cost of the mattress work follows:

CHANNEL MATTRESS NO. 8
(1,480 ft. long by 254 ft. wide, 3,759 squares)

Strand ½ in., 17,192 lbs	$ 453.08
Strand 5/16 in., 6,386 lbs	162.20
Strand ¼ in., 22,797 lbs	624.64
Wire No. 12, 7,520 lbs	165.44
Wire, silicon bronze, 1,431 lbs	214.51
Staples, 700 lbs	14.70
Clips ½ in., 1,712	44.51
Clips 5/16 in., 2,064	148.61
Miscellaneous material	1,803.01
Brush and poles, 5,077 cords	8,377.05
Stone 2,999 cu. yds	3,548.42
Steam boat expense	3,129.82
Labor, subsistence and supervision	12,170.74
Total	$30,856.73
Cost per lin. ft	$ 20.85
Cost per square	8.20
Cords of brush and poles per lin. ft	3.43
Cords of brush and poles per square	1.35
Cu. yds. of stone per lin. ft	2.02
Cu. yds. of stone per square	0.71
Cu. yds. of stone per cord of brush and poles	0.59

CHANNEL MATTRESSES, NOS. 9 AND 10
(596 ft. long by 250 ft. wide, 1,514 squares)

Strand, ½ in., 6,843 lbs	$ 172.72
Strand, 1/16 in., 3,184 lbs	78.64
Strand, ¼ in., 9,057 lbs	248.16
Wire, No. 12, 4,573 lbs	100.61
Wire, silicon bronze, 650 lbs	97.43
Staples, 400 lbs	8.40
Clips, ½ in., 559	14.53
Clips, 5/16 in., 988	12.45
Brush and poles, 1,881 cords	3,103.65
Stone, 860 cu. yds	1,017.55
Steamboat expense	1,271.70
Labor, subsistence and supervision	8,827.92
Total	$14,953.76
Cost per lin. ft	$ 25.09
Cost per square	9.21
Cords of brush and poles per lin. ft	3.16
Cords of brush and poles per square	1.24
Cu. yds. of stone per lin. ft	1.44
Cu. yds. of stone per square	0.57
Cu. yds. of stone per cord of brush and poles	0.46

CONNECTING MATTRESSES, NOS. 17 TO 26, INCLUSIVE, 2,542 SQUARES

Strand, ½ in., 1,817 lbs	$ 47.24
Strand, 5/16 in., 7,287 lbs	179.99
Strand, ¼ in., 14,560 lbs	398.94
Wire, No. 12, 7,862 lbs	172.96
Staples, 725 lbs	15.23
Clips, ½ in., 223	5.80
Clips, 5/16 in., 2,126	101.39
Brush and poles, 3,790 cords	6,253.50
Stone, 3,241.45 cu. yds	3,835.28
Steamboat expenses	2,135.28
Labor, subsistence and supervision	9,666.06
Total	$22,811.67
New work	2,291 squares
Repair work	251 squares
Cost per square	$8.96
Cords of brush and poles per square	1.49
Cu. yds. of stone per square	1.28
Cu. yds. of stone per cord of brush and poles	0.81

The bank grading amounted to 51,617 cu. yd. for new work and 6,268 cu. yds. for repair work, or a total of 57,885 cu. yds., and its cost was as follows:

6,492 bus. coal	$ 714.00
Labor, subsistence, and supervision	3,318.00
Total	$ 4,032.00
Cost per lin. ft. (new work)	$ 1.50
Cost per cu. yd	0.0696

The bank paving with stone amounted to 25,225 sq. yds., of which 3,772 sq. yds. were repair work. The cost of this paving was as follows:

Stone, 6,352 cu. yds	$11,546.00
Steamboat expense	1,500.00
Labor, subsistence, supervision, etc	7,517.00
Total	$20,563.00
Cost per sq. yd	$ 0.815
Cost per lin. ft. (new work)	9.22
Cu. yds. of stone per sq. yd	0.25

The amount of concrete paving was 5,196 sq. yds., or a stretch of bank 500 ft. long and 93½ ft. wide; its cost was as follows:

Gravel, 631 cu. yds	$ 441.70
Cement, 1,702 sacks	765.90
Coal, 438 bushels	48.18
Wire, Pittsburgh fence, 49,500 sq. ft	245.03
Lumber	25.00
Labor, subsistence and supervision	926.75
Total	$ 2,452.56
Cost per sq. yd	$ 0.472
Cost per lin. ft	4.905
Cu. yds. of gravel per sq. yd	0.12
Sacks of cement per sq. yd	0.33

A summary of the total cost follows:

Total field cost	$115,374.68
Office expense	2,200.36
Surveys	478.60
Care of plant	3,088.73
Repairs to plant	14,741.57
Depreciation of plant	13,879.66
Total cost	$149,763.60

The unit costs for the whole work summarize as follows:

Channel mattress, per lin. ft	$28.45
Connecting mattress, per lin. ft	8.93
Grading, per lin. ft	1.95
Paving per lin. ft	10.82
Total cost per lin. ft. of bank protected	$50.15
Field cost per lin. ft. of bank protected	$38.58

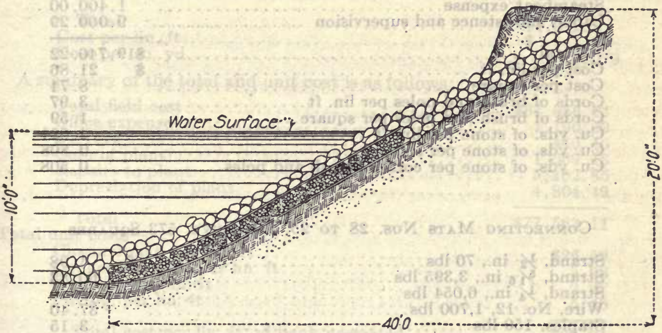

FIG. 1.—Cross section of mattress construction for shore and levee protection

Old Town, Ark.—The work comprised an extension of 1,700 ft. to the previous season's work. The following is the cost of the mattress work:

CHANNEL MATTRESS NO. 9

(798 ft. long by 250 ft. wide, 1,995 squares)

Strand, ½ in., 13,432 lbs	$ 380.13
Strand, 5/16 in., 4,072 lbs	103.43
Strand, ¼ in., 11,243 lbs	309.18
Wire, No. 12, 4,770 lbs	104.94
Wire, silicon bronze, 860 pounds	128.91
Staples, 400 lbs	8.40
Clips, ½ in., 976	24.50
Clips, 5/16 in., 1,406	101.25
Brush and poles, 3,019.7 cords	4,227.58
Stone, 1,682 cu. yds	2,312.30
Steamboat expense	1,236.73
Labor, subsistence and supervision	9,023.53
Total	$17,960.88
Cost per lin. ft	$ 22.50
Cost per square	9.00
Cords of brush and poles per lin. ft	3.78
Cords of brush and poles per square	1.51
Cu. yds. of stone per lin. ft	2.11
Cu. yds. of stone per square	0.84
Cu. yds. of stone per cord of brush and poles	0.55

Channel Mat No. 10

(903 ft. long by 250 ft. wide, 2,257.5 squares)

Strand, ½ in., 12,931 lbs	$ 365.95
Strand, 5/16 in., 5,556 lbs	141.12
Strand, ¼ in., 14,616 lbs	401.94
Wire, No. 12, 6,350 lbs	139.70
Wire, silicon bronze, 704 lbs	142.91
Staples, 450 lbs	9.45
Clips, ½ in., 449	11.27
Clips, 5/16 in., 544	18.73
Brush and poles, 3,589 cords	5,184.14
Stone, 1,825 cu. yds	2,924.72
Steamboat expense	1,400.00
Labor, subsistence and supervision	9,000.29
Total	$19,740.22
Cost per lin. ft	$ 21.86
Cost per square	8.74
Cords of brush and poles per lin. ft	3.97
Cords of brush and poles per square	1.59
Cu. yds. of stone per lin. ft	2.021
Cu. yds. of stone per square	0.808
Cu. yds. of stone per cord of brush and poles	0.508

Connecting Mats Nos. 28 to 25, Inclusive, 573 Squares

Strand, ½ in., 70 lbs	$ 1.98
Strand, 5/16 in., 3,395 lbs	60.83
Strand, ¼ in., 6,054 lbs	160.49
Wire, No. 12, 1,700 lbs	37.40
Staples, 150 lbs	3.15
Clips, ½ in., 36	1.40
Clips, 5/16 in., 650	8.19
Brush and poles, 8,677 cords	1,214.78
Stone, 520 cu. yds	977.08
Steamboat expense	380.00
Labor, subsistence and supervision	2,801.34
Total	$5,646.64
Cost per square	$ 9.85
Cords of brush and poles per square	1.51
Cu. yds. of stone per square	0.91
Cu. yds. of stone per cord of brush and poles	0.60

Connecting Mat No. 27, 191 Squares

(Repairs to old work)

Strand, ½ in., 420 lbs	$ 11.88
Strand, 5/16 in., 600 lbs	15.24
Strand, ¼ in., 1,680 lbs	46.20
Wire, No. 12, 524 lbs	11.53
Staples, 50 lbs	1.05
Clips, ½ in., 10	.25
Clips, 5/16 in., 132	1.66
Brush and poles, 280 cords	396.00
Stone, 180 cu. yds	338.22
Steamboat expense	100.00
Labor, subsistence and supervision	1,082.00
Total	$2,004.03
Cost per square	$ 11.07
Cords of brush and poles per square	1.54
Cu. yds. of stone per square	1.00
Cu. yds. of stone per cord of brush and poles	0.65

The cost of 2,149 lin. ft. or 11,975 sq. yds. of paving was as follows:

Stone 3,711 cu. yds	$6,054.51
Labor, subsistence and supervision	3,632.95
Total	$9,687.46
Cost per sq. yd	$ 0.808
Cost per lin. ft	4.50
Cu. yds. stone per sq. yd. of paving	0.31

The cost of 51,758 cu. yds of grading was as follows:

Coal	$ 570.0
Labor, subsistence and supervision	3,502.0
Total	$4,072.0
Cost per lin. ft	$ 1.89
Cost per cu. yd	0.079

A summary of the total and unit cost is as follows:

Total field cost	$64,956.14
Office expense	1,190.29
Surveys	440.16
Care of plant	1,069.18
Repairs to plant	5,102.85
Depreciation of plant	4,804.49
Total	$77,563.11
Total unit costs—	
Channel mat, per lin. ft	$26.59
Connecting mat, per lin. ft	3.98
Grading, per lin. ft	2.27
Paving, per lin. ft	5.40
Total cost per lin. ft. of bank protected	$38.24
Field cost per lin. ft. of bank protected	$31.87

Panther Forest, Ark.—The work consisted in constructing 2,037 ft. of standard revetment down stream from the lower end of previous work. Two mats were constructed, 1,131 × 253 and 946 × 253 ft., and four shore mats containing 264 squares, to connect the main mattress with the upper bank paving. The bank was cleared of heavy timber for a distance of 2,300 ft., the clearing extending about 1,000 ft. below the end of the revetment. Work was begun Aug. 23 and completed Nov. 12, 1910. The cost was as follows:

	Cost
5,254 squares channel mat, at $6.477	$34,032.86
1,960 squares paving bank, at $7.307	14,322.85
Property	4,892.59
90 days' towing, at $48.338	4,350.39
264 squares pocket mattress, at $8.103	2,139.34
Sundries	2,056.87
1,900 lin. ft. hydraulic grading, at $1.002	1,904.86
1,900 lin. ft. grade dressed, at $0.461	876.51
Supervision	860.82
Outfitting	735.84
2,300 lin. ft. bank cleared, at $0.31	711.77
Transportation of labor	424.25
250 lin. ft. hand grading, at $1.299	324.89
475 lin. ft. ditching, at $0.271	128.94
Repairs to old paving	75.70
10 squares revetment, at $5.464	54.64
Total	$67,893.12

Leland Neck, Ark.—The work comprised the extension of existing revetment 1,057 ft. down stream by a channel mat 250 ft. wide, and two shore or connecting mats containing 652 squares. Its cost was as follows:

	Cost
2,642 squares channel mat, at $8.4257	$22,260.63
652 squares pocket mat, at $6.9897	4,557.26
1,173 squares bank paved, at $6.8063	7,983.77
309 squares revetment, at $6.4986	2,008.06
63 days' towing, at $58.31	3,673.77
1,287 lin. ft. hydraulic grad'g, at $1.9254	2,478.10
1,287 lin. ft. hand grading, at $0.477	614.05
Supervision	393.75
Transportation of labor	706.80
Engineer office charges	727.74
Hire of barges, etc	5,332.86
Loading stone	944.10
Total	$51,680.89

Albemarle Bend, Miss.—The work carried out here is designed to prevent further caving in this bend, where this action has progressed for a great many years, destroying many levees and involving large expenditures for new ones. During the past four years the bank has been eroded at the rate of about 500 ft. per year. The approved project contemplated the construction of about 10,000 ft. of revetment, and work was begun in August, 1910, and during the period Aug. 17, 1910, to Mar. 3, 1911, 11,650 ft. of revetment were constructed, located so as to cover the zone where the caving had been most active for several years past. Since the completion of the work the main force of the current has been changed, so that it now strikes the bank along the lower third of the completed revetment.

The work was done by forces from three engineer districts, but the report gives details for one district force only, and these follow.

The grading was unusually heavy, due to the old levee near the edge of the bank, which had to be cut in several places for the mat cables to pass through. It was necessary to wash a large portion of this levee into the river and then regrade the bank, fully one-half of the bank having to be graded a second time for this reason. Brush and poles for the revetment work were obtained under contract. Stone was procured from the reserve at Greenville; from contract delivery on the bank at Greenville, loaded on barges at Vicksburg, and delivered at the different revetments on contractors' barges.

On account of lack of familiarity with this portion of the river and difficulty in obtaining a suitable willow bar, mattress construction was somewhat slow. A sudden rise of the river and the caving in of one set of ways tended to delay the work and to increase the cost, as did also the necessity of bringing some of the brush by barges from a considerable distance. The field cost was as follows:

90,230 ft. B. M. 3 × 6 in. lumber	$ 1,398.56
140,000 ft. B. M. 2 × 4 in. lumber	2,170.00
2,000 ft. B. M. miscellaneous lumber	31.00
6,000 lbs. 9-in. steel wire nails	138.00
16,600 lbs. 6-in. steel wire nails	348.60
5,000 lbs. 4-in. steel wire nails	105.00
3,500 lbs. No. 12 galvanized wire	82.25
4,100 cords brush	5,398.62
10,000 9-in. treenails	28.80
40,000 6-in. treenails	107.20
Steamers and tugs	1,825.00
Miscellaneous	40.60
Provisions	1,318.58
Pay rolls, services	5,371.96
Total	$18,364.17
Sq. ft. of mattress built	394,620
Cost per sq. ft. for construction	$ 0.04653

The item of 4,100 cords of brush given in the foregoing table is analyzed as follows:

Cutting and piling, building roads, etc.	$4,047.29
Transportation to ways	1,184.37
Privilege of cutting brush	166.96
Total	$5,398.62
Estimated cords of brush used	4,100
Cost per cord delivered at ways	$ 1.316

Of the 4,100 cords of brush used, 750 cords had to be transported from outlying bars on barges.

Three sets of ways had to be built, one on the mainland at Salem, one on the towhead, and one on Arcadia bar. Their cost is included in mattress construction, but is separated and analyzed as follows:

Lumber and nails	$161.60
Labor and superintendence	425.07
Total	$586.67
Average cost of each set	$195.56

The expense of towing lumber and other materials, except rock, has been added to and is included in the cost of such materials delivered at the site of the work. As Salem bar is located only a short distance above Albemarle Bend, the cost of towing the mattresses from the place where built to the locality where sunk is too small to be given as a separate item, and is included in the cost of construction and sinking.

The cost of sinking 394,620 sq. ft., or 3,946.2 squares of mattresses, was as follows:

487 tons of rock, at $2.40	$ 1,168.80
2,473.61 tons of rock, at $2.25	5,565.62
Steamers and tugs	2,105.00
Lumber, wire nails, wire, etc	432.56
Miscellaneous	64.74
Provisions	990.34
Pay rolls, services	3,110.69
Total	$13,437.75
Cost per sq. ft. to sink	$ 0.03405

Summarizing the field cost of construction and sinking we have:

Construction of mattress per sq. ft	$0.04653
Sinking of mattress per sq. ft	0.03405
Total field cost per sq. ft	$0.08058

All grading was done with a hydraulic grader. Operations were commenced Nov. 3 and completed Nov. 13, during which time 1,586 lin. ft. of bank was graded. The grader was operated with a single crew. The total cost of grading 1,586 lin. ft. of bank was $2,045.55 being $1.29 per lin. ft.

A total of 129,121 sq. ft., covering 1,635 lin. ft. of bank, was paved. The cost was as follows:

Steamers and tugs	$ 877.00
1,271.19 tons of rock, at $2.40	3,050.86
1,271.71 tons of rock, at $2.32	2,950.37
437.04 tons of rock, at $2.25	983.34
896 tons of rock, at $1.93	1,729.28
Miscellaneous	35.00
Provisions	441.62
Pay rolls, services	1,606.95
Total	$11,970.42
Cost per sq. ft. for paving	$ 0.0919

Clearing the bank of logs, etc., preparatory to grading cost $375.30.

Rock for this work was obtained from various sources and at various prices. A total of 6,837 tons was used, of which 3,807 tons was obtained under contract delivered on barges at Vicksburg, Miss., 1,758 tons delivered on barges in Albemarle Bend, and 1,272 tons purchased in open market, delivered on railroad cars at Vicksburg, Miss. The lack of rock at times delayed the work and increased its cost.

The same plant was used in Albemarle Bend as was operated at Reid-Bedford, and the actual expense of moving it upstream about 40 miles was not very great, but has been prorated with the Reid-Bedford work and assumed to be $1,500.

The cost of such survey work as was necessary to the location and placing of the revetment was $129.

The total length of completed revetment placed by the district force mentioned above was 1,615 ft., and the summarized cost was as follows:

Const. of mattress, incl. 3 sets ways	$18,364.17
Sinking of mattress	13,437.75
Grading bank	2,045.55
Paving bank	11,970.42
Clearing	375.30
Installation, estimated	1,500.00
Surveys	129.00
Miscellaneous	62.00
New plant, manila rope, etc., estimated	2,000.00
Total field cost	$49,884.19
Total field cost per lin. ft. completed revetment	$ 30.89

A summary of the unit and total costs of work done by the two other district forces which were engaged at Albemarle Bend is as follows:

27,172 squares channel mat, at $7.851	$213,296.35
4,960 squares connecting mat, at $9.089	45,079.50
5,468 squares bank paved, at $9.897	54,120.09
32 squares revetment, at $7.207	230.64
8,550 lin. ft. slope dressed, at $0.497	4,254.88
12 acres bank cleared, at $135.47	1,625.68
3,000 lin. ft. ditching, at $0.068	202.47
11,000 lin. ft. hydr'lic grad'g, at $1.190	12,310.97
200 days' towing, at $173.914	34,782.71
Outfitting	671.42
Inspection	3,181.70
Supervision	4,737.62
Property	10,426.01
Transportation of labor	3,090.81
Rent of barges	7,134.23
Engineer office charges	1,500.00
Sundries	17,703.74
Total	$414,348.82

Reid Bedford Bend, La.—The conditions at this bend of the river were very unfavorable for either revetment or levee work. It has a sloughing bank, where large sections settle slowly and slide out. The adjacent land is low and swampy, and the current attains a high velocity in the deep water close to the bank. Each of the numerous sections of abandoned levees has its borrow pit, from which the impounded water seeps through the bank, assisting in its destruction.

Work was begun in 1906, when about 2,000 ft. of revetment was placed, but on account of high stages of the river no upper-bank paving was possible. The work described consisted in adding 1,880 ft. of revetment and some repairs to old work.

Mattress construction was commenced when the river was at about a half stage, and as the employes were unfamiliar with the low-water conditions in this part of the river, some errors were made in the location of the ways, with the result that the cost of mattress construction was more than it would have been under favorable conditions. The detailed field cost is as follows:

103,986 ft. B. M. 3 × 6-in. lumber	$ 1,611.78
205,398 ft. B. M. 2 × 4-in. lumber	3,183.67
2,000 ft. B. M. miscellaneous lumber	31.00
8,000 lbs. 9-in. steel wire nails	184.00
19,600 lbs. 6-in. steel wire nails	411.60
4,100 lbs. 4-in. steel wire nails	86.10
2,400 lbs. No. 12 galvanized wire	56.40
6,000 cords brush	6,912.65
10,000 9-in. treenails	28.80
40,000 6-in. treenails	107.20
Steamers and tugs	2,389.50
Miscellaneous	218.10
Provisions	2,387.32
Pay rolls, services	7,174.63
Total	$24,782.75
Total sq. ft. mattress built	573,100
Cost per sq. ft. for construction	$ 0.04324

The item of 6,000 cords of brush given in the foregoing table is analyzed as follows:

Cutting and piling, building roads, etc	$4,472.00
Transportation of ways	2,146.27
Privilege of cutting brush	294.38
Total	$6,912.65
Estimated cords brush used	6,000
Cost per cord delivered at ways	$ 1,152

Two sets of ways were built. Their cost is included in mattress construction but is separated and analyzed as follows:

Lumber and nails	$182.00
Labor and superintendence	268.60
Total	$450.60
Average cost of each set	$225.30

The expense of towing lumber and other materials, except rock, has been added to and is included in the cost of such materials delivered at the site of the work. As Browns Point and Halpino bars, where the mattresses were built, are less than 30 miles above Reid-Bedford Bend, the cost of towing the mattresses from the place where built to the locality where sunk is too small to be given as a separate item, and is therefore included in the cost of construction and sinking.

The work of sinking was somewhat difficult. On account of the swift current three tow boats were required to handle the plant and mattresses. At times the current attained a velocity of 8 ft. per second. No disasters occurred, but the cause stated made the work of placing mattresses slow and expensive. The total field cost was:

4,289.93 tons rock	$ 9,661.09
Lumber, wire, nails, etc	588.66
Steamers and tugs	4,877.00
Miscellaneous	194.47
Provisions	2,022.21
Pay rolls, services	7,238.81
Total	$24,582.24
Total sq. ft. mattress sunk	573.000
Cost per sq. ft. to sink	$ 0.04289

Summarizing the field cost of construction and sinking of mattresses in place we have:

Construction of mattress per sq. ft	$0.04324
Sinking of mattress per sq. ft	0.04289
Total field cost per sq. ft	$0.08613

The grading consisted of 2,082 lin. ft. of new work and of 1,017 lin. ft. of regrading; it cost as follows:

Grading	$4,950.14
Re-grading	1,814.07
Total	$6,764.21
Cost per lin. ft. to grade	$ 2.33
Cost per lin. ft. to re-grade	1.78

A total of 119,066 sq. ft. covering 1,750 lin. ft. of bank was paved on the extension of revetment and 31,169 sq. ft., covering 565 lin. ft. on the repairs to work placed in previous years. The cost was as follows:

Steamers and tugs	$ 703.16
2,106.36 tons of rock, at $2.25	4,739.31
1,193.68 tons of rock, at $2.32	2,769.34
Miscellaneous	51.00
Provisions	887.58
Pay rolls, services	2,388.49
Total	$11,538.87
Cost per sq. ft. to pave	$ 0.077

Kempe Bend, La.—During the year the upper revetment was extended upstream 900 lin. ft. and the lower revetment downstream 2,373 lin. ft. The upper bank along the lower extension was graded and 1,439 lin. ft. was paved. The timber along the bank between the upper and lower revetments was cut to prevent its caving in and obstructing future work. Mat construction cost $28,919 for 882,300 sq. ft. or about 3.27 cts. per square foot. The mats had to be towed 50 miles and the cost was as follows:

Tug "Tuniaca," 6 days, at $29	$ 174.00
Tug "Marengo," 30 days, at $26	780.00
Steamer "Tensas," 15 days, at $24	360.00
Total	$1,314.00
Total sq. ft. towed	882,300
Cost per sq. ft	$0.001489

It required 180,000 sq. ft. to extend the upper revetment upstream 900 lin. ft. and 702,300 sq. ft. to mattress the 2,373 ft. of bank at the lower end of the bend. The following is the detailed cost of this part of the work:

Steamers and tugs	$ 1,510.57
Lumber, wire, nails, etc	287.45
5,198 tons of rock, at $1.93	10,032.14
761 tons of rock, at $2.377	$ 1,808.39
Miscellaneous	66.96
Provisions	1,755.57
Pay rolls	6,408.41
Total	$21,870.00
Total sq. ft. sunk	882,330
Cost per sq. ft. to sink	$ 0.02479
Total cost per sq. ft. in place	$ 0.05905

The grading was done by a hydraulic grader, the bank being dressed also by hand where necessary. The material was mostly stiff clay on top, with layer of sand at bottom. At the lower end of the bend two thousand five hundred lin. ft. of bank were graded. The following is the detailed cost:

Hydraulic grader No. 1:	
Steamers and tugs	$ 450.00
Coal	821.10
Miscellaneous	80.65
Provisions	772.75
Pay rolls	2,495.98
Hand grading (labor and provisions)	627.53
Total	$5,248.01
Lin. ft. of bank graded	2,500
Cost per lin. ft. to grade	$ 2.099

A total of 92,606 sq. ft. or 1,416 lin. ft. was paved with rock as an extension to the lower upper bank revetment; the following is the detailed cost of the work:

Steamers and tugs	$ 687.00
2,454 tons of rock, at $1.93	4,736.22
405 tons of rock, at $2.377	962.69
Miscellaneous	40.00
Provisions	420.00
Pay rolls	1,871.60
Total	$8,717.51
Cost per sq. ft	$ 0.094

New Orleans, La.—A total of 1,960,000 sq. ft. of mattress was built at the following cost:

265,204 ft. B.M. 3 × 6-in. lumber	$ 3,702.40
670,349 ft. B.M. 2 × 4-in. lumber	9,048.09
16,000 ft. B.M. miscellaneous lumber	382.00
22,100 lbs. 9-in. steel wire nails	472.42
61,700 lbs. 6-in. steel wire nails	1,240.36
7,600 lbs. 4-in. steel wire nails	224.16
8,700 lbs. No. 10 galvanized wire	220.95
30,500 9-in. treenails	72.89
145,000 6-in. treenails	295.80
20,000 cords brush	20,676.07
Steamers and tugs	4,259.50
Miscellaneous	176.83
Provisions	5,443.09
Pay rolls, services	21,759.25
Total	$67,973.81
Cost per sq. ft. for construction of mattress	$ 0.0347

The item of 20,000 cords of brush given in the foregoing table is analyzed as follows:

Cutting and piling, building roads, etc.	$11,273.69
Transportation to ways	8,467.68
Privilege of cutting brush	934.70
Total	$20,676.07
Cost per cord delivered at ways	$ 1.0338

Six sets of ways were built and their cost is included in mattress construction. Of the six sets the cost of only four was kept in detail, as follows:

Lumber and nails	$610.00
Labor and superintendence	380.75
Total	$990.75
Average cost of four sets, each	$247.69

The expense of towing lumber and other materials for mattress construction has been added and is included in the cost of such materials delivered at the site of the work. The cost of towing mattresses from the places where they were built to New Orleans is given below. A total of 1,960,000 sq. ft. of mattress was towed, of which 505,500 was from Halpino bar, 390 miles; 315,000 from Warrenton bar, 360 miles; 300,000 from Kempe Island, 315 miles, and 839,500 from Palmetto bar, 237 miles. The cost was as follows:

Steamer "Ramos," single crew, 11 days, at $35.50	$ 379.50
Steamer "Ramos," double crew, 43 days, at $58	2,494.00
Steamer "Plaquemine," double crew, 68 days, at $65	4,420.00
Tug "Morganza," single crew, 15 days, at $30.50	457.50
Total	$7,751.00
Average cost per sq. ft. for towing	$ 0.00395

With the exception of some slight difficulties caused by the high stage of the river at which some of the mattresses were sunk, work proceeded in a routine manner. The detailed cost was as follows:

13,644.02 tons rock	$27,393.67
Lumber, wire, wire nails, etc	917.66
Steamers and tugs	3,473.50
Miscellaneous	153.45
Provisions	3,500.43
Pay rolls, services	9,153.67
Total	$44,792.28
Cost per sq. ft. to sink	$ 0.02285

Summarizing the field cost of construction, towing, and sinking of mattresses, we have:

Construction of mattress, per sq. ft	$0.03470
Towing of mattress, per sq. ft	.00395
Sinking of mattress, per sq. ft	.02285
Total field cost per sq. ft. in place	$0.06150

Proposals for furnishing 13,000 tons of rock were opened Nov. 5, 1910, and contract awarded for delivery on railroad cars in New Orleans at $1.90 per ton. The cost of transferring from cars to barges was 25 cts. per ton.

A summary of the New Orleans work is as follows: A total of 7,850 lin. ft. of revetment was constructed, of which 2,765 lin. ft. on the Gretna Front was 300 ft. wide; 3,975 ft. in the Carrollton Bend was 200 ft. wide; and 675 and 435 ft. in the third district reach, respectively, 300 and 200 ft. wide. This work involved the placing of 1,960,000 sq. ft. of mattress, and the detailed cost of it is as follows:

Construction of mattress, including cost of ways	$ 67,973.81
Towing of mattresses	7,751.00
Sinking of mattresses	44,792.28
Installation	2,141.00
Surveys	275.00
Rock, lumber, etc., on hand for future construction	20,419.89
Repairs to plant	288.17
Care of plant	680.78
New plant	2,649.38
Office and administrative expenses	5,680.17
Total	$152,651.48
Deduct value of material on hand for future work	20,419.89
Gross cost of season's work	$132,231.59
Deduct repairs and care of plant, new plant and office and administrative expenses	9,298.50
Net field cost of season's work	$122,933.09
Gross cost per sq. ft. for mattress in revetment	$ 0.0675
Gross cost per lin. ft. for revetment 200 ft. wide	13.55
Gross cost per lin. ft. for revetment 300 ft. wide	21.09
Net field cost per sq. ft. for mattress in place in revetment	0.0627
Net field cost per lin. ft. for revetment 200 ft. wide	12.58
Net field cost per. lin. ft. for revetment 300 ft. wide	19.74

Cost of Plank Mattresses.—These are used whenever cull lumber can be procured cheaper than brush. They are woven of 1 in. boards, 4, 6 and 8 in. wide and 10 to 20 ft. long. A cheaper construction consists in merely joining the boards by nailing. Plank mats have been built and successfully sunk in sections 150 ft. wide and 10,000 ft. long. Charles W. Durham furnishes the following cost data in Engineering and Contracting, Aug. 13, 1913.

For a 30-ft. wide mat, built in 1911, in which 62,590 ft. B. M. of lumber were used, the cost of 1,969 lin. ft. was as follows:

62,590 ft. lumber at $10 per M	$625.90
438 hrs. labor at 1.75 per day of 8 hrs	95.81
280 lbs. wire at 3 cts	8.40
800 lbs. 10-penny nails at $2.05 per 100 lbs	16.40
	$746.51

or $0.379 per lin. ft. Had the mat been built of brush, the cost per lin. ft. would have been as follows:

1.7 cu. yds. brush at 16¾cts	$0.2847
Labor $^{16}/_{300}$ day, at $1.75	.0933
Wire	.0070
	$0.3850

This shows very little saving, but the plank mat has the advantage in the less number of material barges needed. One barge will carry from 100 to 120 M. ft. B. M. of lumber, an equivalent to which in brush would require 10 barges. This indicates a considerable saving when we figure the value of the barges at $3.50 per day.

In 1912, a better showing was made in work done in the vicinity of Hannibal, Mo. It was found that in a mat 20 ft. in width, 1 cu. yd. of brush is equivalent to 15.9 ft. B. M. of lumber, or in other words, 63 cu. yds. brush equal 1,000 ft. lumber. As, however, some extra pieces are used in the 30 and 40-ft. lumber mats, 60 cu. yds. brush are used as the average equivalent of 1,000 ft. of lumber. The width of boards should be 4, 6 and 8 ins. Boards of less width than 4 ins. are deficient in strength and those of greater width than 8 ins. leave too large spaces and a consequent waste of small rock, if the standard plan of making the space equal to the width of board is adhered to. The length of boards is an important factor in the cost, for, the longer the boards, the less cross pieces, less nailing, less handling and moving of ways, but this

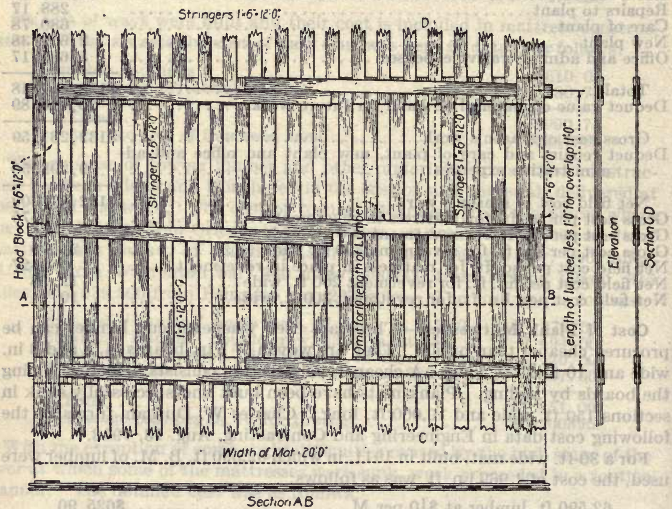

FIG. 2.—Standard lumber mat for shore protection, Upper Mississippi River improvement.

advantage may be wholly or in part offset by the increased cost of the longer lumber. With brush at 21 cts. per yd., we can afford to pay $14.44 per M. ft. for lumber, for

Cost per lin. ft. nails in 20 ft. lumber mat	$0.0034
Labor cost per lin. ft. building 20-ft. lumber mat	0.0412
Labor cost per lin. ft., sinking 20-ft. lumber mat	0.0352
	$0.0798
Cost per lin. ft. of 20-ft. brush mat in place	0.0352
Cost per lin. ft. of 20-ft. brush mat in place	$0.2820
Available for lumber	$0.2022

At 14 ft. per lin. ft. this is equivalent to $14.44 per M.

In a 20 ft. mat there are 14.0 ft. B. M. of lumber or 0.88 cu. yd. brush per lin. ft. It was also found that within practical limits an increase of 2 ft. in length warrants paying $1.25 more per M. for the lumber. The actual saving in 1912 of 4.3 cts. per lin. ft. of mat amounted to $551.26 for the 12,820 ft. of lumber mat built in the vicinity of Hannibal, Mo. There was also a saving on the barges as only two were required for the lumber service, while to have handled an equal amount of brush would have required at least five barges and the consequent extra towing.

Comparative Cost of Board Mat and Brush Mattress for River Bank Protection.—In 1915 records were kept by the U. S. Engineer Office at Rock Island, Ill., of board mat and brush mattress construction which are quoted by Engineering and Contracting, June 14, 1916, as follows:

The average quantities required per square (100 sq. ft.) of apron mat were: 66 ft. B. M. lumber, or 4.8 cu. yd. of brush. In other words, 13.75 ft. B. M. lumber was equivalent to 1 cu. yd. of brush. The cost of material (on barges) was: Lumber, $11.95 per M ft. B. M. and brush, $0.24 per cu. yd., making the initial cost per square, $0.789 for lumber and $1.152 for brush. During the same season, it was found that eight laborers could construct an average of 120 squares (12,000 sq. ft.) of lumber apron mat per day, while with brush the average was 75 squares (7,500 sq. ft.) per day. The best day's work with twelve laborers was 180 squares of lumber mat. There was used in bank revetment work in this division during 1915, 136,206 ft. B. M. of green cull lumber, made up of elm, willow, cottonwood, etc. This amount was carried on two standard barges (100 × 20 × 5 ft.), whereas the average barge load of brush is about 400 cu. yd. Using 13.75 ft. B. M. lumber to 1 cu. yd. of brush, the above 136,206 ft. B. M. of lumber would be equivalent to 9,905 cu. yd. of brush, which would make approximately 25 barge loads. The cost of towing the above amount of lumber was $40, or about 30 ct. per thousand. The cost of towing the equivalent in brush fascines at 4.2 ct. per cubic yard was $416, which shows a large percentage in favor of lumber. Owing to the greater buoyancy of a brush mat, it requires more than twice as much rock to anchor it safely on the bottom. The average amount of rock used to sink a square (100 sq. ft.) of apron mat was: For lumber, 0.77 cu. yd.; for brush fascines, 1.70 cu. yd. The following tables give the comparative costs of lumber and brush fascine apron mats for season 1915:

Cost of Brush Fascine Mat, 1,000 Ft. Long, 30 Ft. Wide (300 Squares)

Brush, 1,440 cu. yd. at 24 cts.	$ 345.60
Rock, 510 cu. yd. at 85 cts.	433.58
Towing brush, 1,440 cu. yd. at 4.2 cts.	60.40
Towing rock, 510 cu. yd. at 21 cts.	107.10
Labor constructing mats, 8 laborers 4 days at $1.75 per day	56.00
Labor sinking mat, 510 cu. yd. rock at 4 cts.	20.40
Wire, 80 lb. at 3 cts.	2.40
Total	$1,025.48

Cost of Lumber Mat, 1,000 Ft. Long, 30 Ft. Wide (300 Squares)

Lumber, 19,800 ft. B. M. at $11.95 per M	$ 236.61
Rock, 231 cu. yd. at 85 cts.	196.35
Towing lumber, 19,800 ft. B. M. at 30 cts. per M	5.94
Towing rock, 231 cu. yd. at 21 cts.	48.51
Labor constructing mat, 8 laborers 2½ days at $1.75 per day	35.00
Labor sinking mat, 231 cu. yd. of rock at 4 cts.	9.24
Nails, 4 kegs at $2.05 and 25 lb. wire at 3 cts.	8.95
Total	$ 540.60

The above shows a balance of $484.88 in favor of lumber mat (300 squares) of $1.62 per square.

Cost of Concrete Paved Bank Revetment.—This is described in Engineering and Contracting, March 20, 1918, being an abstract of a paper by G. C. Haydon in Professional Memoirs. In this case a departure from the standard form of brush mattress construction was made which consisted in paving the upper bank with a 4-in. layer of reinforced concrete slabs instead of broken stone, and the protection of subaqueous willow mattress for about 10 ft. width from the shore edge with reinforced concrete blocks connected to the solid upper pavement.

The plant used on the work consisted of the following: One double-decked quarterboat with a capacity of housing from 60 to 70 laborers and necessary foremen, 1 hydraulic grader, 1 mattress barge, 1 barge for concrete mixer plant, 6 material barges, and 1 tow boat. The working plant was supplemented by an 8-in. suction pump, installed on a material barge, for procuring gravel. The value of this plant is estimated at $60,000.

The principal material used, which was procured locally and delivered by barge, consisted of willow brush at $1.60 per cord; stone at $0.68 per cubic yard, and sand and gravel at $0.08 per cubic yard; manufactured material

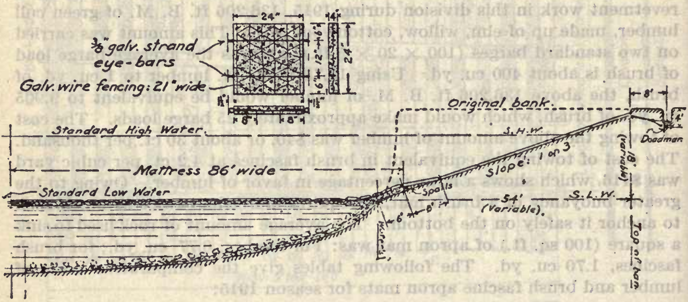

FIG. 3.—Cross section of combination concrete and willow mattress.

delivered by freight consisted of ⅜-in. galvanized strand at $0.71 per linear foot; 50-in. galvanized woven fence wire, for the paving, at $0.06 per linear foot; 22-in. fence wire, for blocks, at $0.03 per linear foot; lumber, for forms, at $22 per M. B. M., and Portland cement at $0.75 per barrel (f. o. b. factory).

The bank is graded by the hydraulic method to 1 on 3, which gives a length of slope from 42 to 54 ft. according to height above standard low water, which also determines the length of a slab.

After the bank is graded the continuous mattress, 86 ft. wide, is woven of bar-growth willows, from ½ to 2 in. in diameter at the butt end and 10 to 25 ft. long. The header, about 12 in. in diameter, is formed by lapped bundles of willows bound together to the desired width of mattress, by ⅜-in. strand. The stitch is then started by inserting single willows into the bundle at an angle of about 45°, from one end of the header to the other; then the willows are inserted at the same angle to the reverse direction, the last willow inserted being on top. This makes the weaving of a continuous over process, the stitch having an over and under appearance. The willows are placed in such numbers and closeness of weave as to make a mattress 12 in. thick. As the weaving progresses a selvage is made along each side of the mattress by turning in the tops of the outer willows, or an equally good selvage (known as the "sidewalk") is made by platting willows, longitudinally along the edges.

The mattress is strengthened by a longitudinal and cross system of ⅜-in. in diameter galvanized strand. The longitudinal system for an 86-ft. mattress consists of 6 pairs of strands, spaced as required, each pair consisting of 1 strand underneath and 1 strand on top of the mattress. The cross systems are in pairs, one underneath and 1 on top, spaced 16⅔ ft. apart. At each intersection of the 2 strands underneath and the 2 strands on top, all 4 are drawn together tightly with a 7/16-in. U-shaped clip, after all the slack has been taken out of the strands by block and tackle. The head of the continuous mattress, or any section of mattress, is anchored by 3 pairs of strands fastened to the respective longitudinal strands, 1 pair 4 ft., 1 pair 16 ft., and the remaining pair of 46 ft. back from the outer corner and run ashore at 45° angle with the upper edge of the mattress and fastened to deadmen 50 ft. back from the edge of the bank. The continuous mattress is anchored to the bank by each pair of cross strands carried up the slope and fastened to a deadman placed 8 ft. back, and 4 ft. below the top of slope.

The mattress was weighted down with one-man stone sufficiently to make it sink into close contact with the river bed, after which, the concrete paving was placed.

The statement given below contains only field expenditures with the cost divided as follows:

	Per lin. ft.
Grading bank	$0.55
Weaving mattress	1.98
Concrete blocks in place	1.16
Ballasting mattress	1.13
Concrete paving	2.76
Total, per linear foot	$7.58

As two other pieces of this type of revetment have since been completed under similar conditions, their costs are given here for general comparison, and, to a certain extent, permit the establishment of a proper basis for estimates.

Marthasville Bend: 11,960 ft. at $8.05 per linear foot, completed Nov. 25, 1914. The cost was as follows:

	Per lin. ft.
Grading bank	$0.84
Weaving mattress	1.85
Concrete blocks in place	1.56
Ballasting mattress	.83
Concrete paving	2.97
Total, per linear foot	$8.05

Dewey Bend: 7,215 ft. at $8.13 per linear foot, completed Dec. 17, 1915. The cost of this was as follows:

	Per lin. ft.
Grading bank	$0.67
Weaving mattress	2.31
Concrete blocks in place	1.45
Ballasting mattress	1.22
Concrete paving	2.48
Total, per linear foot	$8.13

Additional data on the cost of this work are given by Lt. Col. J. F. McIndoe, Corps of Engineers, as an addendum to Mr. Haydon's article. These figures follow:

Bates Island Bend: The cost, per square (100 sq. ft.) of the completed concrete paving of upper bank, was $6.59; and of subaqueous work, was $4.65, of which $2.31 was cost of mattress, $1.34 the cost of concrete blocks, and $1 the cost of ballast. The quantities and unit costs of materials for each square were approximately as follows:

Upper bank work—
- Grading, 33 cu. yd. at $0.025 per cubic yard.
- Concrete for paving, 1.24 cu. yd. at $4.52 per cubic yard.

Subaqueous work—
- Brush for mattress, .6 cord, at $1.59 per cord on barge.
- Stone for ballast, .8 cu. yd., at $0.67 per cubic yard on barge.
- Concrete blocks, 24, at $0.28 each.
- Strand for mattress, 9.2 lb., at $0.085 per pound.
- Clips for mattress, 3 lb., at $0.06 per pound.

Marthasville Bend: The cost, per square (100 sq. ft.) of the completed upper bank paving, was $7.17; and of subaqueous work, was $4.86, of which $2.12 was cost of mattress, $1.70 the cost of concrete blocks, and $0.95 the cost of ballast.

The quantities and unit costs of materials for each square were approximately as follows:

Upper bank work—
- Grading, 33 cu. yd., at $0.046 per cubic yard.
- Concrete for paving, 1.24 cu. yd., at $4.57 per cubic yard.

Subaqueous work—
- Brush for mattress, .7 cord, at $1.58 per cord on barge.
- Stone for ballast, .7 cu. yd., at $0.693 per cubic yard on barge.
- Concrete blocks, 25, at $0.313 each.
- Strand for mattress, 9.2 lb., at $0.085 per pound.
- Clips, .3 lb., at $0.06 per pound.

Dewey Bend: The cost, per square (100 sq. ft.) of completed upper bank paving, was $6.55; and of subaqueous work, was $5.80, of which $2.69 was cost of mattress, $1.69 the cost of concrete blocks, and $1.42 the cost of ballast.

The quantities and unit costs of materials for each square were approximately as follows:

Upper bank work—
- Grading, 29 cu. yd., at $0.048 per cubic yard.
- Concrete for paving, 1.24 cu. yds. at $4.08 per cubic yard.

Subaqueous work—
- Brush for mattress, .56 cord, at $1.96 per cord on barge.
- Stone for ballast, .86 cu. yd., at $0.86 per cubic yard on barge.
- Concrete blocks, 25, at $0.21 each.
- Strand for mattress, 9.2 lbs., at $0.085 per pound.
- Clips for mattress, .3 lb., at $0.06 per pound.

Concrete Slab for Bank Protection.—Where the bottom consists of material not washable by the force of the current, concrete has been successfully used on the Southern Pacific Ry. for protection of their fills.

Engineering and Contracting, Feb. 14, 1912, gives the following data on such a protection (Fig. 4). The slab is 6 ins. thick and is reinforced at the center with wire netting. In one case where it was put on a new fill which settled badly, the concrete did not pull apart and did not allow the water to wash the fill.

A slab containing 376 square yards was constructed as follows: The bank was sloped 1½ to 1, and 12 × 18 in. trench was dug along the foot of the slope. This trench was filled with concrete embedding the ends of the strips of mesh reinforcement. A strip of reinforcement was then stretched up-bank and its edges were clamped by forms as shown by Fig. 4. Braces driven between the edge forms made the mesh taut, and the forms held it 3 ins. clear of the slope surface. The space between forms was next concreted, the forms serving as templets for thickness of slab. When the concrete had hardened the forms were removed leaving a 4-in. selvage of mesh projecting beyond the slab edges. The next strip of mesh but one was then stretched and concreted and so on completing alternate sections of the slab. The intermediate sections were constructed by stretching the strip of mesh up-bank and wiring its edges

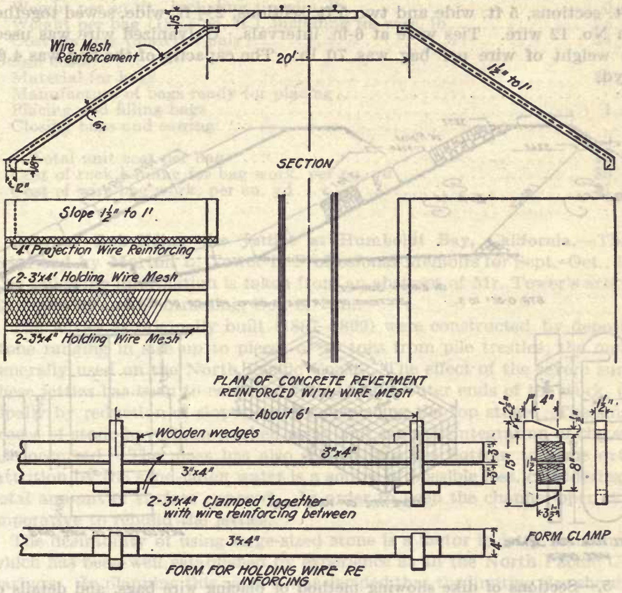

FIG. 4.—Reinforced concrete slab for bank protection, Southern Pacific Ry. Co.

to the selvage edges projecting from the completed slabs, and by concreting the open spaces. The cost of the 376 square yards of slab was as follows:

Materials:		Revetment, per sq. yd.
2 rolls fence wire, 50 rods, at 45 cts. per rod	$ 22.50	$0.0598
82 cu. yds. gravel and sand at 30 cts	24.60	0.0654
82½ bbls. cement at $1.70	140.25	0.3731
Total material	$187.35	$0.4983
Labor:		
Building mixing platform	$ 11.50	$0.0305
Unloading gravel	25.00	0.0665
Unloading cement	10.50	0.0279
Putting up forms and wire	116.50	0.3099
Placing concrete	119.00	0.3165
Total labor	$282.50	$0.7513
Total materials and labor	$469.85	$1.2496

The work was done by a gang of eleven men working 10 hours per day at the following daily wages: One foreman, $4.50; one concrete mason, $3.25; six laborers, each, $2.25, and three laborers at $2.50.

Cost of Riprapping Embankment with Wire Bags.—The following is abstracted by Engineering and Contracting, Feb. 12, 1919, from an account by L. E. Foster in the Reclamation Record.

On certain work the toe of an embankment had to be protected against water velocities of from 5 to 16 sec. ft. Wire bags were used, composed of two 15 ft. sections, 5 ft. wide and two 5 ft. sections, 2½ ft. wide, sewed together with No. 12 wire. Ties were at 6-in. intervals. Galvanized wire was used. The weight of wire per bag was 70 lb. The capacity of the bag was 4.63 cu. yd.

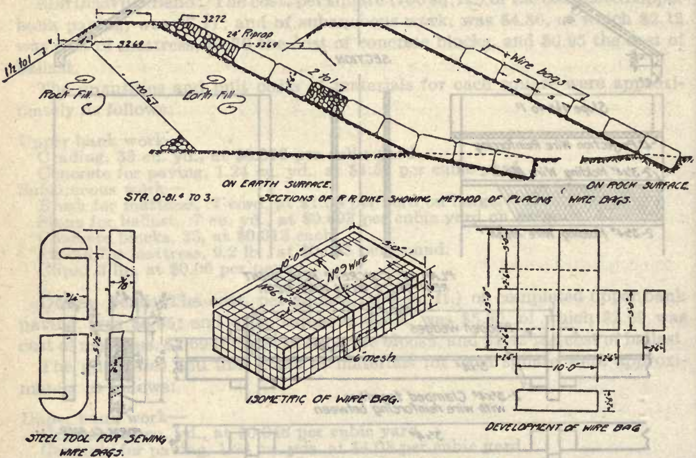

Fig. 5.—Sections of dike showing method of placing wire bags, and details of wire bag and tool for its manufacture.

The bag material was cut and sewed in the shop into the developed form shown in the right-hand corner of the drawing, then folded together flat, and hauled to the work. The bags were then sewed into rectangular form with the lid loose. The bags were set in a horizontal row in place and filled directly from the rock wagons. The labor of filling the bags proved to be less than to lay riprap of the same thickness.

Care was taken to have all rock next to the wire mesh of greater dimensions then 6 by 6 in. Since this is a relatively small sized rock, much rock is available for bag work and would be too small for riprap.

After the bags were level full the top was closed down and sewed securely on the front and two sides. The bags were also tied to each other along these edges, thus forming a continuous mat. Quarrying and loading on this job was charged to another feature as excavation.

Besides the 181 bags placed on spillway No. 1, 78 bags were placed as protection at the toe of spillway No. 2. The costs given below are based on a total of 259 bags.

Material required per bag.	
31 lin. ft. of 60-in. wire mesh.	
11 lin. ft. of 30-in. wire mesh.	
5 pounds No. 12 tie wire.	
Cost:	
Cost per sq. ft., including tie wire	$0.0229
Weight per sq. ft., including tie wire, lb	0.38
Weight per bag (182.5 sq. ft.), including tie wire, lb	75.4
Cost per bag (material only)	$4.20
Detail costs:	
Material for bags	$4.20
Manufacture of bags ready for placing	.905
Placing and filling bags	1.125
Closing bags and sewing	.446
Total unit cost per bag	$6.676
Cost of rock hauling for bag work, per cu. yd	$0.17
Cost of wire bag work, per cu. yd	$1.681

Cost of Rebuilding the Jetties at Humboldt Bay, California.—This is described by Morton L. Tower in Professional Memoirs for Sept.–Oct., 1913. The following information is taken from an abstract of Mr. Tower's article in Engineering and Contracting, Oct. 8, 1913.

The jetties as originally built (1887–1899) were constructed by depositing stone ranging in size up to pieces of 10 tons from pile trestles; the method generally used on the North Pacific Coast. The effect of the severe surf on these jetties has been to cause subsiding of the outer ends of the work, principally by reduction of slopes and by displacing the top stone. The smaller pieces of stone have been washed away and some disintegration of the stone has occurred. The mass has also settled into the bottom to some extent. Attrition by the sand-laden water is a source of possible loss, considering the total amount of surface exposed. In order to keep the channel open it was imperative to rebuild the jetties.

The desirability of using large-sized stone is a factor in jetty maintenance which has been well established by experience at all the North Pacific Coast harbors. In planning this work it was decided that the limiting size should be 20 tons. It was also considered desirable that these stones be lowered to place to avoid breaking them or the stone they fell on, which often occurs when stone is deposited by dumping from cars on an elevated track. The use of an unloading crane also permits the placing of stone in a selected position in the jetty, which cannot be done when it is dumped from a tramway.

All the quarries adjacent to Humboldt Bay are at a considerable distance from the navigable channels, thus rendering rail transportation essential from the quarry to tide water. The quarry used is seven miles from the nearest landing.

The largest single item of plant involved in the construction is the cars. It was deemed that it would be cheaper in the end if these were of standard design and hence salable when the work was completed.

A tramway of sufficient strength to carry a 20-ton crane and standard 40-ton railroad equipment is necessarily much heavier and more expensive than the jetty tramways used along the Oregon and Washington coasts, where narrow gage, special dump cars are used.

The storms of many years had beaten the old enrockment into a compact mass, such that it would have been impossible to drive piles into it, and for a tramway it would have been necessary to place a portion of the piles of each bent in the sand to give it any lateral stability.

The estimated cost of a suitable trestle is as follows:

Six-pile bents 14 feet apart with two lines of 10 by 18-in. stringers under each rail and 6 by 8-in. ties. Rails to be 28 ft. above mean low water.

MATERIAL

6 piles, each 50 ft. long, 300 lin. ft at 15 cts	$ 45.00	
3,500 ft. B. M. lumber, at $20 per M. ft	70.00	
170 lbs. bolts, nuts and washers, at 3 cts. per lb	5.10	
2 rail joints, at $3 each	6.00	
1,120 lbs. rails, at 2½ cts. per lb	28.00	
107 lbs. nails and spikes, at 5 cts. per lb	5.35	
Material for 14 ft	$159.45	
Material for 1 ft		$11.39
Labor, fuel and supplies, per day, $59.		
Rate of progress (estimated 2 bents, 28 ft.), cost per ft.		2.11

PLANT REQUIRED

1 revolving driver, complete	$20,000	
1 supply and material car	5,000	
3 flat cars, at $600	1,800	
Material yard platforms	5,000	
For 9,000 lin. ft. tramway	$31,800	
Plant charge per foot		$ 3.53
Cost per foot		$17.03

In addition to the cost of the tramway over the actual length of the jetty to be rebuilt, about 9,000 ft., it would have been necessary to raise the short tracks across the sand on a short trestle, amounting in all to about 7,000 lin. ft. at an estimated cost of $10 per foot. While the cost of the shore track at elevation 12 has been:

For labor	$1.13
For rails, spikes and ties	2.50
Cost per foot	$3.63

The low elevation for the shore tracks possible with the system used has therefore effected a total saving of $44,590 over the cost of the shore trestle necessary to reach a tramway 24 to 28 ft. above low water at the ocean beach line.

The desirability of making full use of the existing enrockment with its established slopes and compact mass, as well as the advantage of having a thoroughly stable foundation for the stone unloading crane, and the high cost of the tramway of sufficient strength to permit the use of the large stone proposed, were the conditions which led to the adoption of the concrete cap.

The main idea of the concrete is to hold the track when the jetty is swept by waves. The only portions of the structure that will float are the ties, and these are firmly imbedded in concrete and held in place. A further advantage of the concrete cap method is that the ties are the only portion of the structure which is not of a permanent nature and an addition to the value of the structure as a jetty. The concrete top on the crest of the structure will greatly retard the unraveling action of the waves, and when finally broken up by the settlement and washing away of the rock slopes it will still be of value as jetty material.

The cost of the concrete cap and tracks has been:

For labor		$ 2.86	
4½ tons class 3 stone in voids of jetty enrockment	$6.75		
2 tons of class 4 stone	3.00		
.95 bbls. cement	2.00		
Total concrete material		$11.75	
50 ft. B. M. lumber, at $14 per M	$0.70		
Fuel, oil, repairs, etc	.66		
		1.36	
			$15.97
Rails and joints (recoverable)			2.13
Total cost per linear foot			$18.10

Some loss of freshly laid concrete has occurred when it has been exposed to severe wave action within four or five hours after placing. This loss has not been sufficiently great to add materially to the cost. One severe storm carried away 25 ft. of the outer end of the track, but to all appearance the damage was caused by unraveling the enrockment which allowed the concrete to break down.

The above costs include the cost of portions of track lost by wave wash before the concrete had time to set, amounting to 1 per cent.

The plant cost for the concrete method had been:

One concrete mixer, complete, with boiler and engine	$1,500
One flat car	600
Tanks and small tools	250
Labor assembling plant	200
Total	$2,550
Cost per ft., for one jetty, 53 cts.	

Construction Methods.—The method of construction is as follows: The enrockment is first brought to an elevation averaging 2 ft. below the finished grade with Class 2 stone; pieces weighing from 1,000 lbs. to 10 tons. None of the pieces of Class 2 stone are allowed to project above 6 ins. below grade—the bottom of the ties. Voids in the mass are then filled with Class 3 stone, pieces weighing from 3 lbs. to 500 lbs., and the top is leveled off at from 18 to 10 ins. below grade. Holes are chocked by hand-placed stone. A rough form is made by tying wale pieces, 6 × 8 in. × 20 ft. ties, together with wires 5 ft. apart, and nailing to them short vertical boards with bottoms in contact with the rock. A rock dam is built at the front end of the form. Concrete is mixed rather dry, deposited with a 1 cu. yd. self-dumping and self-righting bucket, handled by the stone-unloading crane. The concrete is brought to within an inch or so of the bottom of the ties. The end tie is brought to grade, the crane rails laid, and the ties placed and spiked. Concrete is then continued to the top of the ties.

The concrete mixer is mounted on the end of a standard flat car, the discharge shoot delivering over the end. Mixing water is supplied by gravity from a tank on the opposite end of the car. Oil fuel is supplied by gravity from a tank near the water tank. The oil and water tank also supply the stone unloading crane. Oil is pumped and water flows by gravity to the crane supply tanks. Cement for a day's operation is carried on the concrete mixer car. The concrete is machine mixed in a Foote Batch Mixer of 21 cu. ft. capacity, end-discharge type, steam driven.

At the outer end of the jetty there are two working tracks. All material and equipment are regulation master-car builders' pattern and dimensions. The tracks are 14 ft. 7¾ ins. center to center. When in operation the concrete mixer car occupies the left-hand track, and the car containing the aggregate the right-hand track. A working movable platform fills the space between the cars, leaving about 1 in. clearance over the stake pockets. The elevation of the platform is the same as that of the car decks. The aggregate is shoveled directly from the cars into the charging skip and a large barrow. The charging skip is marked by a row of rivets at the height containing the charge required. In order to work a sufficient number of shovelers to keep the depositing bucket in motion it was found necessary to provide a greater length than was possible by shoveling into the skip alone. A two-wheel barrow, running on rails and holding about 15 cu. ft., was mounted on the mixer car. This allows the charging shovelers to be distributed over the whole length of a standard flat car.

The most economical crew for depositing concrete is eight laborers charging aggregate, one laborer charging cement and one engineman operating mixer. The concrete is placed, spread, and tamped by the regular stone unloading crew, consisting of engineman, four laborers and the foreman. This crew will generally build a section of track 18 to 20 ft. in length in 2 hours and 15 minutes, including the construction of forms and placing ties and rails.

Under the specifications for the material the contractors are allowed to supply either broken stone, crusher run, or unscreened river gravel for aggregate. The material supplied is tested for proportioning in the following manner: The aggregate as delivered is screened and the portion passing a plate containing ¼-in. diameter holes is considered sand, and the balance stone. If necessary, sand is added to form a mixture corresponding to a 1:2½:5½. The gravel supplied contains rather larger proportion of sand than is required. When broken stone is delivered it is necessary to add about 16 lbs. of sand per 100 lbs. of aggregate as received.

Stone for the work is supplied under contract by the Hammon Construction Company at the following prices:

	Per ton
Class 1	$1.74
Class 2	1.56
Class 3	1.50
Class 4	1.50

The following is taken from the specifications under which the stone is being supplied:

Descriptions of Material.—Class 1 Stone. To be of large pieces only, weighing from 10 tons to 20 tons each piece. These stones will be used for slopes on the outer end of the work, and none will be received until the jetty repairs have been extended 2,300 ft. from the high water shore lines. Delivery of this stone will be required up to 500 tons per day when work is in progress on the outer ends of both jetties. Stone of Class 1 will be loaded directly on the flat car without the use of skips.

Class 2 Stone. To be in pieces of 1,000 lbs. each to pieces of 10 tons each, in the following proportions:

One-fourth of each day's supply may be in pieces of 1,000 lbs. to pieces of 3 tons; one-half of each day's supply must be in pieces of from 3 tons to 6 tons each; and one-fourth of each day's supply must be in pieces from 6 to 10 tons each.

This class of stone will form the major portions of the repairs to the jetties. It is expected that the delivery required will not be less than 1,000 tons per day after the work has been well commenced on both jetties, and about 500 tons per day for the first season's work.

Stones of Class 2, when in pieces under 6 tons each, must be loaded on suitable skips holding up to 10 tons of stone each. Skips will be strong and designed for lifting at the four corners. Four corner hooks will be provided on each skip for the convenient attachment of the unloading crane spider chain. Skips will be kept in good working order by the contractor.

Class 3 Stone. Will be used only for bringing the top of the rough mound to a nearly smooth, tight surface and for concrete displacers. It will be in pieces not less than 3 lbs. nor more than 500 lbs. each, delivered on skips similar to those above described. Stone of Class 1 or Class 2 must not be loaded on cars carrying stone of Class 3. Stone of Class 3 will be used in decreasing amount as the jetties are extended. From 120 tons per day at the commencement of the work to about 10 tons per day when the outer end of the work is reached.

Class 4 Stone. Will be used for making concrete. It may be clean crusher run of the same rock as used for the other classes, or a good selected or washed river gravel may be used. It must vary in size from pieces with greatest dimension not more than 3 ins. to the finest product of the crushers. If river gravel be used, it must be thoroughly washed, all organic matter of any nature removed, and screened, if necessary, to exclude pieces greater than 3 ins. largest dimension. Either gravel or stone must be of hard, durable rock which will not disintegrate in the finished work.

Broken stone or gravel will be loaded on flat cars, provided with suitable sides. The amount required will vary from about 70 tons per day during the first part of the work to 8 tons per day for the outer ends of the jetties.

The larger portion of the stone supplied is a close-grained igneous rock, weighing about 198 lbs. per cu. ft. It is very difficult to quarry, breaking into very uneven fragments. However, by proper manipulation, a minimum of waste is secured and, as there is no covering soil to be contended with, the quarry is very satisfactory.

A second stone supply from the same vicinity is a close-grained metamorphic sedimentary rock with irregular planes of division of argillaceous material. This stone weighs 167 lbs. per cu. ft. and is easily worked. On account of the seams and a considerable covering of soil, which cause a large amount of waste, it has not been found advantageous to furnish any considerable quantity of this stone so far.

The stone is loaded by the contractors on standard flat cars and hauled 7 miles to a loading point on a navigable channel, where it is placed on barges carrying eight cars each. When delivered at the jetty receiving plant, it is unloaded and the empty cars are returned to the barges. From the loading point to the jetty landing is 9 miles.

The above arrangement permitted the contract to be made for the material only and the contractors have nothing to do with the actual jetty construction. The United States is not required to pass on the rock until it is offered for use at the jetty wharf.

The contractor's crew has numbered generally about 100 men, employed for 7 10-hour days per week. The following plant has been installed by the contractors:

Four 20-ton stiff-leg derricks, 100-ft. booms, with steam-driven hoisting and swinging engines; one steam crane, with shovel attachment, used for grading pits and tracks and for loading cars; one two-stage, 16 × 10 × 14-in. Ingersoll-Rand cross compound air compressor, electrically driven; one small jaw rock-crushing plant, electrically driven. In addition, there is the usual equipment of air drills, small tools, shop and mess equipment and appliances.

Hollow drill bits are used, and since the installment of an air-driven Leyner sharpener no difficulty has been experienced in successfully quarrying the stone. The contractor's transportation plant consists of fifty flat cars, 60,000 lbs. capacity, 36 ft. long, two car ferry barges and two tow boats. From the quarry to the landing the cars are handled over a logging railroad by the logging companies' motive power. The contractors are now providing 15 additional cars and a third barge.

The receiving and depositing plant at the jetty, belonging to the United States, consists of a 100-ft. span, three track apron for transfer from barge to shore tracks, adjusted to tidal elevation at barge end by counterweights, and fixed at 10-ft. elevation at shore end; two locomotives; three flat cars for miscellaneous materials; a 20 cu. ft. concrete mixer mounted on a flat car; a 10-ton revolving and traveling unloading crane, gage of gantry 14 ft.; water supply and distributing system; fuel oil storage and distributing system; a repair plant with power-driven tools for ordinary blacksmith, carpenter, and light machine work; an electric light plant; store house, mess house; crew quarters and necessary minor equipment for the work in progress. A new stone unloading crane of 20 tons capacity is now in course of construction. The jetty crew varies from 40 to 50 men working 6 8-hour shifts per week.

Cost of Repointing Sea-Wall with Cement Gun.—A cement gun was used for repointing about 22,000 lin. ft. of joints in the west side of the Government sea wall at Governors Island, N. Y. The work is described by Henry W. Babcock, in the July–Aug., 1917, Professional Memoirs. The following notes have been taken from an abstract of Mr. Babcock's article published in Engineering and Contracting, Aug. 15, 1917.

The sea-wall is built of heavy stones laid in courses; none of the courses were required to be of uniform height throughout except the coping, which was 1 ft. high and 3 ft. wide. The joints were ordinarily 1 to 1½ in. thick, sometimes reaching 2 in. On the northwest, or Hudson River, side of the wall the mortar had come out of the joints, almost generally, indicating that the joints had not been made full, but voids had been left in which ice formed. Frequently the joints were found open to a depth of 2 ft. or more.

The Cement Gun Co. furnished the cement gun at $250 a month; the air compressor at $5 a day; an operator for the gun at $6 a day, and an engineman to run the compressor at $4 a day. The United States furnished 5 to 7 laborers, a horse and cart and an overseer. The lease with the Cement Gun Co. also provided for payment to them of transportation charges on the plant and for 4 days' time allowed for transportation. The transportation charges were $216, being about trebled for the requirement of delivery on the island.

Work was begun at the north end of the extension sea-wall near Castle William on June 1, 1916, and was stopped June 29, 1916, at a point of 4,170 ft. from the beginning. The linear feet of joints pointed was about 22,320, averaging 900 ft. to the working day. At the beginning, although the location was near the sand pile and the cement storage, the rate was much slower on account of inexperience and bad weather. The rate also varied on account of tides, more work being accomplished when low tides occurred near the middle of the day.

In filling the joint, the operator turned on water only until the joint was washed clean, then the mixture of cement and sand with the water, sweeping over any convenient length of 4 to 8 ft. at a time. The mortar filled the joint gradually in from 2 to 5 minutes, depending largely on the voids as well as on the length covered. When the joint was nearly full, the visible completion appeared sudden.

The operator stood on the riprap foundation of the wall during work until the tide rose too high for rubber boots, when a plank swing was hung over the wall for a platform; this was for about 33 per cent of the time.

Some difficulty was met with in the lower joints, which are under water at high tide. They could be filled only at low tide, and the swash of waves or swells from passing steamers would often wash out the mortar for a depth of 3 to 6 in., a result which would happen from any pointing. Covering these joints with a weighted canvas screen was tried, but it was not effectual. Towards the close of the work, a few linear feet of joint were covered with plaster of Paris, which set at once and stayed on for a day, when the cement had hardened. It was rather slow and expensive for general use.

This kind of work unavoidably makes a joint without finish and spatters mortar on the face of the wall. One of the laborers was assigned to smoothing off the joint and cleaning away the surplus mortar before it had set.

It was at first intended to mix the cement and sand at 1 to 2. The Cement Gun men said that their experience led them to believe that the force with which the mortar was driven caused some of the sand to rebound, and that 1 to 3 was a better proportion. This was adopted. In these closed joints, however, the loss of sand from this cause was small. It is estimated that between 10 and 15 per cent of the mortar was wasted from spattering and overfilling the joints, and that this contained practically the same proportion of sand as the original mixture.

To drive the cement and sand through the hose with compressed air, it is essential that the mixture be quite dry. In the early part of June there was much damp, foggy weather and the sand got damp and, although the cement was kept quite dry, the mixture clogged in the hose. It is very probable that the compressed air was also fully saturated. The trouble was overcome by heating the sand on an iron plate over a fire of drift wood.

The cost of the work follows:

Expenditures:		
Rental of cement gun	$250.00	
Rental of compressor	125.00	
Services of operator	150.00	
Services of compressor engineman	100.00	
Transportation, including 4 days' rental time	216.00	
		$ 841.00
Rental, 3 tarpaulins to cover cement		41.85
Services:		
Manisees and Ingalls and crew, freighting supplies and general assistance	$171.58	
U. S. inspector and overseer, with 5 to 7 men	641.09	
2 horses, carts, and drivers, 34 days	136.00	
1 double team and driver, 1 day	8.00	
		956.67
Materials:		
800 bags cement	$324.00	
$125\frac{28}{100}$ cu. yd. sand	91.71	
635 gallons gasoline	152.40	
Force pump, fittings, and hose for water	81.66	
Lumber, runways and mortar beds	59.76	
Tools: Wheelbarrows, shovels, sand screen, etc	34.60	
Rope, for moving machines	24.09	
Miscellaneous: Canvas, rubber boots, etc	39.48	
		807.70
Office expenses and travel	$258.93	
Photographs	7.45	
		266.38
Total		$2,913.60

This cost will be reduced by a rebate of about $60.00 on cement bags returned in good condition.

The value of materials and tools not used up on the work is estimated at $262.70. This will not far exceed the cost of removing them and storing them until needed, and must be regarded as part of the cost of work in a locality such as Governors Island.

The length of joints repointed, 22,320 ft., was measured, and is essentially correct. The open widths varied from 2½ in. to nothing, and the depths repointed from 36 in. to 3 in. These cannot be averaged with any accuracy, being almost wholly out of sight. It is roughly estimated that the average thickness of joint is slightly less than 1 in., and the average depth perhaps 12 to 15 in.

The cost of this work with the cement gun was not far from the cost for the same lengths of joint repointed by hand. Hand work would give a better finish, but would hardly extend more than 4 in. into the wall.

The cost at Governors Island is 10 to 15 per cent more than it would be at an accessible point in the city.

In operating the cement gun, a large supply of compressed air is needed. It is used to turn the cement and sand free as well as to carry the dry mixture. This mixture will choke in the hose unless diluted with a large amount of air. From such observations as could be made, it appeared that the volume of sand and cement carried was from 1 to 2 per cent the volume of the air used as a vehicle.

The amount of water required was given by the Cement Gun Co. as 5 gal. per minute, at a pressure of about 45 lb. This quantity was seldom used, and the stated pressure is not needed. The suction from the air blast would draw in the water if delivered at the nozzle under a much lower head.

At Governors Island, fresh water could not be had along the line of the sea-wall; and salt water from the bay was used, pumped up through a fine brass mesh.

An examination was made Oct. 9, 1916, and another May 17, 1917. In neither case was there found any deterioration since the repointing was done. For about half the length of wall repointed, the lower joints, at and below half tide, are from 2 to 3 in. slack; and for a length of 125 ft., near the lighthouse, the lower joint is from 10 to 15 in. slack. This 125 ft. was repointed June 22, 1916, when the sea from a strong northwest wind washed the mortar out while it was fresh.

On May 17, test drills were driven 6 in. into the joints at these places; the mortar was everywhere firm and very hard. With hand pointing, the joints would not be filled to a depth of 6 in.

Percentage of Voids and of Settlement in Rubble Mount Breakwater.—In Jan.-Feb., 1918, Professional Memoirs, abstracted in Engineering and Contracting, Feb. 20, 1918, Clarence Coleman describes the methods of constructing the breakwater extension at Marquette, Mich. In this paper Mr. Coleman shows that the percentage of voids in the rubble foundation (deposited by being dropped or dumped into the water) was 37.43 per cent, and the voids in the remainder of the breakwater including the covering stone (10–15 ton size) were 40.57 per cent. In estimating for the work an allowance of 8 per cent additional tonnage was made to cover loss from settlement. The final results checked this figure very closely.

Cost of Unloading Stone for Rubble Mound Breakwater.—Table I, from the records of H. F. Alexander, gives the cost of unloading small or hand stone from deck scows, and is taken from Engineering and Contracting, Jan. 24, 1912.

TABLE I.—COST OF UNLOADING STONE FROM SCOWS BY HAND

Scow	Tons	Total number of hours required	Av. No. of tons per man per hour	Cost	Cost per ton
1st	828	326	2.54	$ 84.17	$.1015+
2nd	849	334	2.542	86.17	.1014
3rd	702	344	2.04	88.67	.1263
4th	485	160	3.03	41.67	.0859+
5th	914	274	3.335	72.00	.0787+
6th	444	174	2.55	45.17	.1017
7th	840	327	2.57	84.08	.1000
8th	641	250	2.564	64.83	.1011+
9th	592	243	2.436+	63.08	.1065
Totals	6,295	2,432	average 2.623	629.84	average $.1000

The high cost per ton on the third scow was due to unfavorable weather conditions. Owing to a severe storm the work of discharging this load had to be done on two different days, and considerable time was lost during a heavy rain. It will be seen that the average tons per man per hour on both the fourth and fifth scows, was much higher than on any of the other scows. When the fourth scow was unloaded, a number of ore shovelers and experienced men were employed; on the fifth scow, nearly all the men were of this class.

Although these men were paid more per hour than the men employed on the other scows, the results show them to have been the cheaper in the end. The men who unloaded the other scows were unskilled, being simply picked up on the streets, and while paid less per hour, they finally cost the contractor considerably more than the experienced and higher-priced men.

Method of Making Rapid Cost Estimates for Crib Pier and Breakwater Construction.—G. A. M. Liljencrantz has developed a method, which he describes in "Professional Memoirs," for making rapid cost estimates of pier and breakwater construction. Engineering and Contracting, June 5, 1912 publishes the following abstract of Mr. Liljencrantz's article.

Types of Structures.—There are six different types of structures considered. These are illustrated by Figs. 1 to 6. Each consists of a crib construction 100 ft. long. The first four types are 16, 20, 24, and 30 ft. wide and rest on piles. The last two are 30 ft. wide each and rest on stone foundations, 4 ft. and 6 ft. deep, respectively.

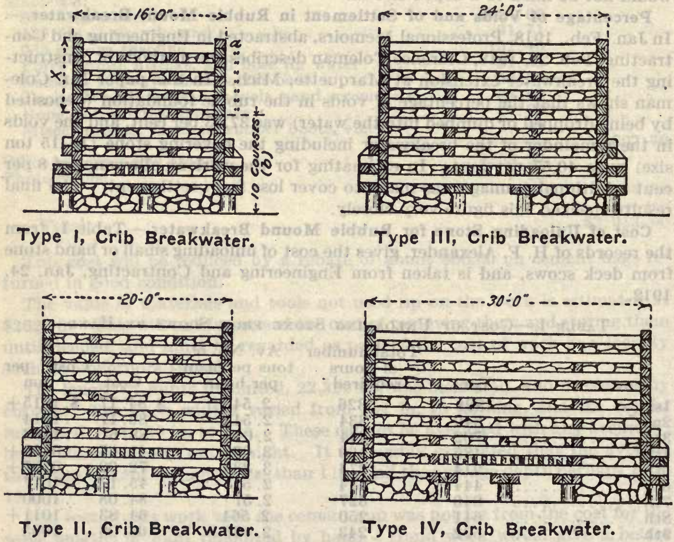

FIG. 6.—Types I–IV, crib breakwaters.

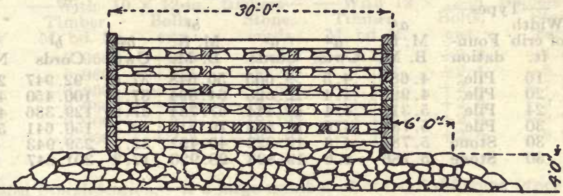
An examination of the various plans will show that in each of the above types the amount of materials contained in the ten lower courses (counting from the lake bottom) is a constant quantity for that type; and that in every two successive courses above the tenth course the quantities are the same for each type, respectively.

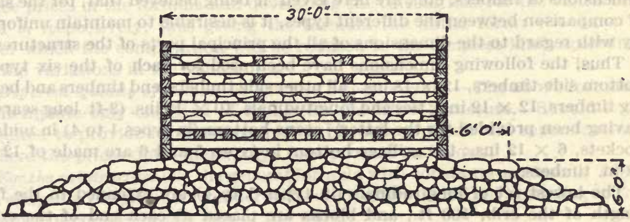
This fact suggested the practicability of using the formula for a straight line for the computation of the total cost of a crib of any desired height, after the materials of the ten lower courses, and in the two upper courses, respectively, have been ascertained. Thus we have the formula $Y = aX + b$, in which Y represents the cost of a crib structure 100 ft. long, according to either of the types; a represents the cost of all materials in one of the upper courses (the constant given in the table below being the average of the two upper courses), X equals number of courses desired above the tenth course; and b equals the cost of all materials used in the lower ten courses. The height of the timberwork above the lake bottom (2 ft. in types 1 to 4, inclusive) is counted as two courses. The stone foundations in the other types shown are counted as four and six courses, respectively. The bottom course of the crib work is 1.5 ft. high, all other courses being 1 ft. each.

There is one discrepancy in the formula which would affect the accuracy of the results if not remedied. This is accounted for later on.

Use of Formula.—As stated, the constants a and b represent the cost of *all* materials in the different parts of the crib as noted. These materials consist



Type V, Crib Breakwater.



Type VI, Crib Breakwater.

FIG. 7.—Types V and VI, crib breakwaters.

of lumber, drift bolts and stone and (in types 1 to 4), of piles and screw bolts. The unit prices of each of these materials will also be factors. The formula containing all these items will be as follows:

$$Y = (a^tT + a^dD + a^sS)\,X + b^tT + b^dD + b^sS + pP + cC$$

In this a^t and b^t, a^d and b^d, a^s and b^s, p and c represent, respectively, the quantities of timber drift bolts, stone piles and screw bolts (as shown in Table II), for each type, and T, D, S, P and C the unit prices of materials, viz., per thousand board feet of timber, per hundred weight for bolts per cord of 128 ft. for stone, and for each pile. All prices are for materials "secured in the work." It must be particularly remembered that X represents the number of courses above the tenth course.

As has already been stated, the constant a^t represents the amount of timber required in *one* of the courses above the tenth course, and the constant b^t

the total amount in the ten lower courses. From this it follows clearly that the total amount of timber required in 100 lin. ft. of a crib of any of the types, respectively, will be found by means of the simple formula:

$$Y^t = a^t X + b^t,$$

using the respective values for the constants in Table II. In the same manner the amount of drift bolts, stone, etc., may be obtained.

The discrepancies referred to above have been remedied and the constants have been corrected accordingly and are to be used *as given* in the table.

TABLE II.—CONSTANTS FOR TYPES WITH TIES AND LONGITUDINALS OF 10 × 12-INCH TIMBERS

——Types——										
No.	Width of crib ft.	Foundation	a^t M. ft. B. M.	a^d Cwts.	a^s Cords	b^t M. ft. B. M.	b^d Cwts.	b^s Cords	p No.	c Cwt.
1	16	Pile	4.680	4.3	9.605	56,648	37.0	92.947	27	5.1
2	20	Pile	4.996	4.4	12.525	64.894	37.5	100.450	40	6.7
3	24	Pile	5.312	4.4	15.444	67.734	37.8	129.336	40	6.7
4	30	Pile	5.786	4.6	19.823	79.518	38.3	150.641	53	8.4
5	30	Stone	5.786	4.6	19.823	40.492	25.9	259.943	0	0
6	30	Stone	5.786	4.6	19.823	28.920	17.3	301.547	0	0

Chief Elements in the Structures.—It may be found desirable to verify the various amounts entering into the calculation, and for that purpose the general dimensions of timbers, etc., are here given; it being believed that, for the sake of comparison between the different types, it is desirable to maintain uniformity with regard to the dimensions of all the principal parts of the structures.

Thus, the following dimensions have been used for each of the six types: bottom side timbers, 12 × 18 ins.; all other side timbers, end timbers and bearing timbers, 12 × 12 ins.; ties and longitudinals, 10 × 12 ins. (2-ft. long searves having been provided for the latter); stone bottom (in types 1 to 4) in middle pockets, 6 × 12 ins.; the grillage bottom in types 5 and 6 are made of 12 × 12-in. timbers.

The lowest set of longitudinals (in types 1 to 4) are extended to the full length of the crib, 100 ft., and blocks are placed at each end of the crib, between these longitudinals and the bearing timbers, which are also 100 ft. in length. An extra bearing timber, 12 × 12 ins., is provided—in type 4, above the stone bottom. All cross ties are dove-tailed into the side timbers and the longitudinals into the end walls. Stone has been provided for in the walls between the cribs, the calculation thus covering the filling of the crib for its entire length.

In estimating the amount of stone required, calculation has been made on the assumption that the whole volume of the crib, less the space occupied by timber, is filled with stone. While this is not strictly correct, it has been done to compensate for such stone that will usually settle down into the sand bottom and work out on the sides; also, to some extent, for irregularity in the lake bottom.

Drift bolts, 32 × 20 ins. in length, are provided for in regular columns in the side and end walls; also through bearing timbers and protruding ties, and in the crossings of ties and longitudinals, alternately in each crossing.

Discrepancy in the Formula and Its Remedy.—It was stated above that the quantities in each set of two courses above the tenth course are constant amounts for each type. There is an exception to this rule. The top course of every structure has less timber and stone than each of the other courses, because there are no longitudinals in this course and no stone in the upper half of it. There are, however, more bolts in the top course, as a 20-in. bolt is placed in each of the top, side and end walls, in each column of 32-in. bolts, where these reach only to the upper face of the third course from the top.

To remedy this, the respective amounts are deducted—for timber and stone —and added for drift bolts, to the corresponding materials in the constants *b*. for each respective type. These amounts are given in Table III. The figures given in Table II are the corrected amounts, as already mentioned.

TABLE III.—CONTENTS USED TO COMPENSATE FOR DISCREPANCY IN THE TOP COURSES

	With 10 × 12-in. timbers			With 12 × 12-in. timbers		
Types	Timber, M. bd. ft.	Bolts, cwt.	Stone, cords	Timber, M. bd. ft.	Bolts, cwt.	Stone, cords
1	−0.960	+2.3	−4.747	−1.152	+2.3	−4.625
2	−0.960	+2.4	−6.279	−1.152	+2.4	−6.157
3	−0.960	+2.4	−8.591	−1.152	+2.4	−7.687
4	−0.960	+2.5	−10.107	−1.152	+2.5	−9.984
5	−0.960	+2.5	−10.107	−1.152	+2.5	−9.984
6	−0.960	+2.5	−10.107	−1.152	+2.5	−9.984

Suggested Simplification.—If a large number of cribs of different types and heights are to be estimated for, and prices suitable to the locality and period have been determined, the formula may be materially simplified by inserting these prices in the formula and developing the calculations for the values of *a* and *b*, respectively, thus giving the formula the initial form: $Y = aX + b$, after which the computation will be reduced to the simplest kind, according to the variations in the values of X.

Different Quality of Timber in Sub and Superstructure.—The above formulas contemplate only one kind of timber for the whole structure. Should it be required to provide for different quality of timber for sub and superstructure (where the prices differ materially) then proceed as follows:

For the substructure use the general formula with constants as given in Table II; adapting the prices for timber to be used, and with X fixed according to the number of courses in *this part* of the work.

For the superstructure use the same formula with the constant *a* as above; but for the constant *b* substitute the values for this constant (with + or − signs as indicated) as given in Table IV and make X = the number of courses desired in the superstructure, and use the price for the proposed kind of timber accordingly.

Rebuilding Superstructure.—Should it be required to prepare an estimate for the cost of rebuilding the superstructure over old crib work the same method should be followed, adding, however, only the cost of removing the old work.

Modification in Types.—If it is preferred to use 12 × 12 in. timbers for ties and longitudinals, this would increase the constants for timber and decrease the constants for stone. The constants for bolts would not be affected. Table V gives the constants calculated to fit such cases, all other elements remaining unaltered.

Decking.—The crib work is generally covered by some kind of decking to protect the stone filling, especially if the work is exposed to severe storms. The form of decking generally used in this district consists of 6 × 10 in.

planking laid flat, 2 ins. apart, and spiked to the cross ties with $\frac{1}{2} \times 14$ in. spikes, washers being used under the heads of the spikes, which has proved very advantageous in giving much better hold. One hundred linear feet of a deck plank contains 500 ft., B. M., and the spikes required for that length of deck plank, including washers, will weigh approximately 50 lbs.

The total cost of the decking, of the kind described, for any of the types of cribs may be obtained by the simple formula: $Z = \frac{(E + K)X}{2}$ in which Z represents the cost of the decking over 100 lin. ft. of the crib; E = the cost per M. ft. B. M. of the deck timbers; K = the cost per cwt. of the spikes and washers, and X = the width (*inside* of the side timbers) of the crib to be covered.

Intermediate Decking Supports.—When a pier or breakwater is greatly exposed to severe gales, it is very desirable to place intermediate supports under the decking, half-way between the cross ties. These supports may be made of 3×12 in. planks placed on edge and resting on the two top longitudinals and, at each end, on a 3×12 in. $\times$ 2-ft. piece of plank spiked to the side walls, with their tops level with the tops of the longitudinals. The length of each plank will be equal to the inside width of the crib. If, however, they are estimated equal to the *outer* width of the crib + 2 ft., in length, the two pieces to be spiked to the side walls will be provided for. The decking should, as a matter of course, be spiked to this planking. As there are twelve spaces between the ties in each crib, the cost of the decking supports will be obtained by the formula: $Y = 0.036\ F.\ (W + 2) + 0.3\ K\ (W - 2)$ in which Y represents the total cost of the decking supports for a crib 100 ft. long; F equals the cost per M. ft. B. M. of the planks; K equals the cost per cwt. of spikes and washers and W equals the outside width of the crib.

TABLE IV.—CONSTANTS FOR TYPES WITH TIES AND LONGITUDINALS OF 12 × 12-IN. TIMBERS

Types	a^t M. ft. B. M.	a^d Cwt.	a^s Cords	b^t M. ft. B. M.	b^d Cwt.	b^s Cords	p Piles	c Screw bolts

Types of Breakwater Construction and Their Costs.—This is given in the report of J. F. Hasskarl before the 12th International Congress of Navigation. The following notes are taken from an abstract of Mr. Hasskarl's paper in Engineering and Contracting, June 26, 1912.

Delaware Breakwater.—The Delaware Breakwater was commenced in 1828 and completed in 1869. Its principal dimensions and cost are: Length 2,558 ft.; length of Gap and Ice Breaker, which are connected with the same, 2,709 ft.—making the total length of this structure 5,267 ft. Area of average cross section above sea bottom, 4,067 sq. ft. Area of average cross section above mean low water, 547 sq. ft. Area of average cross section below mean low water, 3,520 sq. ft. Tons per average lin. ft., 277.69. Cost per average lin. ft., $608.95. *Note:* The great excess of material placed in the structure over the enrockment at present remaining above the bottom is explained as follows: The bottom is very soft, there are no mattresses, and much of the material has sunk into the soft mud. The weight of a cubic yard of solid stone is approximately 2.24 tons, and a cubic yard of enrockment weighs about 1.68 tons.

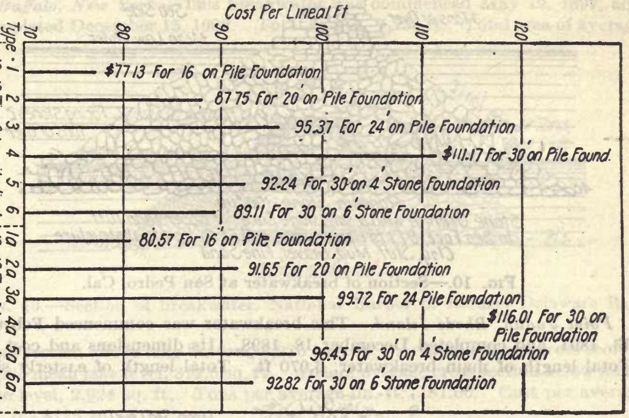

FIG. 8.—Relative costs of crib breakwaters of different types.

San Pedro, California.—This breakwater was commenced November 12, 1898, and is still (1912) under construction. Its dimensions and cost are: Total length when completed, about 11,100 ft. Total area of average cross section above sea bottom, 6,466 sq. ft. Area of average cross section above mean low water, 412 sq. ft. Area of average cross section below mean low

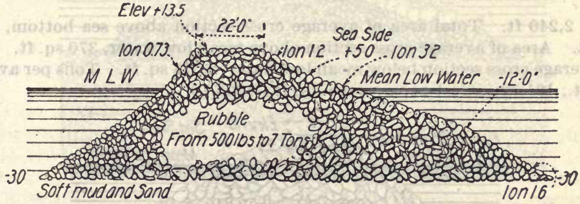

FIG. 9.—Section of Delaware breakwater.

water, 6,054 sq. ft. Tons per average lin. ft., 344.31. Cost per average lin. ft., $285.

Colon, Panama, West Breakwater.—This breakwater was commenced in 1910 and is still under construction. Its dimensions and cost are: Total length when completed, 11,322.5 ft. Total area of average cross section above sea bottom, approximately 6,777 sq. ft. Area of average cross section above mean sea level, approximately 335 sq. ft. Area of average cross section below mean sea level, approximately 6,442 sq. ft. Tons per average lin. ft., 340. Estimated cost per average lin. ft., $481.

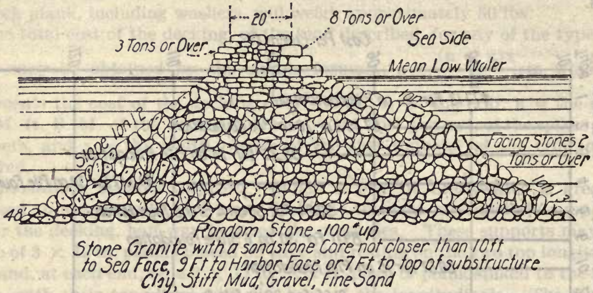

FIG. 10.—Section of breakwater at San Pedro, Cal.

Point Judith, Rhode Island.—This breakwater was commenced February 13, 1891, and completed December 18, 1898. Its dimensions and cost are: Total length of main breakwater, 6,970 ft. Total length of easterly shore

FIG. 11.—Section of Colon breakwater, Panama.

arm, 2,240 ft. Total area of average cross section above sea bottom, 2,948 sq. ft. Area of average cross section above mean low water, 370 sq. ft. Area of average cross section below mean low water, 2,578 sq. ft. Tons per average lin. ft., 161.72. Cost per average lin. ft., $206.70.

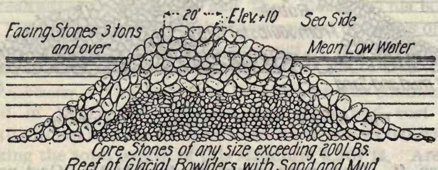

FIG. 12.—Section of Point Judith breakwater, Rhode Island.

National Harbor of Refuge, Delaware Bay.—This breakwater was commenced in 1897 and completed in 1901. Total length, 8,040 ft. Total area of average cross section above sea bottom, 3,474 sq. ft. Area of average cross section above mean low water, 550 sq. ft. Area of average cross section below mean low water, 2,924 sq. ft. Tons per average lin. ft., 183.82. Cost per lin. ft., $217.60.

GREAT LAKE BREAKWATERS

Buffalo, New York.—This breakwater was commenced May 19, 1897, and completed December 15, 1902. Total length, 7,250 ft. Total area of average

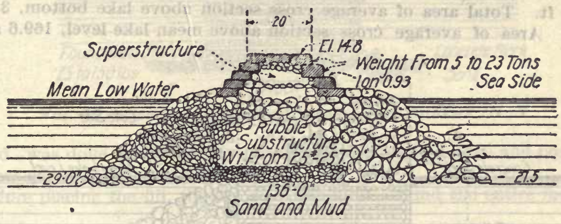

FIG. 13.—Section of breakwater, National Harbor of Refuge, Delaware Bay.

cross section above lake bottom, 3,236.5 sq. ft. Area of average cross section above mean lake level, 312.5 sq. ft Area of average cross section below mean lake level, 2,924 sq. ft. Tons per average lin. ft., 181.60. Cost per average lin. ft., $125.26.

Buffalo, New York.—Original breakwater built October 7, 1898—October 27, 1900. New superstructure work commenced June 18, 1901, completed May 18, 1902. Total length, 1,800 ft. Total area of average cross section

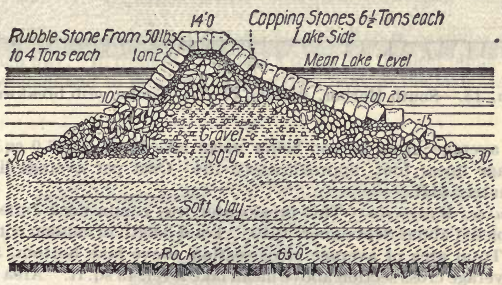

FIG. 14.—Sorted rubble mound breakwater at Buffalo, N. Y.

above lake bottom, 2,417.68 sq. ft. Area of average cross section above mean lake level, 302.68 sq. ft. Area of average cross section below mean lake level, 2,115 sq. ft. Tons per average linear foot above lake bottom, 105.34. Cost per average linear foot above lake bottom, $242.53. Total tons per average linear foot, including gravel fill in trench, 268.84. Cost per average linear foot including trench and gravel fill, $278.89.

Dunkirk, New York.—This breakwater was commenced August, 1897, and completed August, 1898. Total length, 310 ft. Total area of average cross section above lake bottom, 535.2 sq. ft. Area of average cross section above mean lake level, 175.2 sq. ft. Area of average cross section below mean lake level, 360 sq. ft. Tons per average lin. ft., 28.557. Cost per average lin. ft., $65.12.

Cleveland, Ohio (Eastern Extension).—This breakwater was commenced May 4, 1903, and is still under construction. Total length when completed, 15,600 ft. Total area of average cross section above lake bottom, 3,246.5 sq. ft. Area of average cross section above mean lake level, 169.6 sq. ft.

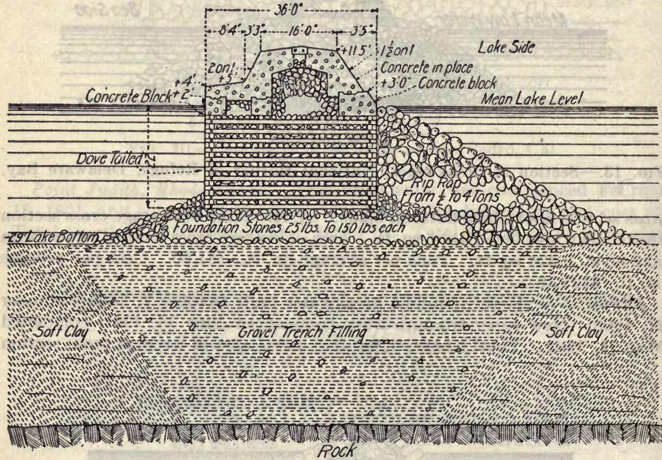

FIG. 15.—South Harbor, Buffalo, N. Y. Timber crib breakwater.

Area of average cross section below mean lake level, 3,076.9 sq. ft. Tons per average linear foot, approximately 164. Cost per average linear foot, approximately $175.

Milwaukee, Wisconsin.—This breakwater was commenced June 14, 1909, and completed about September, 1910. Total length of caisson construction, 577 ft. Total area of average cross section above lake bottom, 531 sq. ft. Area of average cross section above mean lake level, 43 sq. ft. Area of average cross section below mean lake level, 488 sq. ft. No data for weight per linear foot obtainable. Cost per average linear foot, $117.94. *Note:* Stone for riprapping caissons, except about 800 tons of large stone placed on lake side, was obtained from the razing of an old pier and is not included in above estimate of cost.

Cost of Sea Wall for Land Reclamation at New Orleans.—Engineering News, June 25, 1914, gives the following data from the report of a commission of the Sanitary District of Chicago.

The city of New Orleans in making about 27 acres of new land at the "West

End" for municipal purposes, constructed a pile and concrete sea wall on Lake Pontchartrain, about 2,650 ft. long, and dredged and deposited a fill averaging 8 to 12 ft. deep behind this wall. This dredging, amounting to about 400,000

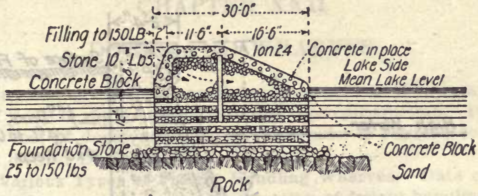

FIG. 16.—Section of detached breakwater, Dunkirk, N. Y.

cu. yd., was done in the lake by means of a hydraulic dredge and cost 11.37 cts. per cu. yd., placed in fill.

Before placing the fill, the sea wall was built around the entire inclosure.

FIG. 17.—Extension of East breakwater, Cleveland, Ohio.

The wall is of concrete, placed on a double row of 50-ft. oak piles spaced 5 ft. c. to c. each way. In front of this piling a triple row of sheet piling was driven as a coffer-dam and to prevent the fill sliding back in the lake. About 3 ft.

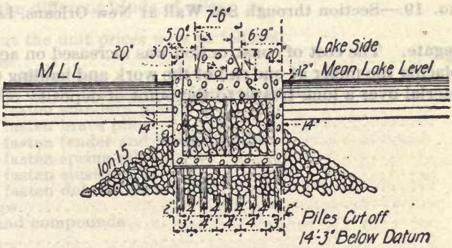

FIG. 18.—Reinforced concrete caisson, South Pier, Milwaukee, Wis.

of material was excavated for the base of the concrete cap, so that the piles are entirely protected from the action of the teredo. The wall is provided with two rows of weep holes, and has expansion joints 50 ft. apart.

Including the piles, excavation and concrete, the wall has cost about $26 per lin. ft., or $13 per cu. yd. of concrete. The labor costs were $1.75 to $2 for common labor and $3 per day for skilled labor. Gravel was used for the

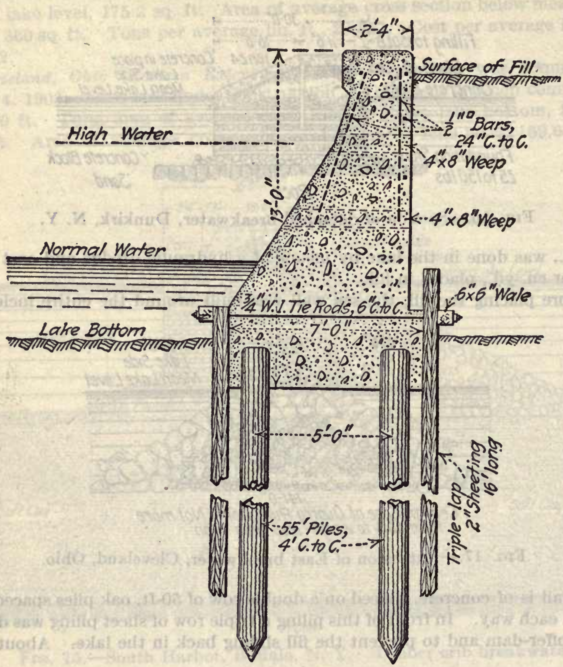

FIG. 19.—Section through Sea Wall at New Orleans, La.

concrete aggregate. The cost of construction was increased on account of the necessity of placing the mixer at one end of the work and hauling the concrete and other material over a long trestle to the point of deposit.

CHAPTER XXII

DOCKS AND WHARVES

This chapter contains costs of complete pier structures of various types and also costs of items of work entering into this type construction. For further data on the cost of docks and wharves the reader is referred to Gillette's "Handbook of Cost Data."

Costs of Various Types of Freight Handling Wharves.—Data concerning the latest and best practice in the construction of freight-handling wharves has been collected by a committee of the American Railway Engineering Association. The information was obtained from members of the association and is summarized in the July (1917) Bulletin of the association by W. H. Hoyt as a portion of an article on the design of docks and wharves. The following abstract of Mr. Hoyt's article is given in Engineering and Contracting, Sept. 26, 1917.

Docks at San Francisco, Ferry Point and Oakland, Santa Fe System.—The Atchison, Topeka & Santa Fe Ry. Coast Lines has about 4,000 ft. of frontage of wharf at San Francisco, practically all of which is over a rock seawall and is supported on creosoted piles, spaced 10 ft. each way. The intermediates are 4 in. by 12 and tracks are carried with two pieces of 12-in. by 12-in. under each rail over the 10-ft. spans. At Ferry Point the railway has a wharf 70 ft. wide by 700 ft. long. In 1913 this wharf was extended and a new freight apron built on the end. The extension was designed primarily for the accommodation of barges handling cars. The wharf on either side of this dock was constructed as a support for the spring line of the slip. This also is true of a new slip at Oakland. The latter wharf was driven with a 10-ft. spacing of piles. In all of the wharf work piles treated with 16 lb. of creosote are used for salt water driving. All the above mentioned jobs were constructed by contract covering the labor only, the railway company furnishing all the material. Each contract was made up on the basis of unit prices covering each kind of lumber and the different kinds of piles.

At Ferry Point the unit prices were as follows:

Pulling piles	$15.00 each
Taking out old lumber	6.00 per M
Cutting piles off on present wharf to new grade	1.25 each
Drive and fasten standard piles	9.35 each
Drive and fasten brace piles	15.50 each
Drive and fasten fender and mooring piles	7.15 each
Drive and fasten spring piles	11.00 each
Drive and fasten cluster piles	16.00 each
Drive and fasten dolphin piles	18.50 each
Placing caps	21.00 per M
Stringers and compounds	16.00 per M
Planking	11.35 per M
Guard rail	9.60 per M
Chocks	32.00 per M
Ribbing	31.70 per M
Spring line chocks	45.00 per M
Sheathing	18.50 per M
Intermediate stringers	12.75 per M
Total labor (approximately)	$15,000

At Oakland the unit prices were as follows:

Drive and fasten standard piles	$ 9.00 each
Drive and fasten brace piles	15.00 each
Drive and fasten dolphin piles	18.00 each
Drive and fasten cluster piles	12.00 each
Drive and fasten spring piles	12.00 each
Placing caps and sub-caps	21.00 per M
Placing stringers and compounds	16.00 per M
Placing intermediate stringers	12.75 per M
Placing planking	11,00 per M
Placing guard rail	9.00 per M
Placing ribbing	34.00 per M
Placing chocks	40.00 per M
Placing sheathing	18.00 per M
Taking up old timber	6.00 per M
Total labor (approximately)	$19,000

At San Francisco the unit prices were as follows:

Drive and fasten fender piles	$ 8.00 each
Drive and fasten standard piles	8.00 each
Drive and fasten mooring piles	8.00 each
Placing caps	20.00 per M
Compound stringers	16.00 per M
Track stringers	16.00 per M
Intermediate stringers	15.00 per M
Fillers	10.00 per M
Guard rail	10.00 per M
Planking	10.00 per M
Removing old lumber	6.00 per M
Placing chocks	32.00 per M
Breaking off old piles	3.00 each
Pulling piles	12.00 each
Placing sub-caps	25.00 per M
Total labor (approximately)	$17,500

Pier No. 5, Weehawken, N. J., New York Central & Hudson River R. R.—Designed for handling outward business (boats to cars) only. Built on pile foundations. Has adequate floor space and numerous gangways to make short trucking possible. It is securely sway braced with 4-in. × 8-in. plank bolted to each pile, also girt timbers running across piling underneath wharf. Has double layer deck, consisting of a lower 4-in. plank deck covered with 2-in. × 4-in. beech flooring. The total contract cost of the substructure and superstructure, including heating, dry fire protection line, electric wiring and fire alarm system, was about $3 per square foot.

Pier and Bulkhead Platforms, James Slip and Olive St., New York City.—Has a 9-in. reinforced concrete deck on timber stringers and pile foundation. On top of the 9-in. concrete is a 2½-in. asphalt wearing surface. The front of the wharf is fendered with oak piling and timber securely bolted to the main frame work. The unit costs are stated to be as follows: Timber decks, including rangers, about 52 cts. per square foot; reinforced concrete deck, 46 cts. per square foot, and with 2½ asphalt wearing surface 55 cts. per square foot. The figures for concrete do not include the cost of timber construction at deck level on the sides of the dock.

Dock at Sandusky, O., for Pennsylvania R. R.—This is a new dock for coal machine. It is a good example of filled timber crib on rock foundation with monolithic concrete superstructure. The average height of crib is 18 ft. The unit cost per lineal foot of dock was as follows:

	Per lin. ft. of dock
Hemlock lumber	$ 35.00
Framing, placing and sinking	25.00
Iron (tie bolts, drift bolts, etc.)	14.00
Stone (for sinking cribs)	12.00
Leveling foundations	2.00
Concrete top	19.50
Cast iron mooring posts	1.50
Total	$109.00

Dock at Port Bolivar, Tex., Gulf, Colorado & Santa Fe Ry.—This dock is a timber platform supported on pile foundations. Back of the dock proper sheet piling has been driven and tied back by ½-in. iron rods to anchor piles, and the dock filled. The geological formation at the site consists of alternate layers of water, sand and sea inlet to an indefinite depth. It is estimated that the cost of a pile foundation for concrete walls with the cost of the necessary caisson work would more than equal the entire cost of the present bulkheads and aprons. The unit costs were as follows:

Total cost of bulkhead per lin. ft	$33.27
Total cost of apron 30 ft. wide per sq. ft	0.7343
Cost per linear foot marine treated piles	0.385
Cost per linear foot untreated piles	0.085
Cost per M. feet B. M. marine treated timbers	47.80
Cost per M. feet B. M. full-cell treated timbers	31.00
Cost per M. feet B. M. untreated timbers	21.80
Cost per linear foot driving marine treated piles	0.17
Cost per linear foot driving untreated piles	0.15
Cost per M. feet B. M. placing marine treated timbers	16.00
Cost per M. feet B. M. placing other timbers	15.00

Average cost of freight on piles about $0.05 per lin. ft., and on timbers about $5 per M. B. M.

Pier No. 9, Hoboken Terminal, Delaware, Lackawanna & Western R. R.—This pier has been in use for about 8 years. It is a 2-story steel and reinforced concrete structure supported on pile foundations stiffened with riprap and rubble filling. The cost was $4.25 per square foot.

Lumber-Handling Dock, Lake Superior, Duluth, Winnipeg & Pacific Ry.—This dock was designed exclusively for handling lumber from railroad cars to boats.

Its cost was as follows:

Engineering charges	$ 1,409
Freight charges on piling, ties and planking	5,089
Piling, 103,185 lin. ft	17,539
Timber, 818,230 ft. B. M	22,702
Machine bolts, drift bolts, etc	1,480
Iron cleats, 25, at $8.75	219
Contract price driving piles, 92,791 lin. ft. left in work at 5¾ cts	5,335
Contract price framing deck and bracing, 781,699 ft. B. M. left in work, at $6.90 per M	53,94
Excavation for mud sills on bank	119
Crib at end of dock:	
Iron rods for tieing crib	19
Labor applying rods	44
Stone for filling crib, 64 cords at $7	448
Dredging, 177,427 cu. yd. at 11 cts	19,517
Track, 60-lb. rail, and fastenings, second-hand	1,689
Track, labor	320
Saunders car stoppers, 2 at $45	90
Freight on car stoppers	7
Total	$81,422

Dock, Toledo, O., Hocking Valley Ry.—This structure is typical of the ore and coal-handling docks on the Great Lakes. It is an excellent sample of crib-filled structures and of concrete pier supported directly on piling. On account of the heavy distributed loads to be carried and the heavy machinery foundations it requires a very solid substructure. It is also thoroughly tied back with anchor rods. The unit costs were:

12-in. × 12-in. timber grillage placed	$43.00	per M. B. M.
2-in. plank, hardwood	38.00	per M. B. M.
2-in. plank, hemlock	35.00	per M. B. M.
Timber piling driven	.28	per lin. ft.
Steel piling driven	.02	per lb.
Concrete placed	6.80	per cu. yd.
Steel "I" beams placed	.02	per lb.
Steel reinforced rods placed	.02½	per lb.
Wrought iron rods placed	.05	per lb.
Dredging and waste	.23	per cu. yd.
Dredging and backfill	.27	per cu. yd.

The above do not include company freight or supervision.

Dock on Chicago River, Chicago, Milwaukee & St. Paul Ry.—This is a very simple structure composed of a front row of piling with sheet piling anchored back to anchor timbers and piles with 1¼-in. rods. The dock is then filled. These docks in Chicago and Milwaukee cost from $18 to $25 per lineal foot, depending upon local conditions.

Costs of the Terminal Piers of the Norfolk & Western Ry. at Norfolk, Va.—In Engineering News-Record, May 16, 1918, F. P. Turner gives the following matter.

The general layout and dimensions of the piers are shown in Figs. 1 and 2.

The outbound or northbound freight is cared for on the southerly of the two piers, which is 800 ft. long and 222 ft. wide and carries a warehouse 208 × 750 ft. Incoming freight is handled by the northerly pier, which is 222 × 1,200 ft. in plan with a 208 × 1,150 ft. warehouse. A water depth of 28 to 30 ft. is provided in the slips around the piers.

The type of construction, determined after a thorough investigation of the first cost, annual repairs and life of various kinds of floors and roofs, was such that the average life of the component parts would be the same.

The pier-shed, being of steel, will under normal conditions have double the life of substructure supporting the floor. The pedestals around the edge of the pier are creosoted piles protected by a steel cylinder, extending two to three feet below maximum depth of water and filled with earth. Experience on similar structures has led to the belief that steel cylinders will last 20 to 25 years and that creosoted piles, after exposure, will last equally as much longer.

The roof, floor and pile substructure may be renewed in sections after 20 to 25 years' service without taking down the steel trusses or interfering with the remainder of the pier. Since the renewal of the substructure would require the destruction of the floor and roof it was not considered advisable to select the more expensive concrete fireproof construction for these two elements, but to use materials having a normal service the same as the substructure.

Creosoted pile substructure was adopted for the entire pier area outside of the bulkhead line established by the War Department. Inside the bulkhead line it proved more economical to drive an uncreosoted bulkhead at the location shown upon the plan and fill it with dredged material for supporting the pier-shed floor and tracks. Creosoted posts, caps, bracing and floor stringers were used above the low-water line. A 3-in. white-oak floor, dressed on one side and two edges, was adopted for wearing surface, this type of floor having

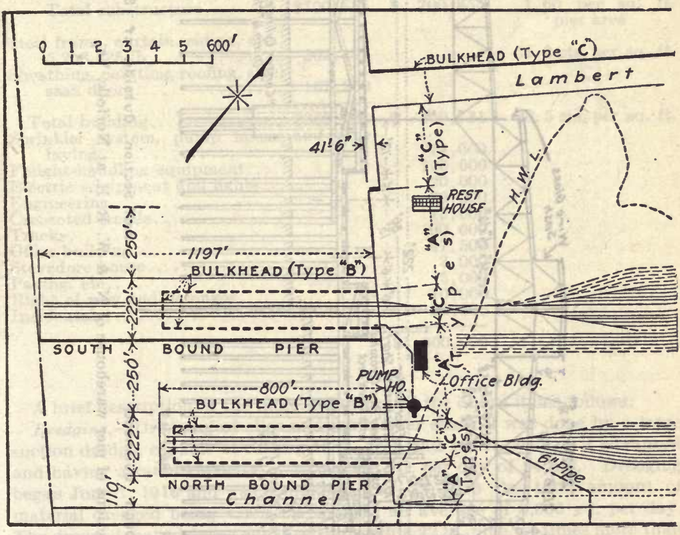

FIG. 1.—General plan of piers of the N. & W. R. R. at Norfolk, Va.

a record of long service in similar warehouses of this company. The roof selected was a 5-ply felt, pitch and gravel, laid on 1¾ in. tongue-and-groove yellow pine sheathing resting on steel purlins.

Dimensions and spacing of timbers and steelwork entering into the construction of these piers are indicated on the accompanying drawings. The loads assumed in the design are as follows:

Floor—500 lb. per sq. ft.
Roof—Purlins, 40 lb. per sq. ft.
Trusses, 50 lb. per sq. ft.
Piles—17 tons each.

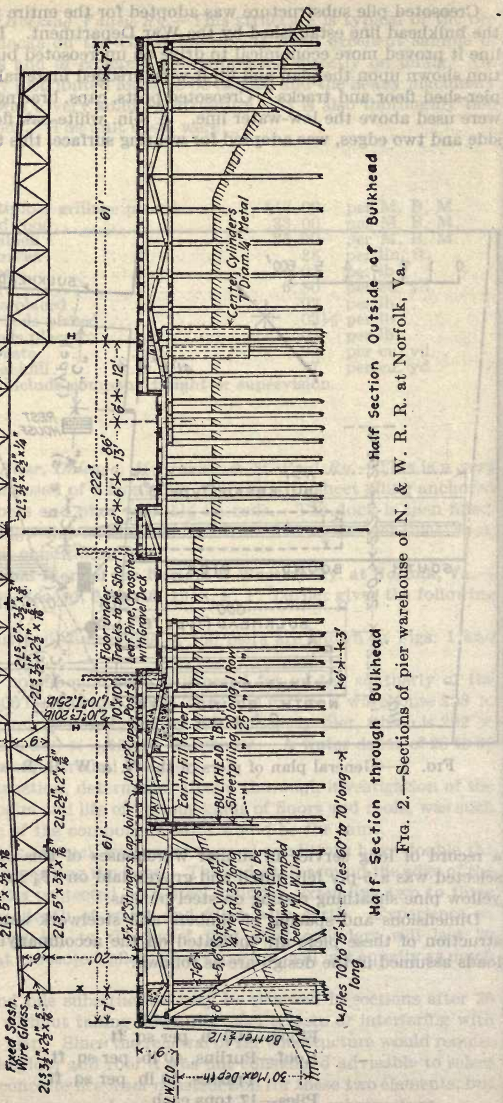

FIG. 2.—Sections of pier warehouse of N. & W. R. R. at Norfolk, Va.

The quantities and cost of the development, which was built during 1916 and 1917, follow:

Dredging—1,373,226 yd.		$ 108,922	$0.0794 per cu. yd.
Bulkhead A—775 ft. long		37,565	$48.50 per ft.
Bulkhead C—8,300 ft. long		138,291	16.70 per ft.
Main pier substructure:			
Bulkhead B, 3,320 ft. long	$ 65,355		19.70 per ft.
Pile and timber work	577,675		
Steel cylinders, 700,800 lb.	23,000		
Floor	34,825		
Total substructure	$700,855	$ 700,855	1.60 per sq. ft. pier area
Steel frame, curtain, siding, etc., 5,258,425 lb.	202,481		51.2 cts. per sq. ft.
Sheathing, painting, roofing, steel sash doors	167,250		
Total building	$369,731	$ 369,731	93.5 cts. per sq. ft.
Sprinkler system, pump house and pipe laying		74,000	
Freight-handling equipment		126,600	
Electric equipment and lights		20,000	
Engineering		30,000	
Creosoted trestle		12,000	
Tracks		90,000	
Office building		47,500	
Stevedore house		3,000	
Paving, etc.		5,000	
Right of way and damages		10,000	
Incidentals		26,536	
		$1,800,000	

A brief description of the more important of the above items follows:

Dredging.—Dredging of slips and main river channel was done by a large suction dredge, capable of cutting 16 ft. deep and 150 ft. wide as it advanced and having a rated capacity of 10,000 cu. yd. per day of 24 hrs. Dredging began June 1, 1916 and was completed Nov. 23, 1916 the total amount of material dredged being 1,373,226 cu. yd., an average of 8,000 yd. per day. The dredged material was conveyed through a 22 in. pipe, at times more than 4,000 ft. long, and was discharged along the line of the bulkhead. Thus, the heavy material was deposited immediately adjacent thereto and the light silty material was forced to the interior. Most of the material dredged was white sand and clay and it immediately gave good resistance after depositing.

The results of this method reduced the pressure against the bulkhead and no failures resulted. Spillways were provided in the bulkhead, at the extreme end of the area to be reclaimed, for water to return to the channel.

Bulkheads.—Figs. 2 and 3 show the type of construction of Bulkheads A, B and C.

Pile and Timberwork.—Creosoted piles were generally 14-in. diam. 2 ft. below butt with 7-in. points, in lengths varying from 50 to 80 ft.; untreated piles driven inside the bulkhead B were 12-in. diam. 2 ft. below butts and 6-in. points. All bulkhead piles were creosoted and of the larger size.

Sound square edge short-leaf pine lumber, creosoted with 12-lbs. of dead oil of coaltar per cu. ft. was used for all exposed bracing and floor supports.

Steel Cylinders.—The pedestals supporting the center columns, outside bulkhead B, were constructed in cylinders 7-ft. diam. Six creosoted bearing piles were driven in each cylinder.

Floor.—Interior floors consisted of 3-in. white oak dressed one side and two edges, outside the building long leaf yellow pine similarly dressed being used.

At about 300-ft. intervals the two buildings have concrete floor slabs 9-ft. wide resting on pile bents and extending from side to side. Precast reinforced concrete fire walls 4-in. thick, 10 to 13 ft. long are hung from this concrete panel and extend 1.5 ft. below low water.

Steel Frame.—The steelwork of the two buildings, 5,167,000 lbs. was erected in 62 working days. A locomotive crane was used in setting the columns and

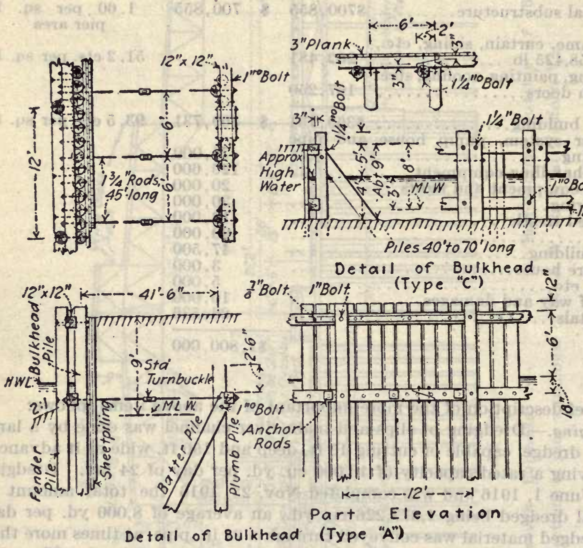

FIG. 3.—Details of bulkhead types A and C.

trusses which were shop riveted complete with the exception of the center longitudinal and transverse trusses; the latter were shipped in two pieces and riveted at the splice before erecting.

Sides.—The sides of the piers were practically solid vertical rolling lift doors, the width and spacing being such that the doors of practically all vessels using the piers would be accommodated. Three lines of windows fitted with steel sash, wireglass, ventilators and operating device are provided on either side for admitting light and ventilation. No. 22 ga. galvanized corrugated steel siding covers the ends and sides, with the exception of window and door space.

Sprinkler System.—The warehouses are equipped with an automatic dry-pipe sprinkler system to meet the underwriters' requirements. In each of the 14 fire areas two dry valves are located, one on either side of the building. From these dry valves the sprinkler pipes radiate, the total number of sprinkler heads being 5,158. Hose valves are provided on each dry valve, and each one is equipped with 75 ft. of 1½ in. linen hose, nozzle and rack. Alarm gongs are also placed outside the buildings, one to each dry valve.

Water-supply is furnished from a 100,000-gal. steel tank, the bottom of which is 90 ft. above the ground. Emergency water-supply will be furnished from an intake in the edge of the river and will be forced into the mains by two 750-gal. per min. underwriters' centrifugal pumps, each driven by a 100-hp. motor. The piping system is so arranged that the water may be pumped into the tank or direct to the mains.

The unit cost of the sprinkler system complete was $14.33 per sprinkler head. Each sprinkler head covers an average area of 77 sq. ft., the unit cost per sq. ft. being 18.7 cents.

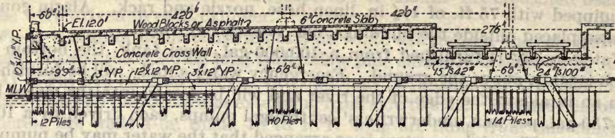
Freight-handling Equipment.—To reach the decks of vessels at various stages of the water and loading, hinged ramp bridges, constructed of steel with wood floors, are provided. These bridges are 27 ft. long and 13 ft. wide, set on a hinge 20 ft. inside the building and having a movement up or down of 20° (9 ft.) from the level position. The bridges are supported by heavy chains, being hung from an overhead gallows frame set 18 ft. from the hinge end. Counterweights are used to assist in lifting the bridges and the movement is controlled by chain and worm gearing. The bridge has a capacity of 10,000 lb. either concentrated on a small 4-wheel truck or distributed.

An endless sprocket chain sliding on the surface of the bridge in a steel trough, with teeth 6-in. above the floor level, is electrically driven through transmission shaft and sprocket wheel set at the hinge end, and pulls trucks from a low level into the warehouse, from warehouse up into a boat, or holds back a load going in the opposite direction. This chain is driven by a 20-hp. reversible motor operating at 220 volts d.c. and has a variable speed to accommodate any class of material being loaded or unloaded. The teeth on the chain engage the axle of a truck, and a load of 4,000 lb. may be handled at a speed of 125 ft. per min. At 250 ft. per min. four individual loads of 1,000 lb., and at 400 ft. per min. eight individual loads of 500 lb. may be handled, the total load at all speeds amounting to 4,000 lb. The chain is located 4½ ft. from the edge of the ramp bridge, and will permit an empty truck to pass in one direction while the load is moving in the opposite direction.

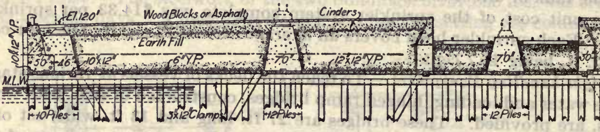
Forty-six bridges are provided on the two warehouses, 34 being equipped with elevators, and the spacing has been made to fit the doors in any vessels operated by the different steamship companies discharging at the space assigned.

Costs of Steamship Piers, Philadelphia, Penn.—In 1913 and 1914, the department of Docks, Wharves & Ferries of the city of Philadelphia, received bids for two steamship piers to be located in the Delaware River, in the new Southwark improvement. On account of radical local differences of opinion as to the relative economy of various types of design, the department made five different designs, three for one pier and two for the other, all of the designs being for the same dimensions and loadings. Bids were received on all five designs and in addition one bidder submitted a sixth design. The following details of the designs, the bid figures, the department's comments upon the designs and bids are given in Engineering News, May 28, 1914.

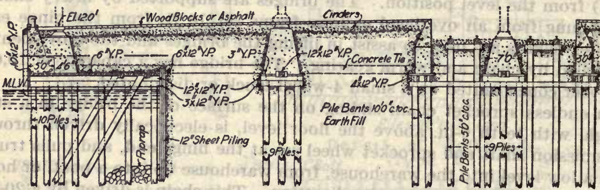
Comments by Department of Wharves, Docks and Ferries.—The accompanying prices are for the construction of the substructures only, and do not include any portion of the sheds. All of the pier types mentioned are similar in general dimensions, in height of deck (12 ft. above mean low water), and in the superposed loads for which they are designed. The main deck slab is designed for



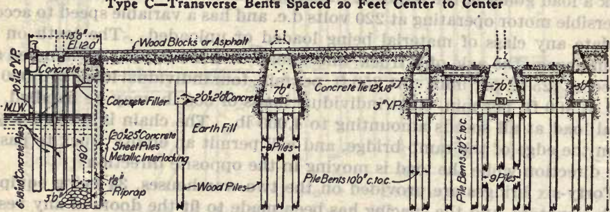
Type A—Double Rows of Piles—Bents 20 Feet on Centers



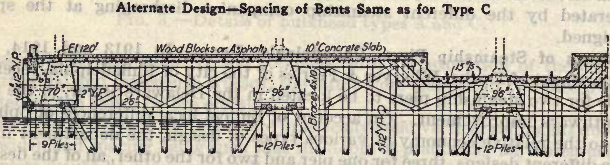
Type B—Pile Bents 5 Feet, Column Bents 20 Feet on Centers



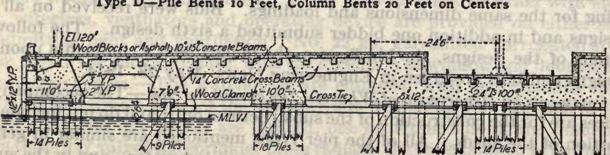
Type C—Transverse Bents Spaced 20 Feet Center to Center



Alternate Design—Spacing of Bents Same as for Type C



Type D—Pile Bents 10 Feet, Column Bents 20 Feet on Centers



Type E—Transverse Bents Spaced 20 Feet Center to Center

Fig. 4.—Transverse half sections, with superstructure omitted. General dimensions on Type A apply to all; depth of dock, 35 ft.

a superposed load of 600 lb. per sq. ft., and the column bases for a second floor superposed load of 300 lb. per sq. ft. and a roof total load of 70 lb. per sq. ft.

In comparing the prices obtained under schedules "A," "B" and "C," in November, 1913, with those under schedules "D" and "E," in March, 1914, the following differences in conditions should be taken into consideration: In the "A," "B" and "C" bids the deck paving was included. The price on this in the low bid was about $18,000, or $0.18 per sq. ft. of gross area of the pier. This should be added to the square-foot price of bids "D" and "E" to make a proper comparison. Also, owing to a change in the specification requirements for piles between the first and second biddings, changing from 15 in. diameter 4 ft. from the butt in the first, to 14 in. diameter 2 ft. from the butt in the latter, an estimated allowance of $10,000, or $0.10 per sq. ft. of pier area, should be added to the square-foot prices of bids "D" and "E" to make a proper comparison.

The quotation for the "C" type includes $25,000 for riprap. This was to be deposited at the toe of the sheet piling and was included because it is an essential portion of the design. The prices for the other different types do not include cobble or gravel fill. It is estimated that there will probably be $10,000 expended for this material to give lateral support to the piles. This costs per square foot of pier area for all types but "C," approximately $0.10.

The prices under Alternate Bids are the quotations of the Raymond Concrete Pile Co. and were used in determining the minimum and maximum costs.

Following is a brief description of each type:

Type "A" consists of: A double row of piles in transverse bays, on 20-ft. centers longitudinally, cut off in a plane approximately 1.5 ft. above low water. The piles are clamped and capped, and this framing covered with a light timber deck, upon which are set concrete walls approximately 11 ft. high. These support a system of reinforced-concrete floor-beams and slabs. On the slabs the deck paving is laid.

Type "B" consists of: Timber piling driven on 5-ft. centers longitudinally and transversely, cut off approximately 1.5 ft. above mean low water, then clamped and capped, and upon the caps a heavy decking placed, which forms a timber platform covering the whole pier area at an elevation of approximately 3 ft. above mean low water. On the outer edges of this decking, along the sides and ends of the pier, concrete walls are constructed approximately 11 ft. in height. A dry fill is deposited on the platform, retained by these concrete walls, and brought to the subgrade of the paving. Upon this fill, a 6-in. concrete base is placed, on which the paving is laid.

Type "C" consists of: A solid earth fill retained by bulkhead walls on the sides and outshore end of the pier. For these bulkheads, piles are driven approximately 5 ft. on centers in both directions, clamped and capped, upon which a heavy timber platform, approximately 25 ft. wide, is laid. Its surface is 3 ft. above mean low water. Timber sheet-piling is driven along the inner edge of this platform and a concrete wall approximately 11 ft. high constructed on the outer end of it. This construction is essentially a bulkhead type and practically consists merely of the standard bulkhead section as used at the ends of the docks, extended around the three sides of the pier. Transverse reinforced-concrete ties connect the longitudinal bulkhead wall together. A wet or dry fill is deposited behind the sheet-piling and on the platform and brought to the underside of the 6-in. concrete slab which supports the paving.

Alternate Bid (Raymond Concrete Pile Co.) consists of: A solid earth fill retained by reinforced-concrete sheet-piling 20 in. thick. This sheet-piling

(The above prices are the minimum and maximum quotations received) is driven 13 ft. back from the sides of the pier. The design of the column footings inside of the rows of sheet-piling is similar to those of Type "D"—that is, concrete pedestals supported on timber piling. The center rows of column bases outside of the sheeting are supported on concrete pedestals, each one carried by five reinforced piles 18 in. square. Transverse reinforced-concrete beams 12 × 18 in., running from side to side of the pier, on 20-ft. centers, tie the construction together. The wall and sheeting across the outshore end of the pier are held in place by reinforced-concrete ties running to concrete blocks, supported and braced by vertical and inclined timber piles.

Type "D" consists of: Timber piling in transverse bays, spaced 10 ft. c. to c., cut off and clamped at about 12 ft. above mean low water. Upon these clamps a 10-in. reinforced-concrete floor slab is constructed. On this slab the deck paving is laid. In addition to the above clamps a lower set is also provided at about 2 ft. above mean low water and the piles are thoroughly braced together both longitudinally and transversely.

Type "E" consists of: Piles driven in clusters about 20 ft. apart c. to c., in transverse bays, spaced on 20-ft. centers. These piles are clamped and decked over at about 2.5 ft. above mean low water to support concrete pedestals. These pedestals are approximately 11 ft. high and from them spring the girders of a reinforced-concrete floor system of beams and slabs. On the surface of the slabs the deck paving is laid.

The ruling considerations in these designs were: First, practical permanency of construction and second, as great a degree of economy as was consistent with permanency and stability. No marine borers of any type are prevalent in the waters of the Delaware River as far up as Philadelphia and consequently no necessity existed for providing in these designs against their attacks.

All of these designs are considered to be of permanent character, except Type "D." In this the timber piles extend up to the bottom of the main deck slab, at elevation approximately 12 ft. above mean low water, and their upper ends would be subject to complete renewal in from ten to fifteen years. The portion of the structure subject to decay is readily renewable in this type, and it was thought originally that a material saving in first cost might be accomplished by this design sufficient to offset its partially temporary character. The difference in bid prices obtained, however, was not sufficient to justify the adoption of this type in the contract award.

Of the four permanent types, the "E" design, or the so-called concrete-beam type, is the most economical for the particular width of pier under consideration, and presumably for narrower ones. A comparison of the unit prices named, indicates that this type will continue to be the most economical for piers up to 200 ft. in width. For widths above this, the "C" design, or the solid earth-fill type, would be cheaper under local conditions in Philadelphia, its economy over the other designs increasing steadily with the width of the pier.

The Department of Wharves, Docks and Ferries has adopted a policy of wide-pier construction for city wharves, it being believed that structures of upwards of 300 ft. in width are necessary to properly accommodate the handling and storage of inbound and outbound cargo of large, modern ocean freightcarriers, so that the solid earth-fill type will probably be generally used for future municipal steamship piers.

Life, Maintenance and Cost of Pile Piers with Timber and Concrete Decks. Charles W. Staniford, Proc. A. S. C. E., Vol. XXXIX, gives the following (see Engineering and Contracting, June 18, 1913).

The United States Government requires that all piers constructed beyond the bulkhead line, along the entire water front of New York harbor, must be of such construction that the free flow of the tidal water shall remain uninterrupted by supporting columns.

The pier which meets these requirements, and was adopted by the city in its early history as the type of structure for berthing vessels (and also adopted by all private and corporate interests), is a wooden structure throughout, consisting of a deck resting on piles driven into the mud or hard bottom. The physical features of the harbor, the geological formation of the bottom, and the condition of the water, fortunately permit the adoption of this type of construction, which, in many other parts of the world, is not adaptable because the life of the timber itself in the water would not be permanent or fairly long. Wood-boring animals, the teredo, limnoria, etc., are very little in evidence, and, therefore, wooden piles are practically permanent below the water-line in almost all parts of New York harbor.

The prominent objectionable feature to wooden pier construction is the expense necessitated by the constant repairs of the deck sheathing and the continuous wear and tear of the fender system extending along the sides and outer ends of the piers. As to the remainder of the structure, piles, floor system, etc., its maintenance and repair is very economical and consists generally in the replacement, from time to time, here and there, of decayed portions of the timber above mean low water only, at inconsiderable expense.

Until seven or eight years ago, the piers were generally built with decks of yellow pine, 4 ins. thick, laid on a system of yellow pine floor structure of rangers and stringers. This deck plank in turn was covered with a second layer of either 3 or 4-in. plank sheathing, laid diagonally or at right angles to the deck proper, to form a wearing surface for the traffic.

Constant repairs and renewal of this deck sheathing, caused by the wear and tear of team traffic, is augmented in great measure by the moisture, horse urine, etc., which saturates the wood and eventually finds its way to the underlying deck and rangers. This forms the greatest item incident to the expense of pier maintenance, the average life of the sheathing for most busy piers being about six years, or requiring a 17 per cent renewal annually. As the cost of the deck sheathing is generally about 12 per cent of the total cost of a pier, it will be seen that these sheathing repairs would aggregate 2 per cent per annum of the cost of the entire structure.

The unit cost of construction of a pier depends in a large measure on the size of a pier. As the outer portions, the sides, and outer end of a large pier are more rigid and heavier than those of a smaller pier, and therefore, cost more in both labor and material, the relative cost per square foot of a short pier is considerably larger than that of a long one. The average cost of the old wooden deck pier of large dimensions is from \$1.00 to \$1.15 per square foot.

Notwithstanding the necessity for constant repairs to the deck sheathing of the wooden pier, the parts of the remainder of the structure—rangers, caps, stringers, piles, and bracing—give excellent service. Maintenance is economical, the average life of the structure above mean low water line being from 20 to 25 years, the repairs aggregating an entire renewal above low water in that period of time. As the life of the piles supporting the structure is practically permanent when submerged below the water, the entire structure can be rebuilt after this period and made practically new by "bench capping" such piles as may be decayed above the water line and renewing the stringers, caps, deck, and sheathing; in other words, the pier structure proper, after a

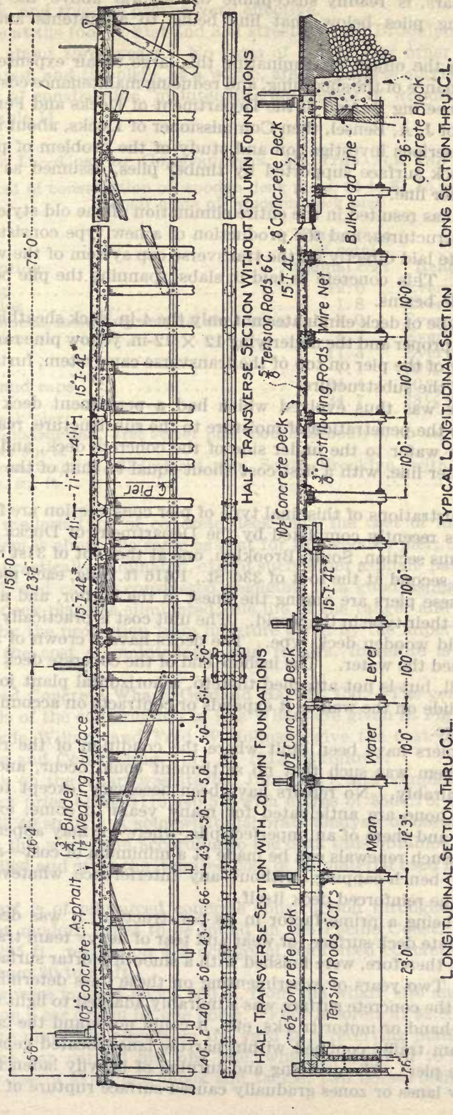

FIG. 5.—Sections of standard reinforced concrete deck for piers, New York Harbor.

life of 25 years, is readily susceptible of renewal above the water line, the supporting piles below that line being to all intents and purposes permanent.

It was with the object of eliminating this large repair expense incidental to the maintenance of the sheathing, and reducing maintenance cost generally, that the Engineering Bureau of the Department of Docks and Ferries, under the direction of J. A. Bensel, then Commissioner of Docks, about seven years ago, began a serious investigation and study of the problem of producing a permanent deck surface supported by timber piles, assumed as permanent below the water line.

This study has resulted in the entire elimination of the old style of wooden deck in new structures, and the production of a new type consisting of reinforced concrete laid directly on the transverse cap system of the wooden pier substructure. This concrete is laid in slabs, spanning the pile bents practically as simple beams.

This new type of deck eliminates not only the 4-in. deck sheathing, but also the 4-in. deck proper and the underlying 12 × 12-in. yellow pine ranger system longitudinally of the pier on top of the transverse cap system, further increasing the life of the substructure.

A structure was thus evolved which had a permanent deck practically impervious to the penetration of moisture to the substructure, readily renewable from low water to the under side of the concrete deck, and permanent below the water line, with a first cost about equal to that of the old wooden deck pier.

Definite illustrations of this final type of pier construction are found in the two new piers recently completed by the Department of Docks and Ferries at the Gowanus section, South Brooklyn, one at the foot of 31st St., 1,475 ft. long, and the second at the foot of 33d St., 1,616 ft. long, each pier being 150 ft. wide. These piers are among the finest in the harbor, and are probably the largest of their type in the world. The unit cost is practically the same as that of the old wooden deck type. The decks have a crown of about 8 ins. in order to shed the water. The inshore end of the concrete deck rests on the bulkhead wall, but is not attached thereto, a horizontal plant joint allowing the deck to slide on the wall as it expands or contracts on account of changes of temperature.

All these piers have been built where the condition of the river bottom underlying them was such that no settlement could occur, and they have behaved admirably. No repairs have been necessary, except to the fender system, and none are anticipated for many years to come, excepting the renewal here and there of an imperfect pile, where rot may appear above the water line. Such renewals can be made at a minimum of cost—a few dollars per pile—by bench-capping, without any interference whatever with the integrity of the reinforced deck itself.

Economy being a prime factor in its construction, it was decided to try out the concrete deck surface for wear and tear of heavy team traffic, and the earlier decks, therefore, were finished with a smooth mortar surface to receive this traffic. Two years of experimenting on these lines determined the fact that though the concrete surface was admirably adapted to light traffic, cargo handling by hand or motor trucks, etc., it could not stand the concentration of heavy team traffic confined within narrow lanes located generally in the center of the pier. The grinding and turning of heavily laden trucks inside these narrow lanes or zones gradually caused surface rupture of the top coat of mortar. It was decided, therefore, to place an asphalt wearing surface on the deck, and this has proven very effective.

The piers at the foot of 31st and 33d streets, South Brooklyn, have been in service for about three years. No signs of cracking or other imperfections have appeared, and the piers, as a whole, are a complete success.

The cost of construction, maintenance and repair of wooden deck piers is given in Table II.

TABLE II.—COST OF CONSTRUCTION, MAINTENANCE AND REPAIRS

(Average cost of construction of wooden deck piers, $1 to $1.15 per square foot.)
Repair costs of wooden deck pier

Description	Percentage of total original cost	Renewal required
Sheathing	12.0	Every 6 years
Backing log	1.8	Every 8 years
Fender chocks, including vertical sheathing	4.0	Every 10 years
Fender piles	4.7	Every 12 years
Decking	11.3	Every 15 years
Bracing	7.1	50% in every 20 yrs.
Rangers and caps	24.4	50% in every 20 yrs.
Piles	34.7	33⅓% every 20 yrs.

Concrete deck pier:

Cost of construction, 31st street pier, South Brooklyn, no asphalt surface, per sq. ft.	$0.87
Cost of construction, 33d street pier, South Brooklyn, with asphalt surface, sq. ft.	0.97

For the modern type of concrete deck pier, the cost of maintaining the fender system is about the same as that for the wooden pier; deck sheathing repairs are practically eliminated, except such minor asphalt patching as may be required, and can be considered negligible in a good asphalt deck under cover; the deck plank is eliminated; the life of the ranger and cap system is prolonged by the protection from moisture given by the impervious concrete deck, and the cost of maintenance and repairs, therefore is reduced to a minimum.

Reinforced Concrete Wharf, Oakland Harbor, Cal.—The general plan and some details of the construction of this Wharf are given in Fig. 6.

Wm. Clyde Willard and Fred W. Johnson give the cost of this wharf in Engineering and Contracting, July 16, 1913, as follows:

The work on the wharf was started June, 1911, and completed April, 1912 the contract price being $119,440.57, with extras of $506.76, totaling $119,-947,33 or $3.40 sq. ft. A somewhat elaborate analysis of costs was made by the city on this work, and according to the data thus obtained Table III has been compiled and gives the itemized cost of all material used in constructing the wharf.

The wharf is of reinforced concrete construction throughout, and is one of the most modern types to be found on the Pacific Coast. The wharf is 124 ft. × 295 ft., resting on 422 octagonal reinforced concrete piles varying in length from 30 to 50 ft.

The piles were molded about 800 ft. from the wharf site and were hauled to the site on a car drawn by one horse. Four laborers at $2.50 per day were employed to move the piles from the yard to a receiving platform, near the wharf. The car carried but one pile, which was rolled to it and loaded thereon by use of skids and block and tackle, two horses being used to haul the tackle. A donkey engine was at first tried for this work but proved to be too expensive. From the receiving platform the piles were loaded by the floating driver onto a barge, the barge holding about eight piles, and hauled to the desired location at the wharf.

Molding Piles.—The bottom for the pile forms was made of two 2 × 10-in. pieces cleated together, 3,000 lin. ft. of this being used. The sides were of 2-in. plank with triangular strips, having approximately a 7-in. face nailed on at top and bottom so that when the two sides were placed on the bottom a

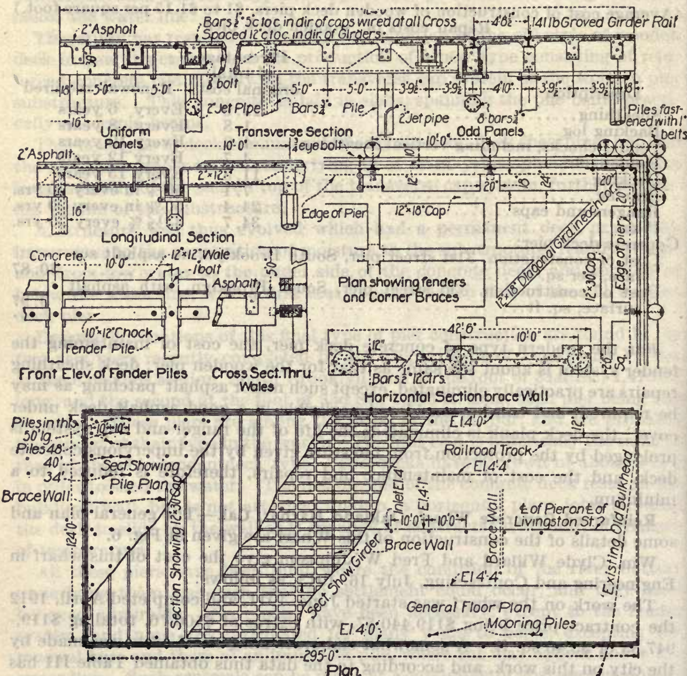

FIG. 6.—Plan and details of Livingston St. Wharf, Oakland Harbor.

cross section of the enclosed space was approximately an octagon whose diameter between faces was 16 ins. A total of 2,360 lin. ft. of sides were used. Fig. 7 shows the details of the reinforcement and jet pipe.

To make the form, a bottom of the desired length was placed on the ground, shimmed to a firm and even bearing, and the steel cage of reinforcement placed on the bottom by laborers. (The cages were built by union labor at $6 per day for foremen and $5 per day for iron workers.) The sides were put in place by carpenters at $3 to $4 per day, toe-nailed to the bottom and tied together at the top with 1 × 2-in. cleats. The steel and jet pipe were sus-

TABLE III.—COST OF MATERIALS FOR CONSTRUCTING WHARF

Items	Remarks	Prices	
Piles, concrete	73 50-ft., 97 48-ft., 63 40-ft., 59 34-ft., 130 30-ft., = 16,734 lin. ft.	$ 0.9449 per lin. ft.	$15,876.48
Piles, creosoted	95 piles = 5,593 lin. ft.	0.44 per lin. ft.	2,460.92
Piles, untreated	19 30-ft., 30 40-ft., 12 50-ft. = 2,370 lin. ft.	0.17 per lin. ft.	402.90
Lumber, untreated	184,921 B. M. O. P., assorted sizes	16.00 per M.	2,958.74
Lumber, creosoted	198 pieces 4 × 12-in. O. P. = 17,816 B. M.	39.30 per M.	700.17
Lumber, creosoted	70 pieces 10 × 12-in. O. P. = 7,000 B. M.	37.80 per M.	264.60
Cement	2,081 bbls. Portland, from Tolenas, Calif.	2.04 per bbl.	4,245.24
Rock	12,436 cu. yds., from S. F. Quarry Co., Marin County, Calif.	0.90 per cu. yd.	1,119.24
Sand	6,62 1cu. yds., from Howard & Co., pumped from Bay of San Francisco	1.05 per cu. yd.	695.21
Steel	80,565 lbs. 7/8-in. twist bar	2.30 per 100 lbs.	1,853.00
Steel	115,669 lbs. 1/2-in. twist bar	2.50 per 100 lbs.	2,891.73
Wire, tie and stretcher	6,055 lin. ft. No. 8	4.62 per 100 lbs.	80.10
Nails	6d, 8d, 20d, 40d, 60d, 7-in. spikes—45 kegs	2.85 per keg	128.25
Bolts, nuts, washers	Mixed sizes and lengths		1,066.07
Corner angles	4 1″ × 12″ × 4′, 4 1″ × 12″ × 5′ rolled iron		207.60
Sockets	69 C. I. sockets		146.77
Springs	69 3-spiral car springs		217.50
Pipe	800 lin. ft. 2-in. No. 2 galv. and C. I.	0.08 per lin. ft.	64.00
Pipe	550 lin. ft. 3-in. galv.	25.65 per 100 ft.	141.08
Rails	20 30′ 0″ 141-lb. grooved girder = 84,600 lbs.	44.00 per ton	1,861.20
Rails	2,400 ft. old street car at 5 cts. ft., 3,600 old ties at $5 per 100, old turntable, $15.00		315.00
Fuel	Lampblack from gas works, 293 tons	5.00 per ton	1,465.00
Fuel	Gasoline, 62 gals.	0.20 per gal.	12.40
Water			61.40
Rings, mooring holes	11 rings		116.85
Shingles and oakum			9.30
Total			$39,360.75

pended by wire from these cleats. Headers were then placed at each end, the form thoroughly wetted and the concrete poured. The day following the pouring of the concrete these sides were removed, cleaned and used again. Four days after pouring, the pile was rolled off the bottom, which was then cleaned and re-used. A total of 424 piles, only two in addition to the number actually used in the wharf, were molded, and at the end of the work the forms were still in good condition. The form work was not economically handled and the cost of this item was relatively high, being nearly $1 per ft. of pile.

Of the 1,047.5 bbls. of cement used in the piles, 986 bbls. were delivered f. o. b. the job at $2.05 and the balance by team at $2.20. The rock, sand and screenings were delivered by team, the haul being about one-half mile. The concrete was mixed by an old type Ransome mixer in poor condition, run by a gasoline engine which caused considerable trouble. From time to time the mixer was moved along the work so that the round trip from the mixer to forms was about 75 ft. An extra wet mixture was used and was hauled in wheelbarrows holding 3 cu. ft. The labor consisted of a crew of from 11 to 14 men, exclusive of laborers who brought the cement from the storehouse.

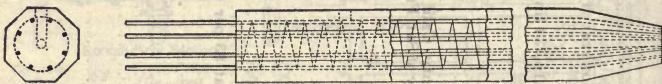

Fig. 7.—Details of reinforced concrete pile, Oakland Harbor.

The concrete mixtures specified were: For 40-ft. piles, 1:2:4; for 30 and 34-ft. piles, 1 of cement to 2 of sand to 2 of screenings to 2 of rock; for the 48 and 50 piles, 1 : 1½ : 1½ : 1½. On account of the character of the materials these mixtures were changed slightly by making an excess of grout and reducing the quantity of stone.

Driving Piles.—The piles were driven by jetting and churning, a drop of from 6 ins. to 2 ft. appearing to give the best results. The time of driving averaged from one to two hours. In using a longer drop, it was found that the material caved under the end of the pile, and also that in penetrating a layer of cemented gravel which underlaid part of the work the square edges at the end of the pile became rounded. An attempt was made to do the driving with a steam hammer by using a special iron follower so cast as not to interfere with the reinforcing rods, which projected 2 ft. beyond the top of the piles, and inserting a wooden cushion block between the pile and follower. However, the outer edge of the head of the pile chipped off during driving and the method was abandoned.

The jet was supplied by two pumps developing a pressure of about 80 lbs. per square inch. A floating driver working two shifts drove 348 piles; and 74 piles inshore were driven with a top driver on false work, the two drivers being similarly equipped. The crew consisted of a foreman at $6, engineer at $5 and four journeymen at $4 per day.

In driving the 48 and 50-ft. piles inshore, some difficulty was encountered in penetrating the layer of cemented gravel 4 to 10 ft. thick and lying at a depth of 35 to 40 ft. below mean tide. This layer inclined towards the water and only seriously interfered with the driving of the piles nearest shore. In order to get the piles through this stratum it was necessary to use a mud pump, the time of pumping averaging from two to three hours.

In order to prevent the concrete in the pile from cracking under its own weight while being hoisted into the gins, all 48 and 50-ft. piles were braced with 12 × 12-in. stiffening timber 30 ft. long, firmly clamped to the pile. The average time of placing stiffening timber and adjusting hoisting collar was about 40 minutes.

Occasionally the jet pile would become plugged by the edges of the pipe jamming together at the lower end. When this occurred the pile was hoisted into the gins and the hole drilled out. In a few cases the nipple at the upper end of the jet pipe was found plugged with concrete, in which case a hole was drilled into the jet pipe lower down the pile and a new nipple inserted and calked with lead. With the exception of the layer of cemented gravel all other material encountered in driving was compact blue clay and mud. After being driven, each pile was sprung into place and held so by 3 × 4-in. timber ribbons bolted around the pile with ¾-in. bolts. The friction of these ribbons on the piles was sufficient to carry the weight of the deck forms.

Brace Walls.—The concrete brace walls, each enclosing five of the concrete piles, were constructed as part of the substructure of the wharf, as shown by Fig. 6. A cofferdam of 2-in. T & G sheet piling, about 10 × 50 ft., was driven for each brace wall and left in place after the work was finished.

The construction of brace walls was poorly handled, the machinery almost worn out, and on brace walls Nos. 1 and 2 there was considerable overtime work at time and a half, all of which unnecessarily increased the costs, which were, for brace walls Nos. 1, 2 and 3, $1,293, $878 and $626, respectively.

Deck Forms.—All form lumber was 2-in. plank with the exception of the side pieces on the pile caps, which were 4 × 12 ins. The lumber was ordered for half of the wharf only and was re-used for the second half.

Concrete.—The rock, sand and cement for the deck structure were delivered on barges, from which they were fed directly to the mixer, a one-half yard Smith in fair condition, run by a vertical steam engine supplied by steam from a separate donkey boiler. This machinery was mounted on a 30 × 50-ft. barge. From the mixer the concrete was hoisted vertically to a hopper about 30 ft. above and poured by a 10-in. O. D. casing some 50 ft. long, a length sufficient to reach the center of the wharf. This tube was suspended from a boom, and by mooring the barge the concrete could be poured at any point on half of the wharf during any stage of the tide.

Two hinged chutes about 40 ft. long, hoisted by a gypsy, were attached to the rear of the mixer barge and extended out over the material barge. The rock and sand were shoveled into these chutes, the outer ends of which were then hoisted by the gypsy so that the contents dumped into iron dump cars, which, in turn, were run up an incline and dumped into the mixer. These chutes were 8 × 18 ins. and as each running foot of chute contained 1 cu. ft., it made a very convenient method of measuring quantities. The capacity of the dump cars was insufficient to supply the full capacity of the mixer, so that on the outer half of the wharf only ⅓ cu. yd. of mix was obtained. For the work on the other half, side boards were placed on the cars and the mixer charged to its full capacity of ½ cu. yd.

From 30 to 33 men distributed as follows were required to handle the equipment on the wharf: One foreman at $6 to direct the placing of concrete and handling of barge; one man at $4 to swing tube; three men at $4 shoveling and tamping. On the barge: One finisher at $6; one engineer at $5 hoisting skip and dump cars; one engineer at $5 on mixer engine; one man at $4 on gypsy hoist; three men at $4 to handle mooring lines; two men at $2.50 firing boilers; two men at $2.50 handling cement; one man at $4 cleaning hopper;

11 to 14 men at $4 running mixer, shoveling, etc.; 2 to 6 men at $2.50 shoveling. The mixer averaged about 25 batches per hour, as the dump cars did not deliver the material fast enough to keep it supplied.

Considerable time was lost in moving the barge to change the location of the tube, which, in reality, was too cumbersome for the work it was required to do. Had the mixer been of 1-yd. capacity the cost could have been greatly reduced, as doubling its capacity would have required only about four men in addition to the actual crew.

Fenders, Etc.—The fender piles which were treated with a 12-lb. treatment of creosote, were driven by a top driver on the wharf. The average time of trimming the head of a pile and getting it into the gins was 15 minutes. The time of driving was from 5 to 7 minutes. The waling was formed in sections and hoisted into place.

The railroad tracks on the wharf were of 141-lb. grooved rails without spacers, embedded in concrete.

Cost of Cellular Concrete Superstructures for Timber Piers.—J. A. B. Tompkins in Professional Memoirs, describes the methods and costs of repairing timber piers and jetties. The following matter is taken from an abstract of Mr. Tompkins' paper published in Engineering and Contracting, Aug. 22, 1917.

Concrete superstructures are cellular in type, consisting of two parallel walls connected at intervals of about 8 ft. by cross walls from 12 to 18 in. thick, thereby forming open pockets or "cells" which are filled with rubble stone. The superstructure is built in monolithic sections, 24 or 25 ft. in length, and is provided with a continuous walk of reinforced concrete slabs, supported by the cross walls.

In all cases where an old pier is to be provided with concrete superstructure of this type, the work has been done by hired labor and use of Government plant.

The work of building cellular superstructures on old piers does not require a large or special plant. The plant now being used in the Milwaukee District for such work consists of a floating derrick of 3 to 5 tons' capacity, two flat scows, and a small gasoline tug. A steam-driven concrete mixer, having a capacity of about two-thirds of a yard of finished concrete, is placed on one scow; the other scow is used for carrying materials. With this plant and a crew of about 15 to 20 men, from 200 to 300 lin. ft. of superstructure are built per month, including the cutting down of the old pier.

The total cost of the concrete superstructures described, including the cost of cutting down and preparing the old pier for reception of the superstructure, has been from about $12 to $15 per linear foot of pier, depending upon the width of pier, which usually varies from 14 ft. to 18 ft. center to center of parallel rows of round piles.

An adaptation of the form of superstructure described has been used for original pier construction. In this case the sides of the pier are alike, consisting of round piles spaced 4 ft. centers, with 9-in. triple-lap sheeting; 12 by 12 in. spreaders are used between round and sheet piles. The general method of construction is the same as that previously described. All work constructed according to this design has been done by contract. The timber, cement, and reinforcing steel were furnished to the contractor by the United States; all other materials were furnished by the contractor. Table IV shows the approximate cost of building 100 lin. ft. of this style of pier in this district by contract, including the cost of materials furnished by the United States.

Cost of a Timber Pleasure Pier on Pile Bents.—In Engineering and Contracting, Sept. 28, 1910, Benjamin Brooks gives the following. The site of the pier was a prospective beach resort upon the coast of California.

It was 10 miles from the nearest port, about 3 miles from the nearest broad-gage railway (which, however, did not connect with the port) had absolutely no roads leading to it, and was girt on one side by heavy surf and on the other by barren sand dunes.

After a preliminary trip, the writer decided to run the risk of beaching the materials on the spot and to ship the pile driver outfit through the port to the nearest narrow gage station—about 7 miles away—and team it from there to the beach.

An experienced freighting company was hired by the day to transport the pile driver outfit. The first four miles of road were perfectly level and good; the last three were simply trails over the deep, dry sand leading on to the hard beach, where, however, a small stream was to be crossed. A team of four horses and driver cost $6.50 per 9-hour day. For the first part of the journey the teams worked separately, but on the last three miles they doubled and trebled, the engine sinking its wagon down in the sand till it dragged. The trip required twelve team days, or $78—over $11 per mile.

Setting up the driver took three days and was done in a piecemeal manner according as the outfit arrived by team. A foreman at $5 and a crew of three men at $3 brings this setting up expense to $42.

Beaching the lumber and piles proved to be a somewhat uncertain but satisfactory method of getting them there, and much cheaper than any other way. The material comprised the deck load of a small coasting steamer. After having coaxed a few farmers in the neighborhood to appear on the beach with their teams on a certain morning to be named later, the writer left things in charge of the pile driver foreman and set out to meet the steamer at the nearest port. She was only three days late, but arrived at night so that orders could be phoned to have the farmer-teamsters on hand next morning.

On the following day the weather was so thick that the steamer sailed past the wharf site twice before it could be identified from the sea;

TABLE IV.—APPROXIMATE COST PER 100 LIN. FT. OF PILE PIER WITH CONCRETE SUPERSTRUCTURE

Materials	Unit cost	17-ft. pier—16 ft. water Quantities	Cost	14-ft. pier—12-ft. water Quantities	Cost	11-ft. pier—8-ft. water Quantities	Cost
Round piles, lin. ft.	$ 0.37	1,450	$ 536.50	1,250	$ 462.50	1,050	$ 388.50
Sheet piles, ft. B. M.	44.00	39,600	1,742.40	32,400	1,425.60	25,200	1,108.80
Timber, ft. B. M.	47.50	10,633	505.07	10,633	505.07	8,033	381.57
Bolts, spikes, etc., lbs.	0.05	3,761	188.05	3,412	170.00	3,064	153.20
Concrete superstructure, cu. yds.	10.50	98	1,029.00	93	976.50	87	913.50
Concrete slabs, cu. yds.	12.00	12	144.00	6	72.00	6	72.00
Reinforcing bars, lbs.	0.02	3,249	64.98	2,303	46.06	2,003	40.06
Stone—filling and riprap, tons	1.60	2,000	3,200.00	1,100	1,760.00	425	680.00
Cost of 100 lin. ft. of pier			$6,904.93		$5,418.33		$3,737.63

so that it was 1 p. m. before the first stick was thrown overboard. The teamsters meanwhile continued leisurely to draw their pay on the beach, as did also two expert surf boatmen in a dory hired to take lines ashore if necessary or to rescue stray timber. These latter proved unnecessary, but were a good safeguard in case of change of wind.

The first pile thrown over showed that the vessel was not anchored exactly in the right place, and she was accordingly moved. Her final position was about a mile off shore. The surf was rather heavy, the wind light and the timber took about an hour to drift in. It arrived a good deal faster than seven teams could pick it up, but the surf and wind kept it on the beach. It did not, however, all come to one place, but scattered out about 1,000 ft. wide. No attempt was made to pile it, but each piece was pulled up the beach, where it struck and left above high water mark. The last piece left the vessel about 5 p. m., and the last snaking out occupied the teams until 10 p. m. They had the advantage of a moon and free hot coffee.

The following costs are worked out without regard to the six hours lost in waiting for the vessel, for this delay is always likely to happen; and both teams and boats are counted as having worked from 7 a. m. until about 10 p. m. On this basis the landing and snaking to safety required:

0.090 boat hours per M at $2.00	$0.180
0.785 team hours per M at $0.40	.314
0.64 man hours per M at $0.20	.128
Total	$0.622

The following day at daylight a few teams were engaged to sort out and gather up the lumber from the beach and pile it at the wharf site. Owing to bruised legs and other discomforts incident to working in the surf, the price of teams had increased over night, so that the cost of stacking the material was:

1.40 man hours per M at $0.25	$0.35
1.36 team hours per M at $0.50	.68
Total	$1.03

which brought the total cost of bringing the lumber to the pier site $1.65 per M ft. B. M.

The pier was of simple construction, with bents 20 ft. apart, four piles to the bent (the two outside ones battered) under a 12 × 12 in. cap 16 ft. long, which was drifted and strapped to each pile. The deck was 2 × 12 in. on 3 × 12 in. joists. There was a light railing on each side.

The piled iver had 35 ft. swinging leads and 64 ft. gunwales, a 3,500-lb. hammer and an oil burning engine big enough to keep up steam under hard driving. The sand was so compact that piles sometimes collapsed under the hammer before they had reached the required 10 ft. penetration. After the driving was well under way the time of each operation was as follows:

BENT No. 9

	Minutes
Rigging staging for cross-cut saw men	13½
Placing battons	8
Sawing off four piles	15
Hoisting cap in position	2½
Boring and drifting cap (straps put on later)	12
Removing staging and tieing bent to previous one	5½
Pulling driver ahead	3
Placing first pile	6½
Driving first pile (81 blows)	7½
Plumbing leads	1½
Placing second pile	5
Driving second pile (83 blows)	9
Placing third pile	9
Driving third pile	6
Placing fourth pile and swing leads	5½
Driving fourth pile	6
Total for driving and capping bent	115½

BENT No. 10

	Minutes
Pulling driver in position	5½
Hoisting and placing first pile	3
Driving first pile (67 blows)	6½
Plumbing gins and placing second pile	5
Driving second pile (62 blows)	5
Placing third pile	2½
Driving third pile (58 blows)	5
Placing fourth pile	5
Driving fourth pile (63 blows)	3
Rigging staging for cut-off	10
Placing battons	8½
Sawing off four piles	12
Placing and drifting cap	13½
Tieing bent to previous one	5
Total for driving and capping bent	89½

Occasional delays brought this down to four bents per 9-hour day. The crew comprised an excellent foreman, a well drilled set of seven men and a team. The daily expenses of running the driver were:

Crew (foreman, $5.00; men, $3.00)	$26.00
Team	4.50
Extra man on beach	2.25
Fuel oil (including teaming of same)	4.00
Interest and depreciation on outfit	3.00
Engine oil (assumed)	.25
Total	$40.00

This gives a cost of $10 per bent. To sum up, we have a piledriver expense of $78 teaming and $42 setting up, and assuming an equal cost of removal brings this to $240. Since the pier was 800 ft. long, the piledriver charges would be $^{20}/_{800}$ of $240 or $6 per bent.

Pile driver expenses	$ 6.00
Beaching and stacking 3¾ M lumber at $1.65	6.19
Driving and capping	10.00
Placing joists and deck, 1½ M at $4.76	7.14
Placing railing, 0.13 M at $10	1.30
Placing cap straps (estimated)	2.00
Total	$32.63

which is equal to $1.63 per foot.

This is, with the exception of oil for the pile driver and interest on it, a strictly labor cost. The time of the writer for surveys, soundings and steamer piloting is not taken into account, nor are the railway freights, fares for the crew, rent of quarters in the "pavilion," reconnaissance, and so on.

This method of landing lumber requires a wide beach and a steady wind blowing directly or almost directly on it. If the wind blows at an angle with the beach, the lumber will drift a long way before beaching, and scatter very much. A change of wind is fatal, so that not too much lumber should be afloat at a time. Anything smaller than 2 × 10 ins. should be fastened in square bundles to avoid breakage in the surf. Too much care cannot be taken to avoid broken legs.

Cost of Driving Sheet and Bearing Piles and Placing Concrete for the Concrete and Steel Ore Dock of the Duluth and Iron Range R. R.—Leland Clapper in Engineering and Contracting, July 17, 1912, gives the following.

The concrete steel dock, erected on the site of a former one of timber, is made up of a timber approach 220 ft. long, a steel approach 329 ft. long, the dock proper 1,344 ft. long, and an end tower of 32-ft. span. The timber approach has three-pile bents and twelve-trestle bents of 15-ft. centers, with a 10-ft. span joining onto the steel approach. The steel approach has four 32-ft. towers with three spans of 63-ft. deck plate girders joining them and a 12-ft. span joining the last tower to the dock proper. In the dock proper, there are 112 spans 12 ft. long, each span supporting an ore pocket on each side of the dock. The dock proper and end span are level, the steel approach is on a 0.304 per cent grade, the timber approach on a 0.20 per cent grade and the ore yard on a 0.51 per cent grade, all being down grade away from the dock.

Foundations.—The entire area to be covered by the foundation of the dock proper was enclosed by sheet piling. The two side walls of sheet piling were 55 ft. inside to inside, while the end walls were about 1,404 ft., making the total area enclosed about 1.8 acres. The sheet piles, of which 2,350 were required, were made of 12 × 12-in. fir 32 and 34 ft. long, by spiking to these, with ⅜ × 8-in. boat spikes, 3 × 4-in. strips flatwise, to form tongues and grooves. The points were made by sawing them on a long bevel of about 2 to 1 sloping up from the groove side to the tongue. Any side beveling, necessary to hold the pile to line, was done at the drivers.

The sheet piles were handled from the framing yard to the drivers by a derrick scow. Two roller drivers were used, one on each side of the dock, each having a 2,800-lb. hammer and 35-ft. leads.

The lake bed, at this point, is red clay, so that jetting was impossible. However, little difficulty was experienced in driving. An occasional wedge was used to keep the piles plumb. These were made by ripping the 12 × 12-in. timber diagonally and then nailing on the tongue and groove. A sliding block, made with a groove to fit over the tongue of the pile being driven, and with a line passed around it to the engine, held the pile firmly to place during the driving. A hand winch was used to hold the tops of the piles tight after they were driven. A temporary inside waling or guide timber was bolted to the ends of the pile caps of the old foundation and to this about every fifth sheet pile was bolted to hold it in place and to maintain a true line until the temporary outside waling timbers could be placed. These temporary outside waling timbers were 14 × 14 in. second-hand fir and were placed 11 ins. below the sheet pile cut-off, which was 6 ins. below mean water level. The two walls were then tied together through these timbers with 1-in. × 59-ft. rods, spaced

6 ft. centers, and using a center turnbuckle. The final anchoring of the sheet piling was by placing a 1-in. bolt 4 ft. 8 ins. long through each pile at a point 8 ins. below the cut-off.

Following the sheet pile driving, a swing driver having a 4,200-lb. hammer and 65-ft. leads, drove the bearing piles, varying from 30-ft. to 60 ft. in length in the main foundation. These piles were unloaded from cars at a point where they could be easily pointed, sorted, and rolled into the water for rafting. The piles were cut off by hand at a point 1 ft. 3 ins. below mean lake level. The rows of new bearing piles are spaced 6-ft. centers with a row of the old timber dock bearing piles half way between. In each row on each half of the dock, there are seven piles spaced 2½ ft. centers, the first being 1½ ft. from inner edge of the sheet piling. The pile driving specifications called for a penetration of not over 6 ins. in six blows under a 40-ft. drop of a 3,000-lb. hammer, or its equivalent.

In Table V for sheet piling, the item "preparing and handling" includes spiking on the tongues and grooves, using about 50 ⅜ × 8-in. spikes per pile, also sharpening, loading by derrick from skidway to scow, and unloading at the drives. The item "waling and tying" covers the placing of the temporary inside guide timbers, the temporary outside waling timbers and all temporary and permanent bolts and anchors.

TABLE V.—TIME COST OF SHEET PILING (2,350 PILES)

	Hours	Hours per 100 sheet piles
Preparing and handling:		
Foreman	370	15.58
Carpenters	520	21.89
Skilled labor	1,630	70.73
Common labor	4,950	208,40
Engineer	340	14.31
Tug and crew	40	1.68
Derrick scow	250	10.53
Driving:		
Foreman	590	24.84
Skilled labor	1,890	79.57
Common labor	2,160	90.94
Engineer	830	34.94
Drivers	570	24.00
Cutting off:		
Common labor	1,700	71.57
Waling and tieing:		
Foreman	760	32.00
Carpenters	2,380	100.20
Skilled labor	6,330	266.49
Common labor	13,370	562.88
Engineer	1,960	82.52
Tug and crew	40	1.68
Derrick scow	1,040	43.78
Drivers	570	24.00

Table VI for round piles includes only those piles in the dock proper. The item "pointing and handling" includes sorting, pointing, rafting and delivering to drivers. The cutting includes the removing of the old pile heads.

TABLE VI.—TIME COST OF ROUND PILE WORK (163,500 PILES)

	Hours	Hours per 100 lin. ft.
Pointing and handling:		
Foreman	20	.0122
Engineer	350	.2135
Skilled labor	2,330	1.4213
Common labor	2,390	1.4579
Derrick scow	130	.0793
Team	350	.2135
Driving:		
Foreman	670	.4087
Engineer	670	.4087
Skilled labor	2,670	1.6287
Common labor	2,690	1.6409
Pile driver	660	.4026
Cutting off piles:		
Foreman	130	.0793
Skilled labor	600	.3660
Common labor	3,180	1.9398

The forms for all concrete work were made of 2-in. matched lumber and were set, removed and carried ahead by a small derrick scow. The outside forms, of which 19 sections 24 ft. long were used on each side of the dock, rested on the temporary waling timber 4 ins. outside the sheet piling. An expansion joint above mean water level was used every 72 ft. A key 6 ins. × 3 ft. was made in the end form at each joint so that there could be no transverse movement of sections. As soon as the outside and center core forms had been set, the reinforcing rods were bent and placed. In each 72-ft. section about 12,100 lin. ft. of 1-in. smooth circular rods and 900 lin. ft. of 1½-in. rods were used. The main slabs are 19 ft. 4 ins. wide, with an opening of 19 ft. between them and are 5½ ft. thick, extending from 2½ ft. below mean water to 3 ft. above the same. These slabs are tied together every 24 ft. by 3 × 4-ft. concrete tie walls reinforced with four 1½-in. × 36-ft. rods. Raising from the main slab by three 8-in. steps and extending from its outside edge to its center, is a parapet slab 2 ft. thick. On the main parapet and at its outer edge is a parapet walk 9 ins. thick and 2½ ft. wide. The tops of the parapets and slabs were given a slope of ⅛ in. to the foot toward the center of the dock to insure drainage. The center line of the piers, which are 4 ft. 9 ins. square on top with batters of 1 in. to 4 ins., is 18½ ft. from the center line of the dock. These piers are tied to the main slab by four 1½-in. × 9-ft. reinforcing rods.

Two scow mixers were used on this work, one on each side of the dock. The one was a ¾-cu. yd. Smith mixer with chain conveyors carrying materials from hoppers on main deck to a measuring hopper which fed into the mixer about 15 ft. above the main deck. A derrick scow supplied sand and gravel to the hoppers. The ¾-cu. yd. mixer mixed two-thirds of the total yardage: Its scow was about 80 ft. long and 25 ft. wide. A three-story tower about 16 ft. square was erected in the center of the scow. On the lower floor of the tower were the boiler, pumps and conveyor engines. On the second floor were the mixer, mixer engine and the gate controlling the measuring hopper. And on the third floor were the measuring hopper and the levers controlling the conveyors. On the deck of the scow and 6 ft. from the edge of the tower toward the one end was the sand hopper, and toward the other end was a gravel hopper. Behind the sand hopper on the end of the scow was a small cement shed holding about 200 bbls.

Conveyors handled the cement in sacks from the deck to the third story and gravel and sand from the hoppers on the main deck (holding material for about 30 cu. yds.) to the measuring hopper.

The mixer required for running, an engineer, a fireman, two laborers handling cement to the conveyor, one man at the mixer, and three men on the top floor dumping cement and operating the conveyors. The maximum day's run for this mixer was 280 cu. yds.

The second scow had two ½-cu. yd. Smith mixers mounted about 20 ft. above water level. Here the material was shoveled into a bucket on the deck of the scow, hoisted and dumped into a hopper which discharged into the mixer. With either scow, the mixers would dump to any part of the section by the use of spouts. Cement was supplied to each mixer by a small cement scow. The maximum day's run for both mixers was 438 cu. yds., while the average day's run was 245 cu. yds.

The materials used for concrete were lake gravel and sand in proportions so that when mixed with five sacks of Universal Portland cement per yard it would give the densest concrete.

In placing the concrete, every other 72-ft. section, for five sections, was filled to the top of the main slab, including the tie walls. Forms were then set and filled for the parapets in these sections. As soon as these parapets had set, the end forms were removed and the sections between filled. These end walls were painted with tar before filling the section between, the tar destroying the bond of the concrete and making a good expansion joint.

The forms for the piers were set and filled about half full of concrete, which was allowed to set before anchor bolts were placed. The anchor bolts were then set in templets and wired plumb, after which the piers were filled to within 1 in. of elevation. Triangular strips, so beveled that the tops were horizontal when placed, were nailed to exact elevation. The tops of the piers were leveled from these strips with a steel-faced straight edge by using 1 to 3 mortar. Castings were set without grout.

A fender of two timbers was used. The top timber, which was a 14 × 16-in. recessed 4 ins., was placed with its edge 1 in. below the parapet walk and bolted through pipe through this walk. The lower timber was a 12 × 12 in. recessed 2 ins. and fastened by 1-in. upset bolts threaded at both ends and placed in pipe in the main slab before concreting.

In Table VII the item for handling and placing new concrete includes unloading cars; loading on and unloading from scows, and fastening the reinforcing in place with wire. The item "forms" includes the making, placing, bracing and removing of all forms. The item "anchor bolts" includes making and placing templets and setting bolts. The item "mixing and placing" covers the handling to the mixers of the sand and gravel from a stock pile on the old foundation, or a portion of the finished new foundation; of handling cement from cars and all mixing, placing and finishing of the concrete.

The time shown in the above tables does not include the time required to get outfits to the work and in shape to run.

A top traveler with two 70-ft. steel booms was used for erection. This traveler erected all of the heavier members and sufficient bracing to allow it to proceed. A portion of the lighter bracing and the platforms were placed by a derrick car. The riveting was all done by compressed air, furnished by the railroad company from its permanent compressors. Riveting followed erection as closely as convenient, usually with about six hammers working and driving 2,500 rivets daily.

TABLE VII.—TIME COST OF HANDLING AND PLACING CONCRETE
(15,040 cu. yds. concrete, 746,000 lbs. reinforcing)

	Hours	Hours per cu. yd.
Bending reinforcing:		
Foreman	200	.0132
Skilled labor	680	.0449
Handling and placing reinforcement:		
Foreman	560	.0370
Skilled labor	3,260	.2152
Common labor	4,750	.3135
Flat scows	520	.0343
Forms:		
Foreman	1,510	.0997
Carpenters	9,340	.6164
Engineers	315	.0176
Skilled labor	5,770	.3808
Common labor	6,300	.4158
Derrick scows	320	.0211
Anchor bolts:

Common labor	950	.0627
Mixing and placing:		
Foreman	1,680	.1109
Engineer	2,250	.1485
Skilled labor	6,770	.4668
Common labor	9,990	.6593
Derrick scows	620	.0409
Flat scows	640	.0422
Scow mixers	1,120	.0739

Cost of Driving Piles with a Gasoline Hoist.—Engineering Record, July 18, 1914, gives the following.

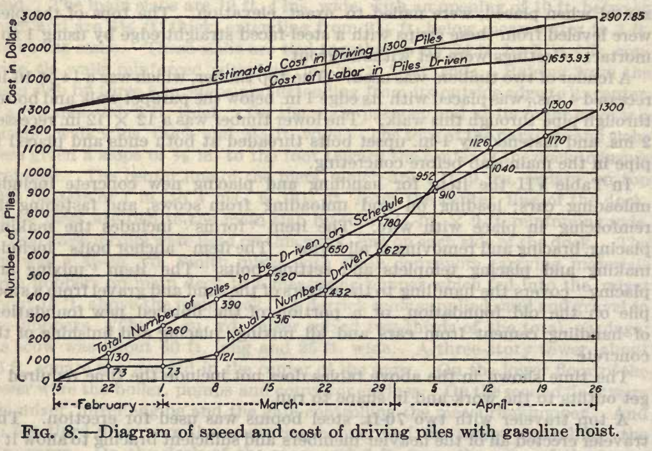

FIG. 8.—Diagram of speed and cost of driving piles with gasoline hoist.

A reversible gasoline hoist with a 6½-hp. engine and operating a 1,650-lb. drop hammer has been used for driving 1,300 piles to support a stage for 7,000 singers during the St. Louis pageant. These piles were driven from a scow about 6 ft. deep in the bottom of the Mississippi River at Forest Park.

In the accompanying diagram (Fig. 8) are shown the total number of piles to be driven on schedule and the actual number of piles driven, the estimated cost of driving 1,300 piles and the actual cost of labor on piles driven. The largest number of piles driven in one day was seventy-five. In the estimate were included 17,105 lin. ft. of piling at a cost of 17 cents, giving a total cost of $2,907.85. The average length per pile was estimated to be 13.15 ft.

Actually 1,326 piles, aggregating 19,104 lin. ft. and averaging 14.4 ft., were driven. Of this number 25 piles were driven out of line, so that the useful number was 1,301 piles, aggregating 18,735 lin. ft. Allowing 100 per cent depreciation on engine and scow, the cost of driving 18,735 lin. ft. was $2,148.38 or 11.5 cents per foot. This depreciation, of course, is excessive, and if 20 per cent is allowed on engine and scow and 15 per cent for over head charges the total cost of driving was $2,000.92 or 10.7 cents per linear foot. The cost of the piles delivered was $1,432.80 or 7.5 cents per linear foot, so that with a cost of driving of 10.7 cents the cost per linear foot of pile in place was 18.2 cents. The crew consisted of four men.

The itemized costs were as follows: Cost of piles delivered, $1,432.80; total payroll, $1,653.93; engine and hoisting outfit, $340; scow, $154.45.

On this work, union men were employed, at the following rates:

Hoisting engineer, 80 cts. per hr.; piledriver foreman, 75 cts. per hr., piledriver laborers, 40 cts. per hr.

The driver leads were 20 ft. high, built with 6 × 6-in. timbers, braced back to the rear portion of the scow. The hoisting equipment, built by the Whitman Agricultural Co., St. Louis, consisted of a 6½-hp. "Sultan" reversible gasoline-driven engine, geared into two drums with necessary controls, etc. A winch head, on the hoist, was used to pull in the piles. The weight of the drop hammer was 1,650 lb. The scow was 14 × 16 ft. and 3 ft. deep.

Cost of Driving Sheet, Foundation and Marine Piles.—In a paper presented by Victor Windett before the Western Society of Engineers and abstracted in Engineering and Contracting, June 21, 1911, the following is given.

Trench Sheeting.—A sand trench 4,017 ft. long and 10 ft. deep was sheeted with 2 × 10 in. × 14 ft. hemlock and yellow pine sheeting, to carry a steam shovel over the trench. Triple lap sheeting was made by nailing 1 × 6 in. × 12 ft. hemlock sides to give a 2 in. groove. The cost of making the sheeting ready for driving was 8.8 hours of labor at $2.63 per 1,000 ft. B. M. with labor at $0.31 per hour. The work was nailing on the side pieces, pointing the driving end, and cutting the hammer end to 8 in. in width to permit the use of a steel driving cap. The total labor cost, including the making of the sheeting in place, with labor at $0.30 per hour, was:

	Per M. ft. B. M.	Per lin. ft. of trench	Per sq. ft. of penetration trench side of sheeting
Hours of labor......................	21.9	1.4	0.12
Cost of labor........................	$ 6.56	$0.422	$0.035

A pile driver having two sets of leads complete was built for this work at a cost of about $600 for labor and material, excluding the double-drum hoisting engine. The leads and sheaves for the hammer line were fastened on the deck timbers so that when the width of the trench was reduced at a change in the size of the sewer, the leads were moved in towards the center line of the machine. This change took 1½ hours to make.

The sheet piling was pulled by a machine consisting merely of a platform to carry a hoisting engine and an A-frame carrying two sheaves. Over these sheaves two lines ran from the engine, on the free end of which was a few feet of ½-in. chain and a hook with which to pull the sheeting.

This machine would be manned by a pickup crew of engineman, fireman, and four laborers, who would pull, in 1½ hours to 2 hours' work, all of the sheeting corresponding to a day's progress of the work, which would be from 130 to 160 ft. The average rate of wages per hour was $0.30. The average of work was:

	Per M. ft. B. M.	Per lin. ft. of trench
Hours of labor	3.72	0.24
Cost of labor	$1.11	$0.07

One disadvantage of such sheeting was that the 1-in. side pieces had a short life, requiring renewing after about four times of use. The loss of the center pieces from hard driving and even though used nine times was very little. The pulling chain was rather severe upon the sheeting, as it was liable to cut into the wood. At the close of the work the sides were stripped off and half of the 2 × 10-in. pieces were sawed up for catch-basin bottom, which otherwise would have required the purchase of new lumber. The total waste of sheeting was about one-fourth and the remainder was shipped to another job.

Hand driven sheeting of 2-ins. × 10-12 ft. long is best driven in sand by a combination of hand mauling and the use of the water jet. Employing labor at $0.314 per man per hour, the expense of this work for 1,102 ft. of trench was:

	Per M. ft. B. M.	Per lin. ft. of trench	Per sq. ft. penetration
Hours of labor	11.9	0.973	0.042
Cost of labor	$ 3.70	$0.305	$0.013

Table VIII.—Foundation Piles. Chicago Drop Forge & Fdy. Co.

	Hours	Cost	Cost per lin. ft.
Erection and dismantling driver	386.5	$160.53	$0.088

Soil, hard clay; hammer used, 3,000-lb. drop hammer.
Material—96 piles, 20 ft. long. Crew 10 men.

Foundation Pile Driving.—Table IX is the record of a large piece of work carried on by the contractor with great vigor. At times as many as 9 pile drivers were at work simultaneously.

In foundation pile driving, where piles are driven in clusters, the general level of the ground will be higher after driving than it was before. This swell or rise of the level will cause an extra amount of excavation for the placing of the footing concrete around the pile tops.

Careful levels were taken over an area in which 1,570 piles were driven 2½ ft. centers. The piles were 35 ft. long, having 12-in. tops and 7-in. points. The swell of the ground amounted to 1.5 ft. in height, or 8.3 cu. ft. net measurement of the earth per pile, or 0.28 cu. ft. of pile penetration. Inasmuch as the volume of the piles below the original surface averaged 14.1 cu. ft., the consolidation of the earth amounted to 5.8 cu. ft. per pile. The soil consisted for about 10 ft. of a mixture of loose sand, gravel and clay. Below this was a moderately soft blue clay.

At the job for the hammer shop, a drop hammer, weighing 3,000 lbs., was used. In fact, the same driver and crew foreman did this work as the drop-hammer driving, for which costs are given in Table IX. But in the case of Table VIII the soil was clay, whereas the first 10 to 12 ft. was sand, in the other case.

TABLE IX.—FOUNDATION PILES

	No. 1 Vulcan steam hammer	3,000-lb. drop hammer
Total number of piles	10,417	519
Total length of piles	373,715 feet	71,855 feet
Total length of pile penetration	358,090 feet	16,817 feet
Average length per pile	36.0 feet	34.4 feet
Average length of piles undriven	1.5 feet	2.0 feet

Supplies and repairs, est	0.01	0.01	0.015	0.015
Piles	0.125	0.125	0.12	0.12
Total "field expense"	$0.178	$0.180	$0.295	$0.220

From points of view of speed, economy, and excellence of driving, the comparison between drop and steam hammers is strongly in favor of steam hammers.

In addition, a proportional share of local general office and yard expense and the general office expense, should be added.

In sawing off pile-butts two saw filers kept the saws sharp for the gang of sawyers. A pair of sawyers would cut 40 to 60 mixed wood piles per day at a cost per pile of $0.10 to $0.12.

Other men were employed in making runways and unloading piles from cars which were delivered at the edge of the work—a team and 2 men hauling piles to the more inaccessible drivers.

The ordinary pile driver crew was composed of men as follows:

Foreman, $0.58¾ per hr	$ 4.80
1 engine runner, $0.55 per hr	4.40
1 fireman, $0.37½ per hr	3.00
1 winchman, $0.45 per hr	3.60
1 leadsman, $0.45 per hr	3.60
3 groundmen or deckhands, $0.40 per hr	9.60
1 coal passer, $0.25 per hr	2.00
1 pile hooker and trimmer, $0.37½ per hr	3.00
Total labor crew	$34.00
Auxiliaries, 6 men	15.00
Proportion of pumping station labor, supplying water for jetting	2.00
Field superintendence	2.75
Total labor	$53.75

Marine Pile Driving.—The marine pile driving, as given in Table X was all within a protected harbor shielded from the heavy waves of the open lake, so but little time was lost by rough seas. In the delivering of piles from cars to scows, a large part of the labor was done by steam devices, but it is considered as being equal to the expense of six men all of the time the marine driving was going on. The soil was sandy for a few feet and below that it consisted of a moderately soft clay. The piles stood out of the water on an average of 12 ft. per pile, undriven. A tug was occupied about one-third of a day per driver in towing out and back to the yard. A drop hammer of 3,500 lbs. weight was generally used, being attached continuously to the hoisting rope. Each driver had two scows for piles, one on the work and one at the yard being loaded with piles.

TABLE X.—MARINE PILE DRIVING BY GREAT LAKES DREDGE & DOCK CO.

Number of piles driven	9,896	
Length of piles driven	326,295 lin. ft.	
Length of pile penetration	207,816 lin. ft.	
Average of piles	33 lin. ft.	
Average of piles driven	21 lin. ft.	
Total days' work and driver	137	
Piles per day work and driver	72.2	
Piles per day work and driver	2,380 lin. ft.	
Penetration per day work and driver	1,516 lin. ft.	
Crew of driver	10 men	
Auxiliaries driver	6 men	
Total men per driver	16 men	
Total crew time	1,370 days	
Total auxiliaries time	822 days	
Total	2,192 days

Tug service		$15.00
Crew		34.00
Auxiliaries		19.75
Total		$68.75
Costs	Lin. ft. of piling	Lin. ft. of penetration
Labor	$0.029	$0.0453
Supplies and repairs	*0.015	*0.0235
Piles	*0.125	*0.1962
Total "field" expense	$0.169	$0.265

* Estimate.

Foundation Pits.—Triple lap sheeting was driven for three foundation pits. The upper 15 ft. of ground is sound, below which is a soft clay. Through the sand, driving was assisted by using a water jet. The expense of this work is given in Table XI.

TABLE XI.—FOUNDATION SHEET PILE DRIVING

Piling driven, pieces	405
Piling driven, lin. ft.	9,291
Piling driven, ft. B. M.	83,622
Moving out and off job, 5 days	$227.50
Driving, 19 days	679.00
Total, 24 days	$906.50

Unit cost of labor—

$ 2.24 per pile
0.098 per lin. ft.
10.84 per M. ft. B. M.

Two No. 1 Vulcan steam hammer drivers were used. Hence the item of moving on and off the work was somewhat high. The average rate of pay per man per 8-hour day was $3.50; including men nailing the sheeting planks together, the average size of crew per machine was from ten to twelve men. Including supplies and repairs, the expense per machine per day was approximately $50.00, whereas the labor as above given amounted to $37.77 per day.

At the same place 717 pieces of 9-in. by 12 in. 28 ft. triple-lap sheeting were driven. This formed a subaqueous front of a concrete-topped wharf. Table XII gives the cost of this work.

TABLE XII.—WHARF SHEET PILING—TIME OCCUPIED IN THE WORK, 29½ DAYS

Piling driven—	
405 pieces	
14,340 ft. driven in ground	
180,784 ft. B. M. of lumber	
Towing, ⅓ of cost of 30 days at $10.00	$ 300.00
Making sheeting, 75 days at $3.00	225.00
Driving, 285 days at $3.50	997.50
Pulling, 10 days at $3.50	35.00
Total, 370 days	$1,557.50
Labor cost per piece	$2.17
Labor cost per lin. ft. driven	0.109
Labor cost per 1,000 ft. B. M	8.62

Durability of Untreated Piling Above Mean Low Water.—Engineering and Contracting, April 24, 1918 publishes the following information prepared by Mabel E. Thorne, Statistical Clerk, and C. H. Teesdale, in charge Section of Wood Preservation, Forest Products Laboratory, Forest Service.

It has long been recognized that wood constantly immersed in water is not subject to decay. Instances are on record of wood being preserved in this way for centuries. Timber structures in fresh water or in water free from the various forms of marine woodborers remain sound indefinitely, unless affected by some destructive agent other than decay.

In tidal water, where marine borers are not active, portions of piles that are completely immersed at each high tide may be exposed at other times without danger of decay, for though completely immersed only part of the time, they may be practically saturated all the time. The extent of this saturation, and therefore permanent preservation against decay, is an item of considerable interest and importance in designing pile construction. The difficulties of cutting off piling at low water, as well as the extra cost and weight of the superstructure, when joints are made at low tide level, may well be avoided wherever immunity from decay exists for any distance above this level.

Because there is so little available data as to the extent of this immunity zone, the Forest Products Laboratory has recently been conducting a study of the subject by the questionnaire method. They show careful thought, and several of them contain records of actual investigations made after the questionnaire was received.

Replies received from 25 different sources were divided into two classes, those which state that for permanent foundation work piles can be safely cut off at mean tide level or above and those which state that the zone of safety does not extend to mean tide level. It is noticeable that the grouping of these replies according to their character is a geographical grouping as well. The climate of the northern states is more favorable to the long life of piling than that of the southern states. From the data at hand, it would seem that the line of demarcation between the harbors in which it is safe to cut off piling at mean tide level or above and the harbors in which it is not safe lies somewhere between New York and Baltimore.

The rate at which a pile dries is largely dependent on temperature and relative humidity. The relative humidity varies only slightly from Maine to Florida, while the temperature variation is considerable. This means that, a few hours after high tide, piles in southern waters will have a much lower percentage of moisture than those in northern waters, which, combined with the encouragement to the growth of fungi furnished by the higher temperatures, probably accounts for the variation in the extent of the zone of safety.

Life of Creosoted Piles.—From time to time as structures are demolished to make way for extensive improvements there is afforded an opportunity for observing on a large scale the behavior of treated piles. An instance of this kind is noted in Engineering and Contracting, July 23, 1919, from which the following is taken:

A wharf of the Southern Pacific Railroad on San Francisco Bay was removed to make room for port improvements. The wharf was the oldest creosoted pile structure which thus far had been dismantled on the Pacific coast and contained about 14,000 creosoted piles which had been in service for periods ranging from 18 to 29 years. Of these piles, interest centers particularly in 600 which were of Douglas fir, well seasoned before being treated with creosote by the Bethel process in the fall of 1889, and were driven in 1890. Records show that under a pressure of 200 lb. per square inch and a temperature of 260° F., the piles absorbed 14.17 lb. of creosote per cubic foot.

Of these 600 piles, 33 were selected at random for test purposes when the wharf was dismantled. Out of this number 22 (67 per cent) were entirely sound; 2 (9 per cent) had been slightly attacked by borers; 6 (18 per cent) had been severely attacked and 2 (6 per cent) were so damaged as to be unfit for further use. These percentages were typical of the entire lot, it is reported, and about 70 per cent of the 600 are to be redriven just as they are. In fact, this percentage of piles suitable for redriving, it is reported, applies approximately to the entire 14,000 piles. Those not as suitable showed damage only between mud line and high-water mark, and other portions of these piles were in good condition.

The results of this study are believed to confirm the theory that a creosoted pile is absolutely immune from attack of marine borers such as exist in Pacific Coast waters, so long as the shell or portion of the pile impregnated with creosote remains intact.

Cost of Driving Piles for the Panama-Pacific Exposition.—L. F. Lewrey in Engineering News, July 30, 1914, gives the following:

The site on which the Main Exhibit Palaces of the Exposition are located was originally a tidal flat of San Francisco Bay, with occasional deeper bights that had been dredged out for wharves and anchorage for vessels. About twenty years ago, private interests received a grant of these tidal lands and built a rock sea wall. A large sand hill that overlay the site of the Concessions District was graded and the excavated material deposited over a large portion of the submerged area but the work was not carried to completion, and an area of water about 80 acres in extent remained to be filled by the Exposition.

Hydraulic Fill; Subsidence.—The exposition company pumped 1,300,000 cu. yd. of fill into the submerged area. This brought the surface to Elev.—2.75 approximately. The fill material averages from 60% to 70% of sand, the remainder being mud and silt. Due to the superior weight and density of this material, it crushed its way 2 to 5 ft. into the soft ooze of the old bottom, to such extent that where the original soundings showed Elev.—15, the actual bottom of the dredger fill is nearer Elev.—20.

Due to the varied lines of flow of the dredger fill and its varying character, numerous "kidneys" or watery pockets were found in the fill. These kidneys often had skins of tight sand overlying them, but on driving in a long pile their presence would be indicated by a geyser of water coming up around the pile and by the corklike action of the pile in floating up when relieved of the weight of the hammer.

Test borings were made and test piles driven covering the site of each building. The results obtained were not only valuable in giving the engineers assurance in the use of short piling, but also reduced contractors' prices by furnishing them with accurate information, thus eliminating unnecessyar waste.

Table XIII gives data on the foundation piles as driven for the exposition buildings and Table XIV gives unit costs of the tests.

TABLE XIII.—QUANTITIES AND COSTS OF FOUNDATION PILES, PANAMA-PACIFIC INTERNATIONAL EXPOSITION

Buildings	No. of piles driven	Lin. ft. piling driven	Lin. ft. piling cut-off	Piling below cut-off	Percentage of waste	Average length of pile below cut-off	Approx. cost per lin. ft. of pile below cut-off
Machinery	1,577	47,573	2,487	45,086	5.2	28.6	27 cts.

Total	15,654	......	......	645,692	....	41.2	24½ cts.

NOTE.—All piles were driven with No. 1 Vulcan Steam Hammers.

Weight of moving element approximately, lb.	5,000
Fall of hammer element approximately, ft.	3½
Average cost of Douglas fir piles delivered at site, per lin. ft.	14 cts.
Approximate cost of erecting and dismantling pile driver	$500

TABLE XIV.—UNIT-COSTS OF TESTS

(Total cost, including material, labor and engineering)

Loading piles by means of 30-ton sandboxes, per test	$70
Loading platforms with sand load, per test	15
Hand borings with auger and 3-in. casing, holes 15 to 65 ft. deep in sand and clay, per lin. ft	0.26

High Records of Pile Driving.—Engineering and Contracting, July 17, 1918, gives the following:

What is probably a world's record for pile driving was made on June 12 at the Hog Island Ship Yard, when a crew of 11 negroes in charge of Edward Burwell, working for the Arthur McMullen Co., put down 220 65-ft. piles in 9 hours and 5 minutes. The best previous record at the yard was 165 62-ft. piles driven in 9 hours and 15 minutes by the Raymond Concrete Pile Co. In the construction of the foundation for the extension of the Northern Pacific Ry. ore dock at Superior, Wis., the contractors, Siems, Helmers & Schaffner, drove 168 60-ft. piles in 9 hours with a turntable device. In the ore dock work the piles were driven through holes thawed through 4 ft. of ice and in 28 ft. of water.

The equipment used in driving the 220 piles at Hog Island consisted of a

Vulcan No. 1 hammer and a skidding rolling machine, with a 3-drum 9 × 10 hoisting engine. Hammer and hoist were driven by compressed air. The log for the day follows:

7:00 a. m.—8:00 a. m.	27 piles
8:00 a. m.—9:00 a. m.	23 piles
(Delay 4½ minutes due to broken steam line; raining very hard from 8:15 a. m. to 10:00 a. m.)	
9:00 a. m.—10:00 a. m.	28 piles
10:00 a. m.—11:00 a. m.	22 piles
(Delay 8 minutes due to pile fall breaking.)	
11:00 a. m.—12:00 a. m.	27 piles
12:00 noon—12:30 p. m.	lunch
12:30 p. m.—1:30 p. m.	25 piles
(Heavy rain with electric showers from 1:25 p. m. to 2:50 p. m. 1:25 p. m. to 1:40 p. m. air pressure dropped considerably, which held up hammer.)	
1:30 p. m.—2:30 p. m.	23 piles
2:30 p. m.—3:30 p. m.	23 piles
3:30 p. m.—4:35 p. m.	22 piles
9 hours and 5 minutes	220 piles

Total linear feet piles, 14,260. Stopped driving at 4:35 p. m. as shipway No. 46 was completed and there are no remaining piles to be driven on the shipways or piers on Group No. 5. The only piles yet to be driven are fender piles, dolphins, spur piles and a few special piles for derrick footings.

The Burwell crew since it began work at Hog Island in January last has driven 4,131 piles with a total of 241,573 lin. ft. The record of this gang for 6 months follows:

Month	No. days	Piles	Lin. ft.	Average No. piles per day	Av. lin. ft. per day
January	10	190	8,531	19.0	853.1
February	11	361	20,560	32.8	1,869.1
March	23	711	42,730	30.9	1,857.8
April	23	780	47,333	33.9	2,057.9
May	27	1,470	86,173	54.4	3,191.6
June	7	619	36,246	88.4	5,178.0
	101	4,131	241,573		

Average number of piles per day (6 mos.)	42.68
Average linear feet per day (6 mos.)	2,391.82
Average length of piles	58.5

Cost of Cutting off Submerged Piles.—Arthur C. Freeman in Engineering and Contracting, Sept. 7, 1910, gives the following:

The physical conditions encountered during the building of the foundations for supporting the rails of the Old Dominion Marine Railway at Norfolk, Va., required cutting off 306 piles under water at a depth of from zero to 26 ft.

There were not enough piles to be cut to justify bringing to the job a steam outfit and diver, so it was decided to make a device for cutting by hand without the use of a diver. This was done and proved a complete success. It consists of a rectangular frame 4 ft. 3 ins. wide and with varying length, made up of 2 × 2 × ⅜-in. angles, stiffened by curved braces at the lower end and by knee braces at the upper end so bolted to the top of frame that the length from saw to the point of support is adjustable for any distance. An ordinary 4-ft. cross-cut saw was attached to the bottom by means of split bolts and tightened by nuts to the frame. The top of the frame has a small lug which fits into a saddle for support at the center of the top of the frame and free to allow a rocking motion while restrained from rising during the sawing. Two ropes were attached to the side of frame at the bottom near the saw, one pair being to supply power to produce the see-saw motion for cutting, the other to apply pressure to the saw in the line of cutting. The saddle supporting the frame rests on a "ribbon" or grade line made up of 4 × 4s placed some uniform distance above line of cut-off and to the same grade. Clamps hold the saddle to the "ribbon" and are easily detached to move the frame to the next pile for cutting. The foreman stands at the frame to steady it and give directions, two to three men were placed at each of the power lines, while one man held both of the pressure lines. The cuttings were made in three lifts, 12, 18, and 26 ft. from the point of support. The grade of cut-off was ⅜-in. to the foot descending to the water, making the cut of the last piles 26 ft. under water. After cutting the elevations were tested and showed in no case a variance over ¼ in., which was as close as could be done by hand work above surface. The maximum number of piles cut in one day was 47.

The following table shows the costs taken from the time book: Wages: Foreman $4.00, helper $2.00, labor $1.50.

75 piles at 12 ft. cutting av. cost	33⅓	cts. each
67 piles at 18 ft. cutting av. cost	32	cts. each
164 piles at 26 ft. cutting av. cost	42	cts. each

Cost of Making and Sinking Premoulded Concreted Piles.—Geo. K. Leonard, in Engineering and Contracting, July 26, 1916, gives the following:

The plans for the construction of the Lexington, Neb., State Aid Bridge, across the Platte River, called for the placing of three concrete piles 12 in. square and 45 ft. long under each of 26 piers. The bed of the Platte River, throughout its entire length, is composed of successive layers of sand and gravel, varying in size from quicksand to 5-in. stones. At this particular point, clay was struck at a depth of 40 ft. below low water, and the piles were to penetrate this 3 ft., the remaining 2 ft. projecting into the pier. The piles were reinforced, as shown in Fig. 9.

Two moulding floors 24 by 48 ft. were made and the piles cast in lots of 16, by moving the side forms from one floor to the other. Following is the material bill for the forms:

	Ft. B. M.
Sleepers, 26–4″ × 4″–24′	832
Two floors, 48–2″ × 12″–48′	4,608
Sides, 32–2″ × 12″–48′	3,072
Top braces, 14–4″ × 4″–24′	448
Miscellaneous for wedges, etc	260
Total	9,220
56–¾″ × 2′–6″ bolts.	

Cost of Material and Labor for 78 Piles

Material:	
Cement, 751 sacks @ $0.432	$ 326.51
Rods, 52,645 lb. @ $0.0275	1,084.23
Mesh, 12,166 sq. ft. @ $0.0314	382.01
Gravel, 118½ cu. yd. @ $0.75	88.88
Lumber, 9,220 ft. B. M. @ $26 per M	239.72
Bolts, 56 @ $0.15	8.40
Total	$2,129.75
Material, cost per pile	27.31
Material, cost per lin. ft	.607
Labor:	
Making, placing and removing forms	$ 148.60
Placing reinforcing	353.50
Mixing and placing concrete	97.96
Total	$ 600.06
Labor, cost per pile	7.69
Labor, cost per lin. ft	.170

Ordinarily a concrete pile will sink in the Platte River of its own weight, if properly jetted. This was tried by the contractor, but at a depth of 40 ft. a coarse layer of gravel was encountered, which carried off the water as fast as it could be pumped, and the piles would sink no further.

Not deeming it advisable to hammer on the piles, 3 ft. was cut off of each one, and the following method used in sinking them so that they would rest on the clay:

By means of a specially designed sand bucket, which will be described later, a 22-ft. length of ¼-in. steel casing, 24 in. in diameter, was sunk until the top was about 2 ft. above the water. Into this was set a 40-ft. length of casing 20 in. in diameter, which was sunk until it rested on clay. The pile was then set into the open well, and the two sections of casing pulled. The sand running in around the pile held it as firmly as if it had been driven. A steam hoist and derrick handled the casings and piles.

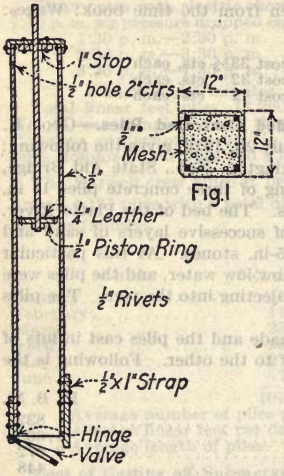

FIG. 9.—Section of pile (1) and sand bucket (2).

The bucket, which was used in excavating and sinking the casings, is shown in Fig. 9, and is described as follows: A piece of heavy steel pipe 8 in. in diameter and 6 ft. long was fitted with a hinged bottom, containing an ordinary valve opening inward. The bottom was held shut by means of a dog, which could be tripped with a hammer when the bucket was full of sand. Riveted to the top of the bucket was a steel head through the center of which the piston rod slipped. The piston was an ordinary pump piston, with leather attached. In operation, the bucket, with the bottom closed, is dropped to the bottom of the casing by means of a gasoline hoist, the hoisting line being fastened to a ring in the upper end of the piston rod. As the piston is pulled to the top, the sand is sucked in at the bottom and the bucket settles. When the piston is at the upper end of the bucket it strikes the top and bucket and all is hoisted to the top of the casing and dumped. As the sand is taken from the casing it settles, due to its own weight, and to a number of sand bags on a platform, hanging from the top of the casing. In this way, with a gang of two men at 30 cts., and one man at 20 cts. per hour, working ten hours per day, one pile could be placed per day.

The cost of sinking the piling for the job, excluding superintendence, cost of equipment, repairs, etc., is:

Labor	$634.55
Coal, 5 tons	31.50
Gas, 210 gal.	23.10
Total	$689.15
Sinking cost per pile	8.84
Sinking cost per lin. ft	.221
Total cost per pile in place	43.84
Total cost per lin. ft. in place	.998

Cost of Cutting off Concrete Piles.—Some precast concrete piles in one of the navy yards were driven to refusal while their tops were still above proper grade. The method of cutting them off is described by Civil Engineer Kirby Smith, of the United States Navy, in Bulletin 28 of the Public Works of the Navy, abstracted in Engineering News-Record, Jan. 17, 1918. The piles were 18 in. square at cutoff, reinforced with eight ¾-in. square rods tied together with ⅜-in. wire hoops 2 in. c. to c. for a distance of 3 ft. from each end and 8 in. c. to c. between these limits. They were driven 3 to 20 ft. above the required elevation, the difference being due to a varying stratum of rock. Outside the reinforcing rods there was a protective concrete covering of 2 to 2½ in. This was chipped off at the required level with a cold chisel and a sledge, leaving the rods exposed. An air drill was tried, but the chisel-and-sledge method was found to be easier. Then the rods were cut with an acetylene torch. This left the concrete core, which had a low tensile strength. Where the projecting pile was of sufficient length to give good leverage, a 1½-in. manila rope was slung around the top and four men pulling on the rope snapped the pile off at the cut. Where the projecting portion was short, the same result was accomplished by a direct pull from a stationary engine and a ⅞-in. steel cable attached to the top of the pile. Two men were employed in cutting out the concrete, and four men to snap off the piles. The average time for each pile was one hour, and the total cost per pile averaged 60 cents.

CHAPTER XXIII

BUILDING CONSTRUCTION

References.—For further data on cost of building the reader is referred to Gillette's "Handbook of Cost Data," Section X, which contains 108 pages and to Gillette and Dana's "Handbook of Mechanical and Electrical Cost Data," Chaper III which contains 70 pages.

Rapid Methods of Estimating Costs of Buildings.—In Engineering and Contracting, Nov. 28, 1917, I gave the following suggestions:

The square foot of floor area and the cubic foot of total volume are the two units in which the costs of buildings are commonly expressed by those who apply rough and ready methods of estimating. But obviously such unit costs are subject to wide variations, even in buildings of the same type. Much more satisfactory than the square foot of floor area for approximate cost estimating purposes is the square foot of wall, floor and roof, with the basement and foundation estimated separately. Then each type and class of wall, floor and roof can be estimated by itself.

To prepare unit costs for estimating a given type of wall, for example, the estimator first prepares a bill of materials for, say, 100 sq. ft. of wall, and applies unit prices, including labor, to all the materials, totals the items and divides by 100. The same is done for windows and doors, so that, knowing the total area of "openings" the cost is readily estimated.

Preferably the cost of columns is estimated by the linear foot, but, if desired, the cost of columns may be included as a part of the cost of the floors. Basements may be estimated by the cubic foot, to which may be added the cost of any special foundation work, such as piling, and the cost of the floor. The "equipment"—plumbing, heating, lighting, sprinkler system, elevators, etc.—should be estimated separately; but this, at least in part, may often be estimated by the square foot of floor area. Thus the cost of a factory heating system may be taken at 25 cts. per square foot, and the cost of a fire sprinkler system at 20 cts. per square foot of floor.

Between the very crude method of expressing the entire cost in terms of the square foot of floor area and the very refined method of detailing all quantities in a building, there stands the method above suggested, in which composite units of different types and classes are used.

How to Estimate by the Square.—I. P. Hicks gives the following in the National Builder, Oct., 1920.

It has long been the desire of carpenters and contractors to find some practical short way of estimating that would do away with the laborious job of making out bills of material in detail. We will now show how to make combinations in a safe and practical way which can be used to save a large amount of the ordinary figuring. We have arranged the items so that carpenters and contractors can fill in the prices and make the combinations to suit the job which they have on hand.

The combinations are to be made to fit the job. For example the outside walls of the house may be sided, shingled or stuccoed. Each would have to be figured at a different rate per square; consequently the different items must be combined to fit the job. The same is true with the floors; some kinds of flooring may cost much more than others both in regard to material and labor. So in every case it is necessary to consider the kind of material and labor that goes into every part of the job. What will do for one job may not answer at all for another and it always will be necessary for the contractor to use discriminating judgment in making estimates no matter how it is done or by what system. A good record of estimates showing the actual cost of work from time to time soon gives the contractor a knowledge of costs which he can rely upon. Keep a record of your work, follow the system given, watch it closely and you will soon be able to establish a rate per square, per lineal foot and per piece that you can depend upon. By this system you can shorten the work of estimating to a large extent without the usual dangerous results from short cuts in estimating. It is no guess work; you simply combine such parts of the work as you can consistently and figure them together in a lump sum. Things that can not be figured in combination, you can figure separately and add them to your estimate just the same. The combinations as given will enable one to figure the cost of the bulk of the material and labor above the foundation without making out itemized lists of material and labor.

Such items as excavating, masonry, plastering, painting, electric wiring, tin work, heating and plumbing should be figured separately and added to make the complete estimate. It is the lumber, millwork and carpenter labor mostly that the carpenter contractor seeks for a reliable and easy way out in the matter of estimating. The following is our form and system of estimating the cost of building:

Floor Cost Per Square

Floor joists, size....set....centers...............	$.........
Rough floor....................................	....
Finish floor....................................	....
Carpenter labor framing........................	....
Carpenter labor laying rough floor	....
Carpenter labor laying finish floor..............	....
Carpenter labor scraping finish floor...........	....
Nails for framing..............................	....
Nails for rough floor...........................	....
Nails for finish floor...........................	....
Floor deadening...............................	....
Total per square...............................	$.........

The above form shows how you can arrive at a correct price per square in a lump sum. In making your total you can figure according to your job. For example all floors may not have the same size joists, they may be spaced different, the finish floor and the rough floor may be different on different jobs. Some floors may not have to be deadened or scraped. In getting the total omit such parts as are not required and fill in the items such as are called for on the job you are to figure. The quantities of dimension for different size joists and the quantities of rough and finish floors for the different kinds of flooring we have given in former articles.

Outside Wall Cost Per Square

Outside studding, size....set....inch centers........	$..........
Outside sheathing....................................	....
Siding...	....
Shingles...	....
Stucco material......................................	....
Building paper.......................................	....
Labor framing..	....
Labor sheathing......................................	....
Labor siding...	....
Labor shingling outside walls........................	....
Labor applying stucco................................	....
Nails for framing....................................	....
Nails for sheathing..................................	....
Nails for siding.....................................	....
Nails for shingling..................................	....
Nails for applying stucco board or lath..............	....
Total per square.....................................	$..........

Not all of the above items will be likely to be required on any one job; in reaching a total combine such items as will be required on the job you are estimating.

Partition Cost Per Square

Studding, size......set......inch centers............	$..........
Labor, framing.......................................	....
Nails..	....
Total per square.....................................	$..........

Ceiling Cost Per Square

Joists, size......set......inch centers..............	$..........
Labor, framing.......................................	....
Nails..	....
Total per square.....................................	$..........

Roof Cost Per Square

Rafters, size......set......inch centers.............	$..........
Sheathing..	....
Shingles...	....
Asbestos shingles....................................	....
Slate roof...	....
Tile roof..	....
Tar and gravel roof..................................	....
Textile shingles.....................................	....
Rubberoid roof.......................................	....
Canvas roofing.......................................	....
Tin roof...	....
Labor framing..	....
Labor sheathing......................................	....
Labor shingling......................................	....
Labor asbestos shingles..............................	....
Labor slate roof.....................................	....
Labor tile roof......................................	....
Labor tar and gravel roof............................	....
Labor textile roof...................................	....
Labor rubberoid roof.................................	....
Labor canvas roof....................................	....
Labor tin roof.......................................	....
Nails, framing.......................................	....
Nails sheathing......................................	....
Nails shingling......................................	....
Nails for other roofings.............................	....
Total per square.....................................	$..........

Make the combinations and total according to kind of roofing used and to fit the job.

Porch Floor Cost Per Square

Joists size......set......inch centers.............. $..........
Flooring..
Labor framing...
Labor flooring..
Nails framing...
Nails flooring..

Total cost per square............................. $..........

Porch Ceiling Cost Per Square

Ceiling joists, size......set......inch centers...... $..........

Estimating Data.—U. M. Dustman gives the following in The National Builder, May, 1918.

First Floor Joist.—The joist can be butted together, or they can run past each other in the center and be spiked together, which is preferable. The first floor joist plan will show the number of joist required for the building; but when there is no floor joist plan, divide the length or space that the joist are to occupy by 4 and multiply the quotient by 3 and add one; then add one for each partition, to double the joist. It is safer to add another extra one, as sometimes the joist cannot be spaced equally, especially for the second floor, when it is sometimes necessary to have a joist on each side of a partition. The first floor joist are generally taken from the basement plan and the second floor joist from the first floor plan, to see where the bearing partitions are. The second floor plan must also be taken into consideration when the floor joist are being taken off, as for double joist under partitions, and extra projections are sometimes given as in a plan where the second floor extends partly over the front porch.

Partitions.—In taking off the number of studs required for inside partitions, each partition should be taken by itself. A partition 12 feet long will require 12 divided by 4 and multiplied by 3 equals 9, add 1 equals 10. No allowance should be made for openings, as the doubling of the studs on each side of an opening will take the ones left out for the opening.

Plates.—Figure a single plate at the bottom and a double plate at the top for all bearing partitions; partitions that are not bearing will only require a single plate at each end. Outside walls should be double plates at the top.

Outside Wall Studs.—Studs for outside wall should be taken on 16 inch centers, not taking out any openings unless they are 4 feet or more. Corners must be doubled.

Rafters.—If 16 inch centers, take the same figures as for the studs. If 24 inch centers, then divide the space by 2 and add 1. To get the length of rafters when figuring out a bill of material for a one-half pitch roof, add 5 inches to each foot of run. Take a building 24 feet wide with a projection of 2 feet on each side; then the starting place for the roof will be 24 feet plus 4 feet or 28 feet wide. One-half of 28 equals 14 feet run; 5 times 14 equals 70, or 70 inches to be added to 14 feet, or 19 feet 10 inches; it will then require a timber 20 feet long for the rafter. For the one-third pitch roof add 2½ inches to each foot of run.

Shiplap, Flooring and Siding.—For 8-inch and 10-inch shiplap add 15 per cent or one-seventh of the number of square feet. If there are 1,400 square feet requiring shiplap it will take one-seventh of 1,400 or 200 square feet extra to cover the same or 1,600 feet. For 6-inch flooring add one-fifth; for 4-inch flooring add one-fourth, and for 2-inch flooring add two-fifths. For 6-inch lap siding add three-tenth, for 5-inch siding add one-third, and for 4-inch siding add two-fifths.

Roof Sheathing.—Take the number of square feet in the roof.

Shingles.—If laid 4½ inches to the weather it will require about 900 shingles to the square of 100 square feet, but as there is always a waste it is safer to figure 1,000 shingles to the square.

Plastering.—Multiply the length of a partition by the height and divide it by 9; for the ceiling the same. It is safer to take each room by itself when the actual number of yards must be had. If the height of a ceiling is 9 feet then every foot of run will be 1 yard. No allowance is made for openings unless they contain more than 40 square feet. The rules are different in most cities. If the openings are taken out the contractor must figure more per yard.

Lathing.—It takes about 14 lath 4 feet long to make one square yard. The price for lathing varies in different cities, and one figuring work must figure the price figured in the city where the work is to be done. Metal lathing is also done mostly by the square yard, though sometimes by the day.

Painting.—Painting is mostly figured by the square yard. When lap siding is used, allowance must be made for the under edge of the siding. Measure the projection of the cornice. No allowance is made for windows as they take more work than if it were all solid. Inside doors generally are figured the same way, by the number of square yards they contain. A 2 feet 6 inches by 7 feet door with the jambs and casing will contain about 3 square yards on each side. Floors are very easily figured by the square yard.

Cement Work.—Some contractors figure cement work by the cubic yard and some by the cubic foot for foundation work, footings, etc. Cement floors and sidewalks are figured by the square foot of surface. Cement blocks are figured at so much a block; prices vary in different localities according to wages paid and the price of material. A cubic yard of sand and gravel contains 27 cubic feet. One sack of cement contains 1 cubic foot of cement. When water and cement are added to pit gravel it settles more solid than the loose gravel and when in place it will only measure about 25 cubic feet; so when figuring cement work obtain the actual number of cubic feet and divide it by 25, which will give the number of yards of pit gravel required. A wall containing 600 cubic feet will require 600 divided by 25 or 24 yards of sand and gravel. A mixture of 1 part of cement to 6 of gravel will require 100 sacks of cement, 4 sacks to a barrel or 25 barrels. For top dressing it will take more cement, as the mixture is sometimes in equal parts and sometimes 1 of cement to 2 of sand. For cellar floors or sidewalk work, determine the number of cubic feet of concrete by multiplying the length by the width in feet, then if 4 inches thick divide by 3. A floor 10 × 30 feet will then have 10 × 30 or

300 square feet; divide 300 by 3 and we find that there are 100 cubic feet of concrete. For the top dressing, which is generally 1 inch thick, there will be for the same floor 10 × 30 feet equals 300 square feet of dressing 1 inch thick, then by dividing 300 by 12 we have the number of cubic feet of top dressing or 25 cubic feet. One cubic yard of sand will be sufficient sand, and if mixed 1 part of cement to 2 of sand then it would require 12½ sacks of cement; if in equal parts it will take 25 sacks, 4 sacks to a barrel. When washed gravel or broken stone are used, mixed with sand, it will require more material than for pit gravel, as the sand will fill the voids in the gravel or broken stone. If it requires 600 cubic feet of solid concrete, add 15 per cent to this which will make 600 cubic feet of material. A mixture of 4 parts of gravel, 2 of sand and 1 of cement would then take 690 divided by 3 or 230 cubic feet of sand or 8½ cubic yards; 460 cubic feet gravel or 17 cubic yards; 100 sacks of cement, to do the work for 600 cubic feet of solid concrete.

Brick Work.—When figuring brick work the walls are figured solid and the corners two times. Brick are generally figured by the thousand, laid in the wall. For a 4-inch wall figure 7½ brick for each square foot of wall surface, 15 brick for an 8-in wall, 22½ for a 12-inch wall, and so on, adding 7½ brick for every 4 inch in thickness. When figuring the actual number of brick required to do a certain job, take the number of surface feet and deduct for all openings and multiply by 6½, which will give plenty of brick and allow for broken ones. For mortar to lay 1,000 brick it will take 2½ bushels or 200 pounds of lime and about ¾ yard of sand. For lime and cement mortar take 2 bushels lime, 1 barrel cement to ¾ yard of sand for 1,000 brick. The amount of mortar required depends largely on the thickness of the mortar joint. Mortar coloring requires about 50 pounds of color to the thousand brick, depending on the shade of mortar color required.

Stone Work.—Stone walls for foundation work are generally figured by the perch. While 24¾ cu. ft. contain one perch, in some localities 16½ cu. ft. are figured as one perch and the price made accordingly. Foundation walls for a residence are generally figured 18 in. thick, corners counted to times; that is, the outside measurement of the wall is taken. To find the number of perch in a wall if 18 in. thick, multiply the length by the height of the wall, then by 1½ and divide by the number of cubic feet in a perch. A wall 40 ft. long, 8 in. high, 18 in. thick, will contain 40 × 8 × 1½ or 480 cu. ft. of wall.

Interior Trim.—The interior trim is generally taken from the plans by the mill man and figured, but the contractor should be able to take off a mill bill and send it out for figures to different mill men. Give the number of doors, size and thickness, and the kind of wood; give the number and size of all windows, also the number of window frames, size of casing, kind of head casing, and whether for a wood, plastered or brick building. Give length of inside casing and number, number of feet of base, quarter round, picture mould, head mould, etc.; number and size of cupboard doors, drawers and shelving; window and door stops; stairways, size of tread and rise and length, number of feet of railing, number of balusters, cove, newels, hand rail; number of feet of chair rail, and closet strips, porch columns, balusters and railing, mantle shelf, seats, colonnade, etc.

Hardware.—Make out a list of hardware wanted and get figures on same, or let the hardware dealer give you an estimate of what he will furnish for so much money. When making out list of hardware mention the number of locks, hinges and size of same; valley tin, ridge roll, gutters, down spouts, tin roof and flashing; drawer pulls, sash lifts and locks, weights, sash cord. Figure the nails as follows: 5 lbs. of shingle nails to each 1,000 shingles, 18 lbs. siding nails to 1,000 feet siding, 20 lbs. 8d. for sheathing and 25 lbs. for 4-in. and 6-in. flooring per 1,000 ft. Dimension, 20 lbs. per 1,000 ft.

Estimating carpenter labor with labor at 50 cts. per hour. No exact method can be established to do carpenter work. Some men do more work than others in a day, which makes a difference in estimating. A very close average can be had by keeping track of work done on other buildings. The following is a very close way of estimating; it is better to make your estimate too high than too low and lose money on work. Add together the number of feet of lumber required for the framing, sheathing for outside wall, roof, and for sub floors, siding and partition studs and figure the same at $15 per thousand feet. Suppose there are 15,000 feet of lumber required for a residence; at $15 per thousand, the labor would cost $225 to put all of the lumber in place. For a one-story porch with floor, ceiling and wood shingle roof, the labor will cost about 25 cts. per square foot of floor surface. A porch 10 ft. wide by 16 ft. long contains 160 sq. ft.; thus at 25 cts. per square foot will amount to $40 for labor to build the porch. For a two-story porch 40 cts. per square foot if screened.

Hard Wood Floors.—To lay and scrape a hard wood floor is worth 5 cts. per square foot of floor laid. A room 12 × 20 ft. contains 240 sq. ft. of floor space, and at 5 cts. per square foot will amount to $12. For yellow pine floor figure at 3 cts. per square foot.

Exterior Trim.—Find the number of feet required for exterior trim and multiply by $20 per thousand feet.

Window Frames.—To set the frame, hang the sash and do the casing for ordinary windows it is worth $1.50 each for yellow pine and $1.75 for oak.

Door Frames.—To set case on outside frames, hang the door and put on lock and stops complete, $2 each. Inside Doors.—To set jamb, case, hang and put on lock and stops for yellow pine, $1.75 each; oak, $2.25. Cupboard from $8 to $10. Base 3 cts. per running foot; picture mould, 75 cts. a room.

Stairs.—Main stairs from $8 to $10, cellar stair $2, and rear stairs $4. Porch steps—front, $4; rear, $2. Screens, 40 cts. each; colonnade from $6 to $8; seat, $4 to $6. Cased openings, $2.

Component Costs of Building Construction.—At the national conference of the construction industries held in Feb., 1921 at Philadelphia, Barclay White, a contractor, of that city, gave some information on this subject that should be of interest. The following abstract of his statement is given in Engineering and Contracting, June 22, 1921.

The relative values of the various parts of the building have not been very carefully studied heretofore but we have made an attempt to fix an approximate proportion covering the whole building field in this territory. We have gone about this by taking a composite of building, which includes a reinforced concrete factory building; slow burning or heavy construction warehouse building with brick walls; the typical style of two-story dwelling; detached brick and frame residence; stone schoolhouse with wood floor construction; fire-proof institutional building; the apartment house; and the steel frame office building.

How the Costs Were Arrived At.—From our own records of cost we have taken typical instance in each of these eight types of building and have divided it up according to the actual cost figures, into labor and materials, and have then tried to proportion the various types of building as nearly as possible, in their correct relation to the total volume of business which is done in this territory. Of course, right there you will realize that there is bound to be a great deal of leeway which should be brought out, for in the course of the last few years house building has fallen off very largely in proportion to the heavier types of construction. These figures will have to be taken as the best approximation that the circumstances permit.

After arriving at a makeup of the different types, and proportioning the various types into their proper ratios, we have summarized, for instance, the main item as skilled labor on the building. It is a little difficult to say where skilled labor stops and unskilled labor begins, but we have based the calculation on the mechanics on one side as against the apprentices, helpers, hod carriers and common laborers on the other side. The result of our calculation is given in Table I.

Overhead, Expenses and Profit.—There is really a duplication of overhead expenses and profit because possibly 65 per cent of the work is sublet, and on that work sublet to the plumber, the plasterer, the painter, etc., there is really a double overhead, because the general contractor, as superintendent of the work, makes arrangements with the sub-contractor and divides the work, so that we find office rent, general expenses and overhead—but not including office wages—to be 5.8 per cent. The net compensation of the sub-contractors, assuming they do 65 per cent of the work, 3.90 per cent, and the net compensation of the general contractor, assuming he does 35 per cent of the work, directs and supervises the balance, 3.42 per cent, bringing the total up to 100 per cent.

Table I. —Percentages of Elements in Composite Building

The division of costs of an imaginary composite building has been arrived at by taking the actual cost figures on different types of buildings, including an ordinary two-story brick dwelling (row type), a detached residence, a reinforced concrete factory building, a slow burning construction warehouse building, a steel frame office building, a fireproof and wood floor school building, with stone walls, and a brick apartment house.

The relative importance of these different types of building in determining the figures for the composite whole, were determined by reference to the published lists of building permits and similar statistics as furnished by F. W. Dodge Co., so that the result as given represents as nearly as possible the exact relative importance of the various items in the make-up of the total volume of building business transacted in this territory

Analysis in percentages of cost of a composite building, showing average values of various items for each $100 worth of building work normally done in Philadelphia district:

Labor:	Per cent	
All skilled labor and supervision on the building including also stone cutting, and shop work on sheet metal and millwork only	27.55	
Unskilled labor as above	9.44	
Office, estimating, general supervision and engineering salaries.	5.60	
Liability insurance	1.41	
Total labor (no manufacturing except as stated)		44.00

	Per cent
Materials:	
Lumber for millwork, concrete forms and structure delivered at site	$ 8.86
Bricks—delivered at site	6.10
Steel—structural, miscellaneous and reinforcement, delivered at site	5.93
Boilers, heaters, piping, etc., for heating	3.05
Plumbing fixtures, piping, etc	2.76
Cement f. o. b. cars	2.60
Hardware, nails and similar misc. materials	1.78
Sand, delivered to site	1.69
Electric fixtures, conduit wire, etc	1.60
Stone, slag and pebbles for concrete	1.49
Sprinklers and fire protection apparatus and minor unclassified items	1.04
Building stone	.90
Paint	.76
Roofing and sheet metal materials	.70
Plastering materials (no sand)	.65
Lathing materials	.65
Steel sash, etc., delivered to site	.50
Lime (no plaster)	.45
Glass	.40
Cut stone (materials) and terra cotta	.38
Elevators (delivered to site)	.28
Mechanical equipment, cranes, etc	.21
Tile and marble (materials only)	.10
	42.88
Overhead expense and Profit:	
Office rent, taxes, interest, depreciation of equipment, general expense and overhead (not wages)	5.80
Net compensation of all sub-contractors (assumed as doing 65% of the work direct)	3.90
Net compensation of general contractor (assumed as doing 35% of the work direct and supervising the balance)	3.42
	100.00

Cost of College Buildings from 1851 to 1916.—Interesting information on building costs at the University of Wisconsin from the period from 1851 to 1916 is given by Arthur Peabody, State Architect of Wisconsin, in an article in the Wisconsin Engineer, from which the matter following is abstracted in Engineering and Contracting, June 26, 1918.

The original buildings at the University consisted of three halls and a residence. These buildings were completed by 1857, after which for 14 years no others were added. They were constructed of local stone, the walls being of rubble masonry with a facing of ashler. The floors, roof and partitions were of timber. The costs of these four structures were as follows:

Year built		Cubic feet, gross	Cost per cu. ft., cts.
1851	North Hall	331,655	6.0
1855	South Hall	331,650	6.4
1855	Residence of director of observatory	110,000	4.5
1857	University Hall	682,500	9.3
	Average for 4 buildings		7.5

The buildings erected between 1871 and 1887 followed the general practice of construction employed in the other buildings. The cost per cubic foot of these buildings ranged from 5.1 cts. for a structure erected in 1879 to 17.7 cts.

for one erected in 1878. The cost of the Chadbourne Hall built in 1871 was 15.2 cts. per cubic foot.

The new Science Hall built in 1888 was a departure from previous buildings. The use of fireproof construction and steel and hollow tile in this building was one of the first, if not the first, example of the use of these materials in modern public buildings. The gross contents of building of the building was 1,751,310 cu. ft. and it cost 16.3 cts. per cubic foot. The only other fireproof building erected at Wisconsin up to 1906 was the State historical library. This building was of structural steel and hollow tile with a facing of Bedford stone. It was erected in 1900, had 1,410,000 cu. ft. gross contents and cost 53.1 cts. per cubic foot.

Some comparisons of cost as between fireproof and non-fireproof buildings are interesting, as they tend to show a decrease in actual cost, if the greatly enhanced value of the buildings erected is taken into consideration.

The following buildings are of ordinary construction, having masonry walls, and wooden floors and partitions:

	Year built	Walls	Cubic feet, gross	Cost per cu. ft., cts.
Chadbourne Hall	1871–1896	Stone	775.250	17.4
Dairy building	1892	Brick	300,000	13.3
Soils physics building	1894	Brick	123,750	15.0
South wing University Hall	1895	Stone	518,320	12.5
Engineering building	1901	Brick	746,144	13.4
Agricultural Hall	1902	Brick	1,041,000	14.8
Main Chemistry building	1905	Brick*	1,420,000	8.2
North wing University Hall	1906	Stone	518,320	14.3
Average for 8 buildings	....	......	....	13.6

* Built of sand lime brick walls, except on small part of front; very plain.

The following buildings have masonry walls, concrete floors and tile partitions:

	Year built	Walls	Cubic feet, gross	Cost per cu. ft., cts.
Agronomy building	1906	Brick	193,500	14.3
Agricultural Engineering	1906	Brick	345,000	14.8
Central heating station	1908	Brick	1,011,500	10.38
Forest Products laboratory	1909	Brick	573,600	8.5
Lathrop Hall	1909	Stone	1,476,000	13.0
Dairy laboratory	1909	Brick	144,377	11.0
Biology building	1910	Stone	1,198,450	16.7
Wing on Engineering building	1910	Brick	277,000	13.6
Horticultural building	1910	Brick	325,600	15.4
Wing on Chemistry building	1912	Brick	545,200	13.2
Home Economics building	1912	Stone	746,200	15.9
Barnard Hall	1912	Stone	647,700	19.07
Wisconsin High school	1913	Brick	900,000	13.15
Agricultural Chemistry building	1913	Brick	658,250	12.66
Physics building	1915	Brick	1,323,000	13.3
Soils building	1915	Brick	333,800	15.9
Average for 16 buildings	....	.....	....	13.75

Cost of Seven School Buildings at Pittsburgh, Pa. (Engineering and Contracting, Aug. 22, 1917).—During the past five years the Board of Public Education of Pittsburgh, Pa., has completed seven new elementary schools and two new high schools at a cost of $3,168,721. The average cost of the general work has been 14.6 cts. per cubic foot. The cost of the heating and ventilating has been 2.9 cts. per cubic foot. The cost of the plumbing has been 1.2 cts. per cubic foot and the cost of the electrical work has been 0.8 cts. per cubic foot. The total cost of all buildings has been 19.5 cts. per cubic foot. Bids taken Dec., 1916 indicated an increase in the cost of construction amounting to 56 per cent above contracts let a year previous to that date.

Unit Costs of Forty-Seven School Buildings (Engineering Record, Oct. 4, 1913).—Total costs of forty-seven school buildings in Boston are given in the (1912) annual report of the Schoolhouse Department, and from these figures the cubical contents and the number of pupils accommodated, costs per cubic foot and per pupil are derived. The total costs range from $23,000 to $329,000, the number of pupils per school varying from 160 to 1832. The costs per cubic foot are very uniform, averaging between 22 and 23 cents, two running as low as 17 cents and one as high as 28 cents. The costs per pupil fluctuate more widely, ranging from $117 to $208, exclusive of several high school and normal school buildings, in which the cost per pupil is as high as $940. The figures are further divided into the building proper, heating, plumbing and electrical equipment. The buildings proper cost from 76 to 86 per cent of the whole, the heating from 6 to 15 (most of them being from 8 to 11 per cent), the plumbing 4 or 5 per cent, except in a few cases as low as 3 or as high as 9, and the electrical equipment slightly less.

Cost of Nine School Buildings in Cincinnati.—W. P. Anderson, in Engineering Record, Aug. 7, 1909 gives the following:

TABLE II.—SIZE AND COST OF NEW SCHOOLS IN CINCINNATI

Year opened	Remarks	Construction	Cubic feet contents	Cost per cubic foot	Class rooms	Auditorium	Gymnasium	Play rooms	Toilet rooms	Other rooms
1906	3 stories and basement	Joist.—Fireproof corridors	949,354	$0.151	14	1	1	2	2	..
1907	2 stories and basement	Joist.—Fireproof corridors and stairs	786,239	0.165	10	1	1	2	2	1
1908	2 stories and basement	Fireproof except attic and roof	871,796	0.159	12	..	..	2	2	5
1908	2 stories and basement	Fireproof..........	1,460,266	0.155	20	1	1	2	2	5
1908	3 stories and basement	Fireproof..........	1,475,811	0.168	28	1	2	2	2	4
1909	2 stories and basement	Fireproof..........	1,108,105	0.163	17	1	1	2	2	4
.... 1909	2 stories and basement, cage construction	Fireproof..........	778,461	0.151	10	1	1	2	2	3
....	3 stories and basement	Fireproof..........	766,176	0.180	10	1	1	..	2	5
....	3 stories, basement, subbasement and tower.	Fireproof..........	4,525,179	0.147	29	1	2	*	2*	5*

* Miscellaneous shop rooms.

Costs of Warehouses at Navy Yards.—Civil Engineer Kirby Smith, U. S. Navy in "Public Works of the Navy," and in Engineering and Contracting, Aug. 28, 1918, gives the following.

The general features of design in all the structures are the reinforced concrete columns with a flat-slab floor system, and brick curtain walls with adequate glazed areas. Buildings are equipped with extensive toilet and locker facilities, sprinkler systems, fire walls, and a sufficient number of elevators, the larger structures having both freight and passenger service. The buildings are generously provided with loading platforms and large doors for handling incoming and outgoing stores. Contracts for all these buildings were let between April and Nov., 1917.

TABLE III.—DETAILS OF GOVERNMENT STOREHOUSES

Location	Size	Stories	For soil, tons*	For piles, tons*	Rein. steel, tons†	Struc. steel, tons†	Cement, est., bbls.
New York	180 × 360	11	...	28	2,150	50	63,000

* Allow bearing on foundations. † Steel tonnage, estimated.
[1] L-shaped, 104½ ft. and 224½ ft. on ends; 304½ ft. and 200 ft. on sides.
[2] U-shaped, 184½ ft. × 264½ ft. with court 33½ ft. wide. [3] And 50-ft. 1-story annex.

TABLE IV.—COST OF GOVERNMENT STOREHOUSES

Location	Cubic contents, cu. ft.	Total floor area, out to out of bldg., sq. ft.	Floor area, inside of walls, sq. ft.	Actual cost, per cu. ft.	Actual cost, per sq. ft.
New York	8,737,000	712,800	696,300	$0.133	$1.63
Philadelphia	3,604,300	307,900	300,300	.141	1.65
Boston	2,996,100	251,700	243,200	.173	2.04
Mare Island	1,338,400	128,700	125,600	.148	1.54
Charleston	995,000	96,600	93,100	.218	2.24
Puget Sound	2,976,700	287,800	280,600	.170	1.76
New London	665,000	57,000	54,900	.180	2.10
Hampton Roads	3,994,123	352,423	345,073	.179	2.03
Pearl Harbor	416,000	37,000	35,300	.232	2.61
Newport	731,474	59,409	56,985	.202	2.49
Washington	1,981,250	137,500	133,900	.190	2.74
Brooklyn	795,675	74,263	71,379	.250	2.69
Mare Island	473,507	39,757	38,264	.....	....

Costs of Twenty-Two Hospital Buildings.—Costs of hospital buildings are given by O. H. Bartine in a paper read before the American Hospital Association. The following data, published in Engineering and Contracting, July 26, 1916, are summarized from detailed tabulations.

For twenty-two buildings the building and equipment costs per cu. ft. were as follows:

Item	Per cu. ft., cts.
Total building	38.2
Heating and ventilating	3.3
Electric system	0.9
Electric fixtures	0.3
Plumbing	2.9
Refrigeration	1.2
Vacuum cleaner system	0.2
Elevators	0.7
Kitchen equipment	0.4
Power plant	4.7
Total	52.8

The segregated building costs per cu. ft. for thirteen hospitals were as follows:

Item	Per cu. ft., cts.
Excavation	2.6
Masonry	12.4
Structural steel	4.5
Carpentry	2.8
Roofing	1.0
Glass and glazing	3.6
Skylights and sheet metal	1.1
Painting	0.6
Lathing and plastering	1.23
Composition flooring	0.8
Tiles, mosaics and marbles	2.11
Hardware	0.5
Cast iron	2.2
Total	43.2

In determining cubical contents the author states: "Measurements should be taken from the basement or subbasement (lowest) floor level to the mean of the outside of the roof, and from outside to outside of walls. In other words, the cubic feet of air displaced by the exterior dimensions of the building should be considered, eliminating approaches, balustrades and other projections not enclosing space."

Cost of Fireproof Loft Building, Chicago.—Harold Doerr, in Engineering and Contracting, March 18, 1914, gives the following:

The building, completed in the fall of 1913, is seven stories high with provision for the addition of three stories in the future and covers an inside lot 50 × 170 ft. The foundations are of reinforced concrete having a maximum thickness of 3 ft. 1 in. and cover practically the whole building area.

The foundation and columns are stronger than are actually required to meet the present conditions. The present roof beams, which are to form the framework for a future eighth floor, have been set level. The pitch of ⅛ in. in 1 ft. required for the roof is obtained by means of a graded cinder fill, over which is built a 1-in. layer of cement mortar, mixed in the proportions of 1 part cement to 2 parts sand, on top of which was laid a tar-and-gravel roof. There are three pent houses on the roof for the tanks and two elevators in addition to a stair hatch. The building contains a large six-ton high-speed freight elevator, large enough to allow a truck to drive onto it from the alley, and a ten-passenger elevator located in the front part of the building. A sprinkler system of the wet type is installed complete, with pumps for water and air, and a 5,000-gal. pressure tank and a 25,000-gal. gravity tank being provided. The floors throughout the building are of maple, the best quality being used on the first three floors and first-grade factory maple on the upper floors. The 10-in. tile floor arches are covered with a 3-in. cinder concrete fill. All columns are fireproofed with a 1:2:4 mixture of stone concrete, the minimum protection afforded being 2½ ins.

Contract Price and Unit Cost.—The contract prices of the principal items are:

	Total	Cents per cu. ft.	Per cent
Steelwork, 703 tons at $60.00	$ 42,180.00	4.15	28.60
Foundation and sidewalk	11,300.00	1.11	7.65
Fireproofing	16,000.00	1.58	10.82
Masonry	14,000.00	1.38	9.49
Carpenter work	8,500.00	0.84	5.40
Sprinkler system	7,500.00	0.74	5.10
Elevators	7,000.00	0.69	4.75
Heating	6,575.00	0.65	4.46
Ornamental iron	4,800.00	0.47	3.25
Plastering	4,500.00	0.44	3.05
Architectural terra cotta	3,979.70	0.39	2.69
Cinder concrete	3,900.00	0.38	2.64
Excavation (15 ft.)	2,637.50	0.76	1.78
Total for above items	$132,872.20	13.08	89.68

Other contracts increase the total cost of the building to about $147,808. The cubic contents of the building, including foundations and pent houses, are 1,016,965 cu. ft., making the cost approximately 14.5 cts. per cubic foot.

Cost of Railway Buildings of Concrete and Brick.—The following examples of structures with their cost are abstracted from the report of the American Railway, Bridge and Building Ass'n. by Engineering and Contracting, Oct. 23, 1912.

On the Lehigh Valley Railroad the passenger station at Cortland, N. Y., was built with hollow tile walls with a cement-stucco finish. The foundations are of concrete. The partitions are of hollow tile. This building is a one-story structure 25 × 109 ft., with a second story over the ticket office 28 × 31 ft. The cost of the building was $19,000, exclusive of platforms, or about $6.50 per square foot. The cost per cubic foot was 24 cts.

A combined passenger and freight station on this road at Milan, Pa., was built with concrete foundations and hollow tile partitions. The floors were of concrete and the roof of timber, covered with roofing paper. The size of the building is 19.5 × 52 ft., and its cubic contents are 18,200 cu. ft. The freight house portion of the building has a raised platform of reinforced concrete, and the platforms for the passenger station are also of concrete. The cost of the building was $3,600, or $3.50 per square foot. The cost per cubic foot was 20 cts.

A freight house built by the Lehigh Valley Company at Bethlehem, Pa., cost $35,000. The office portion of the building had concrete foundations, hollow tile with stucco finish, wood floors, roof trusses and partitions. It is finished with wood trim inside and is plastered. The building is two stories high and 45 × 54 ft. in area. In the freight portion of the building the foundations, outside walls, fire walls and floors are of concrete and the roof is of timber.

The area is 59 × 254 sq. ft. and the height is one story. A raised platform is built of reinforced concrete. There are three fire walls. The building has a basement. The cost of the entire building per cubic foot was 6.7 cts. The cost of the office portion of the building was 12 cts.; of the freight house portion 5.7 cts. and of the platform was 80 cts. per square foot.

A roundhouse of 16 stalls was built by the Lehigh Valley R. R. at Coxton, Pa., at a cost of $50,000. The foundations were of 1 : 3 : 5 concrete and the columns, roof beams and roof of 1 : 2 : 4 concrete. The side curtain walls were of plastered hollow tile. The floor was also of concrete. The windows were of wood. The cost per stall was $3,125, or 8 cts. per cubic foot, or $1.87 per square foot. The cubic content of the roundhouse was 626,040 cu. ft.

Costs per Square Foot of Buildings, Panama-Pacific Exposition.—A. H. Markwart, in Engineering Record, June 6, 1914, gives the following:

TABLE V.—DIMENSIONS AND COST OF BUILDINGS, PANAMA-PACIFIC EXPOSITION

Palace	Size of building, ft.	Volume of building, cu. ft.	Average height of building, ft. and in.	Total cost	Floor area—Sq. ft.	Floor area—Cost per sq. ft.
Agriculture	579 × 639	20,634,000	62 6	$425,610	328,633	$1.30
Education	394 × 526	14,053,000	68 6	304,263	205,100	1.48
Festival Hall				270,000	57,400	4.70
Fine Arts				580,000	204,325	2.84
Food Products	424 × 579	15,609,000	66 0	342,551	236,690	1.45
Horticulture				341,000	201,000	1.70
Liberal Arts	475 × 585	16,038,000	64 0	344,180	251,300	1.37
Machinery	367 × 967	38,000,000	103 0	659,665	369,600	1.78
Manufactures	475 × 552	15,650,000	67 0	341,069	234,000	1.46
Mines and Metallurgy	451 × 579	16,199,000	64 0	359,445	252,000	1.43
Transportation	579 × 614	20,413,000	65 0	481,677	314,000	1.53
Varied Industries	414 × 541	14,648,000	67 0	312,691	219,000	1.43

Cost of a Cotton Storage Shed.—E. S. Pennebaker, Jr. (Engineering News, Jan. 2, 1913) describes a large cotton-storage shed at Mobile, Ala., to provide for the protection of cargoes of export cotton from damage by bad weather. It is a timber structure 135 by 410 ft., covering a smooth concrete floor, and fronting the Mobile River.

The building was erected and thoroughly equipped by labor contract, the railway company furnishing all materials. The work was done under the supervision of the construction department and completed in approximately 60 working days at a cost of 22.2 cts. per sq. ft. of floor area, exclusive of fire line and lighting, or at a total cost of 27.5 cts. per sq. ft. of floor area. This structure covers a floor area of nearly 1⅓ acres, and has a capacity of 7000 bales of compress cotton piled single tier. It is provided with ample fire protection, is lighted with tungsten lamps, and is served with track facilities which reduce to a minimum the cost of shipside delivery.

1921 Cost of Building Materials.—The Architect and Engineer, gives the following, based on reliable information furnished by San Francisco material houses. Date of quotations, June 20, 1921.

All prices f. o. b. cars San Francisco or Oakland. For country work add freight and cartage to prices given.

American Institute of Architects' Fees.—New work—6 per cent minimum basis. Alterations—7 to 10 per cent as a minimum basis. High class residence work—10 per cent as a minimum.

Bond—1½ % amount of contract.

Brickwork—

Common, $40.00 per 1000 laid.
Face, $90.00 per 1000 laid.
Common, f. o. b. cars, $16.50 plus cartage.
Face, f. o. b. cars, $55.00 per 1000, carload lots

HOLLOW TILE FIREPROOFING

12 × 12 × 3 in., 10¼ cts. per square foot.
12 × 12 × 4 in., 11¾ cts. per square foot.
12 × 12 × 6 in., 16¼ cts. per square foot.

Hod carriers, $7.40 per day.
Bricklayers, $9.25 per day.
Lime—$3.25 per bbl.; carload, $2.75 per bbl.

Composition Floors—30 cts. per sq. ft.

Concrete Work (material at San Francisco bunkers)—

No. 3 rock	$2.25 per yd.
No. 4 rock	2.25 per yd.
Niles pea gravel	3.25 per yd.
Niles gravel	2.50 per yd.
Niles top gravel	3.00 per yd.
City gravel	2.25 per yd.
River sand	1.50 per yd.
Bank sand	1.00 per yd.

SAND

Del Monte, $1.25 to $1.50 per ton.
Fan Shell Beach, $2.50 to $3.00 per ton.
Car lots, f. o. b. Lake Majella.

Cement (f. o. b. cars)	$ 3.69 per bbl.
Rebate for sacks, 15 cts. each.	
Atlas "White"	$12.60 per bbl.
Medusa cement	$12.60 per bbl.
Forms	$25.00 per M

WAGE—

Concrete workers	$ 7.50 per day
Cement finishers	8.35 per day
Laborers	6.95 per day

Dampproofing—

Two-coat work, 25 cts. per yard.
Membrane waterproofing—4 layers of P. B. saturated felt, $6.00 per square.
Hot coating work, $2.00 per square.
WAGE—Roofers, $8.35 per day.

Electric Wiring—$8.00 to $12.00 per outlet for conduit work (including switches)
Knob and tube average $4.50 to $6.00 per outlet.
WAGE—Electricians, $9.25 per day.

Excavation—

$1.75 per yard.
Teams, $10.00 per day.
Trucks, $28.50 to $38.50 per day.
Above figures are an average without water.
Steam shovel work in large quantities, less; hard material, such as rock, will run considerably more.

Fire Escapes—Ten-foot balcony, with stairs, $100.00 per balcony.

Glass—(Consult with manufacturers.)

21 ounce, 20 cts. per square foot.
Plate, $1.40 per square foot.
Art, $1.00 up per square foot.
Wire (for skylights), 44 cts. per square foot.
Obscure glass, 28 cts. per square foot.
Note.—Add extra for setting.
WAGE—Glaziers, $7.85 per day.

Heating—Average, $2.00 per sq. ft. of radiation, according to conditions.
WAGE—Steamfitters, $9.25 per day.

Iron—Cost of ornamental iron, cast iron, etc., depends on design.
WAGE—Iron workers, bridge and structural, $9.25 per day.
Lumber—(Prices delivered to bldg. site)
Common, $34 per M (average).
Common O. P. (select), $45 per M (average)

Flooring—

1 × 3 No. 1	$77.00 per 1000
1 × 3 No. 2	72.00 per 1000
1 × 4 No. 1	73.00 per 1000
1 × 4 No. 2	70.00 per 1000
1 × 4 No. 3	47.00 per 1000
1 × 6 No. 2 and better	73.00 per 1000
1¼ × 4 and 6 No. 2	75.00 per 1000
Slash grain, 1 × 4 No. 2	48.00 per 1000
Slash grain, 1 × 4 No. 3	39.00 per 1000
No. 1 common run to T. & G.	35.00 per 1000
Lath	6.50 per 1000

Shingles—(Add cartage to prices quoted)

Redwood, No. 1	$1.00 per bdle.
No. 2	.90 per bdle.
Red Cedar	1.10 per bdle.

Hardwood Floors—
Maple floor (laid and finished), 30cts. per foot.
Factory grade floors (laid and finished), 20cts. per foot.
Oak (quartered, finished), 40cts. per foot.
5/16 Oak (clear), 30cts. per foot (plain).
5/16 Oak (select), 28cts. per foot (plain).
5/16 Oak, quartered, sawed, clear, 35cts.
WAGE—Floor layers, $9.35 per day.

Hardwood Floors (not laid)—

		Per M ft.
5/16 × 2″ sq. edge	Clear quartered oak	$173.50
	Select quartered oak	121.50
	Clear plain oak	119.00
	Select plain oak	95.00
13/16 × 2¼″ face	Clear quartered oak	210.00
	Select quartered oak	144.00
	Clear plain oak	157.50
	Select plain oak	114.00
	Clear maple	134.50
	Clear maple—white	178.00
13/16 × 3¼″ face	Clear maple	134.50
1⅛ × 2¼″ face	Clear maple	134.50
⅜ × 2″ face	Clear quartered oak	158.00
	Select quartered oak	112.50
	Clear plain oak	112.50
	Select plain oak	78.00
	Clear maple	89.50

Millwork—
O. P., $100 and up per 1000. R. W., $120 and up per 1000.
Double hung box frame windows (average) with trim, $7.50 and up each.
Doors, including trim (single panel), $10 and up each.
Doors, including trim (five panel) .... $9.00 each
Screen doors, $3.50 each.
Window screens, $1.50 each.
Cases for kitchen pantries seven feet high, per lineal foot, $9 each.
Dining room cases, if not too elaborate, $10 each.
Labor—Rough carpentry, warehouse heavy framing, $13.00 per 1000.
For smaller work, average, $25.00 to $35.00 per 1000.
WAGE—Carpenters, $8.35 per day.
Laborers—Common, $6.00 per day.
Marble—(Not set) add 60cts. up per ft. for setting

Columbia	$2.05 sq. ft.
Alaska	2.05 sq. ft.
San Saba	3.65 sq. ft.
Tennessee	2.50 sq. ft.
Verde Antique	4.55 sq. ft.

WAGE—Marble polishers and finishers, $6.00 per day.

Painting—
Two-coat work, 35 cts. per yard.
Three-coat work, 50 cts. per yard.
Whitewashing, 5 cts. per yard.
Cold water painting, 9 cts. per yard.
Turpentine, $1.05 per gal. in cases and 90cts. per gal. in tanks.
Raw linseed oil, 94 cts. per gal. in barrels.
Boiled linseed oil, 96 cts. per gal. in bbls.
Pioneer white and red lead, 11¾ cts. lb. in one ton purchases; 12½ cts. lb. for less than 500 lbs.
WAGE—Painters, $8.35 per day.
NOTE—Accessibility and conditions cause wide variance of costs.

Patent Chimneys—

6-inch	$1.50 lineal foot
8-inch	1.75 lineal foot
10-inch	2.25 lineal foot
12-inch	3.00 lineal foot

Pipe Casings—$8.00 each.
Plastering—
Interior, on wood lath, 70 cts. per yard.
Interior, on metal lath, $1.30 per yard.
Exterior, on brick or concrete, $1.30 per yard.
Portland White, $1.75.
Interior on brick or terra cotta, 60 cts. to 70 cts. per yard.
Exterior, on metal lath, $1.85 to $2.25 per yard.
Wood lath, $6.50 at yard per 1000.
Metal studding, $1.25 to $1.50 per yard.
Suspended ceiling and walls (metal furring, lathing and plastering), $2.25 per yard.
Galv. metal lath, 33 cts. and up per yard, according to gauge and weight.
Lime, f. o. b. warehouse, $3.25 per bbl.
Hardwall plaster, $22.00 per ton, f. o. b. warehouse. (Rebate on sacks, 15 cts).
WAGE—Plasterers, $10.20 per day.
Lathers, $9.25 per day.
Hod carriers, $8.35 per day.
Plumbing—
From $70.00 per fixture up, according to grade, quantity and runs.
WAGE—Plumbers, $9.25 per day.
Reinforcing Steel—Base price for less than car load lots $3.50 per 100 lbs.
Carload lots, $3.25 per 100 lbs., f. o. b. San Francisco. (Mill delivery.)
Roofing—Five-ply tar and gravel, $6.50 per square for 30 squares or over.
Less than 30 squares, $7.00 per square.
Tile, $35.00 to $50.00 per square.
Redwood shingle, $10.00 per sq. in place.
Cedar shingle, $10.00 per square in place.
Reinforced Pabco roofing, $8.25 per square. WAGE—Roofers, $8.35 per day.
Rough Hardware—
Nails, per keg, $5.50 base.
Deafening felt, $110.00 per ton.
Building paper, P. & B.,
1 ply, $3.50 per 1000 ft. roll.
2 ply, $5.50 per 1000 ft. roll.
3 ply, $8.00 per 1000 ft. roll.
Sash cord,
(Sampson spot), $2.25 per hank 100 ft.
Common, $1.00 per hank 100 feet.
Sash weights, cast iron, $80.00 per ton.
Sheet Metal—
Windows—Metal, $2.00 a square foot.
Skylights—
Copper, $1.25 a square foot (not glazed).
Galvanized iron, 40 cts. a square foot (not glazed).
WAGE—Sheet metal workers, $9.25 per day.
Stone-granite—
WAGE—Stone cutters, $8.35 per day.
Stone setters, $8.35 and $8.80 per day

Store Fronts—
Kawneer copper bars for store fronts.
Corner, center and around sides, will average $1.35 per lin. foot.
Zouri bar, $1.25 per lin. foot.
Zouri Underwriters' Specification sash $1.60 per lin. foot.
Structural Steel—$130.00 per ton (erected).
This quotation is an average for comparatively small quantities.
Light truss work higher; plain beam and column work in large quantities, less.
Steel Sash—
Fenestra, from S. F. stock, 28 cts. to 34 cts. per sq. ft.
Fenestra, plant shipment, 28 cts. to 34 cts. per sq. ft. (Includes mullions and hardware.)
Trus-con, from San Francisco stock 27 cts. to 33 cts. per sq. ft.
Trus-con, plant shipment, 27 cts. to 33 cts. per sq. ft.
U. S. Metal Products Co., 30 cts. per sq. ft. in San Francisco.
Tile—White glazed, 80 cts. per foot.
White floor, 80 cts. per foot.
Colored floor tile, $1.00 per foot.
Promenade tile, $1.00 per sq. ft. laid.
WAGE—Tilesetters, $8.35 per day.

Comparative Costs of Small Houses for 1914, 1920, and 1921 (Engineering and Contracting, May 25, 1921.) At the national conference on the construction industries held at Philadelphia Feb. 15–18 under the auspices of the Industrial Relations Committee of the Philadelphia Chamber of Commerce and the National Federation of Construction Industries, Daniel Crawford, Jr., an operative builder of Philadelphia, gave an interesting analysis of the cost of the general construction of a typical dwelling. According to his figures a 2-story house of 6 rooms and bath, built in Philadelphia. cost $2,969 in 1914, $8,346 in 1920 and could be built for $6,676 in 1921. These figures are based on an operation of 100 houses. Mr. Crawfords' figures follow:

	1914	1920	1921
Ground	$500.00	$600.00	$600.00
STREET IMPROVEMENTS			
1. Sewer	22.50	60.00	60.00
2. Water pipe	15.00	30.00	30.00
3. Curb (plain)	6.00	16.50	16.50
4. Cartway paving	25.00	90.57	90.57
	$ 68.50	$197.07	$197.07

GENERAL CONDITIONS

	1914	1920	1921
1. Plans	$ 1.00	$ 2.00	$ 2.00
2. Survey	3.50	5.00	5.00

Mr. Crawford comments on the above costs as follows:

In 1914 it was possible to buy small lots for dwelling house construction on 40-ft. streets for about $500. The price of the same lot today on a 50-ft. street is a little bit more. I say a 50-ft. street because there has been a general tendency in this community to develop on wider avenues, and the land has been laid out by the surveyors or engineers with a view of getting not less than a 50-ft. street, if possible, so that it is difficult today to find a piece of land that is divided up into 40-ft. streets. So that we have taken the same basic value, and merely added the land that is added. and made it $600 for 1920 and $600 for 1921.

The next item that enters into the cost of construction is utilities—the drainage, the water pipe, the curb, the paving—that the builder must pay for. In 1914 they cost him $68.50, and last year they cost him $197.07. This year the rates are the same. Some folks have said that we are going back to pre-war levels. The first important item that we find is the sales expense of 2 per cent, advertising 1 per cent, and office expense about 1 per cent. Generally, that is the total overhead charge of an operative builder. Four per cent represents his selling expense, his advertising and his office expense. The next item is taxes that amounted in 1914 to $11.25, $85 last year and $77.45 this year.

The next item is interest. You will notice that when a man starts in to build a hundred houses, it takes a lot of money. He must go to a trust company and negotiate a loan, and, of course, he must pay interest on that loan until he repays it to the trust company. We have predicated that charge on 9 months' interest on three-quarters of the cost of the house, the average operation taking anywhere from 15 to 18 months from the time it is started to the time it is disposed of. The title company charges cover title insurance and guaranteeing against mechanics' liens, and searches, recording, and all that sort of thing, which, of course, are perfectly legitimate charges. The next large item is the expense of placing first mortgages. In 1914 we had no difficulty whatever in placing a mortgage of $2,000 on a $3,200 house at an expense of 1 per cent. People were glad to take those mortgages because they were a very good investment. In 1920 the conditions had reversed themselves very much. It was necessary to pay 5 per cent in most cases to place that mortgage, so that the cost of that item jumped from $20 to $220. That condition has been changed this year, and we can place mortgages now at 3 per cent, so that there is run into the expense of building that house a charge of $108. The next item is the expense for placing second mortgages. In 1914 most of the building and loan associations which took the mortgages were in funds, and there was no difficulty in placing that second mortgage by paying the charges of the attorney who represented that association, their solicitor, for drawing the papers, and looking after the settlement, a charge that generally amounted to $23. But the conditions of 1920 changed materially. It was necessary to pay 10 per cent in 1920 for placing second mortgage loans and that amounted to $278. That has changed, and we can place them today at 5 per cent so it is $128. Supervision and so on, is estimated at $18, $36 and $36. The general conditions in the construction of the average small dwelling house rose from $395 to $1,445, and now stands at $1,036.

Relative Output and Cost of Labor in Building Trades in 1914 and 1919.—John B. Miles in a letter published in Engineering and Contracting, July 28, 1920, gives the following data which were obtained from reputable contractors.

EFFICIENCY OF LABOR IN BUILDING TRADES, NORFOLK, VA.

Trade	1914	1919
	Production per 8-hr. day	
	9 doors	5 doors
Carpenters	11 openings	6 openings
Brick masons	1900	800
Plasterers	150 sq. yds.	75 sq. yds.
Painters	1800 sq. ft.	900 sq. ft.

Cost Estimating for Reinforced Concrete Buildings.—Engineering and Contracting, March 27, 1918, gives the following abstract of a paper presented at the 14th convention of the American Concrete Institute by Clayton W. Myers.

The process of estimating various designs for comparative cost purposes is not nearly as difficult as may be supposed. After the quantities have been calculated for the various designs, unit prices are fixed and the total cost of the member estimated. It is not necessary to fix absolutely accurate unit costs to these quantities in order to obtain reasonably accurate cost comparisons. As long as the same unit costs are used for similar types of work in the various designs, the comparative costs will be surprisingly accurate. In fact, some of the unit costs may be in error 25 per cent or 30 per cent, and yet the resulting costs will show unquestionably which type of construction should be used. However, the alert engineer will soon become as interested in having his unit costs in accordance with current prices of material and labor as he is in having his design correct.

Concrete.—A list of approximate unit prices has been tabulated here which may be used to calculate the comparative costs of the principal members in a concrete building. Judicious use of these unit costs will enable the designer to incorporate in his design the most economical methods and at the same time develop a keener eye for economical construction. The following tabulation is a detailed estimate of the cost of concrete mixed in the proportion of 1:2:4.

Concrete (1:2:4 mix), per cu. yd.:		
Cement, 1⅔ bbl. at $2 per bbl. at the job		$3.33
Sand, ½ cu. yd. at $1.50 per cu. yd. at the job		.75
Crushed stone, 1³⁄₁₀ ton at $2 per ton at the job		2.60
Plant, cost per cu. yd.:		
Freight charges	$0.05	
Rental of mixer, etc	.35	
Small purchases, fuel and supplies	.45	
Labor	.40	
		1.25
Labor of mixing and placing		1.25
Total cost per cu. yd		$9.18
Total cost per cu. ft		.34

Concrete mixed in the proportion of 1:1½:3 will require about ⅓ bbl. more cement per cubic yard. This will add about 67 cts. to the cost of 1 yd. of concrete in place, making the unit price about $9.85 per cubic yard, or 36½ cts. per cubic foot. If a 1:1:2 mix of concrete is used, the cement will be increased about 1 ²⁄₁₀ bbl. over and above that used in a 1:2:4 mix. At $2 per barrel this would make the cost of 1:1:2 mix concrete about $11.58 per cu. yd. or 43 cts. per cubic foot. In large plain concrete footings it is sometimes advisable to use a concrete mixed in the proportion of 1: 2½:5. Concrete mixed in this proportion requires about ³⁄₁₀ bbl. less cement than 1:2:4 mix. Figuring cement at $2 per bbl., concrete mixed in the proportion of 1: 2½ :5 works out at approximately 32 cts. per cubic foot in place.

In calculating the amount of materials necessary to make 1 cu. yd. of concrete, it has been assumed that a cubic yard of 1:1:2 concrete will require the same quantity of sand and crushed stone as a cubic yard of 1:2:4 concrete. Theoretically this is not true, but in general practice there is some waste of material and it has been found that the small differences of aggregate used in the various mixes of concrete in a building are negligible. A very large part of the concrete in a building is a 1:2:4 concrete, therefore, the aggregate quantities of 1:2:4 mix are generally used for all concrete work and the cement alone is changed for various mixes. It will also be noted that the quantity of cement, sand and stone used here is somewhat in excess of the amount usually given in the tables published in various text-books. It must be borne in mind that the waste of materials on the job must be absorbed and the quantities in tables compiled by laboratory tests must be somewhat increased. It is actually necessary to estimate on about 1⅔ bbl. of cement to make 1 cu. yd. of 1:2:4 concrete on a job where the usual construction methods are employed and in other mixes of concrete the cement should be proportionately increased.

The prices of concrete work as tabulated here are about 30 per cent in excess of pre-war prices and 50 per cent more than the prices of 1913. These costs based on the present high cost of material and labor should be adjusted from time to time as necessary.

Plant Cost.—In making estimates for the cost of concrete in place, the most uncertain element entering into this cost is the item of "plant." At the present high cost of all building materials and labor, "plant" costs cannot be safely assumed to be less than $1 per cubic yard and will very seldom run as high as $2 per cubic yard of concrete. Owing to this wide variation in the cost of "plant," it is necessary in estimating concrete to strike an average cost which, while not accurate, will cover the usual "plant" work, and give a unit cost for concrete in which all times of material and labor have been considered. It is with this in view that a "plant" cost of $1.25 per cubic yard has been used in making up the unit cost of concrete in place as given in the foregoing tabulation.

The cost of steel reinforcement is extremely erratic in its fluctuation, but at present it may be assumed at $90 per ton exclusive of the labor of bending and placing. It will cost from $6 to $15 per ton to cut, bend and place this reinforcement, $100 per ton, or 5 cts. per pound, being a unit price which may be used to give reasonably close cost ratios. Reinforcement requiring much bending and made up of small bars should be figured about ½ ct. per pound higher than steel requiring only a small amount of bending. Spiral reinforcement for columns should be figured at an extra cost of about ½ ct. per pound over and above plain bars. In estimating the weight of spiral reinforcement it should be remembered that about 7 per cent should be added to the weight of the spirals for welding laps. Also, it will be necessary to add about 3 lb. per lin. ft. of column for spacers used to hold the spirals in proper pitch.

Forms for round columns are usually made from sheet metal and in flat slab construction it usually works out cheaper to use round interior columns formed with this material. However, the cost of forming an interior column 26 in. in diameter for flat slab construction is about the same as forming a column 20 in. in diameter designed for the same purpose. This being the case, it is not necessary to consider the difference in the cost of forms due to different diameters of round interior columns. It may be well to remember that it costs somewhat less to build an interior column having a head by using a steel form than it does to form the column of wood, as the cost of forming the head in wood is no small part of the column cost. The list of unit prices given here covers the cost of labor and material for form work for the principal operations in a concrete building, and are tabulated for use in making comparative estimates for weeding out the more expensive designs but not for making actual estimates of buildings without regard to conditions and what not. While these costs might be more or less useful in arriving at the total cost of a concrete building it should be remembered that they are only approximate units to be used for the purpose outlined.

Type of construction	Square feet cost (Surface measurement)
Forms for flat slabs, including drop panels	$ 0.09
Slab, beam and girder construction, slabs to span not less than 9 ft.	.12
Slab, beam and girder construction, slabs to span not less than 7 ft.	.13
Slab, beam and girder construction, slabs to span not less than 5 ft.	.14
Column forms	.15
Floor beams and girders, not including slabs	.16
Wall beams	.14
Partitions and wall forms	.15
Footing and foundation forms	.15
Round steel column forms, including heads, each	15.00

For making complete estimates, typical dimensioned sketch cross-sections of the building from the roof slab to the footings should be made and the work of estimating done from these sketches. In this way the extra column lengths required to obtain the same clear story heights will enter into the estimate. This is quite a factor in comparing flat slab with beam and girder designs. Estimates made from these cross-sections for a length of building equal to one bay only, is the usual practice. In this way the cost per lineal foot of building as well as the cost per square foot of floor space may be calculated. Comparisons of costs made in this manner are genuine proofs to the designer that he is giving the design proper study for economy, and will result in a conservation of building materials, save good dollars for the owner, and establish for the engineer the reputation of being a designer of economical concrete buildings.

Interior Columns.—A typical interior concrete column as used in certain types of flat slab construction is illustrated in Fig. 1. Several comparative designs have been made for this column using in each case standardized formulae and fibre stresses. The cost of the various schemes is worked out in detail in Table VI the unit prices fixed to the quantities of material and labor being taken, principally, from figures previously given.

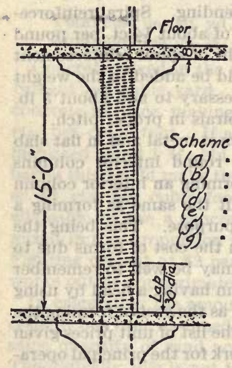

FIG. 1.—Typical interior column.

From the estimated comparative costs in Table VI perhaps the most noticeable fact is that the columns using the 1:2:4 mix of concrete are among the most expensive. Using this lean mix necessarily produces a column larger in diameter which means, also, a loss of valuable floor space. It will also be noticed that the smallest column designed is not the most economical. The column which shows the most economy in this case is one having a 1:1:2 mix and about 1 per cent of vertical reinforcement together with 1 per cent of spiral reinforcement. Hence, a rich mix of concrete and comparatively small percentages of steel reinforcement seem to show the most economicalre sults for a column carrying a fairly heavy load.

For comparative purposes, the difference in the amount of concrete in the column heads may be neglected as the top diameter of the head usually remains the same throughout the building. The cost of forming the column and its head has been estimated here at $15 each. This is done for convenience in arriving at a total cost of the column shaft Ordinarily this cost is neglected in making comparative estimates of interior columns, as it costs about the same to form a round column of small diameter as it does a column of larger diameter. Many other schemes may be designed for this particular column and the comparative costs estimated. However, the several examples, some of which are obviously too expensive to consider, will suffice to give the reader a working knowledge of the methods of calculation employed to determine the costs of the various types of interior columns. It is readily appreciated that even though a larger column were somewhat cheaper to build, the additional floor space occupied by this larger column might be worth more to the owner of the building than he would save in the construction of

TABLE VI.—COMPARATIVE ESTIMATES FOR SEVERAL DESIGNS OF INTERIOR CONCRETE COLUMNS

Design	Comparative Estimates		
Scheme (a):			
36-in. dia. column	Concrete	99 cu. ft. at 24 cts.	$ 33.66
11 1⅛-in. rd. vert. rods	Forms	Round steel	15.00
⅜-in. rd. hoops 12 in. o/c	Reinforcement	716 lb. at 5 cts.	35.80
Mix 1:2:4	Lost floor space	5 sq. ft. at $2.75	13.75
	Total		$ 98.21
Scheme (b):			
32-in. dia. column	Concrete	79 cu. ft. at 34 cts.	$ 26.86
23 1⅛-in. rd. vert. rods	Forms	Round steel	15.00
⅜-in. rd. hoops 12 in. o/c	Reinforcement	1,437 lb. at 5 cts.	71.85
Mix 1:2:4	Lost floor space	3 1/10 sq. ft. at $2.75	8.53
	Total		$122.24
Scheme (c):			
32-in. dia. column	Concrete	79 cu. ft. at 36½ cts.	$ 28.84
23 1⅛-in. rd. vert. rods	Forms	Round steel	15.00
⅜-in. rd. hoops 12 in. o/c	Reinforcement	770 lb. at 5 cts.	38.50
Mix 1:1½:3	Lost floor space	3 1/10 sq. ft. at $2.75	8.53
	Total		$ 90.87
Scheme (d):			
26-in. dia. column	Concrete	52 cu. ft. at 36½ cts.	$ 18.98
11 1-in. rd. vert. rods	Forms	Round steel	15.00
1 per cent spirals (18½ lb.) per lin. ft.	Reinforcement (vert.)	514 lb. at 5 cts.	25.70
Mix 1:1½:3	Spirals	264 lb. at 5½ cts.	14.52
	Lost floor space	7/10 sq. ft. at $2.75	1.92
	Total		$ 76.12

Table VI.—*Continued*

Design	Comparative Estimates		
Scheme (e): 28-in. dia. column; 20 1⅛-in. rd. vert. rods; ⅜-in. rd. hoops 12 in. o/c; Mix 1:1:2	Concrete	60½ cu. ft. at 43 cts.	$ 26.02
	Forms	Round steel	15.00
	Reinforcement	1,255 lb. at 5 cts.	62.75
	Lost floor space	1.45 sq. ft. at $2.75	3.99
	Total		$107.76
Scheme (f): 26-in. dia. column; 7 ⅞-in. rd. vert. rods; 1 per cent spirals (18½ lb.) per lin. ft.; Mix 1:1:2	Concrete	52 cu. ft. at 43 cts.	$ 22.36
	Forms	Round steel	15.00
	Reinforcement	245 lb. at 5 cts.	12.25
	Spirals	264 lb. at 5½ cts.	14.52
	Lost floor space	7/10 sq. ft. at $2.75	1.92
	Total		$ 66.05
Scheme (g): 24-in. dia. column; 10 1⅛-in. rd. vert. rods; 1 per cent spirals (16 lb.) per lin. ft; Mix 1:1:2	Concrete	44½ cu. ft. at 43 cts.	$ 19.14
	Forms	Round steel	15.00
	Reinforcement (vert.)	606 lb. at 5 cts.	30.30
	Spirals	229 lb. at 5½ cts.	12.60
	Total		$ 77.04

the column. Hence, it becomes necessary to consider the value of this additional floor space as a part of the cost of this larger column. It is difficult to say just what this floor space is really worth. However, a satisfactory way to deal with the situation is to consider the smallest column designed as a basis to which the other columns are to be compared. In the illustration this column is 24 in. in diameter. Consider the area of floor space occupied by a column equal to the square of the diameter of the column. The additional area occupied by any one of these larger columns is equal to the difference between the square of the diameter of the column in question and the square of the diameter of the smallest column designed. This additional or lost floor area is priced at a unit cost equal to the approximate unit cost per square foot of floor space of the completed building, including heating, lighting, sprinklers, etc. The unit cost per sq. ft. of building is calculated by dividing the approximate total cost of the building by the number of sq. ft. of floor space in the building, measurements to be taken "out to out" of the floor plan. For

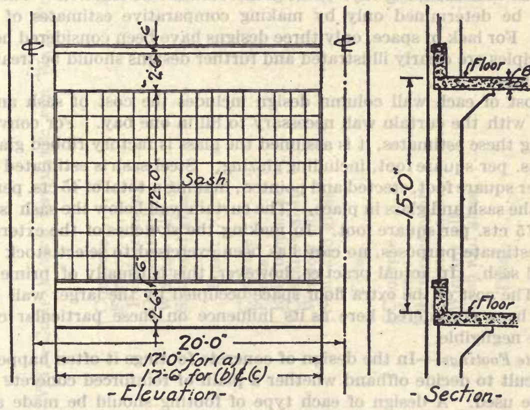

FIG. 2.—Typical wall column.

example, a building 200 ft. × 60 ft. and five stories high may cost $165,000 complete. This works out at $2.75 per square foot and for general purposes this will give fairly accurate results for the purpose described above.

In the comparative estimates of the interior column given, if we strike out of each estimate the cost of lost floor space, the relative cost of each column will remain unchanged. This is not always the case, and even in our examples it will be noticed that the columns having the leaner mixes show up much more favorably when this item of cost is excluded from the total cost of the column. Frequently, the omission of this item will result in a transposition of the economic order of the various designs. In many buildings the loss of a few feet of floor space is immaterial, but in other cases it is of great importance, as in shorehouses or in buildings where the machinery layout would be interfered with by a larger column. Where loft buildings or offices are rented by the square foot of net area the cost of this floor space should be figured at a considerably higher figure than the one given in our tables.

Wall Columns.—In determining the economical wall column, the method is very similar to that used for interior columns except that the item of the cost of wood forms enters into the estimate. It will be necessary also in designing exterior columns to consider the width carefully, as every inch added or deducted will change the corresponding dimension of wall sash a like amount.

Fig. 2 shows a typical exterior wall column for a concrete building having these columns spaced 20 ft. apart. Three designs of this column have been compared, and the respective estimates are shown worked out in detail in Table VII in an effort to determine which one of the three designs would be the most economical to use. Three different mixes of concrete have been used and again, as in the case of the interior column, the column designed to use a 1:1:2 mix concrete appears to be the least expensive to build. Generally speaking, with the present high price of reinforcement, cement is the cheapest reinforcement for a concrete column. Nevertheless, it must not be concluded that a rich mix should always be used in column construction. The proper mix can be determined only by making comparative estimates of several designs. For lack of space, only three designs have been considered here, but the principles are clearly illustrated and further designs should be treated in a like manner.

The cost of each wall column design includes the cost of sash and glass together with the curtain wall necessary to fill in one bay. For convenience in making these estimates, it is assumed the glass is factory ribbed glass costing 20 cts. per square foot, including glazing. Steel sash is estimated here at 25 cts. per square foot, erected and pointed, making a total of 45 cts. per square foot for the sash and glass in place. The curtain wall below the sash is figured here at 75 cts. per square foot. In making the sketches of the exterior wall bay for estimate purposes, no care has been exercised to select stock sizes of steel wall sash. In actual practice, however, this is usually of prime importance. The cost of the extra floor space occupied by the larger wall column has not been considered here as its influence on these particular columns would be negligible.

Concrete Footings.—In the design of concrete footings it often happens that it is difficult to decide offhand whether a plain or reinforced concrete footing should be used. A design of each type of footing should be made and the comparative costs calculated. The engineer knowing the kind of soil these footings will rest upon should price the excavation required at a proper figure. This is a very important part of the footing cost, in fact, many times the most vital part of the estimate for foundation work. In the absence of any more reliable information the unit costs of excavation per cubic yard (not over 5 ft. deep), may be assumed as follows:

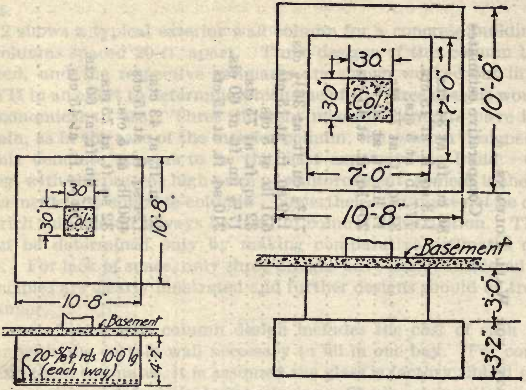
Loam or other easy excavation	$0.75 cu. yd.
Gravelly earth containing small stones	$1.00–$1.50 cu. yd.
Frozen earth	2.25– 2.50 cu. yd.
Rock or ledge excavation	3.50– 4.00 cu. yd.
Backfill	.30– .50 cu. yd.
Sheeting around excavated holes for footings	.10 sq. ft.

For excavation work over 5 ft. deep and down to 10 ft. deep, the unit cost on the yardage below the 5-ft. depth should be increased approximately 50 per cent. The unit price of excavating to a depth exceeding 10 ft. is based on the number of times the excavated material must be rehandled before it is finally deposited where it may be teamed away or disposed of in some other

Table VII.—Comparative Estimates for Wall Columns

Design	Comparative estimates		
Scheme (a):			
36 × 24 in.	Concrete	86 cu. ft. at 34 cts.	$ 29.24
12 1/8-in. rd. rods 17 ft. 6 in.	Forms	143 sq. ft. at 15 cts.	21.45
3/8-in. rd. hoops 12 in. o/c	Reinforcement	777 lb. at 5 cts.	38.85
Mix 1:2:4	Curtain walls	31 sq. ft. at 75 cts.	23.25
	Window sill	17 lin. ft. at 60 cts.	10.20
	Sash and glass	204 sq. ft. at 45 cts.	91.80
	Total		$214.79
Scheme (b):			
30 × 24 in.	Concrete	71 2/3 cu. ft. at 36 1/2 cts.	$ 26.16
10 1 1/8-in. rd. rods 17 ft. 10 in.	Forms	129 sq. ft. at 15 cts.	19.35
3/8-in. hoops 12 in. o/c	Reinforcement	651 lb. at 5 cts.	32.55
Mix 1:1 1/2:3	Curtain walls	32 sq. ft. at 75 cts.	24.00
	Window sill	17 1/2 lin. ft. at 60 cts.	10.50
	Sash and glass	210 sq. ft. at 45 cts.	94.50
	Total		$207.06
Scheme (c):			
30 × 22 in.	Concrete	66 cu. ft. at 43 cts.	$ 28.38
12 7/8-in. rd. rods 17 ft. 2 in.	Forms	124 sq. ft. at 15 cts.	18.60
3/8-in. rd. hoops 12 in. o/c	Reinforcement	460 lb. at 5 cts.	23.00
Mix 1:1:2	Curtain walls	32 sq. ft. at 75 cts.	24.00
	Window sill	17 1/2 lin. ft. at 60 cts.	10.50
	Sash and glass	210 sq. ft. at 45 cts.	94.50
	Total		$198.98

manner. An example is given in Table VIII here with comparative costs for the two types of footings, reinforced and plain, shown in Fig. 3, schemes a and b respectively. The excavation is assumed as costing \$1 per cubic yard to remove, and the excavated holes are sheeted close in order to do away with form work around the large footing block.



(Scheme a) (Scheme b).

Fig. 3.—Typical concrete footings.

Table VIII.—Comparative Estimates for Footings

Scheme (a), reinforced type (mix 1:2:4):		
Concrete 1:2:4	460 cu. ft. at 34 cts	\$156.40
Forms (none)		
Reinforcement	420 lb. at 5 cts	21.00
Excavation	19¼ cu. yd. at \$1	19.25
Backfill and level	19¼ cu. yd. at 30 cts	5.78
3-in. (close) sheeting	182 sq. ft. at 10 cts	18.20
Total		\$220.63
Scheme (b), plain type (mix 1:2½:5):		
Concrete 1:2½:5	507 cu. ft. at 32 cts	\$162.24
Forms (top block)	84 sq. ft. at 15 cts	12.60
Excavation	24 cu. yd. at \$1	24.00
Excavation below 5-ft. mark	5½ cu. yd. at \$1.50	8.25
Backfill and level	29½ cu. yd. at 30 cts	8.85
3-in. (close) sheeting	270 sq. ft. at 10 cts	27.00
Total		\$242.94

The estimates in Table III indicate that the reinforced footing is the most economical to use in this case. However, provided stones or "plums" were obtainable at a small expense, the cost of the plain footing could be considerably reduced. It will be noted in the estimates for these two footings that the excavation for the plain footing is the determining factor in its cost. The materials used in the plain footing cost somewhat less than those used in the reinforced type, but the extra depth of the excavation makes the plain type the more expensive one to use. This extra cost becomes still greater when the footings are placed in wet or frozen ground, for which excavation costs are considerably more. In case the reinforced type of footing is built with a sloping top, and a wood form is used for this top, the cost would be about the same as though the concrete were placed up to a level with the top of the footing, and the form work omitted, as above estimated. In some operations the top part of a footing is sloped and the concrete placed "dry." This necessitates a change in the batch, slows up operations and many times does not work out economically. For estimating comparative costs of footings it is not a safe procedure to assume that the top part of the footing will be placed "dry" in order to do away with forms on the slope. Either estimate a form for this sloping surface or figure on the concrete as being placed up to a level with the top of the footing.

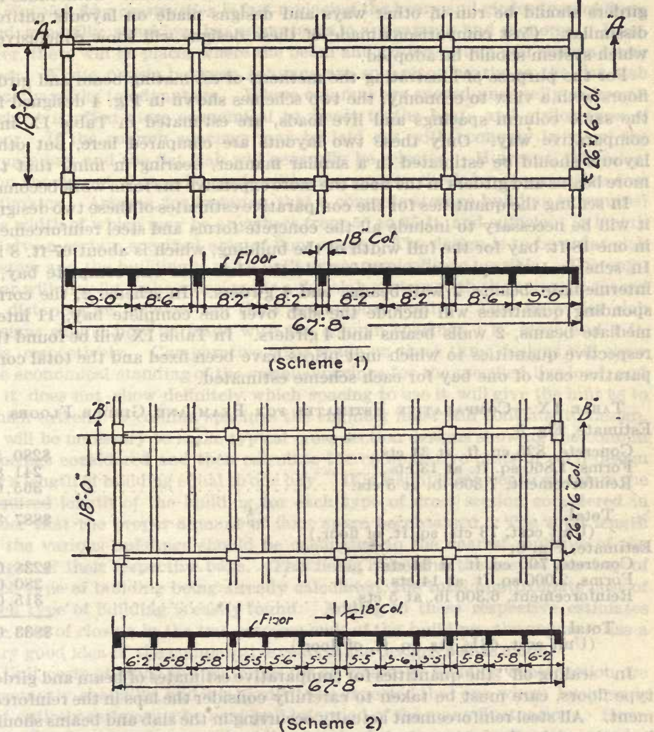


FIG. 4.—Typical beam and girder floors.

Concrete Floor.—In the design of the beam and girder type floor, the omission or addition of one intermediate beam per bay may influence the cost materially. Although this problem is usually handled economically by engineers designing concrete buildings which have usual floor loadings and column spacings, it sometimes happens that when unusual floor loadings and column spacings are required, it is necessary for the engineer to determine a layout which will show the most economy. In a proposition of this kind it is first necessary to make the design which looks most likely to be the economical one. Then, two more designs should be made, one having one more intermediate beam and the other having one less intermediate beam. Sometimes the girders should be run in other ways and designs made on layouts entirely dissimilar. Cost comparisons made of these designs will show conclusively which system should be adopted.

For the purpose of illustrating the methods of estimating beam and girder floors with a view to economy, the two schemes shown in Fig. 4 designed for the same column spacings and live loads, are estimated in Table IX in a comparative way. Only these two layouts are compared here, but other layouts should be estimated in a similar manner, bearing in mind that the more beams and girders in the floor the more expensive the form work becomes.

In scaling the quantities for the comparative estimates of these two designs, it will be necessary to include all the concrete forms and steel reinforcement in one 18-ft. bay for the full width of the building, which is about 67 ft. 8 in. In scheme 1 the quantities will include the slab over one complete bay, 7 intermediate beams, 2 wall beams, and 4 girders. In scheme 2, the corresponding quantities will include the slab over one complete bay, 11 intermediate beams, 2 walls beams and 4 girders. In Table IX will be found the respective quantities to which unit prices have been fixed and the total comparative cost of one bay for each scheme estimated.

Table IX.—Comparative Estimates for Beam and Girder Floors

Estimate, Fig. 5:	
Concrete, 825 cu. ft. at 34 cts.	$280.50
Forms, 1,860 sq. ft. at 13 cts.	241.80
Reinforcement, 7,300 lb. at 5 cts.	365.00
Total	$887.30
(Unit cost, 73 cts. sq. ft. of floor.)	
Estimate, Fig. 6:	
Concrete, 700 cu. ft. at 34 cts.	$238.00
Forms, 2,000 sq. ft. at 14 cts.	280.00
Reinforcement, 6,300 lb. at 5 cts.	315.00
Total	$833.00
(Unit cost, 68½ cts. sq. ft. of floor.)	

In "scaling off" the quantities for comparative estimates of beam and girder type floors, care must be taken to carefully consider the laps in the reinforcement. All steel reinforcement actually occurring in the slab and beams should be estimated. In taking off the quantities, also, it will be found most convenient to first get the quantity of concrete, then the square feet of forms and lastly the pounds of reinforcement. The order of scaling for the form work and reinforcement should be the same as that followed in getting the quantity of concrete; that is, if beams follow slabs in the concrete scaling, beam steel should follow slab steel in the reinforcement scaling. This method will eliminate to a large extent the liability of error, and also lessen the work of scaling dimensions since the form areas may be taken directly from the scaled dimensions of the concrete work.

The slight changes in column and footing design which might actually occur in two buildings designed with floors like those above estimated, have not been considered here. However, in buildings several stories in height this phase of the design should be carefully considered in conjunction with the cost of floor designs when the cost comparisons are made. Even though the spacing of columns remains the same for all schemes considered, the different dead loads may influence the cost of the columns and footings considerably and the different girder depths may make it possible to vary the overall height of the columns in order to get the same clear head room.

Flat slab floor construction is fast replacing the beam and girder type of floor, and generally speaking, has advantages in appearance and economy. However, there will be places where the beam and girder system will show a lower cost. Where panels between columns are square or nearly so the flat slab usually works to advantage. Where columns are spaced unequally or irregularly it is often more economical to resort to the beam and girder type of floor. If the column spacings may be laid out with economy in view, the square bay and the flat slab will generally be selected. However, this selection should not always be made without a proper check by comparative cost estimates. Assume, for instance, that a concrete storage building is required the width of which may be anywhere from 55 to 65 ft. and sufficient in length to give a certain specified area of floor space. The design is to be a flat slab system and the building is to be built as economically as possible. The engineer will usually make a design for a flat slab system with the columns spaced at distances he believes will show economical results. Two more flat slab designs should now be made with the column spacings 1 ft. more and 1 ft. less, respectively. Comparative costs made on these three designs will show the economical standing of the various spacings for the specified live load, and if it does not show definitely which spacing to use it will give the hint as to which extreme of column spacings the engineer must still continue to design. It will be necessary to make typical cross-section designs showing the column spacings considered and then calculate the comparative costs of each design for a length of building equal to one bay. It is a simple matter to calculate the required length of the building for each type of cross section considered in order that the proper amount of floor space be obtained. The total length of the various buildings should be calculated to the nearest multiple of the length of their respective bays. This being done and the cost of one bay of each type of building being already calculated, the total approximate cost of each type of building is easily found. Adding to these respective estimates the cost of closing in the two extreme ends of the building, the engineer has a very good idea of the comparative costs of the designs he has made.

Unit costs of labor and materials for all classes of building construction are constantly changing, and it is hardly to be expected that one whose business is not entirely estimating be kept well informed of the many fluctuations. However, the designer does not have to use absolute accurate unit costs in order to determine by comparative estimates, the relative economic standing of his designs. A review of the market conditions from time to time in a general way will give him enough information to revise his unit costs in order that his comparisons may show more accurately the true status of his work. The prices tabulated and used throughout this paper, as before mentioned, are much higher than the prices of two or three years ago. It is quite possible that two years hence they may undergo another change equally great, and the engineer must look out for this and act accordingly. Five years ago the ratio of cost of concrete, forms and steel in a building was roughly 2:2:1. Today it is about 2:1:1—that is to say, five years ago the total cost of the concrete about equaled the cost of the forms, and the reinforcement equaled about one-half of the cost of either. Today, the cost of the concrete in a building is slightly less than twice the cost of the forms, and the cost of the reinforcement is about equal to the form cost. It is quite probable that five years from now the ratio may be again changed.

Items Making up Cost of Concrete Building.—C. E. Patch gives the following data in Engineering and Contracting, July 28, 1920.

	Percentage referred to Structural cost of building	Percentage referred to Total cost including sub-contracts
Concrete	24.0	19.2
Reinforcing	16.0	12.76
Forms	14.6	11.8
Engineering	5.5	4.50
Cold weather	5.2	4.25
Doors and windows	5.2	4.15
Plant	4.6	3.85
Miscellaneous and extras	4.5	3.6
Excavation	3.7	3.05
Carpentry	3.7	3.05
Masonry	2.5	2.08
Fire main and roof drains	2.3	1.95
Miscellaneous iron and steel	2.2	1.85
Overhead	1.56	1.28
Superintendence, travel, etc	1.50	1.23
Roofing and flashing	1.36	1.12
Liability insurance	0.62	0.51
Watchman	0.54	0.45
Clean up job	0.42	0.35
Heating and sprinklers	59.7*	11.20
Plumbing	15.3*	2.93
Elevators	14.6*	2.86
Electrical work	10.4*	1.98

* Of total cost of equipment sub-contracts.

Cost of Reinforced Concrete Power House.—John W. Ash in Engineering Record, Jan. 25, 1913, gives the following cost of constructing a power house in connection with the waterworks plant at Dalton, Ga. The floor area of the power-house, including the filter, covers about 4,650 sq. ft.; the walls average a little over 20 ft. in height, 6 and 8 in. thick, with columns averaging about 11 ft. on centers. A beam 12 in. square runs around on top of all walls. The concrete mixture was 1 : 2½ : 5.

TABLE X.—POWER-HOUSE COSTS

	Labor	Material	Total
Excavation, 437 cu. yd	$253.80	....	$ 253.80
Forms	677.80	$ 182.50	860.30
Concrete, 315 cu. yd	417.20	1,176.60	1,593.80
Steel, 15,500 lb	93.90	316.90	410.80
Roof trusses	21.30	292.50	313.80
Lumber, floors and roof, 19,020 ft. B.M.	104.60	387.00	491.60
Wood doors and windows	87.20	178.85	266.05
Fire-doors, 302 sq. ft	29.50	201.00	230.50
Composition roof, 5,000 sq. ft	30.00	150.00	180.00
Pipe connections	25.00	....	25.00
Concrete floor, 2,340 sq. ft	65.10	145.50	210.60
Reinforced concrete floor, 80 sq. ft	6.50	14.50	21.00
Handling and placing outfit	88.90	....	88.90
Coal, oil, waste, etc	....	42.50	42.50
Depreciation, repairs	....	....	78.50
Ventilators and granite slab	7.50	109.60	117.10
Grand total			$5,184.25

Cement cost $1.35 per barrel; sand $1.05 per ton; stone $1.43 per ton. Labor was $1.35 and $1.50 per day; carpenters $2.25 to $3.50 per day. The labor item in the above table includes foremen and superintendence.

Cost of Constructing a Reinforced Concrete Storehouse.—Civil Engineer, E. R. Gayles, U. S. N., in Public Works of the Navy, June, 1916, and in Engineering and Contracting, Aug. 23, 1916, gives the following:

The structure was built by contract and consists of a six-story main building 100 × 250 ft. and of a one-story crane runway annex 50 × 250 ft. The construction is reinforced concrete except the exterior brick curtain walls of the main building and the roof of the annex which is steel frame with ferroinclave roofing.

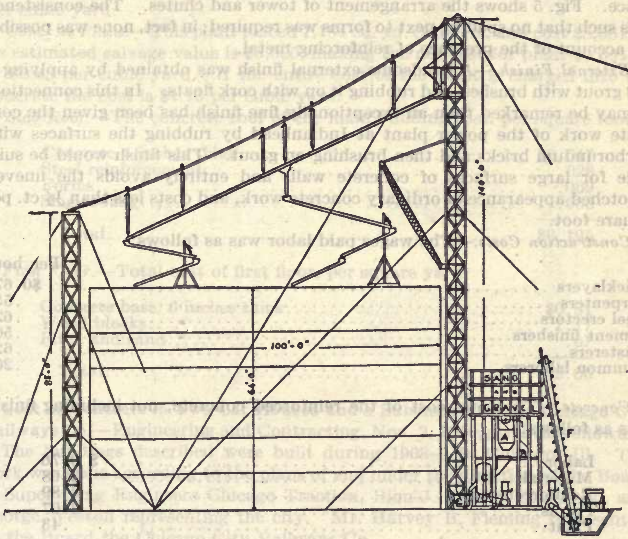

Fig. 5.—Concreting plant for storehouse.

Structural Features.—The building has pile foundations designed for a loading of 20 tons per pile, penetrating through partly consolidated filling and alluvial deposits to a fairly flat layer of gravel and sand at a depth of about 43 ft. below cut-off. The piles were driven by drop hammers weighing 2,500 lb. and the slow rate of progress, averaging only 11.4 piles per driver per day, gave a striking illustration of the inefficiency of this antiquated method of driving.

The concrete piers were 1:3:6 gravel concrete, chuted into place, the pile heads being embedded 6 in. in the concrete.

The columns were designed for the total dead load plus 75 per cent of the live load. The columns are square, 3 × 3 ft. with eight 1⅝-in. diameter round rods in the first story, diminishing uniformly at each story to 12 × 12 in. with four ¾-in. diameter round rods in the sixth story. At the first story the longitudinal reinforcement is 1.5 per cent of the effective area, and at the sixth story 2.2 per cent. One-fourth inch diameter round hoops were used spaced 12 in. apart; the percentage of hooping is as a result very small, and the columns were therefore designed as with longitudinal reinforcement only.

The floors with the exception of the first, which rests on ground, consist of slabs and T beams and were designed for loads varying from 400 lbs. per sq. ft. on the second floor to 150 lbs. per sq. ft. on the sixth floor.

Forms.—The forms were made of tongued-and-grooved pine; new lumber was provided for forms for three stories, and the same forms were altered and repaired for the upper two stories and roof.

Handling Concrete.—The concrete was hoisted by tower and chuted into place. Fig. 5 shows the arrangement of tower and chutes. The consistency was such that no spading next to forms was required; in fact, none was possible on account of the presence of reinforcing metal.

External Finish.—A handsome external finish was obtained by applying a 1:2 grout with brushes, and rubbing it on with cork floats. In this connection, it may be remarked than an exceptionally fine finish has been given the concrete work of the power plant at Indianhead by rubbing the surfaces with carborundum bricks and then brushing on grout. This finish would be suitable for large surfaces of concrete walls and entirely avoids the uneven splotched appearance of ordinary concrete work, and costs less than ½ ct. per square foot.

Construction Costs.—The wages paid labor was as follows:

	Per hour
Bricklayers	$0.67
Carpenters	.55
Steel erectors	.62
Cement finishers	.50
Plasterers	.62
Common laborers	.20

Concrete.—The total cost of the reinforced concrete, not including finish, was as follows:

Labor	$ 0.76
Materials	3.08
Reinforcement	3.89
Forms	3.07
Plant	.43
Total	$11.23

The cost of 1:3:6 foundation concrete was as follows:

Labor	$0.78
Materials	2.65
Reinforcement	.60
Forms	.20
Plant	.43
Total	$4.66

Materials were received in bottom dump wagons. Labor cost includes dumping materials into receiving hopper, handling by bucket conveyor to bins, mixing, hoisting into tower, chuting, distributing and working into place, setting anchor bolts and column dowels.

The concrete of the first floor was handled by industrial track and tip cars;

including placing track, etc., 2,670 sq. yd. cost $0.81 per square yard for labor and material for 6-in. floor without cement finish.

Reinforcing steel for 5,264 cu. yd. reinforced concrete weighed 1,170,000 lb., corresponding to an average throughout the building of 8.2 lb. reinforcement per cubic foot of concrete, or 1.7 per cent, and cost $3.89 per cubic yard of concrete, at the rate of $0.475 per pound in place.

Forms were generally used twice. Forms per 5,264 cu. yd. reinforced concrete cost $17,200, or $3.07 per cu. yd. There were 247,500 sq. ft. of forms used in the entire building, costing $0.024 per square foot for labor and $0.045 per square foot for materials, total $0.069 per square foot of forms in contact with concrete. Cement cost $1.10 per barrel net; sand $0.98, and gravel $1.20, per cubic yard.

Concrete Plant.—This plant placed 7,184 cu. yd. concrete, and cost $8,061.92 its estimated salvage value is $5,000, making the net cost for plant $3,061.92 or $0.43 per cubic yard. If the entire cost of the plant is charged into the concrete the cost is $1.13 per cubic yard.

Slab Roof.—The concrete roof of the main building cost, per square foot:

Concrete 4 inches thick	$0.047
Steel reinforcement	.026
Forms	.069
Slag roofing	.053
Total	$0.195

First Floor.—Total cost of first floor, per square yard:

Concrete base, 6 inches thick	$0.81
Wood blocks	1.17
Pitch and sand	.07
Total	$2.05

Cost of Concrete in Two Car Houses and a Substation for the Chicago City Railways Co.—Engineering and Contracting, Nov. 2, 1910, gives the following:

The buildings described were built during 1908–9 in Chicago, Ill. The work was done according to the plans of and under the direction of the Board of Supervising Engineers Chicago Traction, Bion J. Arnold, Chairman, and George Weston representing the city. Mr. Harvey B. Fleming represented on the Board the Chicago City Railways Co.

The general plans of the Board of Supervising Engineers call for double ended car houses divided into longitudinal bays by fireproof partitions. The exterior walls are of brick. The columns and walls have concrete footings and the floors are of concrete. The pits are open and have concrete walls and floors. Between pits the floors are reinforced concrete and the roof is reinforced concrete slab and girder construction with skylights along the center of each bay nearly the whole length.

Sixty-Ninth St. and Ashland Avenue House.—This car house was built during 1908. It is 485 × 265¼ ft., divided into six car storage bays and one repair bay by six longitudinal partitions. Each bay has three tracks with a pit under each track. In the storage bays the pits are all 288 ft. long and in the repair bay they are 176 ft. long. The roof construction is shown in detail by Fig. 6. The concrete work comprised foundation footings and walls, floors, pits, wells and floor and roof slabs and girders. The cost of the concrete work was as follows:

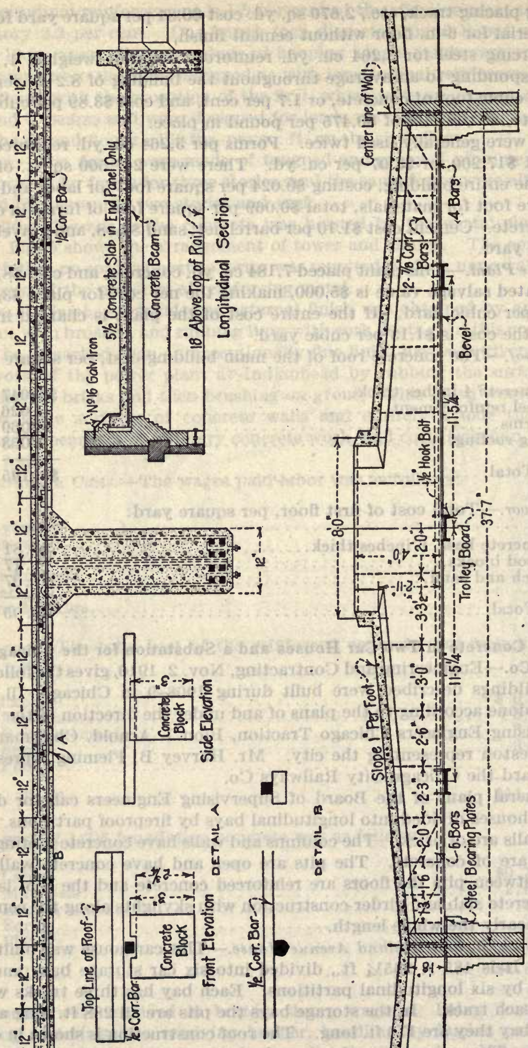

FIG. 6.—Reinforced concrete car barn roof.

For 1,776 ft. of 1:3:6 plain concrete in footings and foundation walls the cost including forms was $11,181 or $6.30 per cu. yd. The cost of 380 cu. yds. of 1:3:6 concrete in pit walls, including form work, was $3,026, or $7.96 per cu. yd. The pit floors, containing 1,287 cu. yds,. cost $9,515 or $7.40 per cu. yd. The cost of pit floors per square foot was 13.6 cts. There were also 12,200 sq. ft. of cement walk and 1,186 ft. of curb. The walks were 4½ ins. thick, of 1:2½:5 concrete, with a ¾-in. top coat of cement and granite screenings; the cost was as follows:

Item	Per sq. ft.
Materials	$0.056
Labor	0.123
Total	$0.179

The curbing was 2 ft. deep by 6 in. thick and the cost of 1,186 lin. ft. or 43.9 cu. yds. was:

Item	Per lin. ft.	Per cu. ft.
Material	$0.127	$ 3.44
Labor	0.390	10.54
Total	$0.517	$13.98

The cost of 89,935 sq. ft. of roof, including 168 girders, of the construction shown by Fig. 6 can be given in more detail. There were in this roof 2,365 cu. yds. of 1:2½:5 concrete. The cost of concrete materials and labor concreting was as follows:

Item	Per cu. yd.
5,075 bbls. cement at $1.21	$1.57
1,675 cu. yds. sand at $1.60	1.14
1,635 cu. yds. stone at $1.40	0.96
Labor concreting	3.06
Total	$6.73

The cost of reinforcing rods and labor placing was as follows:

Item	Per cu. yd.
329,900 ft. ½-in. bar at 1.62 cts	$2.22
14,629 ft. ½-in. stirrup at 1.84 cts	0.12
153,605 ft. ⅞-in. stirrup at 1.75 cts	1.14
Labor on reinforcements	1.18
Total	$4.66

The cost of incidentals and labor for forms was as follows:

Item	Per cu. yd.
91 M. ft. B. M. hemlock at $18	$0.69
149 M. ft. B. M. pine at $20	1.26
Spikes, bolts and wire	0.21
Labor on forms	5.34
Total	$7.50

Summarizing the above figures and extending them to include cost per square foot we have the following:

Item	Per cu. yd.	Per sq. ft.
Concrete	$ 6.73	$0.177
Reinforcement	4.66	0.123
Forms	7.50	0.197
Total	$18.89	$0.497

Archer Ave. and Rockwell St. House.—The dimensions of this house are 309 × 490 ft. and it is divided into seven bays by longitudinal fireproof walls. The concrete construction comprises foundation walls, pits and roof of the design shown by Fig. 6.

The foundation walls of 1:3:7 concrete cost for 1,953 cu. yds. as follows:

Concrete	Per cu. yd.
1,894.41 bbls. cement at $1.22	$1.183
839.79 cu. yds. sand at $1.43	0.614
1,972.53 cu. yds. stone at $1.54	1.555
Labor, mixing and placing	1.471
Total concrete	$4.823
Forms	
Lumber	$0.321
2 rolls No. 10 wire at $2.23	......
2,000 18-in. form clamps at 4¾ cts	......
500 26-in. form clamps at 5¾ cts	......
125 25-in. form clamps at 5½ cts	0.134
500 keys for form clamps at 3 cts	......
48 kegs of nails at $2.36	......
Labor building and removing	1.321
Total forms	$1.776
Supplies	
7.65 tons coal at $4.15	......
5 gals. cyl. oil at 48 cts	......
10 gals. eng. oil at 23 cts	......
10 lbs. lubricant at 12 cts	......
Total supplies	$0.019
Grand total	$6.618

The pit tracks are supported by cast iron columns on each side and these columns have concrete footings. The cost of these footings which are of the usual stepped pedestal type was as follows:

Item	Per cu. yd.
270 bbls. cement at $1.22	$1.355
118 cu. yds. sand at $1.40	0.694
241 cu. yds. stone at $1.54	1.525
Labor mixing and placing	1.867
Coal and oil	0.007
Total	$5.448

The following was the cost of 211 cu. yds. of concrete in the side and end walls of the pits:

Concrete	Per cu. yd.
235 bbls. cement at $1.22	$1.35
105 cu. yds. sand at $1.43	0.72
209 cu. yds. stone at $1.54	1.52
Labor mixing and placing	1.02
Total	$4.61
Forms	
16 kegs nails at $2.40	$0.18
½ roll wire	0.05
Lumber	0.51
Labor erecting	3.06
Labor removing	0.57
Total	$4.37
Grand total	$8.98

The floor work of the building comprised the floors between tracks for the end sections of each bay not occupied by the pits; the floors for store room, shops and other service rooms; the pit floors and the reinforced concrete floors between pits. All these floors except the reinforced concrete floors between pits are the usual concrete basement floor construction:

End floors (63,630 sq. ft.)	Per sq. ft.
1,684 bbls. cement at $1.22	$0.03
744 cu. yds. sand at $1.43	0.01
1,190 cu. yds. stone at $1.54	0.02
Labor	0.06
8.45 tons coal at $4.15	0.0005
32 tons coke at $5.25	0.02
38 loads manure at $2	0.001
Oil	0.00006
Total	$0.14156

Service floors (11,921 sq. ft.)	Per sq. ft.
239 bbls. cement at $1.22	$0.025
105 cu. yds. sand at $1.43	0.015
155 cu. yds. stone at $1.54	0.015
Labor	0.095
1,380 cu. yds. cinders at 30 cts	0.032
1 ton coal at $4.15 and oil	0.0003
Total	$0.1823

Excluding the cost of cinders we have a cost of 11.33 cts. per sq. ft.

Office floors (8,793 sq. ft.)	Per sq. ft.
120 bbls. cement at $1.22	$0.016
53 cu. yds. sand at $1.43	0.008
107 cu. yds. stone at $1.54	0.018
Labor	0.095
1,010 cu. yds. cinders at 30 cts	0.035
Coal and oil	0.0004
Total	$0.1724

Excluding the charge for cinders we have a cost of 10.58 cts. per sq. ft.

Pit floors (58,559 sq. ft)	Per sq. ft.
1,377 bbls. cement at $1.22	$0.028
609 cu. yds. sand at $1.43	0.014
940 cu. yds. stone at $1.54	0.024
Labor	0.069
6.675 tons coal at $4.15	....
28 tons coke at $5.25	0.002
43 loads manure at $2	0.001
56 gals. gasoline at 12½ cts	....
Oil	....
Total	$0.1422

Reinforced concrete floors (37,048 sq. ft.)	Per sq. ft.
1,126 bbls cement at $1.22	$0.037
497 cu. yds. sand at $1.43	0.019
822 cu. yds. stone at $1.54	0.034
37,048 sq. ft. wire netting at 17 cts	0.017
Labor on concrete	0.061
Form lumber	0.007
Labor erecting forms	0.061
Labor removing forms	0.010
7.05 tons coal at $4.15	0.001
18.05 tons coke at $5.25	0.002
23 loads manure at $2	0.001
Oil	0.0001
Total	$0.2501

The roof construction, as previously stated, was substantially that shown by Fig. 1. The cost of 121, 881 sq. ft. or 2,869 sq. yds. was as follows:

Item	Per cu. yd.
Concrete materials	$ 4.11
Labor on concrete	3.58
Small concrete blocks	0.02
Total concrete	$ 7.71
Form lumber ($9,531.04–$3.321.25 salvage)	$ 2.16
Butts, washers and nails	0.15
Labor erecting forms	6.69
Labor removing forms	1.64
Labor moving forms to storage	0.21
Total forms	$10.85
Reinforcement	$ 2.74
Wire	$ 0.01
4 kegs round rods	0.004
Labor on reinforcement	1.37
Total reinforcement	$ 4.13
Coal	$ 0.02
Cylinder oil	0.001
Engine oil	0.001
Imperial lubricant	0.001
Tar paper	0.01
Manure	0.008
Total supplies	$ 0.05
Grand total	$22.74

This gives a cost per square foot of roof of 53.7 cts. Neglecting the salvage in lumber the cost is 56.42 cts. per sq. ft.

Substation.—The substation was built during the fall and winter of 1908–9. The building is of dark pressed brick so designed as to be an ornament to the neighborhood in which it is located. The construction is fireproof throughout, with tile roof carried on structural steel trusses.

The building is 60 ft. wide by 120 ft. 7 ins. long over all, and the operating room has a clear height of 32 ft. to the under side of the steel roof trusses.

The concrete work comprises footings for walls and piers, building walls, rotary converter walls, basement floor and drives, station floors, partition walls and battery shelves. The costs of these various items of work were as follows:

Wall and Pier Footings	Per cu. yd.
234 bbls. cement at $1.21	$ 1.32
110 cu. yds. sand at $1.60	0.82
197 cu. yds. stone at $1.55	1.42
Labor placing concrete	3.01
Total concrete	$ 6.57
Form lumber	$ 0.28
Labor on forms	0.25
Total forms	$ 0.53
Grand total	$ 7.10

Building Walls	Per cu. yd.
272 bbls. cement at $1.21	$ 1.45
116 cu. yds. sand at $1.60	0.83
187 cu. yds. crushed stone at $1.55	1.28
Labor on concrete	2.08
Total concrete	$ 5.64
Lumber for forms	$ 1.48
Nails, etc	0.18
Carpenter work on forms	2.04
Removing forms	0.63
Total forms	$ 4.33
Miscellaneous labor	$ 0.24
Grand total	$10.21

Basement Floor and Drive	Per sq. ft.
353 bbls. cement at $1.21	$ 0.08
146 cu. yds. sand at $1.60	0.04
91 cu. yds. stone at $1.55	0.03
Labor placing concrete	0.21
Labor finishing floor	0.05
Total concrete	$ 0.04
170 cu. yds. cinders at 25 cts	$ 0.008
Manure	0.0019
Miscellaneous materials	0.012
Carpenter labor	0.029
Labor placing cinders, etc	0.11
Total	$ 0.165
Grand total	$ 0.576

Station Floor	Per sq. ft.
286 bbls. cement at $1.21	$ 0.079
121½ cu. yds. sand at $1.60	0.045
108 cu. yds. stone at $1.55	0.038
Labor placing concrete	0.160
Patching floor	0.008
Total concrete	$ 0.33
Lumber for forms	$ 0.045
Beam clips	0.007
Bolts	0.010
Miscellaneous	0.010
Labor building forms	0.460
Labor erecting forms	0.063
Labor cleaning forms	0.026
Labor removing forms	0.065
Total forms	$ 0.686
Grand total	$ 1.016

The cost of water-proofing 1,040 sq. yds. of foundation walls, footings and floors was as follows:

Item	Total	Per sq. yd.
177 rolls felt at $1.30	$ 230.10	$ 0.221
39 bbls. tar at $3.80	128.70	0.123
Mops, etc	16.87	0.016
Labor	359.90	0.346
Total	$ 735.57	$ 0.706

None of the above costs include engineering, superintendence or overhead charges.

Labor rates were the union wage for 1908, which ran about as follows per hour: Enginemen, 70 cts.; carpenters, 60 cts.; finishers, 56¼ cts., and common labor, 37½ cts.

Perhaps the most interesting of the various costs given are those of roof work. The character of this work is indicated clearly by the drawings of Fig. 6. In one case the unit cost was $18.89 per cu. yd. and in the other case $22.74 per cu. yd., and of the total cost about 70 per cent and 50 per cent, respectively, and chargeable to form work.

Labor Cost of Placing Concrete with Tower and Chutes.—W. D. Jones in Engineering and Contracting, Dec. 27, 1916, gives the following:

The work consisted in building a six story and basement warehouse for the Harbor Commission of Los Angeles. The structure was 152 ft. wide and 484 ft. long. The basement was 7 ft. 9 in. high, first story, 14 ft. 6 in. high and upper stories 10 ft. high. All materials were furnished by the city f. o. b. cars at building site, and contractor was required to unload, sort and shelter these in a building provided by the city and be responsible for their incorporation in the structure in good condition.

In the call for bids the approximate quantities were given as follows. Opposite each of these approximate quantities is set the unit price bid for the performance of this work.

27,000 cu. yds. of concrete in place	$ 3.25 cu. yd.
1,290 tons of reinforcing steel in place	12.05 tn.
75 tons of structural steel in place	11.20 tn.
475,000 sq. ft. floor finish	0.01⅞ sq. ft.
Excavating, grading and cleaning up	4,098.00 lump sum

Concrete.—The materials used for concrete Portland cement, sand and gravel, the latter from ¼ in. to 1 in. in size, in order to work readily through the reinforcement, etc. The most of the concrete was a 1:2:4 mixture, though some columns in the lower floors were of a richer mixture in order to reduce the size.

For the concrete pouring two Insley steel towers 160 ft. high were placed on one side of the building and were provided with hoisting buckets of 24 cu. ft. capacity water measure. These were hoisted by 50 h. p. Crocker-Wheeler motor driven hoists with a line speed of 150 ft. per minute when pouring the lower floors, but when upper floors were reached it was found expedient to increase the speed of the hoisting buckets in order that the mixer not be forced to wait on the hoist. This was accomplished by rigging hoisting lines in such a manner as to connect directly to hoisting bucket with a single line instead of passing the line through a pulley on a bucket and fastening the end in the top of the tower. This worked a hardship on the hoist, especially the friction blocks, but these were watched closely and renewed often and no serious consequences were encountered.

Each tower was equipped with a Bremer mixer having a capacity of 32 cu. ft. of loose material, a hoisting bucket of 22 cu. ft. capacity and a 50-ft. boom supporting 100 ft. of gravity spout. One extra piece of spout 50 ft. long and one about 20 ft. long were also provided and used at each plant when that plant was working.

On either side of the mixer was placed a rock bin and a sand bin each holding about 4 carloads of material and dumping directly by gravity into measuring bins which in turn dumped by gravity into mixer charging hopper. Directly over the charging hopper and between the sand and gravel bins was placed a cement bin. Into this the cement was dumped from sacks and passed by gravity through measuring bins as in case of sand and gravel, to the mixer. This method of handling the cement was not found to be as cheap as the old method of loading the mixer by cheap labor and was consequently later abandoned. There is no reason, however, that it should not have been successful had it been properly operated.

The sand and gravel bins, as well as the cement bin, when it was used, were loaded with an industrial traveling crane equipped with a 1¼-cu. yd. bucket.

The floor finish consisted of equal parts of cement, sand and fine crushed rock taken from the ledge and was put on the base before this was thoroughly set. This necessitated several changes of system at the mixer during the day but by a systematic arrangement of the necessary materials the changes were made with hardly a perceptible interruption and the system of pouring top and base practically as one monolithic mass worked out as cheaply, if not cheaper, than the system of pouring for a day or for a day and a half and then topping this out.

A fair day's work with the above concrete plant on slabs was about 300 cu. yd. and on walls and columns was about 200 yd. This varied of course a great deal with conditions. In pouring walls and columns it was found expedient to run concrete with gravity plant to a hopper centrally located with reference to the day's work and distribute from this with carts. On slab pouring, however, the gravity chute was used to pour the concrete directly into place and very good results obtained. The gravity system was also used to spout the floor finish to place.

Costs.—The actual pouring costs observed on several different occasions including labor only and taking materials from bins by gravity, measuring, mixing and placing were as follows:

On slab	30 cts. per cu. yd.
On walls	39 cts. per cu. yd.

Scale of wages was as follows:

Foremen, $6; sub foreman, $4; steel men, $2.25; steel men, $3; carpenters, $3; laborers, $2.25; laborers, $2.

Cost of Placing Concrete and Installing Equipment.—In planning for the construction of the Austin Nichols Building, Brooklyn, N. Y., according to a paper by T. Arthur Smith before the American Concrete Institute, the method for placing concrete was carefully considered by the Turner Construction Co. who executed the general contract. The following is taken from an abstract of Mr. Smith's paper published in Engineering and Contracting, March 31, 1915.

The building is 439 ft. 11½ ins. by 178 ft. 8 ins., and is 6 stories high with basement, and required about 19,620 cu. yds. of concrete.

Records of the cost of wheeling concrete on similar buildings showed that its cost did not exceed 9 cts. per cubic yard, cost being based on labor at 37½ cts. per hour. Assuming that, of the total 19,620 cu. yds. of concrete to be placed, 16,000 cu. yds. could be placed by spouting, the cost of wheeling would be $0.09 × 16,000 = $1,440. Hence $1,440 would have to cover both the cost of installing two spouting outfits and the following additional installations incidental to placing concrete in this manner: raising tower additional height; guying tower; and moving spouts.

This analysis showed conclusively that, for this building, the cost of the spouting equipments plus the additional installation cost, would materially exceed the cost of wheeling concrete.

Unloading and Concreting Equipment.—The layout of the unloading derrick, storage bins, concrete mixers and hoists is shown in Fig. 7. Sand and gravel were delivered alongside the bulkhead, adjacent to the storage bins, on scows — about 400 cu. yds. capacity. A derrick equipped with a clam-shell bucket of 1⅝ cu. yds. capacity unloaded the contents of these scows into storage bins holding 100 cu. yds. of sand and 200 cu. yds. of gravel.

The derrick was operated by a Meade-Morrison three-drum standard hoisting engine having 9 × 10-in. cylinders and a rated capacity of 35 h. p. For swinging the derrick a separate engine was installed. Power was supplied by a 50-h. p. horizontal boiler.

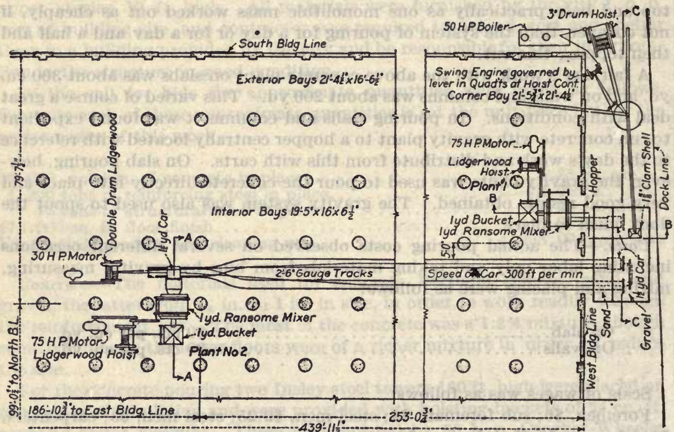

FIG. 7.—Plan showing unloading, mixing and hoisting equipment—Austin Nichols Building.

The sand and gravel were discharged from the bins through "Ransome" gates, into "V" bottom, two-way dump cars for delivery to the mixers. Each car was loaded with 12 cu. ft. of sand and 24 cu. ft. of gravel, a steel partition separating these materials.

One car was used to convey the materials to mixer No. 1, and was pushed by hand from the storage bin to the mixer. For charging mixer No. 2 a 2-ft. 6-in. gage double track was laid from the bin to the mixer, on which two cars were operated, one on each track. These tracks were laid on the first floor, which, in order to follow the grade of North Third St., sloped down 8 ft. from Kent Ave. to the river. A double-drum, motor-driven "Lidgerwood" hoist pulled the cars from the bin to the mixer. These cars were connected by a tail line operating around a sheave at the bin, so that the loaded car going toward the mixer would pull back the empty car to the bin.

Owing to the limited bulkhead space at the building it was necessary to dock the cement lighters one block away and to truck the cement to the building. The cement was stored adjacent to each mixer, six bags being used in each batch.

Two 1-cu. yd. "Ransome" mixers were installed in the locations shown in Fig. 7. Each mixer discharged into a 1-cu. yd. "Ransome" bucket, which was hoisted by a single-drum "Lidgerwood" hoist. Power for the operation of each concrete plant was furnished by a 75-h. p. motor. The concrete was dumped from the bucket into a 2-cu. yd. box on each floor, from which it was wheeled in carts.

The derrick used was capable of unloading 700 cu. yds. of material per day of eight hours. The average capacity of each concrete plant was 45 cu. yds. of concrete per hour. The largest quantity of concrete placed in one day of 8½ hours was 640 cu. yds. In 62 working days, 17,510 cu. yds. were placed an average daily output of 282 cu. yds.

The efficiency of the equipment for conveying materials from the bins to the mixer was demonstrated when, due to a slight breakdown, the derrick was idle for one day. In order to keep one mixing plant in operation, the sand and gravel were wheeled from emergency storage piles on North Third St. Charging one mixer in this manner required 22 additional men, and reduced the output of the plant to about 30 cu. yds. per hour.

In order not to delay the progress of the work it was necessary that the reinforcing steel be placed immediately after the completion of the forms. This required that work in the steel yard be so systematized that the bending and fabrication of steel would be sufficiently in advance of requirements to prevent any delay in the work.

Beam and girder bars were bent in the "Wilson" bender at an average rate of 125 per hour, while the capacity of the "Wilson" stirrup bender was 4,000 stirrups per day.

The total labor cost for installing all equipment used in the erection of the building was 20 cts. per cubic yard of concrete. It must be borne in mind, however, that this cost does not cover any charge either for materials or for the use of plant, depreciation or interest on equipment investment.

Cost of Mixing and Placing Concrete by Hand.—Concrete mixed and placed by hand in a 6-in. wall, with experienced labor, in Riverside, Cal., during 1909 cost $1.19 per cu. yd. An itemized account of the cost of the work is given by C. W. Gaylord in "Cement and Engineering News." The crew was as follows:

1 foreman at $3 per day	$ 3.00
2 men at $2.25 per day	4.50
8 men at $2 per day	16.00
Total	$23.50

This crew averaged 12 batches per 9-hour day, each batch containing 1.7 cu. yds., or 20.4 cu. yds. per day. This amount included 84 sacks of cement, 9.8 cu. yds. of sand and 19.6 cu. yds. of 1½-in. stone. This is over 2 cu. yds. per man per day and is above the average. The work was divided as follows:

	Per cu. yd.
Loading on wheelbarrows:	
Sand, 0.46 cu. yds. at 10 cts	$0.05
Stone, 0.92 cu. yds. at 15 cts	0.14
Total	$0.19

	Per cu. yd.
Wheeling to mixing board and dumping in measuring box:	
Cement (all handling)	$0.04
Sand, average haul 30 ft	0.02
Stone, average haul 50 ft	0.05
Total	$0.11
Mixing:	
Sand and cement (2 turnings)	$0.12
Mortar and stone (3 turnings)	.27
Total	$0.39
Loading into wheelbarrows	$0.17
Wheeling to place (av. haul 55 ft.)	0.06
Dumping, spreading and ramming	0.11
Supervision (⅓ foreman's time)	0.10
Care for water	0.02
Total	$0.46
Grand total	1.15

Adding cost of mixing boards and divided by number of yards mixed with each board gives: 16 × 16 ft. boards 500 ft. B. M. at $40 per M. divided by 500 equals $0.04. Adding this we get a total cost of $1.19.

Cost of Stucco Finish for Concrete House (Engineering and Contracting, Sept. 25, 1918.)—Data on the stucco finish for the walls of a concrete house built in 1917 in Darien, Conn., are given as follows by M. D. Morrill in Concrete:

The stucco finish was put on in a single coat about ¼ in. thick, applied with a plasterer's trowel. The walls were not wet down, but all dry dust was removed. The wall surface was left smooth by the steel forms, and it was at first questioned if there was not danger that this thin coat of stucco would eventually peel off. Experience, however, seems to prove the contrary, and on a considerable number of buildings finished in this way six years ago there is no sign of the separation of the stucco. It appears to be a permanent as well as a rather inexpensive way to finish these steel molded concrete walls. After this stucco was troweled on and had been allowed to stand a few minutes, the surface was gone over lightly with a cork float. A little water was thrown on with a brush, as needed, while the surface was being floated.

In order to get at the exact cost of this wall finish, the time and material used on finishing a surface of 142 sq. yds. was kept, no allowance being made for openings.

Labor and Material, 142 Sq. Yd. of Stucco

½ day, 3 masons, at $4.80 for 8 hours	$7.20	
½ day, 2 helpers, at $3.00 for 8 hours	3.00	
½ day, 2 carpenters, at $4.50, scaffolding	4.50	
Total labor		$14.70
2 bbls. cement at $1.92	$3.82	
1 yd. sifted sand at $3.00	3.00	
Total materials		$ 6.82
Total		$21.52

The total cost of finishing these walls was thus between 15 cts. and 16 cts. per square yard.

Relative Cost of Different Slab Designs.—The following studies relate to different systems proposed for the floors of the buildings of the Massachusetts Institute of Technology, as abstracted in Engineering and Contracting, June

9, 1915, from a paper by Sanford E. Thompson presented before the annual meeting (1915) of the American Concrete Institute. The long-span concrete slab construction proved most economical, when the total cost of concrete, steel, and making of forms was considered. Designs and estimates were made for the following cases:

Case I. Panel with no intermediate beam; slab 15 ft. 6 ins., solid concrete construction.

Case II. Panel with one intermediate beam; slab 7 ft. 9 ins.

Case III. Panel with no intermediate beam; slab 15 ft. 6 ins., with tile.

In Table XI there is summed up the relative costs for the three cases. It is evident that the cost of forms is the important factor, completely upsetting the conclusions that would be drawn from the relative costs of materials actually used in the slab.

Economics of Concrete Columns (Engineering and Contracting, June 19, 1912).—Leonard C. Wason, President of the Aberthaw Construction Co., Boston, states that in one case the saving of concrete by reducing the size of columns on successive floors was $2.30 per column. On the other hand, the increase in form cost was $5.70 per column, entailing a loss of $3.40 per column. This is a very good example of why it is cheaper to use the same size columns on successive floors than to reduce the dimensions. To avoid fre uent changes in column sizes the column reinforcement may be varied in successive stories.

Unit Costs of a Brick and Concrete Building (Engineering and Contracting, Nov. 16, 1910).—The Sanitarium at Battle Creek, Mich., was built in 1902 at a cost of about $1,000,000. It is a fireproof building with brick walls and reinforced concrete floors. The building is 600 ft. long and 400 ft. deep. It is seven stories high at one end, but the slope of the ground makes it only six stories at the other end. The accompanying tables of costs were furnished by John McMichael, who did the work on a percentage basis.

The material for construction was hauled in wagons from switch tracks about four blocks distant. Teams for this purpose were hired at $4 per day.

The following table gives the cost per cubic yard of concrete footings. The concrete was mixed by hand on a board which was shifted along to save wheeling of the mixed concrete. The sand and gravel was bought by the load, mixed, and was dumped at various points convenient to the board.

	Per cu. yd.
Materials:	
Cement, 1.1 bbls.	$1.40
Gravel and sand	0.07½
Gravel and sand hauling	0.50
Total materials	$1.975
Labor:	
Carpenters	$0.18
Common labor	0.68
Total cost of labor	$0.86
Total cost of labor and material	$2.83½

This does not include superintendence. Carpenters received 35 cts. per hour and laborers 20 cts.

Rubble Stone Masonry.—The foundation walls were laid up with boulder stones taken from the old buildings. These are much harder to lay in foundation walls than any other class of stone masonry. The item $6.42 is the cost of wrecking the foundations of the old buildings to get the stone from them.

TABLE XI.—RELATIVE COSTS OF DIFFERENT SLAB DESIGNS

Item	Unit cost	Concrete slab; span, 15 ft. 6 ins.		Concrete slab; span, 7 ft. 9 ins.; 1 intermediate beam		Hollow tile; span, 15 ft. 6 ins.	
		Amt.	Cost	Amt.	Cost	Amt.	Cost
Concrete, per panel:							
Slab, cu. yds.		10.7		6.1		6.6	
Beam, cu. yds.		2.8		2.6		2.2	
Girder, cu. yds.		....		0.65		....	
Total	$ 5.82	13.5	$ 78.50	9.35	$ 55.00	8.8	$ 51.22
Steel, per panel:							
Slab, lbs.		1,080		435		670	
Beams, lbs.		944		1,620		944	
Girder, lbs.		....		690		....	
Total	$ 0.027	2,024	$ 55.60	2,745	$ 75.00	1,551	$ 41.88
Tile, per panel:							
Slab, piece	$ 0.200	....		....		286	57.20
Total cost of materials			$134.10		$130.00		$150.30
Form lumber:							
Slab, 1¼-in. stock, ft. B. M.		1,772		1,435		1,772	
Beam, 1¼-in. stock, ft. B. M.		496		680		429	
Girder, 1¼-in. stock, ft. B. M.		....		267		....	
Total for 4 floors		2,268		2,382		2,201	
Total per floor per panel	$30.00	567	$ 17.00	596	$ 17.86	550	$ 16.50

per M.

Carpenter labor .... 50 cts. per hour.
Ordinary labor .... 25 cts. per hour.

Form labor:						
Slab:						
Make	$ 4.39		$ 3.78		$ 4.39	
Place and remove first floor	12.88		11.48		12.88	
Place and remove second floor	9.88		8.57		9.88	
Place and remove, third floor	11.02		9.31		11.02	
Place and remove, fourth floor	11.02		9.31		11.02	
Total cost 4 floors	$49.19		$42.45		$49.19	
Cost per panel per floor		$ 12.30		$ 10.61		$ 12.30
Beams:						
Make	$ 3.00		$ 2.10		$ 2.70	
Place and remove first floor	5.79		4.40		5.10	
Place and remove second floor	5.20		3.90		4.60	
Place and remove third floor	6.92		5.10		6.80	
Place and remove fourth floor	6.92		5.10		6.80	
Total cost per beam 4 floors	$27.83		$20.60		$26.00	
Cost per panel per floor		$ 6.95		$ 10.30		$ 6.40
Girders:						
Make	......		$ 2.30		......	
Place and remove first floor	......		4.80		......	
Place and remove second floor	......		4.10		......	
Place and remove third floor	......		6.20		......	
Place and remove fourth floor	......		6.20		......	
Total cost 4 floors	......		$23.60		......	
Cost per panel per floor		......		$ 9.50†		......
Total cost forms		$ 36.25		$ 48.27		$ 35.20
Total cost		$170.35		$178.27		$185.50

Costs are from "Concrete Costs," by Taylor and Thompson.

† Multiply cost per panel per floor by 1.6 instead of 2.0 to allow for spandrel beams.

NOTES.—Forms assumed to be used four times and remade once for a change in size of columns. Size of beam below slab, 12 × 19 ins.; size of girder below slab, 14 × 19 ins. Note that cost of forms and not cost of materials used in beams and slab determines relative cost of the three alternate designs.

The costs are given per cord of masonry in place. One cord is equal to 100 cu. ft. as here considered.

	Per cord
Materials:	
Stone	$ 6.42
Sand	0.57½
Cement, 1⁹⁄₁₆ bbls	2.25
Total material	$ 9.245
Labor:	
Masons	$ 1.82½
Common	3.04
Total labor	$ 4.865
Total labor and material	$14.11

Masons received 40 cts. per hour and laborers 20 cts. The amount of stone laid per mason per 8 hours was 1¾ cords.

Brick Work.—The total amount of brick in the building is about 5,250,000, of which about 1,250,000 are pressed brick used for the exterior and for trimmings. About 60 bricklayers were employed during the main part of the work. Three of the Thomas Elevator Co.'s double brick hoists were used for elevating brick and mortar. The costs given are per thousand of brick laid. The number of common brick laid per 8-hour day per man was 2,400.

	Per M brick
Materials:	
Common brick f. o. b. Chicago	$ 4.00
Freight	2.68
Hauling	0.78
Sand	0.57½
Lime (4 bu.)	1.06
Hauling lime	0.16
Total materials	$ 9.25½
Labor:	
Masons	$ 1.65
Common labor	1.82
Total labor	$ 3.47
Total labor and material	$12.72½

Masons received 50 cts. per hour and common labor 20 cts.

Shawnee Buff Pressed Brick were used for the exterior. The number of pressed brick laid by each mason per 8-hour day was 480. The cost of pressed brick work was as follows:

	Per M brick
Materials:	
Pressed brick per M f.o.b	$11.00
Freight	5.50
Hauling	0.95
Sand	0.57½
Lime (3 bu.)	0.91½
Mortar color (buff)	1.82
Cement	0.45
Bonds (wire cloth)	0.57
Total material per M	$21.78
Labor:	
Masons	$ 9.43
Common	6.40
Total labor	$15.83
Total labor and material	$37.61

Masons for pressed brick work received 55 cts. per hour and common laborers 20 cts.

For trimmings, Gray pressed brick were used. The cost of this work was as follows:

Material:	Per M brick
Cost of gray pressed brick f.o.b	$14.00
Freight	6.50
Hauling	0.95
Sand	0.57½
Lime (3 bu.)	0.91½
Cement	0.45
Mortar color (lampblack)	0.18
Bonds (wire cloth)	0.85
Total material	$24.42
Labor:	
Masons	$ 9.45
Common	6.41
Total labor	$15.86
Total labor and material per M	$40.28

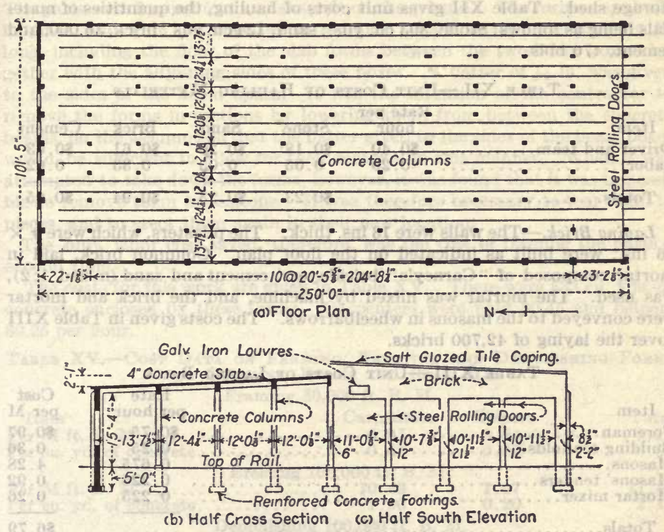

FIG. 8.—Floor plan, half cross section and half south elevation of car storage house of Omaha & Council Bluffs Street Railway Co.

The time required for executing the entire work was about six months.

Costs of a Reinforced Concrete and Brick Car Storage House.—W. L. Fulton in Engineering and Contracting, July 14, 1915, gives following:

The structure, an extension of the existing car house, was built to provide additional storage space required by the Council Bluffs lines. The outside dimensions of the building are 101 ft. 5 ins. by 250 ft. The offices, lobbies, club rooms, repair pit, etc., were provided for in the original building.

Brick and reinforced concrete were adopted as materials of construction. As the building was to be used only for the storage of cars, and therefore the usual clear space between cars not required, a row of columns was placed in each space between tracks, the resulting short spans effecting a considerable saving in cost. Fig. 8 gives the general dimensions and indicates the type of construction used.

Excavation.—The earth excavated from the footing trenches and pits was either back-filled or was distributed over the surface of the ground; no earth was hauled away. The total amount excavated was 233 cu. yds., and the total cost was $51.70, or 22.2 cts. per cubic yard. Laborers were paid 20 cts. per hour.

Hauling Materials.—The cars of building materials were set on a steam railway siding about ¼ mile from the building site. Materials were hauled to the site in flat-bottom wagons of about 1-cu. yd. capacity. The teams stood idle while wagons were being loaded and unloaded, and the drivers helped in loading and unloading. At the building, the sand and stone were dumped on the ground, the brick was piled, and the cement was carried by hand into the storage shed. Table XII gives unit costs of hauling, the quantities of materials being as follows: Stone, 393 cu. yds.; sand, 124 cu. yds.; brick, 36,000, and cement, 470 bbls.

TABLE XII.—UNIT COSTS OF HAULING MATERIALS

Item	Rate per hour	Stone	Sand	Brick	Cement
Driver and team	$0.40	$0.18	$0.20	$0.61	$0.03
Labor	0.20	0.05	0.03	0.33	0.02
Totals	.....	$0.23	$0.23	$0.94	$0.05

Laying Brick.—The walls were 13 ins. thick. The pilasters, which were 9 × 26 ins., were built as indicated on the floor plan. Common brick, laid in mortar composed of "Carney's" bricklayers' cement and sand (mixed 1:2), was used. The mortar was mixed by machine, and the brick and mortar were conveyed to the masons in wheelbarrows. The costs given in Table XIII cover the laying of 42,700 bricks.

TABLE XIII.—UNIT COSTS OF LAYING BRICK

Item	Rate per hour	Cost per M
Foreman	$0.75	$0.97
Building scaffolds	0.25	0.36
Masons	0.675	4.28
Masons' tenders	0.225	0.92
Mortar mixer	0.225	0.26
Totals	......	$6.79

Form Building and Demolition.—(a) *Forms for Walls Below Grade.*—The total length of these walls was 600 ft. and their height 4 ft. 6 ins. Pilasters 9 × 26 ins. were built, as indicated.

The forms were built in sections and were used three times. They contained 5,000 ft. B. M. of lumber. The forms for the pilasters were made of 1-in. lumber, and the remainder of these forms was built of 2-in. lumber, cleated together into sections.

The unit costs of the forms for walls below grade are given in Table XIV.

TABLE XIV.—COST DATA ON BUILDING AND MOVING FORMS FOR WALLS BELOW GRADE

Item	Ft. B. M.	Cost per M ft. B. M.	Cost per cu. yd of concrete
Form building	5,000	$ 6.20	$0.25
Moving forms	15,000	8.10	0.98
Totals	......	$14.30	$1.23

Form Building and Demolition.—(b) *Forms for Columns, Beams and Roof Slab.*—The column boxes were built of 2-in. planks, set vertically and clamped together. In the beam boxes the bottoms were of 2-in. planks, and the sides were of 1-in. shiplap. The floor of the slab forms was also of 1 × 8-in. shiplap. The forms were supported by the column boxes and by 4 × 4-in. shores set below the beam boxes and about 5 ft. apart. The joists under the slab forms were 2 × 6 ins , 16 ins. center to center, and they extended from beam box to beam box. The ends of these joists were supported by 2 × 4-in. cleats extending down the sides of the beam boxes to the bottom of the same, from whence the load was carried directly to the shores.

The forms were used twice, and they contained 50,000 ft. B. M. of lumber. The parts were framed (cut and shaped) on the ground. The forms were built in place, and were put together in sections. Each section was about 6 ft. long, including the floor of the slab forms between the two-beam boxes, together with the adjoining sides of these boxes. A batter of ½ in. was given to the sides of the beam boxes. It was the intention of the contractor to remove the forms in sections by lowering them from between the concrete beams, on the assumption that the batter given to the sides of the beam boxes would be sufficient to allow for their removal in this manner. When it was attempted to take down the forms, however, it was found that it was impossible to remove them in sections. It was therefore necessary to tear them to pieces, and to erect them again in their new location.

The only labor cost saved, therefore, was the cost of framing the parts a second time.

The costs for this work are given in Table XV. There were 533 cu. yds. of concrete enclosed by these forms. Carpenters were paid $0.45 and helpers $0.25 per hour.

TABLE XV.—COST DATA ON FRAMING, ERECTING AND DEMOLISHING FORMS OF COLUMNS, BEAMS AND ROOF SLAB

Item	Carpenters	Helpers	Total
Framing 50,000 ft. B. M.			
Per M ft. B. M.	6.95	0.24	7.19
Per cu. yd. of concrete	0.65	0.02	0.67
Erecting 100,000 ft. B. M.			
Per M ft. B. M.	10.43	1.07	11.50
Per cu. yd. of concrete	1.96	0.20	2.16
Demolishing 100,000 ft. B. M.			
Per M ft. B. M.	3.35	2.78	6.13
Per cu. yd. of concrete	0.63	0.52	1.15

Assembling and Placing Steel Reinforcement.—All of the steel reinforcement was shipped to the job already bent and cut to length. Beam reinforcement was assembled into units, one per beam, before shipping. Column reinforcement was assembled on the job. All reinforcement, except the top reinforcing bars in the roof slab, was put in place and wired before any concrete was placed. The top reinforcing bars in the roof slab and the reinforcing bars in the column footings were placed by the concrete workers, and the cost of same is included in the cost of the concrete work.

The quantity of reinforcing steel in the various portions of the building is as follows:

	Pounds
In column footings	3,000
In columns	12,500
In roof slab, main reinforcement	52,000
In roof slab, top reinforcement	26,000
In beams	27,000

The costs of assembling and placing the steel reinforcement (except as noted above) are given in Table XVI these costs covering 91,500 lbs. of steel and 533 cu. yds. of concrete:

TABLE XVI.—COSTS OF ASSEMBLING AND PLACING STEEL REINFORCEMENT

	Rate per hour	Cost per 100 lbs.	Cost per cu. yd. of concrete
Foreman	$0.45	$0.096	$0.166
Laborers	0.25	0.137	0.235
Totals	.....	$0.233	$0.401

Mixing and Placing Concrete.—The concrete in the floors and walls up to the floor level (including footings) was wheeled from the mixer to the forms in wheelbarrows and poured at the floor level. The concrete in the roof and in the portion of the columns above the floor level was discharged from the mixer into wheelbarrows, which were hoisted to the roof level in a double-cage building elevator and wheeled to place over runways laid on the roof forms. All concrete was mixed in mixers of the batch type. All stone and sand were wheeled to the mixer in wheelbarrows loaded by hand. The costs of this work are given in Table XVII.

TABLE XVII.—COST DATA ON MIXING AND PLACING CONCRETE IN VARIOUS PARTS OF STRUCTURE

Item	Rate per hour	Cost per cu. yd.
Walls and Footings; 163 Cu. Yds.; Dist. Wheeled 75 ft.		
Foreman	$0.40	$0.04
Wheeling sand, stone, concrete	0.20	0.63
Placing concrete	0.25	0.06
Attending mixer	0.25	0.08
Totals	.....	$0.81
Column Footings and Columns Up to Floor Level; 66 Cu. Yds.; Av. Dist. Wheeled, 85 ft.		
Foreman	$0.40	$0.22

Totals	.....	$1.33
Columns Above Floor Level, Beams and Roof Slab; 467 Cu. Yds.; Av. Dist. Wheeled, 90 ft.		
Foreman	$0.40	$0.21
Wheeling sand, stone, concrete	0.20	0.67
Placing concrete	0.35	0.17
Attending mixer	0.25	0.12
Operating elevator	0.20	0.10
Totals	.....	$1.27

Estimating Brick Work.—The following is given by I. P. Hicks in the National Builder.

Brick, as made by different manufacturers, vary in size, and, of course, there is sure to be more or less variations in the actual quantities required for certain jobs; the variations depending upon the size of the brick and the size of the mortar joints made in laying the brick. For common brick we will assume the average size to measure 8¼ × 4 × 2½ inches and that the wall is to be laid up with a ⅜-in. mortar joint.

For this kind of a wall figure 6 brick to each square foot for every 4-in. thickness of wall. Thus, for a wall 4 inches thick, figure 6 brick per square foot; for an 8-inch to 9-inch wall, figure 12 brick per square foot; for a 12 to 13-inch wall, figure 18 brick per square foot; for a 16 to 17-inch wall, figure 24 brick per square foot and so on, adding 6 brick for each 4-inch thickness of wall.

To be very accurate in the number of brick required, deduct the brick required for all openings. In small foundation work, where there are only a few small cellar window openings, it is hardly worth while to deduct the openings, but for the main windows and doors in a brick building, it becomes necessary to deduct the brick for the openings, otherwise the result would be far too many brick.

Brick Footings.—Brick footings, based on steps or offsets of 2 inches, may be estimated by the lineal foot, as follows: For a 9-inch wall, 2-course footing, 10½ brick; 13-inch wall, 3-course footing, 22½ brick; 18-inch wall, 4-course footing, 39 brick; 22-inch wall, 5-course footing, 60 brick; 26-inch wall, 6-course footing, 85½ brick.

Press Brick.—For a standard size of press brick we will assume the following dimensions: 8¼ × 4 × 2¼ inches, and the mortar joint to be ¼ inch. This will require 7 brick per square foot for every 4-inch thickness of wall.

Lump Lime Mortar.—The quantity of material required to lay 1,000 brick with a ⅜-inch joint, using 1 to 2 lime mortar, composed of 1 part lime putty to 2 parts sand, will be 1¾ barrels of lump lime and ⅝-cubic yard of sand.

Hydrated Lime Mortar.—For mortar composed of 1 part hydrated lime and 2 parts sand, figure 6½ 50-pound sacks of hydrated lime and ⅝-cubic yard sand per 1,000 brick.

Cement Mortar.—For 1 to 3 cement mortar composed of 1 part Portland cement and 3 parts sand, figure 5 sacks of cement and ⅝-cubic yard of sand per 1,000 brick, with a ⅜-inch mortar joint. Approximately 2½ bags of cement and ½ of a cubic yard of sand will be required if laid with about a ¼-inch joint.

Cement and Lime Mortar.—Figure 1 sack of Portland cement, ¾-barrel of lump lime and ⅝-cubic yard of sand per 1,000 brick laid in the wall with a ⅜-inch mortar joint.

Estimating Brick for Chimneys (The sizes given are inside of flue measure.)

8 × 8 flue, 24 brick per lineal foot.
8 × 12 flue, 28 brick per lineal foot.
12 × 12 flue, 32 brick per lineal foot.
12 × 16 flue, 36 brick per lineal foot.
16 × 16 flue, 40 brick per lineal foot.
8 × 8 double flue, 40 brick per lineal foot.
8 × 8 and 8 × 12, two flues, 44 brick per lineal foot.
8 × 12 double flue, 48 brick per lineal foot.
8 × 12 and 12 × 12 two flues, 52 to 56 brick per lineal foot.

Chimney breasts for fireplaces and mantels require 90 to 110 bricks per lineal foot the height of the chimney breast. Where the chimney is reduced in size above the breast, figure according to the size and number of flues from there to the top as given above. These figures should enable one to arrive at a very close figure as regards the number of brick required. In the above figures no allowance has been made for any waste in brick and it would be proper to allow a small percentage for broken and wasted brick. If the brick are of good quality, 3 to 5 per cent ought to cover all the waste in handling and laying.

Labor Cost of Laying Brick.—The labor cost of laying brick varies according to the wall, the bond and the kind of mortar joint made. Common brick laid with common bond and plain cut joints: a bricklayer, with one tender, should lay 1,100 brick per 8-hour day, using cement mortar, and 1,350, using lime mortar.

For walls laid in common bond with struck joint one side and plain cut joint on the other side, figure 1,000 brick per 8-hour day, using cement mortar, and 1,200, using lime mortar.

For face walls laid up with selected common brick in common bond and struck joints, figure 950 brick per 8-hour day, using cement mortar, and 1,000 for lime mortar.

For face walls laid with selected common brick in common bond with V-shaped mortar joints, or with joints raked out, figure per 8-hour day, 900 brick, using cement mortar, and 950, using lime mortar.

Face walls laid up with press brick or face brick where there are panels and pilasters, figure 350 to 400 brick per 8-hour day.

For plain walls laid up with press or face brick, figure 700 to 800 brick per 8-hour day.

Figure laborer's time same as bricklayer's time where there is but one bricklayer working; if two bricklayers are working, figure ½ hour laborer's time to 1 hour of bricklayer's time.

Costs of Masonry and Carpenter Work for a Church Building.—Engineering and Contracting, Nov. 30, 1910, gives the following costs taken from the records of the contractor, John McMichaels.

The building was a brick masonry and timber structure constructed at Oak Park, Ill. The work involved rubble masonry foundation walls; concrete footings, brick masonry and timber roof, floors and finish.

Rubble Masonry.—The foundation walls were of rubble masonry about one-fifth of the stone from which were taken from the walls of the old church. The cost per cord of masonry (100 cu. ft.) was as follows:

	Total	per cord
Materials:		
81 cords	$ 619.08	
100 bbls. Portland cement	170.37	
Total material	$ 789.45	$ 9.734
Labor:		
841¾ hrs. masons at 50 cts	$ 420.58	
525¼ hrs. helper at 30 cts	157.55	
296 hrs. helper at 25 cts	73.97	
103 hrs. helper at 20 cts	20.60	
16 hrs. helper at 15 cts	2.40	
Foreman	75.80	
Timekeeper	21.69	
Water boy	12.37	
Night watchman	0.60	
Total labor	$ 785.56	$ 9.698
Grand total	$1,575.01	$19.432

Assuming 5 cu. yds. to the cord of masonry the cost was $3.886 per cu. yd. About 1 2-5 bbls. of cement were used per cord and 1 cu. yd. of sand. Sand was taken from the excavation and is included in labor. It required 105.25 man days to lay 81 cords which is a rate of nearly 0.77 cords per man per day.

Concrete Footings.—A number of small concrete footings in the basement cost for mixing and placing as follows:

395 hrs. labor	$103.49
Foreman	39.20
Water boy	7.16
Timekeeper	6.36
Night watchman	0.15
Total	$156.36

There were 2,400 cu. ft. or 88.9 cu. yds. of concrete in the footings; this gives a cost per cubic yard for mixing and placing of $1.77.

Brick Walls.—The brick building walls averaged 30 ft. in height. All material was carried in hods. The cost of common brick work was as follows per 1,000 brick:

290½ M common brick at $5.70	$1,653.30
340¾ bbls. lime at 45 cts	153.63
42¾ bbls. Louisville cement	24.95
23 bbls. Portland cement	40.00
200 cu. yds. sand	100.00
Total material	$1,971.88
1,328½ hrs. masons at 50 cts	$ 664.25
1,837¼ hrs. helpers at 30 cts	551.21
1,628¼ hrs. helpers at 25 cts	407.06
51 hrs. helpers at 20 cts	10.20
10 hrs. helpers at 17½ cts	1.75
652 hrs. apprentice at $9 per week	122.40
Water boy	3.34
Foreman	176.43
Timekeeper	47.65
Night watchman	43.75
Total labor	$2,028.04

From these figures the cost per 1,000 brick was as follows:

Materials	$ 6.99
Labor	6.79
Total	$13.78

The number of bricks laid per man per day was 800; the rates of helpers' labor to masons' labor was 2⅛ hours to 1 hour; 1⅙ bbls. of cement were used per 1,000 brick.

Nailing Strips.—The cost of placing nailing strips in cinder concrete floor was as follows:

2, 915 ft. B. M. 2 × 4 in. by 16 ft. at $15.50 per M	$45.74
42½ hrs. labor at 42½ cts	8.29
36 hrs. labor at 25 cts	9.12
Foreman	2.75
Timekeeper	0.50
Total	$66.40

The cost per M. ft B. M. was $22.77. One man laid 149 ft. B. M. per hour. The cost per 100 sq. ft. of floor was as follows:

Material	$1.50
Labor	0.70
Total	$2.25

First Floor Girders.—The costs of the first floor girders was as follows:

3, 147 ft. B. M. 10 × 10 in. Y. P. at $20	$62.94
66 hrs. carpenters at 42¼ cts	28.04
Foreman	1.50
Timekeeper	1.50
Watchman	1.00
Total	$94.98

These girders were pitched for an inclined auditorium floor and one man laid 48 sq. ft. per hour. The cost per M. ft. B. M. was as follows:

Material	$20.00
Labor	10.18
Total	$30.18

First Floor Joists.—The cost of laying 2 × 10-in. and 2 × 12-in. joists pitched to an incline for an auditorium floor was as follows:

15, 062 ft. B. M. yellow pine joists	$247.49
239¼ hrs. carpenters at 42½ cts	101.54
4 hrs. labor at 25 cts	1.00
Foreman	22.92
Total	$372.95

One man laid 63 sq. ft. per hour. The cost per M. ft. B. M. was as follows:

Material	$16.50
Labor	8.33
Total	$24.83

Timber Roof.—The timber roof comprised trusses, valley rafters and purlins.

Lumber:	
15, 428 ft. B. M. lumber	$332.14
20 hrs. unloading at 45 cts	9.00
34 hrs. unloading at 25 cts	8.50
1½ hrs. unloading at 30 cts	0.45
Total	$350.09
Framing Trusses:	
333 hrs. carpenters at 42½ cts	$141.39
Foreman	62.40
Timekeeper	7.08
Night watchman	7.00
Total	$217.87
Raising Trusses:	
132½ hrs. at 50 cts	$ 66.25
30 hrs. at 30 cts	9.00
35¼ hrs. at 25 cts	17.82
48 hrs. at 42½ cts	20.37
Iron foreman	36.00
Foreman	9.00
Timekeeper	1.00
Total	$159.44
Valley Rafters:	
54½ hrs. labor at 42½ cts	$ 23.16
Waterboy	1.45
Total	$ 24.61
Purlins:	
136½ hrs. at 42½ cts	$ 57.18
Foreman	4.40
Timekeeper	1.00
Watchman	1.00
Total	$ 63.58
Grand total labor	$483.45

Summarizing we have the following cost per M ft. B. M.:

Material	$21.53
Labor	31.34
Total	$52.87

The cost of material and labor for rafters was as follows:

13, 674 ft. B. M. at $16.85	$229.45
339½ hrs. carpenter at 42½ cts	143.84
Foreman	20.05
Timekeeper	5.50
Night watchman	4.60
62½ hrs. labor at 25 cts	15.62
Total	$419.06

These totals give the following cost per M ft. B. M.

Material	$16.85
Labor	13.86
Total	$30.71

The work amounted to 40 ft. B. M. per man per hour.

Bridging costs for materials and labor $3 per M ft. B. M. of joists.

Boarding Roof.—The cost of covering the roof with 1 × 6-in. D. & M. flooring was as follows:

15, 400 ft. B. M. lumber	$252.80
228 hrs. carpenters at 42½ cts	97.88
12 hrs. labor at 25 cts	3.00
Foreman	18.64
Timekeeper	4.00
Watchman	3.75
Total	$380.07

This gives a cost per M. ft. B. M. as follows:

Material	$16.00
Labor	8.26
Total	$24.26

Ceiling in Rafters.—The cost of beaded out circling securing rafters was as follows:

9 000 sq. ft. ceiling	$315.00
235½ hrs. carpenters at 42½ cts	100.07
35 hrs. labor at 30 cts	10.50
Foreman	13.20
Timekeeper	2.00
Watchman	2.00
Total	$442.77

These totals give the following costs per M ft. B. M.:

Material	$41.00
Labor	14.20
Total	$55.20

The amount of ceiling placed was 38 sq. ft. per man per hour.

Flooring.—The cost of 2 × 6-in. D. & M. flooring was as follows:

14, 414 ft. B. M. lumber	$227.58
101¼ hrs. carpenters at 42½ cts	43.05
56 hrs. labor at 25 cts	14.00
Foreman	19.00
Timekeeper	2.00
Total	$305.63

These totals give the following costs per M ft. B. M.:

Materials	$15.50
Labor	5.42
Total	$20.92

About 143 sq. ft. of flooring was laid per man per hour.

Summarizing the cost of carpenter work per unit we have the following:

Floor strips in cinder concrete	$ 7.00 per M. ft.
First floor girders	10.18 per M. ft.
First floor joists	8.33 per M. ft.
Truss timbers and valley rafters	31.34 per M. ft.
Rafters	13.86 per M. ft.
Roof boarding	8.26 per M. ft.
Flooring	5.42 per M. ft.
Ceiling	14.20 per M. ft.

Cost of Carpenter Work on a Frame Residence.—Engineering and Contracting, Nov. 30, 1910, publishes the following data furnished by the contractor John McMichaels.

The costs are calculated per thousand ft. board measure of lumber used in the construction of a residence at Chicago Heights, Ill., in 1905. Union labor, at 60 cts. per hour for carpenters, was used:

Frame timber	$ 6.00
Bridging (per M. ft. of joists)	3.00
Rough floor and roof boards	6.32
Sheathing	10.40
Siding	20.00
Floors maple 3-in	14.00
Floors Y. P., 3-in	12.00
Ceiling Y. P., 3-in	14.00

Erecting the millwork cost 50 per cent of the value of the material.

Unit Costs of Carpenter Labor on Four Two-Story Frame Flats.—In Engineering and Contracting, Dec. 14, 1910, John McMichaels gives the following. The costs are for labor per thousand feet board measure of lumber with union labor at 60 cts. per hour. The buildings were each two stories in height and were 21 ft. 6 ins. wide by 34 ft. in depth:

Frame timber	$10.90
Bridging (per M ft. of joists)	3.00
Sheathing	8.36
Shingles	2.22
Siding	14.57
Flooring, Y. P	15.00
Flooring, maple	15.00

The millwork was bought by board measurement and was made up on the job. The carpenter work for making up and setting the millwork cost 58 per cent of the cost of the material.

Labor in Different Types of Work in Constructing Frame Houses.—The data given in Table XVIII are derived from a table given by Leroy K. Sherman, President of the U. S. Housing Corporation in Engineering News-Record Feb. 5, 1920.

Table XVIII.—Hourly Labor Output for Building Construction

Item	Kind of labor	Unit Quantity	Labor Output Unit Quantities Per Hour
Excavation (general)	Common	Cu. yd.	0.50
Excavation (trench)	Common	Cu. yd.	0.333
Backfill and grading	Common	Cu. yd.	1.47
Cinder fill, no cement	Common	Cu. yd.	0.625
Plain concrete	Common	Cu. yd.	0.20
Forms for concrete Laborer's time 1½ carpenters	Carpenter and common	Sq. ft.	10.00
Concrete floor, cellar	....	Cu. yd.	0.167
Top dressing	Common	Sq. ft.	31.25
Waterproof painting	Mason	Sq. ft.	50.00
Drainage cellar floor	Common	Cu. ft.	5.00
Flue lining	Mason	Lin. ft.	12.50
Plastering (interior) Laborer's time ⅞ plasterers	Mason and common	Sq. yd.	2.666
Lathing	Lathers	Sq. yd.	11.3
Corner beads	Lathers	Lin. ft.	28.3
Plastering (exterior) Laborer's time ½ plasterers	Mason and common	Sq. yd.	1.693
Plaster board	Carpenter.	....	25.00
Lumber and carpentry Laborers time equal carpenters	Carpenter and common	1000 B. M.	0.0219
Roofing, slate Laborer's time ¼ roofers	Roofer and common	100 sq. ft.	2.75

The rates given above are based upon the experience gained in constructing a large number of houses.

Unit Hour Basis for Estimating Carpenter Work (Engineering and Contracting, Sept. 28, 1921.)—The Quantity Survey Bureau of the Master Carpenters' Association, with the co-operation of several members, has compiled the following tables for use in figuring the cost of carpenter work.

Size	Material	Unit Working Hours per M ft.	Size	Material	Unit Working Hours per M ft.
2 × 4″	Studs	32	1 × 6″	Boards	16
2 × 4″	Rafters	39	1 × 8′	do.	14
2 × 4″	Partitions	54	1 × 8′	Cut betw. Joists.	24
2 × 5″	Studs	31	1 × 4″	D & M Floor	25
2 × 5″	Rafters	37	1 × 6″	Sheathing	18
2 × 5″	Partitions	48	1 × 4″	Siding	46
2 × 6′	Studs	30	1 × 6″	do.	33
2 × 6″	Rafters	36	1 × 4″	Mitered	50
2 × 6″	Partitions	46	1 × 6″	Siding	37
2 × 6″	Joists	26	1¼″	D & M Floor	30
2 × 8″	do.	24	2 × 4′	D & M Floor	25
2 × 10″	do.	21	2 × 6″	D & M Floor	20
2 × 12″	do.	19	1 × 6″	Drop Sidg.	28
2 × 14″	do.	17	1 × 8″	Drop Sidg.	25
3 × 8″	do.	19	1⅛″	Face Maple or Oak Flooring	80
3 × 10″	do.	18			
3 × 12″	do.	17	2″	Face Maple or Oak Flooring	45
3 × 14″	do.	16			
3 × 4″	Sleepers	40	2¼′	Face Maple or Oak Flooring.	40
Furring	On wood	110			
	Brick	240	1¼ × 3″	Bridging	60
1 × 2″	Tile	360		Add for Planing or Scraping Flg.	
	Concrete	600			
1 × 3′	Bridging	75		Maple	50 %
4 × 6—8 × 8	Timbers	24		Oak	80 %
8 × 10—12 × 12	do.	22			

The "unit hours" shown in the third and last columns represent the number of working hours which in the opinion of the committee are required to frame, put in place and finish 1,000 ft. of the various kinds of lumber shown in other columns. By multiplying the actual quantities required for a job by the number of "unit hours" the total number of "work hours" are obtained and the latter are then multiplied by the current wage rate.

Relative Cost Types of Deep Foundations.—I am indebted to J. H. Thornley for the following matter.

Where loads are excessively heavy or the bearing value of the surface soil unusually low, spread footings must be replaced by one of the following types of deep foundation.

The table indicates the effect of various governing factors on the comparative economy of the different types.

The types are given approximately in order of cost per ton of bearing value. That is, if the nature of the proposed work is such that the "Conditions indicating use" would show either type "A" or type "B" to be applicable, then type "B" would *usually* give the cheaper foundation.

Type	Conditions Indicating Use	Objections to Use
"A" Compressed Air Caissons.	1. Very heavy concentrated loads.	1. Extremely high cost.
	2. Water or water bearing material to be penetrated.	2. Slowness.
	3. Rock or material of almost equal bearing value within 100 feet approximately.	
	4. Work sufficiently extensive to warrant heavy installation costs of the necessarily elaborate plant.	

Remarks: Load capacity of finished pier calculated on basis of column to rock.

Type	Conditions Indicating Use	Objections to Use
"B" Open Ended Steel Pipe Concrete Filled Piles.	1. Rock within 40 pile diameter (60′ for an 18″ pile).	1. Danger of occurrence of large boulders or other obstacles which may make blowing out of pile impossible.
	2. Material to be penetrated of low bearing value.	
	3. Pile to be entirely below finished ground level.	
	4. Loads fairly heavy and concentrated, 50 tons or more per column.	
	5. Piles to be placed in cramped quarters, *e.g.*, between shorings.	
	6. Material to be penetrated easily jetted; sand silt or muck.	
	7. Work sufficiently extensive to warrant the installation of the compressor plant necessary for blowing out of piles.	

Remarks: Load capacity calculated on basis of supported column to rock. Within forty diameters (New York building code allows 500 pounds per square inch on concrete section and 7500 pounds per square inch on steel section, less $\frac{1}{16}$ inch steel allowed off for rust).

"C" Closed Ended Steel Pipe Concrete Filled Piles.	1. Load fairly heavy and concentrated 40 tons or more per column. 2. Permissible load per pile not arbitrarily restricted by local building code. Load allowed according to test or formula. 3. Material to be penetrated of some frictional bearing value. 4. Length of piles uncertain. 5. Heavy boulders or other debris liable to be encountered before reaching desired penetration. 6. Small number of piles only required necessitating low plant installation charge. 7. Limited headroom for driving. 8. Enclosed quarters in which driving must be done making blowing dangerous.	1. Larger sizes of pipe only available at a few places in the country. Pipe is bulky to ship and heavy to handle.
"D" Pre-cast Concrete Piles.	1. Site covered by water.	1. Difficulty of ascertaining the lengths of pile which will be required to develop a given refusal and, therefore, a given load capacity. In case of driven piles the last piles of a large pier will sometimes be only half the length of the first piles when driven to the same refusal. Piles in different parts of the foundations of the same building often vary from one half to double the length of the average pile. Except where borings show a level strata of rock or other firm bearing material, borings form only an approximate method of ascertaining the probable length of a pile. The wastage due to cut off of precast piles often makes this system of piling extremely expensive.
	2. Ground through which piles driven such as to permit of jetting,—sand, silt or muck.	2. It is necessary to cast the pile at least 28 days before it is driven which means a serious delay in starting work on a rush job.
	3. Accurate advance knowledge as to the driven depth of piles required to support load.	3. The percentage of breakage in handling and driving precast piles is sometimes high. 4. Piles fractured in driving may not show up until they are under load.

"E" Open Caissons or Caisson Piles.	1. Large concentrated loads. 2. Little or no water in material to be penetrated. 3. Rock or material of high bearing value within thirty feet.	1. Danger of striking quicksand or unexpected springs. 2. Slower method than driven piles.

Remarks: Load capacity of finished pier or pile calculated either on basis of column to rock or on basis of bearing value of bottom material if not rock.

"F" Float Foundations.	1. No safe bearing strata within economical reach of piling. 2. Surface material liable to flow but practically non-compressible when contained. 3. No danger of future excavation occurring in close enough proximity to the foundation to cause flow of the sub soil. 4. No likelihood of change in the local water table which might result in drying out and consequent shrinkage of sub soil. 5. A uniformly distributed load. 6. A surface sub soil of homogeneous material giving uniform bearing value.	1. Uncertainty.

Note: So called float foundations are often merely cases of a spread footing extending under the entire building. The term "float foundation" as here used means a foundation on material which would flow under the building load if not contained.

"G" Wooden Piling.	1. Piles to be wholly below ground water level, or if in open water to extend above the low water level only to such an extent that the part above water level will not become dried out. (This extension above low water level will vary according to climatic conditions.) 2. Comparatively light loads or uniformly distributed loads. 3. Water conditions such as to permit of cut off at time of driving without sheeting and pumping. 4. Assurance that the water table will not be lowered either by climatic changes over a period of years or by artificial changes such as sewers, subways or canals.	1. Where piles are driven through strata of small bearing value to hard pan or rock practically all of the load must be taken in end bearing which may result in end crushing or column failure. The liability to column failure becomes serious in long piles if they are not absolutely straight. 2. In driving in soil containing boulders or in driving to a rock bearing there is always danger of cracking and end booming.
"H" Cast-in-place Concrete Piling.	1. Load sufficiently concentrated to give 20 tons or more per pile. 2. Surface soil of sufficient bearing load value to carry a land pile driving rig. 3. Probable length of pile under 50′. 4. Speed required. 5. Load concentration not in excess of 6½ tons per square foot.	1. Cannot be driven through water.

Note: Where the water table coincides closely with the bottom of the column bases avoiding either expense for pumping and sheeting or the building of a deep cap from cut off to column base, wooden piles will usually be cheaper than cast-in-place concrete piles unless the loads are large and concentrated.

There are numerous other special types of piles and caissons which have been designed to meet unusual conditions. Such, for example, are the steel screw piles and automatic caissons in which the digging is done by water jets or other purely mechanical means.

It is not intended to be understood that *all* conditions shown in the "Conditions Indicating Use" column should be expected in any particular instance. Sometimes the importance of one condition may overshadow all others. For example, where cast-in-place piles may be otherwise the obvious solution a lack of head room for a driver and apparatus may force the use of steel pipe pile.

Cost of Caisson Foundation for a Building in Chicago.—The following is given in Engineering and Contracting, Oct. 22, 1913.

The foundations were built during the summer of 1913 and consisted of 40 wells sunk to rock. Owing to the nature of the sub-soil it is unnecessary to use compressed air and the small amount of water encountered was removed by buckets.

The usual crew for a 5-ft. well was one digger, one man at the niggerhead, one dumper and enough wheelers to remove the excavated material. Usually one wheeler could handle the excavation from two wells, where the haul did not exceed 100 ft. and the runway was in good condition.

The first set of lagging placed consisted of 3 × 3-in. pieces, 6 ft. long, three rings being used for the initial set. After the caissons were topped, platforms were built of 2-in. plank, with a 2-ft. square hole at the center of each caisson, and on these platforms the tripods were erected. Each tripod carries a shaft, on one end of which was an 18-in. sheave and on the other end an 8 × 10-in. niggerhead. Directly over the center of the caisson was placed a block, suitable for a 1-in. Manila rope. This rope supported an iron bucket, 22 ins. in diameter and 24 ins. deep, which was used for hoisting the excavated material. Power was supplied by a hoisting engine, conveniently located, having a bull wheel on a stub shaft. A 5/8-in. cable passed over this wheel and also over each of the sheaves at the caissons. Ten wells were operated from one hoisting engine, and the cable would last on an average for two set-ups.

Progress of Caisson Work.—The caisson work was carried on continuously in three shifts of eight hours each, except for a four weeks' lockout. During the lockout, the only men employed were two foremen, two timekeepers, a superintendent, an assistant superintendent, and a night watchman. The excavated material for a depth of from 50 to 55 ft. below city datum consisted of the typical soft blue clay which could be excavated with a spade. For the next 10 to 15 ft. the material was dry and required grubbing; the following 15 ft. was hard-pan, which was removed with some difficulty; while the last 3 to 5 ft. consisted of water-bearing sand and gravel. In most cases it was necessary to remove some disintegrated rock from the surface of the bed-rock. Large boulders, which required blasting, were often encountered. For about the first 56 ft., 3 × 6-in. lagging, 4 ft. long, was used, and for the remaining distance, about 26 ft., 2 × 6-in. lagging, 5 ft. 4 ins. long was used. The wrought iron rings were 3 × 3¾ ins. in section, made in two parts, with flanges for the connecting bolts.

Arrangements were made with the Chicago Tunnel Co. to receive the excavated material, which was discharged through its station at Madison St. and the river. A chute was dug from the tunnel to the basement level of the site, into which the material was dumped, and by it was conveyed by gravity to the cars.

Table XIX shows the actual progress made by each eight-hour shift for two 5-ft. diameter caissons. It is seen that the progress for each caisson was practically the same for each shift.

TABLE XIX

Shift (8 hrs.)	Caisson No. 14. Depth each shift Ft.	Ins.	Caisson No. 15. Depth each shift Ft.	Ins.
1	6	0	6	0
2	14	0	13	10
3	21	2	20	10

17	77	4	76	2
18	80	2	80	9
19	81	8	82	3

Cost Data.—The total excavation for caisson No. 14 was 59.4 cu. yds., the total labor cost for excavating and for placing the lagging was $328.70, making a cost per cubic yard of $5.53. For caisson No. 15 the excavation was 59.8 cu. yds., the total labor cost was $328.70, and the labor cost per cubic yard was $5.50.

The total pay roll for all work done in connection with the excavation of the site and the digging and concrete of the wells was $23,468.50. This did not include the cost for shoring materials, for electrical work, or for the engineering work, which required the services of three men two days out of every three. The following scale of wages per hour was paid: Common laborers, 40 cts., niggerhead men, 50 cts.; diggers, 57½ cts.; lagging boss, 60 to 70 cts.; rigging foreman, 65 to 75 cts.; foreman, 75 cts.; and engineers, 75 cts.

With conditions such that the excavating operations consisted of excavating, pulling and wheeling, the cost per shift (with the overhead charges properly distributed), when ten wells were being excavated at the same time, averaged about $17.30 per well. This gives a cost of $51.90 per day per well, or $519.00 per day for the ten wells. These costs include the necessary labor for unloading and piling the lagging and rings, and practically all items connected with the actual work done on the caissons. It does not, however, include the disposal of the excavated material (after dumping into the chute), the cost of shoring materials, or the concreting of the caissons.

Concreting of Caissons.—The ¼-yd. motor-driven mixer was mounted on a platform, placed at the level of the street. The concrete materials were stored in the street, and the concrete was, in most cases, spouted to the caissons. For some of the more distant wells, however, the concrete was wheeled in buggies. When it was possible to keep the mixer in continuous operation, a gang of 22 men could mix and place about 100 cu. yds. per shift of eight hours, at a labor cost of slightly less than $1.00 per cubic yard. The labor cost, even with intermittent running seldom reached $1.25 per cubic yard. The concrete was poured in at the top of the caisson and was permitted to fall to the bottom. A mixture of one part Portland cement, three parts torpedo sand and five parts 1-in. crushed stone was used for the caissons.

A Comparison of the Cost of Concrete and Wood Piling.—Philip J. Kealy, in Engineering and Contracting, Jan. 25, 1911, gives the following:

In the erection of a large industrial shop in the Chicago district during the summer of 1910, a pile foundation was necessary and the question as to the kind of piling arose. The building site was on filled ground, near a river, with the ground water line approximately 14 ft. below grade, and the piling depended largely on skin friction for bearing power.

A proposal was made to furnish concrete piles at $1 per ft. but wood piles were selected because they could be secured at 23½ cts. per ft. in place. The piles were designed to carry 20 tons each and the number of piles varied from 4 to 9 under each pier. The contractor was allowed 12 cts. per ft. for each foot followed.

Driving.—The following is the cost data on the pile driving operation:

Total piles driven, approximately	1,250
Total linear ft. driven, approximately	50,000
Total linear ft. followed, approximately	6,000
Actual cost of pile (to company) per foot driven	25.15 cts.
Actual cost of one pile (driven)	$10.21

The piles were driven during July and August.

Sawing Off Heads.—The piles were cut with a cross cut saw about 4 ft. long worked by two men who received 35 cts. per hour each. The heads were hoisted out by a three-leg derrick and single block, six men being required to hoist up and dispose of them. These laborers received 25 cts. per hour. Water existed in many of the holes which varied from 12 to 15 ft. in depth. The average cost to cut off each head, get it out of the hole and dispose of it was 38 cts. The unit cost varied from 17½ cts. to $1.35.

Excavation.—The cost per cubic yard for excavation was $2, which price included backfilling. The pier holes were in many instances full of water, entailing pumping, sheeting was necessary to prevent caving, double and triple casting of dirt was frequently required and much of the material handled was slush, so that the price per yard was not excessive. The amount of excavation required for various size piers and the cost per pile was as follows:

4 piles 6 × 6 × 14.5 = 19.3 cu. yds. at $2 = $38.60, or $9.65 per pile.
5 piles 6.5 × 6.6 × 14.5 = 22.7 cu. yds. at $2 = $45.40, or $9.08 per pile.
7 piles 7 × 7 × 14.5 = 26.3 cu. yds. at $2 = $52.60, or $7.51 per pile.
9 piles 7.5 × 7.5 × 14.5 = 30.2 cu. yds. at $2 = $60.40, or $6.71 per pile.

The majority of the piers rested on the smaller number of piles so that the average cost of excavation per pile was $8.61.

Concrete Caps and Piers.—The coat of the concrete work in the piers was $5.40 per cu. yd., the contractor furnishing all materials and forms. From the detail drawings the cubical contents of the piers are found to be as follows: 4 pile, 6.3 cu. yds.; 5 pile, 6.8 cu. yds.; 7 pile, 8.0 cu. yds.; and 9 pile, 8.7 cu. yds. At $5.40 per yd. the cost of the concrete work in place was as follows:

4 pile 6.3 cu. yds. at $5.40 = $34.02 or $8.50 per pile.
5 pile 6.8 cu. yds. at $5.40 = $36.72 or $7.34 per pile.
7 pile 8.0 cu. yds. at $5.40 = $43.20 or $6.17 per pile.
9 pile 8.7 cu. yds. at $5.40 = $46.98 or $5.22 per pile.

The average price per pile for the concrete cap and the pier from cap to footing grade, was $7.15.

Recapitulation.—From the foregoing figures the following table summarizing the cost of a pile in the various size piers is obtained:

Item	Cost per mile 4 pile	5 pile	7 pile	9 pile
Driving and following	$ 10.21	$ 10.21	$ 10.21	$ 10.21
Sawing heads	0.38	0.38	0.38	0.38
Excavating and backfill	9.65	9.08	7.51	6.71
Concrete	8.505	7.34	6.17	5.22
	$28.745	$ 27.01	$ 24.27	$ 22.52
	4	5	7	9
Cost of completed pier	$114.98	$136.05	$169.89	$202.68

Concrete Piles.—Numerous tests have shown that where the loading is supported by skin friction, a short tapering concrete pile will sustain as great or greater a load than a long wood pile and for that reason it was proposed to use 24 ft. piles on this work had concrete piles been selected. In tests made in just such soil conditions as existed in this case, it was demonstrated that the concrete piles could stand from two to three times the loading, without settlement, that the wood piles could carry, but in order to be conservative 50 per cent greater loading is assumed for a comparative basis of cost. The cost of a 4 pile cluster (assuming same loading as on wood piles) of concrete piles would be:

Piling, 4 at $24	$ 96.00
Excavation for cap at 2 cu. yds. at $1.00	2.00
Concrete in cap 2 cu. yds. at $5.40	10.80
	$108.80

Assuming 50 per cent greater bearing power, piles to be driven on 2 ft. centers, the cost of a 4 pile cluster would have been:

Piles, 3 at $24.00	$72.00
Excavation, 2 cu. yds. at $1.00	2.00
Concrete cap, 2 at $5.40	10.80
	$84.80

This is a saving of approximately 26.5 per cent of the initial cost of the wood piles. Upon the same premises, the cost of the different size piers would have been as follows:

COST OF CONCRETE PILE PIERS

Number of wood piles	4	5	7	9
Cost of concrete piles	$72.00	$ 96.00	$120.00	$144.00
Cost of excavation	2.00	2.00	3.00	3.00
Cost of cap	10.80	10.80	16.20	16.20
Total cost	$84.80	$108.80	$139.20	$163.20

A comparison of the cost of the complete wood pile piers necessary to take care of the same loading, with the concrete piles and the per cent saving in initial cost in favor of the latter is shown in the following table:

SIZE OF WOOD PILE PIERS

	4-pile	5-pile	7-pile	9-pile
Concrete	84.40	108.80	139.20	163.20
Wood	114.98	135.05	159.89	202.68
Per cent saving in initial cost	26.4	19.45	18.1	19.5

It is evident from the above figures that a saving of over 20 per cent of the initial cost of the foundation work would have been effected by the use of concrete piles, under the conditions which existed on this job. This saving is brought about by avoidance of expensive excavation and deep concrete piers necessitated by the wood piling and would be approximately the same percentage in the nine-pile cluster, as it is in the four-pile.

On further analysis, it would appear that where the ground-water line is 8 ft. or more below grade, the initial cost of the foundation work below grade would be less if concrete piles were selected in preference to wood, although the cost of concrete piles would be $1 per foot and wood piles 25 cts. per foot driven.

Output of Steam Pile Drivers on Foundations of the Field Museum of Natural History.—Engineering and Contracting, Nov. 24, 1915, gives the following:

The concrete piers of this building are supported on clusters of wood piles. These piles are 60 ft. long, of Georgia pine, and are almost perfectly straight. They are 9 ins. in diameter at the tip, and vary from 15 to 22 ins. in diameter at the butt, averaging about 18 ins. The total number of piles required is 9,320. Pile driving was begun July 29, 1915, and 8,100 piles had been driven up to Nov. 10. Three steam drivers, equipped with 70-ft. leads, are being used for this work. As the piles are cut off at elevation—1 ft. 9 ins. (the elevation of the pier bases being—2 ft. 6 ins.) it is necessary to use followers in all cases. The piles are driven through from about 16 to 25 ft. of clay fill, through a thin stratum of wet sand, then through from 20 to 30 ft. of soft blue clay, into strata of stiff to hard blue clay and gravel. All piles are driven practically to refusal at these depths. With the exception of about two weeks, during which time it was impossible to secure delivery of piles on account of floods in the South, pile driving has continued without interruption.

Each driver has averaged from 30 to 35 piles per day of ten hours, the pile driving crew consisting of 7 men, in addition to those whose duty it is to prepare the piles for driving and to bring them to the driver.

Cost of Pedestal Concrete Piles.—Fig. 9, and the following explanation, describing the method of forming pedestal piles, are given in the official Bulletin, Investigating Committees of Architects and Engineers.

1. A core and cylindrical casing are first driven to the required depth.

2. The core is now removed and a charge of concrete dumped to the bottom of the casing.

3. The core is now placed on the charge of concrete and the casing is raised to permit the forming of the pedestal.

4. The core is now used as a rammer, to compress this concrete into the surrounding soil. The process is repeated until the base is as large as can be formed under the compression caused by the action of a Vulcan steam hammer.

5. The enlarged base being completed, the casing is filled to the top with concrete and is then removed with the core and hammer (approximately 6 tons) resting on the concrete.

6. The final step is to withdraw the cylindrical casing from the ground. The completed pedestal pile, consisting of a monolithic concrete column 16

inches in diameter surmounting a broad base or pedestal, is thus left in the ground.

The following summaries, of cost and working conditions on two typical jobs where pedestal concrete piles were used, were prepared by J. H. Thornley, chief engineer, MacArthur Concrete Pile & Foundation Co.

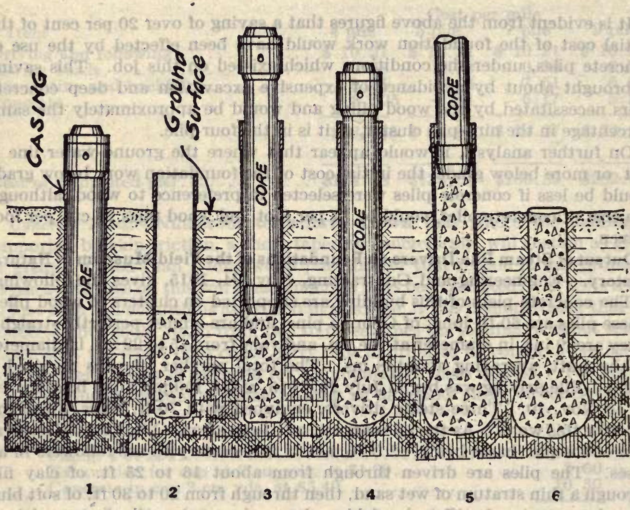

FIG. 9.—Sections showing steps in forming pedestal piles.

1. Location of Job: West Orange N. J.
2. Owners: Ward Baking Company
3. Contractors for whom work was done: John W. Ferguson Company, Paterson N. J.
4. Number of piles in job: 463
5. Average length: 12 feet
6. Piles in groups of: 7 and 8
7. Distance between piers: 16 feet one way—23 feet one way
8. Pile centres: 3 foot 0 inches
9. Soil conditions: Sand and large boulders
10. Remarks: Very hard driving—worst possible conditions
11. Total footage: 5,563
12. Total Cost: $9 503.00
13. Cost per foot of pile: $1.71
14. Wages paid:

Foreman	$52.25	a week
Engineers	52.25	a week
Pile driver Men	1.00	an hour
Concrete Labor	.72	an hour

15. Cost of Material: $2.93 per barrel of cement
    2.75 per cu. yd. of sand and gravel aggregate.

1. Location: of Job: Clifton, Staten Island
2. Owners: Pouch Terminal Company
3. Contractors for whom work was done: Turner Construction Company of New York
4. Number of piles in job: 757
5. Average length: 22.8 feet
6. Piles in groups of: 10 to 21

7. Distance between piers: 20 feet both ways
8. Pile centres: 2 foot six inches
9. Soil conditions: Clay and sand
10. Remarks: Moderate to hard driving.
11. Total footage: 17,282
12. Total Cost: $24 140.00
13. Cost per foot of pile: $1.40
14. Wages paid: Foreman.......................... $52.25 a week
    Engineers.......................... 52.25 a week
    Pile driver men.......................... 1.00 an hour
    Concrete labor.......................... .78 an hour
15. Cost of Material: $2.85 per barrel of cement
    2.75 per cu. yd. of sand and gravel aggregate

Mr. Thornley states, that under average conditions and with wage rates as shown, the average price per foot, for driving and forming complete approximately 500 pedestal piles, would be as follows:

	Wages per 8-hr. day
Foreman	$10.00
Engineer	9.00
Pile driver men	7.00
Concrete labor	3.60

Length of pile, ft.	Price per ft.
10 to 20	$1.60
20 to 30	1.30
30 to 42	1.20
42 to 50	1.25

Rapid Driving of Raymond Concrete Foundation Piles.—Engineering News-Record, July 12, 1917, gives data regarding the speed developed in driving 3776 Raymond Concrete Piles for the footings of the large storage building constructed at the beginning of the war at the Brooklyn Navy yard. Four pile drivers were used and were operated continuously with the exception of Sundays, three 8-hr. shifts being run on week days and three 4-hr. shifts on Saturday.

The average penetration of the piles was 22.85 ft. and the average number of piles driven by each driven crew per 8-hr. shift was 21.

The piledrivers used by the contractor were steel-frame turntable machines, equipped with two-drum hoists and No. 1 Raymond steam hammers. They travel on a nest of rollers under the base of the turntable. A timber runway has to be laid for them. This type of rig is considered the most rapid ever developed, and this in spite of the fact that Raymond piles are more difficult to drive, on account of the process involved, than wood piles. The core on which the shells are assembled before driving weighs about 8800 lb. and, furthermore, must be withdrawn after each pile is driven. A record for the number of piles driven in a single shift, which it is thought has never been approached under similar conditions, was established in 1916, when one of these machines drove 119 twenty-foot piles in 10 hours at the plant of the Chevrolet Motor Co. in Flint, Michigan.

Cost of a Damp-Proof Timber Floor.—In Engineering News, Aug. 27, 1914, J. Albert Holmes gives the following:

The floor was laid in the basement of a manufacturing building on the natural earth, hardpan and sand, without underdrains, and carrying machinery, round steel in racks and square steel piled solid in storage.

The owner, wishing to secure a long-lived floor, purchased kyanized hemlock for the 3-in. underfloor and had two-ply felt and a layer of pitch placed between the plank and top flooring. The ground was prepared by the contractor for the building by rolling or puddling, therefore, the costs given in the accompanying table are for materials and labor above the ground.

The soft-coal cinders used for the foundation course were purchased from the railroad and delivered in cars on a siding from which they were shoveled directly into the basement where used. Materials were delivered and the work performed in the winter, so that storage in the basement obviated the necessity of heating the cinders when mixed with the tar. Tar was purchased from the local gas works and 14 gal. used per cu. yd. of cinders.

The cinders were spread, rolled and tamped to a thickness of 4 in.; the shrinkage from measurement in cars to place was 36%. Sand and tar were heated outside the building and mixed in the basement. This mixture, while warm, was spread over the cinders and screeded off ⅜ in. above the bottom of the plank; planks being laid to grade for screeding. Into the sand while still warm, the 3-in. planks were firmly bedded by ramming.

For specially prepared tars, 50 to 60 gal. per yd. of sand are specified. On this work the greatest amount of tar that the sand could be made to contain, without making a soft, wet mixture, was 35 gal. per cu. yd., the same kind of tar being used in both cinders and sand. The writer has knowledge of floors where the tar has come up through the joints in both plank and top floor due, no doubt, to an excess of tar in the sand.

The difference in volume of sand in place and in carts, due to compression and to inequalities of surface of cinder layer was 68%. The plank was 3-in. kyanized hemlock, planed one side to a uniform thickness of 2¾ in. and not less than 6 in. wide, random lengths, square edged and saw butted; laid to break joints and toe nailed but not driven tightly together. There was no loss of plank by cutting.

Over the plank were placed two layers of felt and one of pitch. The felt weighed 14 lb. per 100 sq. ft. and was laid to break joints one-half the width of the sheet; no pitch was allowed to come in contact with either plank or top floor. The loss in area of felt due to lapping was 21%.

Over the felt and at right angles to the plank was laid a maple-top floor 1$\frac{1}{16}$ in. thick. This flooring was square edge, 3 in. wide, and nailed with 10-penny finish nails through the top every 8 in. on alternate sides.

The waste and shrinkage due partly to laying, but mostly to manufacture, was 40%; in other words, while the market price of the flooring was $45 per M, the shrinkage in manufacturing that must be paid for, plus a small loss by waste in laying, brought the cost up to $63 per M. Builders are familiar with shrinkages in manufactured lumber, but engineers, not having occasion to use it so frequently, are not so familiar and are surprised when as for instance, they purchase 5-in. V-sheathing for building a field office, to find that it covers a width of only 3¼ in. and that the Western rules for inspection of hard pine allow ⅛ in. less than the Eastern, which in turn allow an ⅛-in. or more, less than full dimension for square timber and plank.

Referring to the accompanying table, the quantities are the quantities purchased in the market, as for instance, 4 in. of cinders in place amount to 0.151 cu. yd. measured in cars, or 36% more than the place measurement and similarly for sand, felt and top floor, there being no loss in laying the 3-in. plank.

In this work, two distinct classes of labor or trades were employed, roofers in this case and carpenters, and though they worked together, their organizations were separate. For this reason, the combined items for superintendence

Cost of Damp-Proof Floor

Materials and labor	Thickness of material in place	Quantity per sq. yd.	Unit cost	Cost per sq. yd.	Per cent of waste and shrinkage	Cost* per sq. yd.
Cinders	4 in.	0.151 cu. yd.	$ 0.50 per cu. yd.	$0.076	36	$0.076
Tar in cinders	......	0.0381 bbl.	2.00 per bbl. (57 gal.)	0.076	..	0.076
Sand	1 in.	0.045 cu. yd.	1.00 per cu. yd.	0.045	68	0.045
Tar in sand	......	0.0276 gal.	2.00 per bbl. (57 gal.)	0.055	..	0.055
Felt	2 ply	3.10 lb.	35.00 per ton	0.054	21	......

Totals	9 in.	....	....	3.226	..	2.898
			Materials	1.869	..	1.638
			Labor	1.357	..	1.260

* Cost omitting felt, pitch on felt, labor placing felt and pitch and using untreated Hemlock plank @ $28.00 per M.

is high and that for superintendence of roofers unnecessarily so. Reducing the item for superintendence of roofers and using untreated plank and leaving out the felt and pitch between plank and top floor, the cost would be reduced as shown in the last column of the table.

Cost of Granolithic Floor.—John T. Sullivan in Engineering News-Record, April 4, 1918, gives the following:

A unit cost on concrete floor finishing of 58c. for 100 sq. ft. was recently attained on the first floor of the new Charles Shannon Building in Cincinnati. The entire job, consisting of 3325 sq. ft. was cleaned up by four laborers and two finishers within nine hours. Work started at 7 a. m. Two laborers mixed the finishing material—one wet batch and another dry batch—using iron mortar boxes. Two other laborers roughened the floor with wire brooms, the floor having been poured the previous day. As soon as the first batch was ready, one of the laborers was used to wheel the finish in on the floor.

One finisher spread the batch while the second finisher leveled it off with a 6-ft. screed. The first finisher then floated the surface with a long home-made float and with a hand-float. The second finisher then spread and screeded continuously while his partner worked on floating. At 2 o'clock the whole floor was spread and screeded, so both finishers worked with the floats until the floor was finished at 4:30 p. m. The laborers used on mixing and wheeling were put on other work as soon as their task was completed. Here is a summary of the costs:

Two laborers to mix, 7 a. m. to 2 p. m., 6½ hr. each at 30 cts. per hr. =	$ 3.90
One laborer to wheel finish onto floor, 6½ hr. at 30 cts. per hr. = ...	1.95
One laborer to broom and use big float, 8½ hr. at 30 cts. per hr- = ...	2.55
Two finishers, 9 hr. each at 60 cts. per hr. = ...	10.80
Total labor cost...	$19.20
Total area .... = 35 × 95 ft. = 3, 325 sq. ft.	
Unit cost .... = $\frac{\$19.20}{3,325}$ = 58 cts. per 100 sq. ft.	

One-half hour was taken for lunch.

Cost of Resurfacing Concrete Floors.—C. L. Samson, gives the following data in Engineering and Contracting, Nov. 29, 1911.

Both floors as originally laid consisted of 13/16 in. maple flooring nailed to 2 × 4 in. pine nailing strips laid in concrete. Concrete was flush with the top of nailing strips. In seven years time the nailing strips rotted out and the maple came loose. It was decided to remove the maple flooring and surface the underlying concrete.

The item "cleaning floor," consisted of removing the maple, picking out remains of nailing strips and scrubbing surface of old concrete to receive the finish. It was the intention to make the finish 1 in. thick but the old floor was uneven so that in some cases the finish was 1¾ ins. thick, while in other places the old concrete had to be picked out and renewed. The amount of crushed stone used will serve as a rough indication of the amount of concrete removed and replaced.

The form work mentioned was over a tunnel and formed a slab 4 × 16 ft. which was reinforced by ¼ in. round rods.

The first floor was finished with what was sold to us as Wisconsin Granite chips. It proved to be little more than sand stone and did not make a satisfactory floor. It finished beautifully but the floor was so soft that the glaze soon wore rough under trucking. The mixture of finish was 1 of Portland cement to 1½ "Wisconsin Granite."

The same mixture was used on the second floor excepting that common sand was used instead of the granite. No trouble was experienced in either case in getting the finish to stick to the old concrete. The old concrete was slushed with a neat cement grout before applying the finish.

The first floor was laid in February and the second in June while the weather was very warm. The intense heat is largely responsible for higher cost per square foot of the second floor. The second floor also contained one reinforced concrete slab 13 ft. square and 7 in. thick. The cost of the first floor was as follows:

Labor:	
Cost of cleaning old floor for concrete	$ 89.93
Cost of bringing in material	36.53
Cost of mixing board, floats and straightedge	1.43
Cost of setting screeds	7.15
Cost of forms around two tunnel doors	12.20
Cost of finishing	45.59
Total cost of labor	$192.73
Material:	
82¾ barrels Portland cement	$ 74.47
15 yds. crushed granite	58.50
5 yds. sand	6.25
10 yds. crushed stone	13.00
Cartage	21.12
Total cost of material	$173.34
Grand total	$366.07

The rates of wages paid were: Common labor, 25 cts. per hour, and carpenter labor, 30 cts. per hour. The area of floor laid was 5,120 sq. ft., and the cost per square foot was $0.0710. The cost of the second floor similar to above was as follows:

Total cost of labor at 25 cts	$203.31
Cost of material:	
68¾ barrels Portland cement	61.88
25 yds. sand	37.50
16 yds. stone	24.00
1140 lbs. twisted steel	29.64
Total cost of material	$153.02
Total cost of floor	$356.33

The area of floor laid was 4,217 sq. ft. and the cost per square foot was $0.084.

Labor Cost of Laying Concrete Basement Floor, Columbus, Miss.—C. L. Wood, in Engineering and Contracting, Sept. 14, 1910, gives the following:

The floor covered a 12 × 200 ft. hallway and nine side rooms ranging in area from 759 to 2,069 sq. ft. the total area being 12,952.2 sq. ft. The total thickness of the floor was 6 ins., composed of 4-in. base of 1:3:5 concrete, and a 2-in. surface of 1:2 mortar. The aggregates were sand and gravel. The foundation was 4 ins. of screened coal cinders, wet and tamped. The sand and gravel was delivered in piles opposite the windows of the basement; cement was stored in one room and lumber was delivered in piles opposite the doors. The contract for laying included all labor and supervision necessary to the finished floor, with materials purchased and delivered as mentioned, and with free use of shovels and wheelbarrows, and of water.

The unscreened sand and gravel was shoveled into the rooms through the basement windows, screened and moved with wheelbarrows to the mixing boards, which were set in the hall at two points of which there were water connections. The mixing was done by hand, working 4 men on the mixing board and 1 man at the mortar box. Lights were necessary, but as all work was under cover, no delays were caused by rain. The gang consisted of 1 foreman, who was the contractor and form setter, 1 finisher, 1 mortar mixer, and from 7 to 12 laborers. A 10-hour day was worked, the finisher requiring extra time, since all work was completed the same day that it was begun. The job was completed in 5 calendar weeks and 2 days. The work of electric wiring, steam piping, laying drain, etc., was in progress at the same time as the floor construction, which greatly hindered the progress of the concrete work and in the narrow quarters made necessary a small working party. The following was the cost of the work:

2,010½ hrs. common labor at 10 cts	$201.05
276.4 hrs. mortar mixer at 12½ cts	34.95
296.36 hrs. finisher at 27½ cts	81.50
32 days foreman at $5	160.00
Total	$477.50
Profit	$ 50.00
Contract price	$527.84

The cost per square foot of floor was 3.71 cts. and the contract price was 3¾ cts.

Cost of Concrete Arch and I-Beam Power House Floor.—The following itemized account of the cost of a floor built in a power house in Lincoln Park, Chicago, in 1909 is taken from Engineering and Contracting, March 15, 1911.

The floor was 20 × 25 ft. in area and was made of 10-in. I-beams, spaced 5 ft. on centers. The concrete was 11 ins. thick at the beams and was arched between the beams so that the thickness of the concrete was 5 ins. at the crown of the arch. The area of the floor was 500 sq. ft., but a stair space reduced the area of concrete placed to 475 ft. The total cost was $208.

	Per sq. ft.
Labor:	
2 days engineering at $3.70	$0.0156
1 day superintendent at $3.25	0.0069
15 days labor at $2	0.0631
13½ hrs. finishers at 28 cts	0.0079
64 hrs. carpenters at 60 cts	0.0808
4 hrs. mason	0.0053
Total	$0.1796
Materials:	
Lumber	$0.0526
10-in. I-beams	0.1053
17½ bbls. cement at $1.35	0.0479
10 cu. yds. gravel at $1.65	0.0347
6 cu. yds. torpedo sand at $1.35	0.0170
Total	$0.2575
Grand total	$0.4371

Cost of Concrete Balcony Floors of the Lockport Power House, Chicago Drainage Canal.—In Engineering and Contracting, May 25, 1910, L. K. Sherman gives the following.

The work was done by day labor and consisted of placing the concrete in two balconies, one above the other, 359 ft. long by 26.5 wide. The steel frame and columns of the balcony floors was erected by contract.

Fig. 10 shows a section of the floor, which is composed of concrete arches covering the spans between the 18-in. I-beams and supported by the lower flanges of the I-beams. The floor arches were 5 ins. thick at the crown, with elliptical intrados. The concrete was mixed in the proportion of 1 part Portland cement, 2½ parts limestone screenings under ⅛-in. size, and 4½ parts crushed stone ranging from ¼ to 1¼ ins. The floor surface was made with a "granolithic" finish of mortar composed of 1 part cement to 2 parts torpedo sand, placed from 1 in. to 1½ ins. thick. The granolithic surface was invariably placed before the concrete had an initial set, although this required night work of the finishers at times. Contraction grooves were cut in the floor above each I-beam.

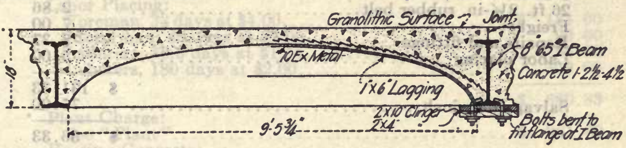

FIG. 10.—Section of balcony floor showing forms, Lockport Power House.

Concrete and Finishing.—The mixed concrete (1-2½-4½) was purchased from the general contractor for the power house at $5 per cu. yd. at the mixer.

The concrete was hauled from the mixer to the elevator in a 1½ cu. yd. Western dump car. The car was hoisted to the balcony floor, run out on a short piece of track and dumped on a receiving platform. The empty car then returned to the mixer. Concrete was carried from the receiving platform and placed in the work with wheelbarrows.

The mortar for granolithic surface was mixed in a box near the receiving platform. The cement finishers followed immediately after the concrete gang. The expanded metal reinforcement was placed on the forms and covered uniformly with about 2 ins. of soft concrete. The expanded metal was then pulled up from the form with hooks and shaken slightly, so that the mortar ran through the mesh and kept the reinforcing about 1 in. away from the lower surface.

The remaining concrete was then tamped in place. Some reinforcing bars were used about the floor openings. The work was done in February, March and April, 1907. Common labor received 17½ cts. per hour in February and March and 20 cts. per hour in April. During freezing weather heat was supplied with four salamanders burning coke. These fires were placed under the section of new concrete floor and canvas curtains were hung around, so as to confine the heat to the required section.

A typical force during the period of placing concrete work was as follows:

1 Foreman.
1 Motor man.
1 Car man.
1 Carpenter on reinforcing and minor form fitting.
1 Laborer on reinforcing and minor form fitting.
12 Laborers, wheeling and placing concrete.
2 Cement finishers on granolithic surface.
1 Mortar mixer on granolithic surface.
2 Mortar wheelers on granolithic surface.

Cost.—The cost of the work is given in the accompanying itemized tabulation. The total cost was \$7,827.50, or 42¾ cts. per square foot. The engineer's estimate was \$8,128. The only bid received was \$11,000.

PLANT

Elevator:	
Cage	\$ 44.00
Guides, lumber	37.62
400 ft. ½-in. wire rope and fittings	26.25
3 16-in. sheaves	26.40
1 ½-in. snatch block	12.00
Labor	43.55
	\$ 189.82
Hoisting winch:	
1 Shannon double purchase winch	\$ 100.00
1 42-in. wood pulley	8.10
26 ft. 2½-in. rubber belt	2.86
Freight	7.00
Repairs and fittings	8.37
Labor placing	5.00
	\$ 131.33
Salvage on winch	75.00
	\$ 56.33
Electric motor:	
Rent of motor 2 hp. 220-volt D. C.	\$ 25.94
Labor placing	5.71
Labor electrician	20.00
	\$ 51.65
Electric Current: 6 cts. hp. hour	76.58
Track:	
Rent of 300 lin. ft. rail 30-lb	\$ 25.00
Labor on track	28.38
	\$ 53.38
Grand total	427.76
Distribution of plant charge:	
To concrete \$427.76 × 85 % =	\$ 361.60
To granolithic surface \$427.76 × 15 % =	66.16
Total	\$ 427.76

COST OF BALCONY FLOORS

Forms:	
Lumber:	
11,000 B. M. 1 × 6-in. D. & M. lagging at \$25.00	\$ 275.00
2,220 B. M. 2 × 10-in. S. I. S. stringers at \$30.00	66.60
1,500 B. M. misc. rough lumber	28.19
316 ribs for 10-ft. span at 66 cts	208.56
99 ribs for 8-ft. span at 62 cts	61.38
48 ribs for 4-ft. span at 50.9 cts	24.42
	\$ 664.15
Bolts, tools etc.:	
1,000 ¾-in. hook bolts at 8 cts	\$ 80.00
9 kegs nails	24.58
Sheet iron	15.15
Tools	9.85
	\$ 129.58
Total form materials	\$ 793.73

Labor:	
Building and Moving Forms:	
Foreman, 29 days at $4.00	$ 116.00
Carpenters, 39.5 days at $4.50	177.75
Carpenters, 51.1 days at $3.50	178.85
Carpenters, 110.2 days at $3.00	330.60
Laborers, 66 days at $1.75	115.49
Laborers, 17.3 days at $2.00	34.60
Craneman, 1 day at $2.50	2.50
	$ 955.79
Total, Forms	$1,749.52
Concrete:	
470 cu. yds. concrete mixed material in car at mixer at $5.00	$2,350.00
Tools	56.61
	$2,406.61
Labor Placing:	
Foreman, 33 days at $4.00	$ 132.00
Motorman, 45 days at $2.00	90.00
Laborers, 56.5 days at $1.75	98.83
Laborers, 180 days at $2.00	360.00
	$ 680.83
Plant Charge:	
See "Plant"	$ 361.60
Heating Concrete:	
4 Salamanders	$ 11.00
2,450 lbs. coke	12.24
6 12 × 30-ft. tarpaulins	54.60
	$ 77.84
Concrete total	$3,526.88
Reinforcing:	
19,734 sq. ft. 3-in. No. 10 expanded metal at 3 cts.	$ 592.02
330 lbs. ½-in. cor. bars at 3 cts.	10.51
585 lbs. ¾-in. rods at 2½ cts.	14.63
Cutter and sledge	1.89
	$ 619.05
Labor:	
1 day, cement foreman at $5.00	5.00
11 days, cement foreman at $3.50	38.50
2 days, motorman at $2.00	4.00
7.6 days, laborer at $2.00	15.28
	$ 62.78
Reinforcing total	$ 681.83
Granolithic surface:	
Materials:	
260 bbls. cement at $1.72	$ 447.20
Cement hauling	21.33
90 cu. yds. sand torpedo	56.90
Sand freight	149.17
Tools	8.24
	$ 682.84
Labor:	
Cement finisher, 25.1 days at $5.00	$ 125.50
Cement finisher, 38.35 days at $3.50	134.22
Cement finisher, 20.05 days at $3.00	60.15

Cost of 2-In. Solid Metal Lath Partitions.—The following data by A. Dixon are given in Engineering and Contracting, Jan. 18, 1911.

The figures on plastering are the amount of completed three coat work which one man can do in one hour and are based on the average of a gang of men and the total time required to apply three coats on a given area.

	12-in. stud centers	16-in stud centers
Steel channels, weight lb. per sq. yd	4.25	3.00
Erecting channels, sq. yds. per hour	6.0	9.0
Metal lath, applying, sq. yds. per hour	6.5	8.25
Plastering, three coats, sq. yds. covered per hour	1.25	1.25

Cost of Metal Lathing and Plastering.—The following data are published by A. Dixon in Engineering and Contracting, Feb. 1, 1911.

Applying metal lath on wooden studs: An expert on straight work will put on 12.5 to 17.0 sq. yds. per hour. On crooked or complicated work the same man will put on 5 to 7 sq. yds. per hour.

Applying metal lath on steel studding: One man will put on from 5 to 9 sq. yds. per hour.

Plastering on metal lath: First coat, from 9 to 14 sq. yds. per hour; second or scratch coat, 6 to 9 sq. yds. per hour; finishing coat, 11 to 14 sq. yds. per hour.

Cost of Laying Composition and Gravel Roofs.—H. Lundt, a roofing contractor (*Engineering and Contracting*, Apr. 12, 1911), states that the cheapest composition roof is 3-ply tar and gravel, using 45 lbs. of saturated felt, 70 lbs. of tar and pitch, ⅛ yd. of screened gravel, and lath and nails at a total cost for material of $1.50 per square, (10 × 10 ft.). The labor cost of the work varied from $0.40 to $1 per square, depending upon the number of squares in each job. It requires 4 men to each gang of roofers, common labor receiving 25 cts. and skilled labor 50 cts. per hour. This would make the total cost of a 3-ply composition roof with tar and gravel from $1.90 to $2.50 per square. This roof, for ordinary uses, will last from 5 to 8 years.

A better roof is a 4-ply composition roof laid in the same manner as a 3-ply, but having one extra ply or 15 lbs. more of saturated felt and 30 lbs. more of composition which will make the total cost from $2.50 to $3.00 per square. This class of roof will easily last 10 years.

The next better roof is the solid mopped roof with a cap sheet over the 4-ply, laid as follows: Each of the 4 layers of felt is mopped over the entire surface and laid 8 ins. to the weather. The entire surface is then covered with a cap sheet which is coated with the hot pitch compound. In this way every seam of the four layers is covered. Over all, the pitch and tar and screened gravel is laid. I have one of these roofs which has been laid 14 years without recoating. The cost of labor and material on this class of roof is $4 per square. The material used per square is 75 lbs. of saturated felt, 150 lbs. of composition, ⅛ cu. yd. of screened gravel and lath and nails.

Any of the foregoing roofs can be laid with asphalt in the same way that the tar and pitch composition is used. This will increase the cost from $0.75 to $1 per square. I put on some of these roofs 10 years ago and they are in good condition today. Asphalt retains its life, but the tar and pitch crumble to dust and require a recoating after about 5 years. The cost of recoating is about $1.50 per square. In recoating, all the loose gravel is swept off and the felt is cleaned of dirt and dust. Then the composition is placed with not less than 60 lbs. to the square.

Unit Costs of Factory Buildings.—A paper by W. E. King before the Civil Engineers Society of St. Paul (Engineering and Contracting, Aug. 5, 1914) gives the following:

One story shop building in fireproof construction will cost from $1.25 to $2.00 per sq. ft. depending upon the height of the story, depth of footings, length of spans and kinds of exterior finish used. Fireproof buildings of more than one story may be built for as little as 50 cts. per sq. ft. of floor area.

TABLE XX.—SOME COSTS OF DIFFERENT TYPES OF CONSTRUCTION

Item	Description	Approximate cost per sq. ft. in place
Roofs*		
Fireproof:		
	1. 3-in. hollow book-tiles laid on steel T-beams, covered with good prepared roofing; including supports	$0.30
	2. Corrugated iron on steel purlins including supports	0.12
Non Fireproof:		
	3. 2-in. matched and dressed sheathing laid on wood or steel purlins, covered with good prepared roofing, including supports	0.20
Walls	12-in. common brick	0.38
	12-in. with facing brick and some architectural decorations	0.40–0.60
Sash	Underwriters, glazed with ¼-in. wire glass	1.00
	Rolled steel sash glazed with double strength glass	0.40–0.45
	Double hung wooden sash	0.25–0.50
Sprinkler Protection		
	Cost per sq. ft. of floor area covered	0.05–0.15

* Types 1 and 3 suitable for heated buildings; type 2 suitable for unheated buildings.

Formulas for Weights of Steel Roof Trusses.—R. Fleming (Engineering News-Record, March 20, 1919) has brought to a common notation many of the empiric formulas for determining the weights of steel roof trusses.

The notations used follow:

T = weight of truss = WSD;

W = weight of truss in pounds per square foot of the horizontal projection of that portion of the roof supported by one truss;

S = span or distance between centers of supports in feet;

D = distance between centers of adjacent trusses in feet;

P = loading of truss in pounds per square feet of horizontal projection of roof;

U = allowable average direct stress in pounds per square inch (found only in the Thayer formula).

The following list includes the formulas most commonly quoted:

Cambria Steel Co., "Cambria Steel," 11th edition, 1914, for spans of 75 ft. or less.

$$T = 5SD$$

Carnegie Steel Co., "Pocket Companion," 19th edition, 1917, for loads of 40 lb. or more per square foot of ground area:

$$W = \frac{P}{40} \times \frac{1}{5}\left(\sqrt{S} + \frac{S}{8}\right)$$

Fowler, "Specifications for Steel Roofs and Buildings," 5th edition, 1909, for Fink trusses up to 200-ft. span:

$$W = 0.06S + 0.6 \text{ for heavy loads}$$
$$W = 0.04S + 0.4 \text{ for light loads}$$

Johnson, Bryan and Turnure, "Modern Framed Structures," early editions: $W = S/25 + 4.0$. In the latest edition, 1916, the Ricker, 1907, formula is used for trusses resting on brick walls, and the Ketchum formula for trusses of steel-frame buildings.

Jones & Laughlin, "Standard Steel Construction," 1916:

$$W = \frac{P}{40}\left(\frac{S}{20} + \frac{12}{D}\right)$$

Ketchum, "Specifications for Steel-Frame Buildings," 3rd edition, 1916 for trusses up to 150-ft. span:

$$W = \frac{P}{45}\left(1 + \frac{S}{5\sqrt{D}}\right)$$

Maurer, "Cyclopedia of Civil Engineering," 1908:

$$W = S/25 + 1$$

Merriman, "Roofs and Bridges," 1888, 1911:

$$T = \frac{3}{4}DS\left(1 + \frac{S}{10}\right)$$

Ricker, "A Study of Roof Trusses," University of Illinois Bulletin, No. 16, August, 1907:

$$W = \frac{S}{25} + \frac{S^2}{6000}$$

Ricker, "Design and Construction of Roofs," 1912:

$$W = \frac{S}{25} + \frac{S^2}{12,600}$$

Thayer, "Structural Design," Vol. II, 1914:

$$T = \sqrt{\frac{PD}{U}} (4S^2 + 60S)$$

Trautwine, "Engineer's Pocket Book," 1911:

$$W = (0.05 \text{ to } 0.08)S$$

Tyrrell, "Mill Buildings," 1911, for roof load of 40 lbs. per square foot of ground area, bays 10 to 20 ft., rafter slope 6 ins. to 1 ft. and unit stresses of 12,000 compression, 15,000 tension:

$$W = \frac{S}{20} + \frac{12}{D}$$

The weights of trusses for other loadings and rafter slopes are obtained from a series of curves.

Conclusions regarding empirical formulas drawn from estimated weights of several hundred trusses may prove interesting. Three light Fink trusses resting on brick walls of 40-, 60- and 80-ft. spans, bays 16 ft., load equivalent to 40 lbs. per square foot of horizontal area uniformly distributed on the top chord, roof slope 6 ins. per foot, weighed 1,370, 2,550 and 4,320 lbs., respectively. The estimated weights of three trusses of the Warren type, same span and loading, but roof slope of 1 in. per foot, were 1,500, 2,900 and 4,800 lbs. The weights, according to the formulas quoted, for trusses with same spans and loading, are given in Table XXI.

Table XXI.—Weights of Roof Trusses—16-foot Bays; Load, 40 Lbs. Per Square Foot of Horizontal Area

W = Weight per square foot of area; T = Weight of truss

Formula	40-ft. span W	40-ft. span T	60-ft. span W	60-ft. span T	80-ft. span W	80-ft. span T
Cambria	5.00	3,200	5.00	4,800	5.00	6,400
Carnegie	2.26	1,446	3.05	2,928	3.79	4,851
Fowler	2.00	1,280	2.80	2,688	3.60	4,608
Johnson B. & T.	5.60	3,584	6.40	6,144	7.20	9,216
Jones & Laughlin	2.75	1,760	3.75	3,600	4.75	6,080
Ketchum	2.67	1,709	3.56	3,417	4.44	5,683
Maurer	2.60	1,664	3.40	3,264	4.20	5,376
Merriman	3.75	2,400	5.25	5,040	6.75	8,640
Ricker 1907	1.87	1,197	3.00	2,880	4.27	5,466
Ricker 1912	1.73	1,107	2.68	2,573	3.71	4,749
Thayer	2.75	1,760	3.75	3,600	4.75	6,080
Trautwine	2.00	1,280	3.00	2,880	4.00	5,120
Tyrrell	2.75	1,760	3.75	3,600	4.75	6,080

Again, three Fink trusses of the same span, spacing and slope as before, but with load of 56 lbs. per square foot of horizontal projection, an increase of 40%, weighted 1,670, 3,200 and 5,500 lbs., respectively. Trusses of the Warren type, roof slope of 1 in. to 1 ft., weighted 1,900, 3,750 and 6,000 lbs. The formulas give weights for this loading as in Table XXII.

The variation—in some cases more than 100 per cent—of weights obtained from the different formulas will at once be noted. The values obtained from a number of the formulas depend upon the span length alone, and are the same for all loadings. Other formulas make the weight of the truss vary directly as the load, which actual weights show to be an error. DuBois, in "The Strains in Framed Structures," gives a formula taking into account the load, span, slope and unit stresses, but it is too cumbersome for use. Moreover, it supposes the chords to be of constant section, and neglects the web members, assuming that these two errors compensate.

TABLE XXII.—WEIGHTS OF ROOF TRUSSES—16-FOOT BAYS; LOAD, 56 LBS. PER SQUARE FOOT OF HORIZONTAL AREA

W = Weight per square foot of area; *T* = Weight of truss

Formula	40-ft. span *W*	40-ft. span *T*	60-ft. span *W*	60-ft. span *T*	80-ft. span *W*	80-ft. span *T*

In fact, as stated by Marburg, in "Framed Structures and Girders," the variables are so numerous that no formula, for the weights of roof trusses which is at once simple, accurate and generally applicable, can be devised. Such a formula is not necessary. In calculating stresses the weight of the truss is usually so small compared with the weight of the covering, the snow and the wind, that an error in its assumption is negligible.

Ordinary steel roof trusses on brick walls with roof slope of 6 in. to 1 ft. and an assumed load of 800 lbs. per linear foot of top chord, uniformly distributed, weigh from 30 to 75 lbs. per linear foot of span for spans up to 85 ft. For less slopes the weight may be from 5 to 25% more. For different loadings the variation in weight is usually from 25 to 75% of the variation in loading. It should be noted that the personal equation of the designer and the many factors entering into the weights of roof trusses may cause a variation of 5 to 25% in the same truss.

Formula and Table of Weights Steel Roof Trusses.—Marshall L. Murray gives the following data in Engineering and Contracting, June 25, 1919.

In the preparation of designs for steel-roof trusses for preliminary estimates for factory buildings, after several designs had been prepared and lists of material and estimates of cost had been made, the data on hand were used in several formulas for giving the weights of steel-roof trusses, in order to find one which would give results closely agreeing with the figured weights. If such a formula could be found it was intended to use it for purposes of preliminary estimates instead of taking time to prepare a design. But no one formula gave results which were considered satisfactory. It was observed that the Ricker formula

$$W = \left(\frac{S}{25} + \frac{S^2}{6{,}000}\right) SA,$$

gave results which were too low and the Ketchum formula,

$$W = \frac{P}{45}\left(1 + \frac{S}{5\sqrt{A}}\right) SA,$$

gave results too high to agree closely with our design data. In these formulas W equals total weight of truss; S equals span of truss in feet; A equals distance center to center of trusses in feet; P equals carrying capacity of truss in pounds per square foot of horizontal projection of roof.

After carefully studying the formulas and reading the explanation of the Ricker formula in University of Illinois Bulletin No. 16, and that of the Ketchum formula in the author's text book on Steel Mill Buildings, it occurred to the writer to combine the two formulas, thereby making use of the span factors in the Ricker formula and the center to center of truss factor and the variable load factor in the Ketchum formula. From the bulletin it seemed the carrying capacity of the trusses upon which the Ricker formula was based was about 50. Therefore the results obtained by using the data on hand with the Ricker formula were increased in the ratio of $\frac{P}{50}$, since the Ricker formula does not take into account the variable load P. These weights were then averaged with those obtained by the Ketchum formula, which considers the variable load P, and the final results agreed quite closely with the data on hand. The tentative formula then became

$$W = \left[\frac{\frac{P}{50}\left(\frac{S}{25} + \frac{S^2}{6{,}000}\right) + \frac{P}{45}\left(1 + \frac{S}{5\sqrt{A}}\right)}{2}\right]SA$$

For trial calculation the two factors $\frac{P}{50}$ and $\frac{P}{45}$ were averaged and made the same for both formulas. Then

$$W = \frac{1}{2} \times \frac{P}{47.5}\left(\frac{S}{25} + \frac{S^2}{6{,}000} + 1 + \frac{S}{5\sqrt{A}}\right)SA$$

After several trials with the slide rule the variable load factor was made $\frac{P}{92}$ instead of $\frac{P}{2 \times 47.5}$ or $\frac{P}{95}$, so as to agree with the figured weights. Therefore the formula finally derived was,

$$W = \frac{P}{92}\left(1 + \frac{S}{25} + \frac{S^2}{6{,}000} + \frac{S}{5\sqrt{A}}\right)SA$$

In order to try out the above formula it was applied to all trusses upon which we had the necessary data, and to others used as examples in text books and the results were remarkably close to the weights obtained from material lists. After finding that the formula was worth while the writer prepared the accompanying table to simplify its use. This was done by making P equal to unity and calculating the value of W for a series of values given to S and A. It will be noted this reduced to a simple multiplication the calculation necessary to find the weight of the steel roof truss, having given the span, distance center to center of trusses, and the carrying capacity of truss. The writer has found this table to be very useful and quite reliable in preparing preliminary estimates, and even as a check on weights figured from a design.

WEIGHTS OF STEEL ROOF TRUSSES

The table gives weight of truss for a capacity of 1 lb. To find total weight of truss, multiply value in table by capacity of truss in pounds = P.

	Span of truss in feet: Out to out of bearings = S																		
A*	20	25	30	35	40	45	50	55	60	65	70	75	80	85	90	95	100	110	120

For general purposes, P = 60 lb.

* Distance C. to C. of trusses in feet = A.

Cost of Private Fire Protection Installations for Industrial Plants.—The following data are given by Leonard Metcalf in a paper before the American Water Works Ass'n. in 1913, abstracted in Engineering and Contracting, July 23, 1913.

A cotton mill having a value in buildings and machinery as follows:

Buildings, including foundations	$ 400,000
Machinery, engines, boilers, shafting, electrical and steam fittings, elevators, etc	900,000
Cost of mill	$1,300,000
Cost of fire protection equipment for this mill:	
Underground piping	2,600
Indicator post gates, valves, check valves, hydrants, etc	1,000
Fire pumps (2)	2,500
Suction supplies	1,000
Hose, hose houses, watchman's system and fire alarm	1,700
Automatic sprinklers and all inside piping	16,000
	$ 24,800
If suction reservoir has to be built, add	3,000
Total cost of fire protection equipment	$ 27,800

This is equivalent to 2.1 per cent of cost of buildings and machinery.

2nd: A smaller plant, where cost of protection is of necessity larger in proportion to cost of mill equipment:

Buildings, excluding foundations	$ 70,000
Machinery, etc., same as above	100,000
	$ 170,000
Cost of fire protection, as items above	6,200

This is equivalent to 3.7 per cent of cost of the buildings and machinery.

In these examples, if elevated tanks or reservoirs had been necessary, the fire protection would have been increased in cost correspondingly. They represent, however, fairly typical cases, but oftentimes difficult conditions add to the estimated cost further amounts from 15 to 20 per cent.

In general the cost of the fire protection equipment will be from 3 to 5 per cent of cost of the mill property.

The operating charges upon such an installation as that cited in the first illustration given above might be as follows:

	Per cent
Interest	6
Depreciation	2
Repairs	3
Supplies and miscellaneous	1½
Coal for use on Sundays and holidays	½
Extra labor on Sundays and holidays	½
Total	13½
Add administration and overhead charges	1½
Grand total upon the cost of the fire protection system	15

This would upon the cost of the fire equipment amount to approximately $4,170. If now the mutual insurance rate upon this property be added amounting to approximately 7 cts. per $100 of risk, or $910 per year, the total cost of the fire protection service and insurance, excluding the payment to be

Cost of alternate water supply (1,500-gal. pump installed in separate pump house, also suction reservoir)	$ 3,500	$ 3,500	$ 3,500	$ 3,500	No city water	No city water

* Maintenance includes cost of night watchman; this service is taken in consideration in fixed final rate. Average yearly cost of maintenance, excluding watchman, is from 2 to 4 per cent of cost of system. (B) Stands for Building, (C) for Contents.

made to the waterworks for the water service, would amount to $5,080. Without the sprinkler service the rate upon such property in the stock insurance companies might be $1 per $100 of risk, in which case the saving effected would amount to approximately $8,000 per year. If the rate given by the stock companies were less than $1 per $100 of risk, the saving would be correspondingly reduced. It is probably safe to say, however, that the equipment would be paid for by the saving in insurance in a period of not over five to six years, if nominal charge only be made by the waterworks for the service rendered by it to the mill.

Data on Erection of Cantonment Buildings.—The following data on the construction of buildings at Camp Meade, Md., are abstracted in Engineering and Contracting, June 26, 1918, from a paper presented to Western Society of Engineers by N. B. Garver.

The construction of the buildings for training battalions designated as Regiment AA was determined upon Friday, Sept. 21. They consisted of:

32 2-story barracks, 30 by 60 feet.
8 1-story mess halls, 20 by 147 feet.
4 1-story officers' quarters, 20 by 133 feet.
1 2-story medical building, 20 by 119 feet.
2 1-stoıy store houses, 20 by 98 feet.
2 stables, 29 by 40 feet.
2 wagon sheds, 29 by 18 feet.
A total of 51 buildings.
The material required was:
2,108 posts.
1,490,000 ft. of yellow pine lumber
321,000 sq. ft. of building paper.
152,000 sq. ft. of roofing.
3,838 window sash.
304 doors.
136,400 sq. ft. of wall board.
782 sq. ft. of brick hearth.
30,514 pounds of nails.
2,184 lin. ft. of mess tables with seats were constructed.
1,600 lin. ft. of fire ladders were erected.

The hauling of posts, lumber, and other materials was begun on Saturday, Sept. 22. Actual construction began on Sunday, Sept. 23. A 10-hour workday was observed. Lumber erection was completed and the buildings were finished at 6 p. m., Oct. 2. Ten days, or 100 hours, was required to complete the 51 buildings of this regiment. Fifteen thousand feet of lumber was erected each working hour, and a building was completed every two hours.

The number of carpenter and labor hours required to complete each stage of construction of a 200-man barrack is as follows:

			Lumber ft. B. M.
Foundation posts	Carpenters	20 hrs.	
	Laborers	60 hrs.	1,000
Framing complete	Carpenters	375 hrs.	
	Laborers	72 hrs.	20,700
Sub-floors and roof	Carpenters	390 hrs.	
	Laborers	50 hrs.	19,400

Trim—			
Finished floors.			
Wainscoting.			
Inside and outside stairs.			
Doors	Carpenters	530 hrs.	
Sash	Laborers	85 hrs.	25,000
Partitions.			
Tables.			
Counters.			
Screening.			
Outside sheathing	Carpenters	450 hrs.	
	Laborers	40 hrs.	5,900
Wall board	Carpenters	320 hrs.	
	Laborers	40 hrs.	
Roofing felt	Carpenters	70 hrs.	
	Laborers	20 hrs.	
Undersheathing and ladders	Carpenters	60 hrs.	2,000
	Laborers	15 hrs.	
Total			74,000

Total carpenter hours on lumber erection, 1,825.
Total labor hours on lumber erection, 322.
Lumber erected per carpenter per day, 407 ft. B. M.
Carpenters received 62½ cts. per hour and laborers 30 cts. per hour.

Cost of Constructing a Camp to Accommodate Forty Laborers.—In Engineering and Contracting, July 2, 1913, Clark A. Bryan gives the following. The camp was built during the summer of 1912, to accommodate laborers employed on the construction of sewerage system and disposal plant at Ridgely, Md., and consisted of store and dining room, bunk house, cook shed, toilet and well. The following matter is taken from Mr. Bryan's article.

Store and Dining Room.—The building itself is 36 × 16 ft. in plan and is built with a gabled roof. The height from the top of the floor to the top of the plates is 7 ft. 3 ins. and the height of the gable is 4 ft. 6 ins., making the total height of the ridge 11 ft. 9 ins. above the floor. This building is divided into two rooms sized 11 ft. 6 ins. and 24 ft. 6 ins. respectively, the former being used as a store and the latter for a dining room. The sills were made of 4 × 6 in. lumber. The four corner posts were made of 3 × 4 in. material and the intermediate posts, of which there were two on each of the long sides, were spaced 11 ft. 6 ins. from each end of the building and were made of the same sized material. These upright 3 × 4 in. posts were all mortised into the plate, which was made of 4 × 4 in. material. To further brace the building a piece of 2 × 4 in. was run completely around the building between the uprights at a height of 3 ft. above the floor. The building was braced in the direction of its short dimension by running a piece of 2 × 4 in. material from the top of one of the intermediate posts to the top of the opposite post, these braces being set flush with the top of the plate. The rafters were nailed to the plate and were made of 2 × 4 in. material. There were 19 rafters on each side of the ridge and they were 10 ft. long, thereby overhanging the sides of the building by about 8 ins. To finish off the exposed ends of the rafters a piece of 1 × 5 in. material was nailed over their ends as a sort of trim. The purlins were laid at right angles to the rafters and nailed to them. They were spaced 1 ft. 6 in. on centers and a 1 × 3 in. lathing was used for this purpose; at the ridge four of these laths were used. For a roof corrugated iron weighing 115 lbs. per square was used and this was nailed directly to the purlins. By this method of construction a roof was built which provided plenty of ventilation, inasmuch as it was not tightly sheathed at the sides of the building, and yet rain could not enter the building through this space. The joists were 16 ft.

long and were made of 2 × 8 in. material; they were notched 3 ins. on the sills and a 1-in. floor was laid on them. The joists were spaced 1 ft. 6 ins. on centers. The sides were built of 1-in. rabbeted barn boards 10 ins. wide. A solid partition of this same material was built across the building, dividing it into two rooms 11 ft. 6 ins. and 25 ft. 6 ins., respectively. There were five windows each 2 ft. 6 ins. × 2 ft., and having six lights; four of these windows were in the dining-room or larger compartment and one in the store room. Three doors, each 2 ft. 9 ins. × 7 ft., were built, one being in the dining room and two in the store room. Table XXIV gives the bill of materials and cost of constructing this building.

Table XXIV.—Bill of Materials and Cost of Constructing Dining and Store Building for Workman's Camp

Items and size	Rate	Cost
104 lin. ft. sills, 4 × 6 ins.	$0.05	$ 5.70

1 padlock	0.28	0.28
112 lin. ft. trim. 1 × 5 ins.	0.035	3.92
Total cost of materials		$135.28
Labor:		
14 hrs. foreman carpenter	$0.275	$ 3.85
66 hrs. carpenter	0.22	14.52
41.5 hrs. carpenter's helper	0.17	7.06
Total cost of labor		$ 25.45
Total cost of building		160.73

Bunk House.—This building is 50 × 14 ft. in plan and is built with a sloping roof. The building is placed with the long dimension parallel to the road leading to Ridgely and the height of the side facing this road is 9 ft. 6 ins., while the height of the rear is 6 ft. 6 ins. The house is divided into five compartments, each of which was designed to accommodate eight men. The sills were made out of 4 × 6-in. lumber, the four corner posts were made out of 3 × 4-in. material. The upright posts along the front and rear of the building were spaced 10 ft. on centers and made of the same sized material. The plate, which consisted of 2 × 4 in. material, was spiked to the tops of these uprights. The rafters rested on the plate and were spiked to it and were of 3 × 4-in. material. They were 16 ft. long and were spaced 2 ft. on centers, and overhung the sides of the building about 8 ins. As in the other building 1 × 3-in. lathing was used for purlins and spaced 1 ft. 6 ins. on centers. The roof was of corrugated iron weighing 115 lbs. per square and was nailed directly to the lathing. To finish off the ends of the rafters they were covered on the front and rear of the building by 5-in. dressed boards. By this method of construction a fresh air inlet 4 ins. high was provided along both front and rear of the building, yet rain could not enter through this space. This building was braced in a manner similar to that employed in the construction of the building previously described with the exception that the 2 × 4-in. braces running from the top of the plates were run level from the top of the rear plate and were spiked at the front to a piece of 2 × 4-in. material. The joists, floors and sides of this building were constructed as in the other and need no further comment. As stated, this building was divided into five compartments, each of which was 10 ft. wide, the compartments being separated by partitions of barn boards and each partition 6 ft. high. Each compartment was provided with a door placed at the front of the building, also with two windows, one in front and over the door, and the other at the rear. In this way complete ventilation of the building was obtained. Against each side of each compartment two tiers of bunks were built. The bunks were 3 ft. wide and extended the 14-ft. dimension of the building. The bottom tier of bunks

TABLE XXV.—BILL OF MATERIAL AND COST OF CONSTRUCTING BUNK HOUSE FOR WORKMAN'S CAMP

24 hours foreman carpenter	$0.275	$ 6.60
95 hours carpenter	0.22	20.90
34 hours carpenter helper	0.17	5.95
Total cost of labor		$ 33.45
Total cost of building		210.73

was about 1 ft. above the floor, while the upper tier rested on the 2 × 4-in. brace that extended around the building. The bunks were supported at the center by means of a trestle consisting of two 2 × 4-in. posts 6 ft. long and spaced 6 ft. apart. The tops of these posts were connected by a piece of 2 × 4-in. material running longitudinally of the building, and were further braced by running 2 × 4-in. braces from the top of the rear plate over each post and spiking this brace to a piece of 2 × 4-in. material that ran across the front of the building. Nailed to these 2 × 4-in. posts and at heights of about 1 ft. and 3 ft. above the floor, respectively, were two pieces of 2 × 4-in. material 6 ft. long and upon these the bunks rested. The bunks were made of 1-in. barn board. Table XXV gives the bill of material used in the construction of this building and the cost of construction.

Cook Shed.—The shed provided for cooking purposes consisted simply of four upright posts about 7 ft. high, supporting a corrugated iron roof 12 ft. square. Under this shed the brick ovens used by the men to cook their food were prepared. The cost of constructing this shed is shown by Table XXVI.

TABLE XXVI.—COST OF COOK SHED

Items and size	Rate	Cost
40 lin. ft. corner posts 4 × 6 ins	$0.05	$ 2.00
Other lumber	......	1.00
144 sq. ft. corrugated iron roofing	0.046	6.63
Total cost of materials		$ 9.63
Labor:		
7 hours carpenter	$0.22	$ 1.54
Total cost of shed		$11.17

The toilet was built along lines typical of out-of-door toilets. It was 4 ft. square and was not roofed over. The total cost of the closet was $2.85. The following is a summary of the total cost of camp:

Combined dining room and store	$160.73
Bunk house or sleeping quarters	210.73
Cooking shed	11.17
Toilet	2.85
Well	10.55
Straw for bedding	5.00
Total cost of camp	$401.03

After the construction work on the sewer system had been finished the town of Ridgely purchased the building used as dining-room and store and remodeled it and made it into a barn. The bunk house and also the well were sold, the total amount received from these sales being $312.98 making the net cost of building the camp $88.05. As the camp was in use for a period of about eight months the net cost per month amounted to about $11.

The first cost of the camp, including a well for water supply and other accessories was $10 per man accommodated. The dining and store building cost just under 30 cts. and the bunk house just over 30 cts. per square foot of area.

Data on the Erection of Steel Work of the Shops of the Lima Locomotive Corp., Lima, Ohio.—Engineering News, May 7, 1914, gives the following:

The steelwork conforms in the Manufacturers Standard Specifications. It was given two coats of graphite paint, one applied in the shop and the other after erection.

All steel erection was done with four traveling stiff-leg derricks of 50 tons hoisting capacity, carrying booms 100 ft. long. These were of steel construction and the booms were long enough to place the roof trusses and monitor roof framing. The book tile for the roof of the erecting shop were handled by a platform elevator in the timber tower at the middle of the building. The steel gang numbered about 85 men. Work was commenced on Jan. 12 and completed Mar. 8, 1913. The tonnage and time of erection of the several steel buildings were as follows:

Building	Tons	Time of erection
Erecting shop	1200	26 days
Boiler shop	225	10 days
Smith shop	260	8 days
Hammer shop	253	6 days
Tank shop	300	7 days
Coal-pulverizing plant	20	10 days
Riveting tower	12	7 days

Cost of Erecting a Large Steel Dome.—In Engineering News, Mar. 8, 1917, M. Van Meter gives the following:

The 92-ft. dome of the Wealthy St. Baptist Church, Grand Rapids, Mich., has a steel frame formed by eight main arch members 35 ft. in span, with 19-ft. rise, framing into an octagonal crown diaphragm, 22 ft. wide across the points. The arches are tied together at the heel by four trusses and four sets of angle ties. This is because that portion of the building under the dome is square, and a part of the roof load is carried by the ties in alternate bays.

The arches are 2 ft. deep at the top and 5 ft. at the outer extremity. Three lines of beams parallel to the base ties carry the wooden ceiling and roof joists. The lateral bracing consists of a system of rods together with a line of struts in the center of each bay at right angles to the roof beams. A steel monitor frame 8 ft. high surmounts the structure.

The erection procedure was as follows: A derrick of the required height was raised, and the eight sides of the diaphragm were riveted up around its base. With two sets of blocks, the ring was raised to the final elevation, 45 ft. above the floor, and light timber falsework placed underneath. The arches were raised with a gin pole, bolted in place, and the base ties erected. The roof beams, struts and rods were then placed, rivets driven and supports removed. The entire job was completed without a mishap, the one anxiety being caused by the extraordinarily high winds that prevailed after the diaphragm was raised and before the timber falsework was finished.

The shop cost of this contract was $25 and the erection cost $28 per ton, with labor at 50 cts. per hour in each case.

Cost of Erecting Steelwork for an Armory Having Three-Hinged Arches.—The following data, taken from an article in Engineering and Contracting, Aug. 6, 1913, refer to the armory building of the University of Illinois.

When completed, this structure will have a clear drilling space of about 200 ft. by 390 ft. In 1913 the two end bays were not built, owing to a lack of appropriations. The width of the portion built is 206 ft., center to center of end pins, the length is 338 ft. center to center of end arches, and the height is 94 ft. 3 ins. from center of pin at the crown to a line connecting the end pins. The present structure has 13 bays, each 26 ft. long. The two future bays are each 26 ft. 6 ins. long.

The arches rest on masonry piers, and the horizontal thrust is taken up by tie rods which connect the end pins. These tie rods are encased in concrete to prevent corrosion.

Although the balcony was not provided at the time of erection the balcony girders were put in and provision made for connecting the future steelwork to them. Lateral bracing is placed in the end panels and in every alternate panel. The bracing in the sides of the building consists of 6 × 3½ × ⅜-in. angles, this bracing being omitted in the three center bays on account of the entrances.

The total weight of the steelwork for this armory was 985 tons. The weight of one three-hinged arch, complete with pins but exclusive of the eye-bar ties and the bases, was 37 tons. Each segment of the arch was shipped in four sections, the weights of these sections, beginning at the bottom, being 5¼ tons, 4¼ tons, 4 tons, and 5 tons. The arches rested on cast bases, each base being anchored to its footing with two 1¼-in. rods 2 ft. long. There are 15,400 ⅞-in. diameter field rivets and 14,900 ¾-in. diameter field rivets in the structure.

Contractor's Equipment.—The contractor's equipment included a large traveling derrick, two riveting outfits, an air compressor plant, an office, block-and-tackle apparatus and ropes for guiding the arches during erection, etc.

On account of the size and weight of the arches, a special traveling derrick was used. It was formed by mounting parts of two stiff-leg derricks on a steel tower, which in turn rested on rollers. One of the legs was taken off of each stiff-leg derrick, and the remaining portion was braced together as shown in the drawing. Heavy bracing was required to give the required rigidity to the tower. The tower was 37 ft. 6¼ ins. by 38 ft. 4 ins. by 32 ft. high. A platform placed on the lower sills of the tower carried the two hoisting engines. These engines were placed at the rear to assist in anchoring the tower, although considerable additional anchorage was required. One hoisting engine was used to operate each boom. The booms could be moved independently, or both could be moved at the same time. The height of the masts was 40 ft., the length of each stiff-leg was 56 ft., and the length of each boom was 90 ft., thus the height and reach of the booms was sufficient to reach any part of an erected arch. The boom had a 17-in. sheave and a 2-in. shaft at the top. Quadruple blocks were used. The masts were fitted with 13-in. sheaves and 1½-in. shafts at both top and bottom. The booms used on this work had three 30-ft. sections, although their total lengths could be changed by substituting sections of different lengths. The total weight of the traveler was about 26 tons, and each hoisting engine had a capacity of about 35 tons.

Method of Erection.—The footings were first put in place, and trenches were dug for the tie rods. The traveler was then shipped to the site and erected. As has been previously mentioned, each segment of the arch was shipped in four parts. These sections were hauled to the site on wagons. The derrick then picked up these parts and placed them on the ground in their proper positions. They were then assembled and riveted together. In the meantime, the cast bases were set on the footings, and the tie rods were laid in the trenches.

Time Account and Cost Data.—About two weeks were required to erect the traveler and to get the equipment in good order. On an average two arches were erected per week. Sometimes as many as three arches were erected in a week, but it was necessary to assemble a segment and rivet the four parts together before it could be erected and this required considerable time. Work was started putting up the traveler on Jan. 20, 1913, and about two weeks later the erection of the steelwork was started. One riveting gang started on Feb. 17 and another on Feb. 24. They finished riveting the first panel on March 1. The men started to take down the traveler on March 22.

The superintendent and the two foremen of the riveting gangs, each received 80½ cts. per hour, the two engineers for the hoisting engines and the engineer for the air compressor received 72½ cts. per hour, the men working on the steel erection 68 cts. per hour, several laborers 25 cts. per hour, and one boy received 20 cts. per hour.

Although the greatest number of men at work at any time was 44, about 75 different ones were employed by the contractor before the work was completed.

The following is a summary of costs and weights:

Total cost of erecting traveler (labor)	$ 634.63
Total cost of erecting steelwork (labor)	4,379.84
Total cost of taking down traveler (labor)	422.47
Total cost of field riveting (labor)	3,969.38
Total cost for erecting and field riveting	9,406.32
Total weight of steel in structure (tons)	985
There were 15, 400 ⅞-in. and 14, 900 ¾-in. field rivets driven, a total of	30,300
Cost of erecting steel (per ton)	$ 9.55
Cost of driving field rivets (cents each)	13.1

Prices of Water for Building Purposes.—Engineering and Contracting, April 11, 1917, gives the following data. The following schedule of rates is in force at Johnstown, N. Y., for water used for construction purposes:

Plastering per 100 yd	25 cts.
Brick per 1, 000	4 cts.
Stone per cu. yd	2 cts.

The supply must be specially applied for, and permission obtained from City Clerk for each separate building, job or piece of work, and paid for at the time application is made for the permit.

The rates at Detroit, Mich., are:

Brick per 1, 000	$0.05
Plaster per 100 sq. yd	.07
Concrete per 100 cu. yd	1.00
Concrete 6 in. thick or less per 100 sq. yd	.20
Tile per 100 cu. ft	.05
Each perch stone	.01

Cost of Manufacturing Concrete Roof Tile.—D. Helmuth (Concrete, Oct., 1919) gives the following:

The size of the tile is 9-in. by 14¾ in. By concentrating efforts on labor saving devices the output of the machines was increased from 250 tiles each man per day to 600.

To quote Mr. Helmuth:

We make our tile on the well-known hand-operated type of machine. We figure a profit of 8% on our entire investment, and from June and July, 1919, figures, it works out as follows:

Cement, per bbl., $2.32, at the mixer.

Washed sand, either river or bank—that is, practically free from loam—at $1.33 per ton, at the mixer.

Pure red and brown color, $0.17 per lb., unmixed.

Tile made on a piece-work basis, at 1 ct. per tile.

The operators have the mix brought to the machine, as well as the pallets, all ready and oiled, and the tile removed from the pallets, for the tile operator, by a laborer that costs us 60 cts. per hour.

A first-class man to make special pieces, at 70 cts. per hour.

Figure 8% as a charge on a capital investment of $50,000.

Water, light, power, heat, factory and office rentals, and every conceivable overhead necessary today in the operation of a modern business that requires about this amount of capital are charged up.

Everybody in the unit is an expert man.

Results—Tile produced and stacked in the yard for 4 cts a piece, or $6.00 per square, counting 150 pieces to a square.

Cost of Concrete Block Manufacture.—S. H. Wightman, in Engineering World, Sept., 1920, gives the following cost analysis made by him in March, 1920.

Quality of block which will stand 1500 lbs. per sq. in. in 28 days

Average capacity per day, 1000 8 by 8 by 16—300 days = 300,000 per year.

Average cost of factory building, $5000. Wood. (For modern plant add $10,000.)

Average cost of equipment, $10,000. (See schedule "A.")

Average cost working capital, $10,000.

FACTORY PRODUCTION COSTS

	Day	Cost per block
Cement—12 blocks to a bag at $2.40 per bbl. net		$0.0505
Loss on cement bags .06 cts. bbl.		
Sand and gravel—50 blocks per cu. yd. at $3 yd		.06
Productive labor—1 Machine operator	$ 8.50	
1 Off bearer	8.00	
1 Mixer man	8.00	
2 Men stocking, etc.	7.50	
	7.50	
1 Cement and gravel	7.00	
	$46.50	.0465
Total per block		.01570

FACTORY OVERHEAD

Non-productive (indirect labor)	Day	
Supt. and general overseer	$10.00	
Extra all around man	8.00	
Night man	7.00	
	$25.00	$0.023
Coal, 1 ton per week @ $8.40 per ton		.0014
Oil, water and light, $1.70 per day		.0017
Power, $2.50 per day		.0025
Repairs and maintenance, materials $9 per week		.0015
Factory expenses, freight & cartage $6 per week		.001
Depreciation on equipment (15% on $10,000 = $5 per day)		.005
Depreciation on buildings (5% on $5,000 = .833 per day)		.00083
Breakage in manufacturing blocks per day at .28 cts. = $5.60 per day		.0056
Workingmen's compensation, 4% of $72.50 per day = $2.90		.0029
Total per block		$0.04542

DELIVERY AND SALES

Loading blocks	$0.008
Freight and cartage out	.035
Extra cartage, Delivery breakage, Commission, Adjustments, Service, Estimates, Advertising	.001
Net discounts on sales 2 % = $7 per day	.007
Total per block	$0.051

EXECUTIVE OVERHEAD

General manager (owner) $5000 year = $16.66 per day	$0.01666
Office expense, $1 per day	.001
Taxes	.0005
Insurance, building equipments and materials	.0005
Interest on loans, $5000 at 6 %	.001
Loss on bad accounts, $300 per year	.001
Rent on land, $100 month	.004
Total per block	$0.02466

SCHEDULE "A"

EQUIPMENT TO MAKE 300,000 BLOCKS PER YEAR

Block machines and attachments	$ 3,200.00
40 Block cars	1,600.00
Tracks, ties and transfers	500.00
Pallets	1,000.00
2 Mixers	500.00
Gravity conveyor	100.00
Boiler	400.00
Piping and heating	200.00
Motor, 10 horsepower	250.00
Wiring	200.00
Millwright installation material	480.00
Office equipment	185.00
Tool and factory supplies	400.00
Bag bundling machine	35.00
Drawings	350.00
General expense	600.00
Total	$10,000.00

From this analysis it may be assumed that good block will cost 29 cts. to manufacture and if sold at 35 cts. each will yield a profit of 17% on the gross sales. As the quantities of materials are stated and other units of labor given any one can substitute local prices for those given, change the total accordingly and arrive at what should be the cost prices in any district. Needless to say, a fair profit should be added to total manufacturing and selling costs.

Costs of Upkeep and Repairs on a Large Building.—Walter R. Metz in Engineering News-Record, Aug. 5, 1920, gives the following:

The costs as given cover a group of ten buildings all connected together but not all under one roof. The main building is seven stories high and the other buildings are from four to six stories high. All of the buildings were designed for heavy loads and heavy machinery and are used for a printing plant. The floors in the main building were designed for loads of 300 lb. per sq. ft. and in the other buildings 200 lb. per sq. ft.

Costs have been given for each year from 1912 to 1919 inclusive and indicates the gradually increased cost of both labor and materials.

Floors.—All floors were leveled up with concrete and finished with hard maple blocks 2½ × 12 × ⅞ in., cut with interlocking grooves and projections on the sides and near the lower faces of the blocks. These blocks were dipped so as to coat the under side with hot bituminous mastic and applied to the concrete, which had been previously prepared by giving it a coat of bituminous varnish. The total area of the floors, in round numbers, is 250,600 sq. ft.

Year	Labor	Material	Total	Cost per square
1919	$2,387.69	$267.48	$2,655.17	$1.06
1918	2,787.91	132.57	2,920.48	1.16
1917	2,454.53	202.30	2,656.83	1.06
1916	1,178.37	125.31	1,303.68	.52
1915	1,058.33	99.01	1,167.34	.46
1914	1,005.17	57.86	1,063.03	.42
1913	1,336.54	95.87	1,432.41	.57
1912	1,055.09	121.59	1,176.68	.47

Roof.—The roof is of reinforced-concrete slabs supported by steel beams. It was finished with flat vitrified tiles, laid on a base of Neufchatel asphalt mastic. The mastic was applied in two coats with a layer of fine wire netting between to serve as a bond. Each tile was stuck fast to the mastic with a spoonful of bituminous cement. The inclination of the roof is about 1 to 7. This is rather steep for tiles on an asphalt base but the whole roof has stood up remarkably well. The total area of the tile roofing is 50,700 sq. ft.

Year	Labor	Materials	Total	Cost per square
1919	$ 726.91	$ 16.20	$ 743.11	$1.46
1918	2,038.80	459.96	2,478.76	4.88
1917	392.38	12.82	405.20	.79
1916	643.78	166.03	809.81	1.59
1915	102.13	4.95	107.08	.21
1914	657.96	89.33	747.29	1.47
1913	493.70	36.94	476.64	.94
1912	239.11	28.54	267.65	.52

Steam Heating.—The total volume of the main building is 7,600,000 cu. ft. The system of heating is the direct-indirect, the coils being placed in pockets under the windows with dampers for admitting fresh air and baffles for deflecting the air to the floor, whence it would have to rise through the coils. The total radiation is 70,000 sq. ft., consisting of 694 steam coils and 35 cast-iron radiators. The ratio of heating surface to the volume of the building is 108.

In addition to this there is approximately 30,000 sq. ft. of radiation in coils in the other buildings, making the total radiation approximately 100,000 sq. ft.

Year	Labor	Material	Total	Cost per 100 sq. ft. of radiation
1919	$3,928.23	$ 601.46	$4,529.69	$4.53
1918	2,631.21	2,000.38	4,631.59	4.63
1917	3,823.02	523.04	4,346.06	4.34
1916	3,183.45	694.11	3,877.56	3.87
1915	2,635.52	222.35	2,857.87	2.85
1914	2,643.43	399.83	3,043.26	3.04
1913	2,870.56	480.71	3,351.27	3.35
1912	2,436.34	343.97	2,780.31	2.78

Plaster.—Plaster on ceilings was applied to a concrete surface and three coats of plaster were applied. The first and second coats were heavily gaged with portland cement, the idea being to secure a hard plaster. Around beams the plaster was applied to wire mesh. The plaster was rather thick and it is believed it would have lasted better if it had been applied thinner, say about ¾ in. thick. The plaster on practically every beam either fell or had to be removed after about eight or ten years' use, but that on the ceilings is still in good shape although about 18 years old. The total area of plastered surface is approximately 360,000 sq. ft.

Year	Labor	Material	Total	Cost per square
1919	$ 993.63	$ 21.83	$1,015.46	$0.28
1918	62.61	......	62.61	.017
1917	9,026.52	956.49	9,983.01	2.77
1916	2,659.62	409.81	3,069.43	.85
1915	681.68	51.66	733.34	.20
1914	466.66	3.59	470.25	.13
1913	858.77	38.44	897.21	.24
1912	578.42	96.47	674.89	.18

Doors.—There are 223 doors of all sizes and types in the buildings, single-acting hinged office doors, double-acting, plain sliding, and automatic sliding fire doors. These doors receive very hard usage and need constant attention. Practically all of the double-acting doors have wire glass in the upper panels.

Year	Labor	Material	Total	Cost per door
1919	$564.58	$109.18	$ 673.76	$3.02
1918	883.44	182.91	1,066.35	4.78
1917	598.88	185.03	783.91	3.51
1916	910.38	224.22	1,134.60	5 08
1915	691.04	148.46	839.50	3.76
1914	855.72	143.85	1,099.57	4.93
1913	440.42	130.28	570.70	2.56
1912	435.80	142.81	578.61	2.59

Windows.—There are 2,290 windows in the buildings, most of them of the double-hung sliding type with a few of the hinged type. Glass sizes vary from 12 × 18 in. to 36 × 50 in.

Year	Labor	Material	Total	Cost per window
1919	$593.67	$220.26	$ 713.93	$0.31
1918	794.70	294.87	1,089.57	.47
1917	486.97	161.72	648.69	.28
1916	729.51	191.99	921.50	.40
1915	421.47	76.46	497.93	.21
1914	758.72	168.70	927.42	.40
1913	474.50	108.95	583.45	.25
1912	564.12	174.40	738.52	.32

Plumbing.—Fixtures in the building consist of 240 water closets, 338 wash-basins, 90 urinals, 21 slop sinks, 120 drinking fountains, 80 fire hose and racks. The repairs includes, of course, repairs to the necessary piping as well as to repairs to fixtures. It is difficult to find any unit basis so total amounts only are given.

Year	Labor	Material	Total
1919	$5,304.63	$406.08	$5,810.71
1918	5,309.31	352.87	5,662.18
1917	4,530.09	556 05	5,086.14
1916	3,291.66	464.90	3,756.56
1915	2,974.87	237.93	3,212.80
1914	2,941.40	238.95	3,180.35
1913	2,738.26	395.26	3,133.52
1912	2,250.82	160.36	2,411.18

Depreciation of Office Buildings.—(Engineering and Contracting, Dec. 25, 1918.) After much research work in many leading cities the committee on Taxation of the National Association of Building Owners and Managers has reached the conclusion that the minimum annual depreciation of normal office buildings is 3 per cent of actual building cost for each of the first ten years, 2.5 per cent for the second 10 years, 2 per cent for the third 10 years, and thereafter doubtful. These figures are given by H. J. Burton, chairman of the committee, in a report to the Government Advisory Council of Real Estate Interests. The report also states:

"The best authorities consider that there is a steady and inevitable annual depreciation ranging from 1.5 to 2 per cent for the structural portion of the average modern office building, and from 7 to 10 per cent per annum for the mechanical plant and equipment. This makes the annual depreciation of the combined structure and plant 3.2 per cent per annum.

"The obsolescence of the ornamental and finishing work and of the architectural plan, which reduces the competitive earning capacity of the building, should also be allowed, and should be differentiated from the obsolescence or decadence of the location, which is reflected in the reduced land values."

CHAPTER XXIV

ENGINEERING, SURVEYING AND OVERHEAD COSTS

References.—Further data on cost of surveying are given in Gillette's "Handbook of Cost Data." Chapter I of "Mechanical and Electrical Cost Data" by Gillette and Dana contains many data on overhead and engineering costs.

Schedule of Charges for Engineering Services.—Engineering and Contracting, March 13, 1918, gives the following abstract of a paper by Edmund T. Perkins presented at the 1918 annual meeting of Illinois Society of Engineers.

The various services rendered are classified as follows, and are generally charged for on a percentage basis, except surveying which should be per diem.

1—Reconnaissance.
2—Preliminary reports.
3—Surveying.
4—Plans and specifications.
5—Details.
6—Supervision and progress estimates.
7—Superintendence.
8—Alterations.
9—Professional advice.
10—Consultation.
11—Court work or arbitration.

Reconnaissance work is necessary when no data, or incomplete data, have been secured, and is preliminary to general planning of project and securing of data.

Preliminary reports are made when the necessary data on which the report is based have been secured of such detail and accuracy as to permit of proper advice being given or design made.

Surveying covers every class of field work which is not a part of reconnaissance work. It includes all location lines for roads, canals, railroads, etc., all level lines, all sinking of wells or experiment work, besides all classes of land surveying and land subdivision, and compensation therefore should be on a salary or per diem basis with expenses paid.

Plans and specifications are required as the basis for letting of contracts or for the information of the owner, employer or consulting engineer, and afford a full description of the work. They are implied by the necessities of the work even when not required by the owner, and include an estimate of the cost of the work. Plans, when adopted and approved, must be so endorsed by both owner and engineer.

Details are not always an essential of the construction work, and the rate charged, therefore, is flexible, varying with the amount of detail work.

Supervision and the making of progress estimates should always be required, that the engineer responsible for the plans and specifications should be satisfied, by personal inspection that the specifications are fully complied with and satisfactory progress made. When superintendence is paid for, as defined in the next section, there is no additional charge for supervision.

Superintendence of construction must be had by a superintendent mutually acceptable to owner and engineer. The schedule rate for superintendence applies when the engineer who has designed and planned the work, or his assistant, superintends construction. All other employes than such assistant or assistants are to be paid by the owner.

Alterations may be required at any time by the owner, or become necessary by reason of unforeseen conditions or changes in the size of projects. The schedule rate applies to such alterations as may be required by the owner—alterations becoming necessary by reason of unforeseen condition or accidents are covered by percentage charges on the aggregate costs.

Professional advice is always charged for according to interests involved, charges being based on value of services rendered, not on time required in arriving at conclusions or opinions.

Consultation with engineers who have made certain branches of professional work a specialty may be requested by the engineer having general charge of the work, or may be required by the owner. Charges for consultation work being based on value of services rendered, not on time required in arriving at conclusion or opinion.

Court work as an expert or as arbitrator in settlement of controversies, condemnation proceedings, etc., in the interest of the owner, is entitled to additional pay at a rate to be agreed upon.

Schedule rates cover compensation only for engineering services: that is, the services of the engineer and his engineer assistants.

All expenses incurred for materials, blue prints, or for transportation, hire of helpers, rodmen, chainmen, teamsters, conveyances, and living expenses when away from regular place of business, are a separate and additional charge against the owner, as is a reasonable charge for general office expenses.

Time of payment is according to agreement; but usually is arranged on the basis of a preliminary payment, or retainer, and an advance for traveling or other expenses aside from services; and further payments on account, if the commission extends over considerable time.

Final pay for preliminary reports is due upon presentation of report.

Final pay for reconnaissance work is due upon completion of same.

Pay for supervision or superintendence becomes due on progress estimates made for payments to contractors, or, if work is done by day labor, on monthly appraisements of work done.

All percentages are computed on the contract price or actual cost of work.

When construction covered by plans and specifications is not carried out, pay for these plans and specifications is due upon completion of the estimate of cost of work.

The several items of payment on the percentage basis become due from time to time when the class of service has been rendered.

Per diem rates apply to an 8-hour day. Extra time is charged for on a basis of 1½ time on week days, and twice time on Sundays and legal holidays.

TABLE OF CHARGES—ON PERCENTAGE BASIS

	Less than $5,000	$5,000 to $10,000	$10,000 to $20,000	$20,000 to $50,000	$50,000 to $100,000	$100,000 to $200,000	$200,000 to $500,000	Over $500,000
	%	%	%	%	%	%	%	%
Reconnaissance	2.0	1.75	1.5	1.0	0.75	0.5	0.4	0.3
Preliminaries	1.5	1.0	0.8	0.6	0.5	0.4	0.3	0.2
Plans and specifications	4.0	3.5	3.0	2.5	2.0	1.5	1.3	1.2
* Supervision	2.0	1.8	1.5	1.3	1.1	1.0	0.8	0.6
* Superintendence	5.0	4.5	4.0	3.5	3.5	3.0	2.8	2.4
† Alterations	7.0	6.5	6.0	5.5	5.0	4.5	4.0	3.5
Everything from beginning to completion of job	12.5	10.75	9.3	7.9	7.4	6.0	5.3	4.2

* Supervision not charged for when superintendence is.

† Alteration relates only to value of work involved in the alteration.

NOTE.—Percentages are computed upon the entire cost of the completed work, exclusive of engineering, or upon the estimated cost pending execution or completion of same. "Cost" refers only to such part or parts of the whole work or project as the engineer may deal with.

TABLE OF CHARGES—ON PER DIEM BASIS

Chief engineer—$500 retaining fee, $100 per day while absent from office and expenses.

Assistant chief engineer—$50 a day while absent from office and expenses.

Topographers, assistant engineers and chiefs of parties—$15 to $25 a day while absent from office and expenses.

Designers—$12.50 a day while absent from office and expenses.

Instrument men, draftsmen, computers—$7.50 a day while absent from office and expenses.

Stenographers, chainmen, axmen—$3.50 a day.

NOTE.—Attendance at court or expert testimony for any fraction of a day is considered as a full day.

Charges on Other Bases.—A fixed fee for services rendered may be charged by agreement where a long engagement for professional services is contemplated; the engineer may accept such retainers on a yearly basis, at a compensation not less than that of the permanently employed engineer of the client. Except in cases where the compensation of the engineer is in the form of an annual retainer, the agreement between the engineer and his client should specify the period of time during which the compensation of the engineer, as determined by per diem charges, fixed fee, or agreed percentages, shall apply. If, through no fault of the engineer, the work should not be completed within the time so specified, an additional charge may be made, the basis for which, if practicable, should be agreed upon in advance.

Mahoning Valley Engineers' Schedule of Fees.—The Mahoning Valley, Ohio, engineers, have a standard fee schedule. The schedule, as given in the 1918 report of the Committee of Standard Fees of the Iowa Engineering Society is abstracted in Engineering and Contracting, Jan. 22, 1918, as follows:

Per Diem Rate.—Consultation, opinion, testimony, preliminary investigation, reports, and consulting capacity upon design, minimum, $25 per day. (While absent from city, attending court, or similar duties, or traveling, each day of 24 hours, or fraction thereof shall be considered as one day irrespective of the actual time spent on the case. Otherwise seven hours shall constitute one day.) For examination or reports of an extensive nature covering several days, minimum, $15 per day. Engineer in charge of field work, minimum,

$10 per day. Assistants, classed as instrumentman of party, minimum, $5 per day. Assistants, classed as rodmen, chainmen, etc., minimum $3.50 per day. Inspector on paving, sewer, etc., minimum, $3.50 per day. Minimum charge for field work, $10. To all the above an additional charge will be made to cover actual expense, including $10. Residence lot, minimum charge, $10.

Office Work.—Calculating, draughting, etc., $10 per day. Minimum charge, $2.50. Minimum charge for one map, $5. Engineer to retain original drawings, but to furnish one print copy to client and if plat is for public record one copy on tracing cloth in addition. Additional copies to be furnished client at cost.

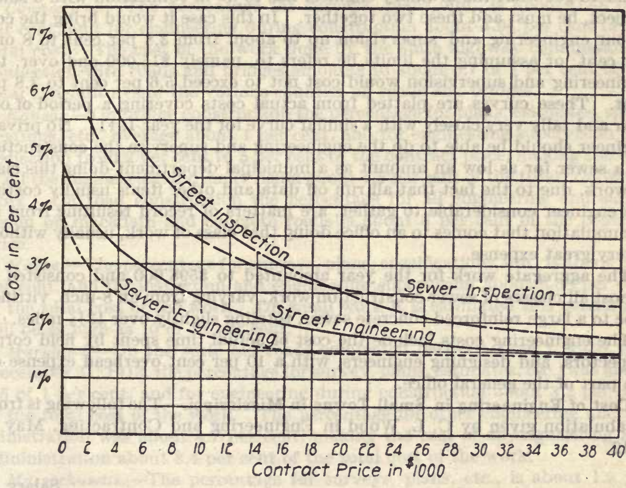

FIG. 1.

Percentage of Cost.—Engineering and supervision for sewer district or system, or disposal plant, minimum:

Contracts under $3,000, per diem rate. Contracts under $30,000: First $15,000, 8 per cent of estimate. Second $15,000, 7½ per cent of estimate.

For Paving.—Contracts under $3,000, per diem rate. Contracts under $30,000: First $15,000, 7 per cent of cost. Second $15,000, 6½ per cent of cost. Client to pay for one inspector on percentage work.

The above rates are a base for contracts with a reasonable time limit in the contract and all overtime to be based on the per diem rate.

Cost of Engineering and Inspection on Street and Sewer Construction in Spokane, Wash.—Fig. 1, given in Engineering and Contracting, July 9, 1913, shows the cost of engineering and inspection on sewer construction and street improvement work in Spokane, Wash., during the year 1912. It will be noted that four curves are given on the diagram showing, respectively, the cost of street engineering, street inspection, sewer engineering and sewer inspection.

The cost of the engineering and inspection is stated as a percentage of the contract price.

In Engineering and Contracting, Aug. 20, 1913, a letter from Alexander Potter commenting on Fig. 1 and a reply by Morton Macartney, City Engineer of Spokane, Wash. are given. The following is taken from Mr. Macartney's reply.

Relative to the diagram giving engineering costs on sewer and street work in Spokane during 1912, I beg to state that, while I agree thoroughly with Mr. Potter, that no engineer in private practice can afford to do sewer engineering and supervision for much less than from 5 to 7 per cent, you will notice that (in Fig. 1) we have segregated our inspection from our engineering, and in order to get what the ordinary engineer has to do in connection with a sewer project, he must add these two together. In this case it would bring the cost of our engineering and supervision up to about from 3.8 per cent to 8 or 9 per cent; or assuming the limits he refers to, namely $15,000 and over, the engineering and supervision would cost not to exceed 5.6 per cent to 3.8 per cent. These curves are platted from actual costs covering a period of one year and tally very closely with a similar curve for the year 1911. No private engineer should be able to do the engineering and supervise the construction of a sewer for as low an amount as a municipal department doing this class of work, due to the fact that all run off data and other items usually costing the engineer considerable to gather, are matters of record resulting from an accumulation that comes to an office doing that class of work, usually without a very great expense.

The aggregate work for the year amounted to $598,000 and consisted of almost all classes of sewer construction work, varying from an 8-inch, vitrified pipe to a large reinforced concrete sewer, totaling slightly over 13½ miles.

The engineering costs include the cost of actual time spent by field corps, inspectors, and designing engineers, with a 10 per cent overhead expense on the part of the general office.

Cost of Engineering in Small Towns in Mississippi.—The following is from a tabulation given by C. L. Wood in Engineering and Contracting, May 1, 1912.

Type of work	Town	Amount of Contract	Engineering Cost, %	Salary Equivalent of Percentage
Street grading, storm drains and brick gutters.........	Newton	$ 8,000	6.6	$125.00
Macadam and storm sewers and sidewalks............	West Point	35,000	4.0	166.67
Storm sewers, concrete curb and gutter................	Columbus	8,000	7.0	166.67
Concrete sidewalk............	Booneville	15,000	3.5	150.00
Macadam paving...........	West Point	6,200	7.3	....

Cost of Engineering on Sewage Disposal Plant.—Richard Gould in giving the costs of the Dallas Sewage Disposal Plant, Engineering News-Record July 5th, 1917, states that the total cost of the plant was $571,575 of which $36,962 was for engineering, or about 6.48%.

Cost of Engineering Supervision in Road Work.—Engineering and Contracting, May 17, 1916, gives the following abstract from a paper before the Pan American Road Congress by Lamar Cobb.

Based on inquiries addressed to state road officials the following data were amassed relating to cost of engineering supervision:

Alabama.—Bulletin No. 4 shows that in twenty counties the percentage for plans and surveys was about 3 per cent and for engineering during construction the percentage was about 5.9 per cent of the total cost of construction. The cost of all engineering work would be, therefore, about 8.9 per cent of the total cost of construction. The administrative charges are not shown.

Arizona.—The percentage for plans and surveys is 4.6 per cent and for engineering and inspection during construction 4 per cent, or total engineering and inspection, 8.6 per cent, based on total cost of construction and engineering. The cost of executive and administration is 3.6 per cent, making grand total overhead expenses 12.2 per cent.

Connecticut.—The percentage for surveys, plans, etc., is about 0.88 of 1 per cent, and for engineering during construction about 4.94 per cent of the total cost. The cost of the work done by the state highway commission in connection with roads and bridges amounts to about 0.7 of 1 per cent of the total expenditures of the various counties on roads and bridges.

Kansas.—On bridge construction the percentage for plans, estimates, specifications, etc., average about 1 per cent, and for engineering supervision and inspection from 2 per cent to 5 per cent of the contract price, making the cost of all the engineering and supervision about 4.5 per cent of the total cost of the work. On road construction the percentage for all engineering and supervision on macadam and concrete roads is about 8 per cent of the contract price.

Maine.—The percentage for surveys, plans, specifications, etc., is about 2.27 per cent, and for inspection and engineering supervision about 3.58 per cent of the total cost of the work. On small work it is estimated this percentage will be as high as 10 or 11 per cent.

Maryland.—On the state aid roads completed between June 1, 1910, and December 31, 1913, the percentage for survey, plans, estimates, etc., was about 0.5 of 1 per cent, and for engineering during construction about 3.2 per cent of the total cost of the work. The percentage for other engineering and administration was about 4.7 per cent, making the cost of all engineering and administration about 8.4 per cent of the total cost of the work.

Massachusetts.—The percentage for surveys, plans, etc., is about 1.9 per cent, and for engineering during construction about 4.5 per cent of the total cost of the work. The cost of administration is about 1.2 per cent, making the cost of all engineering and administration about 7.6 per cent of the total cost of the work.

Minnesota.—For the year 1914 all the expenditures for engineering and supervision amounted to about 5½ per cent of the total cost of the work done. Mr. Geo. W. Cooley, state engineer, states that he believes this amount to be smaller than is desirable. He believes very nearly 10 per cent is necessary for actual close supervision.

New Jersey.—On twenty pieces of work the average percentage for surveys, plans, etc., was 1.8 per cent and for other engineering was 4.1 per cent, making the cost of all engineering about 5.9 per cent of the total cost of the work. The cost of administration was not given.

New Mexico.—On bridge construction the expenditures for engineering and inspection amount to about 3 per cent of the total cost. On road construction the expenditure for engineering and inspection amount to about 5.2 per cent, and for administration and office engineering about 7.42 per cent of the total cost of the work. The cost of all engineering and administration on road construction would be about 12.62 per cent of the total cost of the work.

New York.—The report of the Commissioner of Highways for 1914 shows about 11.2 per cent of the total expenditures to be for engineering and inspection and about 3 per cent for administration, making the cost of all engineering and administration about 14.2 per cent of the total expenditures.

North Carolina.—The information available covers a few roads only and shows that about 4.06 per cent of the total cost of the work was expended for engineering and inspection. The administration charges appear to be in addition to the above.

Ohio.—Bulletin No. 22 shows that about 5.71 per cent of the total cost of road construction was expended for engineering. The cost of administration appears to be in addition to the above.

Oregon.—Upon various pieces of work reported for year ending November 30, 1914, the cost of engineering varies from about 4 per cent to about 9.4 per cent of the total cost of the work. The cost of administration is not shown separately.

Pennsylvania.—The report for the year 1913–14 shows the expenditures for engineering and inspection on completed contracts to be about 5.6 per cent of the total cost and for administration about 1.4 per cent, making the cost of all engineering and administration about 7 per cent of the total cost of the work.

Rhode Island.—On paved roads the expenditures for surveys, plans, specifications, etc., amount to about 2 per cent and for engineering and inspection about 2 per cent of the total cost of the work. The percentage for administration amounts to about 5 per cent, making the cost of all engineering and administration about 9 per cent of the cost of the work.

Virginia.—The expenditures for all engineering and inspection amounted to about 5 per cent of the total cost of construction in 1914. The commissioner states, however, that in his opinion a larger percentage would result in a substantial saving to the state.

Wisconsin.—In 1914 all overhead charges, including engineering and administration were slightly under 5 per cent on road construction. The inspector on the work is, however, charged to construction. The cost of preparing plans etc., for bridge construction was about 2.8 per cent of the cost of construction.

Engineering Cost of County Road and Bridge Work, Iowa (Engineering and Contracting, Sept. 4, 1918).—The total expenditure for road and bridge work in Iowa in 1917, according to County Engineers' reports, was $15,165,476, an increase of $828,420 over the amount for the previous year. Of the total, $7,466,797 was for bridges, $3,588,338 for county roads and $4,140,340 for township roads. The total expenditures for the three previous years were: 1916, $14,337,056; 1915, $13,525,617; 1914, $11,601,000. The percentage of engineering cost for the four years, according to the Service Bulletin of the Iowa Highway Commission, was as follows:

	Per cent			
	1914	1915	1916	1917
County engineering	2.85	2.75	2.53	2.58
Highway commission	.64	.60	.63	.59
Total all engineering	3.49	3.35	3.10	3.17

Cost of Engineering Supervision, Ohio Highway Department (Engineering and Contracting, Nov. 18, 1914.)—A publication of the Ohio Highway Department states that the cost of engineering supervision of road and bridge construction work by the department has been as follows:

Year	Percentage of total cost
1914	4.03
1912 and 1913	5.71
1911 and 1912	6.18
1910 and 1911	6.40
1909 and 1910	5.39
1908 and 1909	5.43
1907 and 1908	5.28
1906 and 1907	7.55

During the current year the state will have expended $3,150,000 and the counties $3,450,000, a total of $6,600,000 in the construction of their system.

Cost of Engineering on Maine Highway Work (Engineering and Contracting, Feb. 7, 1917.)—The cost of engineering by the Maine State Highway Department for 23 gravel road contracts let in 1914 was 6.10 per cent, according to an article by Irwin W. Barbour, assistant engineer, in the December Cornell Civil Engineer. This percentage does not include office administration. Itemized the percentage is:

	Per cent
Surveys	1.02
Plans and computations	.96
Advertising	.04
Engineering during construction	4.11

The roads were located in 16 towns and aggregated 80.11 miles. The total cost was $525,383, the percentages for the various class of work being:

	Per cent
Grading	33.77
Drainage	10.35
Surfacing	39.77
Culverts	8.43
Guard rails	1.55

Division of Costs of $18,000,000 Worth of Highways.—Engineering Record, Oct. 28, 1916 gives the following:

With the expenditure of the last of the $18,000,000 which was authorized in California in 1909 for the construction of trunk highways, the highway commission has been able to show a road system laid out in complete detail with finished roads in every part of the state on those routes where the immediate need was the most urgent. The aggregate mileage completed includes 966 miles of oil-surfaced concrete pavement, 129 miles of oiled macadam and 395 miles of graded dirt road.

Costs Summarized.—A review of the costs and notable features of the work accomplished by the commission, from which the following has been taken, was recently prepared for California Automobile Association by Eric Wold, who was retained for that purpose. His résumé of the commission's statement of expenses shows the following figures:

Construction cost:	
Payments on contracts, materials and day labor work........	$14,284,552.11
Equipment (1.15 per cent of construction cost):	
Expenditures of all classes of equipment and furniture......	164,394.46
Expenses (16.64 per cent of construction cost):	
Expenditures for engineering, legal accounting, purchasing, laboratory, services and expenses incidental thereto.......	2,372,757.41
Total expenditure to June 15, 1916..................	$16,821,703.98
Total amount available from state highway fund......	18,000,000.00
Unexpended balance June 15, 1916..................	$ 1,178,296.02

Since June 15, 1916, at which time the foregoing figures were brought up to date, the commission has obligated itself for the expenditure of approximately the entire balance remaining out of the original $18,000,000.

A general survey of 175 contracts under which the commission has let highway construction work developed the following average prices, which include the cost of material:

Excavation, including clearing right-of-way, shaping and finishing of roadbed, watering and rolling, per cu. yd..........................	$0.41
4-in. concrete pavement, per sq. yd..............................	.738
1½-in. asphalt wearing surface, per sq. yd..........................	.45
⅜-in. oil top, per sq. yd..................................	.054

A total of 2,350 miles of road was surveyed at a cost of $744,957, or $317 per mile. Of this total only 1,490 miles have been constructed, as before stated, so that the cost of locating ready for construction about 860 miles of highway is included in the expenditures made to date. This mileage of survey on which construction was not undertaken was necessary because of the difficulty and delay in securing certain necessary rights-of-way which forced the commission to construct disconnected lengths of road.

The handling and delivery of all materials used on construction were undertaken by the commission, and the overhead charge of 10 to 20 per cent of the net cost of the contract, which is usually allowed for this item, was borne by the commission and is included in the commission's expenses. A summary of the equipment which the commission purchased to carry on this work is as follows:

CALIFORNIA ROAD-BUILDING EQUIPMENT

Equipment	Cost	Per cent salvage	Salvage
Sand plants..........................	$ 27,259.19	100	$ 27,259.19
Construction equipment...............	21,257.49	100	21,257.49
Engineering equipment................	25,716.10	50	12,858.05
Furniture............................	21,328.05	40	8,531.22
Stable...............................	17,070.99	100	17,070.99
Auto.................................	41,380.55	40	16,552.22
Camp.................................	6,429.32	20	1,285.87
Laboratory...........................	3,952.74	50	1,976.35
	$164,394.43		$106,791.38

Therefore the 17.79 per cent of the total expenditure, which is shown in the first table as gross overhead, includes in reality salvable equipment, surveys (the advantage of which has not yet been realized), and other minor items, such as designs, supervision, etc., given gratis to counties undertaking independent road work. The net overhead chargeable to the construction work on the roads actually built, including allowance for these items, amounts to 12.75 per cent of the gross construction costs, which is considered a very reasonable allowance for net overhead on public work of this character.

Cost of Engineering on a Million Dollar Road Project (Engineering and Contracting, April 3, 1918).—The building of 178 miles of roads for McClennan County, Texas, cost $1,075,000 for construction and engineering, of which $35,156, or about 4.6 per cent, was for engineering. This is slightly less than $200 per mile. There were 110 miles of gravel roads, 63 miles of macadam (waterbound) and 5 miles of concrete. The work was done by contract under the direction of the county engineer, Rollen J. Windrow, of Waco, Texas.

The following are the itemized percentages of the total cost of the engineering:

	Per cent
Preliminary surveys	0.28
Office expense	0.61
Transportation (including first cost of motor cars)	0.39
Field engineering and inspection on construction	2.04
Checking gravel and stone	0.85
County engineer's salary	0.41
Total engineering	4.58

The preliminary surveys, inclusive of making plans and estimates, involved surveying 20.3 miles of line, which was done at a cost of less than $15 a mile, inclusive of expense accounts. The salaries, however, were low, being only $90 a month for transitman, $75 for levelman and $50 for the other men.

The office expense covered office supplies and the salaries of a bridge designer at $125, a chief clerk (who was an engineer) at $100, an assistant clerk (also an engineer) at $75 and a stenographer at $50.

More than half a million tons of gravel and stone were used, and, as they were furnished by the county to the contractors, the cost of checking the quantities was treated as an engineering expense, which amounted to 0.85 per cent of the total cost, or 1.8 cts. per ton.

The cost of engineering on this road project was unusually low, perhaps half what such costs average in northern states; but the salaries were low and the construction was fairly continuous, the project being completed within two years.

The Cost of Measuring Base Lines.—In Engineering News, Mar. 16, 1911, a paper by Wm. Bowie, Inspector of Geodetic Work for the Coast and Geodetic Survey, and Chief of its Computing Division, read before the Washington Philosophical Society, explains the changes which have been made on the Coast Survey in the substitution of tapes and wires in place of bars. At the 1914 annual meeting of the American Association for the Advancement of Science, at Atlanta, a paper was again presented by Mr. Bowie in which he more fully covered this subject. The following is from Engineering News, Feb. 19, 1914.

According to Mr. Bowie, not since the beginning of the present century has the Survey made use of the old bar method for measuring its base lines. This change of practice, however, has not been fully appreciated by the textbook writers at least, as treatises on surveying published in recent years describe the use of bars as if they were still a practical tool of the engineer. Mr. Bowie concludes his paper with the remark that base-line measurement bars from now on should be found only in museums and deserve a prominent place only in the history of geodetic surveying.

Cost.—With the modern invar tapes or wires the cost of base-line measurements by a survey party averages only about $50 per kilometer. The work is of a high degree of accuracy, quite comparable with that obtained by bar measurement. This means that in any geodetic triangulation net, base lines can be introduced with much greater frequency, so that in order to secure a given degree of accuracy it is not necessary to introduce so much refinement in measuring the angles of the triangles.

The invar tapes used by the Coast Survey have proved to be much less susceptible to injury in the course of use, resulting in change of length, than was at first anticipated. Mr. Bowie gives values for the constancy of length of four invar tapes used on the Coast Survey, showing that the total range in value during four years for the four tapes varied from one part in 170,000 to one part in 410,000. The difference in length between the values resulting from the length when first standardized and when last standardized varied from one part in 170,000 to one part in 1,110,000. Another great advantage in the use of tapes over bars is that they can be handled by comparatively unskilled persons. In a party of six assigned to base-line measurements, only one or two of its members need to be experts in base-line work, a very different condition from that prevailing with the micrometer bars formerly used.

Cost of Surveys for Federal Aid Roads Project in Kansas.—The following figures, given by E. L. Hageman in Engineering and Contracting, Sept. 3, 1919, relate to surveys made in the early part of 1918 for a Federal Aid road project in Labette county, Kansas. The work covered approximately 44 miles of highway, divided into four sections, as follows: Section A, 9.25 miles; B, 10.1 miles; C, 10.83 miles; D, 13.91 miles.

The transitman received $100 per month until May 1st, excepting two days due to a change of transitmen. From June 12th to June 27th, the transitman received $150 per month. The helpers received $2 per day until March 1st, when they were paid $3 per day. The time was derived from the actual number of days worked, as the helpers were working by the day and the transitman worked in the office during inclement weather.

A cheap cloth tape which had been removed from its case and the free end allowed to drag on the ground was used in measuring, it being impractical to be continually rolling and unrolling the tape. The tape was much easier to handle in this way and being inexpensive the time saved more than offset the additional cost.

Bench levels for Section A were started on Jan. 23 and completed on Feb. 5. The following is a summary of the work for the four sections:

Section	Error of closure	Error of closure-mile	Distance between B. M's., ft.	Length of shots, ft.	Miles-day	Miles of road checked, day	Length of circuit
"A"	0.032	0.0060	1,113	324	2.11	1.85	2.31
"B"	0.036	0.0059	1.532	513	2.66	2.34	2.90
"C"	0.026	0.0059	1.196	352	2.32	2.32	2.17
"D"	0.047	0.0241	1,677	331	2.20	2.02	1.60
	0.141	0.0419	5,518	1,520	9.29	8.53	8.98
Average	0.036	0.0105	1,380	380	2.32	2.15	2.245

The result of inexperienced help is clearly shown in Section "A" under miles per day. The effect of rough, hilly country is also shown in Section "D" under miles per day, and error of closure. The slower progress made on Section "A" was due in part to disagreeable weather. Sections "B" and "C," over which progress was more rapid, are similar in topography to "A." Three circuits were re-run, and two additional circuits have poor closures but were not rechecked, owing to the limited time in which to finish the survey, this being another cause of the poor closures in Section "D."

Center line surveys on Section A were started on Feb. 6 and completed Feb. 15. A summary of this work for the four sections follows:

Section	No. of miles/day	Length of shots, ft.
"A"	1.16	1,815
"B"	1.44	1,624
"C"	1.67	1,518
"D"	1.46	1,295
	5.73	6,352
Average	1.43	1,588

Section "A" shows the least number of miles per day as in bench levels and for the same reasons as stated before; the rate would have been proportionately smaller had it not been for the longer shots. In the same manner the shorter shots in Section "D" retarded the work.

Cross sectioning was started on Section A on Feb. 11 and finished Feb. 28. The following is a summary for all the sections:

Section	Error of closure	Length of foresights and back-sights	No. of miles / day	No. of shots / day
"A"	0.033	272	1.23	570
"B"	0.066	327	1.56	732
"C"	0.027	302	1.48	713
"D"	0.063	298	1.66	639
	0.189	1,199	5.93	2,654
Average	0.047	300	1.48	664

As before, Section "A" indicates a slower rate of progress, while Section "D" shows the best progress, which can be partly attributed to the fact that less shots were taken per distance traveled than upon the other sections. Rainy weather retarded progress appreciably on Section "C." The closures on Sections "A" and "C" compare very well with the bench level closures for the same sections. This would seem to indicate that an accurate line of levels can be run in connection with the cross sectioning by using the necessary precautions. The larger errors accumulated in Sections "B" and "D" are attributed to inaccuracies resulting from too fast work.

The labor cost of the surveys was as follows:

BENCH LEVELS

Section	No. of days	No. of men	Rate	Total	Cost per mile
"A"	5	1	$3.85	$19.25	.....
		1	2.00	10.00	$3.16
"B"	4⅓	1	3.85	16.68	.....
		1	3.00	13.00	2.94
"C"	4.66	1	3.85	17.94	.....
	2.0	1	2.00	4.00	.....
	3.66	1	3.00	7.98	2.76
"D"	2.0	1	3.85	7.70	.....
	4.87	1	4.81	23.42	.....
	6.87	1	3.00	20.61	3.00

CENTERLINE

Section	No. of days	No. of men	Rate	Total	Cost per mile
"A"	8	1	$3.85	$30.80	.....
		2	2.00	32.00	$7.01
"B"	7	1	3.85	26.95	
		2	3.00	42.00	6.83
"C"	6½	1	3.85	25.03	
		2	3.00	39.00	5.91
"D"	9½	1	4.81	45.70	
		2	3.00	57.00	7.38

CROSS SECTIONS

Section	No. of days	No. of men	Rate	Total	Cost per mile
"A"	7½	1	$3.85	$28.88	.....
		2	2.00	30.00	$6.37
"B"	6½	1	3.85	25.03	.....
		2	3.00	39.00	6.34
"C"	7⅓	2	3.00	34.00	.....
	1	1	4.81	4.81	.....

"D"	7.79	1	5.77	44.93	.....
		2	3.00	46.74	7.08

An automobile was used on the survey for five months. The total miles traveled in the survey was estimated at 2,187. This number was arrived at by taking the distance to the center of the road and multiplying it by twice the number of trips, some days there being two trips out and back when the party came in at noon.

The total expense of running the car for the five months was $133.89, less one-eighth the amount the car was used for other purposes, = $133.89 − $16.74 = $116.95. Depreciation = $385 (cost price) − $200 (selling price) = $185. The car had been out nine months when the survey began, was used on the survey five months and had been in use 21 months when sold. The amount of the total depreciation charged to the use of the car during the survey was one-third, or $61.66. The total expense of car was $178.61 for 2,187 miles or $0.082 per mile.

The instruments and materials used on the surveys were as follows:

BENCH LEVELS

	Cost	Depreciation	Amount
Level and rod	$ 50.00	2½ %	$ 1.25
Field books and pencils	....	.....	1.15
			2.40

CENTER LINES

	Cost	Depreciation	Amount
Stakes	$ 57.15	.....	$57.15
Transit	150.00	5 %	7.50
Axe	1.00	50 %	.50
Tape	5.44	15 %	.82
2 cloth tapes	5.00	25 %	1.25
Field books and pencils	2.25	....	2.25
Flag poles	6.00	5 %	.25
Kiel	1.00	....	1.00
Nails	.25	....	.25
			$70.97

CROSS SECTIONS

	Cost	Depreciation	Amount
Level and rod	$ 50.00	2½ %	$ 1.25
Field books and pencils	2.25	.....	2.25
4 cloth tapes	4.00	.....	4.00
			$ 7.50

This gives a total of $80.37 or 3.697 cts. per mile.

Allowing for one-fourth time of the County Engineer for 5 months at $166.66 per month gives a cost of $208.33 divided by 2,187 miles or 9.5 cts. per mile. Figuring in this cost the totals for the surveys were:

	Bench levels	Center lines	Cross sections
Labor	$130.58	$300.48	$277.77
Car	47.64	67.24	46.50
Instruments and materials	2.40	70.97	7.50
County engineer	55.20	77.90	44.02
Totals	$235.82	$516.59	$424.44
Cost per mile	$ 5.35	$ 11.72	$ 9.84

The labor cost of preparing the plans follows:

County engineer, ¼th time from Feb. 1 to July 1, 1918 at $833.33	$ 208.33
County engineer, ⅐th time from Jan. 1 to July 1 1919	142.86
County engineer, ½ time from July 1 to Aug. 15 1919	125.00
Assistant engineer, 45½ days at $3.80	157.64
Assistant engineer, 2 months at $125	250.00
Assistant engineer, 1 month a $125	125.00
Assistant, 7 weeks, at $150 per month	258.61
Assistant, 4 days at $4.17	16.88
Assistant, 6 days at $3.70	33.50
Assistant, 9 days at $5	45.00
Assistant, 3 months at $150	450.00
Assistant, ¼th time for 3 months at	131.25
Miscellaneous help	55.22
Total	$1,999.89

As the surveys covered 44.09 miles of highway, the labor cost of preparing the plans was $45.36 per mile.

The cost of supplies and use of office equipment for plans was as follows:

Ink, pencils, erasers, etc.	$ 5.00
Value of office fixtures, drawing instruments, etc., $300.30; depreciation at 4 % or	12.01
Total	$17.07

On the basis of 44.09 miles of road this gives a cost of $0.39 per mile.

The cost of blue print paper was 11 cts. per sheet; the cost of printing, trimming and binding was 14 cts., making the total cost per sheet 25 cts. Materials as follows were used in preparing the plans for the four sections:

216 sheets blue print paper at 25 cts.	$ 54.00
90 sq. yds. plain profile cloth at 70 cts.	63.00
90 sq. yds. cross section paper at 20 cts.	18.00
11.7 sq. yds. tracing cloth at 37 cts.	43.29
Total 44.09 miles of road at $4.05	$178.29

This gives a cost of $4.05 per mile of road for the blue prints.

The cost of the plans was $48.22 per mile, and the cost of the surveys was $26.69 per mile, giving a total cost of $74.91 per mile.

Cost of Road Surveys, Missouri.—In Engineering and Contracting, March 3, 1920, C. O. Sandstrom, in commenting on the law of Missouri fixing the price of road surveys and plans at $100 per mile, says that in one instance on a 22-mile job an engineering firm broke even at $225 a mile and on another job of 29 miles a small profit was made at $175 a mile. The high cost in the first case was caused by breakage in an organization. In both jobs, the design of culverts and bridges up to 20-ft. span were included.

Cost of Highway Surveys, Pennsylvania.—Engineering and Contracting, Aug. 19, 1914 gives the following record of the State Highway Department of Pennsylvania.

Cost of Surveying About 9, 000 Miles of Highway in Pennsylvania

Item	Total	Cost per mile
Surveying main line	$442,597.98	$ 47.87
Plotting main line	72,432.79	11.36
Checking and tracing main line	8,717.79	7.97
Surveying alternate line	15,461.22	50.45
Miles surveyed, main line		8,827.91
Miles plotted, main line		6,373.81
Miles checked and traced, main line		1,094.40
Miles surveyed, alternate line		306.36

Cost of Road Surveys and Plans (Engineering and Contracting, March 7, 1917).—The cost of road surveys and plans made by the forces of the Wisconsin Highway Commission between Aug. 15, 1915, and July 1, 1916, under survey contracts with counties averaged $24.79 per mile. The figures in more detail, according to the Third Biennial Report of the Commission, are as follows:

	Surveys made	Plans completed
Miles	894.27	706.69
Cost per mile	$ 7.98	$ 16.81

The cost of Isolated Road Surveys (Engineering News-Record, Oct. 4, 1917).—Since 1913 the State Highway Department of Illinois has made more than 400 preliminary surveys of roads under conditions which have made the comparative cost rather high, although the actual cost of $26.40 is but a small item of the final cost of the road and insignificant in comparison to the cost of errors that might have resulted from less careful surveys—or no surveys at all. This work was done on roads in short and entirely disconnected sections. As a result the cost of transporting men to and from the intersections was large in proportion to the amount of work accomplished after they had arrived at the work.

All of this work was preliminary in its nature, some of the surveys being made in prairie land and some in rough country. Altogether nearly 1,100 miles of road were surveyed at an average cost of $26.40 per mile. The average rate was 0.84 miles per day and the average length surveyed was 2.66 miles.

A typical party consisted of two engineers at $4 a day, three helpers at $2.50, and a team at $3. Such incidentals as transportation, board, lodging and supplies brought the total cost per day to nearly $25, and while this figure is less than the cost for similar work done by a private engineer, it does not include such charges as office expenses and profits.

Cost of Location of Mountain Roads.—Will R. White, Chief Engineer of the State Highway Department of Washington, in a paper before the 1912 American Road Congress, abstracted in Engineering and Contracting, Oct. 30, 1912, gives the following:

Costs.—Our location for mountain work should cost us from $150 to $300 per mile. These prices are for work in charge of competent engineers. Some of the work has cost us more, due to inexperienced engineers. Those not familiar with our mountains will think this cost excessive, but when you stop to consider that it is so brushy that it is necessary to have three or more axmen to average a mile of preliminary line a day, the same party averaging a half mile of location a day, you can get some idea of the expense.

Our location parties usually consist of complete transit, level and topographical crews. The camp outfit with the cook make 15 men to the party. In most cases the provisions can be hauled to them, but in some instances pack trains are required. Our final locations are usually made from contours taken from preliminary lines. In the settled districts and in the open country of Eastern Washington the cost of location will range as low as $50 per mile.

Methods and Costs of Some Extensive Railroad Surveys.—Early in 1902 the Little Kanawha Railroad began surveys for extensions eastward from Palestine to Belington, W. Va., and westward from Parkersburg, W. Va., to Zanesville, Ohio, and about a year and a half later for a line northward from Belington to the Pennsylvania-West Virginia State line. These surveys required the running of 1,400 miles of preliminary and 600 miles of located lines, and the methods used and the cost of the work were presented by W. S. McFetridge in a paper before the A. S. C. E., on May 19, 1909. The following notes are taken from an abstract of the paper in Engineering Record, June 5, 1909.

The surveys were conducted under the following charters: Zanesville, Marietta & Parkersburg Railroad, in Ohio; Parkersburg Bridge & Terminal Railroad, from the Ohio-West Virginia State line to Parkersburg (this division included a bridge over the Ohio River a few miles below Parkersburg); Little Kanawha Railroad, from Parkersburg to Burnsville; Burnsville & Eastern Railroad, from Burnsville to Belington; Buckhannon & Northern Railroad from Belington to the Pennsylvania-West Virginia State line; in all, some 328 miles of main-line location, exclusive of branch lines.

The termini, as usual, were fixed; physical conditions also fixed the Little

Kanawha River as the only outlet to the Ohio. Owing to local conditions, it was believed that the heavier traffic would be westbound, and therefore that every effort should be made to get as low a ruling grade as possible for this traffic. All roads previously built through the adjoining regions have long stretches of 1.5 per cent grades, and curves up to 12 and 14 deg. The first surveys, therefore, were of a preliminary nature, in order to determine what grades and curves could be secured.

After a number of surveys, locations and explorations had been made, it was found that the following grades and curves were possible: In Ohio, 0.5 per cent grades, 4 deg. maximum curve; Little Kanawha Division, 0.3 per cent grades, 8 deg. maximum curve; Burnsville and Eastern Division, 1.0 per cent grades against eastbound and 0.5 per cent grades against westbound traffic, 8 deg. maximum curves; all grades compensated for curvature at the rate of 0.04 min. per degree. These results were obtained in each case, and though very easy for parts of the country, required some rather long continuous grade lines, the longest being on the Burnsville and Eastern division, where there are 1.0 per cent grades, 7 miles and 7½ miles long, respectively, and a 0.6 per cent grade 14 miles long, all against eastbound traffic.

The topographical sheets of the United States Geological Survey were found of great value in making a broad, general study of the country. A large number of maps of small scale (1 in. to 1 mile or even smaller) were compiled and traced from various State, county and road maps, on which the several survey lines could be indicated.

The general direction of the survey, except along the Little Kanawha Division, was almost directly across the general drainage of the country.

In Ohio a direct line between termini was first examined, but was found to be impracticable. A systematic examination toward the southwest was then made, and a satisfactory line developed. All the streams here lie in deep, narrow valleys, and are exceptionally crooked. The only feasible way to traverse much of the country was to get up out of the valleys and stay out. Such a method necessitated crossing about 100 ft. above several streams, and running short tunnels between the watersheds; it also gave the shortest line, the easiest grades, and the lightest curvature.

The main problem on the Parkersburg Bridge & Terminal Railroad was the determination of the location for a bridge over the Ohio River. The Government regulations required 90 ft. clear head-room above low water and no piers in the main channel, which necessitated a 700-ft. span. The location finally adopted is about 5 miles below Parkersburg, and is believed, Mr. McFetridge stated, to be the shortest and cheapest railroad bridge crossing the Ohio between Pittsburgh and the Mississippi, the 700-ft. span practically clearing the entire channel.

The Little Kanawha Division, in general, followed the Little Kanawha River. The hills rise abruptly from the river banks. The river is very crooked, and to follow it gave a long line with much curvature. Much distance could be saved by cutting through the country at various points, but the work was very heavy. The line, as finally located, is a combination of river and cross country line. It is 31 miles shorter than the river, in a total distance of 100 miles. There are eight tunnels, usually short, the longest being 4,000 ft. There are seven river crossings, with main spans from 100 to 300 ft.

The Burnsville and Eastern Division is in the central mountain part of the State. The highest altitude reached is 1,725 ft. above sea level. The country was very rough and broken, and supporting ground for grades could not be found. The Buckhannon and Northern Division followed the river for about two-thirds of its length, the other third being cross-country.

Field parties were made up as follows: Assistant Engineer in charge, $125 to $150 per month; transitman, $85 to $100 per month; levelman, $75 per month; rodman, $65 per month; head chainman, $50 per month; rear chainman, $45 per month; rear flagman, $40 per month; stakeman, $35 per month; axemen (from two to five), $30 each; topographer, $65 per month; tapemen (two), $45 each; draftsman (part time), $60 per month. Camp outfits were not used. The parties boarded at houses along the line. Each party was given from 40 to 60 miles of line to cover, depending on local conditions.

After the first route to be examined had been chosen, a preliminary line was run through; then the alternate routes were run, all surveys being tied together; and finally the lines required for a thorough development of all possible routes were run. In locating long grades, it was preferable to start at a summit and run down hill. With a little experience, the assistant engineer could make a sufficiently close estimate of the amount to allow for compensation for curvature, and could run his line accordingly. In the mountainous part of the country here described this compensation amounts to about 6 ft. per mile, equal to 0.12 per cent grade, and preliminaries, for a 1.0 per cent compensated grade, run on an 0.88 per cent straight grade gave the desired information

In following the larger watercourses, it was usual to locate a line on either side for purposes of comparison, and in order to determine the advisability of crossing from one side to the other either to get a better line or to block the country against rivals.

It may appaer to some that there was much unnecessary location and running of preliminary lines, but in rough country like this, and on work of this magnitude (in 220 miles of this line there were twenty-one tunnels, the longest being 4,000 ft., five viaducts from 400 to 1,000 ft. long, and more than 100 ft. in height, besides numerous other bridges), it is, in Mr. McFetridge's opinion, time and money well spent.

Topography, showing contours, houses, roads, and similar features, was taken on practically all lines. This was taken on 12 × 18-in. sheets to a scale of 200 ft. to 1 in. The topography was plotted in the field. This method was preferred to any other; it is quicker; saves much copying and plotting; the work can be plotted better in the field, where everything can be seen at the time of plotting; and at night the assistant engineer has a finished map to look over and study. The topography was taken accurately by using a metallic cloth tape for distances and a hand-level for elevations. The topography was ordinarily taken for 300 ft. on each side of the center line. The sheets were inked in each night.

To obtain a large general map showing all lines, the lines were carefully plotted on tracing cloth, the small sheets were fitted so as to make the center line on each sheet fit the center line on the tracing, and then the topography was traced. By this method any error in plotting or joining the small sheets was eliminated from the large map. The location was projected in pencil on sheets in the usual manner.

In staking out the location, the aim was to get a profile to correspond with the projection, and not to get the lines in exactly the same relative positions shown by the projections. Also, it was often found desirable to change the location at places, giving a corresponding change in the profile. After the first location had been made, it was studied further in the chief engineer's office; if any changes were desired they were taken up with the assistant engineer, usually by the assistant chief engineer and the assistant engineer going over the ground together and there studying the question.

All curves of 3 deg. or more had spiral approaches. These were allowed for in cross-sectioning by offsetting the slope stakes the required distance. For simplicity and ease, all records, profiles, etc., were kept on simple curve data. When spiral curves came in tunnels, a special plan was made for each case, showing the offsets from the tangent and the simple curve to every 10 ft. on the spiral, the alignment being kept on the tangent and the simple curve, and allowing the required offset in giving the widths for the tunnels. Vertical curves were inserted at all places when the change of grade was more than 0.1 ft. in 100 ft. Standard forms were used for all notes, maps, profiles, plans, and reports, and were found to save much work and time in the chief engineer's office.

The greatest number of miles of preliminary line run in one day by one party was 7, and of location, 4½. The location averaged slightly more than one mile per day per party, except on the Burnsville and Eastern and on the Buckhannon and Northern lines, where it averaged ¾ mile. Stakes were set every 100 ft. on tangents, and every 50 ft. on curves. The speed of location parties was usually limited by the amount of clearing that could be done, but the number of curves and the rough character of the ground were also large factors in limiting the speed.

Each party cost from $35 to $40 per day, being allowed all expenses in addition to salaries.

Table I gives the total cost per mile of the completed surveys. It includes office rent, purchase of instruments and supplies, general expenses, all salaries, field expenses, and the preparation of final maps, plans, profiles, and estimates, with everything in readiness to make contracts for the line.

TABLE I.—TOTAL COST OF SURVEYS

Company	Amount spent	Miles of surveys: Preliminary	Miles of surveys: Location	Miles of surveys: Total	Av. cost per mile	Av. cost per mile of location
L. K. R. R.	$25,076.83	428.19	193.85	622.04	$40.31	$129.36
Z. M. & P.	19,812.77	509.03	105.23	614.26	32.25	188.28
B. & E. R. R. . . .	20,466.68	241.75	113.70	355.45	57.58	180.00
P. B. & T. R. R. .	6,651.98	84.56	38.17	122.73	54.20	174.28
B. & N. R. R.	19,249.94	162.51	151.29	313.80	61.34	127.23
Totals.	$91,258.20	1,426.04	602.24	2,028.28	$45.00	$151.53

The last column gives the cost per mile of actual location, including preliminary lines. The third and fourth columns show that there were from 2 to 5 miles of preliminary lines run for each mile of location, except on the Buckhannon and Northern line. Table I also includes 302 miles of check levels, the cost being distributed among the various accounts. The data for the Parkersburg Bridge and Terminal line include surveys and soundings for the Ohio River Bridge. The cost per mile includes the topography on practically all lines, except on the Zanesville, Marietta and Parkersburg line, where it was taken only on the located lines.

The cost shown, being the total charge against engineering from the inception of the project to the beginning of construction, contains a few items which might well be charged to other accounts than location. Instruments purchased could be a credit; some elaborate property surveys and bridge surveys could be charged to construction, but they probably are not large enough to have much effect on the cost per mile. The cost on the Little Kanawha and on the Burnsville and Eastern Division was increased considerably owing to much work being done during a bad winter. The cost on the Parkersburg Bridge and Terminal line was increased by a large amount of property surveying in the city, and by the surveys for the bridge.

The cost on all the West Virginia lines was increased by the immense amount of chopping and clearing necessary. When mountain laurel was encountered, all the axemen that could be worked could not keep a location party moving.

The average cost, including all expenses, of one mile of preliminary or location survey, determined from a detailed study of the daily reports of field parties, or office work done, and similar data, is shown by Table II.

Table II.—Average Cost of One Mile of Surveys

Company	Of preliminary	Of location	Of location, including preliminary
L. K. R. R.	$25	$ 74	$ 99
Z. M. & P. R. R.	23	79	102
B. & E. R. R.	35	105	140
B. & N. R. R.	31	94	125

Table I shows a large variation in the cost of surveys on different divisions, the cost varying from $128 to $188 per mile, with an average of $151. On the assumption that lines located for comparison or similar purposes should be included in the average, one-third should be added in these amounts, as previously noted; the cost per mile would then be as follows: Low, $171; high, $251; average, $202.

Throwing out of account abandoned lines, branch lines, etc., and charging the entire cost to the main line, terminus to terminus, would give $91,258.20 ÷ 328 = $278.23 per mile, which Mr. McFetridge believes would be rather expensive. This, however, is not a fair assumption, because many miles of lines not needed to determine the main line were located for other reasons. Therefore, the plan of throwing out only duplications, for comparisons, as shown in the preceding paragraph, gives the correct average cost per mile, including actual comparative locations where needed. A large proportion of this duplication was necessary, owing to the laws of West Virginia, which require an actual line, located on the ground, and a complete map and profile of that line to be filed with the secretary of state, and at the county seat, before a railroad company has any rights, or priority or otherwise, to that route or line.

On the basis of Table II, it may be assumed that, where the route has been previously determined within such narrow limits that the preliminary and location lines are of equal length, the surveys will cost from $100 to $140 per mile. This is borne out by the results on the Buckhannon and Northern line where the location and preliminary lines were practically equal and the cost was $127 per mile.

These two statements may be combined and put in the following form: To locate one mile, including an equal length of preliminary lines, cost from

$100 to $140, or an average of $115; to locate one mile, final location, including from two to five times as great a length of preliminary lines, cost from $128 to $188, or an average of $151; to locate one mile, final location, including from two to five times as great a length of preliminary lines, and one-third of a mile of location for comparison, cost from $171 to $251, or an average of $202.

A tabulation of the mileage of the Buckhannon and Northern line, with reference to the actual length of line to be built, and showing how the results agree with the averages deduced from Table I is as follows, the Buckhannon and Northern line being used because the conditions there make it the best average of "all conditions" encountered on the various lines: Total miles located, 151.29; miles of main line contracted for, 80; miles of main line not contracted for, 4; miles of connecting line located, but which may or may not be built, about 26. This gives 110 miles of main and connecting lines, leaving 41.29 miles of duplications and comparisons. The cost is then $19,249.94 ÷ 110 = $175 per mile.

Cost of a Triangulation Survey with 48 signals, controlling about 150 square miles of the Grand Valley project of the U. S. Reclamation Survey was made at a cost of $3.63 per square mile, and a plane table survey of 127 square miles, with maps on a 1:12,000 scale with 10-ft. contours, was made at a cost of $57.79 per square mile. The cost of the triangulation survey included that of measuring base lines and making Polaris observations.

Cost of Railroad Surveys in Bolivia.—The following data are from an article in Engineering Record, June 25, 1910, by C. A. Bock.

The model organization of a locating party is given in Table III.

TABLE III.—ORGANIZATION OF BOLIVIAN LOCATION PARTY

Foreigners		Natives	
Title	Monthly salary	Title	Monthly salary
Locating engineer	$200.00	Cook	55.00
Assistant engineer	150.00	Assistant cook	22.00
Transitman	125.00	Camp boy	15.00
Levelman	100.00	Corral boy	15.00
Topographer	100.00	Lunch boy	15.00
Draftsman	100.00	Muleteers, 2, ea	30.00
Head chainman	60.00	General helpers, 2, ea	15.00
Rear chainman	60.00	Rear flag	19.00
Level rodman	60.00	Axeman, 1 to 4, ea	19.00
Topog. rodman	50.00	Stake man	26.00
Commissary	80.00	Tape man	26.00
Doctor	150.00	Inst. carriers, 2, ea	19.00

Tables IV and V show the cost and time of three different surveys, made by different parties in more or less similar country and on the most difficult of the work thus far located. It should be noted, however, that while the work is located in mountain country, and most of it on difficult ground (an average of almost 50 per cent of the entire located line is curves) there is no cutting or clearing to be done, since the plateau portion of Bolivia lies above the timber line. The cost per kilometer of location as given includes preliminary lines, topography and all extra work necessary to accomplish the location, besides completed maps, profiles and estimates. The figures are for the total cost, and include all office and administration expenses, instruments and supplies.

TABLE IV.—DATA OF THREE SURVEYING PARTIES

	Camp 1	Camp 2	Camp 3
Total number of days in field....	593.0	480.0	240.0
Number holidays and Sundays....	86.0	69.0	33.0
Number days lost, bad weather...	23.0	7.0	8.0
Number days lost, moving camp...	16.0	44.0	17.0
Total number of working days.....	468.0	360.0	182.0
Kiloms. prelim. line run..........	500.2	293.0	181.0
Kiloms. located line run..........	242.3	237.4	137.4
Kiloms. completed location per day (av.)........................	.409	.495	.573
Total cost lo'tion (incl. all prelim.).	$53,389.41	$41,962.90	$20,339.26
Average cost location, per kilom...	220.34	176.76	148.03
Average cost location, per mile.....	354.62	284.48	238.24
Average cost of surveys, per day...	90.03	87.42	84.74

TABLE V.—DISTRIBUTION OF EXPENSES, IN PERCENTAGES

	Camp 1	Camp 2	Camp 3
Salaries..................................	46.4	47.5	47.1
Provisions................................	13.0	13.9	13.1
Traveling expense.........................	6.7	6.8	6.8
Instruments and supplies..................	5.8	2.2	4.0
Transportation of contract men............	3.6	5.2	4.3
Maintenance of animals....................	12.0	11.2	11.8
Indian labor (not on pay-roll)............	.3	.3	.3
Freight on supplies, etc..................	1.7	3.5	2.7
General expenses..........................	9.1	7.8	8.3
Miscellaneous charges.....................	1.4	1.6	1.6

The record run in a single day, of preliminary line, is 11.5 km; of located line, 5 km (containing two curves). The best single day's work is nine curves of located line run, including referencing of two points on each tangent. The largest amount of work done in one month by a single camp is 59.2 km. preliminary line, 25 km. of topography and 35.6 km. of located line, including referencing. This work was accomplished on a section of the survey where 53 per cent of the located line is curves.

Cost of Location Survey for a Short Railway Line.—Engineering and Contracting, Feb. 18, 1914, gives the following:

Location surveys for a railroad were made in 1912, in one of the eastern states, during which accurate records were kept for the purpose of producing authentic cost data.

The survey was for a branch 30.75 miles long, from an already established line to a manufacturing city; with a branch survey, to another city, 12 miles in length. Topographical considerations, aside from large bodies of water and high hills, were found to be of minor importance, the chief concern being so to approach the intersected streets that grade crossings might be cheaply avoided. Most of the distance was through a light growth of timber, requiring much chopping and trimming. No topography was taken, but all streets and water courses along the line were carefully surveyed and the boundaries of private lands were run out.

For three weeks the men were boarded in hotels in the two terminal cities; during nine weeks they were carried by team or railroad to the work from headquarters on the main line; and for twenty weeks and two days they lived in camp. From the camp, which occupied three different sites, about 26 miles of location were made, teams being kept with the camp for transportation.

TABLE VI.—DISTRIBUTION OF LABOR

Description of work	Cost	Cost per mile	Pct. of labor total	Pct. of grand total
Running the line finally adopted	$1,500	$35.10	39.7	20.8
Running lines afterwards abandoned	432	10.10	11.4	6.0
Surveys of intersected streets	666	15.60	17.6	9.3
Leveling on line finally adopted	156	3.65	4.1	2.2
Leveling on lines afterward abandoned	65	1.52	1.7	0.9
Leveling on intersected streets	20	0.47	0.5	0.3
Meandering ponds and streams	57	1.33	1.5	0.8
Surveying private boundaries	382	8.95	10.0	5.3
Triangulation and traverse lines	146	3.42	3.9	2.0
Exploration	10	0.23	0.3	0.15
Check levels	10	0.23	0.3	0.15
Office work by field men	61	1.43	1.6	0.8
Holidays, absences and rainy days	279	6.55	7.4	3.8
Totals	$3,784	$88.58	100.0	52.50

Table VI of labor distribution does not include any general officers' salaries nor that of the chief engineer. The map drawing was done in the general office and does not figure in these tabulations.

Surveying instruments were supplied from those previously in use by the company, and interest on their cost is charged under "Field and Office Equipment." The camp equipment consisting of seven tents, complete mess outfit, cot beds, blankets and quilts, was purchased second-hand at a discount of 50 per cent.

During the nine weeks above mentioned many days were lost on account of rain for which the men, being at home, were not paid. The pay of the party was as follows:

Position	Pay per day
Assistant engineer in charge	$ 4.50
Transitman	3.33
Leveler	2.50
Axman and teamster, 7 days per week	2.25
Chainmen	2.00
Rodman	1.75
Axmen	1.50
Cook, per week	15.00

A study of the tables does not suggest much resemblance to similar ones previously published, the most marked difference appearing in the matter of camp maintenance, Table VIII. Much of the higher cost shown here is doubtless due to the high cost of living prevailing. Also much may be due to the fact that all the men were accustomed to a pretty good table and an effort was made to provide them with home comforts.

The total cost per mile given, $168.08, Table VII is the cost per mile of final location, and will be seen to include the cost of preliminary lines, and all the detail surveying necessary for complete land plans.

TABLE VII.—DISTRIBUTION OF EXPENSES

	Cost	Cost per mile	Pct. of exp. total	Pct. of grand total
Field and office equipment	$ 160.49	$ 3.75	4.7	2.2
Railroad and street car fares and expenses	453.73	10.60	13.3	6.4
Board and lodging	167.00	3.90	4.9	2.3
Team transportation	836.32	19.50	24.6	11.6
Camp equipment	209.16	4.90	6.2	2.9
Camp maintenance	1,488.92	34.82	43.9	20.7
Purchased information	81.38	1.90	2.4	1.4
Mail, telegraph and telephone	5.56	0.13	.....	......
Totals	$3,402.56	$ 79.50	100.0	47.50
Grand totals	$7,186.56	$168.08	.....	100.00

TABLE VIII.—ANALYSIS OF CAMP MAINTENANCE

Commodity—	Cost	Cost per meal—4,047 meals	Cost per man per day	Pct. of total cost
Meat, fresh and canned	$ 373.72	$0.092	$0.239	25.1
Fish, fresh and canned	51.93	0.013	0.033	3.5
Potatoes	29.84	0.007	0.019	2.0
Other vegetables	53.93	0.013	0.034	3.6
Fruit, fresh and canned	120.58	0.030	0.077	8.1
Groceries	108.56	0.027	0.069	7.3

Totals	$1,488.92	$0.368	$0.952	100.0

Cost of Making a Relocation Survey of Underground Pipe Lines, Cincinnati, Ohio.—Engineering and Contracting, Aug. 12, 1914, describes in detail the methods used in this survey and gives the following costs.

A typical field party, together with rates of pay, as they were organized in 1913, is here given:

Position	Rate per month
Chief of party	$90
Instrumentman	60
Rodman	50
Rodman	50

The number of field parties was gradually increased from one on May 1, 1912, to five on Aug. 23, 1912, this number was continued until Jan. 16, 1913, when the sixth party was put in the field. The number of field parties was increased to eight in May, 1913, and with this field force of 32 men working during the summer, the field work was completed. The last field party was disbanded on Nov. 22, 1913.

The accompanying cost report, see Table IX, shows a decrease in the average cost per mile during this time from $77.53 for March to $61.20 for November or a decrease of $16.33 in the average cost. There is also a decrease of $8,166.80 in the estimated cost to complete the work. During this same time 283.5 miles of sewers were measured at a cost of $13,880.52, which gives an average per mile cost for this period of $48.96. The average costs are based on payroll charges only.

Complete information, as called for in Instructions to Field Parties was obtained on 496 miles of sewers, together with other information pertaining to the streets of the city. This includes 42 miles of sewers within the city limits for which there were no records.

The increase in the cost of the field work at the end of the season is due wholly to vacation time and the locality in which most of this work was done.

Field Work.—The work consisted of: Running bench levels, to establish elevations; Location of pipes by traverse including the following: Street and curb lines, corners, etc. Sewer center lines. Manholes, sewer, electric, telephone, etc. Inlets and catch basins. Valves, water and gas. Fire hydrants and fire cisterns. Culverts (obtain size). Bridges. Electric and steam railroad tracks.

The size and shape and condition of all pipes and appurtenances was also determined and reported.

Sewer Record Plats.—The primary purpose of these plats is to show correctly all information regarding the sewers: Their sizes, grades, location, inlets and branches. They include all improved portions of the city. These sheets also give information regarding all other underground structure. They show, therefore, the best location for new sewers or pipes. Formerly, it has been necessary to visit the various corporations having pipes or conduits in the streets in order to get this information.

These record plans are 23 × 32 ins. within the border and a binding edge of 1½ ins. is left on the left hand end of the sheet. One portion of the city is platted on a scale of 40 ft. to the inch; all other parts of the city are platted on a scale of 50 ft. to the inch.

Methods of Making Topographical Surveys and Their Cost.—The following discussion and data by D. L. Reaburn, Division Engineer, Los Angeles Aqueduct, are taken from an article in Engineering News, Aug. 10, 1911.

Two methods are in common use in this country for making topographic surveys. The older one, known as the plane-table method, has been used more extensively than any other. It is used either with or without stadia. The other, known as the transit stadia method, has been in use about 50 years.

The plane-table is used by the U. S. Coast and Geodetic Survey, the U. S. Geological Survey and the U. S. Reclamation Service; while the transit stadia has been used exclusively by the U. S. Lake, Mississippi River, Missouri River and other surveys conducted by the Corps of Engineers, U. S. A. It is also used, more or less, by engineers in general practice.

The plane-table is indispensable for geographical surveys, especially in mountainous regions of large relief. When provided with a micrometer eyepiece to the alidade, it can be used to great advantage on reconnaissance and exploratory surveys.

When used with stadia rods the plane-table is adapted to mapping on scales up to about 500 ft. to the inch; on larger scales than this the problem becomes

TABLE IX.—COST DATA OF CINCINNATI UNDERGROUND SURVEY FOR FIELD AND OFFICE WORK

Month	Field work					Platting record plans					
	Progress in miles	Cost per mile for month	Mileage sewers surveyed	Av. cost per mile	Estimated cost based on 500 miles	Progress in miles	Cost per mile for month	Mileage sewers platted	Av. cost per mile	Estimated cost based on 500 miles	Total estimated cost, field and platting
1912—											
December	11.1	$150.17	149.7	......	....	27.4	$39.14	87.4	......	....	....
1913—											
January	19.4	86.05	169.1	$75.74	$37,869.40	27.5	40.06	114.9	$52.93	$26,359.84	$64,229.24

NOTE.—Costs based on payroll expenses only.

a mechanical one of locating points rather than sketching, and compared to the more rapid transit stadia method, the plane-table is decidedly at a disadvantage.

The three-point method cannot be used to advantage on large scale work with the plane-table. A chained traverse line is generally required for control. In rough and brushy country this traverse work is slow, laborious and expensive. In rough country the hand level method is also very slow and expensive, and it is difficult to delineate accurately the character of the ground surface. The transit stadia method, on the other hand, is not adapted to small scale mapping of extended areas.

The writer has, however, used the transit to advantage in connection with the plane-table on 2,000 ft. to the inch work, where it was desirable to do the sketching in the field. The points were located by transit and plotted on the plane-table sheet with a small protractor.

The transit stadia is well adapted to large scale detail surveys. On such surveys the location and plotting of the detail points constitutes the major portion of the work. The transit in the hands of a skilled observer is capable of locating these points with more ease and rapidity than any other instrument. The transit is better adapted to work in brush than the plane-table, and there is not so much lost time from adverse weather conditions.

The *fundamental principles* governing the execution of such work along economic lines may be stated as follows: There should be a rigid horizontal and vertical control, supplemented by a less precise secondary control, upon which to base the details of the work. These principles are fully realized by the transit stadia method. The rigid control being the triangulation and precise levels, and the secondary control the stadia line. In flat country a traverse line control will sometimes be found more economical than a triangulation system.

The question of economical methods of conducting location surveys does not, as a rule, receive much consideration. The writer has observed a number of instances where money has been unnecessarily expended by not adopting methods suited to the country. In one instance, where the hand level method was in use for topography along steep brushy mountain slopes, it required the services of a transitman, levelman, topographer and nine men to make a progress of 2,000 ft. per day. A transit stadia party of six men was substituted and the progress increased to a mile per day.

During the past six years the writer has given much time and thought to the subject and tried out several of the methods in use. The transit stadia method has given the best results. A description of the methods employed, the results obtained and the cost on several pieces of work is given below.

Irrigation Canal Location.—During the summer of 1905, about 100 miles of canal location surveys on the Klamath Project of the U. S. Reclamation Service were made by the transit stadia method. Before the work of canal location was started, topographic maps of all the irrigable lands under the project had been made. About 300 square miles of this work was done. This survey was based on a triangulation and primary level control and was executed by the plane-table and stadia method on a scale of 2,000 ft. to the inch, with a contour interval of 5 ft. The cost of this plane-table work was from $15 to $30 per square mile.

Maps drawn from this survey determined the approximate location and grade of the main canals and from these data the transit stadia survey for final location was made.

Stakes were set along the grade contour from 400 to 800 ft. apart. Azimuths were observed in the forward direction, and distances to feet and differences of level to hundredths were read from each end of the line.

At intervals of every few miles a check in elevation was obtained by a spur line of levels to a nearly B. M. of the primary level system. The errors of closure were never more than 0.2 or 0.3 ft. for the distance of five or six miles between checks. Azimuth checks were obtained by lining in between two triangulation stations or by long sights to prominent points.

The belt of topography developed varied from 200 to 400 ft. in width on flat ground to 50 ft. difference of elevation on steep slopes.

Progress and Cost.—The field party consisted of an observer, recorder and four stadia rodmen. The average number of stadia shots was about 250 per mile. The maximum day's run was four miles with 1,000 stadia shots. The average days run was about three miles.

In plotting, vertical angle readings were reduced by stadia slide rule and the notes were plotted on a scale of 200 ft. to the inch. Stadia readings can be plotted fast as they can be called off from a field book. A good draftsman can usually do all the drafting, including the inking of the sheets. If there are many vertical angles to be reduced an assistant will be required.

No accurate cost data was kept of the work, but an approximation can be arrived at by taking the average daily progress (3 mi.) and the monthly cost of the party, as follows:

1 Transitman at $150	$150.00
1 Draftsman at $125	125.00
1 Recorder at $50	50.00
1 Stadia man at $45	45.00
3 Stadia men at $40	120.00
1 Teamster at $40	40.00
1 Cook at $40	40.00
Total monthly salaries	$570.00
Subsistence 9 men at $20	180.00
Feed for two-horse team	30.00
Total monthly expense exclusive of equipment cost	$780.00

Assuming 26 working days in a month, we have a daily expense of $30, or $10 per mile for the preliminary line.

Los Angeles Aqueduct Surveys.—A triangulation system of simple triangles having sides from one-half to two miles in length, furnished the horizontal control, and a line of precise levels the vertical control for this survey.

The country surveyed was for the most part along steep mountain slopes, in many places covered with brush. The belt of topography developed had a range in elevation of from 50 to 75 ft. The final grade adjustment raised the grade elevation in the Little Lake, Grape Vine and Freeman Divisions above the limits of the first survey, which necessitated a second one on the higher level.

The field party consisted of a party chief, transit stadia observer, recorder, four rodmen, draftsman, assistant draftsman, teamster and cook; a total of eleven men.

The assistant draftsman reduced the vertical angle stadia readings with slide rule and called off the notes to the draftsman. The party chief did the triangulation and sketched the topography after the shots were plotted.

TABLE X.—COST OF TRANSIT STADIA SURVEY, LOS ANGELES AQUEDUCT
(Including Office Work, of 40-ft. Belt of Topography, 5-ft. Contours, Plotted 200 ft. to the Inch)

Month	Feb.	March	April	May	June	Total
Total pay-roll	$200.63	$740.52	$787.25	$794.00	$785.00	$3,307.40
Livery and other expenses	18.68	59.51	80.54	81.40	71.09	311.22
Total cost	219.31	800.03	867.79	875.40	856.09	3,618.62
Miles run	11.0	38.0	43.6	48.1	55.3	196.0
Days worked	9.0	27.0	26.0	27.0	26.0	115.50
Miles run	11.0	1.41	1.68	1.78	2.13	1.70
Cost per day	21.93	25.81	28.43	28.24	28.53	27.41
Cost per mile	19.94	21.05	19.87	18.21	15.48	18.46

The topographic maps were on sheets 22 ins. × 30 ins. in size, drawn to a scale of 100 ft. = 1 in. Rectangular coordinate lines 10 ins. apart were projected on them and the control points plotted by coordinates.

The stadia line was first plotted to a closure between tie points, and the closure error distributed before any topography was plotted. This error was from 1 in 500 to 1 in 1,000 for lines along the grade contour, but where vertical angles entered into the line the results were not so good.

Where the ground was badly broken and for siphon crossings over deep canyons, the sheets were mounted on a plane table, after the transit notes were plotted, and the contours sketched in the field.

Progress and Cost.—The average day's run was about 1¼ miles. The number of stadia shots was from 500 to 750 per day, or about 400 to 600 per mile. The cost, including the triangulation and location of section corners was from $30 to $60 per mile.

During the spring of 1910 about 200 miles of transit stadia location surveys were made in the San Fernando Valley for the Los Angeles Aqueduct distribution system by a party in charge of Mr. J. G. Morgan.

The work was plotted on sheets 22 ins. × 30 ins. on a scale of 200 ft. to the inch, with a contour interval of 5 ft. The contours were followed out on the ground. (See Table X.)

The field party was composed of a transit man, recorder, levelman, four rodmen, draftsman and teamster. Each rodman carried a Locke hand level, for placing his rod on contours above or below the range of the transit or level, by sighting on another rod. As part of the work of spotting the rods was done by the levelman and by the rodmen themselves, the observer was able to keep four rodmen busy.

A belt of topography having a vertical width of 40 ft. was developed from one stadia line which corresponded to a horizontal width of from 100 to 1,500 ft. In some instances several adjacent 40-ft. belts were developed.

The minimum number of stadia shots per day was	240
The maximum number of stadia shots per day was	845
The average number of stadia shots per day was	520
The average number of stadia shots per mile was	300

Level control was obtained from the U. S. Geological Survey B. M.'s.

Two men were occupied 43 days in building signals and observing the angles of the triangulation system, which started from a side of the U. S. Geological Survey primary triangulation. Station marks were made of iron pipes 2 ins. × 4 ft., spread at bottom, set 2½ ft. in the ground and with a flag pole set in them.

DATA AND COST OF TRIANGULATION

No. of stations set and observed	50
Approximate area controlled	400 sq. miles
Total salaries	$463.34
Livery and other expenses	67.43
Total cost including computations	$530.77
Cost per station	10.61
Cost per square mile controlled	1.33

Topographical Survey for Industrial Development.—During the spring of 1909 a topographic survey was made by parties in charge of Mr. A. J. Ford of a large tract of land near Riverside, Cal., for the purposes of industrial development. The work was plotted on a scale of 100 ft. to the inch with a contour interval of 2 ft. The contours were followed out. No stadia readings for elevations of the contours were taken except to an occasional saddle or knoll. The ground was rolling; had a total rise of about 300 ft.; was mostly under cultivation, and the conditions were favorable. All buildings, fences, roads, etc., were located.

This work was executed by both transit and plane-table parties composed of five men each as follows: Transit party: observer, recorder and three rodmen; Plane-table party; plane-table man, levelman, recorder and two rodmen.

The rods were placed on the contour by the transitman in the transit party, and by the levelman in the plane-table party by sighting the target with which the rods were provided. After a contour was followed as far as could be reached from the setup, the rodman moved his target up or down 2 ft. and returned on another contour.

The control work was done before the writer took charge and no data can be given for it. The number of points located by the transit parties was from 500 to 600 per day, or about 7 or 8 per acre.

Table XI gives the total costs of the topographic work for each of the three parties. This includes the salary of the topographer in charge of parties and the cost of supervision.

TABLE XI.—COST OF TOPOGRAPHIC SURVEYS, RIVERSIDE, CAL.

(2-ft. contours, plotted 100 ft. to the inch)

	Party No. 1 Transit stadia	Party No. 2 Plane-table	Party No. 3 Transit stadia	Totals
Field and office labor	$1,644.62	$1,123.73	$ 313.54	$ 3,081.89
Subsistence	414.05	285.51	71.44	771.00
Transportation and supplies	164.00	134.70	38.00	336.70
Total cost	2,222.67	1,543.94	422.98	4,189.59
Acres surveyed	7,448.8	1,716.2	1,695.0	10,860.0
Cost per acre	$0.298	$0.90	$0.25	$0.386
No. days in field	100.0	78.0	18.0	196.0
Average progress in acres per day	74.49	21.95	94.17	55.41
Cost per day	$ 22.23	$ 19.79	$ 23.50	$ 21.38

REMARKS.—The cost of draftsman's work was apportioned between the two transit parties. The cost of supervision was apportioned to the three field parties.

In comparing the costs in the table it should be noted that it was necessary in addition to the main control system to establish two points by triangulation upon each plane-table shot, the cost of which is not included for Party No. 2.

All men employed in the work except the topographer in charge were inexperienced in topographic work. The increased efficiency of Party No. 1 is shown in the table below for a period of three months.

Month	Progress acres per day	Cost per acre
April	40	$0.54
May	99	0.23
June	122	0.18

Stadia Survey for Irrigation Project.—The survey, of the Preston Beck, Jr. Grant in New Mexico, formed the basis of a preliminary design and report for the reclamation of this property. The survey was made during the period from Sept., 1910 to May, 1911. The following is abstracted from an article by Mr. Vincent K. Jones in Engineering and Contracting, July 31, 1912.

Owing to the broken character of the country and the many ridges over which the water in the canals must pass a topographical map was necessary to determine the controlling points of the canal system and to enable a sufficiently close preliminary design and estimate of cost to be made. For this purpose extreme accuracy is not essential and the extra work necessary to obtain a high degree of accuracy would be wasted. The results proved to be sufficiently accurate, the errors of traverse by stadia varying from 1 in 400 to 1 in 600 and the errors in elevation when carried by transit-stadia about 1 ft. in 6 miles of horizontal distance.

The general location of the main canal was first obtained by running several rough level "fly-lines." These showed the only practical line for a main canal to lie somewhere in a strip of land whose outer limits were contours approximately 100 ft. apart vertically.

Starting at one of the controlling points the main canal known as El Paso Gap a line of topography was carried towards the Pecos River covering a strip lying approximately between the 5,200 and 5,300 ft. contours. About 2 ft. per mile of line were allowed for the rise of the canal as the line approached the river. This line, afterward used as a base line on which the topography of the land under the canal was hung, was run as a stadia traverse with elevations carried by an 18-in. wye level and checked by taking vertical angles with the transit.

From this base line the topography of the strip of land mentioned above was taken, sufficient side shots being made to enable 5 ft. contours to be interpolated on a scale of 600 ft. to the inch. The shots between stations varied from 200 ft. to 1,800 ft. in length and the number of side shots from each station from 2 to 200, depending on the roughness of the country covered and the position of the instrument station. The length of this line was 41 miles.

When the Pecos River was reached a stadia traverse was carried up the river for 12 miles to form a connecting link between the canal topography and the survey of a reservoir situated near the town of El Cerrito. The river runs in precipitous box canon between the reservoir and the point of diversion near Tecolotito, which required 2½ days to traverse. Side shots were taken along the sides of the cànon to determine the width and general topography of the river bed. Elevations throughout the base line and river traverse were carried by the wye level.

The same general methods were followed in the survey of the reservoir, the topography being hung on closed stadia traverses and elevations being by level. The high water line of the reservoir covers 401 acres, but the topography covered 20 acres. This job required 3½ days and the topography was taken sufficiently close to enable 1 ft. contours to be plotted on a scale of 200 ft. to the inch.

The "Borrow Pit" method of reservoir surveying is in general use in Southern Colorado, but the results obtained by the method described above, especially in broken country, proved to be as accurate and much better from an economical standpoint.

Cost of Base Line.—The cost of the 41 miles of stadia base line, topography, 12 miles of river traverse and the survey of the reservoir is as follows:

General expense	18.33
Salaries	1,107.60
Board (including cook's wages)	467.75
Team feed and shoeing	51.53
Depreciation of equipment and horses	47.65
Office supplies	42.35
Total	$1,735.21

The salaries paid as follows:

1 Engineer and draftsman	$150.00
1 Transitman and chief of party	90.00
1 Levelman and recorder	60.00
1 Level rodman and head topography rodman	45.00
1 Topography rodman	45.00
1 Topography rodman	35.00
1 Cook	45.00
1 Teamster and camp man	30.00

Board was in each case included in addition to the above salaries. Interest and depreciation were charged on live stock at a rate of 1½ per cent of value at start of survey per month. On the other camp equipment and instruments, interest and depreciation charged at a rate of 3 per cent per month. These percentages were figured to pay 10 per cent interest per annum on the outlay for equipment and to pay for the equipment in the probable active life of the outfit as a whole.

In the above no overhead expense has been charged to the work. Overhead charges vary so greatly on different projects that this expense should not have a place in cost data for engineer's use. These costs must be estimated according to the size of the project, office organization, and intricacies of the general organization and are generally beyond the control of the engineer.

The work was carried on at a distance of from 25 to 50 miles from the base of supplies and shipping point on the railroad and therefore a great deal of hauling was necessary which would not be if operations were carried on near the base of supplies. Two teams and one saddle horse were used. The teams were driven alternately in the field except when one team was hauling supplies or moving camp.

Progress of Work.—With three stadia rodmen and a recorder who drove the team and also acted as rear flagman, the work progressed rapidly. Six to eight miles of traverse line with all side shots were frequently made when in fairly open country. When in the breaks near the river or in close proximity to the large mesas, 2 to 4 miles of traverse was the general average. As the traverse lines were generally a half mile apart the area covered varied from 640 acres in rough country to 2,560 acres per day in open prairie.

The stadia-transit notes were worked up in camp every night and generally plotted the next day, so that if any errors were picked up they could be corrected before moving camp.

The notes were plotted to a scale of 1 in. = 600 ft. on detail paper in the camp. The sheets were not traced.

It was necessary to camp where water was available. The moves between water holes or springs averaged about eight miles. The distance from the camp to the work was frequently as far as 10 miles, which made the job cost more than it would if more camps could have been found.

The total area covered by topography was approximately 200,000 acres, of which 145,000 acres were classed as tillable land and 55,000 acres classed as rough. The topography of the rough land was not taken as closely as that of the tillable land except in places where a canal will be built or in a prospective reservoir site. The total length of traverses averaged one mile for each 300 acres.

Cost of the work, exclusive of the first base line, river traverse, and Pecos Reservoir survey, the cost of which was given above, was as follows:

Salaries	$3,133.00
Board expense (including cook's wages)	768.11
Corral expense	206.04
General expense	155.10
Depreciation equipment and horses	149.40
Office and field supplies	71.43
Total	$4,483.08

The total cost figured on a unit basis is $.0311 per acre, $9.33 per mile of traverse line, including maps and the classification of the land, but not including overhead charges.

The cost of team feed and shoeing averaged $0.214 per head per day. The cost of board, including cook's wages, but not including cartage of supplies, averaged $0.247 per meal. This cost varied from 18 cts. in the winter, when fresh beef could be kept in camp, to 32 cts. in summer.

Cost of Making Topographic Resurvey on the Truckee-Carson Project, Nevada.—L. E. Gale gives the following data in Engineering and Contracting, Feb. 25, 1914.

A portion of the country lying north and west of Fallon being irrigable and water for irrigation being available upon the completion of the Lahontan Dam, it was found necessary to make a topographic resurvey before deciding on a system of irrigation. The country had previously been mapped on a scale of 4 ins. to the mile and 5 ft. contour interval by plane table parties in 1907. This scale and contour interval was inadequate in detail and the resurvey was made on a scale of 400 ft. to the inch with a 2-ft. contours.

The wages paid were as follows: Instrumentmen $100 per month, rodmen $60 to $70 per month, recorders $70 per month, teamster $60 per month, cook $60 per month. Each man was deducted 25 cts. per meal and the mess-house was intended to be self-supporting, including the wages of the cook. The mess-house was on wheels with walls and roof of heavy canvas stretched over a light wooden frame, the whole being easily moved from camp to camp by four mules.

Attached is a detailed cost summary, showing cost per acre of the work in both districts, which includes the cost of moving the camps a total distance of 35 miles.

TABLE XIII.—COST OF TOPOGRAPHIC RESURVEY FOR DISTRICT NO. 2 TRUCKEE-CARSON IRRIGATION PROJECT

Classification	Amount	Cost per sq. mile
Horizontal Control:		
Labor	$ 294.86	$ 11.84
Corral expense	36.00	1.45
Supplies	25.98	1.04
Miscellaneous expense	94.90	3.81
Total for horizontal control	$ 451.74	$ 18.14
Vertical Control:		
Labor	$ 122.15	$ 4.90
Corral expense	18.50	.74
Supplies	9.77	.39
Miscellaneous expense	42.50	1.71
Total for vertical control	$ 192.92	$ 7.74
Plane Table Development:		
Labor	$1,294.77	$ 52.00
Corral expense	114.0	4.58
Supplies	19.14	.77
Miscellaneous expense	389.83	15.65
Total for plane table development	$1,817.74	$ 73.00
Draughting	$ 162.05	6.50
General expense	252.71	10.15
Summary by Items:		
Labor	$1,711.78	$ 68.74
Corral expense	168.50	6.76
Supplies	54.89	2.20
Miscellaneous expense	527.23	21.18
Draughting	162.05	6.50
Total field cost	$2,624.45	$105.38
General expense	252.71	10.15
Totals	$2,877.16	$115.53

The item "Miscellaneous expense," consists of idle time for men and teams, moving camp, equipment depreciation and miscellaneous labor and supplies which could not be charged directly to any of the classes of work shown on sheet. Location of work—Townships 19 and 20 N., R. 27 and 28 E., north of Carson River, in District 2. Area mapped, 24.9 square miles; rough sandy country; scale, 1 in. equals 400 ft.; contour interval, 2 ft. Horizontal control developed from geodetic co-ordinates and maps projected from polyconic projection 41 linear miles of vertical control; 26 triangulation stations calculated and plotted; 15 permanent triangulation station marks placed 4 P. B. M.'s placed. Mess loss of $90.79 is not included in the cost report. Average unit performance in square miles per plane table day 24.9, plane table days 94, unit performance 255.

Plane Table Development.—Relative to the plane table work, Mr. Gale says: Two plane tables were operated, the party for each consisting of plane table man, recorder and two rodmen. The recorder entered the distances and rod readings in the notebook and calculated the elevations, calling the same to the

TABLE XIV.—COST OF TOPOGRAPHIC RESURVEY FOR DISTRICT NO. 3 TRUCKEE-CARSON IRRIGATION PROJECT

Classification	Amount	Cost per sq. mile

General expense	323.25	7.76
Total cost		$85.12

* The item "Miscellaneous expense" consists of idle time for men and teams, moving camp, equipment depreciation and miscellaneous labor and supplies which could not be charged directly to any of the classes of work shown. General expense is administration Washington D. C., Portland, etc. Corral expense is time of teams. Location of work: Townships 18 and 19 N., R. 27 and 28 south of Carson River, in District 3. Area mapped 41.6 square miles; rough sandy country; scale 1 in. equals 400 ft.; contour interval 2 ft. Horizontal control developed from geodetic co-ordinates, and maps projected from polyconic projection; 61 linear miles of vertical control; 36 triangulation stations calculated and plotted; 36 permanent triangulation station marks placed; 8 B. M.'s placed (bronze); 2 camps. Mess house loss of $106.66 is not included with cost report. Average unit performance in square miles per plane table day. 41.6 plane table days, 132 unit performance, .315.

instrumentman who plotted the position of each point and wrote the elevation by it. The two rodmen worked out the country in strips about 300 ft. wide, the width depending on the roughness of the country and varying in length or distance from the table with the visibility of the rod. In this work the contours were not directly located, but a sort of cross-section of the country was taken, the rodmen giving the high and low points, general outlines of hills and pot holes, changes in slopes, low points in saddles and breaks in the contours in general. Each set-up of the table took in an area approximately 2,000 ft. square or 1,000 ft. on each side of the table.

After all shots necessary in each set-up were taken, the plane table man walked over the ground and drew in the contours from the plotted elevations combined with personal observation; verifying doubtful contours by three-pointing at the spot and getting additional elevations where necessary.

The rodmen soon became proficient in their work, after a period of instruction, and when they understood just what was desired very excellent results were obtained. A great deal depended, of course, upon the topographical eye of the topographer.

The average area covered each day by each party was 0.3 square mile. The topographers set a standard for their work of 400 shots per diem and always tried to exceed this standard if possible; 400 shots in one day, in addition to sketching all contours in the field, locating section corners and moving between set-ups, was usually a pretty fair day's work, but this mark was frequently exceeded. It can readily be seen that the number of shots taken indicates much better than the area covered how hard the parties worked during the day.

Cost of Stadia Surveys of 50,000 Acre Flood-Control Basin.—L. R. Howson gives the following in Engineering News-Record, Sept. 27, 1917.

Planning the flood-control system for the protection of Columbus, Ohio, necessitated the survey of an area of 50,000 acres for three reservoir sites of respectively 23,000, 18,000 and 9000 acres. This work is for the Franklin County Conservancy District, of which Alvord & Burdick, of Chicago, are the engineers. It was necessary that the survey information should be available for office computations as soon as possible, and that the surveys should be completed before winter. The stadia method was selected as combining speed with accuracy for the class of survey to be made. The methods of procedure, with instructions to parties and a system of reports for comparing the progress of the three parties, were devised by the writer. The survey was in charge of John C. Prior, resident engineer for the district.

The areas surveyed differ greatly in shape, steepness of slopes, percentage of wooded area and regularity of width or freedom from side ravines. The Delaware basin is the largest and has the most favorable topography for rapid stadia work. The survey covered 23,000 acres on a site about 14 miles long and from ½ to 2½ miles wide. The maximum difference in elevation is about 90 ft. There are only three large side ravines or creek channels.

The Dublin-basin survey covered 18,000 acres, of which about 20% is wooded. The area is 25 miles long, with an average width of about one mile and a maximum of about 2½ miles. The country is somewhat rougher than that in the Delaware basin, and has a range of 150 ft. in elevation. More numerous side ravines, some of which are virtually gorges, cut into the stratified limestone to depths of from 50 to 75 ft., with a scarcely greater width.

The Flint basin, though containing only about 9000 acres, has very rough topography and is largely wooded. Steep side ravines enter the river channel at frequent intervals, one every 600 ft. on each side of the river not being unusual. The basin is about 11 × 1½ miles.

Each party consisted of four field men and one office man, with salaries as follows: Chief of party, $115 to $125 per month; instrumentman, $75 to $85; draftsman (office), $85; two rodmen, $2 per day. All expenses were paid for the first three men. The rodmen received all expenses when away from home, which averaged about half the time. The work of the instrumentman and the draftsman was considered of equal importance. Rodmen were picked up locally, being selected for willingness, agility and physique. A bright country boy under a good chief or instrumentman soon becomes a first-class stadia rodman. For each party there was a Ford automobile with special body.

About nine hours per day were spent in the field. Primary traverse lines for several days' topography were run and closed before topography was started in that area. Primary traverse points were marked with oak stakes, and levels were taken on them. Secondary traverses were run as topography was taken. All these were closed in each night, so as to catch any errors. Two field books were used. The primary traverse line was carried in both books. The draftsman each day plotted the notes taken in the field on the preceding day. Bench marks were established at about ½-mile intervals. All available data were gathered as to adequacy of bridge and culvert openings.

Special rods were made to permit of rapid long-distance reading without eye-strain. The rods were of 1 × 4-in. clear poplar, 15 ft. long, painted in black and white and could be read for 3000 ft. as easily as the ordinary rod at only a fraction of that distance.

The instrumentman recorded his own notes. For the country surveyed a recorder's services were not warranted. For each set-up only about 15 shots could be taken.

The draftsman reduced all stadia notes with the aid of a K. & E. stadia computer. The notes were plotted with the use of an 8-in. full-circle paper protractor, which carried a scale. Both the elevation of the ground and the instrumentman's shot number were marked on the drawing for identification by the instrumentman in his daily checking of the map. The scale was 1 in. to 400 ft. for the Delaware and Flint maps, and 1 in. to 600 ft. for the Dublin map.

Each chief-of-party made a daily report on a post-card blank form. This gave the weather conditions, hours spent in the field, number of transit set-ups, number of readings taken and number of acres covered, with notes or remarks. These were compiled into weekly reports, as shown. Copies of these weekly reports were given to each party. While the figures therein were interpreted in the light of the conditions influencing them, they created an added impetus to make a good showing.

The form of the report was so arranged as to indicate the differences in the character of the topography of the three areas, which has been noted above. It is evident that where few shots per acre are taken, the topography is comparatively uniform. Where few shots per set-up are possible, the country is either wooded or rough.

The greatest area covered in any one week was 2190 acres. The greatest number of shots in any week was 1902, or an average of 317 per day. The average number of shots per day for all parties was slightly over 200, counting all time occupied in running level and traverse lines.

Table XV shows the summarized performance and costs of the three survey parties on this work. Table XVI has been prepared to show the costs of these and other stadia surveys where some details of execution, cost and character of land surveyed were available.

TABLE XV.—STADIA SURVEYS OF RESERVOIR AREAS AT COLUMBUS, OHIO

	Dublin	Delaware	Flint
Total acres surveyed	18,000	23,000	9,000
Av. acres surveyed per day	182	274	105
Av. hours in field per day*	9.1	9.5	9.1

Topographic Surveys.—The accompanying tables, compiled by Franklin & Co., Civil Engineers, Philadelphia, Pa., and published in Engineering News, May 28, 1914, give cost data for a number of different surveys. Under "Remarks" is briefly stated the character of the country, the method of doing work, the time of year, and any notes which affect the cost.

TABLE XVII.—COST OF TOPOGRAPHICAL SURVEYS

	Size	Unit day in hr.	Time		Cost			
			Field	Office (one man)	Field	Office	Total cost	Unit cost per acre
1.	308 acres	6½	40 days 3 men	10 days	$327	$45	$ 372	$1.20 per acre
2.	190 acres	7	22 days 3 men	9 days	$194	$38	$ 232	$1.22 per acre
3.	104 acres	7½	8 days 3 men	1 day	$74	$ 4	$ 78	$0.75 per acre
4.	300 acres	8	40 days 3 men	22 days	$480*	$92	$ 572	$1.90 per acre
5.	99 acres	7½	12 days 3 men	4½ days	$ 115	$23	$138	$1.20 per acre
6.	1,464 acres	8½	87 days 3 men	18 days	$ 1052	$92	$1144	$0.78 per acre
7.	11,264 acres (259 mi. of stadia)	8	222 days 4 men	65 days	$ 3791*	$386	$4177	$0.37 per acre (Topography $14.63 per mi. (stadia lines)

* Field cost includes subsistence.

REMARKS

1. 95 % = points established on 5-ft. contours with Y-level, and located with plane-table. 5 % = points established on 5-ft. contours by, and located with stadia traverse = (woods). Land hilly with rise of 120 ft. Survey made Aug. to Oct. Scale of map—1 in. = 100 ft.

2. 80 % = points established on 5-ft. contours with Y-level, and located with plane-table. 40 % = points established on 2½-ft. contours with Y-level, and located with plane table. 20 % = woods = points on 5-ft. contours established and located with stadia traverse. Land hilly with rise of 180 ft. Survey made in Dec. and Jan. Scale of map—60 in. = 1 ft.

3. 70 % = points established on 5-ft. contours with Y-level, and located with plane-table. 30 % = woods = points on 5-ft. contours established and located with stadia traverse. Land = rolling = rise of 80 ft. Finished plan not made. Survey made in June. Scale of map—1 in. = 100 ft.

4. 70 % = points established on 6-ft. contours with Y-level, and located with plane-table. 40 % = points established on 3-ft. contours with Y-level, and located with plane-table. 30 % = woods = elevations obtained by stadia and vertical angles-contours interpolated. Extra large number of buildings, railroads, etc. were located. Scale—1 in. = 100 ft. Land = rough and mountainous = rise of 430 ft. Survey made Nov. and Dec.

5. Points established on 5-ft. contours with Y-level, and located with plane-table. Land = rolling = rise of 60 ft. Survey made in Feb. and March. Scale of map—1 in. = 100 ft.

6. 90 % = points established on 10-ft. contours with Y-level, and located with plane-table. 10 % = woods = points on 10-ft contours established and located with stadia traverse. All roads traversed and chained.

Land = hilly = rise of 150 ft. Survey made Sept. to Dec. Scale of map—1 in. = 200 ft.

7. Survey made entirely with stadia. Tape never used. Rough and mountainous, streams, ridges, and 2 coal outcrop lines traversed and topography taken by stadia and vertical angles. Contours interpolated. Levels on transit lines carried along by stadia and vertical angles. Survey made Oct. to Feb. Rise in elev. = 1,150 ft. Stadia lines tied on to outline. Survey made 3 months previous. Scale—1 in. = 500 ft.

Location: 1 to 6 inclusive—, in Pennsylvania. 7, in West Va.

TABLE XVIII.—RAILROAD PRELIMINARY SURVEYS AND ESTIMATES

Size	Unit day in hrs.	Time — Field	Time — Office (one man)	Cost — Field	Cost — Office	Total	Unit cost per mile
1. 26 mi.	8½	74 days 4 men	24 days	$1450*	$144	$1594	$66.30
2. 27.5 mi.	8½	75 days 4 men	25 days	$1400*	$150	$1550	$56.40
3. 12 mi.	8½	50 days 4 men	35 days	$1011*	$165	$1176	$98.0
4. 5.1 mi.	8½	14 days 4 men	14 days	$ 236*	$43	$279	$54.60
5. 34 mi.	8	43 days 9 men (inc. axemen)	54 days	$ 848	$238	$1086	$32

NOTE.—Field cost includes transportation (except to Cuba). * Field cost includes subsistence.

REMARKS

1. Transit line chained. Topography taken with Y-level and cross-sections. Land = hilly and wooded. Projected line = 21 miles. Survey made June to Aug. Scale of map—1 in. = 200 ft.

2. Transit line chained. Topography taken with Y-level and cross-sections. Land = 50 % woods and mountainous and 50 % open. Scale of map—1 in. = 200 ft. Projected line = 27½ mi. Survey made Aug. to Nov.

3. Transit line chained. Extra large number of locations of towns, railroads, etc., were made. Land = rolling and open. Projected line = 9 mi. Topography with transit (stadia and vertical angles) and plane-table. Made in Feb. and Mar. Scale of map—1 in. = 200 ft.

4. Transit line chained. Large number of extra locations were made. Topography with transit (stadia and vertical angles) and plane-table. Land = rolling and open. Projected line = 3.6 mi. Made in May-June. Scale of map—1 in. = 200 ft.

5. Transit line partly chained and partly stadia. Scale of map—1 in. = 200 ft. Topography with Y-level and transit (stadia and vertical angles). Land = mountainous and heavily wooded. Survey made Nov. to Jan. No maps of country. Cost of reconnaissance therefore was greatly increased. Subsistence amounted to $18 per mile; was paid for by owner.

Location: No. 1—N. Carolina
No. 2—Virginia
No. 3 & 4—Pennsylvania
No. 5—Cuba.

In taking the Pennsylvania topography each 5-ft. contour was traversed by the rodman along points established by the Y-level and located by plane-table. The excessive cost of the fourth item was due to the extra large number of railroad tracks, buildings, etc., that were located.

The topography in West Virginia was taken by running stadia and vertical-angle transit lines along all streams, ridges and two coal outcrop lines, one of which was about one-third and the other two-thirds of the distance up the mountainside. Elevations were taken from all these lines (which formed a gridiron system) and the 50-ft. contour lines were interpolated.

The railroad preliminaries (with the exception of the Cuban work) were all tape-measured transit lines, with topography taken either with cross-sections, stadia and vertical angles or the plane-table.

In Cuba, the transit line was partly measured with tape and partly by stadia and vertical angles. No maps of the country could be found so that the reconnaissance was necessarily much more extensive than usual, thus increasing the cost. The owner provided subsistence of the men, which amounted to about $18 per mile.

Weekly Report, Week Ending October 23, 1915

"Financial Costs," Frequently Underestimated.—Engineering and Contracting, March 6, 1912, gives the following.

It is rare that an engineer's estimate of the cost of a project contains an adequate allowance for what may be called "financial costs." In fact, even the most self-evident of these "financial costs," interest during construction, is often omitted from cost estimates. Sometimes such omissions are purposely made by engineers, especially when it is known that the owners or promoters will themselves make an estimate of the "financial costs." We question, however, whether it is ever wise for an engineer to omit any element of cost that he is capable of making, unless he is specifically instructed to return an estimate of the physical property only.

What are the "financial costs" of a project? They may be classified as follows:

1. Organization cost; i.e., legal and administrative costs (other than engineering and superintendence), general office expenses, etc.
2. Taxes during the construction period.
3. Brokerage fee or discount involved in marketing securities.
4. Interest on the capital tied up during the construction period.
5. Development cost (being the sequel to interest during construction) or the accumulated deficit below a "fair return" on the invested capital up to the time that a "fair return" begins to be earned.

This last element of "financial cost" is one whose existence has always been recognized by experienced promoters, but one that, until quite recently, has never appeared in any engineer's estimate that we have seen. *Yet failure to provide capital with which to meet the development cost of a project has been the cause of innumerable receiverships.*

During the past year we have published several articles discussing the development cost, or "going value," of public utilities, such as railways; and the method of deducing the development cost by the aid of the ledgers of a company has been illustrated by several examples. It may be added that the writer has appraised the property of about a dozen public utility companies within the last year, and has deduced the development cost in each case. It is rare that the development cost has been less than 25 per cent of the cost of the physical plant.

In Engineering and Contracting Feb. 14, 1912, Norman E. Webster, Jr., discusses "Methods of Financing Irrigation Developments." Mr. Webster gives estimates of the "financial costs" of irrigation projects, expressed as percentages of the cost of the physical plant. The following is a summary of his estimate of these cost items:

	Per cent
Organization and promotion	10
General administration	10
Interest and development cost	21 to 30
Total, exclusive of bond discount	41 to 50

Mr. Webster does not use the expression development cost, but classes it under interest lost on the investment up to the time that the property begins to make sufficient net earnings to meet the interest charges. He estimates 6 per cent per annum on the entire cost of the plant for a period of 3½ to 5 years, making a total of 21 to 30 per cent to cover the interest lost on the investment. He also points out that all the bonds must usually be sold in advance of the first construction work, which results in a long nonremunerative period. For the comparative purposes the following percentages used by the writer in recent estimates of electric railway properties may be of interest.

	Per cent
Engineering and supt. (5 %) and business administration (5 %)	10
Legal, taxes and other general expenses	1½
Interest during construction	5
Brokerage fee (cost of selling bonds)	5
Development cost	30

Calling the cost of the physical plant unity (1), we have the following;

	Cost
Physical plant (incl. 5 % for contingencies)	1.000
Add eng., supt. and adm. (11½ %)	0.115
Total	1.115
Add 5 % of 1.115 for interest	0.056
Total	1.171
Add 5 % of 1.171 for brokerage	0.059
Total	1.230
Add 30 % of 1.23 for development cost	0.369
Grand total	1.599

It is difficult for some people to look upon the development cost—the accumulated deficit below a fair return on the investment—as being a real cost. They argue that a deficit can not be a source of value, but is the reverse. Yet, curiously enough, they concede that interest during construction is an element of the cost of a property. When it is pointed out that the development cost is merely a sequel to interest during construction, it becomes more apparent that the development cost is an essential element of the cost of the going concern.

Can a deficit be a cause of value? Yes, if it is not a deficit that connotes a *permanent* loss. A deficit arising from a fire or a burglary can not be an asset in the absence of insurance. But a deficit arising from a necessary expenditure, either to create a physical plant or to create the business of a going concern, is a wholly different sort of deficit. Such a deficit is, in fact, an investment, which, in all probability, will ultimately yield an adequate return if the project is one that is well managed and is not begun too far ahead of the times. Perhaps no better example can be found to illustrate the confusion that a word can cause than is to be found in this word deficit. Since deficit often denotes a permanent loss, it impresses the mind that there is an incongruity in the argument that any deficit can be the measure of an asset. The word deficit is merely a symbol to denote an outlay of cash. If the outlay is irrecoverable—as in the case of loss of uninsured property by fire—the deficit decreases the assets. But if the outlay is recoverable—as in the case of money reasonably spent for advertising an article or promoting an irrigation project—the deficit increases the assets.

Honest promoters never incur temporary deficits in fair return upon their investments without belief in the ultimate recovery of the deficits. But many an honest promoter is too sanguine as to the short duration of the deficit period—the development period. It is clearly the function of the modern engineer to study the development cost of all sorts of projects of an engineering nature, with a view to estimating development costs with some degree of accuracy. Protection of his clients, and of the public whom his clients seek to interest in a project, should be the prime consideration of every engineer who is called upon to design a plant and estimate the cost. Full protection can only be given by a correct and full estimate of cost up to the time that the project will begin to yield an adequate return on the invested capital.

Contractor Analyzes Overhead Costs from Five-Year Records.—The following is given in Engineering News-Record, April 11, 1918.

Overhead is the deceptive part of a contractor's costs on a sewer contract. So stated Stanley D. Moore, president of the Moore-Seig Construction Co., Waterloo, Ia., at the 1918 annual meeting of the Iowa Engineering Society. Less than 10% of the contractors of the country are successful or even solvent, in his opinion. Further notes from his paper follow: "In this age of production we have kept our eyes only on the lessened cost of the actual operation and have forgotten that much of this saving is taken up in overhead charges that did not exist formerly. The unit basis for moving earth by hand may be 25 cents per yard. The same operation by machine may be performed for 10 cents per yard, but the overhead charges on the machine may equal, if not exceed the 15 cents saved. The only advantage of the machine is a gain in time and escape from labor shortage."

An analysis of overhead charges, taken from records of Mr. Moore's company over a period of five years, represents $500,000 worth of sewer work. It was done in better than average soil, at better than average price, handled with better than average efficiency by a well-equipped, well-financed and well-organized concern. Figures for 1917 were omitted purposely because of the unusual conditions under which the firm sustained a loss.

Contract prices in this analysis were distributed as follows: Profit, 1.6%; overhead, 18.4%; material, 18.0% and labor, 62.0%.

In the table, job expense includes freight on tools, drayage, transportation, straight time men, bunk houses and storage. In the consumed material item are such things as lumber, jute, dynamite, coal, gasoline, kerosene, cement bags and boots.

Figured on the basis of net instead of gross cost the 24% becomes 31.7% and to yield 10% on one's money the total bid should be 146.4% of the net cost made up of net cost 100%, overhead 31.7%; and profit 14.7%. To yield 15% the overhead is the same, 31.7%; but profit is raised to 22.8%, making the total bid 154.5%.

Segregated Overhead Charges

Item	Five-yr. average 1911–16	Estimate for 1918	Item	Five-yr. average 1911–16	Estimate for 1918
Job expense	1.4 %	1.7 %	Dues contractors' association	1.8 %	1.8 %
Maintenance	0.6	0.6	Office expense	0.6	0.7
Plant repairs	1.5	1.8	Salaries	2.3	2.3
Small tools	1.1	1.3	Traveling	1.3	1.5
Depreciation	1.0	2.0	War tax	......	0.5
Consumed material	2.4	2.4	Interest on investment	......	0.5
Bonds	0.7	1.7			
Insurance	1.6	1.9			
Interest	1.1	1.3			
Discount	1.0	2.0		18.4 %	24.0 %

The items of cost for which money was actually paid out compared with those for which the engineer usually allows are listed as follows: Engineer's costs usually cover only sewer pipe, bonds, insurance, labor, discount and association dues, but he forgets, said Mr. Moore, jute, city councils' special requests, cement, tools, inefficiency, depreciation, interest, errors, salaries, bad work, attorney's fees, taxes, transportation, engineer's errors, engineer's delays, engineer's estimate, maintenance, bad weather, freight on tools, straight time, storage, lumber, repairs, shipping delays, office expense, manholes, drayage, bad luck, traveling expense, water pipe and gas mains.

Finally, said Mr. Moore, there has been too much secrecy on the part of the contractor, too little information given by the engineer and too much suspicion on the part of the communities, also a regrettable lack of consideration of the rights of the contractor by engineers. Both engineers and contractors guess too much.

Fixed Plant Charges.—The ordinary "fixed charges" on a plant are (1) interest, (2) depreciation (exclusive of current repairs), (3) insurance, and (4) taxes. Often to these items should be added the cost of housing the plant when idle.

Depreciation is the loss in value that occurs in spite of current expenditures for maintenance. Depreciation may be due to the forces of nature or to the "progress of the art" which renders a plant obsolete. Excavating plant is commonly estimated to suffer a depreciation of 10 to 20% per annum. Sometimes the entire first cost of a special plant is charged up against one job, if there is not a strong likelihood of using it again.

Insurance and taxes are usually so small relative to depreciation that they are not separately estimated, but a liberal allowance is then made for depreciation.

Repairs should be estimated as an operating expense item entirely separate from depreciation, for repair costs depend more upon the activity of the plant than upon the lapse of time, whereas depreciation usually progresses with the lapse of time even in the absence of any use of the plant.

The annual "fixed charges" should be divided by the probable number of days actually to be worked per annum. As previously stated, the average is 150 days or less, for most excavating plants in America.

Fixed charges, repairs, the cost of plant installation and shifting, and time lost through delays from breakdowns, etc., are commonly underestimated. In addition, the cost of surplus or standby plant is seldom included in estimates of cost, yet there are few jobs where it does not pay to have a considerable investment in plant that is on hand for emergencies. Extra cars, wagons, scrapers, plows, pumps, etc. are nearly always necessary.

Operating Expense.—Operating expenses may be divided into direct expense and joint, general overhead expense, which together embrace all costs except the "fixed charges" already discussed.

Direct expenses are those directly assignable to a given number of yards of excavation in a given place.

Joint, or general, or overhead expenses are those that must be allocated or prorated because they are not directly assignable to a given yardage.

Preparatory expense is the expense incurred in installing the plant, building construction trails and roads.

Dismantling expense is the cost of dismantling and removing the plant and outfit.

Shifting expense is the expense of moving the plant and outfit from one part of the job to another part of the same job.

Idleness expense is the expense incurred when the plant is not engaged in excavating, preparing, shifting or dismantling.

Productive expense is the expense incurred when the plant is actually working.

Although it is not customary to analyze expenses in this manner, it is wise to do so at least occasionally on every job, not only to be able to estimate costs of future work with greater accuracy but to effect reductions in the cost of the work in hand.

Schedule of Contractors Fees on Government Work.—The following matter, given in Engineering and Contracting, April 17, 1918, is a revision of the percentage fees on Government contracts made by the Emergency Construction Committee of the Council of National Defense. Under the old schedule the fee for work costing under \$100,000 was 10 per cent; 8 per cent for work costing over \$100,000 and under \$125,000, 8 per cent for work over \$125,000 and under \$250,000, \$20,000 for work over \$250,000 and under \$266,666.67 and 7½ per cent for work costing more than the latter figure and under \$500,000. For work costing over \$535,714 and under \$3,000,000 the old fee was 7 per cent; and for work costing over \$3,250,000 and under \$3,500,000 it was \$210,000 and for work costing over \$3,500,000 the old fee was 6 per cent.

Under the revised schedule no fee is to be in excess of \$250,000. The revised schedule follows:

Cost of work	New fee
Under \$100,000	7 %
Over \$100,000 and under \$125,000	\$ 7,000.00
Over \$125,000 and under \$250,000	
Over \$125,000 and under \$450,000	6½ %
Over \$250,000 and under \$266,666	
Over \$266,666 and under \$500,000	
Over \$450,000 and under \$500,000	29,250.00
Over \$500,000 and under \$535,714	
Over \$500,000 and under \$1,000,000	6 %
Over \$535,714 and under \$3,000,000	
Over \$1,000,000 and under \$1,100,000	60,000.00
Over \$1,100,000 and under \$1,500,000	5½ %
Over \$1,500,000 and under \$1,650,000	82,500.00
Over \$1,650,000 and under \$2,200,000	5 %
Over \$2,200,000 and under \$2,450,000	110,000.00
Over \$2,450,000 and under \$2,850,000	4½ %
Over \$2,850,000 and under \$3,250,000	128,250.00
Over \$3,000,000 and under \$3,500,000	
Over \$3,250,000 and under \$4,000,000	4 %
Over \$3,500,000	
Over \$4,000,000 and under \$4,250,000	160,000.00
Over \$4,250,000 and under \$4,775,000	3¾ %
Over \$4,775,000 and under \$5,175,000	179,062.50
Over \$5,175,000 and under \$5,725,000	3½ %
Over \$5,725,000 and under \$6,225,000	200,375.00
Over \$6,225,000 and under \$6,825,000	3¼ %
Over \$6,825,000 and under \$7,400,000	221,812.50
Over \$7,400,000 and under \$7,750,000	3 %
Over \$7,750,000 and under \$8,350,000	235,500.00
Over \$8,350,000 and under \$8,800,000	2¾ %
Over \$8,800,000 and under \$9,650,000	242,000.00
Over \$9,650,000 and under \$10,000,000	2½ %
Over \$10,000,000	250,000.00

CHAPTER XXV

MISCELLANEOUS COSTS

References.—Further costs, of a nature similar to those included in this chapter, are given in Section XV of Gillette's Handbook of Cost Data.

Cost of Bath House, Lincoln Park Bathing Beach, Chicago.—Engineering and Contracting, May 10, 1911, describes an attractive and economical building for the accommodation of the bathers at Lincoln Park, Chicago. The idea of supplying several lockers for each dressing room or booth is unusual and in this way less booths are required to serve a given number of persons. Clothing is not left in the booths, but is placed in one of the lockers.

The space covered by the buildings is 264 ft. long by 54 ft. wide. This area is enclosed by a fence about 7 ft. in height. The fence is built of stained rough plank laid horizontally on edge, the cracks being closed with battens. The low roof of the enclosed houses, projecting somewhat above the fence line, gives a pleasing effect. The structures are all frame and are built of rough lumber with concrete floors 6 ins. thick.

The 4 × 4 in. posts in the buildings were supported on concrete pedestals carried down 4 or 5 ft. into the sand.

The work was done by the Park Commissioners by day labor and the costs are given below. These costs include everything except electric wiring and lights.

Labor:	
Engineering	$ 158.55
Foreman, 95 hrs	41.31
Teams, 94 hrs	27.50
Teamsters, 107 hrs	28.51
Common labor, 5,491 hrs	1,384.63
Carpenter labor, 8,716 hrs	4,986.56
Plumbers, 240 hrs	68.97
Total labor	$ 6,696.03
Material:	
Lumber	$ 4,506.68
Paint, etc	255.19
Hardware	1,262.22
Plumbing fixtures	1,086.34
Water system	142.57
Sewer system	994.55
Foundations and concrete floors	264.36
Tools	3.69
Total materials	$ 8,515.60
Grand total	$15,211.63
Cost per booth	$ 48.75
Cost per locker	7.41

The above labor was paid at various rates of wages. The carpenters and helpers rates varied from $2.50 to $5 per 8 hour day. The teamsters were paid about $60 per month. The common labor rate was 25 and 30 cts. per hour. Plumbers received from $2.25 to $2.75 per day. The foremen's time is distributed between this work and other work upon which they were engaged at the same time.

Cost of a Reinforced-Concrete Stadium, Brooklyn, N. Y. (Engineering News, May 21, 1914).—The construction of a large reinforced-concrete baseball stadium at the Federal League Grounds, Fourth Ave. and 3rd St., Brooklyn, N. Y., was commenced Mar. 9, 1914. On Apr. 20, the last concrete was placed for the structure. On May 5, all forms were stripped and on May 11 the completed stand was turned over to an audience of 15,000 people viewing the first game of the season. The work cost about $275,000. The rate of erection is shown in the accompanying tabulation.

The plans and specifications for the stadium are the same as those prepared for the Federal League Baseball Grounds in Chicago. The principal modifications were as to grades and code regulations. The Chicago contract was signed on Feb. 27 and completed on Apr. 23; the time elapsed being the same as on the Brooklyn stands. The work was carried out in Brooklyn in accordance with specifications, but in Chicago the contractors were obliged to substitute steelwork for the reinforced-concrete work specified, because the Chicago Building Department would not permit such a concrete structure to be used until the concrete had set 40 days. It will be noted that at Brooklyn only 23 days elapsed from the last pouring of concrete to the loading of the stands.

The Contract.—The contract comprised all work necessary for the erection of a curved-plan grandstand 865 × 119 ft. in area and about 55 ft. high; a bleacher, and a 20-ft. brick wall 1100 ft. long, 12 in. thick, with 20-in. brick piers spaced on 20-ft. centers. Each pier of the brick wall was reinforced against wind pressure by two 8-in. channel uprights, 14 ft. high and kneebraced at the bottom. The channels were fastened to the wall by connecting rods embedded in the brickwork. The grandstand is of reinforced concrete from the ground to the top seat-steps. It is supported on eight reinforced-concrete columns of length decreasing from 29 ft. at the rear or outer chord to 3 ft. at the front or inner. The seat-steps rest on concrete girders 12 in. wide spanning these columns.

The steel roof of the grandstand is carried on two lines of steel columns—numbers 1 and 5, counting the outer chord as number 1. The roof slopes upward from the outer chord to the other support,

PROGRESS SCHEDULE

Grandstand and pavilion	Progress schedule proposed Start	Progress schedule proposed Finish	Actual finish date	Average number of men Laborers	Average number of men Mechanics
Excavation 4,000 cu. yds.	Mar. 9	Mar. 21	Mar. 27	80	5
Concrete footings, 1,500 cu. yds	Mar. 12	Mar. 24	Mar. 29	70	5
Backfilling, 2,500 cu. yds	Mar. 18	Mar. 26	Mar. 30	25	1
Grading and removing 1,500 cu. yds, earth with 5 teams	Mar. 18	Mar. 28	May 1	20	1
Three concreting towers completely equipped	Mar. 11	Mar. 19	Mar. 19	10	12
All forms set	Mar. 13	Apr. 27	Apr. 6	4	25
Pouring 5,000 cu. yds. concrete	Mar. 25	Apr. 25	Apr. 20	72	6
All forms removed	. . . . . .	. . . . . .	May 5	. .	. .

a distance of about 66 ft. and a slope of about 1:5. From the second point of support, it cantilevers out 24 ft. 9⅛ in., the upper chords of the trusses declining toward the lower throughout this distance and joining at the end. This whole grandstand structure is designed with the idea of eventually adding another tier (steel) of seats. When this is done, the roof, with the exception of the cantilevered portion, will be raised. The cantilevered section will form the inside of the new tier which will continue rising to the outer chord.

The Chicago footings were designed to carry 5000 lb. per sq. ft.; but borings in Brooklyn showed that the soil was only good for 2000 lb. per sq. ft. This necessitated the enlarging in plan of 380 footings in order to obtain sufficient carrying capacity. All footings over 8 × 8 ft. in plan were made reinforced-concrete footings; those larger were made of plain concrete stepped up from the base to the column.

Construction.—In addition to the feature of speed, that of efficient organization should be noted. The timber was cut to size by two electric saws. The lumber and reinforcing rods were trucked to the field and distributed where needed. The plant comprised three 90-ft. towers, equipped with concrete chutes, 96 ft. long; ¾-cu. yd. electric-driven mixers, and electric hoists. The plant was erected at the exterior chord of the work and all concreting materials were delivered at the plant.

The concrete was mixed steadily and from the tower was conveyed by chute to a central wood distributing-hopper of about 5-tons capacity. From this hopper, smaller chutes radiated. The hopper acted as a reducing valve.

The main chutes were set at an inclination of 1:4 and worked satisfactorily at this angle. The wetness of the mix was varied with temperature in order to secure uniform flow. The slope of the stand was also about 1:4 and it was feared that the wet concrete would bulge up the lower steps from the upper; but by pouring the concrete in the upper-step forms, it had set sufficiently when it reached the lower step to prevent the expected bulging.

The average total number of men engaged in the work was about 875, divided as follows: carpenters, 250; carpenter's helpers, 60; metal lathers, 75; concrete laborers, 150. In addition to these, there were about 15 timekeepers, foremen and draftsmen. The men engaged in concrete work numbered 550. The balance, about 325, were bricklayers, structural-steel men, painters, plumbers, sheet-metal men, plasterers and laborers.

Cost of the Concrete Palmer Memorial Stadium, Princeton, N. J.—Engineering and Contracting, May 26, 1915, gives the following:

In plan the Princeton stadium is horseshoe-shaped, with two straight parallel sides, each about 454 ft. long, connected at one end by a three-centered curved portion. The total length of the structure is about 652 ft., its width, center to center of outside columns, is 520 ft., and its height, to the top of the main entrance towers, is 72 ft. At the lower, or inside, face of the stadium there is a 3-ft. passageway around the entire structure. The clear playing field is about 250 ft. wide by 510 ft. long. The structure is surrounded by a high iron picket fence forming an enclosure into which the spectators are admitted through turnstiles located opposite to the main entrance at the curved end. From this enclosure the people enter the stadium through 26 runways located at uniform distances around the structure. These runways are inclines and extend from the exterior ground level to openings located at about mid-height of the stadium.

Construction Features.—In leveling the field steam shovels and carts were used, about 40,000 cu. yds. of earth being moved in this way. After the area was excavated to the proper level, the playing field was covered with a 30-in. fill consisting of successive layers of broken stone and cinders, with open-joint drain tiles along the bottom. This base was then surfaced with new turf.

The concreting work was carried on by two separate gangs, each having an organization complete in itself. The work was started at the open end of the stand, one gang operating on each wing. The keen competition which developed between the two gangs resulted in exceedingly rapid progress.

The concrete was hoisted in 160-ft. steel towers and was chuted into place through long flexible chutes suspended from a cableway. These towers were placed back of the stand, being so located that it was possible to pour about two-thirds of one straight side in these positions. They were then moved to points near the curved end, and the structure completed.

The hoisting bucket in each tower was charged from a ¾-cu. yd. motor-driven mixer, the materials being delivered to the mixer in wheelbarrows, from storage piles located near by. With the use of a double set of three-bay forms for each wing the concreting operations were made continuous, the first set of forms being moved and re-erected while the concrete in the second set was being poured.

The first concrete was poured on June 29, 1914, and the two wings were joined together on Oct. 3, 1914, the best day's run being 227 cu. yds. of concrete poured by one gang in 10 hours. The entire structure was completed in 178 working days.

There were used in the construction of the stadium 78,000 bags of cement, 6,000 cu. yds. of sand, 11,000 cu. yds. of stone, 450 tons of reinforcing rods, 375,000 sq. ft. of "Clinton" wire mesh, and 1,670,000 ft. B. M. of lumber.

The stadium was completed during the latter part of 1914 at a cost of about $300,000. This makes the cost per seat about $7.25. This figure compares favorably with the cost of other stadia as given in Engineering Record, March 28, 1914 as follows:

	Cost per seat
Harvard Stadium	$13
Boston Baseball Club	24

Cost of a Reinforced Concrete Sand Bin.—G. A. Flink, in Engineering and Contracting, March 12, 1913, describes a reinforced concrete sand bin built by common labor in the employ of the Lewistown Foundry & Machine Co., of Lewistown, Pa., in conjunction with a sand mill erected for the Berkeley Springs Sand Co., at Berkeley Springs, W. Va.

Bids were invited for this work, and ranged from $12,000 to $6,900; this being considered too high, the Foundry and Machine company decided to build the bin themselves. A good superintendent was employed, material ordered and work started, the engineer who prepared the design assuming charge of the work, and keeping in touch with it by means of daily reports, and an occasional visit.

Shoring had to be erected to keep the railroad track in place while excavating for the footings. These latter were under water at times, and 62 hours' labor was spent at the pump. The concrete was a 1:2:4 mixture turned out by a batch mixer, and hoisted to the top on an elevator, from where it was wheeled to the place desired in barrows. Careful spading was kept up at all times. Work was broken on top of the column-footings while the forms for the columns were being placed, and at top of columns while building beam forms and placing the reinforcement. No surface finish was considered needed, the concrete filling the planed forms to perfection, and no objection being advanced to the appearance of the grain of the wood on the concrete surfaces, or to the ridges caused by the joints between the boards.

The bin, 100 by 16 ft. in plan, is divided into four compartments, the interior dimensions of which were 14 ft. 4 ins. wide, 23 ft. 8.5 ins. long and 17 ft. deep. The bin is supported on 18 columns 24 by 24 ins. and 26 ft. high. The whole structure, with the exception of roof, is of reinforced concrete.

A reinforced concrete slab roof on steel trusses was designed for the bin, but a timber and slate Mansard roof was built in its place.

The following data show the cost of structure:

Supervision and labor	$2,655.40
Material (sand, cement, stone, steel and lumber)	2,568.91
Freight and express	195.54
Electric light	7.25
Hauling, telegrams, telephone, mileage, gasoline, oil	185.18
Total cost	$5,612.28

This total cost was distributed as follows:

Supervision (hours)	874
Carpenters (hours)	3,386
Steel gang (bending and placing) (hours)	1,159
Helpers (hours)	110
Laborers (hours)	4,374
Broken stone (cu. yds.)	250
Sand (cu. yds.)	118
Concrete (cu. yds.)	415
Reinforcing steel (lbs.)	45,135
Inch lumber (ft. B. M.)	16,700
Timber, ranging from 2 by 4 to 4 by 6 (ft. B. M.)	16,000
Molding, ¼ round, etc. (lin. ft.)	3,000

Cost of Concreting Swimming Pool at Riverview Park, Chicago.—Engineering and Contracting, Nov. 3, 1915, gives the following:

The pool has over-all dimensions of 148.25 ft. long by 35 ft. wide with walls varying from 5 to 12 ft. in height. (A large cut showing detailed dimensions and type of reinforcement is given in Engineering and Contracting.) The capacity of the tank is about 450,000 gals.

The form work was all done in one week. One 8 hr. shift was worked per day. The concrete was all placed in 2½ days. No water-proofing compound was incorporated in the concrete but as soon as the forms were removed the inside surfaces were given three coats of Ironite. These coats were applied in 2 days' time. One leak developed after the pool was filled. It was located at the junction of the sidewall and the floor. The leakage, which amounted to ¼ in. in level per day, was not large enough to warrant emptying the pool for making repairs. After two or three weeks' service the leak silted up and the flow from this point ceased. The pool is filled with the comparatively clear water drawn from the Chicago mains.

All the concrete was mixed in a ¾-cu. yd. batch mixer set about 40 ft. outside the building. A runway was built up leading from the mixer to the forms. Concrete was conveyed from mixer to forms in Ransome concreting buggies holding 6 cu. ft. each. Two extra men were required to help in pushing the buggies up the incline. The concrete in the floor was all chuted to place—

the buggies discharging into the chute. An 8-ft. wide platform was constructed all around the wall forms and the buggies, running on this platform, were dumped directly into the wall forms.

The forms were made up of panels 2 ft. wide by 15 ft. long. The contractor's labor cost for placing the concrete was $1.20 a cubic yard. The form labor cost 15 cts. a square foot. Carpenters were paid 70 cts. an hour and laborers 40 cts.

The pool contains 220 cu. yds. of concrete. The contract price, exclusive of excavation, was $3,700, or $16.80 per cu. yd.

Cost of Excavating and Concreting a Swimming Pool.—The following is given by A. Crane, Sup't. for the contractor, in Engineering and Contracting, Nov. 2, 1910.

A swimming pool recently built in the annex to the Sinai Temple, Chicago, was excavated under rather difficult conditions, owing to the water encountered and the nature of the soil, which was clean sand. The excavation for the basement of the building was carried 8 ft. below the street level and that for the pool was carried 14 ft. deeper, 11½ ft. of which was below the level of the ground water. The area containing the pool was enclosed by 3-in. tongued and grooved sheeting, the lines of sheeting being 71 × 32 ft. This area was 11 ft. greater each way than the inside dimensions of the pool and allowed for the walls which were 1 ft., 6 ins. wide at the top and 3 ft., 6 ins. wide at the bottom. The sheeting was driven by hand with a wooden maul, two men being kept at this work while the excavation was being carried on.

In order to keep the site unwatered a point system was used. A 3-in. main was laid around the upper edge of the excavation and 1¼-in. points about 16 ft. long were placed every 3 ft. along the inside of the sheeting and connected by hose to the 3-in. main. The 1¼-in. points consist of galvanized iron pipes having solid cone-shaped points at the lower ends. From the lower ends up for 36 ins. they were perforated with ⅛-in. holes and screened with fine wire mesh. As the excavation proceeded the points were lowered and kept just low enough to unwater the site as low as the excavation proceeded. It was necessary to have one man looking after the points, giving them a twist once in a while to keep the particles of sand from clogging the wire mesh. Two Nye pumps, size No. 6, were used, one being set at each end of the work. These pumps were attached to the main so that each pump handled the water from half of the area. Toward the end of the work, however, the water was held back by the concrete floor and only one pump was necessary. A gage on each of the pumps showed them to be creating over 30 ins. of vacuum at every stroke.

The work was all done by hand. The material was shoveled to a scaffold and on to the bank behind the sheeting and then shoveled back to make space for more. The material in the center of the pit had to be thrown toward the edge before being shoveled onto the scaffold thus making four handlings for that part. When the excavation had reached about 3 ft. depth, 12 × 12-in. braces were set in to hold the sheeting.

They were placed about 8 ft. apart, on centers, and butted against 8 × 18-in walling timbers.

In concreting, a Smith ½-cu. yd. mixer, operated by steam, was used, and plank runways led from the mixer out over the work. Sterling buggies of about 7 cu. ft. capacity were used for transporting the concrete. A floor 12-ins. thick was put in and walls battered on the outside, from 3 ft., 6 ins. at the bottom to 1 ft., 6 ins. at the top. The walls varied in height from 4 ft.

to 9 ft.,6 ins. The forms used consisted of 1 × 6-in. sheathing and 2 × 6-in. studding placed 16 ins. on centers.

The number of laborers used on the work varied considerably as this job was only a part of the work on a large building and men were put on and taken away as necessity required. The largest number used on the excavation at any one time, however, was 25 men. Common labor at 37½ cts. per hour was used for excavating and concreting and carpenters at 62½ cts. an hour built the forms. The costs of all labor was accurately distributed and resulted as follows:

96 points at \$1.00 each	\$ 96.00
2,500 sq. ft. sheet piling at \$0.07	175.00
800 cu. yds. excavation at \$0.20	160.00
70 cu. yds. floor slab at \$0.65	45.50
150 cu. yds. walls at \$0.75	112.50
3,000 sq. ft. forms at \$0.04½	135.00
Total labor cost	\$724.00

The pumps were worked continuously in 3 shifts of 8 hours each. The cost of the labor and pumping amounted to about \$800.

One foreman at \$8 per day was also charged to the work.

A coat of Hydrolithic waterproofing cement was put on the interior surfaces, after which a veneer wall of white enameled brick was laid.

Cost of Out-Door Swimming Pool.—Engineering and Contracting, Dec. 10, 1919, gives the following:

The Clifton Park swimming pool in Baltimore, Md., is one of the largest artificial pools in the United States. It was constructed in 1915 under the plans of the engineer of the City Plant Department, which has charge of the operation of the pool.

Site of Pool.—The area selected for the pool construction was triangular in shape, bounded on two sides by city streets intersecting at right angles, with a high railroad embankment, along the other side, containing about 9 acres. The construction of the highways was upon filled ground similar to the railway embankment, but of much less elevation, so that the area without drainage would have formed a natural pond or pool.

General Features of Pool.—The pool is elliptical in shape, with a maximum diameter of 595 ft. and a minimum diameter of 340 ft.

The deep water section of the pool is also elliptical in shape, with a minimum diameter of 170 ft. and a maximum diameter of 356 ft. This deep water ellipse is at one side of the pool area, and from the line of this ellipse the depth increases at a 10 per cent grade. From the shallow edge of the pool to the deep water ellipse, the grade one-half of the way is 1 per cent and for the balance of the way 1½ per cent.

The maximum depth is 9 ft. and the minimum 3 in. The pool has a capacity of 4,500,000 gals., with a water area, when filled, of 3⁷⁄₁₀ acres.

The water supply is obtained through the city reservoir and filtration plant from the Gunpowder River. The water is supplied through one 8-in. inlet pipe and through one needle shower with 1½-in. supply pipe. There is one outlet or drain pipe 14 ins. in diameter. By regulation of inlet and drain valves there is a constant circulation of water, and the pool is emptied and cleaned annually.. The city filtration is depended on for the purity of the water and chemicals are not used. Bacteriological tests of the water have never been made.

Preliminary Work.—A 48-in. combination storm water sewer line from a residential section north of Clifton Park had been carried to and under the railroad embankment into the triangular area where the line was partly exposed. There was also a considerable wash from the railroad embankment, and by way of preparation for the pool construction considerable grading and filling was necessary. The cost of this work was as follows:

4,230 labor hours at 25 cts	$1,057
356 team hire hours at 62½ cts	222
330 ft. 6-in. terra cotta pipe with fittings	69
11,727 cu. yds. of earth at 10 cts	1,172
Total	$2,522

Plans and specifications were prepared by the Park Engineer and contract awarded by the Municipal Board of Awards at an expense of—

	$ 40.00 for design
	62.45 for printing
	25.65 for advertising
Total	$128.10

Contract Work.—The contract work was commenced about the middle of April, 1915, and completed in 94 working days. The time allowance in the contract was 120 working days, with a bonus of $10 per day for completion in less time, so that the bonus earned was $260.

The items of work, done under contract, cost as follows:

Excavation, 4,651 cu. yds. at 35 cts	$ 1,627
Filling and replacing, 5,888 cu yds. at 25 cts	1,472
Trench excavation and backfill, 1,014 lin. ft. at 45 cts	456
10-in. vitrified pipe, 1,014 lin. ft. at 33 cts	334
Lumber placed under drains, 410 B. M. ft. at 3 cts	12
Concrete drain inlets, 7 at $35 each	245
Underdrains in place, 483 lin. ft. at 75 cts	362
Concrete pit and drainage outlet	20
Changes to sewer line (including manhole)	210
Manhole for drainage valve	90
Excavation and backfill, water supply, 510 lin. ft. at 56 cts	285
8-in. cast iron water pipe with connections, 510 lin. ft. at $1.50	765
8-in. supply valve	25
Excavation and backfill for pool drain, 100 lin. ft. at 75 cts	75
14-in iron drain pipe with connections, 100 lin. ft. at $2.40	240
14-in. drainage valve in place	55
Lighting conduit (1½-in.) in place, 2,402 lin. ft. at 24 cts	576
Lighting conduit (2-in.) in place, 300 lin. ft. at 27 cts	81
Light post foundations, 7 at $24 each	158
Light post foundations, 11 at $8.50 each	93
Concrete life buoy bases, 23 at $5.40 each	124
Excavation and backfill for concrete wall alongside of pool at deepest point, 539 cu. yds. at 50 cts	269
Concrete in wall, furnished and placed, 332 cu. yds. at $8	2,656
Steel reinforcement rods for wall and pool bottom, 68,249 lbs. at 2.6 cts. per lb. in place	1,774
Wire mesh reinforcement, 15,670 sq. yds. at 8 cts	1,253
Concrete for pool bottom in place, 1,838 cu. yds. at $5.86	10,770
Concrete walk around pool, 15,473 sq. ft. at 9.6 cts	1,485
Overflow drains and boxes, 6 boxes, 200 lin. ft. of pipe	310
Springboards in place, 2 at $10	20
Concrete structure for sliding boards, with two concrete slides	1,425
Miscellaneous extra work	280
	$27,564

Electric Lighting and Water Supply Pipe.—Electric lighting was installed by park electrician on force account, at a cost for material and labor, as follows:

18 cast iron posts in place, $27	$ 486
3,942 lin. ft. of cable in place at 10 cts. per ft.	394
18 lamps at $4.14 each	74
18 globes in place at $4 each	72
18 transformers at $0.2777	95
18 switches at $4.50 each	81
	$1,202

The cost of water supply, connection made by the Municipal Water Department, was as follows:

Labor	$109.73
Material	159.20
Total	$268.93

The total cost of the pool, including lighting equipment, but not including showers, diving rafts, dressing rooms or other equipment, was $31,946.

Operation of Pool.—All bathers are required to pass under showers before entering the pool, and the use of soap is strictly forbidden. The average daily attendance during 100 days of operation in 1918 was 900 persons, and the average during the first 50 days of operation in 1919, 1,400 persons. The maximum daily use of the pool in 1918 was 4,254 persons on August 6th, and in 1919, 4,674 persons on July 5th. The pool is opened during the first week in June, and is continuously operated for a period of approximately 100 days.

During the winter months the pool is available for skating when ice freezes a sufficient thickness, which is very seldom.

There is a concrete pool building constructed at a cost of $45,000, in which there are four showers and 949 steel lockers of the best grade, with toilet facilities, and with ample accommodations for handling bathing suits, etc. The building contains a steam laundering and drying plant, with the most up-to-date equipment. There are two frame wing additions to the concrete building, in which there are dressing compartments and racks, in which boxes are used for checking clothing as a substitute for steel lockers. These two wings cost $10,000, and will accommodate at one time 2,400 persons or a maximum of 24,000 persons on any one day. The operating organization is under the Superintendent of Clifton Park, and the employees are classified and paid as follows:

	Per week
1 Manager	$20.00
1 Engineer (laundry machine)	20.00
1 Head life guard	18.00
8 Life guards	16.00
8 Lockermen	16.00
1 Head woman attendant	14.00
1 Ticket cashier	12.00
7 Women helpers	10.00

The annual cost of operating the pool is something in excess of $12,000 per year. The exact cost is not known, owing to the fact that the pool has not been in operation under park management long enough to show the depreciation cost of towels and bathing suits. The receipts from the Clifton pool in 1918 (the first year of park operation) were $4,576.96, and the total patrons, not counting free entries from charitable institutions, 83,865 persons.

Costs of Concrete Work on Three Small Tanks at Lincoln Park, Chicago.— Engineering and Contracting, March 22, 1911, gives the following.

The work considered is the construction of concrete pits or tanks, two of which are used for the animals in the zoo and the other being a wading pool for children, with a small wall enclosing a sand court adjacent to one end of the pool.

The work at the sea lion pit consisted in the construction of a new concrete floor and small walls. The total amount of concrete in the work was 40 cu. yds. The cost follows:

Labor	Total	Per cu. yd.
Engineering	$ 12.49	$ 0.312
Foreman, 5 days at $3.25	16.25	0.406
Teams, 6 days at $4.00	24.00	0.600
Common labor, 61¾ days at $2	122.50	3.062
Carpenters, 12 days at $4.80	57.60	1.440
Total labor	$232.84	$ 5.820
Material:		
Lumber	$ 15.00	$ 0.375
Cement, 57 bbls. at $1.35	76.95	1.924
Sand, 22 yds. at $1.65	36.30	0.907
Gravel, 46 yds. at $1.50	69.00	1.725
Expanded metal, 868 sq. ft. at $0.02⅛	18.45	0.461
Total material	$215.70	$ 5.392
Grand totals	$448.54	$11.212

The concrete work done in the coon pit amounted to 30 cu. yds. and the den was faced with granite. The cost of the work follows:

Labor	Total	Per cu. yd.
Engineering, 5 days at $2.50 Engineering, 11 days at $3.70	$ 53.20	$ 1.773
Foreman, 5 days at $3.25	16.25	0.542
Teams, 3 days at $4.00	12.00	0.400
Common labor, 97½ days at $2	195.00	6.500
Carpenters, 24 days at $4.80	115.20	3.840
Mason, 1 day at $4.50	4.50	0.150
Blacksmith, ½ day at $5.00	2.50	0.083
Total labor	$398.65	$13.288
Material:		
Cement, 32 bbls. at $1.25 Cement, hydrolithic 4 bbls. at $6.00	$ 64.00	$ 2.133
Gravel, 24 cu. yds. at $1.50	36.00	1.200
Torpedo sand, 12 cu. yds. at $1.65	19.80	0.660
Granite, 2 cu. yds. at $6.00	12.00	0.400
Steel	15.20	0.507
Acid, brushes, etc	5.25	0.175
Tools	11.02	0.367
Total material	$163.27	$ 5.442
Grand total	$561.92	$18.73

The wading pool consisted of a concrete elliptical basin of 62 ft. and 49 ft. diameters, with an area of 2,386 sq. ft. The floor was built 6 ins. thick and contained 43.2 cu. yds. The floor was sloped to a depth of 2 ft. in the center.

The concrete in this work was mixed with a Cube mixer. The costs of the work were as follows:

Labor	Total	Per cu. yd.
Engineering	$ 14.20	$0.329
Foreman	3.25	0.075
Common labor, 39⅝ days at $2	79.25	1.834
Total labor	$ 96.70	$2.238
Materials:		
Cement, 52 bbls. at $1.35	$ 70.20	$1.625
Gravel, 27 cu. yds. at $1.65	44.55	1.032
Sand, 18 cu. yds. at $1.65	29.70	0.688
Lumber	4.50	0.104
Expanded metal and pipe	45.00	1.042
Tools	5.80	0.134
Total material	$199.75	$4.625
Grand total	$296.55	$6.863
Total cost per sq. ft. of area		$0.12424

Some time later in the season the above wading pool was improved by the building of a small irregular shaped wall enclosing a sand court at one end of the pool. The wall was built rectangular in cross section (6″ × 15″) and 57 ft. in length. Its cost was as follows:

Labor:	Total	Per lin. ft.
Foreman, 1 day at $3.00	$ 3.00	$0.054
Common labor, 8 days at $2.00	16.00	0.281
Finisher, 2⅛ days at $2.25	4.80	0.084
Carpenters, 2½ days at $4.80	12.00	0.210
Total labor	$35.80	$0.629
Material:		
Lumber, 250 ft. B. M. at $25	$ 6.25	$0.110
Cement, 6¼ bbls. at $1.35	8.44	0.149
Sand, 3 yds. at $1.65	4.95	0.087
Gravel, 5 yds. at $1.60	8.00	0.140
Tools	1.21	0.021
Total material	$28.85	$0.507
Grand total		$1.336

Costs of Encasing Steel Structures in Concrete to Prevent Corrosion.—Two methods of encasing steel structures in concrete, namely encasement by pouring and encasement by cement gun, are discussed in one of the appendixes of the report of the Committee on Steel Structures of the American Railway Engineering Association, of which report, Engineering and Contracting April 15, 1914 gives the following abstract:

1. If the floor is protected by concrete encasement poured in place, the cost will be approximately 25 cts. per square foot for an envelope 3 ins. thick.

2. Encasement 3 ins. thick placed by cement gun will cost approximately 23 cts. per square foot.

Specific data on concrete encasement work are given by W. F. Jordan, manager Grand Central Terminal Improvements, New York Central & Hudson River R. R. and by G. E. Tebbetts, Bridge Engineer, Kansas City Terminal Ry., as follows:

Grand Central Terminal.—The cement gun is being used at the Grand Central Terminal for fireproofing and protecting a part of the steel structure. The yard is in two stories, the upper tracks being supported on a steel structure with concrete jack-arches. It was necessary to get the upper tracks in service at an early date, so the fireproofing of the exposed parts of the steel below the jack-arches was not done at the time the floor was built.

The lower parts of the beams, the girders and columns are now being fireproofed with the cement gun, using a minimum thickness of 2 ins.; the average thickness is from 2½ to 3 ins., as in the angles and around the stiffeners there is generally more than the minimum thickness.

The fireproofing is reinforced with a wire mesh, 1½ × 1½ ins. of No. 12 wires; this is attached to ¼-in. rods, which are bent around the steel and fastened to it.

The mixture has generally been 1 to 3, but in cool weather, and where the steel is subject to vibrations from the trains running on it, a 1 to 2 mixture is found to be more economical, as it is not as likely to drop off. It is necessary with this machine to use fine sand, as sand with pebbles in it clogs the hose; all of the sand, therefore, has to be carefully screened.

We find that a cubic foot of 1 to 3 mixture, when weighed in a box of 1 cu. ft. capacity after being moderately shaken down, weighs 3 lbs.; if this mixture is wet and applied with a trowel, after setting it will weigh 127 lbs. to the cubic foot, when shot through a cement gun onto a steel structure and set up, it weighs 144 lbs. per cubic foot. From this one gets an idea of the density of the fireproofing made with this apparatus

In applying the mixture of sand and cement with the cement gun from 20 to 25 per cent of it is lost. Some bounces off as it strikes the structure, some is shot by the steel in working around the angles and to get a smooth surface the mason scrapes off the irregularities, and to get a good surface it is floated.

The labor required to operate one machine is as follows: 1 foreman, 1 operator of the machine, 1 nozzleman, 2 masons for floating, 4 laborers screening, mixing and charging the machines. Carpenters are used when necessary to erect scaffolds.

One of these machines uses compressed air to the amount of 100 ft. of free air per minute at a pressure from 35 to 40 lbs. The hose through which the mixture is conveyed wears out quite rapidly and renewals amount to about $1 per day. We have averaged covering about 500 sq. ft. per day of the thickness mentioned above. This method would appear to give an excellent protection for the steel. The material is very dense and the method of application such that every inch of the structure is uniformly protected. The great thickness used in this work is due to the municipal laws requiring at least 2 ins. of fire protection.

Kansas City Terminals.—On the new structures, which the Kansas City Terminal Railway Co. is building, the encasement is applied in the majority of cases by use of the cement gun. This machine consists essentially of a hopper into which the cementitous materials, made up of 1 part Portland cement to 3 parts dry screened sand, are placed; a hose connected to the bottom of the hopper, through which the mixture is forced by air pressure; a nozzle at the end of the hose, to which another hose supplying water is attached for hydrating the materials. At the end of the hose is a cylindrical nozzle having an annular ring at its base, to which the hose delivering the water is attached. This water is delivered inside the nozzle in the form of a fine spray, through which the materials from the gun pass. The nozzle is made of brass, and to prevent wear on the nozzle proper a rubber lining is used. This lining can be replaced whenever necessary.

Before adopting the cement gun, the claims of the company selling it were investigated and test panels were encased. The conclusion reached was that if the cost was not too great, it would solve the problem of encasement. Comparative estimates made are shown below:

Encasement by Pouring in Forms.—Encasement to be 3 in. in thickness; mixture to be 1:2:4 concrete; reinforcement, wire mesh and bars.

Stone, 1 cu. yd. at $1.25	$1.25
Unloading 1 cu. yd. at 20 cts	.20
Loss in handling at 5 per cent	.07
Sand, ½ cu. yd. at 60 cts	.30
Unloading ½ cu. yd. at 6cts	.03
Loss in handling at 5 per cent	.02
Cement, 1¾ bbls. at $1.25	2.19
Unloading 1¾ bbls. at 5 cts	.09
Loss in sacks at 5 per cent	.03
Total	$4.18
1 cu. yd. equal to 108 sq. ft. 3 in. thick.	
Cost of material per sq. ft	$0.039
Forms 1.63 ft. B. M. at $0.050	.081
Mixing and placing at $5.40 per cu. yd	.050
Insurance on payroll at 5 per cent	.003
	$0.173
Overhead and profit at 8 per cent + 15 per cent = 23 per cent	.040
Cost per sq. ft. of encasement = $0.216.	
Encasement per sq. ft	$0.216
Mesh No. 3 at $0.06	.018
Bars, No. 5, at $0.03	.015
Total cost per sq. ft	$0.249

Say, 25 cents per square foot.

Encasement by Use of Cement Gun.—Encasement to be 3 ins. in thickness; mixture 1:3 mortar; reinforcement, wire mesh and bars Average number of square feet covered in a day of 10 hours, 275 sq. ft. Loss due to gun work, 20 per cent. Loss due to handling sand, 30 per cent. Quantity of sand used in placing 275 sq. ft. 3 ins. thick, 4 cu. yds.

Sand, 4 cu. yds. at $0.60		$ 2.40
Unloading and screening 4 yds. at $0.25		1.00
Cement, 5½ bbls. at $1.25		6.88
Unloading 5½ bbls. at $0.15		.83
Loss in sacks at 5 per cent		.11
Water, per day		.15
Gasoline for compressor, 12 gals. at $0.15½		1.86
Oil waste and handling per day		.60
		$13.83
1 foreman, 10 hrs. at 37.5 cts		$ 3.75
1 finisher, 10 hrs. at 35 cts		3.50
1 nozzleman, 10 hrs. at 32.5 cts		3.25
1 gunman, 10 hrs. at 30 cts		3.00
2 laborers, 10 hours at 22.5 cts		4.50
1 boy, 10 hrs. at 12½ cts		1.25
		$19.25
Repairs, etc., per day	$2.00	
Scaffolding for 275 sq. ft. at $0.15	4.13	
		6.13
Interest on gun, $3,000 at 5 per cent	$0.41	
Insurance on payroll at 5 per cent	.97	
		1.38
Total		$40.59
Overhead and profit 8 per cent and 25 per cent = 33 per cent		13.53
Cost of encasement		$54.12
Cost per sq. ft		$ 0.1968
Mesh No. 3 per sq. ft. at $0.06		.018
Bars, No. 5, per sq. ft. at $0.03		.015
		$0.2298

Say, 23 cents per square foot.

A comparison of the above shows a saving of 2 cts. per square foot in favor of the gun work over the poured encasement, and it might be stated that since this estimate was made we have received bids on actual work that check very closely with the above.

The steel work to be encased was designed with open holes 11–16 ins. in diameter in webs, stiffeners and flanges, so that in placing and attaching the reinforcement there would be ample provision for rigid attachment to the structure. In attaching reinforcement to girder webs and other large surfaces, the bars were placed on small V-shaped iron saddles and wired through the webs to each other. On flanges the rods were run through steel eyebolts attached to the lower flange, the mesh being attached to the bars by wiring. At the junction of the concrete encasement with the floor, which is also of concrete, a splice was provided by use of mesh placed in the floor previously cast, this splice being four inches in width. Fig. 1 shows typical method of attaching reinforcement to girders.

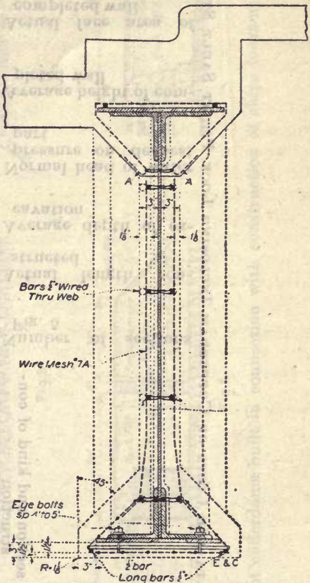

FIG. 1.—Typical concrete encasement of deck plate girder, Kansas City Terminal Ry.

The steel girders were shipped from the shops with a shop coat of linseed oil, which was removed by the use of a caustic soda wash before encasement was started. All rust spots were removed with a wire brush.

Our experience has shown that the 1:3 mixture placed in the gun gives a resulting mortar of approximately 1:2½, this change being due to loss of sand. The sand must be nearly dry, the dryer the better, a mixture of coarse and fine grains giving better results with considerably less loss, than either the coarse or fine alone.

The sand must be screened as particles over ⅛ in. in diameter clog the gun and cause serious delays.

The compressor should be a machine of very ample capacity and an intermediate air storage tank is an advantage.

It was found that it was very difficult to encase the lower flange of a girder, especially so the lower face, and in our work we cast this portion in quite a few cases.

It was also a difficult proposition to get a good, clean job around stiffeners and sidewalk bracket members. On the brackets V-shaped forms were made and used as a backing for the gun work. As to finish, the appearance is fairly good, though far from the smooth, even lines of cast work and a great deal depends upon the finisher as to the final appearance.

Cost of Cofferdams at St. Mary's Falls Canal.—The construction of the third and fourth ship locks at Sault Ste. Marie, Mich., by the U. S. Govern-

TABLE I.—SUMMARY OF GENERAL DATA AND COSTS OF COFFERDAM INCLOSING LOCK PIT AT SAULT STE. MARIE, MICH.

Date of construction	Name of section and kind of construction	Number of sections Fig. 5	Actual length constructed	Average depth of excavation	Normal head of water pressure on deepest part	Average height of completed wall	Actual face area of completed wall	Costs (from engineer's data) Unit cost: Per lin. ft. of wall	Per sq. ft. of wall

Grand total		..	.....	....	..	....	68,776	......	$1.25

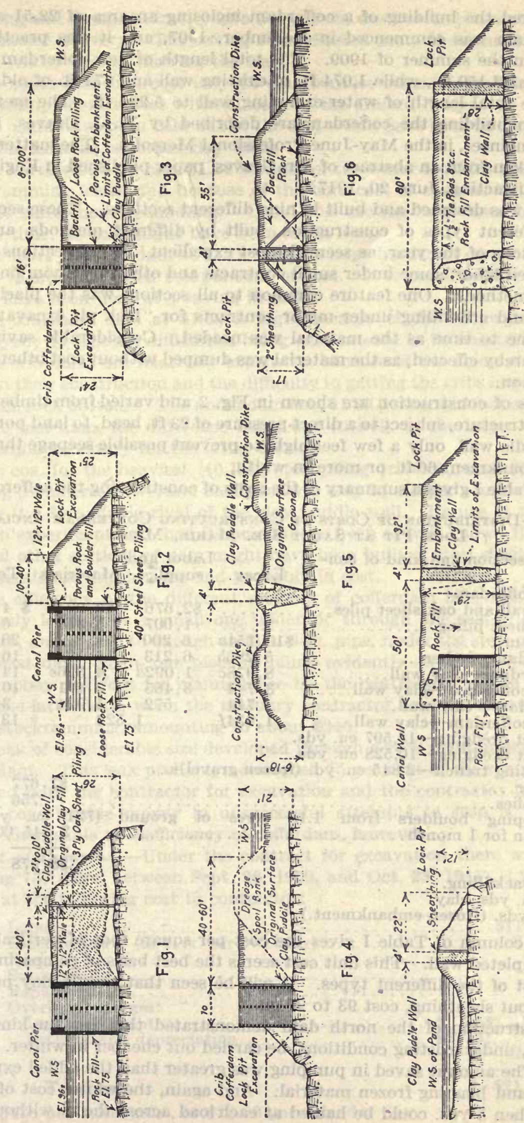

Fig. 2.—Sections of different types of cofferdams built in connection with construction of ships locks at Sault Ste. Marie.

ment required the building of a cofferdam inclosing an area of 22.51 acres. The cofferdam was commenced in December, 1907, and it was practically completed in the summer of 1909. The total length of new cofferdam construction was 3,150 ft., while 1,074 ft. of existing wall and 671 ft. of old dam brought the total length of water-excluding wall to 5,281 ft. The methods employed in building the cofferdam are described by W. J. Graves, U. S. Assistant Engineer, in the May-June Professional Memoirs. The matter that follows is taken from an abstract of Mr. Graves' paper published in Engineering and Contracting, June 20, 1917.

The dam was designed and built in nine different sections. These sections were of different types of construction, built by different methods, and at various seasons of the year, as seemed most expedient. Some sections were built by hired labor, some under small contracts and others by a combination of the two methods. One feature common to all sections was the placing of backfilling and crib-filling under minor contracts for "lock pit excavation," let from time to time as the material was needed. Considerable saving in cost was thereby effected, as the material was dumped without cost other than for excavation.

The types of construction are shown in Fig. 2 and varied from timber crib rock-filled structure, subject to a direct pressure of 23 ft. head, to land portions of clay puddle wall, only a few feet high, to prevent possible seepage through existing embankment 60 ft. or more in width.

Costs.—Table I gives a summary of the costs of constructing the cofferdams.

TABLE II.—DISTRIBUTION OF COSTS OF CONSTRUCTING COFFERDAM INCLOSING LOCK PIT AT SAULT STE. MARIE, MICH.

Name of section and kind of construction	Excav.	Labor and supplies	Materials	Total
Southeast cofferdam:				
1. Clay wall and oak sheet piles		$2,676	$2,224	$ 4,900
2. Steel sheet piling		1,007	5,358	6,365
East crib dam	$10,154*a*	6,200	4,311	20,665
North crib dam, timber	5,286*b*	6,213	5,198	16,697
North cofferdam—clay wall	8,978*c*	1,092*d*	4,326*e*	14,396
Northwest cofferdam—clay wall	3,744	3,465	3,471	10,680
West cofferdam—clay wall	711	572	1,924	3,207
Southwest cofferdam—clay wall	1,934*f*	1,522		13,456

a Contract dredging—15,597 cu. yds.
b Contract dredging—10,528 cu. yds.
c Excavating trench—2,845 cu. yd. (frozen gravel)s.

Labor	$7,677
Supplies	756
Stripping boulders from 1.15 acres of ground (721 cu. yds.), 9 men for 1 month	$ 545.00
	$8,978

d Labor backfilling.
e 7,790 cu. yds. clay.
f 603 cu. yds. (frozen embankment.)

The last column of Table I gives the cost per square foot of vertical face area of completed wall. This unit cost seems the best basis of comparing the relative cost of the different types. It will be seen that simple clay puddle walls, without sheathing, cost 93 to 97 cts.

The construction of the north dam demonstrated that certain kinds of work could, under existing conditions, be carried out cheaper in winter. For example: The amount saved in pumping was greater than the added expense of drilling and blasting frozen material. And again, the winter cost of clay delivery, when 5 yds. could be hauled at each load across the ice without rehandling and dumped directly into the trench, was but 40 per cent of the cost for summer delivery. The saving thus effected more than made up for the added winter cost of thawing the clay.

The southwest dam cost only 66 cts., because considerable work was done by bankrupt contractors without cost to the United States. If the United States could have been held liable, the cost would have been 96 cts. per square foot, the same as for other clay walls.

The northwest dam cost $1.38 because of the water troubles and burden of stockramming leaks, and because of the high cost of summer delivered clay and its subsequent rehandling. Could this section have been built in the winter time, its cost might have been much less.

The short junction dam at $2.78 carries a large burden of overhead expense, and it is unfair to draw comparisons of cost. It is possible that steel piling could have been used at a saving in cost.

The southeast dam at $1.62 is high, because of the elaborate sheathing employed; no especial difficulties being encountered in its construction.

The crib dams are relatively expensive, because of the amount of material used in their construction and the difficulty in getting the cribs in good contact with the rock bottom. The north dam cost $1.85 per square foot against $2.39 for the east dam, the difference being due entirely to the larger quantity of excavation necessary for the latter section.

The cost for the heaviest (40 lbs.) steel piling driven through 25 ft. of hard driving (boulders, gravel and hardpan) was only 96 cts. per square foot. This makes it a formidable rival of the clay puddle wall. Its use at this locality was an experiment and, had its possibilities been as well known then as now, several other sections of dam might have been built of steel sheet piling at a considerable saving in time and probably in cost.

The efficiency of the different sections of cofferdam has been first class. The only leaks were a small one under or through the east crib dam, and another, amounting to enough to fill a 3-in. pipe, under the steel piling of the southeast dam, where one piece of piling evidently struck a boulder. The only money paid out for maintenance by the contractors was in connection with the latter leak, when the masonry contractor bore the expense of a few days stockramming, amounting to about $346.

A leak of considerable size developed through a rock seam under the southwest dam. This leak probably occasioned 75 per cent of the required pumping and both the contractor for excavation and the contractor for masonry spent considerable money in unsuccessful attempts to stop it. This leak is not chargeable to inefficiency of cofferdam, however.

Cost of Pumping.—Under the contract for excavation there was pumped (during 757 days, between Sept. 26, 1909, and Oct. 23, 1911), 1,242,628,000 gals., at the following cost to contractor:

Labor		$11,428
Electric power (at 1 ct. per kw. hour)		6,975
Fuel		403
Supplies		398
Repairs		147
Overhead charges:		
Installing plant	$ 314	
Interest and depreciation	$2,151	
		2,465
Total cost		$21,816

or $0.0176 per 1,000 gals., or $28.90 per calendar day.

Under the contract for lock masonry, the pumping during 858 days (Oct. 23, 1911, to March 1, 1914), amounted to 1,094,760,000 gals., and cost the contractor as follows:

Labor		$12,208
Electric, power (at 1 ct. per kw. hour)		8,221
Supplies, fuel and repairs		2,052
Overhead charges:		
Interest and depreciation	$1,012	
Dismantling (assumed)	300	
		1,312
Total cost		$23,793

or $0.0217 per 1,000 gals., or $27.85 per calendar day.

The battery of pumps originally installed was as follows:

One 10-in. centrifugal with 100-h.p. motor
One 8-in. centrifugal with 85-h.p. motor
One 6-in. centrifugal with 50-h.p. motor
One 5-in. centrifugal with 20-h.p. motor and
One 4-in. centrifugal with 15-h.p. motor

The maximum battery required at any one time consisted of the four latter pumps, the 10-in. being a reserve unit for emergency.

The volume of pumping varied from a minimum daily average of about 850, 000 gals. in winter, while the adjoining canal was unwatered, to a maximum daily average of about 3,000,000 gals. during the summer. The maximum for any one day was about 4,000,000 gals.

Cost of Steel Cofferdam of the Pocket Type.—A steel cofferdam of the pocket type was used in the construction of Lock No. 2, Cape Fear River, N. C., for the U. S. Government. Double rows of Lackawanna sheet piling connected at intervals by transverse rows, were driven around the lock site.

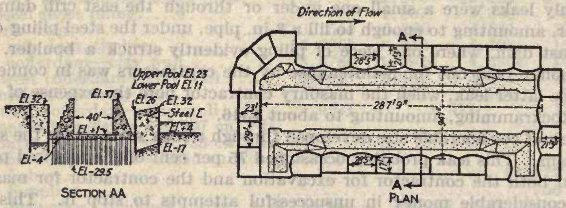

Fig. 3.—Plan and section of cofferdam and lock.

The pockets thus formed were of such dimensions that when filled with earth they could resist the unbalanced pressure on the cofferdam without support. As the steel on the land side was driven well back into the river bank where the ground was level with the tops of the pockets, no filling was necessary on this side. The river pockets were filled with material dredged in the cofferdam enclosure. The following description of the methods employed in the construction of the cofferdam is taken from an abstract in Engineering and Contracting, Jan. 17, 1917, of an article by Norman M. Chivers, Assistant Engineer, in the Sept.-Oct. Professional Memoirs.

The general arrangement of the cofferdam is shown in Fig. 3. The pockets were of two types. Those at the upper end had parallel inside and outside walls tied together by walings and steel cables and rods. The other pockets were without ties, the inside wall being curved to reduce distortions in the steel piling caused by the filling. Driving requirements and limited space for plant dictated the two single wall panels in the upper and lower wings. These panels were held by cables to wooden pile anchorages. Arched web piling, on account of its greater transverse strength, was used in walls held by walings and on the outside of the river pockets; straight web was used in the interior curved walls, the cross walls, and on the outside of the land pockets. The total length of the coffering was 878 ft. It required 1,871.9 tons of piling.

The cofferdam was designed to provide a protection against floods equivalent to that which experience showed to be satisfactory with the cofferdam at Lock No. 1, 33 miles farther down the river. The elevation of the top of the steel was accordingly fixed at 23.4 ft. above the mean low water obtaining at the site before the lower pool level was established by the construction of the dam at Lock No. 1. This elevation corresponded to an average height above the bottom of the river of 28 ft. The lock floor was laid before pumping out so that the coffered enclosure, after pumping out, had a depth of 31 ft.

To make the cofferdam of the height indicated and at the same time secure the necessary penetration in the sand and clay bottom of the river, piles 49 ft. long were required for the outside wall. The piles on the land side of the inside wall were of the same length, but on the river side piles 43 ft. long were used, making the inside wall 6 ft. lower than the outside. By thus sloping the tops of the pockets, the amount of filling required was reduced and dredging operations facilitated. All of the piles in the inner wall were spliced just above the elevation of the lock floor, the lower portions remaining as a part of the permanent construction.

The driving of the steel in the land cofferwall was done by two traveling pile drivers capable of movement parallel and at right angles to the center line of the lock.

The flat on which the tracks were laid was excavated out of the bank and all of the piling driven between the two outer tracks. To form the curve on the inside of the pockets a cylindrical cage moving in the ordinary driver leads and holding one of the hammers at any desired horizontal angle was provided. A similar cage, without any revolving feature, enabled the other hammer to overreach piling already partially driven for making the closure of the pockets. Piles were delivered to the drivers from the stockpiles by hand cars running on a track immediately in front of the machines. Steam for the hammers was supplied from a central boiler plant.

The two hammers used were Warrington steam hammers with striking weights of 3,000 and 1,800 lbs., respectively. Each driver was equipped with two 2-in. jets, supplied by a pump installed on a scow nearby. Both pumps had a rated capacity of 250 gals. per minute at 75 lb. pressure; one with 80 lbs. and the other with 125 lbs. steam pressure. The jets were freely used in both land and river driving.

The penetration of the piles in the land wall varied from 39 to 48 ft. in clay, clay and sand, and marl. Considerable difficulty was experienced in driving to grade, and in several instances of absolute refusal the tops of the piles had to be cut off by the oxy-acetylene flame to permit the travelers to proceed. The smaller hammer drove an average of 9 piles per 16-hour day, and the other an average of 25.6 piles per 16-hour day.

When the land driving was completed, sufficient dredging was done at the upper and lower ends to enable the pile drivers mounted on scows to continue the coffer walls out into the river.

The floating rig being more flexible than that used on the land, and the penetration less, varying from 18 to 21 ft., driving was faster. The smaller hammer drove an average of 17 piles per 16-hour day, and the large hammer 20.5 per 16-hour day.

The curved panels of the river wall were driven to a templet floating on the convex side of the arcs and held in place by adjustable bracing to wooden guide piles located inside the cofferdam enclosure opposite and in line with the cross walls. The bracing was so arranged that the templet could rise and fall with varying stages of the river. Alignment of the templet was secured by means of points established by triangulation on brackets nailed to the wooden piles.

The closure of all pockets was made by a large hammer. This was work which required a great deal of time and care. It was found to be very difficult to keep the piling always vertical, as a leaning tendency often developed in the direction of the driving. This lean gave trouble in closing. In four instances specially fabricated wedge-shape piles had to be used. All of the pockets were closed on the outside wall. Driving proceeded alternately on the rear and cross walls of a pocket until only the four piles nearest a corner remained. These last four piles were then entered, but not driven to grade until all were in place. Driving in succession each pile a few feet at a time completed the closure.

Diagonal steel channel walings were provided for all the cross walls, the holes for the fastening bolts in the piling being burned through with oxy-acetylene flame. The function of these walings was to prevent sliding of one interlock on another, due to the over-turning force on the backs of the pockets. In this they were only partly successful, as will be noted later.

A gap was left at the lower end of the cofferdam for the passage of the dredge which excavated the enclosure and the pile drivers which drove the foundation piles. The dredging was done principally by the Engineer Department Dredge Ajax, with a 5-yd. clam-shell bucket. Approximately half of the material removed, sand and clay, was used to fill the pockets at an average cost of 26½ cts. per yard. The plans required a level bottom everywhere. Considerable material immediately next to the steel could not be handled by a large clam-shell bucket, and had first to be loosened by jetting, and then taken out with a ½-yd. orange-peel bucket. Some blasting also was required in a small shelf of marl encountered in the lower wing. These operations, together with the fact that the over-depth allowance made for shoaling during pile driving proved insufficient, necessitating further dredging by siphon in those areas where piles had been driven, and by the Ajax in other places, greatly increased the cost of excavation. The total average unit cost of material removed was 46½ cts. per yard.

As dredging proceeded in front of the land wall, a serious movement of four of the pockets at the upstream end was noted, showing a tendency to turn over in the direction of the lockpit. The earth back of these pockets had not been disturbed in any way and was not surcharged. No similar movement occurred at the lower end of the wall, although here about 2,500 wooden piles were stacked immediately back of the steel. An examination of the walings on the cross walls of the leaning pockets showed that all of the fastening bolts had sheared off. As it was not found practicable to put in enough bolts to withstand the stress, it was decided to relieve partially the pressure on the back of the wall by excavation and drainage, and to tie the cross walls affected to tree anchorages by means of heavy wire cables. This proved to be a satisfactory solution of the difficulty. The maximum movement of the top of the steel amounted to 7 ft. 6 in., and no further movement was detected when the cofferdam was pumped out.

After all the foundation piles had been driven, the gap left at the lower end of the cofferdam was closed and the bottom sealed with a 5-ft. layer of concrete deposited through a tremie. This concrete was allowed a month to set before the first pump-out.

The pumping plant, located at the upper end of the cofferdam, consisted of a 12-in. Morris direct connected centrifugal designed to discharge 4,200 gals. per minute against a 30-ft. head, and a 10-in. Buffalo centrifugal, of the submerged type, designed to discharge 3,000 gals. per minute against a 32-ft. head. The 12-in. pump was mounted on pontoons inside the cofferdam, and had a discharge pipe made up of short sections to provide for increased lift as the water level fell. The 10-in. pump was rigidly attached to the wall of the cofferdam, and belt-connected to the driving engine on top of one of the pockets.

The first pump-out was purposely extended over two days in order that the coffer walls might be watched. The 12-in. pump alone was used until the pontoons grounded on the lock floor, after which the 10-in. pump completed the unwatering.

A movement of the top of the river wall toward the lock pit of 1½ ins. was the only movement of the cofferdam detected during pumping operations. After the first pump-out the maximum head on the cofferdam was 26 ft. Leakage at ordinary stages of the river amounted to about 200 gals. per minute.

As the Cape Fear River is subject to rapid rises, which at times completely submerged the cofferdam, provision was made for flooding by means of a 24-in. pipe through one of the pockets at the lower end, 12 ft. below the top. Control was secured by an ordinary gate valve operated from a platform outside the cofferdam.

Costs for Driving Summarized.—The unit costs of the different operations in constructing the cofferdam are summarized in the accompanying table. They include payroll, supplies and a charge for repairs to the plant employed.

COST OF DRIVING STEEL SHEETING

	Per pile	Per ton	Per lin. ft.
Driving land piling	$5.18	$5.77	.....
Driving river piling	2.28	2.53	.....
Driving piling, average	3.36	3.75	.....
Splicing piles	.47	.....	.....
Handling piles	.30	.....	.....
Placing wales	.....	.....	$0.79
Driving wood anchor piles	4.57	.....	.....

In addition, it cost $29.45 each to install the tie cables. As 17.7 per cent of the total tonnage of steel in the cofferdam became a part of the permanent structure, the cost of driving chargeable to the cofferdam given above should be reduced by this amount.

Annual Cost of Creosoted Wood Structures.—(Engineering Record, Feb. 7, 1914).

TABLE III.—ANNUAL COST OF STRUCTURES, BASED ON LENGTH OF LIFE

First cost	Length of life in years: 5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	25	30
10	2.31	1.97	1.73	1.55	1.41	1.29	1.20	1.13	1.06	0.99	0.96	0.92	0.89	0.85	0.83	0.80	0.71	0.65
20	4.62	3.94	3.46	3.09	2.81	2.59	2.41	2.26	2.13	1.97	1.92	0.84	1.77	1.71	1.65	1.60	1.42	1.30
30	6.93	5.91	5.18	4.64	4.22	3.88	3.61	3.38	3.19	2.96	2.88	2.77	2.66	2.57	2.48	2.41	2.13	1.95
40	9.24	7.88	6.91	6.19	5.63	5.18	4.81	4.51	4.26	3.95	3.84	3.69	3.55	3.42	3.31	3.21	2.84	2.60
50	11.55	9.85	8.64	7.74	7.04	6.47	6.02	5.64	5.32	4.94	4.81	4.61	4.44	4.28	4.14	4.01	8.55	3.25
60	13.85	11.82	10.37	9.28	8.44	7.76	7.22	6.77	6.38	5.92	5.77	5.53	5.32	5.13	4.96	4.81	4.25	3.90

The annual cost of structures having a life of from five to thirty years and a first cost of from 10 to 60 units (dollars or cents) is given in Table III, from the report of the committee on preservation of timber presented at the 1914 convention of the American Railway Bridge and Building Association. Utilizing this table, which is applicable to structures of various types, the committee analyzes the saving in the use of treated piles for trestles on the Southern Pacific.

The Southern Pacific, according to the report, has about 105,000 creosoted Douglas-fir piles in trestles. They were treated by the boiling process, and range in age from one to twenty-three years, with probably more than two-thirds of them over twelve years old. Of this number not more than 500 have ever been replaced on account of decay, and many of those twenty years old are as good as when driven. The committee does not doubt that they will be good for at least thirty years, and estimates the life of the same timber untreated as eight years.

Assuming these piles to average 40 ft. in length, each pile, at 10 cts. per foot, would cost $4. The driving would cost $6, making the total of $10 per pile. If such a pile would last eight years, its cost, as shown in the table, would be $1.55 per year. Similarly, a 40-ft. creosoted pile, at 30 cts. per foot, costs $12, which, added to the $6 for driving, makes a total of $18. If the pile will last thirty years, the annual cost will be $1.17. The difference is 38 cts. per pile, or nearly $40,000 per year for the entire 105,000 piles.

Costs of Treating Seasoned and Unseasoned Ties.—F. J. Angier gives the following data in Engineering Record, Jan. 20, 1912.

An unseasoned tie is generally taken to mean one freshly cut, or one where the sapwood is so completely filled with moisture that it would be impossible to treat the tie thoroughly until this moisture had been at least partially removed. A seasoned tie is one that has been cut for some time and the moisture allowed to evaporate to a greater or less degree. The time necessary to season a tie so that it can be properly treated varies in different localities, as well as in different seasons and with different kinds of wood. At a fair average it requires six hours to treat a charge of thoroughly seasoned ties and nine hours to treat a charge of unseasoned ties. The treatment referred to is with a mixture or creosote and zinc-chloride, known as the card process. At this rate the cost of treating in a plant having a maximum capacity of 1,800,000 seasoned ties a year is as given in Table IV, and the cost of treating in the same plant, where the maximum capacity is reduced to 1,200,000 unseasoned ties a year, is as given in Table V.

TABLE IV.—COST OF TREATING SEASONED TIES
(Capacity of plant 1,800,000 per year)

Unloading, cars to ground, to season, $0.007 each	$ 12,600.00
Loading from ground to trams, $0.0055 each	9,900.00
Switching trams $0.002 per tie	3,600.00
Loading treated ties out, $0.0065 each	11,700.00
Fixed expenses	23,268.00
Preservatives at 15, cts. per tie	270,000.00
Fuel (assumed one-third less for seasoned over unseasoned)	5,600.00
Insurance on 1,000,000 ties (estimated)	4,000.00
Interest on 1,000,000 ties 6 months 5 per cent on $250,000.00	12,500.00
	$353,168.00
600,000 more seasoned ties treated than unseasoned, worth $0.044 each (See statement Table 3)	26,400.00
	$326,768.00

$0.1815 per tie

TABLE V.—COST OF TREATING UNSEASONED TIES
(Capacity of plant 1,200,000 per year)

Unloading one-fourth cars to ground to enable prompt release of cars, $0.007	$ 2,100.00
Loading 900,000 ties, cars to trams at platform, and 300,000 ties, ground to trams, $0.0055	6,600.00
Switching 300,000 ties, yard to retorts, $0.002	600.00
Loading treated ties out $0.0065 each	7,800.00
Fixed expenses	23,268.00
Preservatives at 15c. per tie	180,000.00
Fuel	8,400.00
Insurance on 300,000 ties (estimated)	1,200.00
Interest on 300,000 ties, or 5 per cent on $75,000.00	3,750.00
	$233,718.00

$0.1948 per tie

TABLE VI.—SAVING IN A TREATED TIE AS COMPARED TO AN UNTREATED TIE

Untreated tie:		
First cost	$0.50	
Cost of putting in track	.15	
Cost of tie in track		$0.65
5 per cent interest on investment for six years		.195
Second renewal, end of six years		.65
5 per cent on first investment for six years, and on second investment for six years		.39
Total cost of tie for 12 years		$1.885
Average cost per tie per year		$0.157
Treated ties:		
First cost	$0.70	
Cost of putting in track	.15	
Cost of tie in track		$0.85
5 per cent on investment for 12 years		.51
Total cost of tie for 12 years		$1.36
Average cost per tie per year		$0.113

Saving per tie per year $0.044

Untreated ties are assumed to last six years and treated ties twelve years.

In each case the total cost of handling is shown from the time the ties are received until they are loaded for shipment. The fixed expenses include the salaries of the superintendent, general foreman, office force, engineers and firemen, or all labor which would not change, whether treating seasoned or unseasoned ties. In the case of seasoned ties, where no steaming is done, it is assumed that insurance is carried on 1,000,000 ties for six months and that $250,000.00 will be continually invested at 5 per cent. In the case of unseasoned ties at least 300,000 will always be in the yard.

The figure $0.044 as the annual saving in a treated tie is derived in Table VI.

In addition to the direct saving at the plant there is a better penetration of the preservatives, and a longer life and lessened possibility of injury by steaming. When steaming there is always a large amount of sewage to dispose of, while in non-steaming there is practically none. The disposition of sewage is a difficult problem at most plants, often leading to damage suits.

The Operating Cost of Open-Tank Creosoting Plant.—In Engineering News-Record, July 26, 1917, C. G. Benham gives the following.

Open-tank treatment of timber is desirable for interurban and the smaller steam railroads that have a number of timber bridges and other timber structures to maintain. Such a plant, as here described, is convenient for treating fence posts, paving blocks and the like on very short notice.

The Virginia Railway and Power Co. has operated an open-tank treating plant at Norfolk, Va., since May 1, 1914, using dead oil of coal tar from its own gas-works as a preservative. Water-gas tar was tried as an experiment for a few months and finally abandoned because of the small saving and its doubtful value.

Yellow pine, mostly of merchantable grade, has been the only species of timber treated in the open tank, and has varied in size from 2 × 4-in. to 14 × 14-in. timber of all lengths. A number of pine poles have also been satisfactorily treated. The penetration obtained has been from 12 to 20 lbs. per cu. ft. of timber. Well-seasoned timber is desirable for open-tank treatment; in the case of green timber it is necessary to keep it in the tanks until it becomes well seasoned from the heated oil.

The method of treatment is, first, to place the timber in the tank and weight it to prevent floating, and then cover it with oil. The steam is turned on for about eight hours, at approximately 100 lb. pressure, the oil being kept at about 200°F. The steam is then cut off and the oil and timber are allowed to cool over night. The next day the timber is removed from the tank and placed on the storage piles by the derrick boom.

The following figures give the actual cost of treating at this plant for one month. One foreman (who also operates the electric derrick) at $3, one fireman at $1.50 and four laborers at $1.50 per day are required, working under the bridge supervisor. A total of 39,098 ft. B. M. was treated. The costs were as follows:

Item	Total	Cost per M. Ft. B. M.
Dead oil of coal tar 7,375 gals. at 6½ cts.	$479.38	$12.23
Coal, 6,800 lbs. at $3 per ton	9.10	.23
Labor, including foreman	83.50	2.14
Maintenance of plant	20.00	.51
Interest on $3,000 investment	15.00	.38
Total expense for one month	$605.98	$15.49*
Average penetration, 19.6 lbs. per cu. ft. of timber.		

* No allowance for depreciation has been included in the charges.

Fig. 4 shows the layout of the treating plant. The smaller tank is used for treating only in emergencies. The dead oil of coal tar is brought from the gas-works in a 2200-gal. tank-car that is fitted with a section of pipe to allow filling the treating tanks directly.

Cost of Creosoting Car Sills and Roofing (Engineering and Contracting, June 25, 1919.)—The average cost of the creosote treatment for car sills at the plant of the Marsh Refrigerator Service Co., Milwaukee, Wis., is estimated to be $4.50 per 5 in. × 8 in. × 35 ft. sill. Of the total $4 is for creosote oil, 10

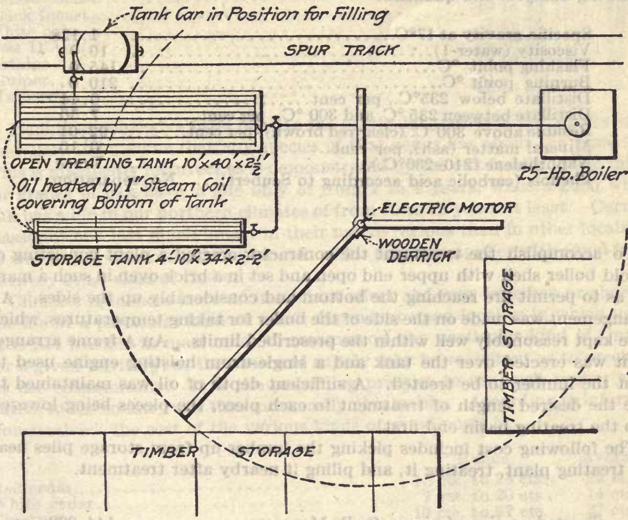

FIG. 4.—General layout of open-tank treating plant.

lb. per cu. ft., for 9.7 cu. ft., or 10.8 gals., and 50 cts. is for labor and overhead. The average cost per M. ft. B. M. is $38.54. In treating the subflooring and roofing two men handle approximately 400 pieces per hour, making the labor cost per piece $.0005. Overhead is estimated at $.0005 and the cost of creosote oil at 8 lbs. per sq. ft. of surface makes a total cost per piece of about $.018 or $10.65 per M. ft., B. M.

Cost of Treating Sheet Piles with Avenarius Carbolineum.—W. D. Jones gives the following, in Engineering and Contracting, July 26, 1916.

In the construction of a timber wharf 50 ft. wide and 1,600 ft. long resting on creosoted piles, at Los Angeles Harbor, a bulkhead was specified as follows:

Lumber.—All lumber for sheet piles must be 4 × 12-in. No. 1 merchantable Oregon pine (Douglas fir), sound, free from large, loose or rotten knots, knot holes, splits, shakes, wain, rot, pitch seams open on both sides of the piece, worm holes or other defects which materially impair the strength of the piece. Each piece shall have a groove 1 in. wide and 1 in. deep cut in each edge. In one of the grooves a spline 1 × 1¾ in. shall be spiked to form a tongue.

Treatment.—All sheeting shall be dipped such that the upper 15 ft. be immersed for at least twenty minutes in Avenarius Carbolineum, which shall be kept at a temperature of 212 to 220°F. during the dipping. The heating to be accomplished by steam coils. (This was not done.) Manufacturers estimate that the amount of Carbolineum necessary for this treatment will be 1½ lbs. per cubic foot of lumber treated. The Carbolineum must be brought to the dipping station in the original containers and must give the following analysis and qualities:

Specific gravity at 17°C.	1.128
Viscosity (water-1)	10.0
Flashing point °C.	145.0
Burning point °C.	210.0
Distillate below 235°C., per cent	0.44
Distillate between 235 °C. and 300 °C., per cent	7.50
Residue above 300°C. (clear red brown), per cent	92.01
Mineral matter (ash), per cent	0.10
Naphthalene (210–230°C.)	Trace
Phenols (carbolic acid according to Seubert)	No separation

To accomplish the treatment the contractor erected a plant consisting of an old boiler shell with upper end open and set in a brick oven in such a manner as to permit fire reaching the bottom and considerably up the sides. An arrangement was made on the side of the boiler for taking temperatures, which were kept reasonably well within the prescribed limits. An A frame arrangement was erected over the tank and a single-drum hoisting engine used to hoist the lumber to be treated. A sufficient depth of oil was maintained to give the desired length of treatment to each piece, the pieces being lowered into the treating basin end first.

The following cost includes picking the lumber up from storage piles near the treating plant, treating it, and piling it nearby after treatment.

Treated portion of pieces ft. B. M.	144,222
Treated portion of pieces sq. ft. surface area	107,984

Cost of treatment—Labor, $1,227.57; equipment service, $66.65; material, $1,136.20.

Cost of treatment per 100 sq. ft. $1.14; equipment service, $0.06; material, $1.05.

Cost of treatment per 1,000 ft. B. M.—Labor, $8.51; equipment service, $0.46; material, $7.88.

A total of 1,196 gals. of carbolineum was used. This amounts to approximately 11,300 lbs., being slightly less than 1 lb. per cubic foot of lumber treated. The cost of this amount of material was, as given above, $1,136.20. Some difficulty was experienced in keeping the shorter lengths of lumber immersed, due to its floating up in the liquid.

Cost and Serviceability of Wood Fence Posts on Railways.—Some discussion of the life and cost of wood fence posts based on the experience of some 44 American railways, are brought out by report of a special committee of the American Railway Engineering Association. Engineering and Contracting, March 19, 1913, summarizes part of this report, as follows:

Wood Posts.—From the data collected the life of wood posts of various kinds actually in use is as follows:

LIFE OF POSTS

	Years	Average years
Red cedar	7 to 25	18
Cedar	10 to 30	—
White cedar	12 to 17	15
Chestnut	10 to 15	12
Locust	7 to 20	—
Yellow locust	15 to 30	20
Black locust	10 to 25	20
White oak	7 to 15	10
Bois D'Arc	12 to 45	25
Catalpa	10 to 25	15
Juniper	15	15
Mulberry	15 to 20	15

Doubtless some give little heed to the particular species of the timber that they use, and assume that any species of that genus has about the same life. This is manifestly incorrect as is demonstrated by the oak family. The inferior grades of oak have a life only of from 2 to 4 years, while a good white oak has a life in our northern climates of from 10 to 12 years at least. Certain classes of oak last much longer in their native regions than in other localities to which they are transported for use. This principle applies with equal force to every other class of timber.

Climatic influences have an important effect and may lengthen or shorten the life of a particular kind of wood, dependent upon locality in which used' It is not feasible in most cases to recommend any particular kind of timber for a given territory, as the source of supply may be so distant as to preclude its use economically. It is the prevailing practice to use such timber as is native to the country and thus most easily obtainable. According to information received, the cost of the various kinds of wood posts is:

	Range	Average
Red cedar	15 cts. to 25 cts.	22 cts.
White cedar	7 cts. to 20 cts.	14 cts.
Chestnut	10 cts. to 27 cts.	27 cts.
Locust	15 cts. to 40 cts.	25 cts.
Yellow locust	20 cts. to 38 cts.	30 cts.
Black locust	15 cts. to 25 cts.	20 cts.
White oak	11 cts. to 40 cts.	20 cts.
Bois D'Arc	13 cts. to 17 cts.	15 cts.
Catalpa	15 cts. to 25 cts.	20 cts.
Juniper	6. cts to 10 cts.	8 cts.
Mulberry	13 cts. to 17 cts.	15 cts.

It will be observed that the relative cost to life of post ranges from ½ ct. to 2 cts. per year of life, the Bois D'Arc and the Juniper being the cheapest posts, but so rare that a more general use is impossible.

It was of interest to know to what extent wooden posts were subject to destruction by fire. Replies received indicated that this varied by from 1 per cent to 5 per cent, with the exception of one road which reported a loss of 30 per cent from this cause. We think it fair to assume that the average loss by fire is around 3 per cent.

Costs of Three Types of Board Fences.—Engineering and Contracting, May 19, 1915, gives the following:

Figs. 5 and 16, show types of board fences built under the supervision of John H. Gardinier of Lake Charles, La. Fairly close cost records were kept excepting for gates, the labor cost for which was included in the placing of boards. In the corral fence there were two 8-ft. gates and in the town fence two 12-ft. and two 8-ft. and one 4-ft. gates.

The holes for the posts were dug with a 6-in. post hole digger, the ground was moist and would have been fairly easy digging if it had not been for the numerous small roots encountered for the first foot under the surface, as these fences were built in the pine woods. The posts for the corral fence were set by contract at 15 cts. apiece, costing the same as for the town fence by day labor. But the three men by contract made $3 a day. The only difference in price of having the posts set by contract and day labor was that the posts set by the day men were a little more carefully set.

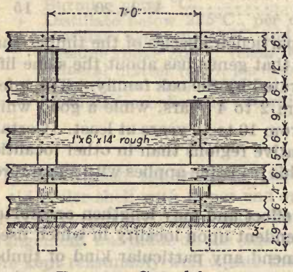

FIG. 5.—Corral fence.

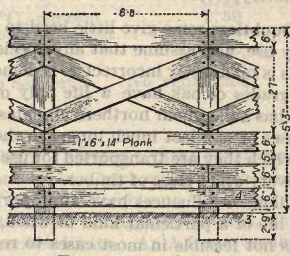

FIG. 6.—Town fence.

ITEMIZED COST OF CORRAL FENCE

360 posts, 4-in. × 6-in. × 8-ft., 5,760 ft. B. M. at $14.75	$ 84.96
Lumber, 1-in. × 6-in. × 14-ft. plank, 6,300 ft. B. M. at $15.50	97.65
160 lbs. nails at $2.20	3.52
Labor setting posts	54.00
Labor placing boards	50.54
Two per cent use of tools on labor	2.09
Distributing material	8.50
Total cost	$301.26
Cost per lineal foot labor	0.04148
Cost per lineal foot, material	.07806
Total cost per lineal foot	0.11954

Posts set by contract at 15 cts. each.
Boards placed by day labor: One man, at $2.50; 2 men at $2.00 each.

ITEMIZED COST OF TOWN FENCE

570 posts, 4-in. × 6-in. × 8-ft., 9 120 ft. B. M. at $14.75	$134.52
Lumber, 1-in. × 6-in. × 14-ft., 11,466 ft. B. M. at $15.50	177.72
248 lbs. nails at $2.20	5.46
Labor setting posts	85.50
Labor placing boards	119.81
Distributing material	31.50
Use of tools	4.11
Total cost	$558.62

Posts set by day labor: One man, at $2.50; 2 men at $1.75 each.
Boards placed by day labor: One man, at $2.50; 2 men, at $2.00 each.

Cost per lin. ft. for labor	$ 0.05371
Cost per lin. ft. for material	.09244
Total cost per lin. ft	$ 0.14615

Cost setting posts 15 cts. each.

ITEMIZED CÔST OF PARK FENCE

173 posts, 4-in. × 4-in. × 5-ft., 1,153 ft. B. M. at $15.25	$ 17.58
Lumber, 1-in. × 4-in., 809 ft. B. M. at $15.00	12.13
Nails 30 lbs	.66
Labor setting posts and placing boards	40.00
Distributing material	2.50
Use of tools on labor	.80
Total cost	$ 73.67
Labor: One man, at $2.50; 2 men, at $1.75 each.	
Labor cost per lin. ft	$ 0.03252
Material cost per lin. ft	.02737
Total cost	$ 0.05989

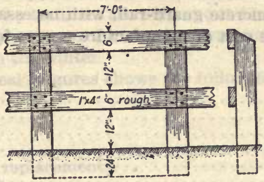

FIG. 7.—Park fence.

Small Pile Driver for Putting Down Fence Posts (Engineering and Contracting Sept. 4, 1918).—Posts for the 17-mile board fence at the American Lake (Washington) cantonment were put down at the rate of about 180 per 8-hour day by means of a small pile driver mounted on a 2-horse truck. The posts were pointed, were 5 ins. to 10 in. ins diameter, and 9 ft. long, of which 3 ft. was below ground. They were spaced 8 ft. apart. The pile driver had a 4-h.p. Fairbanks gasoline engine operating a small drum by means of a friction clutch. The crew consisted of an engineman, a teamster and two men handling posts. The actual driving time per post was 60 to 90 seconds. The hammer weighed 600 lb. and had a 6-ft. drop when beginning driving.

Cost of wooden and concrete guard rails are given in the report of Hubert K. Bishop embodied in the 1910 report of the New York State Highway Commission and abstracted in Engineering and Contracting, Nov. 15, 1911, as follows:

The proper maintenance and repair of guard-rail is a rather serious proposition. A large amount of money was expended during 1910 in rebuilding and repainting guard-rail. In order to serve its purpose and protect the traveling public from danger, the guard-rail should be in sound condition. It is also necessary for the looks of the road that it should present a neat and uniform appearance.

The weakest part of the guard-rail as built under the present standard is the posts which rot off below the ground line, causing the guard-rail to become insecure and to lose its alignment, thus presenting a very bad appearance.

Assuming that a wooden guard-rail will last eight years, the depreciation charge is approximately 3 cts. per foot per year. Adding to this the necessary cost of painting and straightening of 3 cts. per year, we would have an annual cost of 6 cts. per foot per year for wooden guard-rail. On Jan. 1, 1910, there was 1,383,220 ft. of guard-rail in the State. The annual cost of maintenance of this guard-rail at the above figure would be $82,993 per year. It must be borne in mind that this item is constantly increasing with every new road which is being built.

Assuming that the above figure of 6 cts. per foot per year is correct for the annual cost of such guard-rail, $1,25 per foot could be expended in eliminating this guard-rail and the cost to the State eventually would be less. If some form of concrete or pipe rail or even the guard-rail with concrete posts could be substituted for the present standard form of guard-rail, the annual cost of this item could be materially lessened.

During 1910 experimental work was carried on under the direction of Frank W. Bristow, Superintendent of Repairs in Division 5, and John Y. McClintock, county engineer, Monroe County, with a view to devising some form of guard-rail to take the place of the standard wooden type. With this end in view 1,233 lin. ft. of steel-concrete guard-rail, with necessary steel-concrete posts, were constructed. The cost of manufacture was as follows:

		Per lin. ft.
Lumber	$ 32.46	$0.026
Steel	139.64	0.114
Cement	57.62	0.046
Gravel	10.00	0.008
Metal cores	77.00	0.063
Labor	231.83	0.188
Miscellaneous	5.35	0.004
	$553.90	$0.449

The engineer in charge of this work estimated the following as the fair cost when making not less than 128 lin. ft. of rail and 16 posts per day, with metal cores and wooden forms already paid for:

	Per lin. ft. including rail and one post for each 8 ft.
Foreman	$0.03
Steel	.08
Cement	.05
Gravel	.01
Labor	.09
Tools, etc	.01
Total	$0.27

For this guard-rail the bars were made 8 ft. long, except end bars, which were 8½ ft. long. They were 9 ins. wide by 7 ins. high, and were cored out from below to leave concrete 2 ins. thick, and 3 cross diaphragms connecting the sides and top, placed one at center and one 4 ins. back from each end. The steel reinforcement consisted of 4 bars ⅜-in. square placed horizontal at each corner, and a loop of same size at and in each diaphragm. It was expected to sustain without breaking 6 tons pressure concentrated at center, acting either vertically or horizontally. The bars rested on top of the posts without any fastening, while the sides and diaphragms formed sockets inclosing the head of the posts, which prevented their being shoved off either sideways or endways, and the weight of the bar, about 300 lbs., held it firmly on the posts.

The posts were 6½ ft. long by 5 ins. by 7 ins. square, with four ⅜-in. square bars, one in each corner. The posts were set 3½ ft. in the ground, making the finished guard-rail 3 ft. 2 ins. high.

Some data on the cost of setting this guard-rail were:

Six men working 4 hours dug and set 11 posts, without post augur, and fitted and put up 12 rails, which figures 6 cts. per lin. ft.

Six men working 9 hours dug and set 21 posts, without post augur, and set on 20 rails, which figures 7½ cts. per lin. ft.

It was estimated that under ordinary conditions, this guard-rail could be made and erected for 50 cts. per lin. ft.

Cost of Washed Sand and Gravel (Engineering and Contracting, Feb. 21, 1917).—Some interesting figures on the cost of producing sand and gravel were given by B. E. Neal, in a paper presented before the joint meeting of the Indiana and Illinois Sand and Gravel Producers' Associations, Dec. 28, 1916. In submitting the figures Mr. Neal pointed out that the gravel business is a spasmodic one, that in a year there are only about 4 months of good business and that there are heavy expenses for repairs, replacements and for carrying the organization through the winter.

A summary of Mr. Neal's figures shows the following:

	Per ton, Cts.
Plant cost—Operating	12½
Stripping	2
Repairs and replacements	6
Office and selling expense	5
Taxes and insurance	½
Plant depreciation	3
Depletion of gravel deposit	1
Interest on investment 5 per cent	1
Total	31

These figures Mr. Neal believes are about the average cost of producing commercial material under average conditions. By average conditions is meant a bank of gravel 30 to 40 ft. thick covered with about 3 ft. of stripping and running about 40 per cent above the ¼-in. and 60 per cent below. The above conditions are believed to be at least as good as are found in the average pit in Indiana.

The item operating cost includes the cost of loading and washing gravel, the cost of power and labor to transport the gravel from the bank to the plant and the cost of the monthly men while not actually engaged in repairs; also the cost of fuel or electric power, as the case may be. Mr. Neal stated that the experience of his company showed the cost of producing salable material, not considering the material wasted in a production, to be not far from 12½ cts. per ton.

The cost of stripping item varies more or less with local conditions. To move the stripping and get it clear away from the scenes of operation, Mr. Neal believes, would cost on an average 30 cts. per cubic yard of stripping moved. This in the case of the bank mentioned above would make the average stripping cost 2 cts. per ton of gravel. Regarding the item repairs and replacements Mr. Neal calls attention to the fact that producing gravel is heavy and hard work and is the hardest usage that machinery of all kinds can be put to. He believes the average repairs for plants, including repair labor, will average 6 cts. per ton on the year's output.

Plant depreciation is figured on the basis of 15 per cent per year. In giving this figure Mr. Neal states that plants of the cable excavator type must be moved every 3 or 4 years, and that plants of the elevator type with shovels and donkey engines have expensive machinery which does not last for many years. Mr. Neal doubts very much if this amount of depreciation would have covered the cost during the past 6 or 8 years, owing to the changes in gravel specifications which have necessitated rebuilding the plants. As a result of figuring over several plants, their costs and their capacities, Mr. Neal believes that it takes an average plant investment of at least 20 cts. per ton of yearly output. In other words, a plant which will produce 100,000 tons of commercial material could be be erected and made ready for business with a plant investment of less than $20,000. On the basis of 15 per cent depreciation this would mean a cost of 3 cts. per ton for gravel produced.

The item "depletion of gravel deposit" is figured on the basis of there being 65,000 tons of gravel per acre.

Cost of Operating Gravel Washing Plant at Wayne County, Michigan.— Engineering and Contracting, Dec. 3, 1919, gives the following:

A washing plant with a capacity of 200 cu. yds. per day was erected at the gravel pit, leased by the County Road Commissioners to furnish material for two concrete roads. The entrance was graded and an industrial railway laid right up to the chutes from the washing plant bins.

The location of the pit was central to the roads being built, thereby shortening the haul about ½ mile over the distance from the railroad siding if commercial material had been used. The lay-out of the gravel pit was such that it was much cheaper to arrange a yard at the pit than it would have been to unload from railroad cars.

A small stream fed by local springs furnished an abundant supply of water, which was pumped 1,000 ft. through two lines of 3-in. pipe to the washing plant by electric motor. A single line of 4-in. pipe would have been sufficient, but two 3-in. lines were used because this pipe was in stock. The plant was operated by a small electric motor, making it comparatively simple in operation.

The cost of operation, exclusive of interest and depreciation, according to the last annual report of the Commissioners was approximately as follows:

	Total per day
4 teams loading hopper at $8	$32.00
2 scraper holders at $5	10.00
1 foreman at $6.50	6.50
1 operator at $6	6.00
2 car loaders at $5	10.00
Motor rental at $1.50	1.50
Electric current estimated	10.00
Total (200 cu. yds. at 38 cts)	$76.00

On the basis of an average daily output of 200 cu. yds. the cost amounts to 38 cts. per cubic yard, plus 15 cts. for the cost of the material in the pit, making a total of 53 cts. per cubic yard for the material loaded in the industrial cars ready to haul. It will be noted in the above cost that the largest item is the teams loading the hopper which feeds the belt. This item could have been reduced by the installation of a drag line bucket and hoisting engine, but owing to the short run which this plant had it was not considered advisable to invest in so large an equipment.

The plant cost approximately $7,200 erected, and supplied about 10,000 cu. yds. of material, from the pit. It is expected to operate the plant next year for furnishing gravel and sand for maintenance work.

Cost of Excavating, with Drag Line, Aggregates for Concrete Road Work.— Stanley E. Bates in Engineering and Contracting Sept. 22, 1915, gives the following:

The plant is located in Elkhart County, Indiana, and was erected by the contractor for supplying the aggregates for constructing some 3 miles of concrete road.

Fig. 8 shows the general layout of the plant, the essential features of which are a bucket and carriage mounted on a slack line cable running between a mast on one side of the river and an anchor on the other, a hoist to operate the bucket, and a screen, crusher and loading bin. Three-phase, 60-cycle alternating current from a 2,200-volt power line, stepped down by three transformers to 440 volts, is used throughout the plant.

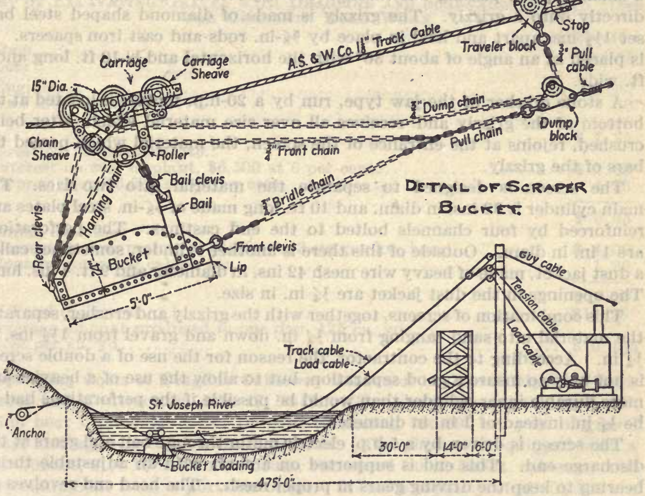

FIG. 8.—Dragline gravel excavating plant at Elkhart, Ind.

From Fig. 8 the operation of the dragline in digging the gravel from the river bed and elevating it to the top of the screening and loading plant, can be followed. The power to operate the cables is supplied by a 50-h.p. two-drum electric hoist, equipped with a friction clutch of the band type which operates the drum at two speeds, high speed being three times as great as low. This two-speed arrangement is particularly adapted to dragline excavation as it furnishes great power at slow speed for digging and then, when the bucket is full, the drum can immediately be thrown into high by means of a single lever clutch, bringing the bucket rapidly to the dumping point.

To the forward drum of the hoist is attached the load cable which passes over a sheave attached to the top of the mast and thence to the bucket. The rear drum operates the tension cable which, through a set of fall blocks also at the mast top, furnishes the means of slackening and tightening the track cable. Both the tension and load cables are ¾-in. diam. Details of the bucket, which has a capacity of 1 cu. yd. and of the carriage and chain mountings, are shown in Fig. 8.

The mast is 65 ft. high, of an A-frame type, the legs 14 ft. apart at the bottom. Each leg is built up of 6 × 10-in. timbers spliced through the middle portion to give added resistance to bending. In addition to this, they are trussed on each side with ⅝-in. wire rope. Three guy lines of 1-in. cable run from top of the mast to anchors about 100 ft. back of the base and 75 ft. apart. Two auxiliary guys of ⅝-in. cable lead to anchors close to the river bank. The track cable running across the river is 1½ ins. in diam. and nearly 500 ft. long.

The bucket drops its contents against a dump board built at an angle of nearly 45° at the top of the structure. The material then slides down into a small hopper, passing out through the 1½ × 2-in. opening in the bottom directly onto a grizzly. The grizzly is made of diamond shaped steel bars set 1½ ins. apart and held in place by ⅝-in. rods and cast iron spacers. It is placed at an angle of about 30° with the horizontal and is 10 ft. long and 3 ft. wide.

A stone crusher of the jaw type, run by a 20-h.p. motor, is located at the bottom of the grizzly and receives all over size material which, after being crushed, rejoins at the entrance of the screen, the material which passed the bars of the grizzly.

The screen is designed to separate the material into two sizes. The main cylinder is 32 ins. in diam. and 10 ft. long made of ⅛-in. steel plates and reinforced by four channels bolted to the end castings. The perforations are 1 in. in diam. Outside of this there is another cylinder, sometimes called a dust jacket, made of heavy wire mesh 42 ins. in diameter and 9 ft. 4 ins. long. The openings in the dust jacket are ¼ in. in size.

This combination of screens, together with the grizzly and crusher, separates the material into sand ranging from ¼ in. down and gravel from 1½ ins. to ¼ in. According to the contractor, the reason for the use of a double screen is not only to insure a good separation, but to allow the use of a heavier and more durable inner cylinder than would be possible if the perforations had to be ¼ in. instead of 1 in. in diameter.

The screen is driven by a 5-h.p. electric motor through belt and gears at the discharge end. This end is supported on a shaft with an adjustable thrust bearing to keep the driving gears in proper mesh. The head end revolves on two wide faced rollers.

To aid in the separation of the sand and gravel, water is pumped into the cylinder through a 2-in. pipe line from the river by a centrifugal pump driven by a 5-h.p. motor. This pipe runs inside and along the axis of the screen and is perforated, thus delivering the water uniformly over the material.

Below the screen are the loading bins, two for sand and one for gravel. Each holds about 15 cu. yds. of material and has two discharge chutes, one on each side. The bottoms of the bins are built in the shape of an inverted V, with a slope of about 30°.

The amount of material excavated and screened per day has averaged about 125 cu. yds., though if necessary this could be increased nearly 100 per cent. Three men are needed to operate the plant, an engineer and two laborers. One of the latter is located at the grizzly and keeps the material moving freely, seeing that it doesn't clog at any point. The other assists in loading the motor trucks.

The gravel from the river runs about two parts of fine material to one of coarse and as the specifications for the road call for concrete of a 1:2:3 mix, there is a large excess of sand. At present this is stored in piles around the plant and sold locally as there is demand for it. It is clean and sharp, an excellent material for concrete work, and brings about $1 per cu. yd. delivered.

Cost of Producing Gravel and Sand.—Owing to rain delaying the progress of the concrete work, the material plant has not been in continuous operation. Cost figures, therefore, are not representative but the tabulation below is based on the work done so far and will give a fairly good idea of what may be expected of a plant of this type, working under unfavorable conditions. In computing interest, etc., it was assumed that the plant was in operation only 150 days out of the year, and was producing each day only 125 cu. yds. of sand and gravel.

Cost of Excavating Gravel with Dragline and Screening to Two Sizes for Concrete Road Work

Item	Per 10-hr. day
Labor:	
Engineer	$ 3.25
Two laborers at $2.00	4.00
	$ 7.25
Interest on Investment, etc.:	
Interest on cost of plant, $6,500 at 6 per cent	$ 2.60
Depreciation $6,500 at 10 per cent	4.33
	$ 6.93
Running expenses:	
Current for four motors at 2½ cts. to 3 cts. per kw. hour	$ 4.00
Repairs, renewing cables, etc	1.20
	$ 5.20
Total daily cost	$19.38
Average amount produced in one day, 125 cu. yds.	
Cost per cu. yd	$ 0.155

Operating Costs of Dragline Cableway Excavator in Gravel Dipping (Engineering and Contracting, Jan. 17, 1917.)—The plant was erected by J. W. Gwinn near Cambridge City, Ind. for furnishing 100,000 cu. yds. of gravel ballast and aggregate for a concrete road. The plant was equipped with a 1-yd. bucket, 8 × 10 in. double drum, two-speed hoist, 500-ft. cableway and other equipment from a portable outfit. It has a capacity of about 300 cu. yd. per 10-hr. day and the total investment in the plant approximates $7,000.

The daily operating costs of the plant are as follows:

Engineer	$ 4.00
Fireman	3.00
Laborers	4.00
Coal	3.00
Oil and miscellaneous	1.50
Total	$15.50

This shows a cost of 5 cts. per yard. But the yearly overhead charges should also be taken into consideration, as follows:

	Per year
Interest on $7,000 at 6 per cent	$ 420
Renewal of cables, blocks and sheaves	400
Depreciation of engine and bucket	450
Total	$1,270

Counting on 200 working days, the daily fixed charges will be $6.30, which, added to the pay roll, gives a total daily expense of $21.80. This means that when the plant is working to capacity, gravel which sells for 25 cts. a yard costs only 7 cts. to produce.

The chief difficulty is that conditions constantly intrude to prevent operating the plant at capacity. Mr. Gwinn suffered from the car shortage and was compelled to cut the daily operating hours more than one-half.

Cost of Crushing Rock at the Pocoima Quarry, Los Angeles, Cal.—W. A. Gillette gives the following in Engineering and Contracting, Oct. 4, 1911.

The quarry is operated under the direction of the Los Angeles County Highway Commission, under the direct supervision of Wm. Davidson. The data and segregations have been reconciled with the ledger and payrolls each month as shown on the books of the Los Angeles Highway Commission, beginning Jan., 1911, and running six months, inclusive.

The plant consists of one No. 4 and one No. 6 Austin gyratory crusher, loading bins 1,700 tons capacity; one Bucyrus steam shovel, Type C, Model 60, 2½-yd. bucket, quarry cars, track, electric locomotive, scale house, bunk and boarding houses, and all the equipment necessary for a complete plant. The cost of the plant is approximately $90,000. For the six-month period—Jan.–June, 1911—the cost of producing crushed rock was as shown in Table VII-

TABLE VII.—COST OF ROCK CRUSHING AT THE POCOIMA QUARRY

	Totals	Per ton	Per cent. of total cost
Supt. and office	$ 2,292.10	$0.0224	3.97
Stripping—labor	8,804.67	.0860	15.26
Drilling and blasting—labor	2,041.46	.0199	3.54
Powder*	789.14	.0077	1.37
Other material	124.83	.0012	.22
Loading and transporting quarry to crusher	27,094.24	.2646	46.95
Material	549.28	.0054	.95
Hauling muck—labor	8,148.60	.0796	14.12
Plant operation—labor	2,000.77	.0195	3.47
Loading and shipping—labor	752.94	.0074	1.30
Maintenance—labor	1,703.89	.0166	2.95
Material	784.93	.0077	1.36
General labor	493.52	.0048	0.86
Power cost	2,134.51	.0208	3.70
Items of improvement	1,130.00	.038	......
Interest on plant investment	2,750.00	....	......
Grand total	$61,594.88	$0.6016	100.02
Credits—boarding house profits	4,217.66	$0.0412	......
	$57,377.22	$0.5604	......

NOTE.—The average number of men employed per day was 92, and per night 58, making a total of 150. The live stock amounted to 31. The total number of shifts was 227, and total tonnage produced was 102,377, making the average per shift 372 tons.

*6,928 lbs. of powder used or .0067 lb. per ton.

The county is buying crushed rock from various other plants at from 53½ cts. to $1.10 per ton f. o. b. at plant, the prevailing price being around 70 cts. per ton.

As far as management is concerned the showing made is very much out of the ordinary, particularly in view of the fact that to a large extent Mexican labor, at $2 per 8-hr. day, has been used.

As will be noted in the table, 15.26 per cent of the total cost is for stripping, and 14.12 per cent of the total cost is for handling muck. This is 29.38 per cent of the total cost, and is equivalent to 16.56 cts. per ton. This is an extra expense which could have readily been saved, had proper judgment been used in selecting the quarry location. There appears to be no logical reason for not having selected a proper site as there are numerous good ledges of suitable rock available.

It will be noted that I have not given the item of depreciation which of course must be taken into account. Part of this, however, is covered in the items maintenance, material and items of plant improvement. We could add 5 cts. a ton for plant depreciation, and still have a good showing. The rock is a disintegrated granite.

The Cost of Unloading Crushed Rock from Railroad Cars by Slip-Scraper.—In Engineering and Contracting, Oct. 22, 1910, H. R. Postle gives the following:

The writer, aided by some experiments and suggestions, has recently constructed and operated a device that is, he believes, the solution of the problem for the ordinary contractor who must have a plant adapted to small jobs, movable from place to place and adapted for all kinds of railroad cars. Unloading crushed rock ordinarily costs from 20 to 25 cts. per ton, but, by means of this apparatus, rock is being unloaded for about one-third to one-half of this amount.

The method is to draw the rock over the end of the car, through a chute hung to the end of the car, and into the wagon by means of an ordinary slip-scraper (largest size), to which is attached a ⅝-in. wire cable connected to a hoisting drum operated by a gasoline engine.

The chute is built of 2-in. lumber and is 6 ft. wide at one end, 5 ft. at the other end, and 5 ft. long, and is supported by two legs, so that it just clears the wagons, allowing them to be driven under or moved ahead. A roller 3 or 4 ins. in diameter is mounted on the outer end, over which runs the cable drawing the scraper and against which the scraper falls when dumping.

The hoist drum and gas engine are mounted on a low truck so as to be easily moved. The engine is a 10 h.p. gas engine, belted to the hoist drum with an 8-in. belt. The hoist drum is 12 ins. in diameter and 10 ins. wide.

The method of procedure is to place the loaded railroad cars in one end of the switch, move each car in turn into the same position for unloading, and, when unloaded, move it to the other end of the switch. An extra length of rope is provided so that a hitch can be made to the cars to move them into position. The cars are thus moved more quickly than the apparatus can be moved from car to car.

Six or seven men are needed to unload from 200 to 250 tons of rock per day. One acts as foreman, two handle the scraper, one is engineer and the others shovel up the surplus rock which the scraper can not reach. The two men handling the scraper drag it to the farthest end of the car, signal the engineer, who throws in the clutch, when immediately the scraper starts toward the chute, gathering a full load of rock and pushing some ahead of itself, is drawn through the chute and dumps its load at the end thereof into the wagon.

The writer in loading 5 yds. (6 ton) dump wagons, found that they could be loaded in an average of 10 minutes by 12 scraper loads. About seven-eighths of a car can be unloaded by the scraper by having the two or three shovelers shovel the rock away from the sides and farther end of the car when the rock is getting low in the car.

From 200 to 250 tons per 8-hr. day can be unloaded for the following costs:

One foreman	$ 3.50
One engine man	3.00
Two scraper men	5.00
Three shovelers	6.00
Gasoline, oil, repairs, etc	2.50
Total	$ 20.00

If only 200 tons are unloaded, the cost is 10 cts. per ton. The cost of the apparatus is:

Gas engine, ten horse-power	$350.00
Hoist drum	125.00
Truck	50.00
Large scraper	10.00
One hundred and twenty-five feet cable	9.00
Pulley block	3.00
Total	$547.00

The irregularity with which cars of rock are received, makes such an apparatus especially valuable to any contractor, inasmuch as when no cars, or less than a day's run, are received, he need not have a gang of shovelers to lay off or provide for.

Cost of Handling Stone from Cars by Slot, Elevator and Bin Method.— During the road construction season (1919) the County of Brant, Ontario, unloaded broken stone from cars and into an elevated bin by the slot, elevator and bin method, at a cost of about 3 cts. per ton. The following information on this method is from an abstract in Engineering and Contracting, April 7, 1920, of a paper presented at the 6th annual conference of Ontario Road Superintendents and Engineers by Alan Mair Jackson.

A slot 4 ft. deep across the track is excavated 16 ins. wide between ties and is lined with ties one on top of the other. A plate some 9 ft. long and 16 ins. wide is set in this slot at a slope on which stone runs freely, i. e., 30 degrees from the horizontal. The plate should be set so that the largest material will pass under the rail at the upper end and the lower end so that it will discharge on the buckets of an elevator. The elevator is set in a pit at one side of the track with the center of the lower tumbler about 5 ft. below base of rail. With this setting, a 30-ft. elevator standing at 60 degrees from horizontal will have sufficient length to fill a 55-ton bin. The motor, consisting in this case of a 9 h.p. oil engine, is set under the elevator in a small portable house and provided with a clutch drive, by 6 in. belt, onto the jack shaft of the elevator. The elevator is of standard construction 14 ins. wide and delivering about 120 buckets per minute.

The flow of stone to the elevator is controlled by an ordinary slide door operated by a lever and is set between angles fastened to two plates lining the sides of the 16 in. slots at the lower end. The pit in which the elevator is set is made large enough for the operator to get down to the lower tumbler and is timbered on the track side and decked over. A trap door is left in the deck so that the lever operating the stone feed may be got at and cover boards are provided for the slot across the tracks so that the whole may be left safe when not in operation. The usual spacing of ties is about 20 in. centers, which leaves approximately 11 in. space between ties.

Two of these outfits were installed by the County of Brant last year and operated during the construction season. The total kerosene purchased at 20½ cts. for unloading 1,854 tons was 33 gals., giving a cost for fuel of about $\frac{4}{10}$

ct. per ton A 50-ton car can be unloaded in 2½ hours, though allowing for oiling round and starting up, Mr. Jackson figures 3 hours about a fair allowance. The operator in each case has been an unskilled man paid 40 ct. per hour. The bin used discharges through four 12 in. × 12 in. openings in the bottom by means of any one of which a 1½ yd. wagon can be filled in 30 seconds. The height from the ground to bottom of bin is 6 ft. 8 in., though this can be increased by lowering the roadway. The cost of unloading 50 tons may be taken as follows:

3 hours' time at 40 cts	$1.20
50 tons at 4/10 ct. for fuel	.20
Oil and waste and grease	.10
Total	$1.50

The outfits cost approximately $1,800, made up as follows:

Engine and clutch	$ 545
Elevator	650
Lumber for bin and pit	215
Ironwork for bin and slot	225
Construction	165
Total	$1,800

Mr. Jackson estimates that the unloaders can be taken down and re-erected for about $200.

A bin of this capacity is not portable in the strict sense of the word but the bins used in Brant county last year were made so that the whole structure could be readily taken apart. No nailed parts would have to be torn out except the lining boards of the end of the bin, each of which requires two 4-in. nails, so that no loss should occur in knocking down the bin.

Cost of Loading Gravel by Mechanical Loaders and by Hand.—Comparative figures on the cost of loading road gravel by various methods were given by P. Philips, District Engineer of the Department of Public Works of British Columbia, in a paper presented at the recent convention of the Provincial District Engineers. The matter following, given in Engineering and Contracting, June 2, 1920, is taken from his paper.

A "Haiss" mechanical loader was introduced to Delta district this past summer and has been in continuous operation up to the present time. This machine has given results which have more than justified its introduction. With a few exceptions the pits in Delta district are not ideally situated for loading gravel, having shallow faces. The machine has reduced the cost of loading gravel by at least 50 per cent, for it will easily load 160 cu. yds. per day at a cost of 12.3 cts. per cubic yard and under more favorable conditions has loaded for 6.6 cts. per cubic yard.

Where the gravel is to be hauled a long distance it is absolutely essential that the loader be kept in constant operation either by having portable bunkers in conjunction with it or by increasing the number of trucks.

The loader is self-propelling, simple to operate, requires only an intelligent skilled laborer to run it. The crew consists of three men, one to operate the machine (this man is paid 50 cts. per hour more than the ordinary laborer), two men stripping the face of pit, loosening the gravel, cleaning away roots and debris. With the above crew the loader can be fed to its full capacity. If the pit has a high face one man can be dispensed with.

A clamshell was used on Nicomen slough for loading rock tailings into scows. The cost of loading 2,000 cu. yds. of material was 6 cts. per cubic yard; 2,000 cu. yds. cost 16 cts. per yard to load on account of an insufficiency of scows.

The capacity of bucket is ⅞ cu. yd. and the daily capacity is 300 cu. yds. The daily cost of operation is:

Engineer, fireman and helper	$15.00
Fuel, oil, upkeep, depreciation	5.50
	$29.50
Cost per cubic yard	6.8 cts.

Where the material is suitable for scraper work this method compares favorably with the mechanical loader. The cost of loading 90 cu. yds. of fine rock with team and scraper was 14 cts. per cubic yard. It must be considered whether the amount of material available will justify the expense of erecting bunkers.

A man will shovel loose gravel at the rate of 15 cu. yds. per day. The cost is 27 cts. per cubic yard.

The following tabulation shows costs for loading truck, assuming the truck makes 8 trips per day with a load of 2 cu. yds., taking into consideration the cost due to delay in loading:

Loading by Hand—16 Cu. Yds.

3 men for 2.8 hours	$ 4.20
2.8 hours delay of auto truck at $30 per day	10.50
Total cost	$14.70

Mechanical Loader—16 Cu. Yds.

16 cu. yds. at 12.3 cts	$ 1.97
⅘ hours delay of truck	3.00
Total cost	$ 4.97

Ration List for Construction Camps (Engineering and Contracting, March 19, 1919).—As the result of an analysis of mess practice in the lumbering industry, made by the engineers of the Spruce Board of the U. S. Army, the following was suggested as a satisfactory ration list for camp messes:

	Pounds per man per day	Pounds per man per 90 meals
Meats, fish	1.25	37.50
Eggs	0.156	4.68
Lard, etc	0.08	2.4
Butter and substitutes	0.15	7.5
Cheese	0.05	1.5
Milk, canned	0.25	7.5
Milk, fresh	1.00	30.00
Beans	0.125	3.75
Potatoes	1.00	30.00
Peas	0.10	3.00
Corn	0.10	3.00
Tomatoes	0.10	3.00
Onions, carrots, parsnips, etc	0.125	3.75
String beans, asparagus, etc	0.062	1.86
Sugar (all purposes, baking, cooking, table, etc.)	0.20	6.00
Syrup and molasses	0.25	7.50
Jams and jellies	0.031	0.93
Flour (all kinds)	0.90	27.00
Oatmeal	0.10	3.00
Cornmeal	0.02	0.60
Cornstarch	0.02	0.60
Rice and barley	0.02	0.60
Dried and canned fruits	0.25	7.50
Fresh fruits, etc	0.25	7.50
Tea	0.01	0.30
Coffee	0.071	2.13
Total	6.670	203.10

Commissary Supplies on a Canadian Survey.—Engineering News, Nov. 5, 1914, publishes the following data from a paper by H. T. Routly in the Annual Report of the Ass'n. of Ontario Land Surveyors.

The average number of men boarded was 18, including the cook.

In a brief comment upon this list Mr. Routly says:

"We have always believed in feeding our men what they liked, within reasonable limits, and it is interesting to note the difference in requisitions of different parties.

CONSUMPTION OF FOOD AND SUPPLIES BY A CANADIAN SURVEY PARTY
(The figures are the amount per man per day)

Supplies	Quantity per day	Supplies	Quantity per day
Apples	.035 lb.	Matches	.006 box
Apricots	.025 lb.	Onions	.005 lb.
Bacon Br.	.215 lb.	Peaches	.025 lb.
Bacon L. C.	.475 lb.	Peas	.049 lb.
Bacon pickled	.022 lb.	Pepper	.007 lb.
Baking powder	.010 lb.	Pickles	.002 gal.
Barley	.005 lb.	Potatoes	.525 lb.
Beans	.120 lb.	Potatoes, desic	.028 can
Butter	.154 lb.	Prunes	.050 lb.
Beef	.813 lb.	Raisins	.077 lb.
Candles	.378 candle	Rice	.037 lb.
Cheese	.062 lb.	Rolled oats	.055 lb.
Coal oil	.003 gal.	Salt	.021 lb.
Cocoanut	.002 lb.	Soap	.041 cake
Coffee	.017 lb.	Spice	....
Corn	.064 can	Sugar, brown	.178 lb.
Corn flakes	.098 lb.	Sugar, gran	.265 lb.
Cornstarch	.004 pkg.	Syrup	.007 gal.
Cream	.200 can	Tea	.036 lb.
Currants	.052 lb.	Tomatoes	.073 can
Flavoring	....	Turnips	.075 lb.
Flour	.825 lb.	Yeast cakes	.007 box
Jam	.015 lb.		
Lard	.092 lb.		
Macaroni	.115 lb.		

The above table is simply an analysis of actual quantities and costs on this particular contract. A change of cooks will often make a great difference in the comparative amounts of various items used.

"In most of our northern work we used desiccated potatoes, but on this contract some of the ordinary tubers were used. These were frozen solid coming in, and it may be of interest to note that the best method of preparing frozen potatoes is not to thaw them with cold water, as is usually done, but to brush them clean, give them a quick rinse with hot water, plunge them at once into a pot of boiling water, and cook them with jackets on."

A Tropical Ration List.—R. C. Hardman, gives the following in Engineering and Contracting, May 3, 1916. In going over some old papers recently the writer found a list of rations used some ten years ago in the Philippine Islands by the Bureau of Engineering, or Bureau of Public Works, as it is now called. The rations were for the use of reconnaissance parties, survey parties and construction camps. It will be noted that all the articles are such as can be well preserved under the extreme climatic conditions encountered in the tropics.

Provision	Quantity		Cost Unit	Cost Total
Pork sausage	6	cans	$0.225	$1.35
Beefsteak and onions	1	can	.325	.325
Corned beef hash	7	cans	.185	1.295
Compressed ham	2	cans	.26	.52
Beef stew	2	cans	.28	.56
Corned beef	2	cans	.275	.55
Mock turtle soup	2	cans	.27	.54
Bacon	4	lbs.	.20	.80
Flour	17	lbs.	.0405	.69
Corn meal	5	lbs.	.095	.475
Rolled oats	5	lbs.	.155	.775
Crackers, soda	4	lbs.	.14	.56
Bread, Boston brown	4	cans	.13	.52
Pork and beans	2	cans	.18	.36
Corn	4	cans	.165	.66
Succotash	4	cans	.18	.72
Potatoes	15	lbs.	.0235	.355
Onions	5	lbs.	.0295	.15
Peaches, evaporated	2	lbs.	.145	.29
Apples, evaporated	2	lbs.	.17	.34
Prunes	2	lbs.	.105	.21
Jam, blackberry	4	cans	.15	.60
Jam, strawberry	2	cans	.15	.30
Coffee	3½	lbs.	.27	.945
Tea, Early Breakfast	⅓	lb.	.40	.135
Sugar, granulated	10	lbs.	.079	.79
Cream, Highland con	8	cans	.11	.88
Lard	5	lbs.	.16	.80
Baking powder	1	lb.	1.07	1.07
Pickles	1	qt.	.425	.425
Vinegar	1	qt.	.065	.065
Mustard, French	⅓	bot.	.205	.07
Salt	⅓	bot.	.18	.06
Pepper	⅓	box	.60	.20
Tomato catsup	2	pts.	.375	.75
Total				$18.60

The above rations were for one American for 30 days, and were ample for the time. In most localities it was possible to supplement this fare with chickens, eggs, fish, shrimps, crabs, frogs, and various native vegetables and fruits.

For Filipino "surveymen" the ration was three condensed milk cans full of rice per day with an occasional can of salmon when fresh fish could not be obtained.

Cost of Reforesting, Wachusett Reservoir, Boston, Mass.—The following matter is taken from an abstract (Engineering and Contracting, March 23, 1910) of a paper by E. R. B. Allardice published in the Jour. Assoc. Eng. Soc., Jan. 1910.

An outline of the general policy adopted in the reforestation of the marginal lands of the Wachusett Reservoir, comprising as they did 1,090 acres of arable, pasture and light sprout land, 280 acres of thick sprouts and young, thin timber land and 1,475 acres of heavy timber or forest land, was as follows: 1st, to establish two forest nurseries, one on each side of the reservoir, for the raising from seed of coniferous trees, mostly native white pines, to form the ultimate or final forest, and of deciduous trees to act as fillers and aid in the final development of the conifers; 2d, to plant all of the first mentioned class of land with a mixture of white pines and hardwoods; 3d, to underplant the second class with white pines, making what are hereafter termed "Improvement Thinnings in Young Pine Stands," as the growth of the pines demanded;

4th, to make "Improvement Thinnings in Original Timber Stands," as opportunity permitted; 5th, to clear and maintain a fire guard 40 ft. wide around the outside limit of the reservation, to serve as a protection against fires having their origin on abutting land; 6th, to maintain some of the present and build necessary additional internal forest roads 15 ft. wide, making accessible all areas and acting as secondary fire lines, dividing the entire reservation into lots containing from 15 to 30 acres; and 7th, to clear and maintain a 50-ft. margin along the forested portion of the flow line of the reservoir, and to plant the inside half of it with white pine and arbor vitæ closely spaced, forming an effectual screen or hedge to keep the greater part of the foliage from adjoining forests from being blown into the reservoir.

Table VIII shows that it costs about $15.40 per 1,000 trees, or $19.20 per acre (1,390 trees per acre), to raise the trees from seed, prepare, plant and

TABLE VIII.—STATISTICS RELATING TO REFORESTING WACHUSETT RESERVOIR LANDS

Work accomplished to Dec. 31, 1908

Total area of nurseries	8.0 acres
Total area planted	1,330 acres
Total number of trees planted: coniferous	948,000
deciduous	902,000
Total length of reservoir margin planted	32.0 miles
Total length of fire guard cleared and maintained	20.8 miles
Total length of forest roads cleared and maintained	30.0 miles
Planted area thinned	488 acres
Original timber stands thinned	209.0 acres

TABLE OF COSTS

(Wage rate, $1.75 per 8-hr. day)

Nurseries:	
Clearing nursery on south shore	$200 per acre
Maintenance of nursery, first-year seedlings	$1.50 per 1, 000 trees
Maintenance of nursery, second and third year seedlings	$1.75 per 1,000 trees per year
Plantings:	
Clearing areas preparatory to planting	$ 4 per acre
Transplanting seedlings from nursery to field	5.25 per 1, 000 trees
Transplanting seedlings from nursery to field	$5.50 per acre (6 × 6 ft. planting)
Improvement thinnings:	
Among planted trees	$6 per acre
In original timber stands	$20 per acre
Fire protection:	
Clearing marginal fire guard 40 ft. wide	$150 per mile
Maintaining marginal fire guard	$27 per mile per year
Clearing and grading forest roads 15 ft. wide	$120 per mile
Maintaining forest roads	$8 per mile per year
Maintaining fire parol	$100 per year

Reforestation—Summary of costs on planted pine stands
(Wage rate, $1.75 per 8-hr. day)

Item	Per 1,000 trees planted	Per acre planted
Preparing nurseries	$0.40	$0.60
Seedlings (1 year)	1.50	2.25
Transplants (2 years)	3.50	4.50
Preparatory clearing	3.00	4.00
Field planting	5.25	5.50
Clearing 40-ft. fire guard	0.75	1.00
Clearing 15-ft. forest roads	1.00	1.35
Maintaining 40-ft. fire guard (per year)	0.14	0.19
Maintaining 15-ft. forest roads (per year)	0.06	0.09
Maintaining fire patrol	0.02	0.03
Improvement clearing	4.25	6.00

protect the lands planted, through the time of the final planting in the field; that it costs about 22 cts. and 31 cts. per year respectively to maintain efficient fire protection; that in sprout and scrub land it costs about $4.25 and $6 respectively for an improvement thinning, which will probably have to be made twice during the first ten years, after which time the trees should care for themselves.

Comparative Costs of Wood and Steel Trestles for Stocking Ore.—Stuart R. Elliott, in a paper before the Lake Superior Mining Institute, gives the following, an abstract of which was published in Engineering and Contracting, Sept. 1, 1915.

From the figures obtained from several mines it has been found that in five years the total cost of repairs and renewals on wooden stocking trestles amounts to the original cost of the trestle. Breakage in legs is exceedingly high, often amounting to as much as 33 per cent per year. If, for any reason, ore is not shipped and the legs are allowed to remain in the pile for several seasons it has been observed that they rot rapidly. Weather conditions have considerable to do with the percentage of broken legs. If ore is dumped on a frozen face of the stock pile, and this new ore freezes rapidly, it will often move in a mass down on the frozen face and break the legs. Large masses of frozen ore also shift in this way during loading with the steam shovel.

The cost for erecting and dismantling was accurately kept at two large mines for a period of years, and was found to amount to $1.20 per foot. Under unusual conditions this cost has run as high as $1.60 per foot. The portion of the trestle between the shaft and the point where the ore is stocked is usually called the permanent trestle, the other part being the stocking trestle. The permanent trestle is put up in a very substantial way and is very expensive, costing as much at $15 per foot. After a period of 10 years this permanent trestle is sure to be in bad repair. A few of the stringers not directly below the tracks will probably last for a short additional time, but for the sake of an estimate it can be assumed that the permanent trestle will have to be entirely rebuilt in 10 years. In making the following comparative statement of the cost of wood and steel trestles, the expenditure each year at 6 per cent compound interest has been used. This yearly expenditure has been capitalized and figured at compound interest for a period of 20 years. It is found that at 6½ years the costs for wooden and steel trestles of the same length are practically identical. As the length of time increases the capitalized amount for repairs, renewals, erecting and dismantling, figured at 6 per cent compound interest, increases very rapidly. At the end of 20 years the saving in favor of the steel stocking trestle is $117,000. It is impossible to estimate the saving due to better tracks and operating conditions, and consequently the minimizing of delays on the surface. With a wooden trestle a certain number of carpenters and extra laborers must be employed. Only a part of their time can be charged against the stocking trestle, but it is necessary to have them so that they can be used when repairs are needed. At the Negaunee mine we have only one carpenter, whose entire time is spent in the shop.

Table IX gives the total and unit costs of the concrete and steel permanent stocking trestle built at the Negaunee Mine. The columns, spaced 114 ft. centers, are 4-ft. in diam. for the upper 28.5 ft. and are belled out to a 6-ft. diam. in the lower 10-ft. There is only one column in each bend.

The plate shells of the columns are ¼-in. thick. They rest on and are bolted to pyramid-shaped reinforced concrete bases, which are 12 ft. wide,

Table IX.—Total and Unit Costs of Piers and Trestle

Piers	Total cost	Cost per yd.
Excavation, 1,800 cu. yds	$ 994.65	$ .553
Concreting, 1,352 cu. yds	5,142.70	3.80
Bolts, washers and forms	2,167.94	2.185
Reinforcing steel	1,423.89	1.053
Total	$9,729.18	$ 7.197
Average cost per pier	540.41	

Trestle (2, 594 lin. ft.)	Total cost	Cost per lin. ft.
Steel erected, 2,594 lin. ft	$35,100.00	$13.53
Columns (18), covering 2,094 lin. ft	9,729.18	4.65
Small piers for curved trestle (20), 500 lin. ft	641.93	1.28
Decking 500 lin. ft	1,870.07	3.74
Ties and fastenings, covering 2,094 lin. ft	1,627.59	0.78
Walk and railings, 500 lin. ft	358.78	0.72
Temporary tracks for unloading 2,594 lin. ft	355.89	0.14
Rails and laying 2,594 lin. ft	1,545.48	0.60
Total	$51,228.92	$19.71

26 ft. long and 6 ft. deep: Each base is reinforced with 52⅞-in. round rods, which radiate in all directions through the base and extend up into the shells for a distance of 20 ft. In the bottom of each pyramid the rods are tied to seven old rails, which extend across the long dimension of the base. At a point about 20 ft. above the base the rods are attached and properly distributed around two horizontal rings in the shells. Above these rings other rods are spliced so that the reinforced bars extend to within a few inches of the top of the columns. The height of the trestle from rail to sollar is 42 ft.

When the excavation for the base of a column was made and the form constructed filled the carpenters were busy constructing the form for the next base. In a short time after one base was completed the forms could be moved to the next excavation. In this way only a small amount of lumber was used. Before the bases were completed the bridge builders were on the ground and were ready to begin placing the steel shells in position. For handling the heavy shells a railroad track was laid along the entire length of the trestle.

The length of span between columns is 114 ft. Extending 19 ft. each way from the center of each column there are two short plate girders, each 38 ft. in length. Between these girders there are two other girders 76 ft. long.

At each column the girders rest on horizontal 8-in. I-beams supported by four braces which are firmly connected to the columns and which extend down at an angle of 45°. The plate girders are made up of angles and two 42 × ¼-in. plates. The distance from center to center of girders, or center to center of tracks, is 20 ft. The entire length of the part of the trestle from which ore can be stocked is 2,094 ft. In addition, there are 500 ft. of curved trestle extending from the shaft and connecting with the trestle. The legs of the curved part are built up of angles and channels, and the stringers are channels and I-beams. On top of the I-beams holes are provided for bolting 5-in. nailing strips. On top of these nailing strips are spiked a 5 × 7-in. sollar to serve as ties. The 40-lb. rails on the plate girders are spiked to 5-in. sawed ties 4 ft. in length. The gage of the track is 30 ins. On the outside of the girders the ties are bolted to 4 × 4-in. timbers placed snugly against the girders. These timbers prevent any shifting of the track at right angles to the length of the trestles. To prevent the ties from creeping they were attached at intervals, by hooked bolts, to the small angles inside of the girders. Since the tracks were completed, about two years ago, not a cent has been spent on them. They are now in as good alignment as when first put in.

Table X gives the comparative costs of wood and steel trestles, taking the life at 6½ and at 20 years.

TABLE X.—COMPARATIVE COSTS OF WOOD AND STEEL STOCKING TRESTLES

	6½ years	20 years
Permanent wood trestle		
Original cost, 500 ft. at $15	$ 7,500.00	$ 7,500.00
Repairs and renewals, 10 per cent per year	4,875.00	15,000.00
Six per cent compound interest	4,692.29	30,798.02
Total	$17,067.29	$ 53,298.02
Temporary wood trestles		
Original cost, 2,094 ft. at $6	$12,564.00	$ 12,564.00
Repairs and renewals, 20 per cent per year	16,333.20	50,256.00
Erecting and dismantling $1.20 per foot per year	16,333.20	50,256.00
Six per cent compound interest	14,063.33	122,822.09
Total	$59,293.73	$235,898.09
Total cost wooden trestles	$76,361.02	$289,196.11
2,594-ft. steel stocking trestle		
Original cost	$51,228.92	$ 51,228.92
Estimated maintenance cost	1,300.00	4,000.00
Six per cent compound interest	23,949.51	116,867.78
Total	$76,478.43	$172,096.70
Net saving of steel trestle	117.41	117,099.41

Cost of Cantilever Type of Reinforced Concrete Retaining Wall.—Engineering and Contracting, March 22, 1911, gives the following costs of a retaining wall some 16 ft. deep and 250 ft. long built under contract for the Saco-Pette Co. at Newton Upper Falls, Mass. The two types of retaining wall shown in Fig. 9 were considered by the engineers Lockwood, Greene & Co. who estimated a saving of some $700 by using the cantilever type with an estimated cost of $3,542.50. This type of wall was therefore built by contract.

The gravel and sand, which were of excellent quality, where hauled from a bank about one-half mile from the site of the work. Because of the large percentage of sand in the gravel, it was necessary to screen all of the latter, which resulted in a rather high cost for this material of $1.70 per cu. yd. The number of yards of concrete placed is based on the actual number of bags of cement used, the figure obtained being slightly greater than that figured for the wall itself, because of excess concrete placed in the footings over and above the actual cross sections. This yardage was allowed as follows: Actual yards of wall, 272.27; bags of cement used, 1,525; yards concrete, based on cement used, 277.27.

The actual costs of labor and material include a sand floated surface which was applied to the wall after the forms had been removed.

Materials:		
1,525 bags cement at $1.70 per bbl.	$	647.13
249.54 yds. of gravel at $1.70 per yd.		424.22
124.77 yds. sand at $0.50 per yd.		62.39
16.5 tons reinforcing steel at $33 per ton.		544.50
12,894 ft. B.M. lumber at $25 per M. ft.		322.35
600 lbs. wire at $4 per 100 lbs.		24.00
Labor:		
Superintendent, 14 days at $5.33	$	74.67
Foreman, 10 days at $4.00		40.00
Steel helper, 4½ days at $2.50		11.25
Steel man, 2 days at $3.00		6.00
Engineer, 11 days at $3.50		38.50
Carpenters, 200 days at $3.82		764.00
Laborers, 171½ days at $2.00		343.00
Masons, 7 days at $4.80		33.60
Total cost		$3,336.61
Cost per yard	3336.61 / 277.27 =	$12.03

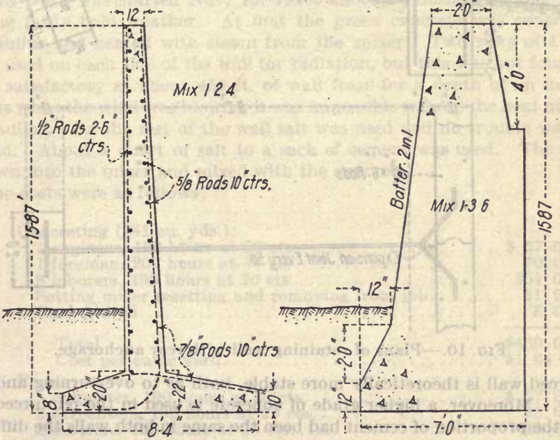

FIG. 9.—Comparative sections of plain and reinforced concrete retaining walls.

Comparative Cost of Plain and Reinforced Concrete Retaining Wall.—J. I. Oberlander, in Engineering and Contracting, May 19, 1915, gives the following data relative to the construction of retaining walls along the banks of the Sandusky River, Tiffin, Ohio.

The city asked for bids on the two types of wall shown in section in Fig. 9, the total length of wall being 2,600 ft. There were 23 bids submitted. The lowest complete bid on the plain concrete design made the cost of this type of wall $5.75 per cubic yard, the total bid being $46,718.75; while the lowest bid received for constructing the reinforced concrete wall was $6.12 per cubic yard, plus 2½ cts. per pound for the steel reinforcement, or a total of $31,476.00. The contract was awarded for reinforced walls. The total bid for constructing the plain concrete wall was thus 48 per cent more than for the reinforced wall.

Considering 17 of the bids received for both types of wall, the average price for plain concrete was $6.117 per cubic yard, while the average prices for the reinforced type were $7.456 per cubic yard for concrete and 2.77 cts. per pound for reinforced steel. The average bid for constructing the plain concrete wall was thus about 32 per cent more than for the reinforced wall, although the

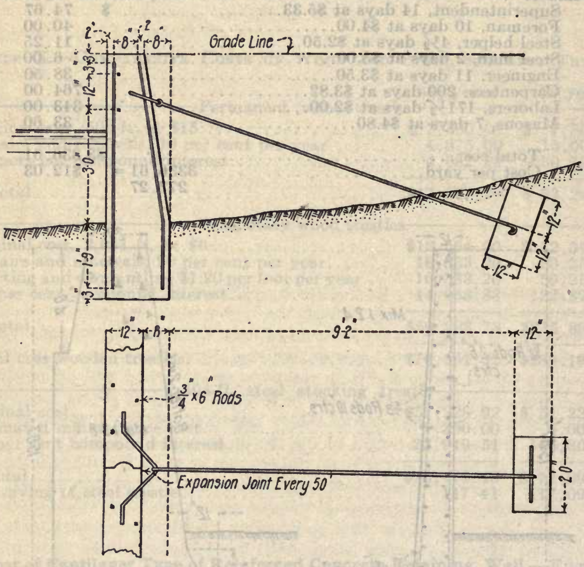

FIG. 10.—Plans of retaining wall with rear anchorage.

reinforced wall is theoretically more stable, both as to overturning and as to sliding. Moreover, a higher grade of concrete is used in the reinforced wall, and if the proportion of cement had been the same in both walls the difference in cost in favor of the reinforced concrete type would have been at least 7 per cent greater.

Cost of Reinforced Concrete Retaining Wall with Rear Anchorage.—R. A. Boothe gives the following costs in Engineering and Contracting, May 20, 1912, for constructing 900 ft. of retaining wall of the type illustrated in Fig. 10.

The wall was built around an island about 10 ft. from the bank. The space between the bank and wall was afterwards filled up with dirt taken out of the beach about 50 ft. from the face of the wall. Normally the water in the lake is about 18 ins. below the top of the wall, but to do this work the lake was drained down until it left a beach in front of the wall about 200 ft. wide.

When the walls were built two openings 10 ft. wide were left in each section so that the dirt could be hauled through. The backfill was a sandy clay and amounted to about 2,000 cu. yds. It was ploughed and hauled in No. 00 slip scrapers. The average haul was 150 ft. and cost 21 cts. per cubic yard including plowing, teams being paid 50 cts. per hour.

The concrete plant consisted of a ⅓ cu. yd. Chicago mixer mounted on skids. The material was hauled about 1 mile from the railroad and dumped in piles near the mixer; from there it was wheeled up runways to the mixer which was fitted with a batch hopper, and from the mixer it was wheeled to the job and placed. As two setups of the plant were made, one in the center of each section the longest haul was about 125 ft.

In placing the concrete the trench was dug for the foundations and the concrete and steel placed, then the forms were placed. These were built in sheets 12 ft. 6 ins. long and 5 ft. high, and were made of ⅞-in. tongue and grooved stuff with 2 × 4-in. uprights on 2-ft. centers. The forms were held together with wiring and two rows of 4 × 4-in. walling on each side. The concrete was poured in 50-ft. sections, and forms enough were built for two sections, so that while one section was being poured the carpenters could be working on the next. As the forms were wrecked on the second day after pouring it was necessary to put the laborers to digging foundation or filling it ahead on every third day until forms could be built.

This work was started Nov. 15, 1910, and was finished on Jan. 3, 1911, during fairly cold weather. At first the green concrete was covered with tarpaulins and heated with steam from the mixer. Two rows of 1-in. pipe were used on each side of the wall for radiation, but this was not found to be very satisfactory as about 450 ft. of wall froze for a depth of an inch. On nights when the wind was blowing it was impossible to keep the heat under the tarpaulins. On the rest of the wall salt was used and no trouble was experienced. About a quart of salt to a sack of cement was used. The salt was thrown into the mixer and mixed with the concrete.

The costs were as follows:

Concreting (281 cu. yds.):	
1 engineer, 190 hours at 30 cts	$ 57.00
1 foreman, 200 hours at 35 cts	70.00
8 laborers, 190 hours at 20 cts	304.00
Setting mixer resetting and removing from job	21.00
Coal and oil	8.00
Total	$460.00
Cost per cubic yard	$1.64 +
Forms:	
1 carpenter, 190 hours at 30 cts	$ 57.00
2 carpenters, 190 hours at 25 cts	95.00
2 laborers, 100 hours at 20 cts	40.00
Total	$192.00
Cost per square foot of forms	$ 0.024
Cost per cubic yard	$ 1.15

Digging the foundation ditch cost 6 cts. per foot.

Cost of Oxy-acetylene Welding.—Engineering and Contracting, May 24, 1911, publishes the following information taken from Bulletin No. 45 of the Engineering Experiment Station of the University of Illinois.

Fig. 11 shows the welding rate and cost in terms of length of weld, section of plate, and volume of filler for blowpipes of various sizes. The cost of operation rises rapidly with the thickness of plate, reaching possibly $4 per hour for labor and gas on ¾ in. plates. The oxy-acetylene blowpipe is best adapted to plates up to ¼ in. thickness. The welding rate is nearly constant at 17.5 sq. ins. of weld section per hour. The cost of welding beveled plates may be estimated also at 25 cts. per cu. in. of filler assuming oxygen at 3 cts. per cu. ft. acetylene at 1 ct. per cu. ft. and labor at 30 cts. per hour. It should also be noticed that, provided this rate holds for any type of grooved joint, if the plates were grooved from both sides, the cost per foot of weld would be only half that for plates grooved from one side only, because the required amount of filler would be reduced one-half.

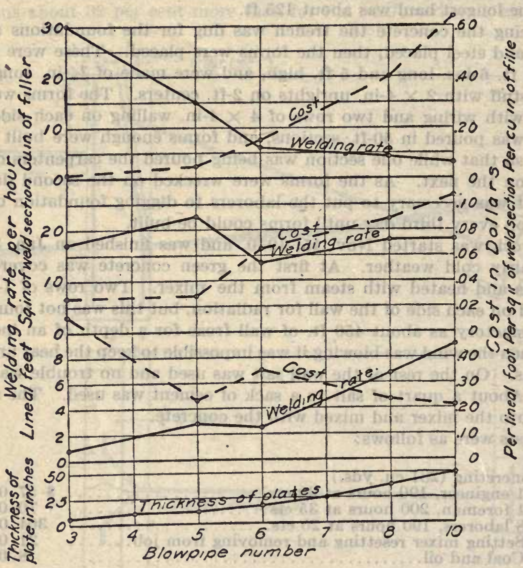

FIG. 11.—Diagram of cost of oxy-acetylene welding.

Diagram for Computing Paint Values.—E. O. Johnson gives the following in Engineering News-Record, April 7, 1921.

In Engineering News-Record of Jan. 6, Prof. A. H. Sabin discussed the question of how much a paint user can afford to pay for paint which will last, say four years and costs $6 per gallon to apply, when he has available at $3.50 per gallon another paint, which also costs $6 to apply, but which lasts five years. The chart reproduced herewith enables such cost calculations to be made more rapidly. It includes the three factors of paint cost, labor cost to apply the paint (both in dollars per gallon), and years of life. Three explanatory diagrams below the main diagram show the method of using it in three different calculations.

In the first example, the case calculated by Prof. Sabin is shown. One paint is worth $3.50 per gallon, costs $6 per gallon to apply, and will last five years; then how much is a gallon of paint worth that lasts only four years, the cost of application being the same? At the intersection of the horizontal for $3.50

paint cost with the vertical through $6 labor cost (upper scale), the diagonal (which represents cost of a gallon of paint applied) is followed down to where it meets the sloping line representing five years of life. From here, following back the horizontal to intersect the line for four years of life, the total-cost diagonal is followed down to intersect the labor-cost vertical, giving the horizontal line $1.60, which is the value per gallon of the second paint.

In the second small diagram the problem is worked out of determining how long a given paint must last in order to be as economical as another paint, for which cost and length of life are known. Following through the lines shown on the diagram, it will be found that a life of 3.47 years should be expected of the cheaper paint.

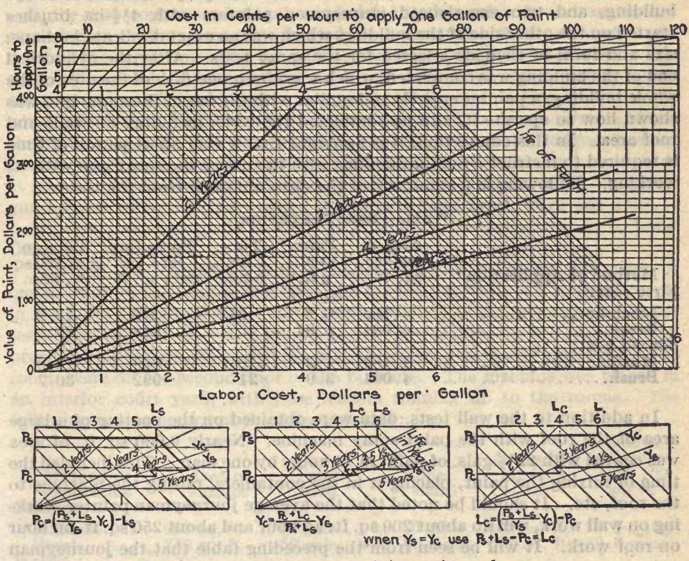

FIG. 12.—Chart for determining paint values.

Sometimes computations of justifiable labor cost to apply paint may have to be made. The third of the small diagrams shows such a calculation. A $3.50 paint is used whose spreading rate requires a man to spend $6 worth of labor time to apply it, and it is customary practice to repaint every five years. If instead a cheaper paint, bought for $1.60 per gallon is used, which, however, requires repainting every three years, it may not pay to spend as much labor in applying it. The calculation, carried out as indicated on the diagram, shows that not over $4.10 labor cost per gallon should be spent.

The formulas by which the calculations may be carried out are noted on the diagrams. Ordinarily, however, the diagrams themselves will be found much more rapid than numerical computation.

Comparative Tests of Applying Paint by Spraying Machines and by Hand.—The following data are taken from Engineering and Contracting, Feb. 25, 1920.

The information which appeared in Paint, Oil and Drug Review was obtained from a private source and is considered as fair and accurate as any individual statement can be. Everything possible was done to make the test thorough and indicative of the results that are to be expected from spray-making machines. The tests were made in government buildings.

The machines used at the United States Naval Hospital, Sept. 17, 1919, consisted of a 4 h.p. motor with a large air tank and a 5-gal. paint tank. The apparatus operated with a 220-volt direct current.

An experienced spray brush operator started the spray on one side of the building, and two experienced journeymen painters with 4½-in. brushes started on the other side of the building, which was an exact duplicate in shape, size and form of the side selected for the spray tests. After the cylindrical end of the building was completed, which was about one-fifth of the area of the whole building, a painter entirely unfamiliar with the use of the spray gun was shown how to operate it, and he completed the tests, including all walls and roof area. In this connection, it is apparent that a very short period of time is required to instruct a man unfamiliar with the use of the spray gun with its working. Following is a summary of the data obtained from the tests.

WALL TESTS (EXTERIOR)

Method of Application	Area of surface, sq. ft.	Paint used, gal.	Time, 1 man, hours	Spreading rate per gal., sq. ft.	Time to coat 100 sq. ft., min.
First coat:					
Machine	4,182	6.5	9½	570	13.5
Brush	4,094	5.97	20	648	29.0
Second coat:					
Machine	4,182	4.3	10½	863	15.0
Brush	4,094	3.9	21	992	30.7

In addition to the wall tests, data were obtained on the coating of a large area of the roof with the paint spray machine. Nearly 9,000 sq. ft. of area was coated with 22½ gals. of paint in 14 hours by one man. This included the time of mixing the paint, placing it in the containers, raising the machine to the roof, etc. It should be noted that the average journeyman painter, working on wall work, will do about 200 sq. ft. an hour and about 250 sq. ft. an hour on roof work. It will be seen from the preceding table that the journeyman painters apparently speeded up their hand brush work, as they were very much interested in the test, and they accordingly made very much higher averages than the figures just given. The results for the roof test follow:

Method of Application	Area of surface, sq. ft.	Paint used, gals.	Time, 1 man, hours	Spreading rate per gal., sq. ft.	Time required to coat 100 sq. ft., min.
Machine	578	1.49	½	386	5.2
Brush	578	1.35	1½	428	15.5

The paint used on the work was a white lead paint, the materials for which were furnished by the Government and mixed by the men. It was tinted with ochre. The first coat weighed 17.6 lbs. per gallon and the second coat, 20 lbs. Both of these paints were easily handled by the spray gun. From observations, it is apparent that the spray gun will successfully handle paint of practically any weight per gallon.

On the first coat all cornices and trim were cut in with the spray gun on the side of the building where the spray gun was used. On the second coat, however, the cornices and trim were cut in with the brush to be sure of a neat job, and the time for this brush work was counted in as spray gun time.

Observation of the character of finish given by the spray versus the hand brush work on the completed first coat showed a slightly more uniform film for hand brush work. On the second coat there was no apparent difference in the appearance. Both coats dried in about the same period of time, whether applied by spray or brush.

In the roof work the paint tank was hoisted to the roof and two hose leaders carried from the spray machine located on the ground. Two operators could work at the same time with the paint tank, which was fitted with two spray guns. The paint used for the roof work was a red oxide of iron paint. Only one coat was applied, which gave very good hiding power. Even in this work, which was done on the roof of the building, subjected to strong currents of air, there was apparently not very much loss of paint, the pebbled roofing showing probably less paint loss by dropping than where hand brush work was used. It was observed, however, that the overalls of the painters using the spray gun became somewhat more soiled than where hand brush work was done.

Another test was made at General Pershing's Headquarters, U. S. Land Office, on Oct. 3, 1919.

This test was conducted with a modern interior lithopone flat paint of cream color for the ceilings and light buff for the side walls of a series of rooms in the Land Office building. Both paints weighed 14 lbs. per gallon. In the tests upon which data was obtained, one room was done by two painters with brushes, and two rooms were done with the spray gun by one operator. The rooms were on the second floor of the building. The machine was placed in an interior court yard, with hose leaders running up to the rooms. The following is a summary of the data obtained:

Method of application	Area of surface	Paint used	Time (1 man)	Spreading rate per gal.	Time required to coat 100 sq. ft.
Ceiling:					
Machine....	660 sq. ft.	1.64 gals.	1 hr. 50 mins.	402 sq. ft.	16.5 mins.
Brush......	250 sq. ft.	.50 gals.	2 hr. 30 mins.	500 sq. ft.	60.0 mins.
Walls:					
Machine....	1,490 sq. ft.	4.75 gals.	3 hr. 30 mins.	408 sq. ft.	10.8 mins.
Brush.......	750 sq. ft.	1.25 gals.	2 hr. 50 mins.	600 sq. ft.	22.6 mins.

It will be noted from the above chart that especially good results were obtained on the ceilings with the spray brush. This method of painting seemed to be very much preferred over the ordinary method of application by hand brush. The ceilings were all arched, four arches meeting in the center of the room. The side walls had four projecting columns, one at each corner, and between the tops of these columns and the arches of the ceiling there was over a foot of school cornice. Each room also had a chimney projection and large recessed combination windows. The surface, therefore, was not of the ordinary type.

The hand brush work was marred by streaks and in places the covering was poor. The spray gun work was much better, as a heavier coat of paint could be applied.

During both the work on the naval hospital and on General Pershing's headquarters, it was found that the journeymen painters did not seem at all hostile to the use of the spray gun. In fact, after they had become accustomed to it some of them became very enthusiastic about its use, stating that they were less fatigued at night than when they used hand brushes, especially on certain types of work. It would appear, therefore, that journeymen painters, after they have had a little experience with the gun would become enthusiastic regarding its use on certain forms of their work.

Cost of Painting Highway Bridges.—Charles D. Snead, in Engineering and Contracting, March 26, 1919, gives the following:

Estimating Amount of Paint Required.—Knowing the weight, or by estimating the weight of a structure, we may approximate the amount of paint required. The old rule, namely, ½ gal. of mixed paint for the first coat and ⅜ gal. for the second and third coats per ton of steel give fair approximations. The weight of light steel bridges may be calculated approximately from the following formula by Kunz:

$W = (0.12\,L + 12)\,(1.6 - 0.03B)\,BL.$

W = weight of steel in pounds.

L = length of span in feet.

B = width of roadway in feet.

Cost of Painting.—The cost of applying the paint will vary due to different prices paid the labor and the same is true with regard to cleaning. This cost may be approximated by assuming a painter to cover 600 sq. ft. of surface per day. Applied to gallons of paint it means that a painter will apply about 1½ gals. of paint in an 8-hour day or if applied to tons of steel, one painter should cover about three tons per day. This approximation will be found to agree fairly closely to the actual cost if much scaffolding is to be done. The cost of cleaning will vary still more. It may be estimated if the steel is in bad condition that it will require one man one day to clean a ½ ton of steel, while if there are places which may be skipped, one may clean a ton within the same period of time. With the data expressed in hours, it can at once be referred to any scale of wages.

Cost of Painting the St. Louis Municipal Bridge.—R. D. Spradling gives the following in Engineering and Contracting, July 15, 1914.

The Municipal Bridge, which spans the Mississippi River at St. Louis, Mo., consists of three main double-deck river spans and a long approach at each end of the structure. Each of the three main spans has a length, center to center of end pins, of 668 ft.

The trusses are spaced 35 ft. c. to c. The lower or railway deck carries two tracks 13 ft c. to c. supported by four stringers connected to the main floor beams which are plate girders 7 ft. 9 ins. deep. The upper or highway deck consists of a 30 ft. roadway between the trusses with side walks 6 ft. wide cantilevered on the outside of each truss. There is a clearance of 22 ft. between the base of rail of the bottom of the main floorbeam of the upper deck and the base of rail of the lower deck.

Paint and Painting.—The specifications required that the shop coat of red lead should be retouched where necessary, and that in doing this all rust and dirt should be removed by scraping thoroughly and brushing with wire brushes. After the retouching was finished a coat of graphite paint was applied, and after about three days another coat was applied. At first, no drier (except that used in mixing the paint) was allowed. Later, however, when on two or three occasions sudden rains had washed off the fresh paint, the contractor was permitted to use a small amount of Japan drier. The specifications required that the red lead should be 94 per cent pure and that 30 lbs. of red lead should be used to each gallon of linseed oil. This made a very thick paint, and it proved to be excellent for retouching rusty places. The first coat was of brown graphite and the second was black, which make it easy to determine whether the structure had been thoroughly covered with two coats. The paint was received at the work ready mixed, and required only a small amount of stirring before its application.

Very little difficulty was experienced in reaching all parts of the structure. In all cases where scaffolds were swung two men worked on a scaffold, and these men were able to move it without assistance. One man was detailed to keep the men supplied with paint, although at times two men were required for this work. The most difficult part of the work consisted of painting about 12,000 sq. ft. of cast-iron grating on the sidewalk. As the apertures in this grating were about 1-in. square, the use of brushes proved unsatisfactory and small swabs were substituted for the brushes. In general the weather conditions were excellent.

Cost of Labor and Materials.—Table XI gives the length of time required, and the labor and material costs for painting each of the three river spans.

By referring to Table XI it will be noted that the cost of labor and of paint materials is not far from the same—$5,989.90 for labor and $5,812.60 for paint materials, a total of $11,802.50 for the 13,775 tons of steel in the three spans. This cost does not include any overhead expense, nor does it include the cost of paint brushes and miscellaneous items. The contractor used 450 paint brushes, at $1.60 each, the total expense for this item being $720. The estimated cost of miscellaneous items was $100.

The great variation in the quantity of materials used and in the cost of painting span No. 1 and spans Nos. 2 and 3 was due to the fact that span No. 1 was erected first and had been subjected to wear incident to the erection of the other two spans. On spans Nos. 2 and 3 the painters were all Greeks, and they proved to be very efficient workmen. They were cautioned to brush the paint out thoroughly, both to obtain a good surface and to insure economy of paint.

The total amount of materials used and the average amount per ton are shown in following tabulation.

Item	Material	Total quantity	Quantity per ton
Retouching	red lead	15,300.0 lbs.	1.11 lbs.
	linseed oil	629.0 gals.	0.0457 gal.
First coat	graphite paint	1,833.5 gals.	0.133 gal.
	linseed oil	50.0 gals.	0.00363 gal.
Second coat	graphite paint	1,497.83 gals.	0.1088 gal.

Cost of Wrecking Buildings of the Panama-Pacific Exposition. *Wrecking by Dynamite.*—Engineering Record, Aug. 12, 1916, gives the following:

In removing the structural frames of the several buildings it was first intended to pull them down section by section and bent by bent, by means of donkey engines and the necessary winches and lines. This plan was abandoned after it had been employed to some extent, and the frames are now being razed by dynamite, as it was found possible to do this with but little more loss of material. In many cases, such as in taking down the domes of the main palaces, the cost of dynamiting is less than 1 per cent of what it would have been if the structures were dismembered and dismantled by hand.

TABLE XI.—TIME REQUIRED AND COSTS OF LABOR AND MATERIALS FOR PAINTING ST. LOUIS MUNICIPAL BRIDGE IN 1914

	Labor					Materials			
Item	Elapsed time, days	Elapsed time, hours	Hours per ton	Total cost at 35 cts. per hour	Cost, cts. per ton	Quantity used	Unit cost	Total cost	Cost, cts. per ton
Span No. 1									
Retouching........	25	1,350	0.294	$ 472.50	10.3	7,000 lbs. red lead.........	$0.055	$ 385.00	13.0
						282 gals. linseed oil........	0.75	211.50	
First coat..........	23	3,551	0.770	1,242.85	26.9	747.5 gals. graphite paint..	1.30	971.75	21.2
Second coat........	23	2,281	0.498	798.35	17.5	557.5 gals. graphite paint..	1.30	724.53	15.8
Span No. 2									
Retouching........	18	893	0.195	$ 312.55	6.7	4,520 lbs. red lead.........	$0.055	$ 248.60	8.5
						188 gals. linseed oil........	0.75	141.00	
First coat..........	24	2,103	0.457	736.05	15.9	557 gals. graphite paint....	1.30	724.74	16.2
						25 gals. linseed oil.........	0.75	18.75	
Second coat........	21	2,296	0.500	803.60	17.5	527 gals. graphite paint....	1.30	685.10	15.0
Span No. 3									
Retouching........	28	761	0.166	$ 266.35	5.8	3,780 lbs. red lead.........	$0.055	$ 207.90	7.1
						159 gals. linseed oil........	0.75	119.25	
First coat..........	18	1,855	0.405	649.25	14.0	529 gals. graphite paint....	1.30	687.70	15.4

Second coat........	16	2,024	0.442	708.40	14.6	514.33 gals. graphite paint.	1.30	668.63	14.5
Totals........	..	17,114	.....	$5,989.90	....		......	$5,812.60	....

The usual procedure of bringing down the domes, which stand 162 ft. high and cover an area of 102 ft. square, is to cut the dome and its supporting columns entirely free from other portions of the structure and dynamite the two corners on the side toward which the dome should fall. Previous to the falling, all of the walls, studding and braces are stripped from the skeleton, leaving only the heavy timber columns which carry the weight of the dome proper. The dome itself consists of segmental timbers supported on a circular girder, which in turn rests on four trusses each carried by two columns. At each corner of the dome there are thus two columns, each consisting of four 12 × 12-in. timbers. The method of dynamiting is to bore each timber and insert a stick of dynamite about 6 ft. from the base, connecting all eight sticks by wire for simultaneous firing by battery. Bringing down the domes this way costs, for labor and powder, about $6.50 for each dome. From the dynamited domes about 60 per cent of the timber in the trusses is salvaged and about 70 per cent of the timber in the columns.

The average cost of salvaged lumber, in the yard was $5.50 per thousand; the value of this lumber varied from $5 to $20 per thousand.

The cost of recovering steel f. o. b. cars exposition grounds was $10 per ton; this steel could be sold for about $16.25 per ton.

The proportion of iron and steel to wood salvaged was as follows:

In domes—1 lb. of metal to 1 ft. B. M.

In other than domes—¾ lb. of metal to 1 ft. B. M.

Wrecking with Oxyacetylene Torches.—The following matter is from Engineering Record, Dec. 16 and Dec. 23, 1916.

In wrecking the Palace of Horticulture, the General Welding & Cutting Works, which purchased the structure for $5,000, stripped off the glass and woodwork, and when nothing remained but the steel skeleton used oxyacetylene torches to cut it down.

The dome proper was 150 ft. in diameter and 100 ft. high above the supporting arches, or 175 ft. from floor level to top of dome. When the structure was stripped down to the steel skeleton, four men equipped with life-belts and oxyacetylene torches were put to work, starting at the top of the dome. In ten days they had entirely dismembered the dome proper. The removal of the entire steel frame, which was accomplished by a crew of only eight men, was completed in about three weeks. The steel totaled about 600 tons in weight, of which 350 tons was included in the skeleton of the dome proper.

The plan first proposed for the wrecking involved the cutting off of vertical members so that the circumferential bands would fall in a single piece. The Department of Safety of the California Accident Commission, however, suggested that it would be better to cut out sections of the circumferential bands between uprights, taking one section at a time. They insisted further that the workmen should be provided with the safety belts. It was pointed out that the dismantling of the structure in this way would not only be a safer procedure but would probably involve the loss of less material due to breakage.

This proved to be the case, as the short sections which were allowed to fall were comparatively light, and it is estimated that not more than 2 per cent of the steel was damaged in falling. This was in large measure owing to the fact that the area into which the pieces fell from the dome was a soft earthfill, and the fallen pieces were removed promptly so that sections falling later would not strike them. Of course, the members of the supporting frame which could be handled by tackle after being cut free were taken down that way. As a result of the precautions to safeguard workmen not a single accident was reported on the work, although it was considered an unusually high risk.

Wrecking the Tower of Jewels is said to have cost $25,000 including insurance and overhead. This structure contained 1800 tons of structural steel and about 2,000,000 ft. B. M. of lumber, but its 435 ft. of height considerably complicated the problem of economical dismantling in a way that would not damage the salvable material. The safety of workmen was also considered an important item. During erection of the structure there were three fatal and a number of minor accidents, and it was believed that the work of dismantling would be more dangerous.

Wrecking operations were started April 2, 1916, and the last standing column was taken down Nov. 23. During this time, in which the crew on the job ranged from 12 to 20 men, neither serious nor fatal accidents were reported.

The wreckers began at the top, lowering most of the material from derrick booms. The steel frame was unbolted or cut with acetylene torch where necessary. The columns which supported the arch 125 ft. high in the base of the structure were stripped and their upper parts removed so that the height of the columns which it was finally necessary to "fall" was only 90 ft.

The work was done in such a way that less than 2 per cent of the structural steel shapes were damaged in handling, and thus the major portion of the steel commanded a high price. The resale of the structural-steel members netted $65,000, in addition to which the major portion of the lumber in the structure was disposed of at from $10 to $12 per 1,000 ft. B. M. Most of the steel was sold to a local rolling mill which manufactures structural shapes.

Comparative Cost of Wood and Coal for Construction Plant Fuel.—J. R. Sherman gives the following comparative data in Engineering and Contracting, April 8, 1914.

Kachess Dam, which was built in 1911–12 by the United States Reclamation Service, is located at the lower end of Lake Kachess, near Easton, Wash. During the construction of this dam both coal and wood was used extensively as fuel on practically all of the dirt handling machinery. The work being located in a heavily timbered forest reserve, wood appeared to be without question the cheapest fuel to use, since no charge was made by the Forest Service for the timber so used. Twelve miles from Easton, however the Roslyn coal mines are located, from which a large part of the bituminous coal burned in the northwest is mined.

The wood used was cut by contractors on individual contracts for $1 for 16 in., $1.25 for 36 in. and $1.40 for 42 in. wood per rick, a rick being 4 ft. high by 8 ft. long; the only requirements being that the wood should be cut as near to the work as possible and piled so as to admit of easy access for the wood wagons.

The wood was distributed to the various machines by Government forces, the average amount hauled with a team, wagon, driver and one extra man being 2½ ricks of 16 in. wood, 2 ricks of 36 in. wood and 1½ ricks of 42 in. wood. The length of haul varied from a few hundred feet to approximately one-half mile, the roads for the greater part of the season being in good condition.

Mine run coal was purchased from the Roslyn Fuel Co., Roslyn, Wash., the contract price being $2.75 per ton f. o. b. Roslyn. At Easton the coal was sacked by hand and hauled by team and wagon from Easton to the works, a distance of three miles. The average load for a four-horse team was three tons.

The itemized cost of the coal delivered at the machines is given below:

Item	Per ton
Purchase price	$2.75
Ry. freight, Roslyn to Easton	0.37
Freighting from Easton to camp	0.90
Sacking and storehouse expense	0.38
Distributing at camp	0.52
Total	$4.92

The unit cost of distributing at camp as shown above was obtained by dividing the total cost of distribution by the total tons used. There was a large amount of coal used that did not have to be distributed, the coal being unloaded near the tracks so that the dinkey engines used to haul the dirt trains could coal up from the storage bins.

A comparison of the costs of fuel used on some of the machines during the season of 1912 is given in Table XII.

TABLE XII

Machine	Fuel used	Total cost	Cu. yds. excavated or hauled	Cost per cu. yd.
Steam shovel	Wood, 16-in., 36-in., 42-in.	$1,275.45	58,799	$0.022
Steam shovel	Coal	1,023.36	82,918	0.012
Lidgerwood drag-line excavator	Wood, 36-in.	902.40	38,709	0.023
Lidgerwood drag-line excavator	Coal	324.72	19,596	0.016
Dinkey engine shovel run	Wood, 16-in.	494.77	57,719	0.0086
Dinkey engine shovel run	Coal	423.12	72,221	0.0059
Dinkey engine excavator run	Wood, 16-in.	182.20	11,610	0.0157
Dinkey engine excavator run	Coal	393.60	44,544	0.0088
Steam roller	Wood, 16-in., 36-in.	275.14	31,750	0.0087
Steam roller	Coal	300.12	77,673	0.0039

It should be stated that while the machines were using wood it was necessary to keep an extra man employed for splitting. On the dinkeys and steam roller this wood splitter was not used all the time, as one man was able to split wood enough in 8 hours to run the machines 16 hours. On the steam shovel and drag line excavator a wood splitter was employed for each shift, the wages being $2.20 for 8 hours' work.

The steam shovel used was a 45-ton Bucyrus with a 1½-cu. yd. dipper and was used to excavate the finer material for the embankment, working in a pit approximately 1,300 ft. long and with an average depth of cut of 20 ft.

The drag line excavator was manufactured by the Lidgerwood-Crawford Co., and was used to excavate gravel for the embankment. It was a 65-ton machine with a 70 ft. boom and a 1½ cu. yd. Page bucket.

The dinkey engines were made by the Vulcan Iron Works and were operated on a 24-in. gage track and weighed 9 tons each. The average length of haul for the dinkeys operating on the steam shovel pit was 1,000 ft. and the average train was 15 1½ cu. yd. cars. The length of the haul for the dinkeys on the gravel run was about 3,000 ft. and the average train consisted of 12 1½ cu. yd. cars.

Approximately 12,000 cu. yds. of the steam shovel excavation was hauled by teams, which accounts for the difference in yardage excavated by the steam shovel and that hauled by the dinkeys on the steam shovel run.

The itemized cost of the coal delivered at the machines is given below:

Item	Per ton
Purchase price	$2.75
Ry. freight, Roslyn to Easton	0.70
Freighting from Easton to camp	0.09
Sacking and storehouse expense	0.15
Distributing at camp	0.33
Total	$4.02

The unit cost of distributing at camp as shown above was obtained by dividing the total cost of distribution by the total tons used. There was a large amount of coal used that did not have to be distributed, the coal being unloaded near the tracks so that the dinkey engines used to haul the dirt trains could coal up from the storage bins.

A comparison of the costs of fuel used on some of the machines during the season of 1912 is given in Table XII.

TABLE XII

Machine	Fuel used	Total cost	Cu. yds. exca- vated or hauled	Cost per cu. yd.
Steam shovel	Wood, 16-in., 36-in., 42-in.	$1,275.15	58,700	$0.022
Steam shovel	Coal	1,023.36	82,848	0.012
Lidgerwood drag-line excavator, 65-ton	Wood, 36-in.	902.40	38,700	0.023
Lidgerwood drag-line excavator	Coal	324.72	19,386	0.016
Dinkey engine shovel run	Wood, 16-in.	404.77	67,719	0.0060
Dinkey engine shovel run	Coal	123.12	72,221	0.0059
Dinkey engine excavator run	Wood, 16-in.	182.20	11,610	0.0157
Dinkey engine excavator run	Coal	393.00	44,344	0.0088
Steam roller	Wood, 16-in., 36-in.	375.14	31,130	0.0097
Steam roller	Coal	300.12	77,673	0.0039

It should be stated that while the machines were using wood it was necessary to keep an extra man employed for splitting. On the dinkeys and steam roller the wood splitter was not used all the time, as one man was able to split wood enough in 8 hours to run the machines 16 hours.
