THE BOOKKEEPING OF HUMANITY*

J. N. HURTY, Phar.D., M.D.
Secretary Indiana State Board of Health
INDIANAPOLIS

The accurate collection, tabulation and analysis of records of births, still-births, deaths, marriages, divorces, and sickness may be said to constitute the bookkeeping of humanity. The bookkeeping of dollars is very important, but of far greater importance is the bookkeeping of those events in the lives of human beings which are fundamental to an understanding of the movements of mankind, and which are also fundamental to the practical application of hygiene, to secure higher efficiency, longer duration of life and fuller measure of happiness.

Without vital statistics, a nation cannot know its vital latitude and longitude, its national time of day on the great ocean of time. Through vital statistics a nation is able to know its temperature and pulse, and follow and understand other vital functions. Or, again, its vital potentialities are reflected and comprehensively expressed in such statistics.

To live a successful life, a man must notice the symptoms which forecast his demise, that he may take action to neutralize them or to prepare for his end; and so should a nation carefully collect and keep such checks and balances that tell of increase or decrease in numbers, and causes affecting the same, and which tell the status of social conditions, so that the question of living or dying may be rationally considered. We have this illustrated in the case of France, where lately vital statistics disclosed the fact that the death-rate exceeded the birth-rate, thus forecasting, if the conditions continued, the demise of a great nation.

Human life in its beginning, its duration and ending, is the predominant consideration in all personal, social, state and national problems. The standing of a nation is finally to be measured by the standard of human lives.

No thoughtful person denies these facts. Yet, what a surprise it is, yes, a shock, to remember that we ignore in great degree these important matters. We do not fail to keep records of all legal procedures, of all commercial transactions, no matter how insignificant; we will deny ourselves needed rest and sleep to record a little or big real estate deal; we will keep careful minutes of a town meeting or of a social club; yet in many states a human being, made in the image of God and endowed with an immortal soul, can be born and can die without any public and frequently no private record of the fact. However, it is not so with animals and plants.

For them, elaborate systems record their birth, entire career and death. Every pedigreed calf, colt, dog, rooster, ram, and even cat, has its birth and death recorded; yet children, our hostages to fortune are born, and fathers and mothers die, without record. The National Government at the cost of millions annually maintains a Bureau of Animal Industry which looks after hog cholera, Texas fever and sheep rot, keeping accurate statistics; it also maintains at a cost of millions annually a Department of Agriculture, which collects crop statistics, beef, pork, poultry and mule statistics, but in not a single place in the whole country do we so accurately know the number of cases of diphtheria and the deaths from this cause among our babies. These conditions make one ask, "Is civilization a failure or has the Caucasian played out?"

IMPORTANCE OF VITAL STATISTICS TO THE INDIVIDUAL

Besides the general importance of vital statistics to a nation as a nation, they also have an importance of the greatest moment to the individual. For instance, by vital statistics must be determined the right to attend school, to enter certain occupations, to vote, to marry, to hold or to dispose of property, to employment by the state or country in military or civil service; responsibility for crime or misdemeanor; exemption from military or jury duty; qualifications or disqualifications for certain public offices; and privileges and immunities of a public nature; also private contracts in great variety, as in insurance and partnership. Indeed, there is hardly a relation from the cradle to the grave in which the evidence furnished by accurate vital statistics may not prove of the greatest individual and general, social or governmental value. The two great important events in the lives of men are birth and death; the alpha and omega, the beginning and the end. For a state not to make these events of accurate record for each individual is to neglect to keep abreast of practical civilization; yes, to be really civilized.

SANITARY VALUE OF VITAL STATISTICS

The public and individual value of vital statistics has been briefly set forth, but after all, their sanitary value is of greater importance. The value of the practical application to every-day life of the ounce of prevention, will hardly be disputed; and surely the prevention of disease constitutes the very crown of scientific medicine. The connection between the accurate registration of the existence of infectious diseases, of all deaths and the causes of death, and the practical prevention of disease, seems to be apparent. Whatever throws light on the causes of sickness and death, or whatever hastens or retards marriages or increases or decreases the number of births, must be helpful, yes, vitally necessary; but to be so, must have numerical treatment.

* Chairman's address before the Section on Preventive Medicine and Public Health of the American Medical Association, at the St. Louis Session, June 7-10, 1910.

Plainly, the capable health officer must have vital statistics at hand to be efficient in instituting such measures as are reasonable and necessary to prevent disease. The general must know the position, numbers, equipment and character of his enemy in order to carry on a successful battle. So for a successful fight the hygienist must have a like knowledge of his enemy.

EDUCATIONAL VALUE OF VITAL STATISTICS

Then there is the educational value of vital statistics. Need this point be dwelt on? Is it required to show how the relative destructiveness of the various diseases, the death-rates and sickness-rates from them, would educate the people to the necessity of action? The fact that the number of deaths from tuberculosis leads all the rest, the fact that pneumonia is the next greatest cause of death, and other life facts, are surely of the highest educational value. To convince and lead to action the keepers of the public purse so that the state can do her part in disease-prevention, vital statistics are absolutely essential. Surely, sanitary administration will be defective where vital statistics are wanting, and it will be efficient where they are accurate and complete. Low ideals of cleanliness and of health, accompanied by low ideals of morals, will exist to a greater degree where vital statistics are ignored than where they are accurately collected. Immediate records of births and deaths should be made, because experience teaches that an accurate record in all cases cannot or will not be secured unless reports are made forthwith and at once. The fact which should be given on birth and death certificates are now pretty well determined, and to the practitioner of medicine alone belongs the highly important duty, and also the privilege in cases of death, to render a correct statement of cause of death. The science of medicine, in the person of the medical attendant, is the only possible source of this knowledge which is fraught with such great importance to the family of the dead, to society at large and to medical science.

REPORTING INFECTIOUS DISEASES

Every parent naturally wishes to protect his household against disease, just as he would protect against the rending of wolves or the sting of serpents. To have this protection, the aid of the physician is necessary, and gladly should the aid be given. When the infection of scarlet fever or other transmissible disease appears in a household, it is indeed wicked for any person possessing the information not to lend his most efficient help to prevent its extension. A physician negligent in reporting an infectious disease which comes under his care, or negligent in warning and instructing the family in regard to the preventing of transmission to others, is an enemy to society, an enemy to himself and an enemy to the profession of medicine. More, he is a dangerous member of society and should be hunted down and brought to book as would a poisoner of wells, the assassin, or the incendiary. In reporting an infectious disease, that proper measures for control may be instituted, the physician not only renders a service to society, for which society might well pay, but he also renders help to his neighbors, he helps himself, he performs a Christian duty, he performs a service to scientific medicine and fulfills his Hippocratic oath.

If the patron asks a physician not to make public the fact that an infectious disease exists in his house that he may not be troubled with placard and quarantine, let the physician kindly and firmly, with proper exposition of the law and with gentle reminder of the Golden Rule,

give his absolute refusal. Let not the representative of the noble and learned profession of medicine for one instant enter into even the shadow of an act which is contrary to the statutory law and which opposes that divine rule of action, "Do unto others as you would have them do unto you."

As to compensation for service in reporting infectious diseases: The public can well afford to give compensation but in case it does not, still the duty of reporting and the honor of fulfilling the duty remain with the physician. We often hear quoted the clause of the Constitution which says in effect that all services rendered to the state shall be paid for; but let us look into this proposition. If required to return many data the physician should certainly be paid therefor, but for the return of the simple fact of the existence and location of an infectious disease, he is not altogether entitled to pay nor should he ask it. The right of the government to require that the physician be licensed need not be argued; the license system is desired by the profession. But what is a license? As regards infectious diseases the license is clearly granted to deal with this class of cases on the tacit understanding, first, that he has the diagnostic ability to recognize these cases when he sees them; second, that he will promptly give the state the benefit of his special knowledge.

The special duty of reporting infectious diseases, is, therefore, imposed when a license to practice medicine is asked for and granted. It has been argued in courts that the payment of fees for reporting the presence of infection would be as contrary to a proper public policy as to give fees for reporting a fire or for reporting a theft clearly seen in operation.

VALUE OF VITAL STATISTICS TO MEDICAL SCIENCE

Medical science, like all other sciences, must, for its development, have coordination of the facts, and numerical expression must be given. In the numerical relations of recoveries to deaths, in the numerical relations of the destructiveness of the various diseases, in the numerical relation of diseases and deaths compared with various age periods, in the numerical relations of sex, nationality, social condition and occupations and employments, scientific medicine finds much valuable material for her advancement. All of these relations and also other facts are supplied by vital statistics. Every true physician is in love with his profession; he would have it make all advancement possible and will always lend his aid and services to such end.

It follows then, that for the science he has adopted for his life work, if not in the service of his patients and if not in the service of society, he will gladly and eagerly contribute his part to vital statistics.

ACTUAL INSTANCES

Two actual instances showing the responsibility of physician to family in the matter of reporting births will probably serve a good purpose. A young man and wife came from Switzerland to Indiana. They were hardy, honest, and industrious, the very kind of people needed to make a nation. They settled in Switzerland County, probably being attracted by the name. In time a child, a girl, was born to them. The father was thrifty and intelligent and within three years became a foreman in a saw-mill. When his child was about two years old the father was accidentally killed by a log rolling over him. Time had not been sufficient for him to accumulate property. So the wife struggled with wash-tub and needle to support herself and child. One day the news

came that a brother of the father, the child's uncle in Switzerland, had left \$12,000 to the issue of his brother. Great was the rejoicing, which on account of the neglect of a physician to record the birth, was to become bitter sorrow. Before the Swiss government would turn over the property it must have proof that the little child was the issue of the dead man. As said, the physician had made no record and now he was dead. Neighbors know of the birth of the child but could not testify except as to their belief of the fatherhood. The testimony of the mother was not admissible in her own country for she could lead any child into court and declare any man to be its father. It was the physician's birth certificate made at the time of birth and presumably in the presence and by the authority of the father, that the law demanded. It could not be produced, and the helpless infant whom the physician should have been eager and happy to protect and serve, lost its inheritance. What a cruel and unnecessary blow was this, from the hand of a practitioner of the learned and benevolent science of medicine! Surely, a physician's duty to the families he serves and to the helpless infants he pilots into this world, are not fully performed until he has made out a certificate of birth and taken reasonable care that it is made of due legal record.

Another incident. Farmer Hadley, of Indiana, dying, left his valuable farm in trust to his unthrifty son, to go to his granddaughter on her twenty-first birthday. The girl had been told the date of her birth and always celebrated as her birthday the annual recurrence of the same. However, when she believed she was twenty-one, and then claimed her inheritance, her father denied her age, saying she was only nineteen. The family Bible was appealed to, but the leaf with the family record was gone. No birth record had been rendered, and the attending physician was dead. The court was in a quandary. A Solomon was needed for judgment. At last a neighbor remembered that a valuable cow belonging to the grandfather had given birth to a calf on the day the girl was born, and he could swear to it. Perhaps the grandfather had recorded the date of the birth of the calf. His farm books showed this to be the case. The date of the birth of the human being was established.

SUMMARY—CONCLUSIONS

The importance of vital statistics to the family, to the state, and to medicine, can hardly be overestimated. The physician, the representative of the science of medicine, is, except in instances, the only member of society who can supply information in regard to causes of deaths and the presence of infectious diseases. As it is of very great importance to the family that its births, deaths, and cases of infectious diseases be legally recorded, and as the family presumably pays for the physician's services, the physician, therefore, should not consider his services fully performed nor that he is entitled to his fee until the certificates which are of such great importance are duly made. And again, the physician should remember when reporting vital statistics, that he is giving obedience to the statutes of his state, on which he depends for protection; that he is protecting the helpless; that he is doing a general good, and that he is serving the science of medicine.

ABSTRACT OF DISCUSSION

DR. PRINCE A. MORROW, New York: The subject is most important, but attention should be called to the fact that there is a large and important class of diseases which are infectious, and dangerous to the public health, but which are practically ignored in our system of vital statistics.

In few of our vital statistics is there mention made of deaths from gonococcus infection, or from syphilis. Now, we all know that these diseases figure very largely as causes of death, for instance, in England and Wales, during the year 1907 there were 1,840 deaths recorded from syphilis. Dr. Osler, in commenting on this statement, says that if we are to appreciate the importance of syphilis among the deadly maladies, we must include the deaths from paresis, and locomotor ataxia, half at least of the deaths from softening of the brain; and other diseases of the nervous system. He estimates that at least 6,000 or 7,000 are annually slain every year in England and Wales by syphilis directly.

Now, this list of 6,000 or 7,000 deaths does not embrace the vast number of still-born children dead from syphilis. He says, in addition to this, if we include in this category the deaths from the coccus of Neisser we shall find that there should be debited to the venereal diseases many thousands of deaths annually—a mortality that comes only after tuberculosis, pneumonia and cancer.

Another point is that in the presence of any infectious disease the cardinal obligation of the physician is to prevent the extension of the disease, and the infection of others, but in the case of syphilis the only duty of the physician, as he understands it, is to cover up and conceal the fact—to protect the secret of his patient. He does not seem to consider it a part of his duty to protect the other members of the household or the public from this very infectious disease. As Dr. Hurty intimated, we can never educate the public in this disease unless we tell the truth. The public has no conception of the enormous extent to which these diseases prevail.

The medical profession has not recognized its obligations to the public in this regard; and if a reform in vital statistics is to be instituted, I know of no one who is better qualified and who is more likely to inaugurate this innovation than the very able and courageous secretary of the Indiana State Board of Health.

DR. ARTHUR R. REYNOLDS, Chicago: Dr. Hurty's paper is most timely and should be placed in the hands of every physician throughout the country. I have always believed that it was the duty of all physicians to report cases of contagious diseases as well as births. They owe it to the public in return for privileges they enjoy. I think that most physicians think so, too; but often they neglect it, and sometimes assert that they should be paid for it. The pathetic instances and forcible illustrations that Dr. Hurty has given show that the duty is binding on us all.

DR. P. M. TOWNSEND, Marshalltown, Ia.: I attended a charity patient with a neglected case of chancroid—gonorrhoea and syphilis—one of the worst cases that I ever handled. The girl was unmarried, and pregnant; and all summer I dreaded the decision as to what my duty was in regard to protecting other physicians. Knowing that the family was poor and that there would be no financial inducement for the physician to undertake the risk, I feared to report the case to the other physicians in the county, lest they might refuse to attend the case when the girl came to the time of confinement. Before I had decided what my duty was toward my fellow practitioners, the girl miscarried and called for a physician, and the secretary of the county association attended her. Later on I learned that a woman who was present at the time, and had to administer the anesthetic, knowing something of the neighborhood gossip in regard to the case, wanted to know if there was any danger of her "getting anything," and thus called the physician's attention to the possibility. Up to that time he had examined the patient without uncovering her person, but he then, in very great exasperation, having looked at the skin and external genitalia, scarred by the chancroids, said that if he had known what kind of a case it was he would not have attended it for a hundred dollars. We need more publicity in regard to venereal diseases, for our protection as well as for the protection of the public.

DR. HENRY B. HEMENWAY, EVANSON, Ill.: Certain diseases like smallpox are common-law nuisances; in other words, the courts have decided that they are nuisances, and therefore reportable. Most diseases are not common-law nuisances. For example, malaria should properly be reported; but it is not a

common-law nuisance, and so legally it can hardly be required to be reported unless the statutes specifically mention it. If gonorrhoea and syphilis are to be reported (and I do not for one second question the advisability of it), the statutes of the state should definitely mention those diseases. The ruling of the board of health is always subject to the court action; and a court uneducated in matters of medicine must take the opinion of one physician as legally as good as that of another. Therefore the ruling of boards of health is liable at any time to be nullified by a court decision. Statistics, in order to be accurate, must be complete. Many physicians imagine that they may be compelled to report a case of scarlet fever, or possibly typhoid fever; but they take it that disclosing the presence of the gonococcus or syphilis in a patient, would be betraying professional confidence. That provision should be covered by a state legislative enactment.

DR. PRINCE A. MORROW, New York: The law in New York state is mandatory that all diseases which are infectious and dangerous to the public health should be reported.

DR. HENRY B. HEMENWAY, Evanston, Ill.: That expression "infectious" must be passed on by the court. Although malaria, for example, is infectious, and we know that it is infectious, there are many physicians who deny its infectiousness to-day; and therefore if we attempted to require the reporting of malaria, we might find that the court would decide against us.

DR. J. N. HURTY, Indianapolis: Of course, there is no doubt about the desirability of reporting the malarial diseases. That they will be reported eventually I have no doubt. But to secure reports of them at present seems to me to present insurmountable difficulties. We cannot yet obtain perfect reports of those diseases that the people think should be reported. The existence of scarlet fever is sometimes hidden. Until people understand their duty to their neighbors, how can we secure the reporting of malaria?

Of course, my conviction is that it is the duty of the physician from every point of view, to report vital statistics.

One of our most prominent gynecologists, a cultivated man, educated at Harvard College, and the Harvard Medical School, contended that he should be paid for reporting a birth. That contention indicates a very serious situation, it seems to me. When the matter so particularly concerns, or may concern the material welfare, of his patient and the child, and the physician is the only man who can do it, I would say that he might just as well at a birth leave the placenta *in situ* as not to report its occurrence, because until he has attended to both matters he has not completed his work. Let him complete his work; then let him have his pay.

A BRIEF REPORT OF THE NEBRASKA EPIDEMIC OF POLIOMYELITIS*

H. M. McCLANAHAN, M.D.
OMAHA

This epidemic occurred during the summer of 1909. In proportion to the population it was greatly more extensive than the epidemic in New York City of 1907. My report is based on personal letters received from fifty-eight physicians, a number of whom I have seen personally. I have been greatly aided by Drs. H. W. Orr and W. H. Wilson of Lincoln, Nebraska, and hereby acknowledge my appreciation of their courtesy. Dr. Orr investigated the epidemic with a view to determining chiefly the nature and extent of the resulting paralysis. His paper was recently read before the American Orthopedic Society. Dr. Orr wrote directly to the people and received replies from 213 families, reporting on 315 cases. The total number of cases reported to him was 619. A brief summary is as follows:

Fully recovered, 151; not reported, 195; died, 91; one arm affected, 21; one leg, 53; side, 7; both arms, 4; both legs, 61; all extremities, 24; trunk, 10; face, 4.

Dr. W. H. Wilson, state health inspector, visited the chief centers and saw many of the cases. I quote as follows from a letter received from him April 25, 1910:

There were something like 275 cases reported to this office but from what I know of the situation, having been out much over the field, I am satisfied that there must have been at least three times this number of cases and perhaps more. The death record is practically complete, inasmuch as death certificates must be filed before burial permits are issued. I find that 137 deaths are recorded in which the cause is given as poliomyelitis, spinal paralysis and cerebrospinal meningitis, but they are manifestly all belonging to the same class. Making an analysis of the first eighty cases reported I find that in seventy-two of these the duration of the disease was from one to five days, about three days being the average. In eight cases the time preceding death was from ten to fifteen days. No patient over 20 years of age. . . . As to the patients who have completely recovered I have no data of any degree of accuracy except on eighty cases, and of these as near as I can learn 75 per cent. have completely recovered.

In my investigation the chief purpose was to determine the variety of the disease. The following points were covered in a letter of inquiry addressed to physicians:

1. Total number of cases.
2. Total number of fatal cases.
3. Clinical varieties as follows: (a) cerebral type, (b) bulbar type, (c) polyneuritic type, (d) ordinary type. (By cerebral type, I mean cases with high fever, delirium, convulsions, rigidity of neck or opisthotonos, when after one or more days these symptoms subside to be followed by paralysis; by bulbar type cases indicating paralysis in the medulla, as evidenced by disturbance chiefly in the breathing; by neuritic type, cases with a great deal of hyperesthesia and severe pains in the extremities; by ordinary type, cases beginning with fever, vomiting, diarrhea or constipation, to be followed sooner or later by paralysis.)
4. Cases of complete recovery without paralysis.
5. Parts paralyzed in cases of recovery with paralysis.
6. Age of patient.

The following-named physicians have reported to me, and I wish to acknowledge my sense of appreciation for their courtesy:

From Polk County, Drs. Shaw, Malster, Anderson, Post, Woepfel; York County, Drs. Hallett, Hylton, Shidler, Stark, Karrer, McKinley, Demeree; Dawson County, Drs. Sayer, Wengert; Custer County, Drs. Sargent, Comstock; Valley County, Drs. Bartoo, Lee; Nance County, Drs. Johnson, Eastman, Ohanerl; Merrick County, Drs. Benton, Robinson; Seward County, Dr. Doty; Webster County, Dr. Wegman; Dodge County, Drs. Davis, McDonald, Smith, Heyne; Nemaha County, Dr. Dillon; Saline County, Dr. Bentz; Phelps County, Dr. Sanders; Hitchcock County, Dr. Mellea; Douglas County, containing the cities of Omaha and South Omaha, Florence, Benson and Dundee, Drs. Gilmore, Porter, Ellis, Adams, Wigton, Rix, Roswater, Lake, Bishop, Morrison, Jefferson, Mack, Somers, Swanson, J. C. Moore, R. C. Moore, Impey, McClanaghan, Brown, Dwyer, Loomis, Van Camp.

Reports from the counties were as follows:

County.	Population.	Cases.
Polk	12,000	384
York	19,000	130
Valley	8,000	90
Custer	20,000	82
Douglas	175,000	79
Nance	9,000	72
Webster	12,000	43
Dawson	13,000	41
Seward	16,000	25

* Read in the Section on Diseases of Children of the American Medical Association, at the Sixty-first Annual Session, held at St. Louis, June, 1910.

Dodge	24,000	17
Merrick	10,000	19
Nahama	16,000	5
Otoe	24,000	5
Saline	26,000	3
Hitchcock	5,000	2
Colfax	12,000	1
Phelps	12,000	1
Hamilton	14,000	...
Total cases		999

DIAGNOSIS

It would be strange indeed if, in the presence of an epidemic like this, mistakes in diagnosis were not made. Except for the literature of the New York epidemic there was nothing in the text-books to guide physicians or to give them any adequate conception of its symptoms or nature and the literature of that epidemic was not available to the large majority of physicians. It was called summer grip, mysterious disease, spinal paralysis, cerebrospinal meningitis and poliomyelitis. There were cases of the cerebral type that could not be differentiated from true meningitis except by lumbar puncture. This was done in a number of cases, and unfortunately one or two misleading reports were received by physicians concerning the bacteriologic findings.

So far as I can ascertain, the *Diplococcus meningitidis intracellularis* was not found in any of the cases. As the disease spread and as other cases appeared without meningitic symptoms, however, it became manifest that we were visited by an epidemic similar to that which prevailed in New York. We now know that some of these are cases of true meningitis and present symptoms similar to that disease, the only distinction being that they are not caused by the intracellular diplococcus.

NATURE OF THE DISEASE

The report of the collective investigating committee on the New York epidemic clearly shows that we must form a new conception of this disease. We must recognize that it is a general infection, that it involves many organs in the body, including the gastro-intestinal tract, the lungs, liver and other organs; that the toxin has a peculiar affinity for the nervous system, that it may involve only a part of the spinal cord or may spread to any part of cerebrospinal axis; hence we may have meningo-encephalo-myelitis. There is a cellular infiltration, chiefly of the anterior horn of the cord and more or less degeneration of the ganglion cells. The extent of permanent paralysis will depend on the degree of degeneration. The fact that many patients having early paralysis recover completely is evidence that degeneration does not take place in all cases, and that the cell infiltration is removed by absorption with complete restoration of function. It is probable that the early weakness and paralysis are due to a toxin which has a peculiar affinity for the nerve centers, inhibiting their function. This conception of the disease will greatly aid us both in diagnosis and in treatment.

My reports show that nearly all the fatal cases were due to bulbar paralysis. By this is meant an involvement of the motor centers in the medulla leading to paralysis of respiration. My reports indicate that nearly 90 per cent. of the cases were of this type, and that nearly all of these cases died within the first three days. When bulbar symptoms occur death may ensue within a few hours. These symptoms may occur in cases that otherwise seem mild. Again there may be cases with serious cerebral symptoms without bulbar symptoms; hence with all cases we have this complication to fear. I believe it to be true, however, that bulbar symptoms seldom or never occur after the first week. This complication was to me the important lesson of our epidemic. It was my sad privilege to witness the death of one of these cases. From the first symptom indicating respiratory failure to the fatal issue was only seven hours. Several of the physicians have frankly

Dr. Orr in his paper gives reports from 13 other counties not included in my list, with a total of 37 cases. I am satisfied from my experience that neither Dr. Orr's report nor mine contains all of the cases that actually occurred. His report showed a total of 91 deaths. Dr. Wilson, whose report is official, gives a total of 137 deaths. The total number of deaths in my report is 61. It follows that my report does not include nearly all the fatal cases. There are several reasons for this. For instance, I saw three cases out in the state which terminated fatally, but which are not included in my report. Again, I know of instances in which the attending physician was discharged and another called in, and, the case terminating fatally, the first physician would not include this case in his list of cases.

I have personally seen 47 cases, 15 during the acute stage and 22 because of the resulting paralysis, and in taking a careful history of these cases I found that 6 patients had no physician during the acute stage, seeking medical advice only because of the resulting paralysis. Physicians in the storm-center of the disease informed me that they were satisfied that there were many cases throughout the country districts in which no physician was called. My reports concerning the resulting paralysis were so incomplete that I shall not attempt to classify them. The chief object I had in view was to determine the clinical varieties, and the reports yield the following results: cerebral type, 107; bulbar type, 86; polynueritic, 113; ordinary, 495; unclassified, 188; total, 989.

The first case was reported in the month of March, but only 7 cases are reported from that time until July 1, and only 20 cases after November 1, four-fifths of all the cases occurring during the months of July and August. Those two months were unusually warm and dry. It is preeminently a disease of warm weather. Fifty-five per cent. of all the cases occurred in the counties of Polk and York, with a total population of 31,000 people, and the greater number of the cases occurred within an area of 20 by 24 miles. It was preeminently a disease of the rural district. A Fourth of July celebration was held in Stromsberg, Polk County, and I am told by reliable physicians that within two weeks after that the disease swept like a wave over the adjoining country. Another center in Webster County existed, with miles of intervening country without a case as far as can be ascertained. There were other centers in Nance, Valley, Custer and Dawson Counties, with considerable areas of intervening country without any reported cases. The physicians in some of these centers requested the state board of health to establish quarantine. This was done and the result seemed amply to justify this procedure. I think I can truthfully say that the physicians having the largest experience are satisfied from it that the disease is not only infectious, but contagious as well. Were there time I might recite many interesting experiences related to me.

told me that they had been greatly shocked and surprised to have a case terminate fatally in which but a few hours before they had given a favorable prognosis.

A careful study of my report and letters written to me indicate that constipation was the rule, diarrhea the rare exception. One physician who saw eighty-six cases did not have a single case in which diarrhea was a symptom. The constipation was obstinate, sometimes requiring two or three days to secure a bowel movement. This would seem to indicate that the disease caused an inhibitory effect on the muscular coats of the bowel. Vomiting was a rare symptom. As nearly as I can gather from the reports over 80 per cent. of the patients vary in age from 2 to 10 years, the extreme limits of age being 4 months and 67 years. A patient who died at the age of 37 was the oldest one reported whose case was fatal.

The most surprising feature of the report, however, was the number of cases reported of complete recovery. I am not able to give the exact figures. Some write that after the acute symptoms had subsided the cases passed from their observation. Dr. Orr's report received directly from the parents indicates that a larger number of patients have permanent paralysis than would be indicated from my report. My personal experience with patients coming to my office leads me to believe that there are many cases of paralysis of which the attending physician has no knowledge. It is certain, however, that a large number of these patients have recovered permanently, and probably 25 per cent. would be a liberal estimate of those who are permanently paralyzed. I can not discuss the subject of treatment but close with the following suggestions:

SUGGESTIONS

This is an infectious disease.

The evidence that it is contagious is accumulating.

The only safe procedure is to treat it as we would measles or scarlet fever: namely, isolate the patient.

We should realize that it is a general disease, that it may involve any part of the nervous system, that the bulbar type is usually fatal, and that our treatment should be directed toward prompt and efficient elimination.

ABSTRACT OF DISCUSSION

Dr. C. A. ANDERSON, Stromsburg, Neb.: Poliomyelitis is an interesting subject to me, as I am from the county in Nebraska in which a larger number of cases occurred than in any other county in the state. I had 86 cases in my own practice and saw a number of others as health officer. I was the first in the state to report these cases, and believe I quarantined the first cases of poliomyelitis quarantined in the United States.

Though I have learned of earlier cases in other parts of the state, the first case I have been able to find in Polk County occurred about the middle of May, 1909, and had come from some distant part of the state. I saw the first case on May 30, and from that day to July 4, 30 cases occurred in Stromsburg and tributary country. On July 26 and 27 I saw the first 3 cases in which I discovered paralysis, and on inquiry found that the other doctors also had patients with paralysis. I at once telephoned the state health inspector, asking him to come without delay, which he kindly did. After seeing the cases we were informed that no legal provision had been made for quarantining such cases and were advised to isolate them. But this, of course, could not be enforced, nor could the impending Fourth of July celebration be averted. This celebration was well attended and a week later cases were

reported from communities far and near previously free from the disease, but which had representatives at the celebration. During the following 30 days at least 115 cases occurred in the city of Stromsburg and tributary country.

On July 21 we were authorized and commanded by the State Board of Health to quarantine, and in 12 days the epidemic was well under control in our community, only 15 scattered cases occurring after that date. The epidemic reached Osceola, our neighboring town on the east, later, when suddenly 9 cases occurred there. Having profited by our experience, the affected families were at once placed in absolute quarantine, with the result that not a single additional case occurred there. The quarantine recommended by our State Board of Health, and which we carried out, was not absolute, but the same as that recommended for diphtheria, i. e., the bread winners were permitted to go about their business after taking certain precautions. The fact that the people of our community were thoroughly aroused by the ravages of the epidemic contributed much to the effectiveness of the quarantine there. In a community where the danger is not known I believe an absolute quarantine is safer.

Of the 86 cases 4 were fatal, the patients dying of bulbar paralysis on about the fourth day. Eighty-four per cent. were less than 10 years old, children 6 to 7 furnishing a larger number of cases than any other age. From 10 to 22 the susceptibility seemed to be about the same, each year of age being represented except 18 and 19. The oldest patient was 36, and died. In only one case was spinal puncture and an examination of the fluid made. The fluid was clear, but the microscopist stated that he found the *Meningococcus intracellularis*, a statement that is now known to be an unfortunate mistake. The numerous punctures done later in a neighboring county also showed clear fluid which contained no intracellular cocci.

Dr. E. H. BARTLEY, Brooklyn, N. Y.: One important thing in the history of this epidemic is in reference to the period of incubation. The essayist has said it was about two weeks, and Dr. Anderson's figures make it about two weeks after the quarantine that the epidemic stopped suddenly. If they would tell us how long after the Fourth of July celebration the large crop of cases appeared, that would also assist us somewhat in determining the period of incubation.

Dr. H. M. McCLANAHAN, Omaha: I had expected to have the pathologist report the findings in eight or ten cases. It was to me a revelation. My cases were limited to forty-seven, and of the seven patients with the bulbar form, all died. Twenty-two patients came to me because of the paralysis, all of the ordinary type, one with complete paralysis of the muscles of the left side. In another case there is complete paralysis of the left side of the face. We did not find in any of the eight cases in which lumbar puncture was done the *Diplococcus intracellularis*. In three the fluid was absolutely sterile.

THE RÔLE OF OPHTHALMOLOGY IN PREVENTIVE MEDICINE *

HIRAM WOODS, M.D.
BALTIMORE

The rôle of ophthalmology in preventive medicine includes, it seems to me, at least three phases which may be profitably studied by the general profession: 1. Prevention of blindness from infectious diseases and accidents. 2. Prevention of eye deterioration by violation of ocular hygiene. 3. Prevention of remote lesions through recognition of early ocular symptoms of systemic disease. It is my purpose to speak briefly of each of these, bearing in mind the fact that this section has to do rather with the practical results of scientific study than with the details of the study itself.

* Read in the Section on Preventive Medicine and Public Health of the American Medical Association, at the Sixty-first Annual Session, held at St. Louis, June, 1910.

OPHTHALMIA NEONATORUM

Among infectious eye troubles, the most destructive, by long odds, is ophthalmia neonatorum. The number of its victims is little short of a professional disgrace. Its cause is definitely known. While due exceptionally to infection other than gonococci, and while differential diagnosis is important, the fact remains that clinical experience shows the preventability and curability of the disease. Credé's prophylaxis was given to the profession about thirty years ago. On account of occasional so-called "silver catarrh," it encountered some opposition. This was largely overcome by reducing the strength of the nitrate solution from 2 to 1 per cent., in which strength it seems equally effective as a preventive, while its irritating qualities are lessened. Rarely—not more than twice or thrice in a lifetime—hemorrhage from the conjunctiva is seen in infants. As the use of Credé's method became more general, this symptom of hemophilia was laid at the door of the silver salt, hemorrhages, usually fatal, from other parts of the body not receiving proper consideration.

Other preventives have been tried. Maternal disinfection has been relied on; other drugs, mercuric chlorid, potassium permanganate, and the protein silver salts, have been used in the eyes. While all have been more or less effective, the consensus of opinion puts the 1 per cent. nitrate solution at the top. When used properly, in a clean way, this solution is practically always effectual. Its routine use in maternities has almost driven this disease away. "Routine" is important, for whenever discretion has been left to a house staff, to use or not according to maternal conditions, ophthalmia has increased. Though it is always used in most maternities, and employed by many obstetricians uniformly in private practice and by many more when there is the least reason to suspect gonococci infection, one studying statistics of blindness meets with an appalling fact; the percentage of blindness from infantile ophthalmia in schools and asylums is practically undiminished. In some places it is larger. The Maryland school will serve as an example. In 1892 children blind from this disease amounted to about 18 per cent. Now it is nearly 28. An average of 30 per cent. holds everywhere. These cases do not come from maternity hospitals or from eye hospitals, provided the cornea is clear when treatment is instituted, nor from the private practice of the careful physician. In my own state, of this 28 per cent. of all blind children, 77 per cent. were born under midwife care, the remainder under medical care. Observations in other states give similar results. Several conclusions are justified:

First, an increasing number of women in the poorer classes are applying to midwives for care during confinement. This seems directly confirmed by the investigations of Miss Crowell in New York and Chicago, and Miss Small in Baltimore. Birth registration is hard to enforce; but an estimate of 40 to 50 per cent. of midwife attendance is certainly safe. This is in spite of the ample hospital provision which our cities afford.

A second conclusion is that the large majority of midwives are ignorant and incompetent. It is necessary only to call attention to Miss Crowell's findings to prove, not only that the American midwife, white and black, is untrustworthy, but that the foreign woman, better trained in her own country, soon degenerates to the level of demand when she comes to our side.

A third conclusion, more mortifying and disgraceful than those bearing on midwives, follows from the fact

that at least a considerable percentage of infantile blindness can be laid at the door of the physician. There are, it is evident, practitioners who either do not know how to prevent and treat the disease, or, if they know, fail to act on their knowledge. It is well-nigh impossible to reach these men. Medical societies and journals are strangers to them. They pursue their own dogmatic, complacent ways, and their patients take the consequences.

But the midwife problem is one which must have serious study. In many countries of Europe the midwife has not only legal restrictions but educational advantages. Her activity is recognized, and the government prepares her for her work among the poor. Not so, to any degree at least, with us. We so often hear it stated that the midwife is here, and here to stay, that it must be true. That 40 or more per cent. of births are supervised by her lends confirmation. She is evidently more popular with the poorer classes than are our hospitals, maternities or relief societies which furnish free medical attention by women physicians. Yet we know that her ignorance often brings blindness to the baby and death to the mother. Preventive medicine means prevention of the effects of disease; elimination of cause, when possible.

We have recently added to our Maryland laws one regulating the practice of midwifery. It requires ability to read and write, attendance on at least five cases of confinement, under capable supervision, and demonstration to the health board of ability to attend normal labor. It requires report, and forbids treatment of infantile ophthalmia. This law, and others similar, aims at making the midwife as harmless as possible, recognizing her standing, because she is a necessity.

If that is the professional attitude toward her, it seems to me that we must go the full length of the situation, and provide, as is done abroad, for education of the midwife up to her legal privileges. She has a unique place. Her patronage can never rise above a certain social line, and persons below this line do not know how to take care of themselves. Naturally they become, in one sense or another, public charges. I do not mean that they must be supported; but I do mean that their ignorance leads to results from which intelligent men and women must save them. How and by what means the midwife is to obtain educational facilities I do not, at this time, at least, stop to discuss. But, on the doctrine of her necessity in American life, it is worth thoughtful discussion, and such a group of men as make up this Section will soon have to grapple with it.

I am going to suggest, however, a side attack on the midwife problem. It is popular education of the persons who employ the midwife. We have in the Maryland Medical and Chirurgical Faculty a bureau of public instruction. Medical men and women go, at the request of philanthropic societies, among the poor and tell them about prevention. Last fall I addressed an audience of some sixty or more pregnant women under the auspices of a branch of the Women's Christian Association. I afterwards learned that a number of my audience canceled midwife retention, and entered hospitals. I have urged this popular education on our social workers in Baltimore, and mention it here only as suggesting a way of enlightening the ignorant poor who are quick enough to follow advice when they are convinced of its disinterestedness. They will not take such advice from physicians in this spirit.

The fight against ophthalmia neonatorum is the most encouraging preventive undertaking in the rôle of oph-

thalmology. Many states have laws compelling the report of midwife cases, and a few convictions impress midwives with the necessity of getting the babies into proper hands at once. Such has been our experience in Baltimore, where some of us have reported neglected cases and secured convictions. In New York state the Board of Health furnishes free of charge prophylactic sterile silver nitrate solution to those willing to use it. A large number of physicians and the better class of midwives are doing so. The Sage Foundation has taken up the fight, and is ready to furnish money and help promote knowledge where it is needed. In several states there are associations of professional and lay men and women for prevention of blindness. The American Medical Association has a special committee in its Section on Ophthalmology, of which committee Dr. Lewis of Buffalo is Chairman; and there are corresponding members in each state.

There is still needed the same sort of awakening to this disease which has come to the profession in the fight against tuberculosis. Why the mere facts in the case fail to impress many physicians is hard to say; but they do not. I heard a leading county practitioner say that he considered putting nitrate solution into the eyes of a new-born baby, "just because the father had had gonorrhoea," as almost criminal. One step might be taken in impressing such men if ophthalmia neonatorum were put in the list of diseases to be reported. It could be easily enforced after a little; for if a child lost an eye the parents would almost certainly take him or her to an oculist, and thus failure to report would be brought home to the first attendant. Such a lesson would induce a man to post himself on treatment and prevention.

ACCIDENTS

Accidents as a cause of blindness have been gone over so thoroughly that I shall hardly more than allude to them. In the line of prevention, however, a sane and safe method of observing Fourth of July merits professional activity. Since passage of an ordinance forbidding the use of fireworks within the city limits, such accidents as we saw in abundance years ago in Baltimore, are now almost unknown. Dr. Robert L. Randolph deserves special mention for activity in this work. The comparison between cities with and without such regulations, as produced by *Collier's Weekly* a year ago, shows what can be done if medical influence is used. Antiseptic treatment of eye wounds from industrial accidents has saved many eyes whose sight was not entirely destroyed, though in former years these eyes would have been removed without hesitation. Sympathetic ophthalmia is now a rare disease. Personally I have seen but one case in a number of years; yet risks which would have been formerly considered unjustifiable, are now taken to save the injured eye.

The principles of treatment are, removal of foreign bodies, if present and removable, rest, cleanliness, cold, and meeting complications with appropriate treatment. Some surgeons claim that hexamethylenamin is highly useful in such cases, and a limited experience with it leads me to agree with them. The most important thing is to get the patient under rigid antiseptic treatment early.

It would be interesting to review, if time permitted, various protective devices now being introduced in factories to safeguard workmen from flying bits of metal, broken machinery, etc. This phase of the prevention of

blindness, however, belongs rather to the industrial than the medical side.

SCHOOL HYGIENE

There is a rôle of preventive medicine in ophthalmology which has received considerable attention from some quarters and has been sadly neglected in others. I allude to school hygiene. The systematic examination of children's eyes for visual acuity often discovers for the first time that refraction is abnormal and enables the child to start school life safe-guarded. General recognition of ocular origin of headaches, etc., does more in the same direction. Recognition that myopia, certainly the progressive type, is a diseased condition, and that it usually comes from neglected astigmatism, is a long stride in saving children from damaged eyes and the numberless remote disturbances which come from the eyes.

Of no less importance than examination of pupils' eyes is school hygiene in the sense of proper lighting of rooms—direction, intensity, etc.; adjustable desks, size of print, character of paper, etc. In such a paper as this it is hardly possible or proper to consider these matters in detail. Yet, with increasing popular interest in medical matters and greater appreciation of hygienic principles, such things demand attention from the physician, because his advice will be sought.

Two phases of school hygiene may be specially mentioned. The adjustable desk, as is known, can be adjusted to the child's measurement. Its use does away with the haphazard method of putting a child in the desk which most nearly fits. It secures comfortable seating, with the body properly supported both in the upright and forward positions, enables the child to bend over the desk, in writing, without elevating one shoulder above the other, and with the page at a proper distance for sustained and comfortable eye work. These desks are not much more expensive than the old-fashioned stationary affairs. They are in use in most of the best private and a few of the public schools. Their universal adoption would, I believe, be most helpful in preventing ocular discomfort and disorders.

Every year an oculist sees a few children with these conditions: vision is below normal, one-half to one-tenth; the child sees well enough to be self-reliant, but study is impossible; either refraction error is absent or its correction does not improve vision; the cause of defective sight is sometimes undiscoverable, apparently a congenital defect. Again, corneal opacities, antipolar cataracts, old superficial chorioidal scars explain the partial blindness. What can be done to educate these defectives? If they try to keep up in a curriculum arranged for children with normal visual acuity, not only does suffering result, but each year sees a little less vision at 20 feet, a little nearer approach of print in order to secure a larger retinal image. In other words, school life is damaging sight.

I, like other oculists, have seen such cases go on to practical, if not absolute blindness. We forbid eye-work, but the prohibition means enforced idleness while the mind is active. A few such children consent to be read to, but the majority rebel, and little by little parents cease the effort. Then either eye-work is done clandestinely, or effort to get education is abandoned. So far as I know, there is no provision made for such children in our educational system. With most of them it is either nothing or the blind school. There has been some recognition of this class in England, and a few men have, in individual cases, done something here.

We need, it seems to me, a midway or modified curriculum in our school system. It should include such studies only as are really necessary for a fair common school education. Maps, diagrams, books, etc., should be large enough in outline or print for the defective to see without effort. I have been able to find a few such maps and books for such children, and the effect of eye-work, under easy conditions, on the eyes themselves, has been surprising and gratifying. Visual acuity has really increased during a period of years.

The principle holds good, too, in a class of squint cases which relapse after operation because the squinting eye is below its fellow in visual acuity and so does not work: that is, its comparatively indistinct retinal image makes no impression on the psychic side of seeing. By selecting type which the eye can see, and forcing work on such type, with the good eye excluded for a little time each day, one is often rewarded by positive increase in vision, sometimes to a point where binocular sight is possible. I have developed such eyes from one-tenth or less to nearly normal.

But it is chiefly to the school idea that I wish to direct attention. Ophthalmology here has a rôle in preventive medicine of both physical and economic value; for not only is such sight as the child has, preserved or improved, but the child himself is made a more or less productive social factor. He will not, with visual acuity assumed, take kindly to instruction designed for the blind, but he will respond to the special efforts made for him. As a class, he merits more attention than he gets.

EYE LESIONS AND SYSTEMIC DISEASE

In conclusion, I want to speak of a rôle in preventive medicine which ophthalmology ought to occupy more than it does. I allude to functional or organic ocular disorders as symptomatic of systemic disease. To the oculist it is important because the best possible work in his own special line will be nullified unless he recognizes the symptomatic meaning of the trouble bringing his patient to him. To the patient it is important, because even if the oculist relieves symptoms without recognition of cause, relapse is inevitable. To the practitioner it is important because the eye, properly studied, often gives indications not gathered otherwise.

There are many ways in which this rôle may be illustrated. How often does a patient go from one oculist to another—to say nothing of the all-sufficient examining optician, or optometrist, as he now calls himself—vainly seeking relief from asthenopia? The mere fact that a half dozen conscientious and capable men have failed should indicate that there is something besides ocular error. This something is often hard to find. Its search demands cooperation of specialist, internist, physiologic chemist, etc. I have traced these persistent functional eye disorders to anemia, incipient and unsuspected nephritis, intestinal auto-intoxication, functional and organic menstrual troubles, supposedly cured or unsuspected hereditary syphilis, etc. Again, the oculist sees interstitial keratitis, or a frank iritis of alleged rheumatic origin; or else it is clearly a secondary syphilitic manifestation. His duty is not done when the eye lesion is cured. Only when he has put the patient where he can receive the systemic review or treatment indicated by the eye symptom can the oculist release himself from responsibility.

On the other hand, the oculist is now, the country over, fighting the so-called optometrist in his effort to secure by legislation a quasi-professional standing. He is doing this disagreeable work because he knows that not only

is the eye itself often injured by delay of proper treatment, while the optician is vainly trying to sell glasses that will cure ocular lesions, but that the symptoms of eyestrain which take the individual to the optician often mean remote and serious troubles. The rôle of ophthalmology in preventive medicine means cooperative medicine. It means that if we view the eye from the standpoint of its own function, this function is often affected by conditions beyond the oculist's power to diagnose or cure; that if ametropia be present, the physician may work in vain to relieve remote symptoms till the oculist helps him; that if the oculist appreciates the meaning of persistent functional disorders, a rigid pupil, seemingly unimportant muscular paresis, he may save his patient from dreadful consequences by asking his brother internist to aid him; that the problem of saving sight is not one which concerns the oculist alone, but is one which demands honest introspection from the physician and effort to educate his patients in the views which medical progress has taught us.

842 Park Avenue.

ABSTRACT OF DISCUSSION

DR. LEARTUS CONNOR, Detroit: Dr. Woods has stated with great clearness the relation of ophthalmology to preventive medicine. But in order to make this relation effective it is necessary that every physician have a definite increase in his working knowledge of ophthalmology. What this shall be and how obtained, is the subject of my remarks. The Section on Ophthalmology has decided that this shall be "a mastery of infectious diseases of the eye" and its "simple refractive defects." Because of the fact that existing ophthalmologists are unable to meet the needs of the one hundred and eighty millions of human eyes in the United States that need refracting, it is proposed that the entire one hundred and thirty thousand physicians be trained to manage simple cases, leaving for specialists the more complicated cases. Using the illustration of an army, we now have the officers, but not the soldiers; it is proposed to recruit the soldiers, and so to organize an effective army for protecting all the people from ocular diseases and disabilities.

If the entire profession is to be trained for the intelligent management of the simple eye disorders, the medical colleges must train them. To encourage them to make such changes as are necessary to ensure such training, it has been found practicable to persuade the state registration boards to require it for license to practice. A year ago the Section on Ophthalmology appointed a committee to promote such persuasion. It reports that four states now make such requirements, viz., Michigan, Utah, Vermont and Nebraska; that the House of Delegates of the American Medical Association, the American Academy of Medicine and the Federation of State Licensing and Examining Boards approve it.

Thus in one department of medicine—ophthalmology—experts have determined what every physician can master and actually practice, without interference with other practice, and so supplement the limitations of specialists and enlarge their own field and supply educated physicians adequate for the ophthalmic needs of all the people, under actual conditions. Farther, it is promoting the actual equipment of every doctor with the skill needful for him to do his part in the service of the people. It is believed that thus the service of ophthalmology in preventive medicine will be infinitely enhanced, just as an army of one hundred and thirty-five thousand is more effective than one of three thousand, and one with both soldiers and officers stronger than one with only officers.

DR. PRINCE A. MORROW, New York: I believe that the gonococcus is responsible for 90 to 95 per cent. (a great many authority say practically all) of the blindness of the newborn. We have the testimony of ophthalmologists that the gonococcus is responsible for at least 25 per cent. of all blindness. Now, I think that in all these discussions on the

prevention of blindness, as far as I have followed them, in the literature put out by the committee on the treatment of blindness, such as "Why Children Need Not Be Born Blind." there is no reference to the education of the public as to the nature and communicable mode of the infection that causes blindness; that is absolutely covered up and concealed; in fact, the entire responsibility is thrown on the shoulders of the physicians and midwives. The only education that the committee attempts to give is the education of the public to an appreciation of the value of the Credé method. As long as the public is ignorant, and kept ignorant, of the nature of the infection that causes blindness, I don't believe that ophthalmia neonatorum will ever be effectively checked. Now, I am a believer in the value of the Credé method; it is the best method in the present state of our knowledge for correcting the effects of this cause; but I regard it as an anachronism in the present day of advanced medical science to endeavor to correct the effects of a cause and ignore the cause itself.

Now, how do we get at this? We are to educate the public, but we cannot do it individually; we cannot say to a mother that her child has been blinded by an infection received from its father; but we can educate the public collectively. The medical secret does not apply to the collectively, it applies only to the individual. I believe that it is the greatest duty, the most urgent obligation on the part of the medical profession of the present day, to enlighten the public in regard not only to this infection, but to all of the infections that come from venereal diseases.

DR. SENECA EGBERT, Philadelphia: In regard to the teaching in the medical schools, I would like to say that, as a matter of fact, some of the students in some of the schools are getting this information and instruction, not only didactically, but also by actual practical work in the ward class. This year I can tell you of a class, numbering eighty at least, every one of whom had practical work in ophthalmoscopy, as well as work with other ophthalmic patients; and, what is more, those men got in final examination a question on refraction. I might say, too, in regard to the examination on ophthalmology, the question on the treatment of ophthalmia neonatorum has been so common in the past years that the students always look for it; and if they don't know anything else about the eye, they do know Credé's method and how to treat new-born infants. That is being done not only in our own school but in other schools throughout the country.

DR. HENRY B. HEMENWAY, Evanston, Ill.: The Chicago Department of Public Health has been conducting, for a short time, what they call a postgraduate school of instruction for midwives. A series of questions is sent out to the midwives, and they are asked to reply to them, and then they are invited to come in and discuss some of those problems with one of the department members. One of the objects of this instruction is this very matter of the prevention of blindness of children.

DR. W. FORREST DUTTON, Carnegie, Pa.: There are three problems presented by Dr. Woods' paper: that of midwife, that of ophthalmia neonatorum, and that of registration of births. I think we should, in the first place, educate the laity to legislate. In Pennsylvania we practically have no midwife law at all; and of those that attempt midwifery, we only have one of those licensed out of about the ninety-nine of those that do the work. I will venture to say that 25 per cent. of the ophthalmia neonatorum is due to the negligence of those practicing midwifery who have no right to practice it at all. Therefore, the blame should be placed where it justly belongs—on the midwife and the laws and not on the physician.

That presents another problem of the registration of births. It may be said that we get back to that when the death certificate is brought in. Well, if those children are allowed to go on until four or five years of age without registration they don't have an opportunity to get back at a midwife. If they would get at the midwife, make the doctor, midwife and parents equally responsible for the registration, I think a great many cases of blindness from these conditions could be avoided. It is legislation, instead of education, in a great

many places, that we want. We must educate the legislators to know that we want this, before we educate the classes up to the standard in preventive measures.

DR. HIRAM WOODS, Baltimore: I agree with Dr. Morrow's general criticisms that an allusion to popular education along the lines of sex hygiene would have made my paper more complete. It was not forgotten, but it is impossible to put in a short paper all one may wish. In the general lectures delivered in Baltimore, under the auspices of the medical and chirurgical faculty, the matter is emphasized. I agree with Dr. Egbert, so far as my experience goes. If my students get away from instruction on eye diseases without realizing that between the eye and the sex problem there is close connection, without appreciating the fallacy of one standard of morality and decency for men and another for women, it is not because such instruction is not given them.

Dr. Morrow claims that advice of ophthalmologists and obstetricians (that Credé's method be general) necessitates the logical deduction that every woman is a possible source of gonococic infection. The thousands of babies who do not have ophthalmia is sufficient proof of the absurdity of such deduction. If statements from the father about his previous life can be relied on, an eye prophylactic can be safely omitted. But, with different standards for the sexes, we must recognize the possibility of undiagnosticable gonococic lesion. And responsibility for risking the baby's eyes rests on the medical attendant. How often does the average practitioner ever think of latent gonococic infection in this light? After possibly two or three children escape, a baby develops ophthalmia. Recent infection in either parent is excluded. What does it mean? It means that an old, forgotten infection was a source of danger to the baby's eyes. In view of the harmlessness of the prophylactic, it is believed that the moral effect or influence of general use of prophylaxis would induce men, who now do not think of it, to use it and thus save many eyes now sacrificed. By noting gross lesions in the mother, the child's danger cannot by any means be determined.

There are physicians not belonging to medical societies, not reading journals, dogmatic, self-satisfied men, who seem beyond reach of new thoughts. They do not know, and the problem is, how to reach them. "There are others" outside of the medical profession, that is so. Post-partum infection, for instance, is most important. When a baby develops ophthalmia on the third or fourth day, you attribute it to maternal infection. How about those that come along later? I recently saw a baby blind in both eyes, the disease having appeared on the twelfth day. There was a dirty nurse, or dirty something, that blinded this child. Here is another problem in midwife training or public medical education. Obstetricians and ophthalmologists have begun their work on the midwife and careless doctor because they are the most conspicuous offenders, and most easily reached. No branch of preventive medicine can live to itself; but in practical, every-day work we must do what we can where we can. I fear it will be a long time before sex hygiene is so generally understood and acted on as to save babies' eyes. In the meantime, the indifferent medical man and midwife should be regulated.

METABOLISM AND MOUTH-DISEASE *

HENRY R. HARROWER, M.D.
CHICAGO

Since there is a very close relationship between the functions of the various organs of the body, it is not unreasonable to suppose that disorganization in one part will be accompanied or followed by disturbances elsewhere. From a study of conditions as they are to-day in both medicine and dentistry, however, it would seem that this important fact is not as fully appreciated as might be expected.

* Read in the Section on Stomatology of the American Medical Association, at the Sixty-first Annual Session, at St. Louis, June, 1910.

It is generally believed that certain more or less intractable diseases of the mouth or its contents are, to a greater or less degree, either accompanied by or associated with changes in the normal metabolic functions of the body. In spite of this comparatively few physicians are stimulated to look carefully into the mouth when evident errors of the metabolism are known to be present; nor do our dental confrères investigate the metabolism of those of their patients who are suffering from the all-too-common and intractable mouth-diseases.

This is not as it should be, for any local manifestation of disturbed function should serve as a reminder that a thorough investigation is not only necessary but imperative. This is just as true of mouth diseases as of skin eruptions, joint difficulties or gastro-enteric disorders. All too often Nature's glaring sign-posts are ignored.

Without a doubt there is a very close relationship between the condition of the buccal mucosa, the gums and teeth, as well as the tongue, and the blood which nourishes them. From time immemorial the condition of the tongue in disease has been used as an important diagnostic sign, and the study of this is given a prominent place in the text-books and current medical literature. For this reason I give it merely passing mention here.

It might be well here to quote a few lines from a valuable editorial entitled "Gingivitis in Diabetes" printed in a recent issue of THE JOURNAL:¹ "The importance of mouth symptoms in the acute infections, such as scarlet fever, diphtheria and measles, is recognized. It is less generally known, however, that in many constitutional conditions the mouth secretions and the mucous membranes covering the gums, cheeks, tongue, etc., furnish early and positive data for diagnosis.

"It becomes a matter of extreme importance, therefore, that the general practitioner shall examine the mouths of all patients, taking careful note of the mucous membrane of the cheeks, beneath the tongue, on the tongue itself, the roof of the mouth, and especially the gums."

The work of a number of broad-minded investigators, among whom the esteemed secretary of this Section, Dr. Eugene S. Talbot, stands preeminent, has called the attention of both the medical and dental professions to the relationship between pyorrhea alveolaris and certain blood dyscrasias.² This subject is of paramount importance and one to which much more attention should be paid. Here we have a vital factor in the solution of a multitude of difficulties, not merely pyorrhea alone, nor, for that matter, mouth diseases *per se*, but of a long list of common and uncommon conditions which embrace almost all the diseases known to medicine. It is a fact that as a profession we have not yet fully grasped the meaning of the Biblical statement, "The blood is the life." I do not mean by this that we do not appreciate the fact that life is dependent on the blood and its healthy condition, but the fact that in the majority of cases disease is due to toxic wastes which are present in the blood-stream and which unquestionably markedly lower its disease-resisting powers.

These poisons are not all of them sufficiently well known to have been isolated and named, but their frequent presence and easily demonstrable untoward effects are apparent to all that take the trouble to look for them.

Principal among these disease-producing toxins are certain acid substances which have been demonstrated to be closely related to indican and other products of intestinal putrefaction. Just what these substances are remains to be proved, but that they are acid in reaction and that their baneful influence is evident in the mouth as well as throughout the whole system is very quickly and easily proved.

Our methods of analyzing the blood and estimating its alkalinity are altogether too complicated for general use. In their place the examination of the urine has been found to be at once convenient, quick and easy; and the results obtained from such examinations will be found at times to be even startling. Probably the one factor obtained by the careful analysis of the urine which in most cases overtops its fellows is the acid index, and, strange to say, hardly more than a mention of it and the method of its estimation is to be found even in the most recent text-books.

Let us for a moment consider the question of the urine analysis and the relations of some of the findings. The urine is usually acid in reaction and the average normal acidity ranges from 30 to 40 degrees (each degree represents the amount of decinormal soda solution required exactly to neutralize 100 c.c. of urine). This acidity, we are told, is due to certain acid salts, principal among which is the acid phosphate of soda. We learn from the text-books that the urinary acidity is very difficult to accurately estimate because of the trouble in securing an indicator which will be responsive to all the various acid salts, and probably for this reason the study of this most important finding has been largely passed over.

Phenolphthalein is the most satisfactory indicator and is used by the majority of investigators. The test is simplicity itself and is fully as accurate as many of the well-known and widely-used tests, as for example, the albumin tests of Esbach or Purdy, or the Doremus urea test. The acidity of the urine should always be determined from a portion of a complete twenty-four-hour specimen, and care should be taken to prevent, as far as possible, alkaline decomposition of the urine. Either a burette or my acidimeter³ may be used. The latter is far more convenient for the physician or dentist in his office, while the former is probably better in routine laboratory work where large numbers of specimens are being handled.

In a paper⁴ published last June I called attention to the frequency with which excessively acid urine accompanied indicanuria and a marked diminution in the amount of urinary solids passed. A series of 250 analyses was mentioned in this paper. These findings, augmented by much further work along this line both by myself and several interested friends, was reported in a paper⁵ read at the annual meeting of the Illinois State Medical Society held last month.

From my findings it would seem, to me at least, that we have conclusive evidence that in the study of the urinary acidity we have something of more than ordinary importance. The relation of this syndrome of findings—acidemia evidenced by a hyperacid urine, intestinal toxemia by indicanuria, and decreased metabolic activity by the frequent low urea index and general

reduction in the total solids—to mouth-disease, is quickly found. It is safe to say that in a majority of patients suffering from pyorrhea are acidemics, and the most conclusive feature of this work is that therapeutic measures calculated to reduce the acidemia and eliminate the toxemia have a decidedly beneficial effect on the pyorrhea.

Many patients have been examined by me personally. Dr. Talbot has made hundreds of examinations and several others have by their work proved absolutely that there is decided and close connection between disturbed metabolism and mouth-disease.

I might go further and discuss the relations of the metabolism as evidenced by the urinary findings to diseases of the buccal mucosa, the pharynx and the tonsils, but this is a subject far too broad to be touched on as briefly as would be necessary here. I will close by relating a short but interesting case which was brought to my attention by Dr. A. H. Hoy. When he was visiting in Seattle last summer he was invited to see a little girl suffering from a membranous condition of the pharynx which seemed to be growing progressively worse in spite of heroic doses of diphtheria antitoxin, swabbing with silver nitrate and other antiseptics and the best treatment that one of the leading specialists could afford. Dr. Hoy asked if the urine had been examined. It had not. He then asked for permission to make an immediate examination of a specimen passed in the office. The acidimeter read 180 degrees. A twenty-four-hour specimen was saved, and the next afternoon was tested, showing practically the same degree of acidity.

To make a long story short, the child was treated with alkalies and within a few days the whole condition had cleared up and no evidence of the affection was to be seen save a marked hyperemia of the pharyngeal walls.

It is hoped that a wide-spread study of the relations between the disturbances of metabolism and mouth affections will shortly be inaugurated among the rank and file of the professions, and that the dentists as well as the doctors will come to see the important influence that the hyperacid state plays in disease causation in general and mouth disorders in particular.

72 Madison Street.

ABSTRACT OF DISCUSSION

DR. EUGENE S. TALBOT, Chicago: For a number of years Dr. Harrower has been making a specialty of this line of work. There is a great amount of suffering among our dental patients. Patients consult stomatologists to have operations performed when they are suffering pain in other parts of the body. I could recall many cases similar to that Dr. Harrower has reported in which by treating interstitial gingivitis I have been able to clear up other conditions of the body from which the patients have suffered for many years. These patients are walking about, yet they are ill. They are not ill so far as the general practitioner is concerned. He must find some lesion—some condition for which they must stay at home or in bed before taking treatment. There is no specialty of medicine wherein prophylaxis is more valuable than in dentistry. If we only knew and understood the mouth symptoms we could ward off disease in many instances. I have under way a series of experiments that are not completed, and I will give here a short report of them to show how these conditions—the urinary acidity and the indican will affect the tissues of the body.

For the past five years I have been making these experiments on seven male patients over 45 years of age who have interstitial gingivitis to a marked degree. All are fleshy,

weighing from 172 to 223 pounds. These patients all have painful micturition. They have been under my personal supervision all the time. All are suffering with acidemia and indicamuria. Four are high livers; three enjoy home life; five at times have urinary acidity of from 82 to 112 degrees; the other two do not exceed 60 degrees; all have abundant indican. These men are always about their business affairs. At times all suffering more or less with rheumatic neurotic pain, headaches, drowsiness, constipation, indigestion, gases in both stomach and bowels. These patients were experimented with in different ways. All were refused meat for a given time; all were refused acids and alcohols in all forms. Sodium bicarbonate was given in doses of from 5 to 20 grains 3 times a day one-half hour after meals until the acidity was reduced to below 35 degrees; from 30 to 40 degrees being normal. All patients were put on buttermilk. In four, the indican was reduced to a minimum and the pain subsided. In three indican remained in the urine. In these latter the buttermilk was withdrawn and intestinal antiseptics given. The indican was reduced by destroying the germs in the intestines. Meat was given for a period of a month or two as the case might be and the urinalysis continued. Painful micturition returned. The experiments showed when the acidity was high and there was abundant indican, painful and frequent micturition occurred. After the urinary acidity was reduced, the pain continued; the reduction of indican in the urine, however, caused the pain to cease and the frequency to lessen. It was also found that the interstitial gingivitis could be more readily reduced and a permanency secured in not only all these patients but in others who were not under special study. It would seem that the decomposition of proteid substances in the intestines and bodily waste do not when alone cause the development of indican but by combination with intestinal germs which are not associated with nitrogenous substances to any extent, and which cannot be destroyed by the lactic acid of buttermilk. One thing is certain, indican and a high urinary acidity act as irritants in the blood stream, and the alveolar process and dental pulp, which are end-organs, are directly and quickly involved.

DR. GEORGE V. I. BROWN, Milwaukee: Dr. E. C. Kirk of Philadelphia has done some interesting work recently. It is evident from the paper just read, that accompanying intestinal putrefaction and other similar conditions, there is a general acidosis which affects the mucous membrane of the mouth in common with other parts. Buccal acidity may also be due to results of local fermentation. We have known for some time that dental caries is fostered in its incipency by the formation of gelatinous plaques. No one, I believe, had satisfactorily shown just how they were formed until it occurred to Dr. Kirk to demonstrate that in the presence of lactic acid the mucin of the saliva is precipitated; he thus easily accounted for these plaques. In the same general way acidosis favors precipitation of mucin; it coats itself along the tongue and the mucous membrane of the cheeks, throat and other parts. Micro-organisms stick to it as flies stick to fly-paper. This explains in a perfectly rational way many of the oral symptoms which have been so long recognized as pathognomonic of many diseases. Dr. Kirk has finally brought this subject to a point at which all the results of the labor Dr. Talbot and others have expended in developing an understanding of the constitutional aspect of buccal disease, and that of Dr. Williams, Fletcher and others who have been investigating along certain other pathologic divisions, may be brought to a focus. The rationale of tonsillitis, pharyngitis and other allied conditions is easily comprehended when one remembers that the tonsillar crypts are filled with this mucin and the micro-organisms thus protected are permitted to multiply under most favorable conditions.

DR. HENRY O. HARROWER, Chicago: Some day when the dental and medical professions are more thoroughly stimulated the discussion of this subject will be much more eager. Dr. Talbot speaks of three patients in whom the indican seemed to remain. It has been proved conclusively that there is a close relation between prolapse of the abdominal viscera and indicamuria, and I would suggest that if Dr. Talbot would look into these three cases, he would find the patients "po-

bellied," and that if the abdominal contents were held in place the indicanuria would eventually disappear. He also referred to frequent and painful micturition. There is more to this than we think. This condition of hyperacidity or systemic acidemia is not only irritating to the kidneys but also to the urinary passages. I found in 25 per cent. of my first 250 cases that hyaline casts were present. Now hyaline casts are mucin, I believe; at all events, they are evidence of renal irritation, and it is not unreasonable to suppose that a condition which will cause the temporary presence of casts may be responsible for permanent kidney disorganization. I am not a crank on alveolitis, nor do I consider this condition of acidemia the sole cause of pyorrhea. Far from it. Unquestionably, local conditions play an important part and the presence of the acids of fermentation in the mouth have a greater bearing, perhaps, than the general condition.

"Acidemia" is the proper word to use in this connection. "Acidosis" is the old word, and Dr. Talbot still uses it. Acidosis is a condition referable in most cases to diabetes, or which only occurs when oxybutyric acid or its congeners are present; it may also be found after anesthesia; but the condition I refer to is properly called "acidemia."

THE PRESENT STATUS OF ANTITYPHOID INOCULATION *

GEORGE H. R. GOSMAN, M.D.

Major, Medical Corps, U. S. Army

WASHINGTON, D. C.

Antityphoid inoculation has been very thoroughly studied since 1896, when Pfeiffer did the pioneer work in it. Wright placed the method on a firm basis by his inoculations in the British army, both in India and during the Boer War; and since then there have been many contributions to the subject, especially by Leishman, whose work has helped greatly to bring the subject up to date, as has also the work of Major Russell of the United States Army. From these investigators I quote freely. Some of the later statistics are those of Leishman. These cover a period of three and a half years, to June, 1908. Of 5,453 soldiers vaccinated against the disease, only 21 took it, and 2 died; in 6,610 soldiers under practically the same conditions of life and surroundings, there were 187 cases, and 26 deaths. That is, there were 3.8 cases per thousand among the vaccinated, and 28.3 cases per thousand among the unvaccinated. The experience of the German army in southwest Africa has also been very satisfactory, the number of cases in their troops being only half as many among the protected as among the unprotected, while the death-rate was three times greater among those not protected by inoculation. At Peshawur, in India, Colonel Skinner, R. A. M. C., states that an actual epidemic of typhoid fever was cut short by inoculating 70 per cent. of the command, in addition to methods of sanitation.

These, with other figures, have proven to us that it has been so successful in reducing not only the death-rate but also the number of cases of typhoid fever, that our army is now using it and advocating its use. Not only does it reduce the number of cases, but when a case does appear in a patient who has been inoculated (which is rare, however), the course of the disease is much milder. The figures obtained from Major Russell of the U. S. Army, show that up to about June 1, 8,510 people have been inoculated by U. S. Army medical officers, and that there have been but few severe reactions to the inoc-

ulation. No bad results from it have been heard of, and the protection given by the inoculation has been very well marked, since there has not been a single case of typhoid in any one whose vaccination was completed, and yet there has been in the army at large, among the unprotected, considerably over 200 cases in the same period of time.

Now this is a very important fact, and certainly proves something; for it must be remembered that these inoculations have been given 8,510 people in 102 different army posts and localities, under entirely different surroundings, conditions of sanitation and conditions of exposure, and many of these must have been exposed to the disease more or less, located, as they are, near different large and small cities, from the northwest to the southeast of the United States. At Toledo, Ohio, Dr. Willard J. Stone has been using antityphoid inoculations for the past two years, especially with the idea of producing immunity among physicians and nurses; and he is firmly convinced of their efficacy, and is continuing their use. But I regret to state that their use for such purpose does not seem to be general, as I think it should be, among medical men in that part of the country, nor does it seem to be general in the large cities—as New York or Philadelphia—so far as I can find out, though in Boston more seems to have been done in the way, as you will see.

Dr. Stone has recently reported the successful treatment of a typhoid carrier by vaccine; and this is a great advance, for in his case the bacilli disappeared completely from the urine after six inoculations. Now if we can cure the carriers, then we are doing something, and my remarks in the latter part of this paper are even more important as showing that we need not be so afraid of the carrier. Dr. Stone, who has done a great deal of work in this line is very much in favor of it and states that he believes it offers more chance of cure of carriers than any other known method. This data has but recently come to me, and it should be considered carefully. Many of the individuals inoculated in the series just spoken of have shown, one month after the third inoculation, agglutinative values in dilutions as high as 1 to 500, so you can see this is good corroborative evidence.

During the past year at the Massachusetts General Hospital, there was carried on a series of inoculations under the direction of Spooner. He employed as a test of his results, not only the diminished amount of fever among the inoculated, but also a determination of the immune substance in the blood, using the agglutination test to do so. His results were so encouraging in his first series that he called for volunteers among the nurses and ward attendants, determined to make an effort to stamp out typhoid among the hospital attendants. A large number volunteered. Spooner inoculated nearly one hundred people to January, 1910, made a careful study of their inoculations, and had not a single bad result and only a few severe reactions. Though the reactions among the nurses as a rule were almost nothing, and the suffering and inconvenience among the majority almost *nil*, they all said they would have taken the inoculation anyway, with the hope of the immunity it held forth. This is a matter of considerable importance, because one of the things that hold people back from taking antityphoid inoculation is that they think they are going to suffer a great deal and have a very sore arm, as sometimes occurs in smallpox vaccination; but the fact that in the army we have now vaccinated over

* A lecture delivered to the officers at the camp of instruction, combined maneuvers, Chickamauga Park, Georgia, July 15 and 27, 1910. Published by authority of the Surgeon-General.

8,500 people is surely sufficient evidence that the procedure is harmless, and when I have shown that none of them has developed typhoid fever, while living all over the United States, even the most skeptical person ought to be convinced of the great value of these inoculations. And now the most important fact of all in reference to this last series of cases is that Spooner has lately written that this is the first year that no typhoid fever has originated in the Massachusetts General Hospital. Now it would seem, and I believe, that we can eradicate typhoid fever as it occurs among the nurses and attendants of all institutions. Think what a great thing that would be!

PREPARATION OF VACCINE AND METHOD OF USE

The therapeutic object to be desired in these inoculations, if we may call it such, is the production of specific antibodies which will antagonize and destroy the typhoid bacillus; and to place the patient as nearly as possible in the condition of one who has had typhoid fever. This is the object expressed in few and simple terms. I shall not attempt a scientific discussion of this part of the subject, as that is foreign to my title. I need hardly discuss here the method of preparation of the vaccine, but suffice it to say that the vaccine is taken from a typical typhoid culture which is grown on agar slants for twenty hours, and is then washed off into a small quantity of normal saline solution. It is then tested for purity, placed in sealed tubes and the bacteria killed by heat at 60 C. for one hour, $\frac{1}{4}$ of one per cent. of trikresol is added as a safeguard. The vaccine we use in the army is administered to at least two animals before being used on human beings, and thus the liability of contamination is very slight. Castellani finds that he can produce a higher degree of immunity by using live typhoid vaccines, prepared by a method of his own, which consists of heating non-virulent broth cultures at 50 C. He says that the method is free from danger. With this method we have had no experience, so I merely mention it. There are other methods spoken of in the various reviews on the subject, but the method as described here seems at present to suffice.

The site of the inoculation is the arm at the insertion of the deltoid muscle, the dose to be given subcutaneously, and not into the muscle or into the skin. The arm should be cleaned as for any other operation. After the vaccine has been injected, it is well to disinfect the needle puncture by touching it with a minute quantity of pure phenol or liquor cresolis comp. U. S. P. It is a good idea to massage the injected area for a few minutes. The glass container should be washed off in an anti-septic solution and opened after making one or more cuts near the top with a file. The vaccine can be drawn out of the container with a syringe, or it may be emptied into a salt cellar which has been sterilized by boiling. The syringe and needles should be sterilized by boiling in a 2 per cent. solution of soda. It is necessary to be sure and have perfect sterilization. A fresh needle must be used for each man, or if the same be used it must be plunged into boiling soda solution to re-sterilize it. The most suitable time for the administration of the vaccine is about 4 o'clock in the afternoon, as the greater part of the reaction then occurs before morning. No applicant should be vaccinated who is not perfectly healthy and free from fever at the time; and it is advisable in case of doubt to take the temperature and examine the urine. In case of any man who has fever or any other signs of illness, it should be postponed until he recovers.

This precaution is necessary to avoid the vaccination of men who may be coming down with typhoid fever.

According to the method most used now, three doses are given, ten days apart: the first of 500 million, and the second and third of 1,000 million each. This interval of ten days has been adopted because experience has shown that nothing is to be gained by giving the doses at shorter intervals. The method of giving it is simple and easy, and it can readily be done by any physician with due care for cleanliness.

REACTION AND PRODUCTION OF IMMUNITY

There is usually some headache and malaise, and local reaction consisting of a red and tender area about the size of the palm of the hand, and sometimes tenderness in the axillary glands. The entire reaction is over in forty-eight hours, and during this period it seems best not to permit any active exercise, such as long walks or rides. Some few individuals may be very susceptible and develop a severe general reaction, (headache, backache, nausea, vomiting, herpes labialis and, rarely, albuminuria, and some loss of body weight). The number of severe reactions has been small, and regardless of their severity they all disappear completely inside of forty-eight hours.

The production of large quantities of specific antibodies does not become evident until about eight or ten days after vaccination. The second dose is therefore not given until the first has become effective, since there may be a temporary fall in the quantity of protective bodies present in the serum after the administration of the second and third doses.

The question of increased susceptibility, or anaphylaxis, as it is termed, is one of some importance and worthy of remark, because it is still under discussion and in dispute to some extent, and has a bearing, perhaps, on the ideas of some against the inoculation. It is believed now, I can properly say, by most investigators, to be of no great importance, and so far I have been unable to obtain the history of any distinct case of anaphylaxis to typhoid vaccine. It is safe to say, therefore, that ordinarily the protection against typhoid commences immediately after the first dose and gets stronger and stronger up to a point as yet undetermined, because the inoculations have been so recently used in any great numbers that it is not yet possible to exactly determine the duration of the immunity from any available statistics.

But we know it gives protection and can do no harm; therefore, even if it only lasts a short time, why not use it? The English statistics quoted above show that it will last three years, and that is certainly long enough, because in the army one can easily revaccinate a man, and three years will carry a soldier through most campaigns. And again, three years will cover most nurses' period of training and most doctors' days of hospital work; and so, again, why not use it?

Antityphoid inoculation has been heartily indorsed by the Surgeon-General and his associates, after a rigid investigation of the subject by a board of eminent physicians of the country; and the Secretary of War has been asked to make it compulsory for all recruits, and it is hoped he will soon do so. So it will be seen how thoroughly convinced the U. S. Army medical department is of its desirability. The British authorities stand in the same position, as also do many civilian practitioners. In the U. S. Army it is explained to the men by lectures, and examples are shown, and so far

we have had a ready response from the men. I personally have inoculated over 200 applicants, and have not seen a patient sick enough to go to bed: and at Fort Barrancas, Florida, where the men have constantly been more or less exposed to typhoid fever, there has not been a case for nearly two years among approximately 700 men: and while as yet they have not all been inoculated, yet many have, and each one protected helps to prevent somebody else from getting the disease.

The history of the use of antityphoid inoculation we know goes back to 1898, and to many of us it may seem strange that such a promising procedure has been used so little up to date: and yet it seems not to have been popular or widely used among hospitals in civil life, in institutions, or among gangs of men working on big jobs. One of the main reasons for this is the idea among the people—and I find this is so to quite an extent in the army, too—that it gives the patient a bad sore arm, makes him sick and really prostrates him. This is not true. Very few suffer at all from it, and it is not to be compared in severity with the ordinary reaction from smallpox vaccination.

CONCLUSIONS*

Now, therefore, considering all the data I have presented on the subject, it seems that the present status of these inoculations against typhoid fever is that they are valuable as a method of preventing the disease and are perhaps the most valuable single asset we have in combating an epidemic, and that there is surely no doubt in the minds of most thinking and up to date medical men that they should be used in the following classes of persons: first, all nurses, ward attendants, hospital corps men, red cross assistants, physicians and medical students; also all persons who contemplate a journey into a section where typhoid is known to exist or is suspected of existing. Also, the inoculations should be done generally in districts suffering from an epidemic, and especially in the families where a case exists, and I might add that in time of war all volunteers at camps of concentration should be inoculated as soon as possible after the camp is started.

Finally, it seems that typhoid will always be with us, but there is no necessity of its always being with us in our armies to any such appalling extent as it has in the past; therefore, the necessity for antityphoid inoculations will surely always be with us, for no matter how careful we are of our sanitation, our milk, our water, our flies, our contact infection, we will always have one or more of our much talked of friends, the chronic typhoid carriers, and it is only by inoculating them and other friends and acquaintances that we can keep more or less of them free from typhoid.

I am convinced of the harmlessness, and at the same time, of the effectiveness of this procedure, and would recommend its universal adoption, to the end that our armies in time of peace and war, and our communities at all times, may be kept as free as possible from that terrible epidemic disease, typhoid.

And last, but not least, I believe I can state from a careful study and investigation of the matter that the present status of antityphoid inoculation as a means of prevention is assured, and that its future possibilities are great.

* Nearly 1,000 additional cases have been inoculated since this article was prepared, with about the same results; and Colonel Leishman's recent lectures before the Harben Society show, I believe, the same good results in the very latest work in the British Army.

THE TREATMENT OF SYPHILIS WITH EHRlich'S "606"*

HENRY J. NICHOLS, M.D.

Captain, Medical Corps, U. S. Army

AND

JOHN A. FORDYCE, M.D.

Professor of Dermatology and Syphilology, University and Bellevue Hospital Medical College

NEW YORK

PART I. THE THEORETICAL AND EXPERIMENTAL BASIS FOR THE USE OF "606"

The object of experimental chemotherapy is the preparation and discovery of drugs which shall possess specific powers over given parasitic micro-organisms. The pursuit of this object has recently been greatly promoted by the discovery by Professor Ehrlich of a drug which possesses extraordinary power of destruction over certain, at least, of the parasitic spirochetes. Ehrlich has for many years been engaged in the synthesis of drugs, the ultimate purpose of which was the destruction within the body of such parasitic organisms as trypanosomes and spirochetes under conditions in which the organic cells of the host would be left unaffected. In other words, and to use Ehrlich's terminology, it was necessary to seek drugs which were on the one hand highly parasitotropic and on the other were quite devoid of organotropic activities. In the course of this quest, Ehrlich has had the good fortune to produce a number of drugs which more or less fulfilled these ideal conditions, but recently the quest has been crowned with an extraordinary achievement that promises to be of the greatest importance in the treatment of syphilis and hence of incalculable benefit to the human race.

We may begin by summarizing a fragment of the conceptions which led Ehrlich to his most recent important discovery: The animal parasites causing malaria, trypanosomiasis, syphilis, amebic dysentery, etc., apparently can not be successfully attacked by means of immune sera, and therefore their conquest must be attempted by means of ordinary chemical substances. The history of the treatment of malaria with quinin indicated that this line of attack is a feasible one, particularly in view of the fact that quinin represents the successful employment of one drug out of an innumerable series tried by man in nature. It is possible through the aid of modern synthetic chemistry to prepare an almost infinite number of combinations which can then be tested on animals infected with the animal parasites of the diseases named, until compounds are found which exhibit a higher degree of poisonous effect on the parasite than on the host. Having achieved this first selection, the partially successful compound can then be further altered by possible substitutions, which may serve to render it still more suitable for the purposes in view.

While Ehrlich was engaged in developing this line of investigation, the substance atoxyl, which is an empirical arsenical compound, came into use in the treatment of sleeping sickness, for which it proved a highly useful although not invariably successful drug. This substance, which was demonstrated to be more poisonous for one of these animal parasites than for the human host, became the starting point for chemical variations which culminated in the preparation of the compound "606."

* From the Rockefeller Institute for Medical Research, New York.

The starting point of the successful substitutions in connection with atoxyl was the working out of its real constitution. It had been considered as an anilid of arsenic acid,

which, being an unstable compound, would not allow of the necessary chemical manipulation and substitution. In collaboration with his chemical assistant, Bertheim, Ehrlich ascertained that atoxyl is in fact the sodium salt of para-aminophenyl arsenic acid,

In this compound the molecule of arsenic is firmly attached to the benzole ring, because of which the compound admits of the necessary manipulation and substitution at different positions in the ring. Different substitution products were next prepared and tested for their therapeutic effects on infected animals. Up to the present time, about 630 substitution products have been made and tested, of which four only have proved to possess the requisite parasitotropic properties, without at the same time being injurious to the organs of the host. These substances are: acetyl-atoxyl; arsenophenyglycin, or "418," tryparosan, and arsenobenzol, or "606." Excepting the drug tryparosan, arsenic is the active principle in all the preparations, the other chemical groups present merely serving to fix this substance to the parasite. Thus for example it has been found that the acetyl group has a special affinity for trypanosomes and the amino and hydroxyl groups a special affinity for the spirochetes.

It is obvious that this kind of pharmacologic research is possible only if animals can be used as the basis of experiment. Fortunately, the discovery of the transmissibility of syphilis to the lower animals and of *Treponema pallidum*, the parasitic cause of syphilis, came to be achieved about this time. Hence the new drugs could be tested not only against fowl spirilla and the spiral organisms of relapsing fever, but also against *Treponema pallidum* in infected rabbits. In due time preparation No. "606" came thus to be tested, and was proved to be efficient in a single dose, which while it sufficed to destroy all the parasites was without perceptible injurious effect on the host.

In the course of previous investigations, Ehrlich had ascertained that it was not safe to attempt to destroy the animal parasites by means of repeated small doses of an injurious drug, and for the reason that in the course of this method of treatment, the parasites often develop a toleration for the drug which they transmit to their progeny. The goal, therefore, became the discovery of a drug which in a single dose would destroy all the parasites, leaving the host uninjured, and this extraordinary achievement apparently is accomplished by "606."

EHRlich's THERAPIA STERILISANS MAGNA

The drug having been proved by repeated tests on animals to be without injurious effect it was next tested on human beings. The first to submit to inoculation were the assistants, since which time several thousand persons suffering from various forms and consequences of syphilis have been treated.

The reports which are appearing at present in practically every number of the important German medical weeklies from different parts of Germany and Austria are almost unanimous in their testimony to the remarkable effects of the drug in syphilis. In all but a few exceptional instances a single dose of the drug has sufficed to bring about a rapid disappearance of the lesions of syphilis and equally rapid improvement in the general condition of the patients. In the few instances in which these rapid effects were not achieved the dose of the drug, which was originally given was, as is now established, too small, and in many of these cases a second and larger injection has brought about the desired result. It is noteworthy that in many instances the patients who have improved rapidly after an injection of this drug had resisted the application of mercury sometimes over many months, or possessed idiosyncracies which made the use of mercury difficult or impossible. Thus far, a special idiosyncrasy against the drug has not come under notice. It is as yet too early to determine whether the patients who have responded so rapidly and perfectly to the administration of the drug as apparently to have been cured of this otherwise chronic disease by a single injection may ultimately suffer relapses. On the other hand many scores of patients have shown no relapses in the several months which have elapsed since the injections. What is highly important in the interests of prophylaxis is that within twenty-four or forty-eight hours of the injection of the drug superficial lesions, such as mucous patches, condylomata and primary lesions are freed from living spirochetes. This remarkable effect of the drug on the parasites can be readily demonstrated on the testicular spirochetal lesions of the rabbit, in which the innumerable spirochetes can be entirely immobilized within twenty-four hours with a single injection of the drug, after which the lesion quickly resolves.

ADMINISTRATION OF THE DRUG

The chemical name of "606" is paradiamidodioxo-arsenobenzole dihydrochlorid.

The substance is a yellowish powder which rapidly oxidizes on exposure to air, and is therefore put up in vacuum tubes. It dissolves in water with difficulty, making a strongly acid solution. As the acid solution is very painful, the substance is administered either as a neutral base (Wechselmann) or as an alkaline salt (Alt). The administration is by injection deep into the muscles, or into the veins or beneath the skin. At first, the administration was made either deeply into the muscles of the buttocks or into the circulation, but at present it is recommended that the administration be made subcutaneously according to the method of Wechselmann.

According to this method, the drug, in a dose which has varied up to the present from 0.3 to 0.6 grams, is dissolved in a mortar in 1 to 2 c.c. of ordinary solution of sodium hydrate. Acetic acid is then added, drop by drop, until the base precipitates out in the form of a fine yellowish suspension. This precipitate is collected in

subdivide the precipitate as finely as possible, which can be done by rubbing. The suspension is then drawn into a suitable syringe and injected subcutaneously below the shoulder blades after previous cleansing and disinfection of the part. It often happens that there is slight pain lasting a few minutes following the injection, and in

TABLE OF RESULTS OF USE OF EHRLICH'S 606 IN SYPHILIS

No.	Age.	Sex.	Infection.	Previous Treatment.	Condition Before Injection.	Injection.	Local Effects.	Condition After Injection.	Serum Reaction.	Remarks.
1	25	M	1 '10, chancre; 2 '10, secondaries.	11 injections 1 gr. Hg Sal.	General secondary eruption; enlarged lymph nodes; serum +	5 12 '10; 8 c.c. each buttock. 0.3 gm. 606, not completely dissolved. Alt method.	Induration for 7 days; slight pain.	No improvement in 3 weeks.	6 16 '10+35 days.	Small dose, resumed mercury.
2	38	M	1905, chancre and secondaries.	Irregular.	Tertiary syphiloma of back and chest; serum ++	5 12 '10; 8 c.c. each buttock. 0.3 gm. 606, not completely dissolved. Alt method.	Marked induration, 7 days, scaly erythema of hands and feet.	Slight improvement in 3 weeks.	6 10 '10++29 days.	Small dose, resumed mercury and KI; drug eruption.
3	21	M	3 1910, chancre; 5 1910, secondaries.	Only local treatment.	Circinate syphilitid of face; macular syphilitid of trunk; enlarged lymph nodes; serum ++	5 16 '10; 0.3 gm. 606; 8 c.c. each buttock. Alt method.	Induration of buttocks for 7 days.	After 8 dys. lesions gone on face, and faint on body.	5 23 '10+7 days.	Left hospital 5, 24, '10, considering himself well. Could not be traced.
4	32	M	5 1907, chancre and secondaries.	More or less constant; liquid.	Sealing syphilitid of palms severe. Serum ++	5 16 '10; 0.3 gm.; 12 c.c. each buttock. Alt method.	Induration lasting 7 days, slight fever 2 days.	5% improvement in palms after 7 days. Completely healed in 1 month.	6 10 '10-25 days.	Began to work as orderly in hosp. 6/6; apparently cured by single injection. See Photographs Figs. 1 and 2.
5	20	F	4 1910, secondaries.	4 grs. Hg Sal. by injection	6 mos. pregnant; faint eruption. Serum +	5 19; 0.3 gm. 606; 10 c.c. each buttock. Methyl alcohol.	Marked induration 5 days, urticarial eruption 2 days.	Apparently well in 21 days.	6 28 - 39 days.	Aborted 5 29; fetus badly macerated, could not be obtained for examination.
6	24	M	10 1909, chancre; 12 1909, secondaries.	Mercury in pill form for several months.	Severe rupial lesions, face, head and arms; hysterical. Serum ++	5 19; 0.3 gm. 606; 10 c.c. each buttock. Methyl alcohol.	Slight induration 4 days.	Marked rapid and progressive improvement. Lesions healed in 39 days.	8 30 - 3 mos. 11 days.	Gained 12 pounds. No recurrence in 3 mos. Photograph Figs. 3, 4.
7	54	M	1882, chancre and secondaries.	10 days treatment in 1882.	Ulcerating syphilitid of knee and leg. Serum ++	5 23; 0.3 gm. 606; 10 c.c. each buttock. Methyl alcohol.	Marked induration of buttocks 7 days.	Sinuses closed induration gone and lesions of light color 21 days.	6 10 - 21 days.	Apparently cured.
8	25	M	10 1909, chancre; 1 1910, secondaries.	2 grs. Hg Sal. by injection	Mucous patches, fading follicular syphilitids of body. Serum +	5 23; .03 gm. 606; 10 c.c. each buttock. Methyl alcohol.	Slight induration.	Marked improvement, lesions gone in 2 weeks.	6 11 - 19 days.	Apparently cured by single injection.
9	28	M	5 1909, chancre; 9 1909, secondaries.	"1 bottle of medicine."	Severe extensive pustular and tubercular syphilitids of face and shoulders. Serum ++	5 26; 0.3 gm. 606; 10 c.c. each buttock. Methyl alcohol.	Induration of buttock 5 days.	Marked improvement. Lesions dry and faint in 14 days.	Gain in weight. Left hospital and could not be traced.
10	24	M	1907, chancre and secondaries.	KI 7 months	Severe periostitis, left tibia. Serum +	6 7/2; 0.3 gm. 606; 10 c.c. each buttock. Methyl alcohol.	Marked induration 7 days.	Pain and swelling disappeared in 8 days.	8 30 - 3 mos.	No recurrence in 3 mos.
11	28	M	1 1910, chancre; 5 1910, secondaries.	No treatment.	Mucous patches and macular eruption on face and legs. Serum +	6 2; 0.3 gm. 606; 10 c.c. each buttock. Methyl alcohol.	Induration 7 days.	Face and leg clear in 7 days.	6 23 - 21 days.	Apparently cured by single injection.
12	22	M	4 1910, 3 chancres on lips; 5/19 0, secondary eruption.	2 grs. Hg Sal. hypodermically.	3 large indurated chancres on lips; erythematous papular eruption on body. Serum ++	6 2; 0.3 gm. 606; 10 c.c. each buttock. Methyl alcohol.	Induration of buttock 5 days.	Chancre gone, eruption very faint; 21 days.	Great improvement in general condition. Photograph Figs. 5, 6. Could not be traced after leaving hospital.
13	29	M	1905, chancre and secondaries.	Treated 4 wks. in hospital, 1905; 1906, 8 weeks in hospital.	Arthritis of knee, broken down glands of groin, emaciated, anemic. Serum +	6 7; .03 gm. 606; 7 c.c. each buttock. Methyl alcohol.	Slight induration.	Marked and rapid improvement in general condition and lesions in 10 days.	6 30 - 23 days.	Apparently cured; 8 30 working as longshoreman; has gained 30 lbs.; serum
14	20	F	6 1910, chancre and secondaries.	No treatment.	Mucous patches, general eruption. Serum.	6 7; 0.3 gm. 606; 7 c.c. each buttock. Methyl alcohol.	Induration 5 days.	Eruption and sores disappeared in 10 days.	Left hospital and could not be traced.

from 1 to 2 c.c. of sterile distilled water, and there are added either 1-10 normal sodium hydrate, or 1 per cent. acetic acid, as needed, until the reaction becomes precisely neutral to litmus. According as the reaction is or is not accurately neutral the injection will be followed by much, little or no pain. It is moreover desirable to

some instances a slight swelling arises on the second or third day following the injection, but no bad effects are produced. There may be slight rise of temperature and in some instances an urticarial eruption has occurred, but no specific toxic effects on the eyes, kidneys, or nervous system have been observed.

PERSONAL OBSERVATIONS

Although the number of cases to be reported on at present is small, the results have been so striking, and are in such accurate accord with the several thousands of cases reported from Germany that it has seemed desirable to make this report, especially because it is probable

one-half of the dose now being employed abroad. Hence it would not be surprising if in this first group relapses occurred. If so it would be both safe and desirable that a second and larger injection be given.

The efficiency of the drug is dependent in part on the dose employed. Hata has permanently cured all rabbits having spirochetal lesions by means of a single dose of an adequate size. We have found that when the dose is too small, relapses occur in the infected rabbits. Hence now that it has been determined that a dose of 0.6 gram is non-toxic for human beings, it is probable that the average dose will approach that quantity. At present, European observers are employing doses varying from 0.45 to 0.6 gram.

The drug is not generally available at the present time. The output is too small for general distribution, and Ehrlich has therefore up to the present been able to supply it to relatively few physicians, whose employment of it has also been in the nature of tests of its value. The final word concerning its value will not of course be said for a number of years, but the fact remains that we possess no drug the extraordinary effects of which in syphilis equals that of "606."

Fig. 1. Scaling syphilitic of palms. A. K. Duration of infection, three years; of palmar lesions, one year. May 16, 1910, 0.3 gm. 606. Wassermann before treatment, ++; June 10, 1910, negative; Sept. 1, 1910, still negative. (See photograph after treatment.)

that the drug will come to be extensively used throughout the United States. The patients were all in the City Hospital on Blackwell's Island, in the skin and venereal wards. The clinical diagnoses were all definite and unmistakable, and the serum reactions which were made regularly were conducted with the Noguchi modification of the Wassermann method.

In injecting the preparation into the first two patients considerable difficulty was experienced in getting the powder into solution, and the full dose of 0.3 gram which it was intended to administer was therefore not given. As we now know, 0.3 gram is a submaximal dose. These patients were injected before the method of Wechselmann had come into use, and even before the earlier modification of the original "Mt" method of preparation suggested by Ehrlich had been published. As a result no marked improvement occurred and the patients were put back on mercurial treatment. The remaining twelve received the full dose intended, and included examples of primary, secondary and tertiary lesions. The effects were in these instances truly remarkable and now, from three to four months after the injections relapses have not been observed to occur. Before the treatment the serum reactions were all positive and at the expiration of the time mentioned, in all the patients who could be traced, they have become negative. Aside from the temporary local disturbance caused by the injection in some instances, no untoward symptoms were observed, except an urticarial eruption in two of the cases. None of the patients received more than 0.3 gram, which is about

Fig. 2. Scaling syphilitic of palms. A. K. Condition of palms two weeks after treatment with 606. (See photograph before treatment.)

The one drug with which it may be compared is quinin, which in many instances is so highly efficient in the treatment of malaria, but even there a single dose does not suffice to destroy all immediately visible parasites, as does an adequate dose of "606."

PART II. THE USE OF "606" FROM THE STANDPOINT OF THE CLINICIAN

Personal experience in the treatment of syphilis has convinced us that mercury given in the early stages in as large doses as the system will tolerate insures the patient more certainly against relapses, and that patients who are treated by small doses over long periods of time in the manner which is still too often employed by even the best known syphilographers sometimes develops in the patient thus treated an immunity to the drug which renders it comparatively inert. This latter class of patients not infrequently become the subjects of obstinate relapsing lesions of the skin and mucous membrane or, later, the victims of paresis, tabes, or other visceral or bone affections. Professor Ehrlich's contention, therefore, as to the value of a drug which at one dose destroys the invading organism is supported by clinical experience in the use of mercury. It is true that the methods of administering the latter have been greatly improved in the last few years, as is witnessed by the greater fre-

treatment by the Wassermann reaction cannot be too strongly emphasized, showing as it does that in the past some patients may have been greatly overtreated while the majority have received too little of the specific drugs. It is well known that there are certain cutaneous and general manifestations of syphilis which respond slowly or not at all to mercury even in heroic doses. Among these may be mentioned certain scaling syphilids of the palms, chronic nodular syphilids in patches of the type which clinically resembles lupus vulgaris, certain forms which affect the flush area of the face and bear a marked clinical resemblance to lupus erythematosus; also mucous membrane affections like leucoplakia, chronic interstitial glossitis and relapsing deep and superficial lesions of the tongue and throat. Aside from these lesions which are under direct observation there are the so-called parasymphilitic manifestations, such as tabes, the treatment of which by the classical drugs leaves much to be desired. In malignant syphilis with early destructive lesions and the development of profound cachexia,

Fig. 3.—Nodular and ulcerating syphilid. W. C. N., date of luetic infection, October, 1909. Rupial and fungating lesions of face and arms of six months' duration. May 19, 1910, received 0.3 gm. 606. Wassermann before treatment, +++; Aug. 30, 1910, negative. (See photograph after treatment.)

Fig. 4.—Nodular and ulcerating syphilid. W. C. N. After treatment with 606. (See photograph before treatment.)

quency with which it is employed hypodermically and by injection, but our present means are still too often slow or inefficient in their action especially in the early stages. Delay or insufficiency in the amount of mercury at this time permits the entire system to become infected by the *Treponema pallidum* and damage to the blood-vessels or important structures takes place which might be prevented by energetic treatment. It will generally be conceded by physicians who come in contact with a large number of syphilitics that while mercury and potassium iodid are efficient in the great majority of cases in controlling the manifestations of the disease, there are certain intractable cases in which they fail to control the symptoms either on account of idiosyncrasy to one or both of these drugs or other causes. Furthermore, owing to the length of time required in treating a case of this infection patients often become discouraged and cease medication after a few months or a year or two. The great advance made in controlling the

mercury, moreover, often fails to do good and not infrequently does harm. When, therefore, Dr. Flexner, of the Rockefeller Institute, in the early part of May, this year, received a supply of the new preparation "606" and asked to be allowed to try it in a number of selected cases in the City Hospital, the proposition was received with favor and the patients in the skin and venereal wards were placed at his disposal. At that time the experience in the use of the drug had been rather limited and the patients who were treated were carefully selected as free from organic disease of the kidneys, heart or eyes; in fact, all the contraindications for the use of the drug, as stated by Prof. Ehrlich, were carefully observed. The patients were also informed that a new drug was about to be employed which would cause them a considerable amount of pain and was yet in the experimental stage. There was no difficulty in obtaining their consent, and the most striking testimony as to its value in the treatment of obstinate cases of lues was furnished by other patients in the wards, who on seeing

the results accomplished by its use repeatedly asked that it be given to them.

The rapid action of arsenobenzol in cases of obstinate syphilis of the palms is strikingly illustrated in Figures 1 and 2.

Patient, aged 32, had a genital chancre three years before, which was followed by the usual secondary symptoms. Following his infection he had taken medicine in "liquid and capsule" form almost continuously. The eruption on his hands was of one year's duration. The Wassermann reaction was strongly positive. On May 16, 1910, he received 0.3 gm. "606." Two weeks afterward his palms presented the appearance shown in Figure 2 and in another fortnight he was entirely well.

The result obtained by the use of "606" in this case was far more rapid than any which we have seen after the use of mercury. Furthermore, after an apparent cure from mercury in these cases of chronic palmar syphilis the majority relapse within a few weeks to a month or two, whereas this patient had had no recurrence up to

obtain complete resolution under several weeks to two or three months; in fact, the induration sometimes persists for a year or longer. As these extragenital initial lesions are a source of great mental distress to the patient and one of danger to his environment, their rapid retrogression under this remedy surpassed the result which could have been expected from mercury.

Figures 3 and 4 illustrate a rather malignant form of eruption which occurred less than one year after infection:

Patient, aged 24, contracted syphilis in October, 1909. A month later a pustular eruption appeared first on his face and then on the body. The lesions become rupial and afterward assumed a fungating type. He also suffered from sore throat, headaches and osteocopic pains. From October up to the time he entered the hospital he had taken mercury in pill form. On May 19, 1910, he received 0.3 gm. "606." There was a perceptible change after a week; the patient's general condition improved and in two weeks he gained 9 pounds.

This form of early malignant syphilis, which indicates low resisting power on the part of the infected

Fig. 5.—Multiple chancres. J. S. C., infection two months ago. Two chancres on upper lip and one on lower in median line; papulo-erythematous eruption on body. June 2, 1910, 0.3 gm. 606. Wassermann before treatment, + . . . (See photograph after treatment.)

Fig. 6.—Multiple chancres. J. S. C. After treatment with 606. (See photograph before treatment.)

September first and the Wassermann reaction has remained negative.

In the case of multiple initial lesions of the lip (Figures 5 and 6) of two months' duration, with secondary manifestations of the skin, complete resolution of the chancres took place within about ten days, leaving practically no evidence of their former existence. The entire appearance of the patient, too, underwent a marked change, as before treatment he was anemic, depressed, and evidently showing considerable constitutional disturbance from his infection. The great improvement which took place in his general condition after the injection continued up to the time he left the hospital. The Wassermann reaction at that time was negative. The duration of the initial sclerosis under mercurial treatment is a very variable one. It is unusual, however, to

individual, sometimes fails to respond to mercury. The almost magical result which followed the use of "606" is illustrated in Figure 4 which was taken about two weeks after the administration of the drug. Up to September 1 the patient had remained well and showed a negative Wassermann reaction.

The cases just referred to are examples of the most brilliant results obtained. In the table additional data are given bearing on the other cases which were treated at the City Hospital. Through the kindness of Dr. Flexner, we have been able in the past month to secure a sufficient quantity of the remedy to treat several private patients who are still under observation; the cases will be reported in greater detail later. One of these was a case of rapidly progressing optic neuritis with tabetic symptoms, the result of a specific infection twenty years before:

Patient, referred by Dr. Marks of Frankfort, was a man, aged 38, in whom it was noticed two and a half years ago

that his pupils were smaller than normal. Shortly afterward, he developed a diplopia which was diagnosed by the ophthalmologist as paralysis of the right abducens and beginning atrophy of the optic nerve. From that time until August 1 he had been under active mercurial treatment but without benefit. His vision since April, 1910, has been rapidly diminishing and he has concentrically contracted field, Argyll-Robertson pupil and partial atrophy of both optic nerves. Although we recognized that affections of the optic nerve are given as a theoretical contraindication to the use of "606," still at the urgent solicitation of the patient and his friends the drug was administered, but he was told beforehand that very little result was to be hoped for. A dose, 0.45 gm., was prepared after the method of Wechselmann and injected beneath the right shoulder blade. This was followed by severe pain which persisted for three or four days and had to be controlled by several hypodermics of morphin. On the second day, a marked swelling appeared at the site of injection which began to resolve at the end of a week. At no time was there any evidence of softening. The patient's temperature rose slightly on the second day reaching 100.4 F.; his pulse was rather high for the first week varying from 90 to 110 and he developed considerable physical weakness. Although little result was expected from the drug in this case, the patient is under the impression that the rapid progress of the disease has been arrested.

In the following case of cerebral syphilis an improvement took place in some of the symptoms which mercury and other medication had failed to influence:

Patient was a man, aged 38, whose infection dated back six years. In February, 1910, the neurologic examination made by Dr. M. G. Schlapp was as follows: "Pupils unequal, the right being larger; they react to light, not to accommodation—very nearly Argyll-Robertson condition. Speech thick, not truly scanning. General involvement of the muscles of the pharynx, tongue and face on right side; anesthesia in the same area. Partial paralysis in the right leg. Foot dragged in walking; weakness in the leg is sufficient to prevent standing on it. Babinski sign pronounced; clonus in both knee and ankle, the whole leg anesthetic." In spite of vigorous mercurial and iodine medication there occurred an increase in symptoms and area involved in June, 1910, while staying in England. The patient lost consciousness on several occasions; he also had facial paralysis complete for a time on the right side. Both legs developed weakness and anesthesia (patient's statement). A similar attack occurred in July, 1910, after a slight improvement, again involving both legs and right side of the face. Incontinence of urine marked. Under 43 injections of a mercury arsenalate, 20 injections and a daily dose of 3 grams of sajodin, rest and hydrotherapy, sufficient improvement occurred to enable the patient to get about.

On August 31 he was given an injection of 0.45 gm. "606" subcutaneously. A Wassermann reaction on this day was positive. Absolutely no pain followed this injection, nor were any unpleasant effects of any kind experienced except the induration which persisted for ten days. Improvement was noted on the day following the injection and he left the hospital on the second day, remaining in bed, however, in his home for two or three days longer. On the day succeeding the injection the patient stated that the mental depression from which he suffered weeks before had become materially less, his facial paralysis showed improvement and his speech disturbance was less marked.

A second examination made by Dr. Schlapp on September 9, nine days after the injection of "606" is as follows: "Pupils in same condition as at first examination. Incontinence has ceased. Paralysis of face and speech muscles has improved; anesthesia the same as at first examination. Right-sided sweating of the face, neck and upper part of the trunk. Both legs show Babinski sign, ankle and knee clonus, indicating extension of the process since February. There is, however, a noticeable decrease in anesthesia and muscular weakness. Diagnosis: Syphilitic obliterating endarteritis of the base, involving both pyramidal tracts and the sympathetic."

The patient was kindly referred by Dr. James C. Johnston, under whose care he is at present. A further report will be made at a later date. (September 21, Wassermann reaction still + —.) The absence of pain in this case was probably due to greater experience and care in preparing the remedy. It is important to emphasize the necessity of thoroughly rubbing the precipitate which follows the addition of acetic acid to the caustic soda solution until a homogeneous paste is obtained. The neutralization of the mixture should then follow and the latest technic as given by Wechselmann¹ observed.

The question of danger in the use of the new drug is one that should be touched on. It would be a marvel should a drug so potent as this one in the destruction of living parasites within the body be wholly devoid of injurious or secondary effects on the organs. We possess indeed no really pharmacologically active drug for which there may not exist contraindications and from which secondary and objectionable effects have not been noted. Certainly neither mercury nor iodid of potassium form exceptions to this rule. The remarkable fact about "606" is that in the several thousand cases in which it has already been employed, and considering the wretched physical state in which many of the patients were at the time of the injection, so very few untoward effects have occurred. It is now clear that the mode of administration is important, and especially the elimination of the methyl alcohol used at an early period to dissolve the drug, since this substance may produce unpleasant if temporary symptoms, as in the three cases reported by Bohac and Sobotka.² The result in a case of Hoffmann's³ in which a central embolic pneumonia, terminating in recovery, followed an intragluteal injection, was probably analogous to the condition of the lungs which may follow from an intramuscular injection of insoluble mercurial salts when the needle has inadvertently penetrated a vein. Ehrlich has warned against the administration of the drug to weak patients suffering from advanced cardiovascular disease, and the wisdom of this precaution has been emphasized by the two accidents encountered at the Charité in Berlin and the neurologic clinic at Bonn. Ehrlich further warns against the use of the drug in cases in which lesions of the optic nerve exist, and urges that in doubtful cases an ophthalmologic examination be made. Finally, it has just been announced that a further improvement in the preparation of "606" has been made which still further reduces the toxicity—indeed it is stated to be one-third that of the older substance. To this preparation Ehrlich has given the name "hyperideal."

From the collective reports of those who have used the drug the impression is gaining that we have in arsenobenzol a most thorough agent in controlling the manifestations of syphilis which are caused by the presence of the treponema. It may reasonably be hoped, therefore, that all the lesions which depend on the presence of the organism will be favorably influenced and the most we can expect in the secondary degenerative changes is that the process may become arrested. Further experience with the drug will determine with more accuracy the dose which is necessary to bring about a cure, the time that must elapse before a second dose can be safely given and the more definite indications for its

use after relapses or failure of a single dose to control the symptoms.

The authors desire to acknowledge the courtesy of Dr. Robert H. Greene and Dr. Eugene Fuller in placing certain patients at their disposal.

CREATININ AND CREATIN METABOLISM IN CHILDREN *

J. P. SEDGWICK, B.S., M.D.

Instructor in Physiological Chemistry and Clinical Instructor in the Diseases of Children, University of Minnesota; Pediatricist to City and Asbury Hospitals
MINNEAPOLIS

In a lecture, delivered before the Harvey Society two years ago, Folin¹ said:

I venture to predict that we shall learn more concerning the abnormal or subnormal metabolism of the sick on the basis of creatinin and creatin determinations alone than could be learned in another thirty years by means of the nitrogen determinations of the past.

Creatin is methyl guanidin acetic acid and may be converted into creatinin by the withdrawal of one molecule of water. It would seem remarkable that creatin, which is the most important of the extractives of muscle and the chief constituent of broths and beef extracts, and creatinin, a constant constituent of the urine, should have received so little attention in clinical medicine. This seems to be even more striking when we consider that uric acid, which appears usually in smaller quantity, both absolutely and in nitrogen content, in human urine, has been the subject of so much discussion.

The explanation lies in the fact that the older method of determination, which depends on the precipitation of creatinin with zinc chloride, was very tedious and unreliable. It was in 1904 that Folin² published his accurate and simple method of determination which has given such an impetus to the study of creatinin and creatin metabolism. Folin's method depends on the fact that creatinin gives, with picric acid and sodium hydrate, a brownish-red color which cannot be distinguished from that of a potassium bichromate solution. The urine is treated with the above reagents, in proper quantity, and the resulting depth of color compared with that of a half normal bichromate solution. The degree of color produced is read off on a colorimeter and the creatinin content is thus given. Creatin may be estimated by boiling it with normal hydrochloric acid, thus converting it into creatin, which latter is then determined as above.

Evidently the creatin and creatinin excreted may come either from the food taken in or from the metabolism within the body, exogenous or endogenous. On a creatin- and creatinin-free diet Folin was able to show that normal persons excrete creatinin but no creatin. Creatin given by the mouth, unless fed in large quantities, does not appear in the urine, and then in part only. The administration of creatin was found to have no effect on the amount of creatinin excreted.

Both Folin³ and Hoogenhuyze and Verploegh⁴ were able to demonstrate the very interesting fact that, although the creatinin excretion differs in different subjects, a given individual, under normal conditions, excretes a remarkably constant amount of creatinin. This is so constant, in fact, that at one time Folin was able to trace the loss of urine from a twenty-four-hour specimen because of the drop in the creatinin content.

* Read in the Section on Diseases of Children of the American Medical Association, at the Sixty-first Annual Session, held at St. Louis, June, 1910.

Position Assumed by Patient in Ear Disease.—According to W. E. Chamberlain in the *Ohio State Medical Journal*, in case of nystagmus of otitic or cerebellar origin the position of the patient in bed is of interest and easy of explanation. With a circumscribed inflammation on the right side and with it a nystagmus to the right, the patient lies on the right side with the head buried in the pillow. In this position, the eyes are turned involuntarily toward the left and the nystagmus and dizziness are decreased. Let now a diffuse supuration follow the circumscribed or let the right labyrinth be removed by operation, then the patient does not lie on the right but on the left side, for in this position the eyes are directed to the right. The nystagmus and dizziness, most extreme with vision toward the left are decreased by looking in the opposite direction. Placed in the Romberg position, a patient with nystagmus to the right will fall to the left and *vice versa*. In other words, he falls in the direction of the slow component.

Hoogenhuyze and Verploegh found the creatinin excretion to be little affected by hard muscular exercise or by protein diet. A professional faster, who had taken nothing but water for fourteen days, did, however, show an increase of creatinin excretion after exercise. This is of interest in connection with the creatinin excretion during the first fasting days of infancy, and will be referred to later.

The creatinin excretion is higher, according to Hoogenhuyze and Verploegh, during the day than at night. The creatinin excretion is somewhat higher under the influence of alcohol and cola, but somewhat lower on days of rest. Van Hoogenhuyze's creatinin excretion rose from 1.85 gm. to 2.781 gm. during fever. A paralyzed patient, on the contrary, showed but 9.2 mg. of creatinin daily in the urine. During periods of excitement in insane patients the creatinin excretion rises. Creatin may appear in the urine of fever patients.

Pekelharing⁵ says that creatinin excreted through the kidneys must be considered as: (1) from the creatin formation through the consumption of proteins in the

creatin and creatinin may be found in the amniotic fluid.

I acidified and boiled the amniotic fluid obtained from the extirpated uterms of a pregnant bitch, and filtered to remove the native proteins: 10 c.c. of the resulting fluid gave a faint but definite Jaffé reaction for creatinin; 50 c.c. of the same fluid evaporated to dryness, redissolved in 10 c.c. of water, added to 10 c.c. of normal hydrochloric acid and heated to 90 C. for four hours, thus converting all of the creatin, if present, into creatinin, gave, by Folin's method, 5.5 mgs.; 25 c.c. of human amniotic fluid, obtained without contamination, by puncturing the bag of waters before the oncoming head, were treated in the same manner. A definite creatinin reaction was given, but it was too dilute for accurate estimation. (Diluted to 100 c.c. it gave a reading of 25 mm. on the colorimeter.)

These results, taken with those immediately following, would point toward a fetal creatin or creatinin excretion.

As the first few days of life are passed under conditions quite different from those of later infancy,

tissues; (2) from the splitting and oxidation of creatin, and (3) from the dehydrating action.

If we turn now from this necessarily incomplete discussion of creatin and creatinin metabolism in adults to that in children, the creatin literature may be shortly disposed of. I know of no other analyses in children than those reported in this study and those of Amberg and Morrill.

We may take up the study chronologically. Are creatin and creatinin excreted before birth? If these bodies are excreted before birth they will appear in the amniotic fluid. Of course it is evident that the converse does not necessarily hold true. Creatin and creatinin in the amniotic fluid are not necessarily derived from the fetal kidney excretion. Their demonstration would, however, be an indication. Panzer's⁶ analyses showed no creatinin or creatin in the amniotic fluid, but his work was published in 1899. Von Winckel⁷ says that

especially as regards food intake, it may be of interest to consider them apart. Here, again, I was able to find no results recorded in the literature. The interesting work of Amberg and Morrill⁸ on the "Excretion of Creatinin in the New-born Infant" misses this period, as their youngest infant was 7 days old. The work of Rietschel,⁹ Van Hoogenhuyze and Verploegh and others was done on older infants.

In the work with the urine of older infants, as carried on by other authors, the dilution of the urine has caused great technical difficulty, resulting at times either in the failure to discover the creatinin with the Weyl or zinc chlorid methods or requiring concentration by evaporation for quantitative work with the Folin method.

One is at once struck, in working with the urine of the first week, by the intense reactions. The per cent. of creatinin is as high as in adult urine, about 0.1.

The amount of creatinin excreted each day for each infant may be seen from Table 1.

5. Pekelharing: Zentralbl. f. d. ges. Physiol., u. Path., d. Stoffwechs., iv, 8.

6. Panzer: Cited from fisiologia e pathologia del liquido amniotico, Trovati.

7. v. Winckel: Handbuch der Geburtshilfe, i, 329, Wiesbaden, 1903.

8. Amberg and Morrill: Jour. Biol. Chem., 1907, iii, 311.
9. Rietschel: Jahrb. f. Kinderb., 1905, lxi, 615.

It will be seen that the daily excretion does not remain as constant as with adults. This may be apparent or real. It is evident that, when working with such small day quantities, a few c.c. of urine retained in the bladder at the end of a twenty-four-hour period would cause considerable difference in the result.

Creatinin was, however, present in each case.

The urines in Table 2 were heated over a water-bath for 10 minutes with 2 c.c. of normal hydrochloric acid in order to avoid any error which might be due to the acetone bodies, as the latter were found to be present at times during the first week. This series shows also that creatinin was continually present.

It will be noted in the table that these urines were also treated with 10 c.c. of normal hydrochloric acid for four hours to convert any creatin present into creatinin. Creatin is represented by the difference between the first creatinin reading and the second or creatinin and creatin reading.

These infants were all at the breast and therefore on an almost starvation diet, receiving nothing at first but a small amount of colostrum. In many cases creatin was present in demonstrable quantities, which seemed to increase markedly about the fourth day. Whether this was because of the period of starvation the infant had undergone, the beginning of feeding, both or neither, I am not prepared to say.

If we proceed to the period following the establishment of lactation we have the results of others for comparison. Most texts on pediatrics make no mention of creatin or creatinin. Langstein and Meyer¹⁰ consider creatinin, and stress is laid on the point that, as the infant's food contains no creatinin, that which occurs in the urine must be of endogenous origin or from the "breaking down of certain body tissues—muscle."

So recent a work as von Noorden's Handbook (1906) follows Hoffmann¹¹ as authority for the statement that the urine of infants contains no creatinin. Hoffmann's work was done with the unsatisfactory zinc chlorid method. Rietschel,⁹ working also with an imperfect method, came to a similar conclusion, although he did find traces in febrile urine, and after the administration of creatinin.

This was the state of our knowledge at the time that my study was taken up, in 1906. I found with Rietschel that the Weyl reaction and the zinc chlorid reaction did not give constant results. I did at that time, however, find that the Jaffe reaction for creatinin is constant in infant's urine. Hoogenhuyze and Vorploegh found creatinin present in infant's urine, although their analyses were not made on twenty-four quantities.

The first satisfactory published analyses are those of Amberg and Morrill,⁸ in which they report five analyses on infants 10, 10, 14, 7 and 13 days of age. The infants excreted respectively 26, 26.92, 27.05, 17.48 and 3.01 mg. of creatinin per day. The last infant excreted 2.87 mg. of creatin. They¹² also report analyses made on the urine of an infant beginning with its twenty-sixth day. The analyses are given in forty-eight-hour periods and show: A, 76.9; B, 59.2; C, 75.2; E, 96.1; F, 66.4; G, 59.7; H, 62.7 mg. The creatin excretion during the same period was 11.6, 17.2, 11.1, 0.4, 8.1 and 11.7 mg.

Funaro,¹³ working with the Folin method, found results similar to those just cited.

Amberg, Morrill and Funaro found it necessary to concentrate the urine of infants in order to get satisfactory results. I found, however, that such evaporation changes the proportion of creatin to creatinin, and I was obliged to depend on the somewhat unsatisfactory method of varying dilutions.

My results during childhood after the first week agree closely with those of the above-mentioned investigators, and I will take your time to cite a few results only for creatin and creatinin as determined without evaporating.

Baby M., 23 days old, creatinin 40.37 mg., creatin 2.41 mg. Baby Charles, 6 months old and weighing 5,580 gm., excreted 76.1 mg. of creatinin; and Eugene, aged 11 years and well, excreted creatinin when on a creatinin-free diet, the excretion during the twelve night hours being greater than that during the twelve day hours. His urine showed creatin rarely. Numerous analyses from older children with diphtheria, measles and scarlatina, all on creatin and creatinin free diets, showed creatinin constantly, but creatin rarely or in small amount. Thomas, a boy weighing 48 pounds, and a subject of cyclic vomiting, excreted on the fourth day of an attack, which was a hunger day, except for a few teaspoonfuls of a carbohydrate water, 1,278 mg. of creatinin and 49.9 mg. of creatin.

This and other analyses simply indicate a line of study which may give interesting results in disease. I wish, however, to warn against generalizations from insufficient data, and will omit further analyses in diseased conditions until sufficient material can be gathered to guard against mistakes.

SUMMARY

The study of the creatin and creatinin metabolism in children, although a promising one, has been little worked on. The opinion held until five years ago that infants do not excrete creatinin is undoubtedly incorrect.

Creatinin is present in the liquor amnii, which may mean that its excretion begins before birth. Creatinin is always in the urine of the first week and in a concentration approximately that of adult urine. Creatin is also excreted during infancy. In later infancy creatinin is present in the urine uniformly, but in much more dilute condition than with adults, or during the first week.

Analyses of urine in disease indicate that we may hope to get some clue to the processes of nitrogen metabolism by the study of creatin and creatinin.

It is a pleasant duty to acknowledge my indebtedness to Professor Folin for valuable suggestions, Dr. Green and the house staffs of the Boston Lying-in Hospital, and my own interns at the Minneapolis City Hospital for aid in collecting material; Dr. Moren, for assistance in some of the analyses, and especially Dr. Beard, without whose aid in procuring apparatus this study could not have been carried out.

Prophylaxis of Ear Disease in Febrile Conditions.—J. J. Pattee, in the *Laryngoscope*, urges: (1) The more general adoption of thorough removal of all adenoid vegetations; (2) the complete removal of hypertrophied or diseased tonsils; (3) the early evacuation of pus from the tympanic cavity by paracentesis, because the streptococcus is nearly always present in otitis due to febrile diseases.

SYSTEMIC CONDITIONS IN RELATION TO
ORAL SYMPTOMS AND SEPSIS*V. A. LATHAM, M.D., D.D.S., F.R.M.S.
CHICAGO

Until recently this subject had not attracted the attention of medical or even dental writers to any extent, being only now and then touched on in connection with other matters. Lacking the aid of authority I shall try to show its importance in daily practice and, at the same time, ask our members to look more attentively into their cases and see if the work of one of us is not worthy of more concentrated effort on our part earnestly to trace the subject better. I refer to the teachings and papers of the secretary of the Section, Dr. E. S. Talbot, than whom no one has done more to bring together this joint work of the stomatologist and physician in systemic treatment for oral conditions.

Who have better opportunities for observing the detrimental effect of a brain-cramming system of education at the expense of the bony and muscular systems than the wide-awake stomatologists?

"Why do my children's teeth decay so young?" is a common question. "I never had a tooth filled until I was 20 years old or more," says the questioner.

Look at the child with her small, delicate frame with large head, bright eyes and a highly exalted nervous system. We are told that she is ready for high school at 13 and began day school at 4½; she does not care for sports, sits up till 9 or 10, or later, with some neighbor children, and spends three to five hours a day practicing, which excites rather than soothes the nervous system. The amusements seem to be visiting other children, fudge parties, with late suppers and later hours for retiring, and consequently too little sleep; dancing lessons on Saturday and going to the city for a matinee. It is one perpetual round of excitement, with no time for the daily care of the body, including the teeth, or assistance in the home duties, and far less desire to please others or be helpful to anyone but the child's immediate circle. The tendency of the times with the immense struggle to keep the family provided for, the extremes in dress and fashions, the daily routine excitement with seldom a moment for relaxation, cannot help but ruin the finest heritage given to man, the vital structures by which his health, wealth, strength and happiness must be secured.

Prophylaxis—preventive medicine or hygiene—comes first and far above the mechanical art of dentistry, which is overdone. The crying demand of the nerves, however weak they are, to continue reacting by stimulation or excesses in food, drinks and automobiling, is fast developing a new set of disorders in vision, bones, muscles and heart strain, to say nothing of the nervous system. A recent recommendation of the use of the automobile (which to-day is seldom anything but a means for securing distance or speed instead of rest, tranquillity and change), in lung and heart diseases as a curative agent, should be carefully considered before it is accepted. The increase in neuralgia, or so-called neurotic pains, is well known and with the present ill-devised clothing it is no wonder that the speed and wind force should cause concussion and congestions with inflammatory conditions of the various parts of the body and especially the teeth. Again, the hurried meals at road-

houses, excessive in many cases for the immediate needs, on account of the increased oxygen inhalation and faulty elimination, must cause auto-intoxication, and many patients admit this when complaining of vague neuralgic pains or backache. The present urging of very young people into business positions of responsibility is a detriment to many; their hurry to escape the uncongenial atmosphere of the study rooms, and their almost universal carelessness in attending to their daily wants become a matter for thought. Austin Flint says: "The inexorable law of the survival of the fittest applies to man educated or uneducated, as well as to the lower animals, and it seems useless to educate man for work which he is physically unable to perform." The present rush to finish school work allows no extra time, as a rule, for broadening out in other lines, because time and money outweigh the study.

It should be remembered that the child consumes twice as much oxygen as the adult; and throws off a corresponding amount of carbonic acid; this is a gauge of its muscular activity and thus shows the need of the growing child for pure air in plenty. All muscular exertion is an expenditure of nervous force, hence, severe mental exertion and heavy physical strain should not be undertaken at the same time. Why should children not be forced to brain activity in tender years? Because, first, the brain grows most rapidly before the seventh year; secondly, the child is called on to assimilate and appropriate enough to nourish its rapidly growing brain and body, and at the same time to make good the wear and tear of its active nature. Is it not expecting too much of the digestive apparatus of the child to furnish material for its bodily development and, while so doing to supply food for an adult brain? Can we expect an overworked and excited child to digest its food properly and to furnish perfect material on which to feed its starving tissues? The food question of to-day is a real one in view of the extreme notions in children in regard to what they must eat, especially their repugnance to green vegetables.

Is it any wonder that the first seven years constitute a period of stress, with the brain growth, dentition, disorders incidental to infections and other childhood diseases? The rapid and great increase in the need for orthodontia, adenoid and nasal operations, the choreic cases, disorders of vision and digestion, etc., are evidence of this. Any mental strain shows itself on the teeth by increased caries as well as increased sensibility of the dentine, and especially as a cause for gingivitis and its allies, alveolitis and pyorrhoea. Overwork of any vascular part such as the overtraining of the muscles for athletic contests, will give like results on the teeth. Mental shocks are also a serious menace to general and dental health. When brain activity is forced, a loss occurs to the system and it is called on to restore the requisite amount of phosphorus.¹ This is a vital component of

1. A measure which has proved useful in bony suppurations and alveolitis is the internal administration of ethereal tincture of phosphorus (1 to 1,000) 3 minims after each meal, well diluted with water. If much pyorrhoeal infection be present, but the teeth sound, the above remedy followed by solution of mercuric chlorid (1 to 1,000) three minims between meals, is worthy of more trial. At the same time the gums should be painted with Dr. E. S. Talbot's iodine and glycerin mixture, or twice daily, anteriorly and posteriorly, with a dilution of iodine liniment (B. P.) made by adding to 2 drams of liniment water to make 4 ounces. In cases of adults in whom there is much gastric flatulence and pain showing intestinal autointoxication, as well as in the infantile form of digestive disturbance, silicate of sodium acts nicely as a sedative and antiferment. Sodium silicate 172 gm., dissolved in 1 liter of water, to which a trace of fluosilicate of magnesia and carbonate of lithium has been added, may be given in doses of one to two teaspoonfuls three times daily before food, according to age and conditions present. Where the teeth are loose and very sensitive protargol in glycerole, used alone or with an electrode on an interrupted current, helps.

* Read in the Section on Stomatology of the American Medical Association, at the Sixty-first Annual Session, at St. Louis, June, 1910.

both brain and bone in nearly equal amounts; hence, we must not forget that small doses of phosphorus produce good results in the reproduction of bone and are therefore a useful adjunct in so-called pyorrheal treatment. Care must be taken in its administration lest it become a detriment instead of a help, and the cooperation with laxatives is necessary.

The condition of the oral cavity is a most important factor in surgery as an aid to antiseptics and sepsis.² The condition of the gingivæ being important to the physician as well as to the dentist, dentists should study and know what is the healthy normal appearance, and its examination should be undertaken regularly and thoroughly. For convenience we may classify the diseases into two groups:

The constitutional:

1. Interstitial gingivitis.
2. Syphilis—Leukoplakia.
3. Tuberculosis.
4. Scurvy.
5. Purpura hemorrhagica.
6. Diabetes mellitus.
7. Addison's disease.
8. Stomatitis (several forms).
9. Noma.
10. Ludwig's angina.
11. Aphthae.
12. Herpes.
13. Metallic poisons (mercury, copper, lead, silver).
14. Rheumatism.

The local:

1. Traumatic inflammation.
2. Epulis, Fibroma, etc.
3. Polypi, simple hypertrophy.
4. Parulis or alveolar abscess.
5. Papillary and warty growths, chancres.
6. Vascular or nevoid growths.
7. General hypertrophy, hyperplasia.
8. Carcinoma.
9. Sarcoma.
10. Gingivitis, interstitial alveolitis, pyorrhea.

Our training should be such that we can make a diagnosis of any case we may meet with, though it requires considerable experience to do this and book knowledge is a poor substitute for the latter. Many of these diseases dentists are often called on to treat, and others, when diagnosed, perhaps should be handled by a general practitioner. If the stomatologist has been trained as it is his right to be, he can and should take care of these cases or (what is not always satisfactory) work in conjunction with the family physician. The earlier the cases are seen the better, and here, the dentist can do good and save life and valuable time in treating such confusing symptoms as gumma, tuberculosis and neoplasms.

The debated question in the treatment of abscessed teeth—when not to extract—is one still in doubt. Why pus should be allowed to stay doing damage by its burrowing and sepsis in the mouth any more than in any other part of the body, seems a conundrum in these days of thorough surgical treatment. The danger of lymphatic infection, necrosis of soft tissue and bone is not to be lightly passed over, to say nothing of the general condition of the patient. An alveolar abscess does not always burst into the labio-dental sulcus; it is more common for those attached to the upper lateral teeth and the palatine roots of molars to burst into the palate.

Abscesses on the lower teeth sometimes pierce the inner alveolar plate and burst into the cavum oris. From the lower teeth pus may pass inward through the bone, or between the bone and its periosteum and point under the chin or among the fascia of the neck, whence it may reach the thorax, and in its course cause the diseases known as angina Ludovici and edema of the glottis. From a molar tooth the pus may extend along the jaw into the pterygoid region, the temporo-mandibular articulation, or masseter muscle, and from these may reach the brain or ear. I have seen pus soaking backward from upper incisors, cuspids, and molar palatine roots discharging into the nasal floor, the aural cavity and cheek, forming a retropharyngeal abscess.

Ulcerative stomatitis is not a pleasant disease to deal with, especially if the patient is not of a vigorous type, and the disease is not usually found, unless by direct infection, in robust people. In adults and after exanthematous fevers in children it is more often seen, and may arise from impure milk and unhygienic surroundings. The infection almost always takes place at the necks of the teeth, causing an acute gingivitis, but, as the germs multiply and spread, it develops from a hyperemia to thrombosis of the vessels, molecular disintegration or ulceration of the gum, and, eventually, of the periosteum and alveoli. The more acute the case, the larger will be the sloughs and the deeper the necrosis. At the same time the absorption of the products of putrefaction will cause pyrexia, sapremia and even, eventually, death. The picture as presented by the gums in this condition is too well known to consider here, but it will be a wise precaution to examine such ulcerations to determine the bacterial flora² which is not only a wise precaution but a just one for the patient and stomatologist. My own experience has taught me that ulcerative gingivæ may have various bacteria of their own which, on general examination, without a microscopic smear or culture, would never have been thought of. One case I remember especially in which the smear gave a typical pure pneumococcal slide, and the patient died four days later of an acute lobar pneumonia, the whole pharynx and lung showing the membranous exudate of the same type, and inoculations of the blood in guinea-pigs showing the same characters. Another patient, who had a chicken-raising business and whom I saw in consultation, presented a condition allied to noma, the whole of the oral cavity being one mass of membrane of a greenish-white color and the lips so swollen as to be almost indefinable. The lower lip especially, was of a blackish gangrenous color, extending to the chin. The temperature was 105 F., yet the patient tried to do her work under great difficulties until she became delirious, with sweating accompanied by violent rigors and chilliness. In this case, in which the etiologic factor was not clear, the patient may have been accidentally inoculated through a hen flying up and picking her face when feeding or being lifted off the nest, as the patient remembered several such instances; or it may have been a dental infection, as her mouth was sadly lacking in hygiene. Bacterial work then was not what it is now, or I think serum treatment would have been a great help and less tedious and difficult convalescence would have been endured. The extreme sepsis and circulatory disturbance that the patient suffered, together with the general debility and metastatic abscesses in the liver, leg and arm, rendered the prognosis very grave. Luckily, it is not a very com-

2. Latham, V. A.: Dental Digest, February, 1906, p. 127; Differential Diagnosis in Dentistry, Dental Register, 1895, p. 469; Am. Med. Jour., July, 1905.

mon condition, but I have seen enough cases to make me fear the results, both from the point of view of cosmetic effects and from that of recovery. Though ulcerative stomatitis usually occurs in children, still adults are affected and it is likely to be confused with a more recently discovered disease, that is, Vincent's angina.

As in many other diseases of the oral tissues, it is thought that certain micro-organisms play a conspicuous part in the rôle of this disease. Froriep³ first called attention to the organisms resembling yeast fungi. Gravitz⁴ found bacilli in nearly pure cultures, which were described by Loeffler⁵ as similar to the bacillus seen in diphtheria of calves. Other investigations have confirmed the finding of this germ. In every case a bit of the exudate should be obtained with a sterile instrument and cultures taken and smears made for immediate diagnosis, which in a few minutes can easily be made, as no cumbersome laboratory stains are needed when the "soloids" can be had, and fresh solutions made from the tablets, as wanted; uniform results can be secured in a moment. If the diphtheria germ is present, a physician can be called and antitoxin administered without delay. In streptococcic infections of a high degree, with much depression, serum inoculations are a great aid in cutting short the disease; also, in some pyorrhœal cases, if the infection is a pure and not mixed type. When the smear shows a spirillum type, we know we shall not succeed in cutting short the case without most vigorous therapeutic measures. The following case, which occurred last fall in my practice, may interest some stomatologists; it shows the conditions very clearly:

History.—The patient was a young man, aged 20 years, a student of good habits, a moderate smoker and a good athlete. He had been ailing for a month, had been under the care of several physicians and dentists, and was treated with caustics, gargles, etc. As the young man was getting worse, showing signs of rapid loss in weight, anemia, great pain on swallowing, and could not eat, his parents became alarmed and saw a prominent surgeon and, then, a throat specialist. Finally, the patient came into my care.

Examination.—The patient was almost prostrated from the effort of walking a block and a half from the street-car, being breathless and very fatigued; he was sweating profusely; the pulse was 125, very weak and irregular; the temperature was 104 F. The breath was exceedingly offensive; the lips were swollen and it was nearly impossible to open the mouth to see the cavity and fauces. The mucous membranes were covered with a grayish-greenish deposit and bled on the slightest touch. The gingivæ from molar to molar in both lower and upper jaw were ulcerated, especially, around the right and left superior centrals (pivot) teeth and laterals. The centrals had the gum ulcerated to one third of the apex of the roots. The gum about the left lateral on the palatal position was so swollen that the patient could not shut the teeth as he bit. A deep, wide pocket came from this oozing blood and pus. The right superior molar was very much diseased and there was a large plaque of dead skin on the buccal surface. The tongue protruded trembling and was swollen, fissured, bleeding and very heavily coated. The throat, which had been sore and had been treated as if the trouble were a simple tonsillitis, on my seeing it, did not look so bad as the oral cavity. The soft palate and uvula were slightly swollen and reddened; the left tonsil had some slimy, whitish membrane. The posterior fauces were very red and had follicular spots, but no membrane. The intense pain was from the swollen tongue and lips. Deglutition was nearly impossible and gargling very difficult and painful. Pain extended along the ramus to the right ear

and up the side of the face, the submaxillary glands were tender, the head ached, the eyes were suffused and slight constipation was present.

Treatment.—I gave the patient a swabbing and took smears and cultures on agar and blood-serum, then carefully irrigated the month with a warm solution of 1 to 1,000 mercuric chlorid, later, with sterilized water; then, irrigated with alphozone solution in the strength of 1 to 50, swabbed with iodin and cleansed off the loose pieces. The patient was ordered malted milk with half cream in small quantities, and elixir digitalin compound. After a good compound cathartic pill, followed in the early morning with a laxative mineral water, the patient was kept in bed while the exhaustion was so marked, and the irrigations were kept up for 20 minutes at a time every four hours. After twenty-four hours, cupric sulphate was applied locally and washed off later; this seemed to exert a marked influence. Then liquid antiseptic washes were applied and tincture of iodin swabbed all over. Gargling and nasal douches were continued with free purgation. After three weeks the patient gained in weight and had only 99 degrees of temperature.

It was with the greatest difficulty that the disease was checked completely, for if the patient failed to attend to his swabbing and douching even for twenty-four hours, a fresh nidus would start on the superior premolar on the left side, then on the superior cuspid and on the mucous membrane of the cheek, and only constant watchfulness kept the disease in abeyance. The patient had a slight hacking cough. The lungs were good except for several small areas of broncho-pneumonia, and these yielded to bed and treatment. The extreme weakness of the patient was most marked and lasted for several months after the month was healed.

The diagnosis was not easy; the patient and his family all thought that the disease was a direct infection from the physician who treated the throat with some application, not silver, but what they did not know. The smears were of the greatest aid in making the diagnosis of Vincent's angina, and especially in differentiating between diphtheria and mixed infection. The ulcerative form of angina and stomatitis may be mistaken for secondary or primary syphilitic pharyngeal ulcers; it may be taken for the latter especially when it is accompanied by marked local glandular swelling. In the second set of smears from the reinfection there was a more suppurative condition. The findings in these mixed infections are never so characteristic as is usual in pure cases.

Usually the pathologic processes are so characterized clinically. This is particularly important since a great variety of bacteria are found on cultural examination of the tonsillar and pharyngeal deposit. With regard to this there is an urgent demand for a more thorough demonstration of the pathogenicity of spirilla and the fusiform bacilli. Again, the question of the occurrence of these micro-organisms in the oral cavity of healthy people is also of special interest. Miller has found them in healthy persons with carious teeth. Vincent* saw some on the gums and pharynx in fourteen out of eighteen healthy subjects examined, and Bernheim† also noted small numbers mixed with other bacteria. In order to determine their significance positively, the determination of their degree of virulence is needed. This, however, is difficult for either the fusiform bacillus or the spirillum, since, thus far unquestionably pure cultures, either by anaerobic or aerobic methods, have been unsuccessful. Nicolat and Marotte did get a marked increase in the number of fusiform bacilli and spirilla in the condensation

water of certain nutrient serum-media, but without pure culture. Bacteriologic proof of the pathogenicity of the spindle-shaped bacilli and spirilla has not, as yet, been positively given. Therefore, we must obtain more evidence by anatomic research or clinical observation. The bacilli penetrate deeply and, in new localities yield almost pure smears; hence, there is a danger of recurrent attacks.

One point to remember with regard to stomatitis is that it may follow a complication of a great number of more or less grave infectious conditions, or may occur in the course of good general health; and when one has to deal with patients in whom one may suppose a more or less abundant elimination of toxins or irritants by way of the secretions, one should always examine the mouths with care; very often more or less advanced lesions will be found. The uremic form of stomatitis is generally a serious condition; the fetor of the breath is very marked, strong and repulsive, even nauseating; the tongue is heavily coated white; when the renal symptoms are helped and the uremic intoxication clears, the inflammation of the buccal mucous membrane recovers quickly. Lancereaux, I believe, was the first to describe especially the buccal uremia and Barie first traced clearly the history of these particular symptoms. The saliva should be carefully tested in these cases for urea, which may be diminished or sometimes augmented. Barie had a patient who produced 900 gm. of saliva in twenty-four hours. As is well known, normal saliva always contains a certain quantity of urea, scarcely exceeding a few milligrams, or from 2 to 3 *cg.*, exceptionally from 20 to 50 *cg.*; in the pathologic state, on the contrary, as in uremia 5 or 6, and even as much as 9 gm. of urea in twenty-four hours has been known; the patient produces almost as much urea in his saliva as in his urine. At present our bacteriologic investigation of the scrapings of the mucous membrane has only shown a few cocci, and what the real pathologic agent of the affection is, as well as the genesis we cannot say. Why the lower gums, particularly in the mouths of soldiers and smokers, are more prone to attacks of stomatitis, is a subject for thought.

A most valuable remedy for fetor of the breath and many forms of stomatitis which it always accompanies is oxygenated water for rinsing the mouths, on account of its tendency to kill out the anaerobic germs which seem to predominate and give the fetid odor and which have been so often noted in typhoid fever, erysipelas, auto-intoxication in the liver and intestinal cases, syphilis, eruptive fevers, infections, purpura and tuberculosis. The tongue has often been called the mirror of the stomach, and we may say that the mouth is the mirror of most of the infectious diseases and of the general intoxications of the body. This is especially true in conditions of anemia and other chronic diseases which, lately, in many countries, occurring in the practice of the physicians, have been referred to the dental specialist for a report on the existence of any septic conditions of the teeth that may be factors in the etiology, etc. I cannot do better than refer to the paper on anemia published by Dr. Walsh⁶ in which one of the best summaries of the subject can be found. Who has not seen the anemia in children most probably due to necrosed roots and abscesses? Here is a point for discussion with the physicians and dentists as to when it

is best to remove the teeth so as to avoid injury to the arch and teeth of both dentitions, and the best methods of treating such necrosed areas by the bismuth paste, etc. The work of Dr. W. Hunter has been noted in my address on oral sepsis² and pernicious anemia and its ally pyorrhea alveolaris before this Section. The various opinions on this latter subject, alone, are enough to make any reasonable man wish something could be done to bring order out of chaos. Mr. Henry Sewill⁷ says that pyorrhea alveolaris has no connection with caries. To this I cannot agree, for caries is certainly to be found sooner or later. He says that it is a disease of middle life and old age only. I believe that most of the members here have seen it in all ages. If it is to be considered as a process of slow wasting of the alveoli and gradual shedding of the teeth, attended by slight inflammation and constant discharge of foul pus from within the free edge of the gum and alveolus, then we certainly can look for it in cases in which much hurried and forcible regulation has been done. I have seen many cases in which the superior lateral has been forced out from an included jaw and become the seat of a typical pyorrhea, so called, even of alveolitis and a suppurating pocket when every other tooth was in a perfect condition, unfilled, and the mouth well cared for. Those cases of long standing may cause us to wonder whether the pyorrhea has arisen from the lowered health or whether the lowered health has arisen from the depressing effect of the local disease.⁸

The great increase of crowning and bridge work which show poor mechanical judgment and poor reasoning has been, I sincerely believe, one of the greatest factors in the increase of this condition from the violent gingivitis and all its sequelæ which we find almost always present except in exceptional, careful, well-fitted cases by a master hand. Again, we must note that the etiologic factor in some cases consists in articulatory disturbances in both youth and advancing age, through the displacement or advancing of the mandibular angle so that it becomes obtuse, and through the loss of elasticity of the bones by the lime deposits; and thus the appearance of pyorrhea in different parts of the arch may possibly be explained.

As this paper has already exceeded my limited space I shall only call attention to the systemic points which are associated with oral sepsis as applied to mucous membranes. Dental caries may become the exciting cause of a multiplicity of the symptoms and is itself due to two principal causes: the anatomic location of the teeth and the polypathogenic part (if I may coin the term) played by the mouth bacteria. If the Loeffler bacillus and the tubercle bacillus each engenders but a single disease and is truly specific, it is not so with the staphylococcus and streptococcus, which according to their virulence, their mode of entrance into the body, the phagocytic power of the person attacked, their different modes of association, and, without doubt, many other conditions which we do not know, may start on the spot a circumscribed or diffuse suppuration, or may reach the lymphatics and cause an angio-leukitis, an adenitis, adenophlegmon, or erysipelas and vast septic infiltrations of the cellular tissue, and may penetrate the veins as a phlebitis. Here they will deter-

7. Sewill, Henry: *Med. Press and Circular*, Oct. 22, 1902, p. 431.

8. Antral suppuration may occur from alveolar infection without the intervention of carious teeth. In cases of alveolar pyorrhea masses of granulation tissue seen on extracted teeth, on sectioning, show a rarefying osteitis spreading into the bone, while the tissue farthest away from the advancing inflammation shows fibrosis.

6. Walsh, David: *Some Points in the Modern Diagnosis and Treatment of Anemias*, *Med. Press and Circular*, Sept. 21, 1902, p. 223.

mine a regional symptom of a septicemia or abscess of the gravest character. The micro-organisms, if they act on the spot, first seek the alveolus (alveolodental periostitis) then the mandible (osteoperiostitis, osteomyelitis of the jaws); or conjointly bone and mucous lining. If they follow the contiguous tissues of the mouth, we get stenoparotiditis: if they penetrate through the alveolus of an upper tooth (first or second molar), maxillary sinusitis. If they pass on to the air-passages, bronchopneumonia follows. If they enter into the digestive apparatus they produce or help to produce in people subject to chronic abscessed teeth, anemia or so-called "dental cachexia" of Lejars,⁹ or the acid putrid intoxication of Richet.¹⁰ Everyone who has followed the clinical evolution of the lymphophlegmonous septicemia of the neck knows that it may be either simple septicemia or septic pyemia. If an incision is made in the phlegmonous parts, it is with great trouble that one will find in the deep parts a minute suppurating point containing only a dram or so of a secretion which may not be pus in character; or nothing at all may be found. Here is a clear proof that we must distrust surgical infections which do not suppurate. Suppuration may be a means of defense for the organism. In many of these severe cases death comes on very rapidly, the nerve centers being profoundly affected and not giving the brain time to react under the cellular intoxication, while the patient has a slight delirium, but depression irregularity and weakness of the pulse, respiratory insufficiency, dyspnea, toxins thrown off by sweats, diarrhea and albuminuria.

1644 Morse Avenue.

ABSTRACT OF DISCUSSION

DR. M. H. FLETCHER, Cincinnati: The thing that presents itself most forcibly to me is the lack of knowledge in parents of the laws of physiology. That is, the lack of proper knowledge of the conditions under which to bring up children, and from our view-point the mouth is very important. I have read in various works that the saliva of animals is strongly alkaline, but to go to the abattoir, apply a bit of litmus paper to the saliva of animals and find it change as quickly from acid to alkaline as it would be in a solution of bicarbonate of soda, and find this in absolutely every case, is something that should be considered by us. I take it that civilized environment has changed the physiology of man to almost the opposite condition. For it is a rare thing to find human saliva more than barely alkaline. Now, with the strong alkaline condition found in the mouths of animals, no acid decay could exist. Again, the eating of the rough food by these animals constantly rubbing against their gums, keeps the tissues healthy and strong. This feature is of great importance for there is a development of large rolls of connective tissue or callus at the necks of the teeth of these animals, especially just inside of the lower front teeth, where the food comes in contact with the mucous membrane. This is true in carnivora, where the teeth are conical, but not to the degree found in the herbivora; the biting with conical teeth also cleans them to the gums. When animals are kept from their normal diet and fed on civilized food, there is a marked delicacy or softening of the gums in consequence. I do not believe these points have been brought before our present generation strongly enough to impress them properly, and, since our teeth are not cleansed by our food, and our mouths do not have this protective alkaline saliva, by all means let us use the superior intelligence Providence has given us and

give our gums this hard rubbing that they need, and the mouth and tongue the proper cleansing and the result will be to the development of healthy, strong gums and good teeth. Our intelligence should lead us to know where to begin and how to correct these defects; then we will know how to teach our children about them.

THE RELATION OF BLOOD PLATELETS TO HEMORRHAGIC DISEASE

DESCRIPTION OF A METHOD FOR DETERMINING THE BLEEDING TIME AND COAGULATION TIME AND REPORT OF THREE CASES OF HEMORRHAGIC DISEASE RELIEVED BY TRANSFUSION *

From the Hunterian Laboratory of Experimental Pathology, Johns Hopkins University

W. W. DUKE, M.D.
KANSAS CITY, MO.

It is my purpose in this paper to report three cases and experiments which furnish additional evidence to show that the blood platelets play a part in stopping hemorrhage, and that one type of hemorrhagic disease may be attributed to an extreme reduction in the number of platelets. The cases possibly explain the relief which sometimes follows transfusion in hemorrhagic disease. It is my purpose also to describe a method for studying hemorrhage called the bleeding time, and to describe briefly a simple method for determining the coagulation time.

In the cases there was marked hemorrhagic diathesis, a normal coagulation time, and almost an absence of platelets. Transfusion was performed in each case. After transfusion there was a marked increase in the number of platelets and remarkable relief of hemorrhage. When the platelet counts returned to their previous low level, hemorrhages returned. Later in the course of the disease in two of the cases, the platelet count rose spontaneously and this rise also was followed by relief of hemorrhage. The cases are reported to show the marked dependence of pathologic hemorrhage in this type of disease on the reduced numbers of platelets. The experiments are reported briefly to show that platelet counts reduced experimentally by benzol are not associated with changes in the coagulability of the blood which account for the hemorrhages of the condition and suggest that this type of hemorrhagic diathesis is due directly to the lack of platelets.

A METHOD FOR DETERMINING THE BLEEDING TIME

A small cut is made in the lobe of the ear. At half-minute intervals the blood is blotted up on absorbent paper. This gives a series of blots of gradually decreasing size. Each blot represents one-half minute's outflow of blood. The rate of decrease in the size of the blots shows the rate of decrease of the hemorrhage. The cut should be made of such a size that the first half minute's outflow of blood makes a blot 1 or 2 cm. in diameter. The total duration of such a hemorrhage is called the bleeding time.

Figure 1 (A, B, C) was made from cuts of different size. These sets of blots show that within certain limits the duration of a hemorrhage does not depend on the size of the cut. If these figures represent capillary hem-

* Read in the Section on Practice of Medicine of the American Medical Association, at the Sixty-first Annual Session, held at St. Louis, June, 1910.

orrhages it is evident that a large number of capillaries will stop bleeding as rapidly as a small number.

The normal bleeding time varies from one to three minutes.

The bleeding time is slightly delayed (five to ten minutes) in severe anemia (Fig. 2).

Great delays in the bleeding time were found in, (1) cases in which the platelet count was excessively reduced (ten to ninety minutes—Fig. 3), (2) cases in which the fibrinogen content of the blood was excessively reduced (ten minutes to twelve hours), and (3) experimental animals in which both platelets and fibrinogen were reduced.

It is remarkable that the bleeding time is independent of the coagulation time. The bleeding time was normal in several cases of jaundice in which the coagulation time was very much delayed. Two of these patients died of pathologic hemorrhage.

Fig. 1.—Normal bleeding times; A, from small cut; B, from larger cut; C, from very large cut.

It was also normal in a patient with hemophilia, who had a slight delay in the coagulation time and pathologic hemorrhage. The bleeding time was found to be normal in several types of purpura hemorrhagica in which the platelet counts were normal. It is difficult to explain why these patients had hemorrhage into the tissues, from mucous membranes, and from operation wounds, and at the same time had normal bleeding from ear-pricks.

The bleeding time, then, in types of disease associated with low platelet counts, or with a reduced quantity of fibrinogen shows a tendency to prolonged hemorrhage. In these types of disease, a delayed bleeding time is a

more reliable indication of hemorrhagic diathesis than hemorrhagic symptoms, for such symptoms usually depend on general and local causes. The latter are, of course, not constant. In the cases reported in this paper the bleeding time was invariably delayed when pathologic hemorrhage was evident, and was often considerably delayed before hemorrhage began.

The method is apparently of no value in determining the tendency to bleed in jaundice and hemophilia, and in the types of purpura hemorrhagica which have normal platelet counts.

A SIMPLE METHOD FOR DETERMINING THE COAGULATION TIME¹

The apparatus consists of a slide on which are mounted two 5 mm. disks. One disk is covered with the blood to be tested. The other is covered with normal blood. The two drops of blood should be of about the same depth. The slide is then inverted over a glass nearly full of water kept at 40 C. and is covered with a warm, damp cloth. The coagulation time is determined by holding the slide in a vertical position for a moment. When the end point is reached the drop does not hang, as in Figure 4a, but retains the contour of a perfect sphere

Fig. 2.—Slightly delayed bleeding time. From a case of secondary anemia.

(Fig. 4b). The end point appears sharply and is easily determined.

The normal coagulation time by this method varies from five to seven minutes. A very shallow drop clots one to two minutes sooner than a very deep one. The normal blood can be used for a control, or can be used for obtaining a comparative time.

If simply the comparative time is desired, the temperature of the water may be allowed to vary between 35 and 40 C., and the glass may be covered with the hand instead of a damp cloth. A delay of two minutes can be easily determined by this method.

PLATELET COUNTS

Wright's method² was used in making the platelet counts. According to this method the blood is drawn up in a 1-100 pipette, mixed with a solution of cresyl blue and potassium cyanid and counted by the red cell

1. This method is a modification of Hinman and Sladen's slide method (Johns Hopkins Hosp. Bull., 1907, xviii, 207). The principle was first used by Millan.

2. Wright and Kinnicut: Tr. Assn. Am. Phys., May, 1910.

technic. The red cells are laked by this solution and the leukocytes and platelets are stained. This is a great advantage, for the platelets can be easily recognized and can be counted with a high dry lens. The counts made by this method are uniformly lower than those made by Pratt's method.³ This method, however, gives constant results if care is used in the technic. The normal count, according to Wright and Kinnicut, varies from 250,000 to 400,000.

of interest in showing relief of hemorrhage, both after the rise in the platelet count following transfusion, and after a spontaneous rise in the count which occurred later in the disease.

History.—S. M., a man aged 20, Armenian, tailor, was admitted to Massachusetts General Hospital May 8, 1909, complaining of epistaxis. The family history is negative for hemorrhagic disease. The patient has always been strong and well, and has had no serious illnesses. He has never had prolonged epistaxis, spontaneous ecchymoses, joint trouble, urticaria, nor abdominal crises. His digestion has always been

REPORTS OF CASES*

CASE 1.—*Summary.*—Acute purpura hemorrhagica. Purpura; spontaneous hemorrhages; practical absence of platelets; delayed bleeding time; normal coagulation time. This case is

3. Pratt, J. H.: A Critical Study of the Various Methods Employed for Enumerating Blood Platelets, THE JOURNAL A. M. A., Dec. 30, 1905, p. 1909.

4. I wish to express my thanks to Dr. F. T. Murphy, Dr. Hugh Cabot, Dr. L. A. Coe and Dr. R. D. McClure for permission to report these cases, and to Dr. J. H. Wright for his kind assistance in making the platelet counts.

good. For three weeks before admission to the hospital he had been feeling run down, and had had slight sore throat. For five days he had been troubled with persistent epistaxis. He noticed that his urine was high-colored, his stools black, and that he was covered with purpuric rash. There was nothing further of importance in the history.

Examination.—The patient was a well-developed and well-nourished young man, pale and weakened by loss of blood. A small amount of blood was then oozing from the border of his gums, and nasal mucous membranes. Scattered over his entire body, including the soles of his feet, mucous membranes, tongue, and sclera, were fine muscular purpuric blotches, 1 to 5 mm. in diameter. In places, especially on the lower extremities, they were confluent, and covered areas 2 to 3 cm. in diameter. Retina were free from hemorrhage. There were a

few mucous râles at the lung apices, and a soft systolic blow at the base of the heart. The spleen edge was palpable just below the costal margin. There were no telangiectases on his skin or mucous membranes. Blood-smears showed almost a total absence of blood-plates, 6,000 by count. On the following day the counts were even lower. The bleeding time was forty minutes. The coagulation time was normal.

The course of disease can be followed by the chart (Fig. 5). During the first four days in the hospital there was an almost constant oozing of blood from the nose, which could be controlled for only short periods of time by packing. The stools and urine each day contained considerable blood.

Transfusion.—On May 11, the patient lost over a pint of blood from the nose, and his condition became so critical that he was transfused at 2 a. m. by Dr. F. T. Murphy. An Armenian friend of about the same age was donor. That a

Fig. 3.—Great delay in bleeding time. From Case 1. Platelet count 3,000, coagulation time normal. The blots in Series A were taken immediately after the ear was pricked; Series B, 20 minutes; C, 40 minutes; D, 60 minutes, and E, 80 minutes later. The bleeding time at this time was 90 minutes. Series F, showing a normal bleeding time, was taken after the transfusion. Platelet count was then 110,000.

large amount of blood was given by transfusion was evident from the improvement in the patient's general condition, color, and pulse, and from the rise in the pulse-rate of the donor.

Course of Disease.—The platelet count, taken six hours after transfusion, was 123,000. The bleeding time had dropped to three minutes. The coagulation time was practically unchanged. Epistaxis had stopped before this time, and the packing had been removed from the nose. The urine was then free from blood. The stools on the following morning

were light yellow, but contained a small amount of occult blood. No fresh purpuric spots appeared and the ones present began to fade, disappearing completely in five days. Thirty-six hours after transfusion it could be seen from stained smears that the platelets were decreasing rapidly in number, and on the third day one could be found only after prolonged search. At this time the bleeding time was again delayed. The day following this the patient's nose began to bleed and fresh blood appeared in the stools. Since the onset of the disease the patient had had an irregular temperature, varying from 99 to 103 F. This came to normal, except for slight remissions, on May 20. Apparently the disease had run its course, for at this time plates reappeared in the blood (80,000), and hemorrhage from ear-pricks would last for only three minutes. There was no further epistaxis or melena. Convalescence was uneventful, and since then the patient has continued his vocation without symptoms.

Differential Counts.—Made on May 8, 9, 12, 15, 23. Polymorphonuclear neutrophils made up from 80 to 86 per cent. of the cells. The remainder were lymphocytes with an occasional mast-cell and eosinophil. Only one blast was seen.

Red Cells.—Moderate variation in size. Shape normal. Moderate amount of achromia and polychromatophilia. An occasional stippled cell.

Coagulation Time.—The comparative method was used. The temperature was kept constant at 40 C. My blood, which had a coagulation time of five to six minutes, was used as a control. Usually several determinations were made and the average taken.

Platelet Counts.—Pratt's method was used in making the platelet counts on May 8, 9 and 10. The other determinations were made by Wright's method. The variations in the platelet count were so marked that estimations from stained cover-glass preparations of the blood proved satisfactory. Smears were looked over carefully with oil immersion lens on the days mentioned, and the number seen per smear or field averaged.

Retraction of Clot.—The clot was non-retractile after standing forty-eight hours on May 11 and 16. It retracted normally on May 12 and May 23.

Bleeding Time.—Determined by the method described. As a rule several determinations were made and the times averaged.

Urine.—Normal except that it contained a sediment of red cells and a slight trace of albumin on May 8 to 11. It contained no sugar, bile, peptone, albuminose, or nucleoproteid.

Stools.—May 8 to 12, rather copious, soft and black; from May 13 to 16, soft and light yellow (milk diet). Guaiac test was faintly positive on May 13 and 14; strong on May 15. On May 17, the stools were brown and soft and mixed with about 50 c.c. of fresh blood and a little mucus. On May 18, the stools gave the guaiac test. May 19 to 23, the guaiac test was negative. No parasites or ova were found.

The patient was seen eleven months after his illness and was then apparently strong and healthy. White count 4,700. Polymorphonuclears, 66 per cent.; lymphocytes, 34 per cent.; hemoglobin, 85 per cent. Plates 240,000. Bleeding time one minute.

CASE 2.—Summary.—Chronic ulcerative colitis; melena; reduced platelet count; delayed bleeding time; normal coagulation time. The bleeding time was normal after the rise in the platelet count following transfusion. The melena was slightly increased by transfusion. The case is of interest in showing a difference between the curative influence of transfusion in normal and in pathologic hemorrhage. Although the general tendency to hemorrhage (shown by the shortened bleeding time) was markedly diminished by transfusion, hemorrhage from the intestinal ulcers was increased. The case shows the difficulty of judging the tendency to abnormal hemorrhage by hemorrhagic symptoms alone.

History.—A. C., American, a boy aged 8, was admitted to Massachusetts General Hospital Nov. 15, 1909, complaining of weakness and diarrhea. The family history is negative for hemorrhagic disease. The patient's early life was normal. He had had no serious acute illnesses. After the age of 2 he suffered almost continually from diarrhea. He developed slowly, was always thin, and never strong enough to go to school. After the age of 4, there were four periods of a month or less in which the stools contained considerable blood, and the patient became pale and weak. He bled excessively from a trivial cut once. He never had ecchymosis on slight injury, joint disturbance, nor other evidence of hemorrhagic disease. For a month before admission to the hospital, the diarrhea was more severe, the stools contained blood, and the boy was becoming pale and weak.

Examination.—The patient was poorly developed, thin and pale, skin clear. Except for evidence of anemia, there was nothing of interest on physical examination. There were no telangiectases on the skin or mucous membranes, and no jaundice. Blood-smears showed a scarcity of the plates. Counts varied from 20,000 to 30,000. The bleeding time was twenty minutes. The coagulation time was normal.

During the first two and one-half weeks in the hospital a prominent symptom was diarrhea. The patient had from eight to thirty stools a day, which consisted mostly of thin pus, and often contained a small amount of blood and mucus. The patient's temperature varied from 98 to 103 F.

Transfusion.—On November 3 the patient was transfused by Dr. Hugh Cabot, preparatory to cecostomy. The child's father was donor. Following transfusion there was improvement in general condition and color. The temperature came to normal, and the pulse-rate dropped from 150 to 110.

Course of Disease.—The platelet count, taken two hours after transfusion, was 20,000, and the bleeding time was two minutes. The coagulation time was unchanged. The amount of blood in the stools, however, was increased. In interpreting this result it must be borne in mind that the patient had an extensive chronic ulcerative colitis (proved by autopsy), a condition which may cause melena when the blood is normal. The increase following transfusion was thought to be due to overfilling of the blood-vessels. Cecostomy was performed on the following day without excessive hemorrhage. As in the previous case, the platelets introduced by transfusion disappeared rapidly, and in a few days the count reached its former low level. The bleeding time again became delayed. The melena continued. The boy gradually became anemic, febrile, and died about a month later of septicemia.

11 4,	Hbg., 85%
11 9,	Hbg., 90%
11 13,	3,600,000	Hbg., 70%

Differential Counts.—Polymorphonuclear neutrophils varied from 40 per cent. to 60 per cent. The remainder were lymphocytes with an occasional mast-cell and eosinophil. No blasts seen.

Red Cells.—Moderate variation in size. Shape normal. Moderate amount of achromia and polychromatophilia. No stippling.

Coagulation and Bleeding Time.—Determined as in Case 1. The platelets were counted by Wright's method.

Retraction of Clot.—On October 26 there was a very slight retraction of the clot after twenty-four hours; on November 3 and 4 a moderate amount of retraction; on November 9 no retraction.

Urine.—Normal.

Stools.—Eight to thirty a day, throughout the patient's illness. Small in amount and of pea-soup consistency. Stools contained considerable pus, a small amount of food residue and mucus. Dur-

ing the first few days, after admission, they contained considerable fresh blood. For ten days before transfusion they contained very little blood. After transfusion the stools were port-wine in color and contained considerable blood. Melena continued until death. Stools contained no parasites or ova. Cultures taken frequently showed only the colon bacillus.

CASE 3.—Summary.—Chronic purpura hemorrhagica: Echinomoses; purpura; hemorrhages from mucous membranes; low platelet count; delayed bleeding time; relief of hemorrhage for three days followed transfusion; relief of hemorrhage after a spontaneous rise in the platelet count.

History.—Georgiana — American, a girl aged 3, was admitted to New York Hospital Oct. 3, 1909, complaining of epistaxis. The patient's parents, and three brothers and sisters are living and well. There is no history of hemophilia in the family. The patient has had no acute illnesses. She has had prolapse of the rectum several times. Since the age of 19 months, she has been subject to nose bleed, and ecchymosis following slight injury. Four months before admission to the hospital, symptoms were more severe, and at one time she became pale and weak from epistaxis and bleeding from

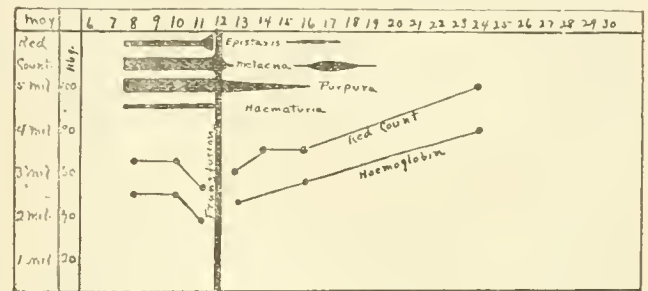

Fig. 5.—Chart of Case 1.

a small cut on the head. She improved somewhat after this, and for the following two months there was little bleeding. Two days before she came to the hospital, epistaxis began again and continued until admission to the hospital.

Examination.—The patient was a moderately developed and nourished little girl. She was pale and rather weak from loss of blood. On the right shoulder, cheek, and lower extremities were several small ecchymoses. There were no telangiectases. The physical examination was otherwise unimportant. Epistaxis continued almost without ceasing for five days, and the child became almost pulseless.

Transfusion.—She was transfused on October 7 by Dr. R. D. McClure. The patient's father was donor.

Course of Disease.—Transfusion improved the patient's pulse—volume and color, but owing to bronchopneumonia, which developed at about the same time, her condition remained serious for a few days. The temperature, which had ranged from 98 to 102 F., began to decrease and reached

5. This case has been reported in another connection by Pool and McClure, *Annals of Surgery*, September, 1910.

normal about a week later. The pulse-rate immediately dropped from 160 to 120 and a few days later to 90, where it remained. There was no bleeding for three days after transfusion. On the fourth day there was slight epistaxis, and hemorrhage from the vagina and transfusion wounds. Later, she had slight epistaxis and melena, as marked on the chart, and a fine petechial rash which followed straining at stool.

Blood Examinations.—August 8—red cells 2,300,000, hemoglobin 24 per cent. Other estimations showed about the same ratio between the red count and hemoglobin. The white count varied from 16,000 to 21,000. Blood smears on some occasions showed an excess of lymphocytes (71 per cent.), but usually polymorphs predominated. The red cells showed polychromatophilia and moderate variation in size. There were no blasts. The coagulation time was about normal (Boggs' instrument). The urine was not remarkable.

For five weeks after leaving the hospital the patient had no further bleeding. During the sixth week, however, she had prolapse of the rectum with bloody stools. One week later, she noticed that ecchymoses followed slight injuries. When seen at this time, (Nov 24, 1909), her color and general health were fairly good. On her head, elbow and legs, were

fusion were 3,000 and 20,000: the bleeding times were, respectively, ninety and twenty minutes. After transfusion the counts were 110,000 and 89,000, and the bleeding time in each case was three minutes. After the disappearance of these platelets, apparently introduced into the patients' circulation by transfusion, the bleeding times were again delayed (forty minutes and twenty minutes). In Cases 1 and 3 the bleeding times (forty minutes and one hour) came to normal after spontaneous rises in the platelet counts.

As to spontaneous hemorrhages, there was complete relief in Cases 1 and 3 for three days after transfusion and after spontaneous rises in the platelet counts. In Case 2 intestinal hemorrhage was slightly increased by transfusion, in spite of the fact that the general tendency to bleed (shown by the shortening of the bleeding time) was less marked. This apparently contradictory result may be accounted for by the fact that intestinal hemorrhage in this case was not entirely pathologic hemorrhage, but was due largely to bleeding from intestinal ulcers. The increase after transfusion may have followed the more complete filling of the blood-vessels.

In each of the cases the coagulation time of the blood bore no relation either to the platelet count or to hemorrhagic symptoms. The coagulation time was practically the same before and after transfusion, and before and after the spontaneous rises in the platelet count.

Other cases of hemorrhagic disease with a reduced number of platelets (twenty) have been reported by Denys, Hayem, Ehrlich, Helber, Bensaude and Rivet, Coe, Pratt and Selling. In one case reported by Bensaude and Rivet⁶ there was a low count (6,000) during a hemorrhage crisis. During a remission in the disease the count was 161,000. Coe⁷ has attached more importance to the relationship between the reduced number of platelets and hemorrhage than other observers. In one of his cases, the most severe epistaxis occurred

when the platelets, estimated from stained smears, were almost absent. Previously they had been present, but in diminished number. In another case of purpura hemorrhagica, platelets, frequently estimated from smears, were almost absent during two hemorrhagic periods, and were present during remissions.

The reported cases differ in etiology. Many belong to the group known as idiopathic purpura hemorrhagica. Some of the cases were evidently symptomatic. One of Pratt's cases⁸ accompanied nephritis. The platelet count was 9,000. Benzol poisoning was the etiologic agent in Selling's cases. The clinical condition was aplastic anemia. In one of his cases the platelet count was 2,500. In Case 2 reported in this paper, the hemorrhagic diathesis may have been secondary to ulcerative colitis. Plate-

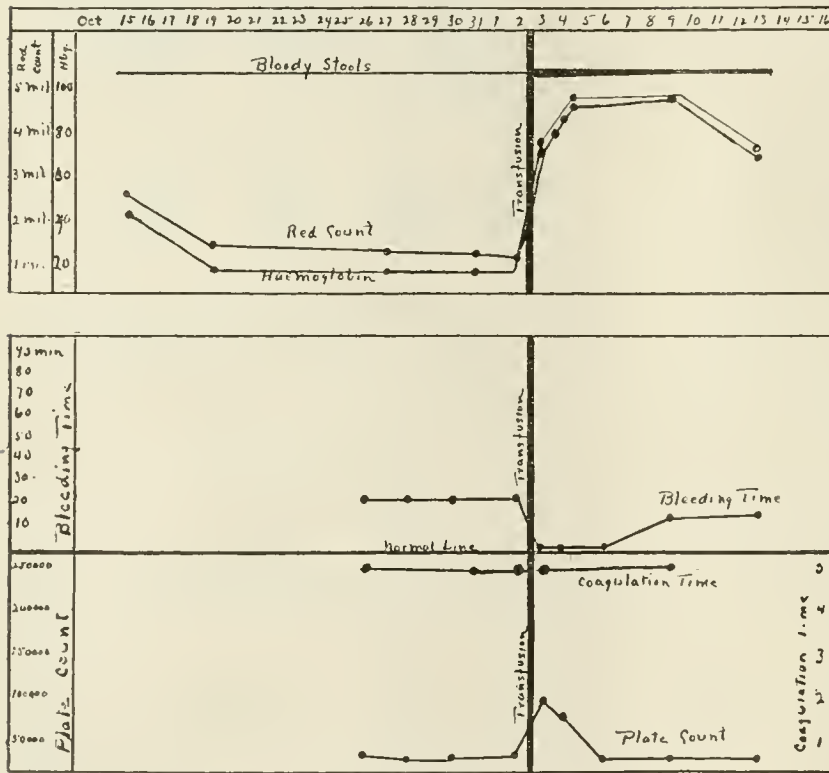

Fig. 6.—Chart of Case 2.

several small ecchymoses. Blood plates, as determined from stained smears and counting chamber, were extremely scarce. The bleeding time was about sixty minutes. The coagulation time was normal. The clot was firm and non-retractile. The white count was 7,000; polymorphs, 45 per cent.; lymphocytes, 55 per cent.; hemoglobin, 90 per cent. The patient was seen again four months later (April 7, 1910). She had been free from hemorrhagic symptoms for some time. Plates were then abundant in stained smears, and hemorrhage from ear pricks would last for from five to ten minutes. The hemoglobin was 85 per cent.

Platelet counts were not made in this case at the time of transfusion. It seems probable, however, that, as in the previous cases, the relief of hemorrhage, after transfusion, was associated with an increase in the platelet count.

COMMENT

A review of the cases shows a striking dependence of hemorrhagic diathesis on the reduced number of platelets. In Cases 1 and 2 the platelet counts before trans-

let counts may also be low in lymphocytic leukemia, pernicious anemia, and early typhoid fever, and in each disease purpura hemorrhagica is a recognized complication.

The data leads one to believe that a reduced number of platelets is not simply a phenomenon accompanying some types of hemorrhagic disease, but rather that it may be the direct cause of hemorrhagic diathesis in several diseases.

EXPERIMENTAL WORK

Experimental work seemed desirable to determine whether the hemorrhagic diathesis was due directly to the lack of platelets, or whether it was due to an abnormal coagulability of the blood which might accompany a reduced number of platelets. It seemed desirable also to know to what extent the platelet count must be reduced to cause hemorrhage.

In benzol poisoning we have a condition simulating idiopathic purpura hemorrhagica. Santessin⁹ has reported cases and experiments in which hemorrhages were produced by benzol. Selling's cases¹⁰ of a similar nature clinically, had very low platelet counts. He has found¹¹ that subcutaneous injections of benzol in animals reduces the platelet count. This reduction is thought to be due largely to the aplastic condition of the bone-marrow caused by the poison.

My experiments were performed mainly on dogs, and, according to a method suggested by Dr. Selling. Benzol was given daily for six to twelve days. The platelet count would usually rise at first, but later would fall and continue low for a number of days after the injections of benzol had been stopped. In several instances the count was reduced to 30,000. The white count was usually high even in the late stages of the poisoning.

The results¹² support a conclusion which might be drawn from this series of cases, namely, that when other conditions are normal, moderately low platelet counts are not associated with hemorrhagic diathesis. The platelet counts, after transfusion, in Cases 1 and 2 were only one-third of the normal, and yet there was no evidence of pathologic hemorrhage. The bleeding time was only moderately delayed (ten to twenty minutes) in Case 2, when the platelet counts varied from 20,000 to 30,000. The tendency to bleed in Cases 1 and 3 was extreme only during the practical absence of platelets. In the experimental work the platelet counts in dogs and rabbits were reduced from the normal (200,000 to 600,000) to from 50,000 to 75,000 without the appearance of hemorrhagic diathesis. Only a more extreme reduction (to 30,000) caused a delay in the bleeding time, and hemorrhages into the organs. There is an analogy between this observation and the observations of Whipple and Hurwitz on chloroform poisoning.¹³ They found that, when other conditions are normal, a moderate reduction in the quantity of fibrinogen does not cause hemorrhagic diathesis. In their experiments hemorrhage was prolonged only when the reduction was extreme. It seems likely, then, that both platelets and fibrinogen play a striking rôle in the control of hemorrhage. Either one

may be moderately reduced without symptoms, but after an extreme reduction there is a tendency to bleed.

The experiments failed to show abnormalities in the coagulability of the blood accompanying low platelet counts, which account for prolonged hemorrhage. The coagulation time was normal, or slightly shortened when the platelet count was as low as 30,000. The quantity of fibrinogen was normal or slightly increased (0.55 per cent. to 0.65 per cent.); furthermore, the fibrinogen present was all convertible into fibrin, and the fibrin examined in a number of ways had a normal microscopic appearance.

The serum in one instance was examined by Professor Howell, and found to contain thrombin. The only abnormality in the clot noted was diminished retractibility, a peculiarity shown by Hayem and others to be associated with and probably due directly to a lack of platelets. Normal plasma deprived of platelets in various experimental ways clots quickly, but does not retract from the sides of the vessel containing it, and extrude serum.

The hemorrhagic diathesis is explained, possibly, through investigations on experimental thrombi. In a bleeding vessel, there are conditions suitable for the formation of a thrombus, that is, injured intima and a flowing stream of blood. Platelets, although they have little, if any, influence on the clotting of still blood, play a striking rôle in the formation of thrombi. The inves-

Fig. 7.—Chart of Case 3.

tigations of Hayem, Eberth and Schimmelbusch, Welch, Pratt, and others, have shown that after trauma to a blood-vessel platelets are the first element to adhere to the injured intima, and that within a few minutes they are massed in great numbers at the injured point. Later, leukocytes, fibrin, and red cells are included in the process, and a plug is formed consisting of masses of each of these elements. The investigations of J. H. Wright¹⁴ show more clearly the rôle which the thrombus plays in stopping hemorrhage. His experiments were made by puncturing vessels with a needle. The resulting thrombi were likewise made up largely of platelets, and were evidently a factor in plugging the opening. An absence of platelets would lead to abnormality in the formation of thrombi, and might be a cause of prolonged hemorrhage. Pratt has laid more emphasis than other observers on the rôle which red cells play in thrombus formation. The failure of erythrocytes in carrying out this function explains, possibly, the delayed bleeding time noted in severe anemia.

CONCLUSIONS

The question now arises whether the facts admit the conclusion that an extreme reduction in the number of platelets is a cause of hemorrhagic diathesis, or whether the low platelet count must be considered a phenomenon which is sometimes found in hemorrhagic disease. The facts are as follows:

1. In the cases of hemorrhagic disease summarized, evidently differing in nature and etiology (acute and chronic idiopathic purpura hemorrhagica, chronic ulcerative colitis, aplastic anemia, nephritis), the constant features associated with the tendency to bleed were the reduced number of platelets, and the modification of the clot probably dependent on it, namely, diminished retractility.

2. In the cases reported in this paper, relief of the tendency to bleed followed not only the rises in the platelet count occurring at a remission in the disease, but followed also the rise brought about by transfusion. In the latter case, the tendency to bleed returned when the platelets disappeared.

3. Experiments in which the platelet count was reduced by benzol failed to show an abnormality in the coagulability of the blood, which accounts for the hemorrhages of benzol poisoning.

4. The structure and the mode of formation of experimental thrombi suggests, from an anatomic standpoint, that platelets play a rôle in stopping hemorrhage.

It may be permissible to mention two more points of interest suggested by the cases.

None of the patients showed so marked a tendency to bleed after transfusion as before, even after the platelet counts had dropped to their previous low level. In Cases 1 and 2, the bleeding times were ninety minutes and twenty minutes before transfusion. On the fifth day after transfusion, when the count was again low, the bleeding times were only half as long, fifty minutes and ten minutes. The spontaneous hemorrhages in Cases 1 and 3 were never so severe after as before transfusion. Since anemia is associated with a delayed bleeding time, this relief might be accounted for by the rise in the red count. In interpreting the beneficial results following transfusion, this point should always be considered.

In each of the cases, the platelets introduced by transfusion disappeared rapidly. It is granted that these platelets may have been destroyed prematurely by the disease from which the patient suffered, or by processes analogous to hemolysis, etc. The uniform rapidity in the rate of disappearance, however, suggests that platelets are short lived bodies. This interpretation is supported by the results obtained from the study of transfusion in benzol poisoning. In this case also, platelets introduced by transfusion disappear rapidly. It is also supported by results, to be reported later, which show that the normal rate of formation of platelets is probably extremely rapid, and may amount to as much as one-fourth of the entire number in the body per day. The evidence suggests strongly that platelets disintegrate or are utilized by the body in enormous numbers, and that the count is kept constant under a given set of conditions by a correspondingly rapid rate of formation.

The type of hemorrhagic disease described in this paper can be sharply differentiated from other types of disease, such as hemophilia, melena neonatorum, purpura simplex, Henoch's purpura, etc., which are due to other abnormalities. To this type of disease belong the

so-called idiopathic purpura hemorrhagica, and some cases of symptomatic purpura. The latter will probably be found most frequently in aplastic anemia, pernicious anemia, lymphocytic leukemia, typhoid fever and intestinal diseases. The symptoms may be mild, or may be so severe and acute that the patient bleeds to death in a few days. In mild cases, purpura may not appear. The only demonstration of the disease may be (as in Case 2) excessive hemorrhage from a local lesion.

The diagnosis is easy. If the platelet count is reduced to a sufficient degree to cause hemorrhage, the fact may be determined by examining carefully made cover-glass preparations. The absence of retractility of the clot is considered by Hayem and his pupils characteristic of the condition, and is of diagnostic import. A point which I have found of value in following the cases and also in the diagnosis is the marked delay in the bleeding time.

Transfusion gives good results in the treatment of the disease. In addition to replacing blood, it stops hemorrhage for a few days, and may tide the patient over a serious crisis. The treatment is probably applicable to the symptomatic as well as to the idiopathic types of disease, and may be useful in the treatment of some cases of typhoid hemorrhage.

In concluding, I wish to acknowledge my indebtedness to Dr. E. H. Whipple, of the department of pathology, to Professor W. H. Howell of the department of physiology, and to Dr. L. Selling for their kind assistance in the experimental work.

2028 Forest Avenue.

ABSTRACT OF DISCUSSION

DR. J. H. PRATT, Boston: There seems to be some relation between the blood platelets in the blood and purpura hemorrhagica. Normally, the number of blood platelets is about 450,000 to the cubic millimeter. In simple purpura I found the platelet count was greatly reduced; in one fatal case it fell as low as 7,000. This patient had continuous hemorrhages from the lips and mouth. The platelet count was made 3 times on different days, and the largest number of platelets found was 16,000. In a case of mild purpura hemorrhagica there were 105,000 platelets per cm. The only other condition in which I have found very low platelet counts is lymphatic leukemia. The relation between purpura and the coagulation time is less clear. Wright asserted that purpura was due to delay in the coagulation time and that the treatment of the disease consisted in reducing the coagulation time to the normal by the administration of calcium chlorid or calcium lactate. I found the records of the Johns Hopkins Hospital and the Massachusetts General Hospital those of 34 cases of purpura in which the coagulation time of the blood had been determined. The average coagulation time of the blood in this series of cases was 5½ minutes, which is within the normal limits. In only a few cases did I find a delay in the coagulation. I have seen a patient with purpura bleeding to death from the mucous membrane when the coagulation time was normal. Over the lobe of the ear at the site of the puncture a thick, moist clot formed, but blood continued to ooze from the wound for a long time. I believe that Dr. Duke's method of determining the "bleeding time" will be found to have great clinical value. In the case I have just cited in which the coagulation time was normal the bleeding time was doubtless greatly increased.

DR. W. W. DUKE, Kansas City, Mo.: Transfusion must be done by the direct method. Defibrinated blood is free from platelets and therefore in itself would not increase the count. There is a special indication for transfusion preparatory to operation in this condition. In addition to the usual results which follow transfusion, the tendency to bleed is diminished.

THE OPERATIVE TREATMENT OF CON-
GENITAL CLUB-FOOTCHARLES OGILVY, M.D.
NEW YORK

When a number of different operations are devised for the same surgical condition, we may assume, first, that the condition is a difficult one to treat successfully, and, second, that no one operation has proved entirely satisfactory in all cases. This is certainly true of club-foot—*pes equinovarus*. Few if any deformities are more difficult of perfect correction, and in few conditions, if any, do we see more postoperative relapses. It is not the object of this paper to discuss at length the various operations which have been devised, but rather to outline the surgical treatment that, from a varied experience with cases personally treated, I have learned to be most satisfactory.

WHEN TO OPERATE

Operation should be done early. Patients should not be allowed to remain with deformity for one to two years before a corrective operation is performed. If the patient is seen at birth or a few days later, forcible manipulation and a retention bandage dressing will suffice. Cases of the severest types of deformity treated thus early are corrected without operation. For the first three weeks when the skin is soft and tender, the corrective position should be retained after corrective manipulation by adhesive plaster, which is applied over a gauze bandage. After the third week the zinc oxid adhesive plaster can be applied directly to the skin. At the end of the third month, if corrective treatment is still required, a plaster-of-Paris dressing should be employed and this should always extend up to the groin. It is impossible to prevent the inward rotation of the foot and leg by a dressing that does not extend beyond the knee joint. If at the end of the seventh month the deformity of varus or equinus, or both, are present, due to contracted structures on the inside of the foot, or contraction of the *Achillis*, then an operation should be performed.

Though there are bone changes in the tarsus, the deformity is due in great part to the abnormal shortening of the soft structures. The bone deformities involve principally the astragalus, and also to a lesser extent the *os calcis*, scaphoid, cuboid and semilunars. The early remodeling of the foot and ankle, however, does not necessitate any operative bone procedure, as the bones are comparatively soft, and the deformities are not such as to prevent a corrective replacement of the foot. The greatest difficulty is the correction of the varus. This is due to the shortened structures on the inner side of the foot, principally the skin, subcutaneous tissue and fascia. Unless these are divided it is impossible to correct the varus. In severe cases, in patients over 6 months of age, corrective manipulation by stretching the structures gives very unsatisfactory results. The inner border of the foot is short and must be lengthened. Stretching skin and fascia does not give permanent lengthening.

OPERATIVE PROCEDURES

1. *Manipulation*.—If the deformity is but slight, it may be treated by manipulative measures with the patient under an anesthetic. Lorenz has emphasized the importance of this line of treatment. The foot is placed over a wedge-shaped block, and the varus is first

corrected. Not until the fore part can be readily everted should manipulation cease. This may mean from a half to three-quarters of an hour's work. When this is accomplished attention should be given in like manner to the equinus, stretching down the *tendo Achillis*. This manipulative operation may be repeated several times at intervals of a few weeks, many operators preferring several sittings to one. The application of the dressing is in all cases one of the most important steps of the operation. The foot is carefully held by a skilled assistant, with both the varus and equinus in overcorrection. A pad of shaken-out gauze about the size of one's fist is placed over the dorsum of the foot, another over the sole, and a third over the back of the heel. These are retained in place by a gauze bandage. Great care is taken not to draw the edge of any turn of the bandage too snugly over the instep, for this has frequently been the cause of subsequent circulatory disturbance. A thick layer of cotton is then applied from the toes to the groin, which is firmly but smoothly bandaged with gauze. A plaster-of-Paris dressing is applied to the whole limb, extending from the tip of the toes to the groin. Each toe should be of a bright pink color and the greatest care should be taken that good circulation is established before the patient is removed from the operating-room. If the circulation is not good a diamond-shaped fenestra should be cut out of the plaster over the flexure of the ankle-joint, and all the dressings over this area removed directly down to the skin. This eliminates the necessity of removing the whole plaster-of-Paris mold.

2. *Subcutaneous Division of Structures*.—Better results are obtained, even in children under 12 months of age, when in addition to manipulative procedures, subcutaneous tenotomies are performed. The plantar fascia and subcutaneous tissues on the inner and under side of the foot are subcutaneously divided. The tenotome is passed in immediately under the skin, and then turned with the cutting edge towards the deeper structures. The inner side of the foot is now forcibly stretched and the tightened structures are easily divided. If the skin is too short, it also should be cut. The varus is then forcibly corrected until an overcorrection of the deformity is obtained. To correct the equinus the tenotome is passed beneath the *tendo Achillis* and with a saw-like motion this tendon is cut, almost, but not quite through, the uncut remainder being torn apart by pressing up against the foot. By this method a few fibers of the tendon remain which act as a bridge in the process of repair and along which reunion may more readily take place. The dressing already described is then applied.

One sees many postoperative cases in which the fore-foot has been successfully everted but the heel is markedly inverted. This should be carefully avoided by correcting the position of the *os calcis*, which cannot be done in the great majority of cases without first cutting the *tendo Achillis* and forcibly everting the heel.

3. *Phelps' Operation*.—Experience has proved to me that Phelps' operation is the one of choice in all severe cases of patients over 2 years of age. It is sometimes advisable even at an earlier age. I have employed this operation as early as 2 years of age and as late as forty-five years of age. An incision is made commencing in front of the internal malleolus and extending one-third of the distance across the sole of the foot. This incision is carried down to the neck of the astragalus on its inner side. The foot is forcibly corrected, all re-

sisting structures being cut. These are the skin, superficial and deep fascia, the abductor pollicis, the tendon of the tibialis posticus, the flexor brevis muscle, and long flexor tendons of the toes, and finally, if necessary, the deltoid ligament wholly or in part. These resisting structures having been cut, the varus can be readily corrected. It is seldom necessary to ligate any vessel. The open wound thus formed when the varus is corrected may be an inch or more in width. This is covered with protective or sterilized rubber tissue over which the shaken-out gauze is placed as already described. Phelps always cut the tendo Achillis first before making his plantar incision. I have found it more satisfactory to correct the varus before the tendo Achillis has been cut, and always to leave the subcutaneous tenotomy of this tendon as the last step in the operation. If sufficient correction is not obtained by this method, Phelps advised a linear osteotomy through the neck of the astragalus.

If this fails, a V-shaped piece should be removed from the os calcis, the apex of the V meeting the linear osteotomy, and this failing, the removal of the cuboid and scaphoid is indicated. The great advantage, however, of Phelps' method is that bone surgery is rarely necessary. The other advantages are, (2) a lengthening of the foot, (3) a perfect correction of the deformity, (4) a permanent correction, (5) a rapid operation, (6) a useful foot without the need of a postoperative brace. Reported failures are generally owing to a fear of making the incision too long and of not opening the gap sufficiently wide, thus obtaining an insufficient over-correction of the foot. The resulting scar is not hypersensitive. The anesthesia on the under surface of the foot anterior to the incision, which sometimes results, is not permanent.

4. *Excision of a Portion of the Cuboid.*—This operation is strongly recommended in selected cases. In treating clinical patients it often happens that the postoperative care is neglected by the parent and the patient returns months later with marked relapse. In three such patients, one of whom had had three previous operations, I obtained a cure by the removal of the proximal third of the cuboid, making a wedge-shaped excision, at the same time removing the articulating surface of the os calcis. When the foot is forcibly corrected, this space thus formed is closed in and the newly cut surfaces brought closely in contact. This forms a fixed joint, which, after union takes place, holds the foot firmly in position. This operation is especially indicated when the resistance to correction is due not so much to the shortened tissue on the inner side of the foot, but more especially to the disproportionate growth of the cuboid, which can be readily recognized.

5. *Osteotomy of the Tibia.*—The inward rotation of the tibia which sometimes is present results in a toeing inward after the equinovarus has been corrected. This is more especially noticed as the child walks. If the rotation is but slight, it can be satisfactorily treated by a brace. This brace must extend from the foot to the pelvis, as any shorter brace will not control the inward rotation of the foot. With the pelvic band firmly fixed we can rotate the lower end of the brace at will, and being attached to the shoe, the foot is rotated out with it. In cases in which correction cannot be obtained in this way operation should be done. A subcutaneous osteotomy of the tibia is performed. The lower end of the tibia and the foot are rotated outwards, and the limb

put up in a plaster-of-Paris dressing, which should be left undisturbed for five weeks. This treatment alone will ensure satisfactory results.

POSTOPERATIVE TREATMENT

The postoperative treatment of congenital club-foot is quite as important as the operation itself. The number of relapses that occur are due in great part to lack of care, either on the part of the parent or on the part of the surgeon, usually of the former. The first dressing need not be removed for five to six weeks, irrespective of the operation which has been performed. After the first dressing is taken off, another should be applied. It is well to remember that a plaster-of-Paris mold makes the best fitting and lightest dressing that can be applied, and so it is advisable to continue these molds for upward of six months. A short mold should not be applied; the mold should always be carried well above the knee. If a brace is deemed advisable after an operation, it should extend up to the pelvis with a pelvic band. This is a good general rule to follow, and will avoid much trouble and unsatisfactory adjustment experienced with shorter braces. A laced shoe with stiffened ankle should be worn. The sole and heel of the shoe should be one-eighth inch thicker on the outer side than on the inner, thus giving an everted tilt to the foot. Such a shoe should be worn for two years.

Supervision of the case should be continued for at least one year and a half after the operation. This is essential because of the great tendency of the deformity to relapse, and the liability of a gradual relapse being unnoticed until a marked deformity has recurred. The prognosis in every case is good. The foot may remain a little shorter than its fellow. In cases in which long-continued retentive bandage dressings have been necessary, the muscular development below the knee is permanently affected. The amount of this atrophy will depend on the conditions of the case.

SUMMARY

- I. Corrective manipulation should begin at birth.
- II. Early operation should be done if necessary (seventh or eighth month).
- III. Operative procedures will depend on the degree of deformity, and are as follows:
 1. Forcible manipulation under an anesthetic.
 2. Subcutaneous division of contracted structures.
 3. Phelps' open operation.
 4. Other bone operations, especially:
 - A. Excision of a portion of the cuboid in selected cases.
 - B. Osteotomy of tibia for marked inward rotation.
- IV. Long-continued and careful postoperative attention is essential.
- V. The best results are always obtained when the treatment is begun at birth.

Ear Disease in Children.—The greatest service we have yet to render to childhood is to recognize ear disease when there are no striking manifestations. This result will be attained when the knowledge of the pathologist is applied by the clinician, and the ears of all sick children are frequently examined as a matter of routine. E. Gruening, in the *Laryngoscope*.

PARTIAL THYROIDECTOMY IN DEMENTIA
PRÆCOX*RANDOLPH WINSLOW, M.D., LL.D.
BALTIMORE

The term "dementia præcox" is applied to a condition of progressive insanity occurring in young persons, usually between the ages of 18 and 25 years, though occasionally it may be delayed until later in life. This disease, whilst presenting many variations, has been divided into the following groups by Kraepelin: hebephrenia, catatonia, and paranoid dementia, which at times are sharply defined from each other, but sometimes resemble each other so closely that a differentiation is difficult. About 15 per cent. of all cases admitted to institutions for the care of the insane are of this character. It is a chronic form of mental disease, usually beginning insidiously, but sometimes acutely, and generally terminating in complete imbecility. In 70 per cent. of cases there is a history of some hereditary taint; in a few cases a history of trauma or of some infectious disease; in others of overexertion, mental or physical, and in some there is apparently no exciting cause. The chief characteristics of this disease, or possibly group of diseases, are emotional dulness and indifference, progressive mental deterioration, lack of judgment, retarded psychical reaction, weakness of will, with little or no disturbance early in the disease in the field of apprehension or of memory. Even in childhood many of these individuals are peculiar and eccentric; some of them are of dull intellect, but others are well educated and of more than average intelligence. These patients for quite a while before mental symptoms appear may complain of various disagreeable cephalic sensations, of inability to concentrate the attention, of ready fatigue, insomnia, restlessness, listlessness and apathy or excitement, or egotism, unreasonable emotional outbreaks, depression, carelessness as to obligations, indifference and neglect of person; their actions and statements may be silly and impulsive; the patients may be indifferent to the feelings of family and friends, or may display peculiarities of action, dress and speech. With these symptoms there is generally loss of weight, disturbance of the menstrual function, loss of appetite, etc.

This period of the disease may extend over a long or short time, and with or without the above symptoms we may have the development of one of the three characteristic forms.

The hebephrenic form is characterized by the above-mentioned symptoms, which increase in intensity, and to which may be added hallucinations and delusions, which are seldom very prominent, spells of excitement and depression, unreasonable outbreaks of temper, disturbance of conduct, which becomes childish and silly, with more or less marked emotional dulness.

The paranoid form includes two groups of cases that are characterized by the great prominence and persistence of delusions and hallucinations leading in a few years to dementia.

The catatonic form, so called from one of its most prominent symptoms, that of muscular spasm or rigidity, is usually subacute in its onset. After a short prodromal period, characterized by an entire alteration in the disposition and character of the patient, with more or less mental depression, anxiety and fear, certain peculiarities

of the motor system set in with marked muscular tension. Hallucinations and delusions often appear, which are usually of a religious character, incoherent and changeable. Consciousness is clouded or lost and thought disturbed, while the emotional attitude is generally sad or one of entire indifference. Soon a stage of stupor supervenes, in which the patient will not talk or answer questions, may not eat and requires to be fed artificially, remains in one position for long periods and becomes absolutely bestial in his habits. This lasts for varying lengths of time, alternating with remissions in which the sufferer regains more or less lucidity but does not become entirely normal, or he passes from a stuporous state into one of excitement of mind and body, after which he becomes progressively demented.

We have in addition to the mental symptoms, in many cases, marked physical signs, the more frequent being temperature disturbances, rapid, slow or irregular pulse-rate, disturbance of the arterial pressure, marked vasomotor and secretory disturbances, increased and decreased tendon reflexes, loss of weight, tremors of the tongue, facial muscles and extremities, increased mechanical irritability of the muscles, dilated pupils, excessive pupillary activity, leukocytosis and convulsive seizures.

The course of the disease as a rule is slow, extending over several years. All the cases of the paranoid form eventually terminate in dementia. In the hebephrenic form 25 per cent. of the cases terminate in complete mental annihilation, 17 per cent. become demented to a less degree and about 8 per cent. apparently recover. In the catatonic form remissions are frequent, lasting from a few hours to several years; 55 per cent. of the cases terminate in total dementia; 35 per cent. of the patients become demented to a less degree and 10 per cent. apparently recover.

For many years this condition has been ascribed to some endogenous intoxication, and the different internal organs have been interrogated, but with very indifferent success. Two Italian observers, Bernigni and Zilocchi, report degeneration in the thyroid and other glands, and Kraepelin also refers to changes in the thyroid gland in some cases. In 1907 Drs. H. J. Berkley and N. M. Owensby of Baltimore, while casting about for some rational basis for the treatment of this disease, observed a superficial resemblance between catatonia and exophthalmic goiter (Graves' disease), and were led to think of the thyroid gland as a causative factor in the production of this condition. Among the symptoms suggestive of increased or perverted thyroid activity were tremor, hyperidrosis, muscular spasm or rigidity, increased reflexes, leukocytosis, and loss of weight. After the failure of methods of treatment by drugs, and various glandular extracts, and a distinct intensification of the symptoms when iodine and thyroid preparations were used, it occurred to them to try the removal of a portion of the thyroid gland.

In June, 1907, permission was secured to operate in the Baltimore Insane Hospital at Bay View, on two patients, who were the subjects of advanced catatonia. The first patient was a girl aged 19, who after the usual prodromal symptoms, with religious delusions, became excited, unmanageable and destructive, and was committed to the hospital in March, 1907. She then became mute, restless, apathetic, catatonic and untidy in habits and dress, with mask-like expression, sweating and a leukocytosis of 20,000. Subsequently hallucinations supervened, with much excitement, sleeplessness and

* Read in the Section on Surgery of the American Medical Association, at the Sixty-first Annual Session, at St. Louis, June, 1910.

refusal of food. The second patient also presented about the same symptoms, with religious delusions, and excitement, subsequently becoming mute, with increased reflexes, hyperhidrosis, tremor, muscular rigidity and slight leukocytosis. This was a man aged 21. The operations were done by Dr. R. H. Follis, who removed about four-fifths of the right lobe of the thyroid gland in each case.

These patients exhibited a marked change in their mental condition within forty-eight hours and in the course of several months were restored to a condition of physical and mental soundness, and became again useful members of society. Two other patients operated on in November, 1907, improved more slowly, but eventually were restored to health; but in one case there was a recurrence of the symptoms two years later. The same physicians also operated in three cases at the Second Hospital for the Insane of Maryland, which were of longer duration and more advanced, but without beneficial result. In the case of a man aged 25, an inmate of the Sheppard and Enoch Pratt Hospital, who was mute, refused food, and remained in one position until moved by an attendant, and had been in this condition for four and one-half months, partial thyroidectomy was followed by most excellent success. The patient made a complete recovery and was seen by me one and one-half years subsequently, and seemed entirely rational and was following his usual avocation, that of a driver of an express wagon. All the above cases were reported by Dr. Henry J. Berkley.¹

The only other cases I have been able to find in the literature are those reported by Kanavel and Pollock of Chicago,² consisting of twelve patients suffering with the catatonic form of dementia præcox, who were submitted to partial thyroidectomy.

Dr. Kanavel reports his results as follows:

There was absolutely no result in any of the old cases. Of three patients operated on in the so-called favorable stage, two showed marked improvement, lasting, in one case, for two months and in the other, for six months. The third showed no change at all. The two who showed temporary improvement relapsed at the end of the periods mentioned, and are now practically in the same condition as before operation. The pathologic examination of the glands removed did not show changes favoring the diagnosis of thyrotoxicosis although the changes were compatible with it.

Kanavel concludes that while we cannot assume any distinct pathologic basis for ascribing dementia præcox to a hyperthyroidism similar to exophthalmic goiter, the pathologic picture cannot definitely exclude a perverted thyroid metabolism as a factor.

Dr. Berkley's conclusions are also very much in accord with those expressed above. He says:

The results of the histologic and chemical examinations have been inconclusive, as to whether or not we have to deal with a perversion of the secretion of the thyroid gland in catatonia. Nevertheless, it is possible from the symptoms that in catatonia we have a perversion of the secretion of that organ, and that partial thyroidectomy induces a return to the normal in the secretion of the remaining portion of the gland.

As a contribution to the literature of this subject, I append the following brief summary of five cases of patients operated on by surgeons connected with the University Hospital, Baltimore: Of these patients one died from acute thyroidism. Two were greatly improved for a considerable period, and then relapsed into their

previous condition. One was not materially benefited and has since been placed in an institution for the insane; and one improved but has been lost sight of.

This experience is not very encouraging; nevertheless I believe the following conclusions to be justified.

CONCLUSIONS

1. There seems to be some connection between the thyroid gland and the peculiar affection called catatonia.

2. Partial thyroidectomy in the early stages of this disease exercises a favorable and sometimes a curative effect on the condition.

3. In late stages of catatonia and in the other forms of dementia præcox, partial ablation of the thyroid is not followed by beneficial results.

4. The operation is attended with the usual dangers of thyroidectomy and should be done with as much care as in exophthalmic goiter, especially in regard to free drainage.

THE INFLUENCE OF COLLOIDAL PROTECTION ON MILK *

JEROME ALEXANDER, M.Sc.

AND

JESSE G. M. BULLOWA, M.D.

Lecturer on Clinical Medicine, New York Polyclinic

NEW YORK

With the aid of the ultramicroscope which brings into visibility particles whose size approximates the theoretical molecular dimensions, it has been demonstrated that colloidal solutions occupy a sphere midway between coarse mechanical suspensions and true crystalloidal solutions. The slight Brownian movement of small suspended particles at the limit of visibility in the ordinary microscope (about $\frac{1}{4}$ micron), is insufficient to keep them afloat, and they gradually settle out of solution; but as the subdivision of the particles proceeds, this motion gradually increases in speed and amplitude, until it becomes so violent that the particles remain permanently afloat and in solution. Ultramicroscopic particles (ultramicros) as small as about 5 microns (the present limit of the ultramicroscopic visibility) describe an average free path of about ten times their own diameter in one-sixth to one-eighth of a second.

From a practical standpoint, colloids may be divided into the *stable* or *reversible* colloids or hydrosols, which do not readily coagulate and redissolve after desiccation at ordinary temperatures (e. g., gelatin, gum arabic), and the *unstable* or *irreversible* colloids or hydrosols, which exhibit contrary properties (e. g., pure colloidal metals and oxides). Most electrolytes cause the flocculation of fine suspensions and the coagulation of unstable colloids. Stable colloids are not only insensitive to most electrolytes, but they possess the striking and very important property, even if present in surprisingly small quantity, of being able to stabilize and protect unstable colloids from coagulation and permit them to redissolve after desiccation.

The accompanying diagram exhibiting the relation of suspensions, colloidal solutions and crystalloidal solutions, will serve to make clear what is above stated:

1. Berkley, Henry J.: Jour. Insanity, January, 1909

2. Kanavel, A. B., and Pollock, L.: THE JOURNAL A. M. A., Nov. 13, 1909, p. 1675.

* Read in the Section on Diseases of Children of the American Medical Association, at the Sixty-first Annual Session, held at St. Louis, June, 1910.

The application of the simple principles of colloid chemistry to foods gives us a new and valuable insight into their behavior during digestion, for it is a well known fact that the digestibility or desirability of a food cannot be expressed solely by its chemical analysis, any more than such an analysis will express the difference between lamp-black, graphite and diamond, all of which the chemist would report as practically pure carbon.

From a colloid-chemical standpoint, the main constituents of milk may be classified as follows:

- In crystalloid solution { salts (such as NaCl, etc.)
sugar (lactose).
- In colloidal solution { casein—an unstable or irreversible colloid.
lactalbumin—a stable or reversible colloid.
- In suspension { milk fat.

It is possible that some of the fat may be in colloidal solution, for sodium oleate may be present, and this salt is a reversible colloid in aqueous solution.

protective action. We are also informed by Prof. H. Bechhold that these results have been confirmed by ultrafiltration experiments recently conducted by Dr. Grosser at the Krankenhaus, Frankfurt.

The subjoined table will show how milks are influenced by a difference in the ratio between the casein and lactalbumin:

Kind of Milk.	AVERAGE COMPOSITION				
	Cascin.	Lactalbumin.	Fat.	Behavior with Acid.	Behavior with Rennin.
Cow	3.02	0.53	3.64	Readily coagulates.	Readily coagulates.
Woman	1.03	1.26	3.78	Not readily coagulated.	Not readily coagulated.
Ass	0.67	1.55	1.64

It is interesting to note that the milks in the above table are arranged in order of their digestibility, which also corresponds with their relative colloidal protection. Thus Jacobi³ has stated that asses' milk has always been recognized as a refuge in digestive disorders in which neither mother's nor cow's milk or its mixtures were tolerated.

The addition of protective colloids to cow's milk stabilizes it and makes it act more like mother's milk when treated with acid and rennin. In fact, if sufficient protective colloid be added, coagulation of the casein in the stomach may be entirely prevented, or at least the coagula kept in a very fine state of subdivision.

The action of protective colloids is beautifully illustrated in the ultramicroscope, which enables us to see the individual particles of cow's casein in active motion and watch the course of their coagulation by acid, first into small and then into larger and larger groups, whose motion decreases as their size increases, until finally they sink out of solution in coagulated masses. If, however, some gelatin or gum arabic solution be added to the cow's milk before the addition of the acid, the casein particles continue their active dance and do not coagulate. In this connection it is interesting to note that the casein particles in mother's milk appear to be much smaller than those in cow's milk, probably because of the more highly protective medium in which they are formed and exist.

Although their method of action was not perfectly understood, protective colloidal substances have for years been used in the modification of cow's milk for infants. For over twenty years Jacobi has advocated the addition of gelatin and gum arabic to cow's milk and infant's diet,⁴ and the use of gruels, dextrinized starch and similar reversible colloids is familiar to all. It is interesting to note that sodium citrate, which is largely employed as an addition to cow's milk, acts as a protective colloid, and when going into solution actually exhibits actively moving ultramicros in the ultramicroscope, a fact which indicates its colloidal condition.

In addition to stabilizing the casein, protective colloids in milk have a very important influence on the milk fat. In the first place is to be considered the emulsifying and emulsostatic action of reversible colloids,⁵ which may be demonstrated by adding ferric chlorid to an ordinary emulsion of cod-liver oil.⁶ This coagulates the emulsostatic protective colloid and the oil separates out. Of much greater importance, however,

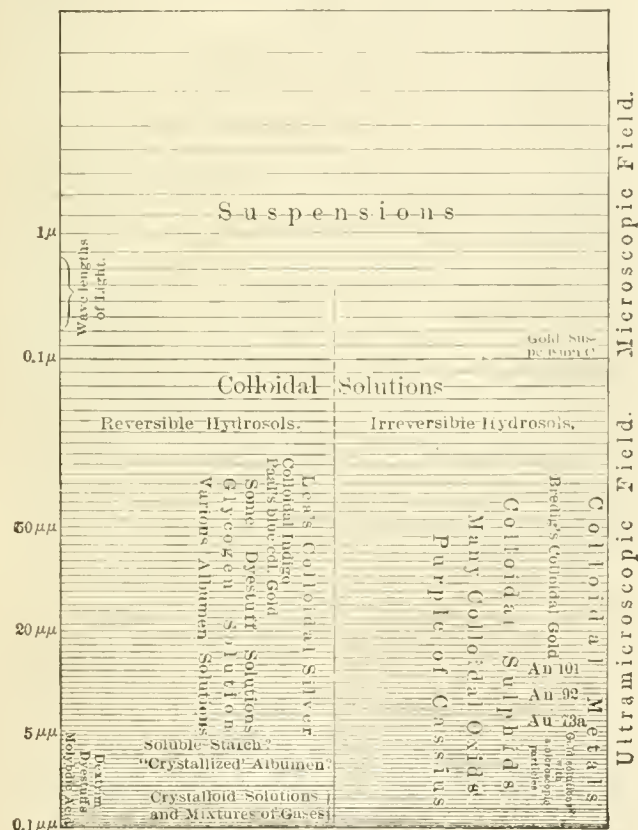

Diagram showing classification of colloidal solutions¹ according to the size of the particles contained in them and according to their behavior on desiccation.

Most formulas and recipes for modifying cows' milk for infant feeding, and for that matter, many analyses, combine the percentages of lactalbumin and of casein under the collective title of "total proteins," thereby obscuring the highly important fact that the lactalbumin stabilizes and protects the casein from coagulation by acid and rennin, as has already been demonstrated.²

Some of our recent experiments have demonstrated that after digestion with pepsin, lactalbumin loses its

6. In the churning of butter, the protective action of the lactalbumin is overcome by mechanical agitation, which frequently coagulates colloids.

is the result of stabilizing the casein, for it is a well known fact that casein in curdling carries down mechanically most of the milk fat present,⁷ yielding a greasy, fatty curd which is very difficult for the digestive juices to work on.

It is evident, then, that there is something to be said on both sides of the much-mooted question as to whether fat or casein is responsible for certain forms of indigestion, for apparently both have to do with the formation of the "fat stools." So-called "fat indigestion" therefore may be, and in many cases probably is, caused by insufficient colloidal protection of the casein, and may in such cases be met by adding protective colloids rather than by reducing the percentage of fat to an undesirable minimum. Indeed, cases of "fat indigestion" occur in which the quantity of fat in the cow's milk fed has been reduced to 2 per cent.

The most conflicting opinions have been expressed regarding the desirable percentages of protein and fat in cow's milk as modified for infants. Thus Jacobi⁸ states that a high percentage of protein does not improve a milk's digestibility (therein disagreeing with Dr. Walls, of the Northwestern University), and he therefore attributes the digestibility of asses' milk to its low fat content.

But, on the average, mother's milk contains more fat than the less digestible cow's milk; and even if cow's milk be so modified that it contains the same percentages of "proteid" and fat as mother's milk, it is still not so readily digested. Jacobi suggests that a difference in the fat itself is a factor of importance, and this is undoubtedly so, for S. Levites has shown⁹ that the most fluid fats are most readily digested. The main source of these conflicting opinions, however, lies in the rather unhappy term "total proteids," which as used, includes substances with such different properties as casein, lactalbumin, gluten, and broth extractives, and thus conceals the protective action that the reversible colloids exert on the coagulable casein.

Colloidal protection may be accomplished by the use of animal proteins (gelatin, albumin), vegetable proteins (gluten) or carbohydrates (gum arabic, tragacanth, Irish moss), so that there is wide choice in clinical practice. The dextrinized gruels now used combine the protective colloids gluten and dextrin. Under the ordinary conditions of digestion, casein is coagulated only in neutral or acid solution; it is quite evident, therefore, that alkalis such as lime water and bicarbonate of soda, may by their antacid action, partially or entirely inhibit the coagulation of casein. Quite different, however, is the case of sodium citrate which acts as a protective colloid, as before stated.⁹

CONCLUSION

Increasing the colloidal protection of the casein in cow's milk by the addition of suitable protective colloids tends to improve the digestibility and absorption of both the casein and the fat, and to prevent the formation of indigestible curds and their consequences.

ABSTRACT OF DISCUSSION

DR. FRANK S. CHURCHILL, Chicago: I think that Mr. Alexander cannot be familiar with the widespread habit among us of "splitting" proteids. In feeding a fairly healthy baby we do not have to split them, but in the case of babies of limited casein digestive power we have to use split proteids, doing it by substituting whey. As a clinician I want to make that statement.

DR. E. H. BARTLEY, Brooklyn: Does milk sugar pass into a colloidal or into a crystalloidal state? It is known that milk sugar when first dissolved will give a certain rotation in the polariscope, which changes gradually for twenty-four hours and then this change ceases.

DR. THOMAS S. SOUTHWORTH, New York: All the information we can get of a collateral order which proves or disproves the theories on which we have been working is of the greatest value to the pediatrician. I hope Mr. Alexander will correct the impression, which he probably did not mean to convey, that it was possible by the protection of colloids to prevent entirely the coagulation of casein. We know as clinicians that though it interferes with it, we may still get pretty large curds in stools when such things have been added to the food.

MR. JEROME ALEXANDER, New York: I was aware of the term "split proteid," and of its significance, but in a paper of this kind I could not go into all the points involved. There is a great difference in the relative protective action of the various colloids. Not only does each substance vary, but it varies according to the particular medium in which it is dissolved. Gelatin is the most efficient of all protective colloids; but as they vary considerably in their protective action, the physician must find out from experience which is the most efficient in any particular case. Whether milk sugar goes into colloidal or crystalloidal solution is a matter of small consequence. It is possible that its particles undergo a progressive decrease in size and there is no way of saying where colloidal solution ends and crystalloidal solution begins. Colloidal protection will not necessarily prevent the curdling of casein entirely, for coagulation would depend on the acidity of the gastric juice, which in turn would be influenced by the sugar content or whatever would tend to produce lactic acid. When we increase the protection of casein in cows' milk we simply tend to make it more difficult to coagulate its casein. Whether the casein will coagulate in the stomach or not we cannot certainly fortell, but so far as the test tubes show it is much less sensitive to coagulation by acid or rennin.

IS ACUTE CHOREA AN INFECTIOUS DISEASE?

ALFRED GORDON, M.D.
PHILADELPHIA

The frequent (though not constant) association of chorea with acute inflammatory rheumatism is a well-established fact. Whether the infectious element of the latter (*Micrococcus rheumaticus*, streptococci) or the toxins elaborated by the suspected micro-organism are the same etiologic causes of the acute chorea it is impossible as yet to ascertain. That other infectious diseases may be followed by attacks of chorea is also well known. Whooping-cough, measles and influenza have been reported as immediately preceding the onset of chorea. All these facts are highly presumptive of the contention of some authors that chorea is infectious in nature. This presumption gains a still more solid ground if we recall the bacteriologic work of Pianese, who found in the spinal cord of a choreic individual a bacillus with the cultures of which he made successful inoculations. Micro-organisms in the brain have also been found by other authors.

While the view of infectious origin of acute chorea is highly possible, nevertheless Charcot's and Joffroy's

original opinion must not be lost sight of, viz., the existence of an inherent degenerative predisposition of the motor apparatus in choreic individuals. This predisposition is brought in evidence as soon as some special cause disturbs the latter. This cause may be any infectious disease.

The observation which I wish here to put on record is in line with the "infection" view of the pathogenesis of chorea. The only difference lies in the fact that instead of being a generalized infectious disease, the cause apparently lies here in an infectious localized focus.

History.—A boy, aged 10, through neglect of his teeth and exposure began to suffer severe pains at the level of lower molars on the left side. The gum became swollen, the jaw at the same level was extremely tender to touch. There was a very marked thickening of the lower maxilla, and the child developed fever and excruciating headache. The pain and tenderness of the jaw increased in intensity. Gradually an abscess formed. An incision was made on the sixth day and a large amount of pus was evacuated; microscopic examination showed the presence of streptococci and staphylococci. The subjective symptoms gradually subsided. While the wound kept on discharging, the mother noticed that things would drop out of the boy's right hand; then he would draw up his right shoulder, wink his eyes and make faces. Gradually the entire body became affected; he could not stand still. The movements were sudden, incoherent and irregular.

Treatment and Course of Disease.—At that stage of the disease, viz., eight days after the onset, the boy was brought to me. It was a case of typical Sydenham's chorea. The remarkable history of the case in regard to the chronologic relationship between the pus formation and the development of choreic movements led me to the thought that there was probably also a causal relationship between the two conditions, and that therefore the clearing up of the nervous phenomena would probably depend on the removal of the focus of infection. Accordingly, energetic measures were taken to remedy the latter condition. The decrease of the purulent discharge became more and more noticeable. The choreic movements did not decrease at first with the same rapidity, but later became less and less marked. Finally the wound healed up. The nervous phenomena continued for a period of six days and eventually have totally disappeared. The entire duration of the chorea was eighteen days. No medication whatever was administered and the whole attention was concentrated on the removal of the focus of infection. General directions, however, were given as to a light diet and removal of stimulants such as tea and coffee.

The parallel development of the localized inflammation, with the development of an abscess and the appearance of typical choreic movements at the time of formation of pus; then later on the gradual disappearance of the purulent discharge with its streptococci and staphylococci and marked amelioration of choreic movements; finally the disappearance of muscular twitchings when the infectious focus was removed—all these facts make the case highly interesting and instructive from the standpoint of the pathogenesis of chorea. This case can be placed alongside of cases with an immediately preceding or accompanying history of acute inflammatory rheumatism, whooping-cough, measles, influenza, etc. The etiologic factor presents itself here, clinically at least, with far more evidence than in the cases with a history of an infectious disease. Of not smaller importance is the therapeutic aspect of the case.

In further support of an infectious origin of chorea I may mention a case seen very recently with Dr. Helen P. Proctor.

History.—A girl of 13 was suddenly taken with chills, fever, headache, vomiting, and general malaise. On the third day, when the above symptoms began to subside, choreiform move-

ments were noticed in the right hand. Gradually the latter spread over the entire body, and at the time the patient was seen by me, viz., twelve days after the onset, she presented a typical form of acute chorea. The irregular and incoherent movements, however, were more marked than in an ordinary case. The twitchings were so violent especially during voluntary acts, that she was unable to sit up or stand up. Bed-ridden position was the most comfortable one for the patient.

The few symptoms immediately preceding the onset of the chorea are identical here with the prodromal manifestations of acute anterior poliomyelitis, which is undoubtedly an infectious disease.

The infectious onset of this case is self-evident and perhaps the severity of the chorea is in keeping with the severity of the infection; the girl indeed complained of very severe headache.

The few facts brought forward speak in favor of some infectious element which irritating the motor tract or motor area produce the characteristic phenomenon of the malady. It is true that in many cases no etiologic cause can be detected in chorea. On the other hand, no apparent cause can be brought out in some cases of acute anterior poliomyelitis and yet being convinced of the infectious nature of this disease, we suppose that the prodromal symptoms are sometimes so slight that they pass unnoticed by the little patient's relatives. It is, possible, therefore, that a similar prodromal condition exists sometimes also in chorea. We do know that infectious diseases may be followed by chorea, also that a local infection may be followed by or develop simultaneously with chorea, as the first of my two cases demonstrates it. The experimental investigations of Landsteiner and Popper, Leiner and Wiesner, Landsteiner and Levaditi, Strauss and Hunton, Flexner and Lewis with regard to transmissibility of anterior poliomyelitis in higher animals are paving the way to a new therapeutic serum.

The same endeavors may perhaps be directed toward the disease discussed in this brief clinical note. The association of an infection, generalized or local, with chorea, as related here, is more than a mere coincidence. Close observation will perhaps reveal in more than in a few cases a prodromal syndrome which happened to pass unnoticed because of the inconspicuousness of the manifestations exactly in the same manner as we learned from experience to consider the onset of acute poliomyelitis. If we wish to carry the pathogenetic analogy between these two affections further, we must turn our attention to pathologic findings. Autopsies in cases of acute chorea are rare. One of the most complete pathologic reports is that of Hudovernig.¹ He found marked vascular lesions in the central nervous system consisting of dilatation of capillaries, perivascular infiltrations with round cells and edema. Cellular changes are found in the cortex and they consist of a glandular degeneration. Vacuolation is seen in the cells of the cornu ammonis. There is also a slight ependymitis and leptomenigitis. He also found a large number of special corpuscular bodies (*Choreakörperchen*) disseminated in the vicinity of blood-vessels and especially in the medulla and pons at the level of the pyramidal pathways. Hudovernig's interpretation concerns chiefly these corpuscles which according to him have an irritative action on the pyramidal tracts and thus produce choreic movements. Whether the corpuscular bodies are specific of chorea is difficult to say. Nevertheless the presence of vascular changes typical of an inflammatory state; also the pres-

1. Arch. f. Psychiat., xxxvii, 1, 1903

ence of cellular changes in the cortex analogous to those in acute poliomyelitis are interesting from our point of view. If the virus of acute poliomyelitis has a special predilection for the cells of the anterior cornua in the spinal cord and sometimes also for the cells of the nuclei in the medulla—in chorea the etiologic agent (to speak cautiously at present) has a predilection for the cells of the cortex and especially in the motor area and not infrequently also for the cells of the nuclei in the medulla. The latter assertion is based on the frequent involvement of the facial muscles and trapezius (seventh and eleventh nerves), also of the respiratory muscles (respiratory center in the medulla), which was so well emphasized recently by W. W. Graves.²

The conclusion to which the few considerations lead is that similarly to acute poliomyelitis, acute chorea is probably associated with some infectious element. The onset of the disease and its pathologic anatomy render the two affections analogous. The fundamental difference lies in the fact that in one disease the motor cells are being destroyed, hence the paralysis, in the other disease the motor cells undergo irritation, hence the twitching. The destructive effect in the former and the irritating effect in the latter point to a difference in the virus in the two affections. As a final feature of interest in this connection may be mentioned the experiments of P. Guizetti.³ He injected cultures of staphylococci under the dura mater and in both carotids in dogs and obtained spasmodic movements partly resembling chorea. It is possible that a certain variety of staphylococcus is specific in chorea, but so far it has not yet been determined. Continuous work in this direction may eventually lead to the discovery of the etiologic factor and, therefore, of a therapeutic serum.

UNUSUALLY QUICK RASH FOLLOWING INJECTION OF DIPHTHERIA ANTITOXIN

LOUIS NEUWELT, A.B., M.D.
NEW YORK

The usual length of time, elapsing between the subcutaneous injection of a dose of diphtheria antitoxin and the following skin reaction is given by various writers as varying between twenty-four and seventy-two hours. The following case showed an unusually quick reaction:

History.—M. K., boy, aged 6, was seen by me twenty-four hours after he was taken ill. I found him in bed with temperature 101.4 F., pulse 104, respiration 23, and complaining of difficulty in swallowing. A pharyngeal examination showed a typical picture of diphtheritic exudate on both tonsils and spreading partly up the pillars of the fauces. A later bacteriologic test by the New York City Department of Health confirmed the diagnosis of diphtheria. I immediately gave a subcutaneous injection of 3,000 units of diphtheria antitoxin of New York City Department of Health into the tissues of the abdominal wall, and after a few minutes left the patient. I was gone about ten minutes when I was recalled by the mother, who told me that the boy's body had "broken out all over." I returned and found the boy covered with urticarial wheals

varying from the size of a lentil to that of a bean. This rash lasted for about thirty-six hours, gradually abating in severity and the boy finally made an uneventful recovery.

ESSENTIAL HEMOSPERMIA

A. NELKEN, M.D.
NEW ORLEANS

Hemospermia, or blood in the seminal discharge, occurring during the course of an acute inflammatory condition involving the posterior urethra, or adnexa, is sufficiently common as to excite no especial interest.

Ricord believed the source of such bleeding to be the testicle and epididymis. Nelaton, among others, thought the condition to be due to urethral stricture. The present belief is that when the seminal discharge occurring during the course of an acute urethritis is blood-stained, the site of the bleeding is usually the prostatic urethra.

It is well recognized, however, that the blood may come directly from the vesicles as a symptom of a severe acute vesiculitis. Dr. Eugene Fuller¹ says that where the mucous surface of the vesicles is granular, bleeding may be free, occasionally producing severe spermatic colic by overdilatation.

Utzmann differentiates the source of the bleeding by assuming that when the blood comes from the prostate, or prostatic urethra, the dried stains on the linen appear irregularly colored, while in bleeding from the vesicle, the stains appear evenly colored, showing an intimate mixing of the blood with the semen. Much the same idea has been advanced by Guyon.

Such fine-drawn distinctions appear uncalled for, since it is not at all difficult to obtain separate prostatic and vesicular secretion by careful rectal stripping of these regions.

My object in writing this paper, however, is to report briefly two cases which recently came under my notice, and which, for want of a better designation, I have called "essential hemospermia."

Bleeding from the seminal vesicles without any assignable cause is referred to so rarely, and then so briefly, in medical literature as to give the impression that it must be of very unusual occurrence.

Tuberculosis, syphilis, and malignancy are given as possible etiologic factors in obscure cases of vesicular hemorrhage. But we must recognize a certain proportion of cases in which no cause can be discovered and in which prompt and permanent recovery negatives any serious disturbance.

R. Cantalupo² reports in detail a case of bleeding which he attributed to sexual overindulgence. But the common tendency to excesses among men, and the rarity of hemorrhage from the healthy vesicle, would seem to cast doubt on excessive coitus as a cause. Some writers (Gulliot, Robin) have on the other hand attributed bleeding to extreme continence.

A plausible explanation is that advanced by Linzar, who described it as a hemorrhage *ex vacuo*. During ejaculation, the sudden emptying of the long-distended vesicle, he says, relieving the accustomed support on the

blood-vessels, may determine a complete rupture of the vessel coats. Such bleeding is similar to the hemorrhage which occasionally occurs on too suddenly emptying the bladder after prolonged retention. In one of my cases, at least, hemorrhage *ex vacuo* would seem to offer a plausible explanation for the bleeding.

CASE 1.—The patient, 27 years old, had been well of an obstinate anterior urethritis for about one month. Because of this infection he had been continent for several months, during which time he had had no seminal emissions. On coitus he noticed the discharge was deeply blood-stained, and consulted me the following day. Alternate stripping of the prostate and vesicles showed the prostatic secretion and that from the right vesicle to be normal. The expressed contents of the left vesicle showed considerable fresh blood—no pus.

Treatment consisted of stripping the vesicle every other day. One week later it showed only a trace of old blood. Seen repeatedly since, he has remained well.

CASE 2. The patient was a Protestant minister, aged 42, married three years, one child. He had no venereal history, had never indulged in sexual excesses, and knew of no cause to which to attribute his trouble. For five or six weeks before, he noticed that the seminal discharge, occurring either while asleep or during coitus, was deeply stained with blood. Nightly emissions had been of frequent occurrence since bleeding was first noticed (probably due to the distention of the vesicle with blood).

Rectal examination showed the prostate and left vesicle to be normal. The region of the right vesicle was slightly tender to pressure and the expressed secretion was deeply blood-stained, but contained no pus. Massage was practiced for six weeks, at the end of which time only a trace of old blood could be expelled. Six months later he reported himself as being altogether well.

HEMATOMA OF VULVA DURING LABOR

C. E. MOORE, M.D.
WILSON, N. C.

History.—Mrs. F., primipara, had been in labor about four hours, dilatation of the cervix had progressed normally and she was in second stage with everything pointing to a speedy delivery. The pains were rather hard, accompanied by a great tendency to bear down, so I had commenced to give chloroform with each pain. About ten minutes after my last examination, she began to complain of a sharp cutting pain in the right labium. On examination I found a tumor about the size of an orange. In pressing my hand over it to determine whether or not it was a hernia, I noticed at once that it was rapidly enlarging.

Treatment.—Recognizing what I had to deal with, I pushed the chloroform and had the nurses prepare things for opening and stopping the hemorrhage, which had now reached the size of a child's head, and had, indeed, very much the appearance of a child's head just delivered. At this stage the tumor ruptured, producing a ragged rent about two and a half inches just at the junction of skin and mucous membrane and I am quite sure that I removed more than three pints of clotted blood. The cavity was packed with sterile gauze. I then found the child's head pressing against the perineum and in very short time the infant was delivered.

Remarks.—The patient had an uneventful puerperium without rise of temperature. The cavity left by the hematoma was irrigated every day and in about ten days there was very little sign left of what seemed at the time to be a serious condition.

PURPURA HEMORRHAGICA IN PERTUSSIS

H. W. KNIGHT, M.D.
RUTLAND, PA.

The fact that numerous contagious diseases have less severe manifestations as a rule during warm months has led to the popular opinion that it is a good thing for a child to contract such diseases as scarlet fever, measles, mumps, and whooping-cough when the mild form prevails. Physicians owe it to the public to correct this erroneous impression. The following case which developed a rare complication illustrates the error of this opinion.

History.—F. M. W., girl, aged 4, residing in the country, previously a robust healthy child, contracted whooping-cough about June 1, 1910; the disease continued for six weeks. The weather was ideal. During the second week of the disease there developed areas of purpura hemorrhagica due to the mechanical cause. Every time there was a severe paroxysm of coughing, either the spot would enlarge or a new focus of hemorrhage would appear and then gradually enlarge with subsequent paroxysms. These hemorrhagic areas were distributed especially over the arms, legs and back. Some spots appeared in the groins and one on the face. They were as sensitive as if due to contusion. When the whooping-cough yielded the hemorrhage stopped and gradually the areas resumed the normal aspect. The heart, which at the beginning of the disease had a normal action, has been left with a valvular lesion which will be a permanent menace to the child's life. The resistance of the child to disease has been lowered; and this, I believe, is the case with every contagious disease no matter how mild.

Therapeutics

ARTERIAL HYPERTENSION

Dr. Arthur R. Elliott, Chicago (*American Journal of the Medical Sciences*, July, 1910), so sensibly discusses this subject of ever-increasing importance that it deserves more than a passing notice. Increased blood tension which is now early recognized and actually measured is the forerunner of all that may happen to a well man. In other words, most other diseases are caused by accident, it may be medical accident or surgical accident, and even pneumonia is a medical accident. Increased blood pressure is an indicator of what is really going on inside of a man, and represents primarily the circulation of irritants or over-stimulation from nervous excitement and tension. Whichever be the cause, the etiologic factor must be removed or the condition will sooner or later cause cardiovascular-renal disease with its varying serious sequelæ. The highest blood pressure occurs in renal insufficiency, and the greater the insufficiency or the nearer uremia, the higher the tension. If an actual arteriosclerosis is present the tension may be apparently high but actually low.

Elliott does not discuss the nervous side of hypertension; probably he thinks in this rapid age it is useless to discuss lowering such tension. The only possible successful method of lowering this kind of tension is to urge such a patient to go to a quiet place for a complete and absolute change of duties and environment. Nothing else, in this age, is successfully advised; in other words, any other advice to remove nervous excitation is not taken.

Elliott's paper treats mostly of the irritants absorbed from the intestine as the cause of hypertension, and of course anything that modifies the absorption of these irritants will lower the blood pressure. The diet, then, is the first thing to be regulated, and Elliott urges that in regulating the diet common sense be used and the patient be individualized. Certainly any laboratory dogma which simply declares that flesh protein must be absolutely withdrawn from the diet and vegetable protein substituted, and which often does not carry with it limitation of vegetable protein or carbohydrates, is a therapeutic mistake. No one disputes the fact that the amount of meat eaten by these patients who have hypertension is generally too abundant. On the other hand, a certain amount of meat, either limited to once a day or a small amount twice a day, is to most men, who must labor either mentally or physically, more likely to meet the needs of their organisms and prevent muscular weakness than is a vegetarian diet. Anything that is found to cause intestinal indigestion more than any other article of food should be prohibited, but excessive amounts of vegetable proteins, starches, and fruits to make up for the withdrawal of meat is generally inadvisable and often produces harm. Whether or not the water intake should be reduced depends on whether the heart is sufficient or not. With a sufficient heart a patient should drink plenty of water; with an insufficient heart it should be restricted. Elliott advises that these patients learn to limit their intake of salt before it is necessary to withdraw it absolutely from their diet. This means not extra salting the food that comes on the table. This is a wise suggestion, because as soon as edemas occur from renal insufficiency, and even from cardiac insufficiency, the amount of salt in the food should be limited. A successful diet is shown not only by a reduction of the blood pressure, but by a stout patient losing some of his weight, and a thin patient, if not actually gaining in weight, not losing any more.

Elliott believes, as do we, that in spite of the belief of some clinicians that increased blood pressure is compensatory and is Nature's method of taking care of the individual and properly supplying blood to the various parts of the body, that especially when there are symptoms caused by the increased pressure, and even if there are no special symptoms, that it is better and advisable to reduce the pressure. The symptoms positively calling for this treatment are dizziness, full-headedness, short breath, a general feeling of cardiac oppression; these on least exertion and perhaps without exertion.

Elliott urges, and it certainly should be emphasized, that in the first attempt to reduce the blood pressure with drugs such as the nitrites, but small doses should be used and the result very carefully watched. A pressure that is excessive may be so quickly reduced as to cause an unpleasant and even serious syncope by lowering the blood pressure at the base of the brain. He advises after the administration of a small dose of nitroglycerin, from 1/200 to 1/100 of a grain, that the blood pressure be watched for half an hour. If it causes a decided fall of blood pressure, it shows that the blood vessels are not sclerosed and are able to respond to the dilator. The amount of reduction thus found will be an indicator of the proper dose, and of the frequency with which it should be given.

If there are signs of cardiac insufficiency which must come sooner or later in every instance of continued high blood pressure, vasodilators should rarely be used at all, except in emergencies of cardiac pain. Elliott thinks

sodium nitrite in small doses, from 0.03 to 0.20 gram (1/2 to 3 grains), three or four times in twenty-four hours, is the best nitrite to use. It certainly acts longer than does nitroglycerin. On the other hand, it sometimes irritates the stomach. It is astonishing how well nitroglycerin, administered three or four times in twenty-four hours, reduces the blood pressure when the arteries are not seriously diseased, and even a dose as small as 1/400 of a grain, given three or four times a day, will often cause a positive lowering of the pressure with an improvement of all symptoms.

Various physical methods of reducing pressure by baths, hot air, and graded exercise have been so recently referred to in this department that they need only be mentioned here.

If there are signs of an insufficiency of the heart which, as above stated, must occur sooner or later to these patients, vasodilators would rarely be needed, and small doses of digitalis will certainly do good and will rarely raise the blood pressure too high. If there is renal insufficiency and actual renal disease some other drug than digitalis should generally be used, such as strophanthus.

If physical signs of cardiac weakness are not in evidence, the heart may still be insufficient, as will be readily shown by taking the blood pressure after slight exercise. If with increasing rapidity of the heart from the exercise the blood pressure either does not rise at all or rises but a moment to fall below what it was when the patient was at rest, the heart muscle is surely insufficient. Elliott urges that such an examination be made before it is decided that vasodilators are indicated. Under these circumstances, with a heart impaired in its ability to do extra work and yet not so impaired that edema or other signs of lack of compensation are present, the best treatment is a combination of small doses of digitalis and nitroglycerin. This, with a corrected diet and the interdiction of any excessive or sudden exercise, and the establishment of such graded muscular exercise as will increase the muscle and surface circulation, will often restore a perfect compensation.

However well a patient with hypertension may be, he should be cautioned against any sudden spurt of muscular exercise or any prolonged severe muscle strain.

ANAPHYLAXIS IN ITS RELATION TO TREATMENT

It is an interesting and instructive psychologic study to observe the various opinions formed of therapeutic measures by different practitioners. For instance, to most men who had watched several children with diphtheritic laryngitis progress to what experience taught was inevitable death, the first case snatched from such a pitiable fate by the use of diphtheritic antitoxic serum was sufficient to bring conviction that the new remedy was a wonderful addition to our resources. Statistics of a series of cases was not a necessary preliminary to the adoption of the remedy. On the other hand the observation of an occasional sudden death after the use of the new remedy was ample demonstration to some physicians that it was a dangerous thing and should not be used. Later studies have shown why sometimes a fatal result followed the use of this generally beneficent remedy.

The hypersensitiveness of some patients from inheritance or from idiosyncrasy to germ diseases, toxins, and serums has been termed anaphylaxis.

In a paper read before the Johns Hopkins Medical Society, the Director of the Hygienic Laboratory, U. S. Public Health and Marine Hospital Service, Dr. John F. Anderson (*Bulletin of the Johns Hopkins Hospital*, July, 1910), has presented this subject in such a clear manner that a brief abstract of the paper will be of value to the clinician.

Since the seventeenth century it has been known that the blood of certain animals is poisonous to man when injected into his circulation. It has been found later that the blood serum of an animal of one species is often poisonous when injected into an animal of another species. The serum of the horse and donkey to a large extent does not possess this poisonous quality. In some cases, however, the injection of horse serum into man is followed by a combination of symptoms which has been described by von Pirquet, and called by him the "serum disease." In rare instances the injection of horse serum into man has been followed by sudden death.

Experimenting with guinea-pigs it was found that horse serum when injected for the first time is comparatively innocuous. If, however, a dose of 0.001 c.c. of horse serum is injected, and after waiting fourteen days a second larger dose is administered, a fatal result almost invariably follows. Other proteins such as egg white or milk act in the same way. This phenomenon is interpreted as meaning that "the first injection of the foreign protein has so changed the mechanism of the animal's organism as to render it very susceptible to the second injection."

Anaphylaxis is a name coined by Richet from two Greek words *ana* against, and *phylax* guard, or *phylaxis* protection, to indicate the opposite condition to that indicated by prophylaxis, which means preventive of disease. But the former term is somewhat misleading, for the phenomena to which it is applied do not act against the protection of the body against disease, but, on the contrary, often constitute "an important step in the protection of the organism against a certain large class of infections."

Anderson points out that the condition of anaphylaxis may be transmitted from the mother, or may be acquired, and also that it may be brought about by the introduction of any strange protein into the body. He cites as a well-known clinical instance of anaphylaxis that induced in an individual by a second vaccination. In a primary vaccination the period of inoculation is about four days, and then the local symptoms appear, and also more or less constitutional disturbance. In a vaccination following a successful vaccination after several months "the period of inoculation is much shortened, and the clinical reaction very much lessened. The power to react has been so changed that instead of an incubation period of four days, we have an incubation period of twenty-four or thirty-six hours. This acquired power of immediate response is an evidence that protective bodies have been formed within the organism; but there is no absolute immunity in this class of infections though, on account of the power of immediate reaction, the individual is protected.

"Other well-known clinical instances of anaphylaxis are the tuberculin and mallein reactions in tuberculosis and glanders. Neither of the bacterial products is harmful in moderate amounts to a healthy individual, but a person suffering from tuberculosis or glanders will respond to a very small amount of tuberculin or mallein respectively."

Recurring to the experimental studies on guinea-pigs, it was determined that "the toxic action following the injection of the serum is due to a protein in the horse serum and is entirely independent of the antitoxic properties of the serum. It would be exceedingly unfortunate if the studies on anaphylaxis should in any way prevent the usage of diphtheria antitoxin, or any other therapeutic serum, when it is indicated."

"The symptoms following the injection of horse serum into a susceptible guinea-pig are exceedingly characteristic." They appear rapidly, and consist of restlessness, distress, respiratory embarrassment, scratching of the mouth, coughing, sneezing, rapid and irregular respiration, deep inspiratory efforts with sinking of the upper part of the sternum, low blood pressure, paralysis, convulsions and death. The heart continues to beat after respiration has ceased, sometimes for thirty minutes.

As antidotes to this condition have been suggested atropin sulphate, chloral hydrate, oxygen, and adrenalin.

It has been found that guinea-pigs could be "sensitized" by feeding them with the foreign protein for several days. After the appropriate interval, fourteen days, they will react to an injection of the protein.

It may be through some such action as this that "certain individuals have a peculiar idiosyncrasy for certain articles of diet; also, why certain individuals who have never previously received an injection of foreign protein should be so acutely sensitive to a first injection of horse serum." The toxicity of the serum does not have as much influence as the susceptibility of the individual in determining an untoward result.

It has been noted "that many of the cases of sudden death following the first injection of serum in man have been in asthmatics or in persons who have an idiosyncrasy to horses. That is, there are certain individuals who show peculiar symptoms, sometimes resembling hay fever or asthma, when in the vicinity of horses or horse stables; and these individuals are the ones who are so extremely susceptible to a first injection of serum. The knowledge of the fact that the injection of horse serum into such persons is a danger which must certainly be taken into consideration in the use of antitoxin."

Finally it should be remembered that the transmission of anaphylaxis takes place through the mother, and not through the father, and that a child of a tuberculous mother is very rarely born with the seeds of the disease in its system, but that there is transmitted from the mother to the child a tendency to the disease.

An Organism Isolated from Water, Agglutinated by Typhoid Serum.—W. H. Frost (Bull. No. 66, Hyg. Lab., U. S. P. H. and M.-H. Service) has isolated from the water of the Potomac River after filtration an organism which he named *Pseudomonas protea* which has the property of being agglutinated quite constantly by the serum of typhoid patients. The agglutinins which produce this effect are not entirely identical with those agglutinating the typhoid bacillus. The results of absorption experiments indicate that the agglutination of *Pseudomonas protea* by specific typhoid agglutinating serum is affected by combination with a portion of the specific typhoid agglutinin; that it is therefore a "group" agglutinin. Animals injected with cultures of *Pseudomonas protea* develop agglutinins for this organism, but do not develop agglutinins for *B. typhosus* or other organisms of the colon-typhoid group. The organism is agglutinated by a larger percentage of cases than is the *B. typhosus*, the difference being especially marked in the earlier stages of the disease. The serum of typhoid fever patients often agglutinates this organism in higher dilutions than it agglutinates *B. typhosus*. The organism is not found in Potomac water before filtration.

SATURDAY, OCTOBER 1, 1910

"ARSENO-BENZOL"—"606"—"ARSEN-PHENOL-AMIN"

The intense interest shown in the new remedy, "arseno-benzol," for the treatment of syphilis—Ehrlich and Hata's "606"—as well as a revival of interest in the use of sodium cacodylate as shown by A. Heym,¹ and more recently by J. B. Murphy,² makes opportune a discussion of the chemical structure of "606," sodium cacodylate and of atoxyl and its acetyl derivative, arsacetin. Sodium cacodylate is the sodium salt of cacodylic or dimethyl-arsenic acid, which differs from arsenic acid by replacement of two hydroxyl groups by two methyl groups. Thus:

Sodium cacodylate, as described in *New and Non-official Remedies*, is a relatively permanent salt of arsenic acid quite soluble in water and faintly alkaline towards litmus but neutral toward phenolphthalein. Atoxyl is sodium arsanilate, the sodium salt of arsanilic acid. Arsanilic acid differs from arsenic acid in that one hydroxyl group of the arsenic acid is replaced by an amino-benzene or amino-phenol or anilin group. Thus:

Atoxyl also is a relatively stable salt of arsenic acid quite soluble in water and practically neutral in reaction. Arsacetin or sodium acetyl arsanilate is the sodium salt of acetyl arsanilic acid, which latter differs from arsanilic acid in that one hydrogen atom of the amino group is replaced by an acetic acid residue. Thus:

The Ehrlich-Hata preparation—"606"—is but distantly related chemically to sodium cacodylate, atoxyl and arsacetin. It has recently been patented by a Ger-

man firm, Meister Lucius & Brüning, which will control its manufacture and sale. Its structural formula is:

According to the patent specifications, it is obtained from nitro-phenol-arsinic acid, which, on reduction, is changed to amino-phenol-arsinic acid, which, by still further reduction, yields "606," a derivative of arseno-benzene ($\text{C}_6\text{H}_7\text{.As: As.C}_6\text{H}_5$). The formula above shows that "606" contains two atoms of tri-valent arsenic united, on the one hand with each other, and on the other hand having replaced a hydrogen atom in a benzene molecule. Each benzene molecule also contains one hydroxyl or phenol group and one amino or anilin group. The chemical constitution may be indicated by the name di-amino-hydroxy-arseno-benzene and the relative position of the several groups shown thus:

3-diamino-4-dihydroxy-1-arseno-benzene

This name has been abbreviated to arseno-benzol or arseno-benzene, which, in a way, is unfortunate, in that it is the name which properly belongs to another body. As it is desirable that the shortest name truly indicative of its composition should be used in the literature, the term "arsen-phenol-amin" is recommended as an abbreviated scientific synonym for this new body which has unfortunately been introduced into medicine under the term "606." Since this product is patented, however, it may be given a catchy rather than a scientific name.

To understand the chemical properties of this body, it should be noted that the arsenic is in the unstable tri-valent form and not in the stable penta-valent form, as in sodium cacodylate, atoxyl or arsacetin. Furthermore, it should be said that the two phenol or hydroxyl groups give the substance a weak acid character enabling it to form weak salts with strong alkalies just as phenol forms them with sodium hydroxid, etc. On the other hand, the two anilin or amino groups give it basic properties, and just as anilin combines with hydrochloric acid to form a salt, so this substance combines with hydrochloric acid to form a chlorid. Since the molecule contains two anilin groups it combines with two molecules of hydrochloric acid. These anilin groups, however, impart but weak basic properties to the molecule, and hence the chlorid, when dissolved in water, is decomposed with liberation of hydrochloric acid, so that the solution is strongly acid. "Arsen-phenol-amin" (or "606"), is very unstable and is put on the market in the form of its hydrochlorid, which, owing to its acid character, however, cause injections of it to be very painful. For this reason the hydrochlorid is treated with an amount of alkali exactly sufficient to combine with the hydrochloric acid of the salt and to liberate the base "arsen-phenol-amin" which is insoluble and which is injected in the form of a suspension in water.

It is impossible at this time to determine the actual value of the drug, but certain deductions can be made

1. New York Med. Jour., Oct. 30, 1909.

2. THE JOURNAL A. M. A., Sept. 24, 1910, p. 1113.

from the large number of cases already reported. There is no doubt that this new remedy produces remarkable results in a surprisingly short time. In some desperate cases of syphilis a cure, temporary at least, followed a single injection: in many of these mercury and other antisypilitics had totally failed. The question as to the permanency of the cure is not answered, and only time can answer it. But if such splendid results may be obtained by one injection, it would seem probable that the remedy would bring about a permanent cure when its action is more clearly understood, and the treatment followed out for a longer or shorter time.

Finally, physicians should remember that this new discovery is, after all, an arsenic preparation. In the past all new arsenic preparations, though at first recommended as wonderfully active and marvelously free from the toxic effects of arsenic, have in the end been found to possess, in varying degrees, the potency for harm common to this element. It will be fortunate if this new discovery is not found to have similar drawbacks.

WHO PAYS THE BILLS?

Newspaper men are not easily misled as to motives, neither are they slow to recognize the real forces behind an effort to influence public sentiment. An editorial in a recent number of the Baltimore *Evening Sun* shows how the better class of newspaper editors regard the strenuous and well nigh hysterical efforts now being made to simulate a popular uprising against the awful iniquity of national health legislation:

"Two objections to the proposed department of health have been raised. The first comes from the more fanatical adherents of the so-called metaphysical healing arts. These persons hold that the art of medicine, as it is practiced, say, at the Johns Hopkins University, is a snare and a delusion. They object to being vaccinated, they deny that typhoid is infectious, they maintain that Dr. Welch is an ignoramus, they believe that magic words are more efficacious against hydrophobia than Pasteur's vaccine. Finally, they fear that, if a national health department is established, its head will induce Congress to pass laws against them. A mere statement of the argument of these folk is all the answer it needs. They have a right to their beliefs, however ridiculous, but they have no right to put the rest of us in peril.

"The other objection to the proposed department is voiced by those who fear that it will be controlled by the American Medical Association, an organization of allopathic physicians. The grounds of this fear are not quite apparent, but, assuming it to be well grounded, what of it? The foremost physicians and surgeons of America belong to the Association; it is in the forefront of the battle against disease; its objects are precisely those of the department under consideration. A nation with such men guarding its health would be a nation to

be envied. They are by no means perfect as men, for human perfection is very rare in the world, but as physicians they belong to the most scientific, progressive and competent of all schools.

"These are the only objections we have ever heard to a national department of public health. We believe that both of them are unutterably silly."

As the *Sun* well says, the mere statement of the arguments of the National League for Medical Freedom is all the answer that is necessary. But the attack on the Owen Bill is only a pretext. The American Medical Association is the real target. The forces behind this movement are endeavoring to take advantage of the popular feeling against trusts and monopolies by branding the American Medical Association as a "doctors' trust", a designation, by the way, which originated with certain so-called medical journals which derived their support from nostrum venders.

Evidently, the manufacturers of "baby-killers", sophisticated and adulterated foodstuffs, cheap and bad whiskies under the guise of "family remedies", and fakers and swindlers doing business under the guise of physicians, hope that the American public and press will accept this designation without asking for proof or evidence, and that by such methods the American Medical Association and its work can be discredited in the public estimation. We related last week that "the delegates smiled" when the members of the committee on resolutions, at the Conservation Congress at St. Paul, were overwhelmed with a flood of telegrams carefully arranged for beforehand, protesting against the endorsement of a national department of health. Truly, newspaper editors and managers must smile with equal persistency when "copy" is received for half-page advertisements at a daily cost of \$25,000, denouncing the national organization of the medical profession as a "doctors' trust." Newspaper men know the cost of a general advertising campaign. They also know that only those who are financially and mercenarily interested in blocking the work which the American Medical Association is doing, and who fear to have any further light thrown on their nefarious doings, would furnish the money for such an extensive and expensive advertising campaign. The National League for Medical Freedom asks no dues of its "members", yet it has used large quantities of the most expensive newspaper advertising space. Who pays the bills, and whence comes all the money?

Certainly it does not come from the few homeopaths who have joined the league, nor from the few eclectics, nor from the small number of osteopaths; and surely the Christian scientists are not shouldering this enormous burden. The obvious conclusion is that the money comes from those exploiters of human weakness and credulity whose fraudulent practices have been exposed by the American Medical Association, and whose pocket-books have been injured in consequence.

Current Comment

THE EFFECTS OF TOBACCO ON BODY AND MIND

While it has been shown that nicotin acts as a poison in the lower animals, depressing the nervous, circulatory and respiratory systems, there is considerable diversity of opinion as to the effects of tobacco on human beings. There is, however, a fairly well-established belief that even the moderate use of tobacco is not without possibilities of evil, while excessive use is distinctly harmful. The effects, naturally, are more pronounced in youth and adolescence than in later life. Some observations made by Dr. George L. Meylan,¹ of Columbia University, are interesting in this connection. In a study of 223 college students from two classes it was found that 115 were smokers and 108 non-smokers. The smokers were a little older than the non-smokers, and they presented only corresponding differences in measurement (weight, height, lung capacity, total strength). On the other hand, the non-smokers exhibited a distinct advantage in scholarship, but in this connection other considerations must be taken into account. For one thing, the smokers participated in larger proportion than the non-smokers in athletics and in fraternity membership, and the scholarship-records of smokers, athletes and fraternity members alike were lower than those of other students. Besides, there is a leisure-class type of college students, who smoke and go in for athletics and fraternity membership, but who, as a rule, do not attain high grades of scholarship. The non-smoker, on the other hand, is usually ambitious, industrious and self-dependent, and with less inclination and opportunity for the athletic and social aspects of college life. There will be no serious dissent from the following conclusions: The use of tobacco by adolescents is injurious; there is no scientific evidence that the moderate use of tobacco by healthy mature men produces any beneficial or injurious physical effects that can be measured; there is an abundance of evidence that tobacco produces injurious effects in (a) certain individuals suffering from various nervous affections, (b) persons with an idiosyncrasy with respect to tobacco, (c) persons who use it excessively. It is generally conceded that the use of tobacco by college students is closely associated with idleness, lack of ambition, lack of application and low scholarship, though these may not be due entirely to the tobacco.

A YEAR AS INTERN IN A HOSPITAL

The time is not far distant when a physician, before receiving license to practice medicine, will be required, after taking the four-year medical course, to spend a year as intern in a hospital. At present, the majority of the graduates of leading medical colleges succeed in obtaining such work and the deans of a number of these colleges say that as a rule the students who do not take these internships are the very ones who most need them. As has been reported, six medical colleges have provided an optional fifth year of hospital work for which the degree of M.D. *cum laude* is granted. It is now

reported that beginning in the fall of 1911 every student matriculating in the medical department of the University of Minnesota will enter on a five-year medical course, the fifth year to be spent in a hospital as an intern. This is in accordance with the "ideal standard" for physicians suggested by the Council on Medical Education and adopted by the House of Delegates of the American Medical Association at Portland in 1905.

NON-ENFORCEMENT OF ANTISPITTING ORDINANCES

From information recently collected it appears that out of seventy-four cities reported as having antispitting ordinances only thirty-six had made any arrests. It is found that in the enforcement of these ordinances health officers are somewhat more vigilant than the regular police. Newton (*Journal of the Outdoor Life*, August, 1910) says that the real reason for the non-enforcement of the ordinance is indifference on the part of citizens, lack of civic pride and failure to appreciate the danger from the unrestrained practice of the habit. He says that the police fail to enforce it as they regard it as merely intended to abate a minor nuisance, but that health officers are primarily responsible, as the community looks to them for leadership in all health matters. It seems to require specially detailed officers or inspectors. It is probable, however, that the public agitation and the numerous means of calling attention to the danger have led to a very decided abatement of the nuisance.

TWO DISEASES TO BE RECKONED WITH

While infantile paralysis and pellagra are not new diseases, their occurrence hitherto has been so comparatively infrequent in this country that no statistical segregation of them as causes of death has been made in the mortality statistics of the registration area of the United States. According to a bulletin of the Bureau of the Census in 1909, 569 deaths were due to acute anterior poliomyelitis and 116 to pellagra. Only 23 deaths from pellagra were reported in 1908. The figures for 1910 will no doubt show many more deaths from the former disease on account of its prevalence and the study and attention given to it. As the registration area includes only a small portion of the country where pellagra occurs most frequently, the actual number of deaths from this disease will not be known until there is a more complete registration of vital statistics.

HEALTH EDUCATION IN FLORIDA

The Florida State Medical Society has inaugurated a campaign against malarial fever and has issued four bulletins for public distribution through the press of the state and otherwise. These bulletins are short and adapted to popular understanding, being written to correct erroneous ideas regarding the transmission of malaria and to emphasize the importance of mosquitoes as a means of disseminating diseases. In one bulletin the experience gained in building the Panama Canal is outlined and a number of popular misconceptions corrected. Some of the views previously held by the medi-

1. Popular Sci. Monthly, August, 1910, p. 170.

cal profession and still believed in by the public are referred to—such as that malaria is transmissible by the atmosphere, through dust-laden air, noxious gases, night air, odors and vapors arising from decaying vegetable matter, recently turned earth, swamps, impure drinking water, etc. The bulletin shows how these apparent causes are in reality connected with the development of malaria only in so far as they make possible the propagation of mosquitoes. Another bulletin discusses the individual attack and emphasizes the necessity of proper treatment. These bulletins are short and interestingly written and are being generally quoted by the press of the state.

THE PUBLIC CONSCIENCE AWAKENING ON PREVENTABLE DISEASE

The public interest in health conditions is rapidly increasing. Evidence of this fact can be found in the changing attitude of newspapers toward public health problems and the growing comprehension of their importance. For instance, the recent editorial comment in the *New York World* on typhoid fever would have been impossible ten years ago:

Every life lost by typhoid is a wasted life. It is absolutely preventable. People who live in marble halls without caring whether poison runs in the pipes behind them; the very rich who spend millions in display, but neglect sanitation; college professors caught unaware by epidemics like that in Ithaca—these have themselves to blame if the disease occurs. Typhoid originating in any community disgraces it.

In former generations, epidemics of typhoid fever and other filth diseases have been regarded as dispensations of Providence just as a high death-rate has been looked on as a natural ratio which could not be altered. The *World* has emphasized one of the most important principles of the coming gospel of health—*i. e.*, that the occurrence of preventable diseases is a discredit to the community.

Medical News

COLORADO

Personal.—Dr. George A. Moleen, Denver, starts for Europe this week.—Dr. William C. Bane, Denver, who was operated on recently for appendicitis, is making a good recovery.—Dr. William W. Grant, Denver, has recovered from injuries received in a recent collision between his automobile and a street car.—Dr. Hubert Work, Pueblo, has been elected state chairman of the Republican party.

Bequests.—The late Joseph Schoenberg, Denver, bequeathed \$25,000 to the National Jewish Hospital for Consumptives in that city.—By the will of the late Louis H. Kaplan, Anniston, Ala., \$15,000 is devised to a hospital for consumptives in Denver. The executors have asked the probate court to determine whether this legacy shall be paid to the National Jewish Hospital for Consumptives or the Jewish Consumptive Relief Society.

State Society to Meet.—The annual meeting of the Colorado State Medical Society will be held in Colorado Springs, October 11-13, with headquarters at the Antlers Hotel. The entertainment provided for the society includes a ball on the first night, a jungle party or barbecue in one of the canyons on the second night, and a banquet at the Antlers Hotel, the third night of the meeting. The mornings are to be devoted to the work of the society, and the afternoons and evenings to entertainment of the delegates.

CONNECTICUT

Infectious Diseases.—During August 32 cases of measles were reported in 14 towns, 63 cases of scarlet fever in 33 towns, 6 cases of cerebrospinal fever in 4 towns, 36 cases of infantile paralysis in 16 towns, 127 cases of diphtheria in 30 towns, more than 88 cases of whooping cough in 17 towns, 224 cases of typhoid fever in 54 towns, and 239 cases of tuberculosis in 45 towns.

Epileptic Colony.—The board of trustees of the Connecticut Colony for Epileptics held its first meeting September 20, and elected Dr. Max Mailhouse, New Haven, president; Dr. William L. Higgins, South Coventry, secretary. Dr. John M. Mountain is the third medical man on the board, which is composed of eight members, one from each county in the state. The superintendent of the colony will be elected in the near future.

GEORGIA

Appropriation for State and Not Local Sanatorium.—The appropriation of \$50,000 noted in *THE JOURNAL*, September 17, made by the Georgia legislature, was for the State Tuberculosis Sanatorium located at Alto, and not for the LaGrange Sanatorium, a private institution.

Staff Shows Appreciation and Regret.—The consulting staff of the Wesley Memorial Hospital, Atlanta, has adopted resolutions setting forth the excellent professional and faithful loving personal qualities of its associate, the late Dr. Abner Wellborn Calloun, expressing its appreciation of the privilege of serving with him on the board, and its sorrow at his death.

Society Meetings.—At the fourth annual session of the Eighth District Medical Association of Georgia, held in Monticello, August 17, the following officers were elected: President, Dr. J. R. Robins, Siloam; vice-president, Dr. James D. Weaver, Eatonton, and secretary-treasurer, Dr. Dan H. DuPree, Athens (re-elected).—The Pike County Medical Association was recently organized at Barnesville with Dr. John M. Anderson, Barnesville, president; Dr. William H. Aycock, Molena, vice-president, and Dr. Marvin M. Head, Zebulon, secretary.

College Open.—The Hospital Medical College, Atlanta, opened for its third annual session, September 15. Since the close of last session new laboratories have been added to the institution.—The Atlanta College of Physicians and Surgeons has recently received a gift of \$50,000 to establish and equip laboratories of histology, physiology and embryology. Dr. Harry S. Bachman, Philadelphia, has been elected professor of physiology; Dr. Justin F. Grant, Morgantown, W. Va., embryology and histology, and Dr. Funk, Philadelphia, adjunct professor of bacteriology.

ILLINOIS

Personal.—Drs. Alfred A. Knapp and Charles G. Farnum, Brimfield; Dr. and Mrs. William D. Hohmann, Kewanee; Dr. Thomas W. Curry, Streator, and Dr. and Mrs. George S. Isham, Dr. Joseph B. DeLee, and Dr. and Mrs. Thomas D. Palmer, Chicago, have returned from Europe.—Dr. Elijah S. Smith has succeeded Dr. William F. Burres, Urbana, as physician of Champaign county.—Dr. Hiram T. Hardy, Kaneville, who was operated on in Chicago recently for the removal of gallstones, has recovered and returned home.—Dr. and Mrs. Arthur Paul Wakefield, Springfield, have started for their post of duty at Chao-Hsien, China.

Chicago

Resolutions of Sorrow.—The Chicago Dermatological Society has adopted resolutions setting forth that in the death of Dr. James Nevins Hyde, the society has suffered an irreparable loss, the medical profession has lost a great teacher, and the community a model citizen.

Hospital Notes.—Arrangements have been completed for the laying of the cornerstone of the Iroquois Memorial Emergency Hospital at 87 Market St. A memorial tablet is to be placed in memory of those who lost their lives in the Iroquois fire.—The cornerstone of the new Deaconess Hospital at Morgan St. and 54th Place was laid with appropriate ceremonies, September 18.

INDIANA

Personal.—Dr. Patrick H. Jameson, Indianapolis, is reported to be ill and confined to his house. Dr. George W. Switzer, LaFayette, has been elected secretary of the Methodist Hospital, Indianapolis, vice Dr. Deloss M. Wood, Battle Ground, deceased.

Sentenced and Paroled.—In the Circuit Court, September 15, Dr. Charles G. Young, Washington, charged with having performed an illegal operation, is said to have changed his plea of not guilty to guilty, and to have been sentenced to imprisonment for from three to fourteen years in the state penitentiary, and to have been fined \$100. He was released on parole, the commission in lunacy having decided that he was sane but a wreck from the excessive use of alcoholic stimulants.

IOWA

Personal.—Dr. Gilbert G. Cottam, Rock Rapids, has disposed of his business and will locate for practice in Sioux Falls, S. D.—Dr. Samuel Druet, physician of the state reformatory, Anamosa, since 1898, has resigned, and Dr. Thomas C. Gorman, Anamosa, has been named as his successor.—Dr. J. Fay Cole, Oelwein, has been elected grand chancellor of the Knights of Pythias of Iowa.—Drs. Nicholas Schilling, New Hampton, Hans F. K. Haerem, Story City, and Willis E. Keith, Lost Nation, have started for Europe.

MARYLAND

Personal.—Dr. J. McPherson Scott, mayor of Hagerstown, while cranking his automobile recently, sustained a fracture of one of the bones of the right forearm.—Dr. F. Webb Griffith, Upper Marlboro, has been appointed visiting physician to the Maryland Agricultural College, vice Dr. Harris Nalley, Mount Rainier.—Dr. Frederick V. Beitler, Halethorpe, has been elected professor of pathology and bacteriology in the Baltimore Medical College.

State Hospital Overcrowded.—Dr. Joseph C. Clark, superintendent of the Springfield State Hospital for the Insane, reports that there are more than 1,000 patients at present in the institution, which is greatly overcrowded. A three-story brick building is to be erected at once to accommodate 150 patients, and a powerhouse is also to be built at an expense of \$75,000.

Baltimore

Personal.—Dr. J. Page Strong, who has been seriously ill with typhoid fever, is convalescent.—Dr. John M. T. Finney has given an infirmary to the Country School for Boys. One ward of the infirmary is to be used for the isolation of patients with communicable diseases.—Dr. G. Milton Linthicum is convalescing from typhoid fever at Maryland General Hospital.

Cause of Typhoid in Militia Camp.—Dr. Alexius W. McGlannan, chief surgeon of the First Brigade, Maryland National Guard, announces that the outbreak of typhoid fever in the Maryland troops last summer was due to an infected spring near the camp. Ten members of Troop A suffered from the disease and one death occurred. Several of the Corps of engineers, United States Army, suffered in a similar way.

MASSACHUSETTS

Warren Prize Awarded.—The Warren triennial prize for 1910, of the Massachusetts General Hospital, Boston, has been awarded to Dr. George H. Whipple, assistant professor of pathology in Johns Hopkins University and resident pathologist in Johns Hopkins Hospital, for an essay on "The Pathogenesis of Icterus."

MISSOURI

Medical School Opens.—University Medical College, Kansas City, opened for the school year, September 6. Dr. John Puntun made a brief address of welcome.

Personal.—Drs. Scott P. Child, Jesse E. Hunt, Otho L. McKillip, Archie N. Johnson, Eugene P. Hamilton, Frank C. Neff, Fred B. Kyger, W. H. Bailey, F. LaMar, and William J. Thompkins have been appointed medical inspectors of the public schools of Kansas City.—Dr. Martin T. Balsey has been made medical examiner of the public schools of Joplin.—Dr. Charles B. Hardin, Kansas City, who has been traveling on account of his health for the last six months, has improved and resumed practice.

St. Louis

Personal. Dr. William A. H. Steinman, an intern at the City Infirmary, vice Dr. Halbert R. Hill, resigned, is said to be the first resident physician to obtain a salary. On September 15, he was granted a salary of \$50 a month.

Faculty Additions.—The following additions to the faculty of the Washington University Medical Department are announced: Dr. George M. Smith, formerly of New York, instructor in pathology; Dr. W. McKim Marriott, instructor in pathologic chemistry; Dr. Walter E. Garrey, associate in

physiology; Robert A. Gessell, instructor in physiology, and Dr. Dennis E. Jackson, associate in pharmacology.

New Dispensary Established.—St. Louis University has established a free clinic adjoining Alexian Brothers Hospital in South St. Louis. Dr. William W. Graves has charge of nervous diseases; Drs. Harvey S. McKay and Carroll Smith are in charge of the department of diseases of women and surgery; Dr. Clarence Loeb is ophthalmologist; Dr. William M. C. Bryan, otologist, rhinologist, and laryngologist; Dr. Charles H. Neilson is in charge of the department of internal medicine, and skin diseases will be treated by Dr. John W. Marchildon.

NEW YORK

Local Health Officers Must File an Oath of Office.—Attorney General O'Malley holds that a local health officer must file an oath of office after his appointment to the local health board within a reasonable time, otherwise the office is considered vacant and the local board of health may appoint another man to the office and the latter appointment is legal.

War on Infantile Paralysis.—Dr. Eugene H. Porter, State Health Commissioner, has issued a statement that there seems to be no reasonable doubt that poliomyelitis is communicable and that even though the cause may not be positively determined, its transmissibility seems to be positively determined, and that as a result of a consideration of the subject, the State Department of Health has decided to put the disease on the list of contagious diseases to be reported to the Board of Health and to be quarantined for twenty-one days. It is believed that this plan will result in the report of a much larger number of cases than hitherto, and will be the means of furnishing much valuable information.

Field Day at Rochester.—The net receipts of the annual field day of the Rochester Public Health Association, held August 6, were \$5,200. While the greater part of the receipts are to be for the benefit of the Children's Free Dispensary, a portion will be used for the running expenses of the dispensary on South Washington Street, and a fixed sum of the balance will be set aside for a basis of the proposed children's hospital. Dr. Montgomery E. Leary, who is actively interested in the plan for this hospital, states that it will be an enlargement of the Children's Free Dispensary in hospital form, and that it will cost about \$30,000.

New York City

Appeal to Nathan Straus.—A letter drawn up by a number of social and philanthropic individuals has been sent to Nathan Straus urging him to reconsider his decision to close the milk stations that he has been maintaining in this city. The letter indicates the desire on the part of individuals and philanthropic agencies to cooperate with him in keeping the depots open.

Mortgage on Academy of Medicine.—The property of the New York Academy of Medicine at 17-21 W. Forty-third Street, has been mortgaged to the Farmers' Loan and Trust Company for \$220,000 for a period of three years. The academy recently acquired the adjoining property and the abutting house on Forty-fourth Street in order to enlarge its building.

Object to Tuberculosis Clinic.—The plans of the Board of Health to open a clinic for the treatment of tuberculous patients on Willoughby Avenue near Stuyvesant Avenue, Brooklyn, has met with strenuous opposition on the part of the Church of St. John the Baptist, which maintains a parochial school and orphan asylum immediately opposite the proposed clinic. A petition signed by all the residents within a radius of two blocks will also be presented in opposition to the plan.

Increased Appropriation Asked.—President Lederle of the Board of Health, has submitted to the Board of Estimates his estimate of the appropriations needed for his department during the coming year. He asks for \$4,076,578, or \$1,328,885 in excess of this year's budget. The principal increases are as follows: Division of chief clerk, \$48,949.50; division of child hygiene, \$320,545; division of contagious diseases, \$113,150; division of general sanitary inspection, \$57,210; division of milk inspection, city and country, \$60,510; research and vaccine laboratories, \$101,759, and division of hospitals, \$486,056.

OHIO

College Opens for Year.—The Eclectic Medical College, Cincinnati, opened for its sixty-sixth annual session, September 19, in its new building on West Sixth Street adjoining the Seton, formerly the Presbyterian Hospital.

Injured in Collision.—Dr. Morris D. Stepp, Cleveland, fractured three ribs and sustained internal injuries in a collision between his automobile and an electric car near Cleveland, September 25. Mrs. Stepp and her two small children were killed in the accident.

Dairymen's License Revoked.—By reason of the report of the dairy inspectors of Dayton to the effect that the dairies of S. C. Burrall and Phillip Erbaugh are in bad sanitary condition, and that neither dairymen has made any effort to place his establishment in a sanitary condition, the licenses of these men to sell milk and cream in Dayton are said to have been revoked.

PENNSYLVANIA

Philadelphia

Woman's College Opens.—The Woman's Medical College of Pennsylvania opened on September 21, for its sixty-second term. Dr. Clara Marshall, dean of the college, delivered the opening address.

Personal.—Dr. James M. Anders returned from Europe September 20.—Dr. Frank Woodbury sailed for Europe September 21.—Dr. G. Carl Huber, Ann Arbor, Mich., has been appointed professor of embryology at the Wistar Institute.—Dr. Edward B. Meigs, formerly connected with the University of Pennsylvania, but in late years associate of physiology at Harvard, has been added to the staff of the institute.

Floating Hospital for Babies.—Dr. Joseph S. Nell, in making his report on the work accomplished during the summer in the campaign against infant mortality, has asked for the purchase or rental of a large boat steamer or barge that can be utilized next summer for a floating hospital. The work at the recreation piers has extended so much that the Department has felt the necessity of keeping the baby hospital on the Chestnut Street Pier open day and night, and the exact time of closing them has not been decided.

Advance of the Pure Food Crusade.—Following up the investigation of the manufacture and sale of impure ice cream, Special Agent Harry P. Cassidy, of the state dairy and food department has turned his attention to the cheaper qualities of candies retailed by small stores in the city and sold almost exclusively to children. Samples were obtained and sent to Professor LaWall. When analyzed many of these were found to be flavored with ethers, colored with coal tar and coated with shellac. Warrants were issued for the arrest of seven dealers.

WEST VIRGINIA

State Physicians to Meet.—The annual meeting of the West Virginia State Medical Association will be held in Parkersburg October 5 to 7.

Personal.—Dr. Carl W. Ulfert, Wheeling, has been appointed physician of Ohio County, vice Dr. John J. Allen.—Dr. Harriet B. Jones, Wheeling, has returned from Europe.—Drs. William R. Whitman, Bramwell, and Wade H. St. Clair, Bluefield, have gone to Rochester, Minn., for clinical studies.

WISCONSIN

Personal.—Dr. Frank E. Darling has resigned as registrar of vital statistics in the health department of Milwaukee.—Dr. Edward B. Bradford, Hudson, has sold the Hudson Sanitarium to Wallace Campbell, Minneapolis.

Refuse to Accept Rucker's Resignation.—The Milwaukee City Council, after investigation of the charges preferred against Dr. William Colby Rucker, health commissioner, have refused to accept his resignation, have importuned him to remain in his present position, and have requested Surgeon General Wyman, P. H. and M.-H. Service, to consent to Dr. Rucker's return to Milwaukee.

GENERAL NEWS

Fraternity Meeting.—The twelfth annual general assembly of the Phi Beta Pi Medical Fraternity will be held in Philadelphia, October 4 to 7. Headquarters will be established in the Continental Hotel, at Ninth and Chestnut Streets, and Mr. William Coffin, Jr., of Jefferson Medical College, is chairman of the committee on arrangements.

Personal.—Dr. Leon T. LeWald, medical corps U. S. Army, has resigned and has been appointed director of the Edward N. Gibbs x-ray laboratory at the New York University and Bellevue Hospital Medical School, New York City, succeeding Dr. E. W. Caldwell. Prior to his service in the Army Dr. LeWald was instructor in gross pathology in New York Uni-

versity and a medical officer of the national guard of New York.—Dr. Charles Wardell Stiles, United States Public Health and Marine-Hospital Service, returned from Europe September 14. Dr. Stiles attended the International Zoologic Congress at Gra, Austria, August 15-20, in connection with the International Commission of Zoologic Nomenclature.—Dr. Charles C. Walker, medical missionary and physician to the American legation at Bangkok, Siam, has returned to the United States for a visit after six years' absence.—Dr. K. F. Meyer, Leipzig, arrived in New York, September 17, from Africa, where he has been pursuing studies of tropical diseases, chiefly those of cattle. He intends to continue his researches in Texas.

FOREIGN NEWS

Cholera in Enrope.—According to cable dispatches, September 26, several cases of cholera have been reported at Rome, 28 in Hungary with 11 deaths between September 24 and 26, and there is quite an epidemic at Naples, 100 new cases and 50 deaths being recorded during the day of the 25th. The last official reports by mail from Russia state that 154,445 cases of cholera have been reported in that country since the beginning of the epidemic last April up to August 14, with 74,723 deaths. A strolling band of gypsies from Russia started an epidemic in Apulia, the southeastern province of Italy, over a month ago, although none of the party had cholera—a typical illustration of the dangers of healthy germ carriers. The Berlin Letter below mentions the few cases that have occurred in Germany. A few other isolated cases have occurred since in Germany, one each at Dresden, Stade and Marienburg, and 3 germ carriers have been discovered among the Vistula River rafters. In the second week in August, 24,000 new cases were reported in Russia, with 11,000 deaths.

The "606 Fever."—Dr. A. Pulido Martin, in an article in the *Siglo Medico*, of Madrid, Sept. 10, makes some caustic and seemingly injudicious comments on the Ehrlich-Hata preparation for syphilis. He says that he is amazed at the extraordinary advertising that a patented remedy is now receiving—the exclusive property of a single manufacturing firm—and warns physicians not to catch this "606 fever," and to go slow in forming their judgments, as there is commercial money-making involved. "The daily papers," he says, "at Hamburg, Cologne, Vienna and especially at Frankfurt, the latter inspired directly by Ehrlich, are publishing columns on the subject but without much scientific value. They add another cipher when they mention the number of cases in which the new drug has been applied; they relate how a Hungarian physician hurried to Frankfort and obtained the details of the manufacture of the drug from Ehrlich and then returned to Budapest and announced the organization of a society to produce the new drug; this was then followed by reports of Ehrlich's indignation at this news and his assertion that the drug is the property of a certain firm of manufacturing chemists and that the Hungarian physician could not possibly have learned the full details of its preparation as he, Ehrlich, related them only in a general way, and, besides this, he has modified the substance since, making it less toxic so that it can be injected in larger doses, the new substance being called by a new name, Hyperideal; this statement is followed by the declaration that the 'Hy' is not to be put on the market, and is not distinct from the original '606' (to avoid spoiling the sale of the latter), but is destined solely for use in his own service, etc., etc." "From the many reports that have appeared on the subject it is evident that the '606' or 'Hyperideal,' or whatever other name it may bear by the time these words are published, does not keep well, the injection is painful, and the fever and other signs of a reaction compel vigilant oversight for a few days. Other authors have reported that the injection of '606' was followed by the death of a patient, but the daily papers, commenting on these fatalities, speak of the authors reporting them as enemies of German science and state that these experiences are negligible as the patients were on the point of dying anyway." He adds in conclusion, "It must not be forgotten that other arsenical remedies, used even for syphilis, which at first were regarded as harmless, later proved to have a decidedly toxic action on remote organs, such as atrophy of the optic nerve under atoxyl treatment. Neither must it be forgotten that, while it has not yet been proved beyond question that a therapeutic problem has at last been solved, there cannot be the slightest doubt in respect to the business end of the '606' matter." Bearing all these things in mind, he urges his readers to restrain their first impulse of enthusiasm as not fully justified up to the present.

CANADA

Dislocation or Fracture.—Judge Lamont of Prince Albert, Sask., is said to have handed down a decision in the case of George Dangertield, who sued Dr. Alfred David for \$10,000 for alleged incorrect diagnosis of an injury, awarding damages of \$1,664.25 and costs to the plaintiff.

Presentation.—Dr. Alexander H. Beaton, Orillia, who has just retired after thirty-three years' service as superintendent of the Provincial Asylum for Idiots, was presented, on September 12, with a handsome oak cabinet of silver. The presentation was made on behalf of the citizens by Dr. William C. Gilchrist, and the address was read by Dr. Ainsley P. Ardagh.

New Medical Journal.—It is announced in the *Montreal Star* that Morang & Company, Limited, Toronto, have made arrangements with the executive committee of the Canadian Medical Association for the publication of the journal of the association, which will be published as a monthly magazine with Dr. Andrew McPhail, Montreal, as editor, and at the appearance of this journal the *Montreal Medical Journal* will be discontinued.

Hospital News.—The Victoria Hospital in Fredericton, N. B., is to be materially enlarged.—Edmonton will increase its hospital accommodation at an expense of \$175,000.—Winnipeg is erecting a tuberculosis hospital for advanced cases.—A sanatorium for tuberculosis has been opened at Ninette, Man.—A hospital for incurables is to be erected in Vancouver.—Victoria, B. C., is to have a new isolation hospital.—Waterloo and Wellington counties, Ontario, are to have a sanatorium for consumptives.

Medical Society Meetings.—The Maritime Medical Association, at its annual meeting in St. John, N. B., elected the following officers: President, Dr. Everind A. Kirkpatrick, Halifax; vice-president for Nova Scotia, Dr. George E. Dewitt, Wolfville; for New Brunswick, Dr. George G. Melvin, St. John; for Prince Edward Island, Dr. Henry E. McEwen, O'Leary; secretary, Dr. David T. C. Watson, Halifax, and treasurer, Dr. George G. Corbet, St. John, N. B.—The British Columbia Medical Association, at its annual meeting, held in Tranquille, elected the following officers: President, Dr. Octavius Weld, Vancouver; vice-president, Dr. Charles E. Doherty, New Westminster; secretary, Dr. Alexander S. Monroe, Vancouver, and treasurer, Dr. James D. Helmcken, Victoria.

Personal.—Dr. Helen MacMurchy has been appointed medical inspector of girls and Dr. Wilmot A. Graham inspector of boys in the public schools of Toronto.—Dr. Joseph W. Lane, Malboroughtown, has been elected president of the Ontario Medical Council.—Dr. John William Scott McCullough, Alliston, has been appointed secretary of the provincial board of health of Ontario, vice Dr. Charles A. Hodgetts, Toronto, resigned to accept the position of medical advisor with the Dominion commission of conservation.—Drs. James M. MacCallum and Samuel Cummings, Toronto, have gone to Europe to spend some months in graduate work.—Dr. E. A. McCullough, who was recently appointed superintendent of the London (Ont.) Sanatorium for Consumptives, has resigned and returned to Toronto.—Sir James A. Grant, M.D., Ottawa, who has been sojourning in Scotland the past summer, has been presented with the freedom of the City of Inverness.—Dr. Andrew W. H. Lindsay of Dalhousie University, Halifax, and registrar of provincial medical licenses for Nova Scotia, has been appointed honorary academic council of the student's representative council of Edinburgh University.—Dr. Charles Sheard, Toronto, has again resigned the office of medical health officer. It is understood that the resignation is due to adverse criticism on the part of newspapers in regard to the quality of Toronto's water and the administration of the Toronto Isolation Hospital, the latter of which is now being judicially investigated.—Dr. Alexander S. Monroe, Vancouver, B. C., has been elected secretary of the British Columbia Medical Society.—Dr. Henry E. Tremayne, Prince Rupert, B. C., has been appointed quarantine and dominion medical health officer at that port.—Dr. William A. Lincoln has been appointed superintendent of the Calgary, Alta., General Hospital.—Dr. John A. Gunn has resigned the superintendency of the Winnipeg General Hospital.—Dr. N. J. James, formerly resident physician at the Muskoka Cottage Sanitarium, has been appointed superintendent of the South Dakota State Sanitarium, Custer, S. Dak.—Drs. Herbert J. Hamilton, Charles J. C. O. Hastings and Augusta Stowe Gullen, Toronto, and William Burt, Paris, Ont., have been elected medical representatives on the senate of Toronto University.

MANILA LETTER

(From Our Regular Correspondent)

MANILA, Aug. 16, 1910.

San José Medical College Closed

The San José College of Medicine and Pharmacy of Santo Tomas University has permanently closed its doors. This leaves the Philippine Medical School the only medical school in the Philippine Islands and the only school to which the Filipinos outside of Manila may look to train medical men for them. Some three months ago by order of the pope, the San José College of Medicine and Pharmacy was turned over to the Jesuit order at the protest of most of the students. It soon became evident that it was the intention to close the institution. The students through a lawyer began proceedings for an injunction against the pope and the papal delegate to the Philippines, Father Algne, to restrain the transfer and closure of the college. Some little mystery seemed to underlie the entire proceedings and considerable dissatisfaction and indignation was felt by most of the students. Now in answer to the medical students Vice-Rector Llanos of Santo Tomas University states that lack of funds render it impossible for the university to maintain a college of medicine and pharmacy. He asserts that "already the College of Medicine and Pharmacy owes the university 143,000 pesos (\$71,500) and it owes another society 113,000 pesos (\$56,500) owing to deficits during past years when it was enjoying the income from its estates (i.e., part of the friar lands bought by the government). Now that the property has passed out of our hands, it is impossible for us to pay from the little money at our disposal, the deficit between the earnings and expenses of the institution." This leaves many of the students in a rather lamentable position. They have spent several years at the institution and have been expecting to get their degrees within the next year or two. Now that the college is closed there is no place for them to go to finish their medical course. The majority of them speak very little or no English and their training in the Spanish schools, where they got very little science, and in the medical college makes it practically impossible for them to complete their course in the Philippine Medical School without beginning almost at the bottom again. A delegation of the students has asked that they be admitted to the Philippine Medical School, but so far arrangements of this kind have not been granted. At present, therefore, for a population of 8,000,000, the supply of physicians comes from one school, which for each of the next few years will graduate a class of about 15.

Cattle and Meat Inspection in the Philippines

As was indicated in a previous communication, there has been established a thorough system of inspection of cattle and meat shipped into Manila. There seems to be some promise of freeing the Philippines from communicable infectious diseases of live stock, and it is desired not only to protect the consumer but also to prevent the introduction of other diseases, that this rigid inspection has been established. The quarantine regulations require that cattle coming from an infected port and those exposed to infection while in transit are to be kept in quarantine for a period of 60 days before being allowed to land. This has proved so expensive that it is not altogether practicable. To obviate this latter difficulty, a Manila business man, Senor Faustino Lichanso, has proposed to erect a floating matadero (abattoir) out in the bay. According to this ingenious plan, which has been approved by the Bureau of Health and the Municipal Board, animals after a thorough inspection are to be unloaded directly from the ship to be slaughtered on the matadero and again inspected. The matadero is also to be equipped with a burning plant for the purpose of destroying diseased parts, offal and such other material as is not used. The prevalence of pleuropneumonia in so many of the Australian cattle coming to this port is to a great extent responsible for these measures.

LONDON LETTER

(From Our Regular Correspondent)

LONDON, Sept. 17, 1910.

Decline of Lunacy in Scotland

In a previous letter (THE JOURNAL, Aug. 27, 1910, p. 788) it was stated that there was a tendency for the increase of lunacy, which has been constantly recorded in England in recent years, to cease. The figures for Scotland, which have just been published, are still more satisfactory. In 1903, for the first time in 19 years, a fall in the number of pauper lunatics in establishments in Scotland was reported. The

report for 1909-10 states that there is reason to believe that the year 1903 marked a turning point and that no permanent increase in the amount of registered insanity is likely to occur beyond that due to increase of population. The following are the proportion of admissions to asylums per 100,000 of the population in the last 5 quinquennial periods: 1886-1890, 73.4; 1891-95, 79.4; 1896-1900, 82.4; 1901-05, 84.4; 1906-10, 77.3.

The Crusade Against Tuberculosis

In spite of the work which has been done for the prevention and cure of tuberculosis there are at present in the United Kingdom between 350,000 and 400,000 persons suffering from tuberculosis, and each year 60,000 die from pulmonary tuberculosis and 30,000 from other forms of this disease. With these figures before it, the National Association for the Prevention of Tuberculosis has decided to make further efforts to educate the people in the prevention and treatment of the disease, which is still responsible for the deaths of 1 person out of every 10. The committee of the association points out that, as the working classes are losing \$15,000,000 a year in wages owing to sickness due to consumption, it is time that steps were taken to disseminate a knowledge of its infectious nature and the method by which its spread may be limited. The committee finds that the quickest and ultimately the cheapest way to educate the nation is by means of (1) traveling tuberculosis exhibitions; (2) caravans with lantern-slides; (3) popular lectures; (4) an information bureau for the press and public; and (5) the distribution of literature. It is estimated that to conduct a campaign efficiently on these lines would cost \$25,000 a year. The committee has also made arrangements for a "campaign by poster," which is being assisted by the billposters' association. One large firm has undertaken to produce 30,000 bills measuring 10 feet by 7 feet 6 inches, printed in eight colors.

The Hygiene of Childhood

State interference in hygiene of childhood has considerably increased in recent years. Presiding at the conferences of the congress of the Royal Sanitary Institute, Sir William Collins, M.P., delivered an important address on the hygiene of childhood. He said in part: Child life is a most sensitive reagent to hygienic and mal-hygienic influence. Early sanitary reformers, like Dr. Farr, have taught us to keep our eyes on the death-rate, but until recently we have complacently regarded the improvements in the general health-rate while ignoring the fact that until within the last few years the infant death-rate has shown little disposition to decline. Happily, attention is now concentrated on child life and the influences which act on it for weal or woe. Voluntary agencies, administrative bodies and the legislature are all alive to the importance of such questions. The years of school life—from 5 to 14—are tending to become not merely educational, but a period of state handling of childhood. There should be hospitals for the treatment of measles and whooping-cough, diseases which lay a heavy toll on child life. Physical education in schools should not be of the nature of military drill, for such is not the best form of exercise; it gives a bias or premature specialization to the child. More attention should be paid to moral education; otherwise the tendency is to make a good animal rather than a good citizen. We should foster self-knowledge, self-reverence and self-control and not a military spirit or a morbid form of spurious patriotism. The state is doing more and more for the individual, but that is no reason why the individual should do less for himself, but, rather, why he should be encouraged and spurred on to do more and to exercise the spirit of self-reliance and independence which they are trying to teach in the schools.

Hygiene of Ships

Another important paper read at the congress was on "The Necessity of a Revision of the Standard of Hygiene of Crews' Spaces in New Vessels," by Dr. Howard Jones, health officer of Newport. He said that it was most unfortunate that the accommodation provided in new vessels constructed in Great Britain was in a considerable proportion of cases very unsatisfactory from a hygienic standpoint. In the designing of new vessels the most elementary rules of sanitation were constantly ignored. In many instances the standard was much lower on new vessels than on old. The conditions were so bad that it was not surprising that the types of men in the merchant service were degenerating. It was humiliating that small countries like Norway and Denmark demanded a higher standard of hygiene in reference to crew spaces than did Great Britain.

PARIS LETTER

(From Our Regular Correspondent)

PARIS, Sept. 16, 1910.

Tuberculosis in Rural Districts in France

At the last meeting of the Association Française pour l'avancement des Sciences, Dr. Maurel, professor in the Toulouse college of medicine, reported the results of the investigation, embracing 2,500 communes, that he had undertaken in regard to tuberculosis morbidity among the rural population. Figures furnished by physicians practicing in these communes (Dr. Maurel selected communes where only one physician practiced) show that the number of subjects of tuberculosis in the country is, on an average, 2.93 per one thousand inhabitants. The departments most affected are those of Mayenne (15 per cent.), Loire (5.9 per cent.), Drôme (5.7 per cent.), Hautes-Alpes (8 per cent.), Côtes-du-Nord (4.3 per cent.), Seine-Inférieure (4.14 per cent.), Vienne (4.6 per cent.), Creuse (4.7 per cent.), Auvergne (4 per cent.), Haute-Savoie (4 per cent.); those less affected are Basses-Alpes (1 per cent.), Hautes-Pyrénées and Landes. In general, the departments of the south are less affected; those of the north are more so. Altitude and the vicinity of the sea seem to play no part. In general, tuberculosis is increasing appreciably almost everywhere. The causes are immigration toward cities, military service and primary schools, through which the contagion is disseminated, bovine tuberculosis, alcoholism, the deplorable domestic sanitation in the country, where dwellings are small and without light and air, and the lack of prophylaxis and disinfection.

Dr. Lafforgue, a military physician, expressed doubts in regard to the dissemination of infection in the country by dismissed tuberculous soldiers. He believes that, while soldiers sometimes contract tuberculosis in the barracks, they often have brought it to the regiment, where it is developed, as Dr. Kelsch has shown, with the first fatigues. Dr. Lafforgue says that excuses from service are at present very liberally granted by the military physicians, who are disposed to grant them even in doubtful cases.

Suit Against Surgeon for Sudden Death During Anesthesia

Dr. Forgue, professor of clinical surgery at the Montpellier college of medicine, was recently prosecuted for professional negligence, the sum of \$20,000 (100,000 francs) damages being asked for the death of the plaintiff's son on the operating-table during chloroform anesthesia. The Montpellier court decided against the plaintiff, on the ground that the syncope to which the patient succumbed was one of those accidents against which science at present has no remedy, and that Dr. Forgue had taken all the precautions usual in such cases. Dr. Forgue then brought a cross-action, on the ground of the injury to his reputation through the prosecution. Taking into account the fact that this prosecution was the outcome of the excitement occasioned by a painful event, he limited his demands to the sum of 20 cents (1 franc). The court sustained this demand and sentenced the father of the deceased to pay Dr. Forgue 1 franc damages.

The Hennequin Prize

Dr. Jules Hennequin, who is well known for his ingenious apparatus for the treatment of fractures, and whose death I mentioned some months ago (*THE JOURNAL*, April 23, 1910, p. 1387), by his will founded a biennial prize of \$300 (1,500 francs), which he has requested the Société de chirurgie of Paris to award to the author of the best memoir on the anatomy, physiology, pathology and traumatism of the human skeleton.

Suppression of Nursing-Bottles With Tubes

About a year ago (*THE JOURNAL*, July 3, 1909, p. 40) I mentioned a bill bearing on the sale of nursing-bottles with tubes. This bill finally resulted in the law of April 9, 1910, which forbids the sale, exhibition and importation of such nursing-bottles, and the courts have already sentenced twelve retail grocers of the neighborhood of Alençon, Normandy, for infraction of the law.

BERLIN LETTER

(From Our Regular Correspondent)

BERLIN, Sept. 8, 1910.

Personal

The associate professor of pharmacology at Göttingen, Dr. W. Heubner, has been made a regular professor. He is 31 years old, the son of the Berlin pediatricist.—At Marburg the associate professor for pharmacology, Dr. Gürber, has been

raised to a regular professorship, and the associate professor of otology, Dr. Ostmann, has received the title of regular honorary professor.—Prof. L. Brauer, the director of the medical clinic at Marburg, has been chosen to be director of the public hospital at Hamburg-Eppendorf, as successor to the late Professor Lenhartz.

Cholera

The second victim of cholera in the neighboring town of Spandau, mentioned in my last letter, died two days ago. No other cases have developed. Berlin is still free from the disease. In Russia cholera continues its ravages unchecked. In the week from July 31 to August 6, according to the recently published official figures, 21,000 cases were reported, and 9,000 of the victims died. An Austrian scientist has suggested in the *Wiener klinische Wochenschrift* that the other European governments will have to bring pressure to bear on Russia to compel the Russian government to take more effectual measures for the prevention of cholera, as it is a perpetual menace, year after year, for the rest of Europe. The Austrian writer is evidently unaware of the difficulties and hopelessness of any diplomatic measures of the kind. It would be impossible to compel the Russian government to undertake any measures on its own soil unless war was declared against it. Besides, there is no doubt that the Russian government is anxious to exterminate cholera within its borders, and the realization of this desire fails solely on account of the inadequate sanitary organization and sanitary official force, the stupidity of the populace and the inadequate financial means.

Russian Discrimination Against Jewish Visitors

As is well known, Jewish physicians who wish to visit Russia find many difficulties thrown in their way, and it has repeatedly happened that German Jewish physicians, summoned in consultation for Russian patients, have not been able to answer the summons, or only with considerable delay, on account of the hindrances placed in their way by the passport authorities. Nonsensical as these regulations are, it has not been possible hitherto to bring the Russian authorities to a more rational point of view. On the occasion of the Moscow International Medical Congress, Virchow was able to obtain from the Russian government the assurance that no difficulties would be placed in the way of attendance at the congress of German Jewish physicians, only by making this the indispensable condition for his acceptance of the chairmanship of the German national committee. It has required repeated efforts also this year to smooth away the difficulties for German Jewish gynecologists to attend the international gynecologic congress, to be held at St. Petersburg in October. In the same way the members of the Naturforscher congress at Königsberg, this fall, have experienced no little difficulty in obtaining passports for the contemplated excursion over the Russian border. Both these meetings, however, will undoubtedly suffer from the fear of the cholera epidemic.

Eddyism in Berlin

Notwithstanding all the exposures which have repeatedly appeared in the daily papers and the statements of physicians to individuals, it has proved impossible to stamp out Eddyism in Berlin. On the contrary, it has obtained quite a number of adherents, some with considerable means, and it is known that especially the members of the so-called better social circles are joining this cult. A few days ago a circular was widely distributed by the society containing exact instructions how to get well without medical aid by prayer, alone or supplemented by the laying-on of hands by the Eddyite "elder."

Medical Inspection of Chauffeurs

It has recently been ordered that the applicant for a chauffeur's license must present the certificate of a physician (*beamteten Arztes*) to the effect that the candidate has no physical defects which would interfere with his management of an automobile, especially defects in hearing and vision.

VIENNA LETTER

(From Our Regular Correspondent)

VIENNA, Sept. 10, 1910.

Personal

After a prolonged vacancy the chair of ophthalmology has been again filled, and Professor Dimmer has consented to be the successor of Professor Schnabel. The new director of the first eye clinic in Vienna is a pupil of Arlt, Jäger and Fuels.

In 1895 he was appointed professor of ophthalmology at Innsbruck; then he was called to Graz. He has published, besides several minor papers, the more important books: "Ophthalmologic Diagnoses," "The Light-Reflexes of the Retina," "Anatomy and Physiology of the Macula Lutea." His contributions to medical literature have always elicited much interest.—Prof. Julius Tandler has been appointed professor of anatomy, and thus is the successor of the late Zueckerkandl. His appointment will be received by the students with the utmost satisfaction, for he is very popular with them on account of his excellent pedagogic qualities. In fact, he is perhaps the best teacher, in the strict sense of the word, here in the university. His classes and courses are famous and are always thronged, and, being the first assistant of the bedridden scientist, Zueckerkandl, he had substituted him for several years. He has been very much engaged in embryologic and ontogenetic work, and one of his favorite lecture-series was that dealing with topographic anatomy. He had been recommended by the senate of the university "primo et unico loco," a rare mark of distinction.

First Cases of Cholera in Vienna

While the first 2 cases of cholera in this city could be traced to the place of infection, and thus all precautions for thorough prophylaxis were possible, 3 new cases happened about a fortnight later in an outlying suburb of the city, where the source of infection remains hitherto unknown. Naturally the endeavors of the board of health are directed, apart from the quarantine and isolation required by the outbreak, to the destruction of all unhealthy conditions existing in the capital. The supply of water is excellent, perhaps the best in all Europe. The sewerage system is also very good and absolutely modern, with the exception of a small area recently incorporated into the city. It was here that the 3 new cases occurred, in a father, mother and child. The method of removing the household refuse and waste is, however, very antiquated and insanitary, and what years of public indignation could not bring about, namely, modern provisions in this respect, may be perhaps accomplished quickly by the threatening approach of a ghastly disease.

State Control of Juvenile and Female Laborers

In a report to the *Wiener klinische Wochenschrift* Dr. Hofmohl deals with the results obtained by the institution of inspectors of factories and home industries as regards the reduction of the work required from females and juvenile workers. The main points aimed at by the state control were the gradual, not sudden, increase of work imposed on young workers, and this has been attained in numerous occupations, and the relief of pregnant women and nursing mothers from the pressure of factory work. Thus in the mining and iron industries, in open shops and in agricultural occupations, persons less than 16 years of age must have no more than 10 hours work a day, with a clear 24 hours of rest each week. Besides this, their work must be at least an hour less than that of their adult work-mates, so that sometimes they have only 8 and 9 hours a day. For women all night-work has been nearly stopped, and in a good number of occupations also the 10-hour limit has been adopted. The conditions of children's work in the factories is regarded as very satisfactory where it is controlled. But in private employment (weaving at home, service as waiters in restaurants, theaters and shows) a law regulating the duration of working hours is urgently required. Here, at present, the inspectors are powerless. The protection of the female laborer during her pregnancy and in childbirth has been given over to the *Krankenkasse*, or wage-earners' insurance society, which is now bound by law to pay the female member coming into such a condition its full sick pay for 6 weeks, commencing 2 weeks before the expected confinement. The death-rate of women engaged in any one of the industries is very high; in fact, it is the highest percentage of all the mortality statistics. Therefore, attention has been turned to that point; married women have a right to a noon rest of 2 hours for the purpose of arranging their household; furthermore, the factories are not allowed to give out work to them to be finished at home. Another clause of the new act dealing with the provisions for sick female workers requires the appointment of a female district doctor wherever the majority (60 per cent.) of the factory hands of a district consists of females, and inspection by that doctor also of all puerperal cases. These are, of course, the main points only, but they suffice to show the trend of the present social legislation in this country and the efficiency of state control of wage-earners.

Marriages

BOYD A. MUSTER, M.D., to Miss Bessie Crady, both of Lyons, Ky., July 1.

JULIUS BLECHSCHMIDT, M.D., to DOTT CASE, M.D., both of Philadelphia, September 14.

JAMES D. HILLIS, M.D., to Mrs. Edna E. Robinson, both of LaFayette, Ind., August 20.

ORIE C. YODER, M.D., Peru, Ill., to Miss Sadie Albrecht of Tiskilwa, Ill., September 15.

HENRY LONGSTREET TAYLOR, M.D., to Miss Ethelberta Geer, both of St. Paul, September 8.

WALTER BAUMGARTEN, M.D., to Miss Louise Knapp, both of St. Louis, Mo., September 20.

FRANK P. WAS, M.D., to Miss Elizabeth Annie Howorth, both of Chicago, September 21.

AUBREY V. JONES, M.D., Louisville, Ky., to Miss Mable Sells, at Anderson, Ind., recently.

HENRY J. NICHOLS, M.D., U. S. Army, to Miss Grace Gundry of Catonsville, Md., September 21.

FRANK W. COWGILL, M.D., Baxter, Iowa, to Miss Estella Werts of Russell, Iowa, September 7.

PAUL BROWN DUNBAR, M.D., Baltimore, to Miss Alice Lenore Davison, at Norfolk, Va., September 7.

JOSEPH MILTON TRIGG, M.D., to Miss Clara Lillian Roberts, both of Shawnee, Okla., September 4.

HURON WILLIS LAWSON, M.D., to Miss Franceska Kasper, both of Washington, D. C., September 14.

WILLIAM GEORGE MCKAY, M.D., Jacksonville, Fla., to Miss Inez Louise Neal of Letts, Iowa, September 14.

GEORGE ROGER ALBERTSON, M.D., Moline, Ill., to Miss Mary K. Klacke of Cedar Rapids, Iowa, at Iowa City, recently.

WALTER HARDING YOUNG, M.D., Freedom, N. H., to Miss Ethel Marie Hardy of Dedham, Mass., September 14.

FREDERICK JOHN JENNINGS WOOD, M.D., to Mrs. Mabel Wheeler Bailey, both of Brooklyn, N. Y., in Boston, July 12.

FREDERICK T. KOYLE, M.R.C., U. S. Army, to Miss Sarah A. Leopold of Savannah, Ga., at Washington, D. C., August 30.

LOWELL MCKEE GREEN, M.D., Nashville, Ind., to Miss Maud Beatrice Fargo of Portland, Ore., at St. Louis, September 15.

Deaths

Henley C. Rutter, M.D. Medical College of Ohio, Cincinnati, 1869; of Columbus; a veteran of the Civil War; a member of the American Medical Association; for four years superintendent of the Dayton State Hospital, and later superintendent of the state hospitals at Athens and Columbus; founder and for several years superintendent of the Ohio Hospital for Epileptics, Gallipolis; up to last year in charge of the Park View Sanitarium, Columbus; an alienist and writer on sociologic problems and diseases of the nerves and mind, died September 17, in an ambulance, while on the way to Lakeside Hospital, Cleveland, from the effects of poison, believed to have been self-administered with suicidal intent while mentally irresponsible, aged 61.

Gustav Baumgarten, M.D. Washington University, St. Louis, 1856; a member of the American Medical Association; passed assistant surgeon in the Navy throughout the Civil War; in 1899, president of the Association of American Physicians; from 1867 to 1871, editor of the *St. Louis Medical and Surgical Journal*, and professor of histology and pathology in the College of Physicians and Surgeons from 1873 to 1892 professor of physiology and therapeutics in the same institution, and since that time professor of practice of medicine in Washington University Medical School; died at his home in St. Louis, September 19, aged 73.

Lucius French, M.D. Berkshire Medical College, Pittsfield, Mass., 1853; a member of the American Medical Association, and International Association of Railway Surgeons; in 1908, made a life-member of the Scott County Medical Society; local surgeon at Davenport for the Chicago, Milwaukee and St. Paul Railway; assistant surgeon of the Thirty-first Iowa Volunteer Infantry during the Civil War; president of the local board of U. S. Pension Examining Surgeons from 1864 to 1884; died at his home, September 19, from angina pectoris, aged 78.

William Smith Nelson, M.D. New York University, New York City, 1887; of Utica; a member of the American Medical Association; a member of the staff of the Faxon Hospital; an authority on pulmonary tuberculosis, and examiner for the State Tuberculosis Hospital, Raybrook, N. Y., died September 12, in Butler Hospital, Providence, R. I., aged 47.

Charles Cook Ransom, M.D. University of Buffalo, N. Y., 1883; of New York City; a member of the American Medical Association; a member of the visiting staff of the City Island, Blackwell's Island, and president of its medical board; died in the Faxon Hospital, Utica, N. Y., September 13, after an operation for intestinal obstruction, aged 50.

Ira Ellis DuPree, M.D. Louisville Medical College, 1874; a member of the Medical Association of Georgia; formerly of Danville but of late years of Athens, Ga.; a surgeon of volunteers during the Spanish-American War; local surgeon for the M. D. and S. Railroad; died at Saranac Lake, N. Y., from chronic pulmonary tuberculosis, aged 56.

Elisha Warick Miller Low, M.D. a graduate in medicine but never in practice; who spent most of his life in developing the lime business, and was for seventeen years president of the First National Bank of Bloomsburg, Pa.; died at his home in Lime Ridge, August 21, from organic heart disease, aged 81.

Milan A. Gates, M.D. Detroit Medical College, 1880; a member of the American Medical Association, and member of the American Association of Railway Surgeons; local surgeon to the Chesapeake and Ohio Railroad; died at his home in Ronceverte, Va., September 14, from locomotor ataxia, aged 65.

John S. Lewis, M.D. Jefferson Medical College, 1868; a member of the Iowa State Medical Society; president of the Humane Society; a veteran of the Civil War; a member of the staff of the Finley Hospital, Dubuque; died at his home in that city, September 14, from pernicious anemia, aged 65.

F. G. Hall (license, Texas, 1907); of San Antonio, Texas, for seventeen years a practitioner, and formerly in the government medical service at Ketchikan, and Juneau, Alaska; died in a hospital in San Antonio, September 6, from shock following an operation for pyelonephritis, aged 47.

Joseph R. Sewell, M.D. Southern Medical College, Atlanta, Ga., 1888; formerly general director of the Carrollton (Ga.), Sanitarium and School of Electrotherapeutics; was shot and instantly killed in his office in Atlanta, September 20, by a patient believed to have been insane, aged 48.

George L. McIntire, M.D. Baltimore Medical College, 1888; of New Martinsville, W. Va.; a member of the American Medical Association, and a veteran of the Civil War; died in the North Wheeling Hospital, Wheeling, W. Va., September 12, from appendicitis, aged 63.

Timothy D. Sullivan, M.D. Bellevue Hospital Medical College, 1884; of Calais, Maine; a member of the American Medical Association; an oculist and special United States pension examining surgeon for the eye and ear; died at his home, August 31, from enterocolitis, aged 54.

Hugh Sloan, M.D. Albany (N. Y.) Medical College, 1865; of Utica; a member of the Medical Society of the State of New York; in 1873 a member of the local board of health; died at his summer cottage at Lewis Point, Oneida Lake, September 7, aged 66.

Everard Mead Grant, M.D. Tulane University, New Orleans, 1872; a member of the American Association of Railway Surgeons, and local surgeon at Terry, Miss., for the Illinois Central Railroad; died at his home, September 3, from nephritis, aged 65.

Samuel White Fain, M.D. New York University, New York City, 1892; a member of the American Medical Association; physician to the Jefferson County Asylum for the Poor; died at his home in Dandridge, Tenn., September 17, from anemia, aged 42.

James Wylie Bowden, M.D. Bellevue Hospital Medical College, 1869, and for sixteen years thereafter clinical assistant to the late Dr. James R. Wood; died at his home in Yonkers, N. Y., May 3, from cerebral hemorrhage, aged 62.

James H. Johnson, M.D. University of Buffalo, N. Y., 1866; a veteran of the Civil War, and for many years surgeon of the North Dakota Soldiers' Home, Lisbon; died at his home in that place, September 14, from cerebral hemorrhage, aged 71.

Richard Kissam Macalester, M.D. University of Zurich, Switzerland, 1890; house physician for the Glenwood Springs (Colo.) Company from 1898 to 1906; died at his home in Denver, September 16, from pulmonary tuberculosis, aged 51.

Joseph Aiken Reid, M.D. Eclectic Medical College of the City of New York, 1908; superintendent of St. Vincent's Hospital, West Brighton, Staten Island, New York; died at the home of his mother in Brooklyn, September 13, aged 23.

James Frank Gillespie, M.D. College of Physicians and Surgeons, Baltimore, 1897; for many years a school teacher in Nova Scotia; died at his home in the Bronx, New York City, September 12, from heart disease, aged 41.

George E. Barth, M.D. Kentucky School of Medicine, Louisville, 1869; State University of Iowa, Iowa City, 1875; formerly of Rock Island Ill.; died at his home in St. Louis, September 15, from nephritis, aged 62.

Walter Peck Miller, M.D. University College of Medicine, Richmond, Va., 1898; a member of the Medical Society of Virginia; died at his home in Newport, September 2, from ulceration of the intestine, aged 34.

Joseph Boyd, M.D. Medical College of Ohio, Cincinnati, 1888; a member of the Kentucky State Medical Association; of Cynthiana, Ky.; died September 16, at a hospital in Oxford, Ohio, from nephritis, aged 47.

Benjamin Whitaker Daniel, M.D. University of Pennsylvania, Philadelphia, 1858; assistant surgeon in the Confederate service during the Civil War; died at his home in Atlanta, Ga., September 13, aged 78.

James Henry Clarke, M.D. College of Physicians and Surgeons, New York City, 1889; died at his home in the Bronx, New York City, September 14, from septicemia following an operation wound, aged 44.

John Samuel Sellers (license, Maryland, 1893), a member of the Augusta County (Va.) Medical Society; died at his home in Weyer's Cave, September 2, from chronic interstitial nephritis, aged 41.

Marcel Pietrzycki, M.D. Cooper Medical College, San Francisco, 1872; a prominent citizen and formerly mayor of Dayton, Wash.; died suddenly at his home, September 12, from heart disease.

Eugene M. Bancroft, M.D. Eclectic Medical Institute, Cincinnati, 1892; of Southington, Ohio; was instantly killed by the overturning of his automobile at Warren, Ohio, September 13, aged 42.

Duncan Hossack Hutchinson, M.D. University of Toronto, 1890; a member of the Ontario Medical Association; died at his home in Port Rowan, Ont., June 2, from heart disease, aged 45.

Ethelbert Norwood Goodson, M.D. Barnes Medical College, St. Louis, 1899; of Hopkins, Mo.; died in the Woodson Sanitarium, September 5, from paresis, aged 33.

Vira Abel Brockway, M.D. Northwestern University Woman's Medical School, Chicago, 1887; died at her home in Chicago, September 21, from cerebral hemorrhage, aged 57.

Samuel T. Botts, M.D. Hospital College of Medicine, Louisville, 1891; a member of the American Medical Association; died at his home in Glasgow, Ky., September 20, aged 68.

Augustus Wierich, M.D. University of Pennsylvania, Philadelphia, 1866; a member of the Illinois State Medical Society; died at his home in Galena, September 13, aged 66.

Ezra Walling (license, twenty years of practice, Mich., 1900); a practitioner in Michigan for fifty-six years; died at his home in Coopersville, September 13, aged 85.

Jimsey H. Rogers, M.D. University of Wooster, Cleveland, 1877; a veteran of the Civil War; died at his home in Louisville, Ohio, September 1, from nephritis, aged 64.

Elizabeth Griselle, M.D. Woman's Medical College of Pennsylvania, Philadelphia, 1856; died at her home in Salem, Ohio, August 23, from pulmonary tuberculosis, aged 79.

Henry T. Reinsel, M.D. College of Physicians and Surgeons, Baltimore, 1886; died at his home in Coraopolis Heights, Pittsburgh, September 12, from heart disease, aged 51.

Americus V. Watkins, M.D. Eclectic Medical College of Pennsylvania, Philadelphia, 1871; died at his home in Dausville, N. Y., August 30, from paralysis, aged 68.

Irving Oscar Cummings, M.D. Harvard Medical School, 1890; a member of the Massachusetts Medical Society; died at his home in Brewster, August 2, from chronic interstitial nephritis, aged 46.

William Cooper, M.D. Eclectic Medical Institute, Cincinnati, 1867; died at his home in Kokomo, Ind., September 17 from disease of the stomach aged 71.

Upton A. Ager, M.D. Rush Medical College, 1867; died at his home in Peru, Ind., September 7, from cerebral hemorrhage, aged 71.

Eugene Scott Alexander, M.D. College of Physicians and Surgeons, Chicago, 1901; of Indianapolis; died in a hospital in Chicago, September 4, aged 38.

John F. McKinley, M.D. Eclectic Medical Institute, Cincinnati, 1876; died suddenly at his home in Arcola, Ill., September 14 from heart disease.

Gregg Garrison, M.D. University of Halle, Germany, 1878; (years of practice, Ill., 1878); died at his home in Wayne City, April 12, aged 79.

Orlando W. Cummings, M.D. Rush Medical College, 1883; died at his home near Buda, Ill., September 6, from cerebral hemorrhage, aged 54.

William T. Wilson, M.D. Rush Medical College, 1863; a retired physician of Bunker Hill, Ind.; died at his home September 3, aged 83.

Katherine Kurt, M.D. Hahnemann Medical College, Chicago, 1882; died at her home in Akron, Ohio, from pneumonia, aged 57.

Pharmacology

REMEDY FOR SORE THROAT

It is not an uncommon occurrence for THE JOURNAL to receive a letter from a layman who believes—or professes to believe—that he has made an epoch-making discovery in therapeutics. The definiteness of the claims made for the therapeutic virtues of these "discoveries" is equaled only by the indefiniteness of the description of the products themselves. So rarely, in fact, is any information of even approximate definiteness sent that a communication received recently by the Council formed a rare exception. This letter was from G. M. Rathbun, of Sedan, Kan.

Mr. Rathbun stated that he had a remedy for "diphtheria, tonsillitis, ulcerated sore throat" and similar conditions. So far the letter differed in no essential respect from others describing the virtues of "cures" proposed by laymen. He went on to say that he wished the medical profession to know of the remedy so that it might be more widely used, and to that end had interviewed Professors Bailey and Havenhill of the State University of Kansas. These men had suggested that he write to the Council on Pharmacy and Chemistry and make known his desire; hence the letter. With the letter were the statements of two physicians of Sedan, Kan., to the effect that the preparation had considerable value as an antiseptic for stomatitis, tonsillitis and similar conditions. Mr. Rathbun was told that if he wished to give physicians the benefit of his remedy he should describe briefly its composition and method of preparation. This he did in the following words:

"This remedy is composed of a strong tea or decoction of sage and garden saffron (about equal parts in bulk), sweetened to make it reasonably palatable, and acetate of copper (verdigris¹), 5 or 6 grains to the ounce, shaken well together and shaken well before using. The acetate of copper must not have remained long in a pulverized or 'floured' condition before being put into the tea. This remedy should be used with a swab, especially when used far back in the mouth or throat."

That this mixture should possess antiseptic and astringent properties is to be expected, and as such is doubtless of value in mild affections of the throat or oral mucous membrane. It may have some place as a local application in cases of diphtheria, providing always that its use is entirely subsidiary to the antitoxin treatment. Therein, however, lies the danger of advising the use of a topical remedy in cases of "sore throat"—that curative measures are apt to be postponed until serious systemic damage has resulted.

Mr. Rathbun's mixture undoubtedly has the astringent and antiseptic action of the copper salts, perhaps slightly fortified by the very mildly similar action of sage and saffron. More than this, however, surely should not be claimed for it.

1. The term "verdigris" is loosely used. Frequently it refers to cupric acetate; more popularly it is used in reference to the carbonate, while rightly it should mean the basic acetate of copper.

MAIL-ORDER MEDICAL CONCERNS

Light Shed on Some of Their Inner Workings by the Rainey-Atkins Tragedy

The sordidness and general disreputableness of the mail-order medical business again has been brought to public attention by the recent Chicago tragedy in which Dr. James M. Rainey shot and killed his one-time partner, Louen V. Atkins. Rainey, a graduate of the Eclectic Medical Institute of Cincinnati, has for many years operated in Chicago, in partnership with Atkins, a quack medicine concern known as the "Dr. Rainey Medicine Company," at the same time he has been manager of the American Animal Therapy Co.

The former concern sold a "general debility cure" called "Vitaline"—said, by the way, to be put up by one of the large "ethical" pharmaceutical houses—which was advertised in the cheap-grade magazines and sold on the mail-order plan, no local business being sought. The nostrum was sold at \$1 a bottle or 6 bottles for \$5. It appeared from the testimony given at the inquest that when a "patient" became dissatisfied with the Vitaline "treatment" and threatened to cause trouble for the concern an effort was made to turn him over

drew from the "Dr. Rainey Medicine Company" and opened in the same building a rival concern called "Dr. James M. Rainey, Incorporated." The similarity of names of the two companies caused much trouble and confusion in the delivery of the mail and recently Atkins had changed the name of his concern to the "American Home Treatment Company."

As is common with mail-order medicine companies, one of their methods of getting the names of prospective victims was to purchase them from "letter brokers." These "brokers" buy and sell the letters of those unfortunates who have been so unwise as to write to quacks or "patent medicine" houses. Not only did Rainey and Atkins buy the names of possible "patients" but they evidently sold the original letters of their past customers. In the list sent out by one of the largest "letter brokers" in the country we find tabulated under "Female Complaint Letters," "7,900 Dr. Rainey Med. Co. 1908 & 1909" letters for sale. It was this very practice of buying letters that led to the tragedy. Atkins had received and cashed a money-order that was intended for Rainey and when the return of the money was demanded Rainey was accused of having taken the name of the person sending it from

FREE Dollar Bottle Vitaline

YOU PAY NOTHING FOR IT

Dr. Rainey says: "My scientific formula of Vitaline is the sure cure for the diseases and symptoms mentioned below—it's the most certain of all and there is no doubt about this. Vitaline tablets are just the treatment so many are looking for, what they should have and must have to be made strong, vigorous and healthy. It makes no difference how weak you are nor how long you have had your trouble, Vitaline tablets will easily overcome it—they will not fail nor disappoint you.

by writing your name and address. Send just 10c in stamps or coin to get the bottle packed and pay postage. This is all you have to do to get a \$1 bottle of Vitaline Tablets free. We give you the \$1 bottle without cost or obligation to prove what a wonderful remedy Vitaline Tablets are. We know when you have taken them you'll say with a glad heart that you have at last found the right medicine.

Vitaline tablets act on the Vital Organs that generate vitality and create the brain force which makes one feel strong, vigorous and healthy, equal to all the duties and pleasures of robust strength and health. They give you vigor and vitality every day and restore you so fast and completely you never know there was anything the matter.

Vitaline tablets are prepared by us under the U. S. Pure Food and Drugs Law by Dr. Rainey, No. 217. You never had anything like them, combining their wonderful strength and strengthening powers.

We send you our illustrated book, "Vitality" You have never seen one like it. Our testimony is from people cured a far longer forty years of doctors will convince you of all we claim for Vitaline tablets.

Exact size of Bottle containing 20 Vitaline tablets.

NERVOUS WEAKNESS, DEBILITY—L. o. e. c. Nervousness, Weakness, Twitching, Jerking, Empty Feeling, Wormed Feeling, Weak, Aching Back, Lack of Strength, Energy or Ambition, Bad Dreams, Poor Memory, Rashful, Restless at Night, Despondent.

STOMACH TROUBLES—Pain in Stomach, Loss of Appetite, Dyspepsia, Indigestion, Bad Taste or Breath, Sick Headache, Bloating, Heartburn, Sour Belching, Spitting Up, Catarrh, Gas, Grawling, Nervousness.

HEART WEAKNESS—Fluttering, Spitting, Fatigue, Pain in Heart, Side or Shoulder Blade, Short Breath, Weak Sinking, Cold or Dirty Spells, Swelling, Rheumatism, Throbbing in Excitement or Exertion.

CATARRH—Rawling, Spitting, Nose Running, Itching, Watery or Yellowish Matter or Stopped Up, Sneezing, Itchy Headache, Coughing, Deafness, Pains in Kidneys, Bladder, Lungs, Stomach or Bowels may be Catarrh.

BLOOD TROUBLES—General Debility, Paleeness, Thin, Weak, Run-Down, Nervous, Rash, Ores, Ulcers, Pimples, Chilly or Feverish, Loss of Flesh and Strength.

NAME

ADDRESS

Reproduction (1/3 size) of typical advertisements of the "Dr. Rainey Medicine Company" and the "American Home Treatment Company." Notice that the only difference between them is that in the latter Rainey's name has been omitted and his picture replaced by that of another. While "Vitaline" is advertised in papers and magazines as a "sure cure" for a vast number of diseases, its exploiters would not dare put such statements on the label of the Vitaline bottles. The federal government, through the "pure food law," prohibits lying on the label, but it cannot—or at least does not—prohibit the printing of falsehoods in periodicals.

to what they called the "special treatment" department. A question blank would be sent which when filled out by the victim was supposed to be used as a basis for "diagnosing" the case.

On the other hand the American Animal Therapy Co., with which Rainey was connected, markets a "lymph compound" which is recommended for "locomotor ataxia," "paralysis," "loss of memory" and "epilepsy;" this, of course, claims to be an "ethical" (save the mark!) preparation as it is advertised to physicians; thus Rainey seems to have been working both the medical profession and the public.

Atkins and Rainey had frequently quarreled over the method of conducting the business of the "Dr. Rainey Medicine Company" and at the coroner's inquest the evidence indicated that Atkins, who was not a physician, occasionally sent out "literature" which the more conservative—or shrewd—Rainey declared would bring the concern into trouble with the postal authorities. Things finally got to the pass where Rainey with-

Atkins' mailing list. Rainey claimed, however, to have purchased the name from a "letter broker" and the quarrel commenced which ended in Atkins' death. It would be interesting to trace back the chain of events which led up to the homicide; doubtless a poor, humbugged victim probably a woman—who had at some time written to a conscienceless quack hoping for relief from some imaginary or real ailment; after being "worked" to the extent of her purse and being no longer profitable prey, her letter is sold to the "brokers."

At the inquest it was shown that Atkins, who was interested in several "Men Specialists" concerns, was of a quarrelsome disposition and had at various times threatened Rainey and others. The jury exonerated Rainey and he was released from custody.

Occurrences like these have an economic and sociologic interest. They turn, for an all-too-brief period, the searchlight of publicity into the dark and noisome pit of quackery and nostrum exploitation and make clear the miserable sordid-

ness and fraud inseparable from it. Did the hapless victims but know the pretense, the sham, the ignorance, the utter disregard for anything connected with the patient save his dollars, that characterize the average individual who conducts a mail-order medical concern, it would be but a short time before an outraged and indignant public would force the whole disreputable business out of existence.

Correspondence

International Hygiene Exposition, Dresden, 1911

To the Editor:—It now seems probable that the United States will not be officially represented at the International Exposition of Hygiene to be held at Dresden next year. This is a most regrettable circumstance as the exposition bids fair in many particulars to be highly important in both a scientific and commercial sense. It will be an important and conspicuous step in a movement that is at once humanitarian, altruistic and utilitarian, one that is world-wide in its extent and to be identified with which the United States cannot afford to miss a single opportunity.

The exposition, which is to be opened in May, 1911, under the patronage of the King of Saxony, is to cover an area of about 300,000 square yards located in a large park in the heart of Dresden. The guarantee fund for its promotion was made up some six months ago of \$75,000 from the city of Dresden, \$50,000 from the kingdom of Saxony, and enough from other sources to make it aggregate \$250,000. It was then expected that other German federal states would make similar contributions. The buildings will be put up by the participating countries and are presumed to cost from \$12 to \$15 a square yard.

The exposition itself contemplates two general classes of exhibits: one will be strictly scientific from various institutions and scientific organization; the other will be commercial and will be derived from leading manufacturing establishments of the different countries. The scientific exhibit is to be grouped according to subject, so that any special branch of hygiene or sanitation in its present state of development can be studied objectively. The adjacent pavilions will be given over to industrial exhibits representing the latest practical application of science to the maintenance of the health and physical welfare of humanity. In addition to these two distinct branches of the exposition there is to be a third devoted to the historical evolution of the subject. This promises to be a most interesting feature as it will embrace demonstrations of the hygiene of the Egyptians, the Indians, the Persians, the Jews, the Greeks, the Romans and other peoples of remote antiquity.

Furthermore, it is understood that, while the greatest scientific precision will be aimed at, a distinct effort will be made to popularize the whole subject by divesting it as nearly as possible of its technical garb. In fact, a distinct department of personal hygiene, designed to teach the people how to maintain their functional powers and thus to conserve their health and prolong and broaden their lives is to be made a distinct feature of the event. In this particular, Germany is simply following its long and well-defined policy of sending its science home to its people—a policy, the results of which are to be seen in the evidences of progress and prosperity discernable to-day in the land of the Kaiser as nowhere else in Europe.

Ambassador Hill, who strives in every way to maintain most cordial relations not only between the governments of Germany and the United States, but between the peoples of the two countries, and who is keenly alive to the scientific and humanitarian importance of the Dresden event, is not losing an opportunity, official or personal, to secure cooperation from America. It is most unfortunate, however, that without respect to the time when that event was first con-

ceived, it was not brought to his attention by its promoters until the very last minute. Indeed, it seems extraordinary that what has evidently been designed as a most important undertaking should have sprung up with such apparent spontaneity and should be forced through with such unusual haste unless possibly the explanation is to be found in the fact that a similar exposition had been previously planned and announced in connection with the International Congress of Hygiene and Demography that is to be held in Washington in 1912. At any rate, the invitation to send a representative to Dresden to attend a Conference of the executive committee of the exposition was not received at the American Embassy in Berlin until within less than 24 hours before that conference of two days' duration was to be opened on February 11 at Dresden. It was too late to communicate with Washington and it was too late to reach Dresden in time for the opening of the conference, but Ambassador Hill of his own initiative requested Mr. Joseph C. Grew, the second secretary of the embassy, to go to Dresden and unofficially attend as much of the conference as possible.

When Mr. Grew arrived at Dresden on the second day of the meeting he found present delegates from all the German capital states and representatives of Chile, China, Denmark, France, Italy, Holland, Austria-Hungary, Portugal, Roumania, Russia and Sweden. The British minister to Saxony was also present but unofficially owing to the lateness of the invitation, from which same cause some other countries were likewise not represented. Mr. Grew made a formal report on the meeting which was referred to Washington by Ambassador Hill with the recommendation that the United States Government take active steps to be officially represented.

It seems, however, that nothing can be done until Congress acts in the matter. This, of course, takes time, too much time it seems, but not more time than is required for similar matters in most other countries. The only exception of which I have heard, is Japan, which, in spite of its depleted treasury, seems to be in a state of preparedness for precisely such events. This was shown by the fact that the envoy that was sent around the world by the Saxon government in the interests of this exposition reached Japan when its parliament was not sitting. There seemed, therefore, no chance to get a commission authorized or to get money appropriated to support such a commission. Yet, somehow, somewhere, about the imperial treasury at Tokio there was found a way by which Japan managed to keep step at Dresden with the march of progress. It would seem wise if the President of these United States could be provided, as the emperor of Japan seems to be provided, with a contingency fund and could be invested with authority to act in precisely such cases as this. As it now stands Congress will not be in session until December; what its temper will be, whether there will be enough of new blood in it to grasp such fundamental problems of progress and of human welfare will depend entirely on the results of the approaching elections. In any event there is hardly a probability that the necessary action can be secured in time for us to take a creditable hand in an event in which our part must be either creditable or no part at all.

All of this goes to show two things:

1. Great international events, to be fairly international, require more time than has been given to the Dresden exposition.
2. Governments ought to be in a greater state of preparedness than is the government of the United States for contingencies such as this.

There is another aspect of the subject that I cannot refrain from mentioning, and I shall do it by a word of caution against a possible spirit of chauvinism that is liable to assert itself in some quarters in America. There ought to be no feeling of resentment in America growing out of the conjugation of circumstances by which Germany in general and Saxony in particular may seem to be engaged in an attempt to forestall interests in the Washington meeting of 1912. Nor should there be any particular feeling because the American idea of an exposition of hygiene bids fair to find its first

exemplification on the eastern side of the Atlantic. The world is large and the republic of science knows no national lines. Any country has a right at any time to have any sort of an exposition for the general welfare. The multiplication of such events only results in a general augmentation of interest. This being true, the attitude of the United States should be to come to Dresden loyally, if there is time to do so creditably, to take an active part in the proceedings, then box up the whole thing and ship it to Washington as a previously fairly well-advertised feature of the real show.

C. A. L. R.

The Oil Treatment of Pellagra

To the Editor:—Much has been written about pellagra, its symptoms, etc., but very little has been written about its successful treatment; some physicians with large experience still believe that no pellagra patient in this country has recovered. Within the past 4 years I have had 16 cases, 7 being so far advanced that little or no treatment was given and the patients all soon died. The other 9 were all without a doubt true cases with all the classic symptoms of diarrhea, offensive stools, dermatitis, red tongue, insomnia, etc., and were treated by the oil method, which no one else so far as I know has used in such cases, with the following results:

The first 3 patients were treated about 4 years ago by means of petroleum emulsion, sulphocarbonates for the diarrhea and Morton wave and static sparks for the insomnia and nervousness. One, a woman, gained 30 pounds and remained symptomatically well for a year; 6 months after stopping all treatment she developed paroxysmal insanity and soon died. The other 2 kept up the petroleum for about one year and are still symptomatically well, though one had very strong religious delusions for some time. A man, treated later, is still taking the petroleum and has gained over 30 pounds and is in very good condition for the past year; though he is still a little nervous it is perhaps as much from fear as anything else because he has been told by so many doctors that he would never get well. Two others are steadily gaining and improving though they have taken the oil only for the past 3 months. Another, a hard-drinking man, was relieved of the severe dermatitis and diarrhea by 3 weeks' treatment and his mental condition cleared up much, but he soon returned to drinking and died.

Another patient has gained 23 pounds within the past 9 months—one teaspoonful of castor oil and 4 drops of turpentine at bedtime being more acceptable to the stomach and stopping the diarrhea better than the petroleum. A patient with chronic diarrhea and colitis of 7 months' standing, in whom the microscope showed no accountable cause, took the same small doses of castor oil and turpentine every night for 5 months and gained 31 pounds. This is simply mentioned to show what a decided effect the oils, neither of which is much absorbed, have on nutrition when kept up for a long period of time. It must be the cleansing and anti-zymotic effect.

In another case of three years' standing the patient improved for a while but soon had so much nausea that oils were not retained; she developed insanity and died.

The petroleum treatment is not offered as a specific. Though my series of cases is small it shows that the petroleum has certainly had a beneficial effect on almost every patient to whom it has been given if kept up long enough, as some of the patients did not improve much for from 4 to 6 weeks. In 4 of the patients a careful examination of the blood, stools and stomach contents was made which did not, however, show anything of importance—there was little or no hydrochloric acid present. Protozoa resembling the *Cercomonas intestinalis* were found in the stools but have never been considered pathogenic.

I ask the profession to make a patient and persistent trial of this method of treatment and report results. The results so far seem better than those offered by any other method of which I have read, 6 of the 9 patients being still alive, 2 being apparently well for 3 years.

J. W. TORRETT, B.S., M.D., Marlin, Tex.

P.S.—The preparation of petroleum used was that made by S. & D. or P. D. & Co., which contains 33.33 per cent. petroleum and 5 gr. each of hypophosphites of lime and soda to each dram given, being a little stronger than the N. E. preparation.

The Home Exchange Plan for Foreign Education of Children

To the Editor:—I believe that there are many physicians who would like to send their children to school in foreign countries for a year or two, but who hesitate on account of the great expense and the absence of parental care while the children are away. It seems to me that the home exchange plan offers a solution of the problem. Could not you, through THE JOURNAL, make arrangements with British, French and German journals by which a physician here would keep in school and be responsible for a foreign physician's boy or girl in exchange for the same care of his son or daughter in a foreign land? It seems to me that this plan has great possibilities.

C. A. EARLE, M.D., Des Plaines, Ill.

The Ice-Cap in Poliomyelitis

To the Editor:—In THE JOURNAL, Sept. 17, 1910, in the special article on "Epidemic Poliomyelitis," under treatment, you speak of elevation of the spine by pillows to prevent hyperemia of cord. Do you not think that the application of the ice-cap would greatly enhance the effect of this procedure?

In a recent case, that of a child 16 months old, the ice-cap was applied at the onset of the disease. The child usually slept when the ice-cap was applied and was peevish and restless until time for its reapplication. Both legs and part of the right arm were paralyzed. The child is responding freely to treatment. In this case the cold application certainly aided in the treatment and afforded relief to this unfortunate child.

CYRUS W. FRIDY, Philadelphia.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

ARTICLES ON POLIOMYELITIS

To the Editor:—Please give me references to recent articles, in English, on acute anterior poliomyelitis.

C. H. TRAVIS, M.D., New Britain, Conn.

ANSWER.—The following are a few of the multitude of articles on this subject which have appeared since the first of this year:

"Acute Anterior Poliomyelitis," by A. J. Rosenberry, in *Southwestern California Practitioner*, January, 1910.

"Acute Poliomyelitis," by W. P. Herringham, in *Clinical Journal*, London, Jan. 26, 1910.

"Some Aspects of Poliomyelitis," by Sir William Gowers, in *British Medical Journal*, Feb. 5, 1910.

"Anterior Poliomyelitis—Infantile Paralysis," by L. L. Cazenaveite, in *New Orleans Medical and Surgical Journal*, February, 1910.

"Acute Anterior Poliomyelitis," by P. J. Peel, in *Chicago Medical Recorder*, February, 1910.

"Anterior Poliomyelitis," by E. J. Melville, in *Vermont Medical Monthly*, March, 1910.

"Acute Anterior Poliomyelitis," by J. W. Cokenower, in *New York Medical Journal*, May 14, 1910.

"Experimental Studies on the Etiology of Acute Poliomyelitis," by I. Strauss and F. M. Hinton, in *New York Medical Journal*, Jan. 8, 1910; abstracted in THE JOURNAL, Jan. 22, 1910, p. 319.

"Medical Aspects of Anterior Poliomyelitis," by L. R. De Buys; "Anterior Poliomyelitis—Etiology and Pathology," by C. W. Juval; and "Nervous Manifestations of Anterior Poliomyelitis," by E. M. Hummel, all in *New Orleans Medical and Surgical Journal*, March, 1910.

"Contagiousness of Poliomyelitis," by H. W. Hill, in *Journal of the Minnesota State Medical Association and Northwestern Lancet*, March 15, 1910; abstracted in THE JOURNAL, April 23, 1910, p. 1496.

"Anterior Poliomyelitis and Its Treatment by Muscle Training," by J. M. Berry and B. van Benbergh, in *Albany Medical Annals*, April, 1910.

"The Acute Stage of Infantile Paralysis," by O. Medin, of Stockholm, Sweden, and "Early Diagnosis of Poliomyelitis," by G. W. McIntyre, in *St. Paul Medical Journal*, May, 1910.

"The Epidemiology of Poliomyelitis," by Joseph Collins, in THE JOURNAL, June 11, 1910, p. 1925.

"Paralysis of the Neck and Diaphragm in Poliomyelitis," by I. Snow, in THE JOURNAL, June 11, 1910, p. 1929.

"A Possible Method of Infection in Poliomyelitis," by N. M. Shaffer, in New York Medical Journal, June 18, 1910.

Abstract of a symposium on poliomyelitis published in report of the meeting of the American Orthopedic Association in THE JOURNAL, July 2, 1910, p. 48.

"Fifty Cases of Poliomyelitis," by J. C. Master, "Clinical Varieties of Poliomyelitis," by H. M. McClanahan, "Acute Poliomyelitis," by F. E. Coulter, and "Poliomyelitis in Polk County, Neb.," by C. A. Anderson, appeared in Western Medical Review, August, 1910, and were abstracted in THE JOURNAL, Aug. 27, 1910, p. 802.

"Poliomyelitis." Editorial in THE JOURNAL, Sept. 3, 1910, p. 861.

"Pathology and Bacteriology of Acute Anterior Poliomyelitis," author's abstract of paper by Drs. H. E. Robertson and A. J. Chesley, in THE JOURNAL, Sept. 17, 1910, p. 1013; published in full in Archives of Internal Medicine, September, 1910, p. 233.

"Anterior Poliomyelitis: Methods of Diagnosis from Spinal Fluid and Blood in Monkeys and in Human Beings," by F. P. Gay and W. P. Lucas, in Archives of Internal Medicine, September, 1910, p. 330.

"Epidemic Poliomyelitis," discussed in Department of Therapeutics, in THE JOURNAL, Sept. 17, 1910, p. 1024.

"Epidemic Poliomyelitis—Infantile Paralysis." Editorial in THE JOURNAL, Sept. 17, 1910, p. 1031.

The following articles by Drs. Flexner and Lewis of the Rockefeller Institute have been published in THE JOURNAL since Jan. 1, 1910:

"Epidemic Poliomyelitis in Monkeys," January 1, p. 45; February 12, p. 535; April 2, p. 1140; May 28, p. 1780, and August 20, 1910, p. 262.

"The Contribution of Experimental to Human Poliomyelitis," by Dr. Flexner alone, Sept. 24, 1910, p. 1105.

ETIOLOGY AND TREATMENT OF ACNE

To the Editor:—Please give me the etiology and latest treatment of acne.
G. G. WHITE, Elkader, Iowa.

ANSWER:—Acne is a disease depending on both general and local causes. One important general cause is auto-intoxication frequently due to disturbances of the digestive organs and probably consists in the absorption of toxic products originating in the intestinal tract. These toxins lower the resistance of the skin to infections and consequently the sebaceous glands become a nidus for the proliferation of various micro-organisms. Among these, the most prominent are the *Bacillus acne*, described by T. W. Gilchrist, in an article in the *Journal of Cutaneous Diseases*, March, 1903, which was abstracted in THE JOURNAL, April 11, 1903, and various forms of pus cocci, particularly the *Staphylococcus albus*, which is said to be found especially in acne indurata.

The treatment of acne must be varied to suit the individual case. Elimination should be promoted and the diet so regulated that both the gastric and intestinal digestive processes proceed properly and thus prevent auto-intoxication. The bowels should be kept open by appropriate laxatives and in certain cases colonic flushing will be useful. Other general treatment depends on the condition of the individual patient.

The local treatment of acne depends on the principle of exciting an artificial hyperemia which is subsequently quieted by sedative measures. Accumulations of pus should be evacuated and comedones removed by the aseptic needle and comedo-extractor. Sulphur in lotion or ointment is one of the best applications for stimulating the skin. It may be applied as sulphur ointment U. S. P. or as liquor calcis sulphuratæ N. F. (Vleninck's solution). Before the application of sulphur it is well to bathe the skin in hot water for a moderate time and thoroughly wash with limimentum saponis mollis (tincture of green soap). This is rinsed off and the skin dried, after which the ointment may be applied. For soothing purposes an aqua calcis and zinc oxid lotion is of value:

R	
Zinci oxidl	10
Pulveris talci	8
Glycerinl	8
Sodii bicarbonatis	8
Aquæ calcis	120
Aquæ rosæ q. s. ad	240
M. Sig. For external use.	

In severe forms, Bier's hyperemic method may be found useful. Therapeutic vaccine injections have been used with considerable success. For these injections a stock or autogenous vaccine may be used. If the stock preparations are employed, the acne bacillus and *Staphylococcus albus* give the best results. In obstinate cases radiotherapy is useful, but should always be used with the greatest caution.

The treatment of acne is discussed in the Department of Therapeutics, in THE JOURNAL, Jan. 30, 1909, p. 384.

WAS IT A CURE OF "CONGENITAL DEAF-MUTISM?"

To the Editor:—A deaf-mute child, aged 3 years, was taken to an aurist. The parents stated that the child had given no signs of hearing since birth, except for very loud noise, and had never had any accident or disease to cause deafness. On inspection, the aurist found that the child responded to a sharp clap of the hands near the head. The tympanic membranes were slightly retracted, and there was a red glow from both middle ears. There were diseased adenoids; otherwise the child was all right. The birth of the child was natural. Removal of the adenoids and treatment developed hearing, and the child learned to talk. Is the aurist justified in claiming to have established hearing and speech for a "congenital deaf-mute?" If not, why?

MAURY M. STAPLER, M.D., Macon, Ga.

ANSWER.—The question asked by our correspondent is one capable of a double answer. "Congenital deaf-mutism," as generally understood, refers to a congenital, incurable, labyrinthine disease. Practically all children who have never talked, and who apparently do not hear by the time they are 2 or 3 years of age, have been condemned to this class and have been regarded as hopeless. Recently, however, some of these children, on careful and intelligent examination, have been found to be afflicted with prematurely developed adenoids, or more or less complete closure of the Eustachian tubes—or both—and relief of this condition, by operation and treatment, has resulted in the production of useful hearing. It is likely that the case to which our correspondent refers belongs to this class of relievable cases. The question as to whether the condition is congenital or not is a delicate, uncertain and technical one. It may have been—or it may not have been. Very likely it was, but the case is not one of the kind which is usually referred to when "congenital deaf-mutism" is mentioned. Nomenclature should be based on pathology. It is not in these cases. Further investigations will compel a more exact nomenclature.

VESICULAR STOMATITIS

To the Editor:—Please publish some information relative to this condition: A patient of mine for many years has had recurrent stomatitis in the form of small discrete ulcers. There is no discernible cause that I have been able to find. Burning with trichloroacetic acid relieves the pain for a short time. The ulcers appear in great numbers and then disappear, only to reappear.
X. Y. Z.

ANSWER:—This condition is a form of vesicular stomatitis. Its etiology is not well understood but it appears to be favored by depressed states and by disturbance of the digestive tract. The treatment indicated above or touching with a stick of silver nitrate is usually efficient. The urine should be examined for indican or other indications of auto-intoxication and search should be made for any general condition which may serve as an etiologic factor. Good hygiene may assist in preventing the recurrence.

INTERNATIONAL HYGIENE EXHIBITION

To the Editor:—Please give the date of the International Sanitary Congress, which will be held in Dresden.
E. M. VANBUSKIRK, Fort Wayne, Ind.

ANSWER:—Our correspondent probably means the International Hygiene Exposition, which is to be held in Dresden, May to October, 1911. A letter appears in the Correspondence Department of this issue on the subject.

PARALYSIS (POLIOMYELITIS?) IN YOUNG ANIMALS

To the Editor:—Owing to the wide-spread interest in the etiology of anterior poliomyelitis, I take the liberty of reporting the following coincidence. I have had several cases of this disease, but in no instance could I trace it to any pre-existing disease or condition. Recently I was informed by the parents of one of my patients that about three weeks prior to the sickness of the child a spring pig became paralyzed in its hind legs and a week later two more pigs were affected in the same way. The paralysis lasted about two weeks, during which time the pigs were helpless and then gradually improved.

I have talked with farmers who tell me of several such instances among young pigs, but they ascribe it to overfeeding. What relation this trouble among the pigs bore to the paralysis of the child is not known.
MERTON FIELD, Minnesota Lake, Minn.

ESPERANTO GRAMMAR

To the Editor:—As there is much irresponsible criticism of Esperanto, especially on occasion of the recent international convention in Washington, I want to offer an opportunity for every thinker to judge for himself. I have had prepared 100,000 brief grammars of the language in pamphlet form, and will send one free to any person who is sufficiently interested to ask for it, enclosing stamp for reply. I think it really due to this great movement for an international auxiliary language, which now embraces fifty nations in its scope, that all interested have the opportunity of judging for themselves.

700 E. Fortleth Street, Chicago. ARTHUR BAKER.

The Public Service

Medical Department, U. S. Army

Changes for the week ended Sept. 24, 1910.

Long, Charles J., dent. srng., Sept. 16, left Madison Bks., N. Y., on 2 months' leave of absence.

Munson, Edward L., maj., Sept. 17th, is detailed to attend and deliver lecture at the Twelfth Annual Convention of the National Guard Association of the United States at St. Louis, Oct. 3, 1910.

Frick, Euclid B., lieut. col., Sept. 13th, in addition to his present duties will take charge of the office of the chief surgeon, Department of California, during the absence of Lt. Col. H. S. T. Liarris, Med. Corps, at Camp Atascadero, Cal.

Ashburn, P. M., maj., Sept. 14, left Army General Hosp., San Francisco, enroute to Camp Atascadero, Cal.

Gibson, Paul W., M.R.C., Sept. 15, left Ft. Yellowstone, Wyo., on 10 days leave of absence.

Burket, John A., lieut., Sept. 15, left Ft. Riley, Kansas, with the 17th Cavalry, on practice march.

Cole, C. C., capt., Sept. 16, granted leave of absence to and including Oct. 15, 1910.

Marshall, John S., E. S. and D. S., Sept. 16, ordered to Columbus Barracks, Ohio, for duty.

Scott, Harold O., D. S., Sept. 16, relieved from duty at Columbus Barracks, Ohio, and ordered to Ft. Hamilton, N. Y., for duty.

Norris, H. C. R., M.R.C., Sept. 16, granted leave of absence for one month and 19 days. Sept. 16, left Vancouver Barracks, Wash., enroute to Martin, N. D., for further orders.

Lauderdale, D. S., civil engineer, Sept. 17, left Ft. Logan, Colo., on 10 days' leave of absence.

Bayley, R. C., lieut., Sept. 19, relieved from further duty in Philippine Div., to take effect on arrival at San Francisco, on transport *Logan* and will report to Supt. Army Transport Service for assignment to duty as surgeon of the *Logan*.

Cowles, Calvin D., Jr., lieut., Sept. 19, will on being relieved from duty as surgeon of the transport *Logan*, by Lieut. Bayley, report by telegraph to the Adjutant General of the Army for further orders.

Kerr, Robert W., lieut., Sept. 19, relieved from further duty in the Philippine Div., to take effect on arrival at San Francisco, on transport *Sheridan*, will report to the Supt. Army Transport Service for assignment as surgeon of the *Sheridan*.

Tasker, Arthur N., lieut., Sept. 19, will on being relieved from duty as surgeon of the transport *Sheridan*, by Lieutenant Kerr, report by telegraph to the Adjutant General of the Army, for further orders.

The following named first lieutenants, Medical Reserve Corps, recently appointed, are ordered to active service, to take effect Sept. 20, 1910, and will proceed to this city and report in person, at 9 o'clock, a. m., Oct. 1, 1910, to Col. Louis A. La Garde, Med. Corps, President of the Army Medical School, for a course of instruction at that school: Fred R. Burnside, Frank N. Chilton, John S. Coulter, William Denton, Harry G. Ford, James F. Johnston, William P. Lamb, Carl A. Scherer, Gordon B. Underwood, James H. Wilson, Faris M. Blair, Albert P. Clark, Edgar D. Craft, George G. Divins, Frederick H. Foucar, Lloyd A. Keffauver, Charles E. McBrayer, Joseph L. Siner, Alleyne von Schrader, William T. Cade, Jr., Billis S. Connor, Samuel S. Creighton, Lauren S. Eckels, Bert R. Huntington, George B. Lake, George E. Pariseau, John H. Trinder, John M. Willis.

Le Wald, Leon T., capt., resignation of his commission as an officer of the Army accepted, to take effect Sept. 25, 1910.

Norris, Harry C., M.R.C., Sept. 20, honorably discharged from the service of the United States to take effect Nov. 7, 1910.

Cole, Blase, M.R.C., Sept. 20, relieved from duty at Ft. Crook, Neb., and ordered to proceed to this city for a course of instruction at the Army Medical School, commencing Oct. 1, 1910.

Pierson, R. H., capt., September 17, left Vancouver Barracks, Wash., enroute to Ft. Plager, Wash., for duty.

Register, E. C., M.R.C., Sept. 19, left Ft. H. C. Wright, N. Y., on 10 days' leave of absence.

Knox, Howard A., lieut., Sept. 22, left from detached duty to Ft. Myer, Va., on 10 days' leave of absence.

Heflebower, Roy C., lieut., Sept. 22, left Ft. Hamilton, enroute to Ft. Slocum, N. Y., for temporary duty.

Flynn, Thomas J., M.R.C., Sept. 21, 1910, the leave of absence granted him by S. O. No. 156, Sept. 17, 1910, Fort Ethan Allen, Vermont, is extended three days.

Cruo, Wayne H., lieut., Sept. 21, granted two days' leave of absence.

Davis, Wm. R., capt., Sept. 21, granted two months' leave of absence.

Sweazey, Verge E., capt., Sept. 21, now on leave of absence, will repair to this city and report in person to the Adjutant General of the Army, for further orders.

Medical Corps, U. S. Navy

Changes for the week ended Sept. 24, 1910.

Pleadwell, F. L., surgeon, detached from the Naval War College, Newport, R. I., and ordered to temporary duty in the Bureau of Medicine and Surgery, Navy Department.

Koltes, F. X., P. A. surgeon, commissioned P. A. surgeon from May 4.

Hollard, H. L., P. A. surgeon, commissioned P. A. surgeon from July 12.

May H. A., P. A. surgeon, detached from the *Charleston* and ordered to the Naval Hospital, Mare Island, Cal.

U. S. Public Health and Marine-Hospital Service

Changes for the week ended Sept. 21, 1910.

Cassaway, James M., surgeon, granted 1 month's leave of absence from Sept. 7, 1910, on account of sickness.

White, J. H., surgeon, granted 7 days' leave of absence from Sept. 17, 1910.

Williams, L. L., surgeon, granted 7 days' leave of absence from Sept. 19, 1910, under paragraph 189, Service Regulations.

McIntosh, W. P., surgeon, granted 7 days' leave of absence from Sept. 23, 1910.

Parker, H. B., P. A. surgeon, granted 3 days' leave of absence from Aug. 25, 1910, on account of sickness.

Anderson, John F., P. A. surgeon, directed to proceed to Ellis Island, N. Y., on special temporary duty.

Goldberger, Joseph, P. A. surgeon, granted 1 month's leave of absence from Sept. 26, 1910.

Schereschewsky, J. W., P. A. surgeon, directed to report at Bureau on special temporary duty.

Francis, Edward, P. A. surgeon, directed to proceed to Philadelphia, New York and Detroit, on special temporary duty.

McCoy, George W., P. A. surgeon, directed to proceed to Berkeley, Cal., on special temporary duty.

Warren, B. S., P. A. surgeon, detailed to represent the Service at the meeting of the state health officers, to be held in Waterloo, Iowa, Sept. 20, 1910.

Rucker, William C., P. A. surgeon, leave of absence for 1 year without pay from June 4, 1910, amended to read from June 4, to Sept. 14, 1910. Granted 10 days' leave of absence from Sept. 14, 1910.

Stanton, J. G., acting asst.-surgeon, granted 26 days' leave of absence from Sept. 21, 1910.

Curley, C. P., acting asst.-surgeon, granted 21 days' leave of absence from Sept. 22, 1910.

Board of medical officers convened to meet at the marine hospital, San Francisco, Sept. 26, 1910, for the examination of Assistant Surgeon Frieuch Simpson, to determine his fitness for promotion to the grade of Passed Assistant Surgeon. Detail for the board: Surgeon Rupert Blue, chairman; Passed Assistant Surgeon F. E. Trotter; Passed Assistant Surgeon R. E. Ebersole, recorder.

Board of medical officers convened to meet at the marine hospital, Stapleton, N. Y., Sept. 26, 1910, for the examination of Assistant Surgeon R. A. Herring, to determine his fitness for promotion to the grade of Passed Assistant Surgeon. Detail for the board: Surgeon Hiram W. Austin, chairman; Passed Assistant Surgeon W. A. Korn; Passed Assistant Surgeon George L. Collins, recorder.

Board of medical officers convened to meet at Philadelphia, Pa., Sept. 21, 1910, for the purpose of determining the physical condition of Surgeon Eugene Wasdin. Detail for the board: Surgeon Hiram W. Austin, chairman and Surgeon W. G. Stimpson, recorder.

MISSISSIPPI VALLEY MEDICAL ASSOCIATION

Thirty-Sixth Annual Meeting, Held at Detroit, Sept. 13-15, 1910
(Concluded from page 1135)

President's Address: Teaching of Clinical Psychiatry; A Medical Educational Problem

DR. FRANK P. NORBURY, Hospital, Ill.: The opportunities at hand should be utilized, new ones developed, higher ideals created, and ethical educational standards readjusted. The fundamental fact of the present controversy regarding medical education is that it is a part of the educational propaganda of the century—a world movement. In this country, guided in constructive analysis in medical education by the Council on Medical Education of the American Medical Association, this progress is based first on the integration of the educational system; second, on the standardizing of undergraduate work; third, on the standardizing of professional courses in medicine. A virile contributory constructive power is the report of the Carnegie Foundation for the Advancement of Teaching. Modern medical education is in the transitory stage in teaching clinical medicine. This transition began with Osler's work at Johns Hopkins when he demonstrated that "teaching hath her victories no less than research." Clinical medicine to-day includes the interpreters as well as the research workers. Medical sociology is the enlarged appreciation of the value of clinical medicine extended to the problems of etiology, preventive medicine, occupational diseases, and general and special civic problems. The scope and value of such work is unappreciated by the unthinking masses of our profession. Clinical psychiatry is prominent

in this field of newer clinical activity. It is in contact with more points in life, its realities, its ignorance, its prejudices, its ethical discordances, and falsifications, than any other department of medicine. The teacher must be a biologist in its widest clinical interpretation, a sociologist that he may grasp all etiologic factors, and an internist that he may be in touch with all of the physical factors entering into the problem. Modern medical teaching must give to the student the opportunity to see the whole at near range. The teaching of psychiatry is a state need, just as much as any other problem of preventive medicine.

Address in Surgery: Diagnosis of Surgical Lesions of the Kidney by the X-Ray and the Cystoscope

DR. LOUIS FRANK, Louisville, Ky.: Although the diagnosis of the character of new growths in the kidney may be impossible before operation, the recognition of a surgical lesion and of the surgical indications is not, as a rule, attended with great difficulty, provided thorough, painstaking and complete examination of the individual is made. In renal calculus the cystoscope and the radiograph furnish a means for physical examination which in the presence of even obscure symptoms will render the diagnosis in most cases practically certain. The cystoscopic examination frequently shows a swollen ureteral orifice. The passage of the ureteral catheter will at once show from which kidney the blood or pus in the urine is coming. The cystoscope is not nearly so valuable an aid as the Roentgen-ray. It does show whether one kidney alone is involved, or whether or not a kidney has ceased to functionate. As a confirmatory diagnostic means the greatest value of the radiograph is in connection with renal calculi. The predominant signs of most renal affections of a surgical character are pain, hemorrhage, urinary disturbance, and tumor. One or more may be absent, or they may all be present in any given case.

Address in Medicine: The Modern Physician, His Successes, His Failures, His Future

DR. JOHN K. MITCHELL, Philadelphia: A time will come, since the disappearance of all disease is unlikely, when governments will make a more organized contest against it, and will teach and enlist all physicians in a common army as now they educate and pay the soldier. This must come, because with improved sanitation and the constant advance of preventive means, illness will grow infrequent, so that unless he is a paid servant of the state the physician will not be able to exist. When that army is enlisted, the occurrence of preventable diseases will be as much a matter for court martial and the punishment of the person who allowed it to pass him as the failure in duty of a soldier asleep at his post. In that golden future in which sickness will be as rare as war is now, instead of being a single-handed fighter, the physician will serve as an enlisted man in the great battle for life and strength against illness and pain; he will have no new duties, perhaps, but new powers—ability to enforce obedience to laws of health—until, under wise ways of life, death, the one unmedicable disease, shall come only to the aged, approaching without notice, to be met without fear, bringing an ending peaceful and calm after an active life and a quiet old age.

Pulmonary Tuberculosis and Syphilis

DR. ROBERT H. BARCOCK, Chicago, discussed the relationship of these diseases and drew the following conclusions:

1. The effect of the association of pulmonary tuberculosis and syphilis seems to depend largely on the stage of the primary disease during which the second infection is acquired.
2. The acquisition of syphilis during the incipient or early period of tuberculosis appears to be of a negative influence or even in some instances to exert a retarding or curative effect on the tuberculosis.
3. Syphilis acquired by a consumptive in an advanced stage is likely to aid the downward progress of the tuberculosis.
4. Tuberculosis when developed during the primary or secondary stage of syphilis offers a bad prognosis and is apt to run a rapid course.
5. When pulmonary tuberculosis develops during the third or late stage of syphilis, it is apt to pursue a slow course, probably because of the tendency of the lues to sclerosis during this stage.
6. The association of these two diseases does not preclude the mercurial treatment of the syphilis by intramuscular injections and

inunctions, but iodine if administered at all must be used cautiously because of its tendency to hasten softening of the tuberculous foci.

7. During the antisyphilitic medication there should be no relaxation in the hygienic measures recognized as necessary in the management of the tuberculosis.

The Interpretation of Jaundice

DR. C. N. SMITH, Toledo, Ohio, gave an interpretation of jaundice as observed in gallstone disease and its associated conditions—the interpretation of a symptom which is both infrequent and inconstant, and, at best, indicative only of complications, or terminal events.

DISCUSSION

DR. J. H. CARSTENS, Detroit: Catarrhal jaundice is caused by gastroduodenal catarrh, so-called. A patient will have jaundice and in the course of five or six weeks it will disappear, and whether treatment has any effect or not I have grave doubts. I had this form of jaundice myself. I took everything my physicians told me to take—sweet oil, calomel, and many other things—but the jaundice continued. I then restricted my diet to nitrogenous food, and did not take any carbohydrates, oils, fats, etc., but some good lean beef, some eggs and water, and in a short time the jaundice disappeared.

DR. R. N. MURRAY, Flint, Mich.: After suffering from jaundice for a considerable period of time and having tried various remedies, at the request of a Flint physician I took ammonium hydrochlorid in doses of from 10 to 15 grains every 2 hours, and in 4 days the jaundice cleared up.

A New Principle in Treatment of Exophthalmic Goiter

DR. G. W. CRILE, Cleveland, Ohio: The benefits which follow the ligation of the superior thyroid artery are due for the most part to the break of the nerve supply which is inevitable in the course of the ligation. In exophthalmic goiter the thyroid shows a work hyperplasia, and the brain cells show a work exhaustion. In this condition the brain sends a more or less constant flow of stimuli into the thyroid, and which responds by an increase in its secretion. This increased secretion causes an increased activity of the brain cells. In this manner the brain and the thyroid reciprocally goad each other, and this deadlock, if not broken, continues until one or the other is worn out. This, I believe, is the explanation of the curious ending one occasionally observes, namely, the sequence of myxedema and exophthalmic goiter. Breaking of the nerve connection between the brain and the thyroid gland renders the disease curable. In no case is a cure effected by operation alone, and no patient is cured until the thyroid and the brain are both restored to the normal. This is best secured by operating in such a manner that there is no excitation of the nervous system, nor of the thyroid; hence no volatile outbursts during or after the operation, and no operative danger; the patient then should be placed in a rest cure for a month or more, depending on the severity of the disease. If, on the other hand, the patient after the operation is at once immersed in the environment in which the disease originated, there will be many disappointments. The plan of treatment by a combination of a benign operation, followed by a prolonged rest cure, will restore the patient, in so far as tissues are not already irreparably destroyed, to the bloom of health.

Surgery of the Great Sciatic Nerve

DR. B. M. RICKETTS, Cincinnati, reported two cases of complete severance of this nerve with subsequent anastomosis, and drew the following conclusions:

1. Compression for sciatic neuralgia hardly justifies the effort.
2. Acupuncture with the injection of electricity or medicaments through an open incision is to be recommended.
3. Acupuncture without open incision is most difficult and uncertain to accomplish good results.
4. The use of a metal wire and tube for direct multiple injections should be encouraged.
5. Stretching the nerve for neuralgia has been more or less beneficial, and second in choice before more radical measures are employed.
6. Neurotomy without suture is to be condemned, but it should be employed before sacrificing any of the nerve tissue.
7. Neurotomy is the last of surgical measures to be employed for neuralgia.
8. Neurorrhaphy (primary or secondary) should be done in cases in which the nerve has been partially or completely severed by any cause.

9. The great sciatic nerve may be completely divided and may remain so indefinitely without great loss of sensation.

10. Both sensation and motion may be improved or completely restored by coapting the severed ends with sutures.

11. A small needle and silk are attended with less trauma than those of larger size.

12. Anesthesia may be local or general.

Surgery of Musculospiral Paralysis

DR. A. H. BARKLEY, Lexington, Ky., drew the following conclusions:

1. Many patients have been operated on but comparatively few cases have been reported.

2. In cases of trauma, associated injury of the musculospiral nerve may be and frequently is overlooked.

3. The anatomic position of this nerve renders it peculiarly liable to trauma.

4. Injuries, such as fractures, falls and blows, are the most frequent cause in the order named.

5. The paralysis occurs with equal frequency in both arms, the middle and lower third being the most often affected.

6. The musculospiral nerve is injured oftener than any other nerve and the injury not infrequently serves as ground for legal action.

7. The condition is more frequent in males and may occur at any age, more especially between 10 and 30 years.

8. In cases in which complete loss of sensation and motor function follows severe injury, the probabilities are that the nerve has been injured and operative interference is indicated. In cases following slight trauma the patients often recover without operation; however, if no improvement is noticed after 2 or 3 months, operation is justified.

9. Secondary cases sometimes present technical difficulties not present in primary cases.

10. No one symptom is pathognomonic and the pathologic condition varies so widely that it is impossible to state before operation with much certainty the exact condition present in a given case.

11. Prognosis is good in clean cases. Especially is this true when operative has been resorted to early. One of the most important determining factors is the length of time the injury to the nerve existed.

12. Operative treatment depends on the individual case; the earlier the operation the better the result. Small round needles and fine silk have given best results.

13. All patients with injuries to the arm, especially fractures, should be impressed with the possibility of the development of musculospiral paralysis.

Rôle of the *B. Coli* Communis in Acute and Chronic Dilatation of the Stomach

DR. F. B. TURCK, Chicago: The *B. coli* plays a part in the gastrointestinal tract in producing lesions in the liver, kidney, stomach and other organs. Experiments were begun with intraperitoneal injections into dogs, rabbits, guinea-pigs and rats. The results obtained were variable and inconstant. On feeding animals with bouillon cultures of the *B. coli* daily over a period ranging from 3 to 14 months, lesions were found in the stomach, duodenum, liver, kidney, brain and spinal cord, varying according to the methods, quantity and character of culture. It was found that animals fed with cultures of *B. coli* would acquire acute or chronic dilatation of the stomach by overworking or overloading the stomach. Examination of the blood showed that it remained sterile during the experiments, and the heart's blood at death was also sterile. In feeding cultures of the bacillus pronounced changes were revealed in the blood and tissues. Agglutination of *B. coli* by the dog's serum was noted; hemolysis of the blood was evident; cytotoxicity and autolysis of the cells of the mucous membrane of the stomach, kidney, liver and other organs were marked on microscopic examination. But there was no bacteremia, no inflammatory reaction in the form of round-cell infiltration, such as one would expect in a reactionary inflammation induced by pyogenic micro-organisms or toxins. It was not the picture of reaction to an infection, but rather a systemic condition of induced cellular change. When feeding was continuous, an acute process was the characteristic picture. When feeding was stopped, the lesions healed. If the feeding was interrupted for a considerable period at short intervals, then resumed, chronic lesions were produced, with round-cell infiltration. It would seem that chronic lesions were simply acute processes interrupted at certain intervals, or a series of acute processes. To obtain spontaneous acute or chronic dilatation of the stomach in animals, it was necessary to feed the animals with cultures of *B. coli* over a long period of time, followed by over-use of the stomach, especially increasing the intragastric pressure. The usual methods of treatment are gastric lavage; diet frequent, but light meals; drugs, such as tonics, laxatives, alkalies, or acid, as indicated; electricity and exercise; hydrotherapy, balneology, rest and recreation. On the failure of these methods, surgical operation is indicated.

Acute Abdominal Manifestations of Syphilis

DR. LOUIS A. LEVISON, Toledo, Ohio, read a paper on this subject which he summarized as follows:

1. Syphilis showing acute abdominal manifestations is not uncommon, but is not generally recognized.

2. The liver is the organ most often affected.

3. Abdominal manifestations occur more often in the tertiary stage.

4. Syphilis of the stomach can simulate most of the ordinary gastric diseases.

5. The symptoms of acute abdominal manifestations of syphilis are in no way diagnostic and include pain, tenderness, fever, jaundice, chills and sweats.

6. The gastric crises of tabes may be considered syphilitic in nature.

Etiology of the Functional Neuroses

DR. ELEANORA S. EVERHARD AND DR. GERTRUDE FELKER, Dayton, Ohio, contributed a joint paper on this subject, in which they drew the following conclusions:

1. The common element in the attributed causes of the functional neuroses is to be found in the fact that the mental processes are not directed; therefore, the patient is the victim of any stimulus which chance may keep before the mind, and that there is no limit to the destruction of efficiency which may result.

2. Those symptoms commonly called nervousness are worthy of serious consideration because they indicate some degree of lack of control of nerve processes.

3. Self-indulgence by training the mind to follow the lines of least resistance predisposes to these neuroses.

4. The value of living in accord with the laws of hygiene cannot be overestimated, both because of its influence on nutrition, and because it requires a measure of self-control, but that alone is insufficient.

5. Conditions of life which demand of the individual, in his vocation or avocation, less exercise of attention and will than he is capable of enduring without fatigue, bear to his nervous system the same relation that lack of muscular exercise bear to his muscular system.

6. Intelligent education at any age is effective, but since the ideal is prevention, the habit of directing mental processes should be established early.

Standardization of Bacterins

DR. R. T. PETTIT, Ottawa, Ill.: The value of bacterin therapy as a general aid to local treatment in certain types of bacterial infections is pretty well established. In the preparation of vaccines I do not try to estimate the number of bacteria present in a given volume. I take up a twenty-four hour blood agar growth of streptococci in a definite amount of salt solution, shake thoroughly, centrifuge to throw down the clumps, put in a bottle specially prepared and kill by heat or carbolic acid. Then I make a 1:10 or 1:100 dilution of this full emulsion and give an initial dose of 5 c.c. of the 1/100 dilution. This induces very little or no reaction. The dosage is then increased up through the 1:10 dilution and full emulsion to the point of local reaction. Then I proceed slowly, keeping in mind that the reaction induced and results obtained are the true indices of dosage. The reaction to be aimed at is a slight or moderate local reaction, an area of redness about the size of a dollar, without the localizing or general phenomena. By using increasing doses up through a series of dilutions this can be procured with a fair degree of accuracy and an estimation of the number of bacteria used is entirely superfluous. The full emulsion can be called 100 per cent. and 10 per cent. and 1 per cent. dilution of this full emulsion may be made. The doses can be recorded as 1, 2, 5, 7 c.c., etc., of the 1 per cent., 10 per cent., or 100 per cent. emulsions. The advantages of a dilution method of estimating bacterial suspensions over a numerical are several. 1. The reaction, the real index of dosage is relied upon and the empirical administration of bacterins is made less possible. 2. An index of antibody production is aimed at. 3. By using this method vaccines can be prepared with much greater rapidity, at least an hour is saved on each bacterin prepared, and if bacterins prove to be of value in acute infections—and the recent work of Dr. Rosenow, of Chicago, on artificial immunization in pneumonia seems to point in this direction—the time saved will be an important factor.

Treatment of Pernicious Anemia Associated with Achylia Gastrica

DR. A. C. CROFTAN, Chicago, submitted a clinical report in regard to the treatment of a certain group of pernicious anemia cases and described three cases in which the patients had been improved rapidly and have remained symptomatically well, without remissions, to date. The one constant factor

seen in the cases of pernicious anemia observed during a period of years that were not distinctly attributed to the effect of syphilis, carcinoma, parasites or profound and continuous loss of blood was a lack of hydrochloric acid from the stomach contents, associated with a variety of digestive disturbances, allied with varying degrees of chronic under-nutrition. That all cases of hyperchlorhydria and all cases of chronic under-nutrition do not develop pernicious anemia calls for the inclusion of some specific factor or factors, hitherto unknown. At all events, the supplying of large quantities of hydrochloric acid, together with abundant proteids by mouth and by rectum, seemed a favorable point of attack and was persistently carried through with gratifying results. From the results obtained, the conclusion was drawn that a trial of this plan in this group of cases is decidedly worth while and seem to produce results not otherwise obtainable by any means so far described.

Diagnosis of Trifacial Neuralgia

DR. H. T. PATRICK, Chicago: In the majority of cases the diagnosis of the douloureux should be easy and certain, as the traits of the disease are few and striking. But a number of other disorders have been referred to me as trifacial neuralgia; the most frequent have been migraine and sinus disease. Others were syphilis, brain tumor, alveolar abscess, and other dental disease, nasal disease, herpes zoster, neurasthenia and lesion of the optic thalamus. The pain of trifacial neuralgia is practically unique. There is nothing else just like it. It is short and sharp, in the beginning only a flash or jab or shot. The interval may be anywhere from a second or two to weeks or months. In the fully developed disorder the paroxysms may last a minute or two and the free intervals be so short that the pain seems continuous. It never really is so. Nearly every patient has intermissions of weeks, months, or even years, during which he is entirely free from pain. One of the most striking peculiarities of the affection is that the paroxysms or jabs of pain are started by slight peripheral irritation, such as washing the face, using a handkerchief, stroking the mustache or the touch of a glass to the lips. I think that the automatic act of winking often acts as an excitant. Such slight sensory stimulus in the area of one division of the nerve may occasion pain in another division. For instance, touching the lower lip may start a pain not in this region, but in the supraorbital area.

Water, the Main Factor in the Prevention of Disease

DR. J. C. MIXER, Hot Springs, Ark.: Nutrition and elimination are the main factors in maintaining health; but of the two elimination is absolutely necessary and must be continuous and invariably performed equally by the sewers of the body. There is little or no vicarious action in the emunction of health and disease. One cannot flush sewers without water and if regular flushing is to be done the water must be furnished the body regularly, and the purer the better. Normal resisting power prevents invasion of any and all diseases; it depends on normal distribution of food, normal lubrication of all body structures and normal excretion of all waste products. Unless food be distributed to the system properly it will become a detriment instead of a help. It cannot be distributed properly without the proper amount of water taken in at the proper time. The stomach is the kitchen in which pabulum is prepared for the system. The small intestine is the table from which the system is served. The system will be served with only just enough, the remainder is thrown through the cecal valve into the sewer. If food is badly digested the system rejects it. If food be more than the system requires the surplus is also rejected. All rejected food is an irritant. May it not be a cause for appendicitis? There is a proper time for taking the proper amount of water. One's judgment should govern the measure of water to be taken with food. To take too much water just before, during or just after a meal, would, so to speak, be to put out the fire in the kitchen, while not enough fluid would compel the stomach to borrow too heavily from the systemic volume. The one would retard digestion and the other would give imperfect digestion.

Gradual Evolution of a Sane Therapy in Tuberculosis

DR. F. M. POTTENGER, Monrovia, Cal.: The position of the sanatorium in the rational treatment of tuberculosis is important. If the sanatorium is conducted on the proper lines it affords the best circumstances under which the known measures, which have influence in building up and curing the patient, may be applied. The home treatment, however, is one of the greatest boons to tuberculous patients, because most patients are not able to be treated in sanatoria and must be treated in their own homes. The true position of home treatment can be readily understood by the fact that it is an attempt to apply sanatorium discipline and sanatorium conditions to the home.

Intestinal Surgery with a Demonstration of a New Method of Suturing the Bowel

DR. A. E. BENJAMIN, Minneapolis: The various instruments and appliances formerly used to facilitate the surgeon in his work on the intestines have almost all been discarded for the simple but efficient method of intestinal anastomosis by thread and needle. The work should be carefully but rapidly performed. A positive blood supply to the tissues making up the anastomosis is necessary. The end-to-end method is not so certain; therefore, the side-to-side anastomosis should be chosen when convenient. The evolution of the intestinal suture has brought us to the point where we are certain of good results, when the sutures are properly applied and are of the right material. Non-absorbable suture material should be cast off into the lumen of the intestine after serving its period of usefulness, and this is best accomplished when used for the inner layer; there is then less destruction of tissue. When placed externally it promotes unnecessary adhesions, plastic exudate and fibrous bands. It may interfere with proper bowel function, because of its prolonged irritation. Absorbable suture material used for the outer layer is soon taken care of and does not cripple the action of the intestine. The application of the suture in intestinal work has been carefully studied. It must serve the purposes of controlling hemorrhage, proper coaptation of the tissues, security against leakage, must avoid pursing, be quickly introduced and not strangulate the tissue. The back-lock stitch of Pagenstecher's thread as applied by the author for the inner-layer serves all these purposes. Experimental work has demonstrated that chromic catgut lasts sufficiently long when employed as the outer suture for positive and firm union to occur. The after-treatment of cases of suturing the bowel should be carefully supervised by limiting the diet, starvation treatment, if necessary, until the union is sufficiently strong before it becomes necessary for the bowels to be called on to pass their contents onward. A perfect, clean and satisfactory result is obtained with the inner Pagenstecher lock-stitch, and a chromic catgut stitch for the outer in intestinal anastomosis.

Read, Hospital, Ill.; "Rôle of Physician, Philanthropist, Publicist and Politician Regarding a Federal Department of Health," by Dr. L. H. Montgomery, Chicago; "Non-Operative Treatment of the Prolapsed and Dilated Stomach and Abdominal Viscera," by Dr. N. Rosewater, Cleveland.

AMERICAN ELECTRO-THERAPEUTIC ASSOCIATION*Twentieth Annual Convention, held at Saratoga Springs, N. Y.,
Sept. 13-15, 1910*The President, DR. T. D. CROTHERS, Hartford, Conn., in the
Chair**The Physics of Light Therapy**

DR. T. D. CROTHERS, Hartford, Conn., reported an exhaustive study of the theories of light, of the many forms and modifications of light, and of the diverse ways in which light is utilized in treatment of disease.

Report on Phototherapy and Apparatus

DR. C. R. DICKSON, Toronto, Canada: Further observations have served to confirm the theory, which is now a well-established fact, that light rays do penetrate the skin and underlying tissues and exert their influence not alone locally, as when concentrated in the treatment of local lesions even to the point of desiccation and canterization, but are also taken up by the circulation and induce systemic changes not equaled by any other physical agent.

Report on Dietetics

DR. BYRON S. PRICE, New York, read this report, which gave the present-day opinion of authorities in experimental work with regard to foods and their effects when taken into the body, and their relation to auto-intoxication, especially having in view the prevention of arteriosclerosis and allied conditions. The report considered in this relation the physical, chemical, physiologic and pathologic conditions of food and of digestion and elimination, as well as the scientific explanation of why milk, farinaceous and other foods act differently in different conditions.

Standardization of Therapeutic Measures

DR. W. B. SNOW, New York, reported that a survey of the year's progress in physical therapeutics marked a movement toward a more general tendency to the adaptation of rational standardization, away from irrationalism and empiricism, and discussed the various physical therapeutic measures in detail.

Report of X-Ray Treatment of Splenomyeloid and Lymphoid Leukemia, with Blood Findings in Each

DR. J. W. TORBETT, Marlin, Texas, reported two cases, one of each variety, in order to emphasize the importance of observing Pancoast's and Stengel's precautions in treating each class of cases. In the first case, the patient died 16 days after taking the first x-ray treatment. It would have been better to treat the arms and legs alone as Pancoast had advised. The second patient showed some improvement under x-ray treatment.

Psoriasis

DR. HERBERT MCINTOSH, Boston, reported several cases of psoriasis in which the characteristic eruptions were removed by a combination of physical methods of treatment. In his practice he had usually associated the x-ray with the light treatment, in a desire to hasten the cure, though the x-ray could probably be dispensed with. One should not fail, he said, to counsel hygienic living, proper exercise and regulation of the diet, excluding meat as being unfavorable to the progress of the cure.

High Frequency Currents

DR. F. DEKRAFT, New York, called particular attention to the bi-polar utilization of the D'Arsonval current. This could be used in the cavities of the body; for example: for destroying papilloma of the bladder, in the nasopharynx, and also for its sterilizing effect on infected tissues, abscesses, pustular acne, etc.

Treatment of Inflammation not Complicated or Caused by Infection

DR. W. B. SNOW, New York: The systematic proper application of the static current, in the case of a sprained knee, for instance, at the first administration softened the exudation, relieved the pressure and consequently the pain, relaxed muscular tension, and restored motility and utility to the joint. The best means for relieving local inflammations in

which infection does not enter as a factor are the application of the static wave current, the static sparks, the static brush discharge or the direct vacuum tube static current, singly or conjointly. In prostatitis and seminal vesiculitis the results have been most striking, as also in dysmenorrhea and subinvolution and urethral caruncles. Neuritis, herpes zoster, intercostal neuritis, tic douloureux and Bell's palsy have been successfully treated in the same manner, as also anterior poliomyelitis, rheumatoid arthritis, traumatic arthritis and phlebitis.

Electricity in Gout

DR. F. DEKRAFT, New York, said that treatment by drugs has been unsatisfactory, and recommended autocondensation with sufficient D'Arsonval current to produce perspiration. In his experience, the pain and stiffness in the muscles were the last to disappear under the usual mode of treatment. The use of a powerful and thoroughly concentrated resonator effluve accomplished a most valuable purpose by reason of its deep contracting effect on the tissues and the blood vessels. As improvement took place the static brush discharge might be substituted with benefit. Concentrated light was also of benefit; diet and gentle exercise should not be neglected.

Etiology and Treatment of Eczema

DR. H. F. PITCHER, Haverhill, Mass.: The majority of these cases are due to some metabolic or vasomotor disturbance, and the most prominent cause of that disturbance is over-eating. The hygienic and dietetic treatment should be attended to; internal treatment is symptomatic. External treatment of acute eczema should be soothing and protective. The blue light should be used in the early stages, and later, the x-ray and the static brush discharge. The x-ray is the most important, and is the most valuable remedy for relief of the intense pruritus which accompanies this disease; it is the last court of appeal in many of the chronic cases, and seldom fails if properly used. In the subacute form and in the vesicular and seborrheic varieties a very low tube should be used, the treatment lasting from ten to fifteen minutes. When there is much induration the static brush discharge would hasten more rapid resolution. The effluve from the high frequency currents or from the vacuum tubes is also beneficial in this type.

Osteo-Arthritis of the Spine

DR. F. E. PECKAM, Providence, R. I., described this condition in detail, and emphasized the importance of finding the focus of the trouble and the cause before beginning treatment. Auto-intoxication, he said, was the cause in most such cases. In the treatment of this condition there must be produced elimination of toxic material from the tissues locally and a stimulation of the physiological processes to perform their duties in a more nearly normal manner. This might be accomplished by physiotherapeutic measures, no one modality alone usually giving so much benefit as a combination.

Case of Splenic Leukemia Successfully Treated by Modern Methods

DR. G. W. STROBELL, Rutland, Vt., reported this case: Fowler's solution, Bland's iron mass and blue mass were used. x-ray treatments were made over the spleen, alternating with chlorin cataphoresis, the treatments each day concluding with static insulation. By the end of the fourth week the patient declared that she had not felt so well for twenty years. The myelocytes were reduced from 50 to 15 per cent, and the size of the spleen was reduced two-thirds. At the end of the second month the spleen, which had been the size of a man's head, could scarcely be felt.

Lumbago

DR. F. H. HUMPHRIS, London, England: Lumbago should be distinguished from the neurotic spine, from sacro-iliac disease, from cancer of the spine, cancer of the sacro-iliac notch, from the pain from an enlarged prostate, from the backache which ushers in dengue, influenza and other conditions of toxic origin, from Pott's disease and from sacro-iliac relaxation. The ideal treatment is to see that the bowels move freely with mercury and a saline. Sodium salicylate

and sodium of citrate of each 20 grains should be given in a glass of hot water every 4, 5, or 6 hours. The 500-candle-power light should be applied for 15 or 20 minutes, followed by the static wave current for the same length of time.

Treatment of Chronic Metritis with Descent or Displacement

DR. G. BETTON MASSEY, Philadelphia: The form of treatment that I prefer in these cases, when not accompanied by inflammation of the adnexa is the intra-uterine employment of from 20 to 60 milliamperes positive, of the constant current, diffusing copper-mercury ions from the amalgamated electrode for 4 minutes about twice a week, each application being followed by a strongly contracting induction current from a course wire secondary.

Treatment of Cataract by Electricity

DR. S. J. HARRIS, Boston, discussed the history of cataract, the anatomy of the lens, the different varieties of cataract, their etiology and treatment in detail. He reported a number of cases of cataract successfully treated by the direct or galvanic current, a special form of electrode being used over the eye. Mature cataracts were not suitable, he said, for this treatment, and he preferred to operate in such cases. He had had experience in a large number of incipient cases, and in many of these had been able to effect a cure. The subject was still in its infancy, but the rapid progress so far made encouraged him to continue investigation along this line.

Oscillatory Desiccation in the Treatment of Accessible Malignant Growths and Minor Surgical Conditions

DR. W. L. CLARK, Philadelphia, read this paper, drawing the following conclusions:

A current from a static machine of large output with properly adjusted accessories is capable of producing desiccation in morbid tissue. We are able to destroy malignant growths without opening up blood or lymph channels. It is possible to get gradation of current, producing simple stimulation, desiccation or cauterization. Following an extensive surgical operation where there is suspicion of infection or malignancy this current would appear to be ideal in instantly sealing up blood and lymph channels. In cancer of the breast in which the axillary glands are involved a surgical procedure is indicated, but on the first appearance of recurrence it might be used in arresting further recurrence. It might be used in cancer of the cervix to supersede the curette and cautery as a palliative measure. Apparently we can accomplish as much in a few seconds by this method in malignant growths as by the x-ray in weeks or months. In disfiguring neoplastic blemishes of the skin we have a potent weapon.

X-Ray and Light in Infections

DR. F. C. TICE, Roanoke, Va., reported a number of cases of hay-fever treated with bland oil atomization and insulated low-vacuum high-frequency tube to each nostril, with prompt cures, and also cases of acute infections treated with the light and x-ray.

Report of a Noteworthy Case of Sciatica

DR. J. W. TRAVELL, New York, reported a case of sciatica of nine months duration in which during the last three months the patient received constant and thorough treatment in a hospital along the usual lines without appreciable improvement. Sedatives were given regularly at night and the patient could not sleep in bed. Treatment was begun with light, the static wave current and static sparks on the third day after leaving the hospital and all medication was stopped. The patient was able to sleep in bed after the third treatment and was entirely and permanently relieved of all pain after the seventh treatment, treatments being given daily.

Infantile Paralysis

DR. A. W. BAER, Chicago, directed attention to the prevalence of the disease and to the many cases of deformity and paralysis which continue unrelieved in spite of all treatment commonly employed. He has found that contractions and

deformity can be relieved and that the muscles will regain their tone and function even after many years by the use of the direct current applied to the spine followed by the static breeze and sparks, treatment being given three times a week for a number of weeks.

Other Papers Read

Papers were also read by Drs. G. B. Massey, Philadelphia; F. H. Morse, Melrose, Mass.; F. H. Munroe, Newark, N. J.; A. Bassler, New York; L. G. Rabinovitch, New York, and A. W. Yale, Philadelphia.

Medical Economics

THIS DEPARTMENT EMBODIES THE SUBJECTS OF ORGANIZATION, POSTGRADUATE WORK, CONTRACT PRACTICE, INSURANCE FEES, LEGISLATION, ETC.

United States Life Insurance Company Restores Five Dollar Rate

The United States Life Insurance Company of New York has issued a circular letter to its medical examiners, announcing that the New York law regulating life-insurance companies has been so amended as to make it possible to resume the payment of a five dollar fee for medical examinations. In November, 1906, this company reduced its examination fees, on account, it claimed, of the interpretation placed on the Armstrong Law by the Insurance Department of the State of New York. This interpretation compelled insurance companies to charge the cost of the examination against the individual policy, whereas the amendment, adopted last spring, permits them to charge the total cost of medical examinations for the year against the whole volume of business written for the year. The company therefore notifies its examiners that after September 1, the former flat rate of five dollars for insurance examinations will be re-established. It is evident that any legal reason which may heretofore have made the five dollar rate impossible is now removed and that there is no legal or economic reason why life-insurance companies can not now pay a five dollar rate for medical examinations.

POSTGRADUATE COURSE FOR COUNTY SOCIETIES

DR. JOHN H. BLACKBURN, DIRECTOR
BOWLING GREEN, KENTUCKY

[The Director will be glad to furnish further information and literature to any county society desiring to take up the course.]

Second Month—Third Weekly Meeting

ANEURISM

VARIETIES: True, false, dissecting, and arterio-venous.
ETIOLOGY: Syphilis, age, sex, alcohol, strain.

ANEURISM OF THE THORACIC AORTA

PATHOLOGY: Changes in aneurism of ascending portion of arch, transverse portion, descending portion of arch, descending thoracic aorta.

SYMPTOMS AND PHYSICAL SIGNS: Relation of symptoms to size and location of aneurism. Pain, cough, dyspnea, aphonia, hemorrhage, dysphagia, cardiac symptoms, pupils.
ANEURISM OF ABDOMINAL AORTA AND ITS BRANCHES: Frequency, location of sac, form. Differential diagnosis.

ANEURISM OF FEMORAL AND POPLITEAL ARTERIES: Symptoms and diagnosis of each.

ANEURISM OF CAROTID, AXILLARY AND BRACHIAL ARTERIES: Diagnosis.

ARTERIO-VEINUS ANEURISMS: Etiology, vessels involved, pathology, symptoms.

TREATMENT OF ANEURISMS

MEDICINAL TREATMENT.

TUFFNEL'S TREATMENT.

SURGICAL TREATMENT: Methods of Antyllus, Arel, Hunter, Brasdor, Matas, Compression, Gelatin treatment.

State Boards of Registration

COMING EXAMINATIONS

ARIZONA: Phoenix, October 3-4. Sec., Dr. Ancil Martin.
 COLORADO: The Capitol, Denver, October 4. Sec., Dr. S. D. Van Meter, 1723 Tremont Place.
 GEORGIA: Regular, The Capitol, Atlanta, October 11. Sec., Dr. I. H. Goss, Athens; Homeopathic, Atlanta, October 3. Sec., Dr. R. E. Hinman, 153 Whitehall Street.
 IDAHO: Boise, October 4. Sec., Dr. O. J. Allen, Bellevue.
 ILLINOIS: Coliseum Annex, Chicago, October 19-21. Sec., Dr. James A. Egan, Springfield.
 KANSAS: Topeka, October 13. Sec., Dr. H. A. Dykes, Lebanon.
 LOUISIANA: New Orleans, October 18-19. Sec., Dr. A. B. Brown, 108 Baronne Street.
 MICHIGAN: Lansing, October 11-13. Sec., Dr. B. D. Harison, 504 Washington Arcade, Detroit.
 MINNESOTA: State University, Minneapolis, October 4-6. Sec., Dr. W. S. Fullerton, St. Paul.

Iowa June Reports

Dr. Guilford H. Sumner, secretary of the Iowa State Board of Medical Examiners, reports the written examinations held at Des Moines, June 6-8, and at Iowa City, June 9-11, 1910. The number of subjects examined in was 8; total number of questions asked, 100; percentage required to pass, 75.

At the examination held at Des Moines the total number of candidates examined was 43, of whom 41 passed and 2 failed. The following colleges were represented:

College.	PASSED	Year Grad.	Per Cent.
College of Medicine and Surgery, Chicago.....	(1909)		83
College of Physicians and Surgeons, Chicago.....	(1910)		89

Book Notices

A SYSTEM OF OPERATIVE SURGERY. By Various Authors. Edited by F. F. Burghard, M.S., Teacher of Operative Surgery in King's College, London. In Four Volumes. Vol. III. Cloth. Price, \$10. Pp. 764, with 381 illustrations. New York: Oxford University Press, 1909.

This volume keeps up the high standard set by the two which precede it. The first chapter, dealing with operations for the removal of tuberculous cervical nodes, gives plain indications for the treatment of these and outlines in a lucid way the knowledge of anatomy required in doing a radical operation for glands of the neck. Mr. Stiles has written this chapter largely from his own experiences and consequently only those procedures which have been found most valuable by him are included.

The chapter dealing with goiter is good, but does not add much to our present knowledge. The author states that he has seen marked benefit follow ligation of both superior arteries and one inferior artery in a very bad case of exophthalmic goiter, but that he considers it to be a dangerous proceeding, and is of the opinion that in acute cases it should never be employed. Ligation of the superior poles, including all the structures connected with them, has been employed so extensively and with such good results in mild and severe cases that such a sweeping condemnation is surprising. Although ligation of the arteries alone may not be followed by such good results as ligation of the poles it has been the experience of many that the ligation of arteries alone has prepared an extremely sick patient for a more radical procedure and has benefited mild cases. The lines of incision and the operative technic concerned in the removal of the thyroid are clearly discussed. The chapter dealing with the surgery of the bile tract is one of the best that has been presented upon this subject. It is based entirely on the experiences of Mayo Robson and the indications to be met in treating lesions of the bile passages are as clearly set forth as is possible in a text-book of this character. The chapter on prostatectomy by Mr. Freyer is largely based on his own experience and is therefore valuable. This work will take front rank as a reference book of operative surgery.

DISEASES OF INFANCY AND CHILDHOOD: THEIR DIETETIC, HYGIENIC AND MEDICAL TREATMENT. A Text Book Designed for Practitioners and Students in Medicine. By Louis Fischer, M.D., Attending Physician to the Willard Parker and Riverside Hospitals of New York City. Third Edition. Cloth. Price, \$6.50 net. Pp. 980, with 303 illustrations. Philadelphia. F. A. Davis Company, 1910.

This is a revised edition, containing considerable new material. The chapter on cerebrospinal meningitis is especially good. The technic of the diagnostic and therapeutic punctures is explained thoroughly and the intraventricular method of injecting serum is shown clearly by an excellent plate. Two

new colored plates, illustrating the von Pirquet reaction have been added. They show not only the normal reaction of a tuberculous subject, but also the degree of reaction to tuberculin in various dilutions.

The hemostatic value of injections of horse-serum in hemophilia and postoperative tonsillectomy is described. The chapter on diphtheria and intubation covers 83 pages. It is exhaustive and well illustrated with charts and plates. Some of the latest ideas on lordotic, or orthostatic, albuminuria are presented and new articles on scabies, acetonuria, indicanuria, pyuria, and diabetes have been added. The book would be improved if the treatment of diabetes were discussed more fully. The dietetic management which is so important in this disease should certainly be considered more at length. The chapters on urinalysis and bacteriologic technic could be omitted from a work of this kind inasmuch as there are so many good books dealing with these subjects. To the various methods of infant-feeding described in the previous editions the caloric method has been added. The author illustrates his method of feeding by cases from his own practice.

The work is well written and is on the whole up to date and valuable to both the student and the general practitioner.

DAS KYSTOSKOP. Eine Studie seiner optischen und mechanischen Einrichtung und seiner Geschichte. Lehrbuch für Aerzte und Studierende. Von Dr. Otto Ringleb, Spezialarzt für Urologie in Berlin. Paper. Price, 7.50 marks. Pp. 194, with 98 illustrations. Leipzig: Dr. Werner Klinkhardt, 1910.

This work is divided into three parts, the theoretical, the practical, and the historical. In the theoretical part the author thoroughly considers the basic principles of light reflection and refraction. He makes free use of excellent diagrams and mathematical formulas to illustrate all points. Perspective is thoroughly discussed. In the second or practical part, the author discusses briefly a few anatomic points in regard to the urethra and bladder and then in elaborate detail describes the construction of the modern cystoscope, including the lamp, the insulation, the shaft of the instrument, the position and method of operation of the prisms.

The various types of cystoscopes, as the children's cystoscope, the retrograde and the different types of catheterizing and operating instruments, are all shown. In the third or historical chapter the evolution of the cystoscope is traced from the original endoscope of Desormeaux to the modern instruments. The photographic cystoscope of Nitze and the demonstration apparatus of Kutner are mentioned in the historical part. This is not a book that will interest the general practitioner at all, but for the cystoscopist it is one of great interest.

PHYSIOLOGY AND PATHOLOGY OF THE SEMICIRCULAR CANALS. Being an Excerpt of the Clinical Studies of Dr. Robert Barany with Notes and Addenda Gathered from the Vienna Clinics. By Adolph E. Ibershoff, M.D. An Foreword by Royal S. Copeland, M.D. Cloth. Price, \$1 net. Pp. 64, with illustrations. New York: Paul B. Hoeber, 69 E. 59th St., 1910.

This book brings the teachings of the younger Vienna school of otologists, especially of Dr. Barany, closer to the English-speaking part of the profession. No otologist can afford to ignore these teachings. Notwithstanding the shortness of the book, almost 7 pages are devoted to subjects foreign to its title, namely "Indications for Labyrinthine Operation in Acute Diffuse, Latent Diffuse and Circumscribed Labyrinthine Suppuration." The radical standpoint exposed there is not warranted by facts and not shared by the profession. On page 9, the author says, "The right anterior vertical (semicircular canal) and the left posterior vertical lie in the same plane." They lie in parallel planes. The writer of the preface deems it necessary to draw attention to the writer of the book: "The profession is to be congratulated that so finished a scholar, and so able a physician and surgeon as"....

DIE UNTERSUCHUNG UND BEURTEILUNG DES WASSERS UND DES ABWASSERS. Ein Leitfaden für die Praxis und zum Gebrauch im Laboratorium. Von Dr. W. Oldmüller, Verwaltungsdirektor des Virchow-Krankenhauses, und Dr. O. Spitta, Privatdozent der Hygiene an der Universität. Third Edition. Paper. Price, 12 marks. Pp. 422, with illustrations. Berlin: Julius Springer, 1910.

The responsible work of sanitary engineers and chemists in looking after municipal water supplies calls for constant

experimenting and research in meeting problems and new conditions. For such work this volume is an authoritative handbook, giving complete methods for the examination and control of water supplies. A great many methods of examination are given, including the results of most recent researches in sanitary chemistry. The results obtained by the methods given are discussed and their sanitary significance explained, presenting a very complete guide for the exhaustive and exacting control of water supplies. The volume is supplemented by a full list of references to allied literature and is well indexed.

HANDBOOK OF ELECTROTHERAPEUTICS. By William James Dugan, M.D., Lecturer on Electrotherapeutics at Jefferson Medical College, Philadelphia. Cloth. Price, \$2 net. Pp. 242, with 91 illustrations. Philadelphia: F. A. Davis Company, 1910.

The author has undertaken to produce a simple and concise handbook of electrotherapeutics, and he has succeeded well in that hard task. The book is without the elaboration of detail that confuses the elementary student, but it is full enough to be a satisfactory guide. The usual topics of electrotherapeutics are covered. The author's position in regard to the therapeutic uses of electricity is temperate and judicious. One historical matter which has received scant justice in the past is given attention by the author in crediting to Dr. William J. Morton the discovery and therapeutic application of high-frequency currents. On the whole the book is worthy of recommendation. It is marred by the large numbers of illustrations of proprietary apparatus—particularly of one manufacture—so that it suggests a commercial catalogue.

THE AFTER-TREATMENT OF OPERATIONS. A Manual for Practitioners and House Surgeons. By P. Lockhart Mummery, F.R.C.S., Senior Assistant Surgeon, St. Mark's Hospital for Fistula and other Diseases of the Rectum, and to the Queen's Hospital for Children. London. Third Edition. Cloth. Pp. 251, with 38 illustrations. Price, \$2.25 net. New York: William Wood & Co., 1909.

The distinction of being the first printed text on this subject probably belongs to this book, and none of the good features which marked the first edition has been omitted. The book has been thoroughly revised, especially the chapters on abdominal surgery, to which has been appended an excellent discussion of the treatment of general acute peritonitis in which the author favors the continuous saline rectal irrigation and withholding food by mouth for the first few days. The chapters on genito-urinary surgery and rectal operations have been added to materially and a new chapter on the serum and vaccine treatment of sepsis is an excellent review of present-day knowledge on this subject.

Medicolegal

Railroad Relief Department Contract and Liability

The Supreme Court of South Carolina had for the first time, in the case of *Barden vs. Atlantic Coast Line Railway Co.* (67 S. E. R. 971), the question of the validity of a regulation or contract of a relief department of a railroad company providing that the acceptance by a member of benefits for injury shall operate as a release and satisfaction of all claims against the company for damages arising from such injury, and, in the event of the death of a member, no part of the death benefit shall be due or payable until releases of all claims against the relief department and company have been executed by all who might legally assert such claims, while if any suit shall be brought against the company for damages arising from the injury or death of a member the benefits otherwise payable and all obligations of the relief department and of the company, created by the membership of such member in the relief fund, shall be forfeited.

The authorities agree, without dissent, the court says, that all contracts made by railroad companies to avoid liability for their own negligence, are void. If an employee is injured by negligence, why should he be required to stipulate in advance that he must choose between a forfeiture on the

one hand, of all benefits which accrue to him under the rules and regulations of the department to which he has contributed each month, and, on the other hand, his right of action, of which he cannot be deprived by any agreement, express or implied? Is not all the benefit to the company? This choice of remedies is to be made only by those employees whose injuries or death are caused by the negligence of the company. On no other contingency is the employee forced to choose. Further, those who are injured or killed by negligence can receive no benefit "unless and until" a complete release of the action for damages is properly executed. Such is the compulsion of the stipulation; such is the "letter of the bond." The election of remedies originates in and is predicated on this stipulation. In the court's opinion, this stipulation is an ingenious scheme devised by the company to avoid responsibility for its negligence, and, as such, is inequitable and void.

Eliminating this regulation and stipulation as void, there was a relief department or association, supported by the mutual contributions of employee and employer, maintained for the sole purpose of relieving and mitigating the suffering of its members—a charity whose noble purposes were untainted by selfish interest. With its character thus defined, the law is well settled that the only duty imposed on the railroad company is the duty to exercise reasonable care in the selection of the physicians and surgeons who are reasonably competent, and, having exercised this duty, the company is not chargeable with the want of skill of the physician or surgeon whom it has selected, in the performance of the service he is required to render.

Inadmissibility of Farmer-Plaintiff's and Other Testimony to Reputation of Physicians—Limiting Examination of Party to One Physician

The Court of Civil Appeals of Texas says, in *International & Great Northern Railroad Co. vs. Lane* (127 S. W. R. 1066), a personal injury case brought by the latter party, a farmer, that he was permitted, while on the stand as a witness, to testify as to the standing of two physicians in another county, who had testified as to the character of his wound and had given opinions as experts as to the permanency of his injuries. The reputation of the two physicians, professionally or otherwise, had not been questioned by any evidence admitted on the trial, and, under such circumstances, the evidence was clearly inadmissible. The mere fact of the physicians being non-residents, in the absence of any attack on their competency, could not justify the introduction in evidence of the opinion of the plaintiff as to their standing in the community in which they lived.

The rule has been stated to be that, after a witness has been adjudged competent as an expert by the court, which is done when his testimony is admitted, his reputation can be sustained only after it has been impeached. In some instances it has been held that, where a physician's skill had been attacked, evidence of reputation was not admissible for or against him. The court need not go so far in this case, but simply hold that, in the absence of any attack on the skill or reputation of a medical witness, testimony as to his reputation as a physician would not be admissible. Especially does it seem objectionable to permit evidence, under such a state of facts, by a plaintiff, a farmer, not skilled in medicine, in regard to the reputation of his own witnesses. The error in the admission of the testimony was not cured by the fact that no other medical witness testified as to the condition of the wounds at the time they were examined by the medical witnesses for the plaintiff. The evidence as to the reputation of the witnesses had a tendency to give undue importance to their testimony, and may have had an influence with the jury.

One physician, offered by the defendant, was allowed to examine the plaintiff's arm, and it had no ground to object because other physicians offered by it were not permitted to examine the arm, although the plaintiff had exhibited the arm to the jury, the physician being a reputable one, whose testimony was not attacked in any way, while the defendant

gave no reason for wanting more than one physician to examine the arm, and did not attempt to show that it was injured by the examination being confined to one physician.

Charitable Hospital Not Liable From Pay Funds For Negligence of Nurse

The Supreme Court of Pennsylvania says that the case of *Gable vs. Sisters of St. Francis* (75 Atl. R. 1087) was brought to recover damages for the scalding with hot water of a young woman on whom an operation had just been performed and who was still unconscious and helpless, the water having escaped from a hot-water bottle placed beside her by a nurse. But it is a doctrine too well established to be shaken, and as unequivocally declared in Pennsylvania as in any other state, that a public charity cannot be made liable for the tort (wrongful act) of its servants. The doctrine rests fundamentally on the fact that such liability, if allowed, would lead inevitably to a diversion of the trust funds from the trust's purposes. The fact that a hospital receives pay for a certain class of patients detracts nothing from its character as a purely charitable institution. It was wholly immaterial that the plaintiff who here complained of injury was admitted as a pay patient. It was insisted, however, that the reason for the rule did not obtain in this particular case, since she had filed a paper in the court below disclaiming any right of execution against any fund of the defendant corporation held for charitable uses and all income of said corporation other than that received from pay patients; and had asked that the verdict be paid out of funds derived from pay patients only. The argument overlooked the fact that every dollar received by the hospital, from whatever source, was stamped with the impress of charity. For what did the plaintiff pay? For accommodations which the hospital was enabled to provide through the use of money charitably donated to it. The room, the bed, the furnishings and conveniences for which the plaintiff paid were all of them the direct and immediate product of the voluntary donations it received. It followed that the money that the hospital received from its pay patients was as strictly the increment of the charitable donations it had received as would be the interest on the money given it if invested on loan. If any profit resulted from this source it could only be regarded as an incidental addition to the trust fund or income.

Current Medical Literature

AMERICAN

Titles marked with an asterisk (*) are abstracted below.

The Boston Medical and Surgical Journal

September 15

- 1 *Present Status of the Treatment of Exophthalmic Goiter. J. M. Jackson and T. J. Eastman, Boston.
- 2 *Surgical Treatment of Exophthalmic Goiter. C. A. Porter, Boston.
- 3 Distortion of the Face and Skull Due to Continued Fixed Posture in Early Infancy. J. E. Goldthwait, Boston.

1. Present Status of Treatment of Exophthalmic Goiter.—Jackson and Eastman are of the firm belief that in practically every case it is our duty to treat the patient medically for three months. If at the end of that time no improvement has taken place, preferably ligate the vessels. This may effect a cure. If it does not, and the patient later comes to the operation of partial thyroidectomy—which is as yet the most satisfactory of the radical operations—the ligation will make the operation easier and less dangerous. If the goiter is very large, it is well to remove only the larger lobe and then treat the remaining lobe with the x-ray and medical procedures. Patients who show beginning cardiac failure should be operated on as soon as possible after being put in fair condition by medical treatment. Many cases, however, come to the doctor only after the myocardial changes have begun. Patients in this condition must be treated as cases of advanced myocarditis, for all treatment beneficial to this condition is also beneficial to the exophthalmic goiter. The strictest rest, with ice bags

over the heart and thyroid, a carefully regulated diet, the hydrobromid of quinin, and, if necessary, the cautious use of strychnin and bromids is the treatment to be carried out. We must not expect an absolute cure in the cases in which the myocarditis is advanced, though symptomatic recovery does sometimes occur, and we can hope only to lessen the symptoms and make life better worth living for the patient and the patient's family. In the earlier cases we may be able to effect a cure, and if not we may, by careful medical treatment, improve the condition to such an extent that the patient can be operated on with much less danger than before treatment.

2. **Surgical Treatment of Exophthalmic Goiter.**—Porter agrees with other surgeons that surgery, in properly selected cases, offers more and quicker improvements than medical treatment. To be successful, earlier operation must become the rule before incurable degenerations have developed. When reasonable medical treatment has been carried out the surgeon should be consulted. While from the very nature of the disease permanent cures may not be common, permanent improvements follow timely and appropriate operation in the large majority of cases after medical treatment has proved unavailing.

- 17 Aconite. J. Knott, Dublin, Ireland.

11. **Duodenal Regurgitation.**—Bassler directs attention to a stomach condition in which clinically the oils or fat foods, such as olive oil, milk, cream, butter and eggs, seem to be indicated, but in which they do harm and perpetuate the condition. During the past winter he has seen four individuals, all men of middle age, who were definite instances of this, each of whom had been in the hands of competent practitioners without benefit, and each of whom made substantial recoveries when the fat had been stopped and he was placed on a fat-free diet (skimmed milk, white of eggs, carbohydrates, green vegetables, boiled meats, etc.). These cases occurred in individuals who gave a history of having had no stomach disorder up to the onset of acute symptoms. The subjective symptoms were those of sharp pain in the epigastrium, radiating to the back, which persisted for from several minutes to several hours, and sometimes over one or two at a time. In each instance these pains were described as most severe, irregular in duration, quite incapacitating the patient for the time being and then suddenly ceasing, at which time the individual was as well as ever. There was no distinction in any of them as to when this spasmodic pain would begin or cease, and it was independent of meals or the ingestion of foods of different character or quantities. One of them said that nausea was present at the time that the pain was severe, but none had vomiting at any time during the illness. Other than the seizures of pain, which came on acutely in the first attack, there was nothing particular in the history of any of them.

15. **Foreign Body in Peritoneal Cavity.**—This patient, a woman, had three distinct attacks of abdominal cramps and vomiting before Roth saw her. On opening the peritoneum a considerable quantity of clear serum escaped. Digital exploration revealed a cord-like structure running from the right

side toward the median line and downward, and attached to a mass of adherent intestine which it constricted. On separating this cord-like structure, which proved to be omentum, and withdrawing it from the abdomen, a foreign substance, about two and a half inches long and about one-quarter inch wide, was brought out with it. On examination this foreign body proved to be a pledget of absorbent cotton discolored by blood. Further examination revealed two loops of the ileum adherent at the mesenteric borders. The adhesions were broad and firm and required ligation before division. In the midst of these adhesions some more cotton was found and removed. After repairing the denuded surfaces the cord of omentum was examined and in its lowest portion, the one which was attached to the mesentery, another piece of cotton was found firmly embedded.

Knowing that the patient has never had an abdominal section, suspicion pointed to the uterus as the most probable organ which might have been perforated during an induced abortion. The pelvic organs were therefore carefully examined, but, with the exception of a small indurated area in the lower part of the posterior wall of the uterus—perhaps at the level of the internal os—there was nothing noteworthy. Later the patient confessed to having had several abortions induced, the first in 1906, and the last about March 28, 1908, when about two months pregnant, or about six weeks before the onset of the present illness.

38. **Unusual Case of Strangulated Hernia.**—The patient complained of intense pain in the left inguinal region and an examination by Dempsey revealed a large mass, very tender to touch, indurated and inflamed. Constipation was absolute, not even flatus passing, abdomen was much distended, face hippocratic, pulse small and tension low, subnormal temperature and moist skin; in fact, many of the symptoms of shock. A hernia had been cured some years ago by injections of a clear substance in solution, probably

zinc chlorid, into region of both rings and at various other places in the inguinal region. It was plain that the man had strangulated hernia, and as taxis failed to reduce it, Dempsey arranged to operate. The regular Bassini incision was made through the skin, revealing a sausage-shaped tumor composed of the pampiniform plexus, vas deferens, a loop of intestine, and the hernial sac, all matted together by dense fibrous adhesions and grown solidly to the pillars of the internal ring. Within the abdominal cavity were numerous adhesions binding the intestines into a mass and firmly adherent to the peritoneum.

The intense inflammation produced by the injections had caused the entire disappearance of the muscular fibers of the external oblique for some distance from the canal, leaving in its place a fibrous membrane, probably the sheath of the muscle, so thin as to be transparent, and loosely adherent to the skin, the fatty layer having disappeared as had the muscular fibers. The conjoined tendon of internal oblique and transversalis had numerous areas of heavy scar tissue distributed throughout its substance, and the only structure not affected was Poupart's ligament. The cord was composed of the vas deferens, with remains of numerous veins and arteries, all occluded and imbedded in a mass of fibrous tissue about three inches long and two inches thick and within the mass was a knuckle of compressed intestine, causing the obstruction.

Little was done but to dig out and separate the knuckle of intestine, remove some of the veins of the cord and return that structure to the abdomen, suturing the remains of the conjoined tendon of internal oblique and transversalis over the cord, as in Fowler's operation, there being not sufficient left to form a floor for a new canal. The remains of the aponeurosis of the external oblique were sutured to Poupart's ligament and the skin closed with a subcuticular stitch. The history of the following month was that of an ordinary hernia. At present the abdominal wall is firm, and the hernia will probably not recur, as the intestines are firmly adherent to the abdominal wall and can not descend.

47. Acute, Febrile and Probably Infectious Disease of Unknown Origin.—This was a case of fever which after a period of slight prodromes for three or four days, had an abrupt onset, the temperature rising rapidly and reaching a point between 103 and 104 F. within two or three days, remaining steadily at about this point for about ten days or more, and then falling, either by crisis or by rapid lysis, and defervescence had begun. The patient's convalescence was uncomplicated, rapid and satisfactory. Among the other and somewhat striking features of the case were a rather severe bronchitis, which persisted as long as the fever continued; a very severe headache, not in any particular part of the head, which continued until defervescence; marked congestion of the

conjunctiva, and rather obstinate constipation, enemata being required to secure a movement of the bowels. There was slight nose-bleed on one or two occasions while the fever was high. There was no labial herpes; no retraction of the head; very slight, if any, stiffness of the neck; no convulsions. Kernig's sign was not present on June 25. The patient showed considerable restlessness while the fever was at its height, and was at times delirious. The results of the laboratory test certainly constitute a strong point in the evidence against the case having been either typhoid or paratyphoid fever. Lumsden is of the opinion that the case was very probably of the same nature as the cases of which M. E. Brill made such an admirable study in New York. [Brill's paper was published in the *American Journal of the Medical Sciences*, April, 1910, and was abstracted in THE JOURNAL, April 30, 1910, p. 1477.]

56. Gall-Bladder Infections.—Billings has made an analysis of the conditions of 60 patients suffering from cholelithiasis to ascertain the secretions and motility of the stomach in this class of patients. These 60 patients were selected out of 335 patients, because in these 60 there were made careful observations of the digestive power of the stomach. Of these 60 patients, 50 suffered from cholelithiasis with cholecystitis and 10 suffered from cholecystitis with cholelithiasis of the gall-bladder and the common duct. The majority of these patients presented practically normal gastric juice. In a few instances the total acidity was high. In one, 122; in two, 112; in one, 116. In a few the total acidity was low, practically an anacidity, with no more total acidity than would be expressed by the acid phosphates of a test meal. Of these one showed a total acidity of 9 and two of 10. All of the remainder showed an acidity within normal limits. Hyperchlorhydria as represented by a large amount of free hydrochloric acid occurred in only a few. The record shows free hydrochloric acid in one of 70; another 78, and two 88.

Motility was disturbed in 45 of the 60 patients during acute exacerbations of the disease as shown by vomiting. A study of the motility of the stomach during intervals between paroxysms showed that there was practically never an anatomic insufficiency of the gastric muscle. The fasting stomach of the morning showed the presence of gastric juice without microscopic food remnants. In the 2 patients a seven-hour motor meal showed the presence of gastric juice of rather a high acidity with a few food remnants. The remainder of the patients showed an entirely empty stomach with a seven-hour motor meal. The stools of these 60 patients, with 2 exceptions, showed an absence of chemical blood. The analyses of the stomach condition of these 60

patients would seem to indicate that the digestive power of the stomach was not disturbed by cholecystitis, excepting in the acute attack or in exacerbations of the chronic disease. During the acute attack or the exacerbation the disturbance was due to the pain and was manifested by nausea, vomiting and usually anorexia.

58. **Surgery in Cholelithiasis.**—The technical part of the surgery of cholelithiasis, Ries says, has reached a very high and satisfactory stage of development. The limitations of surgical success are few and these are due more to pathological conditions preceding the operation than to any shortcomings of the art of surgery.

62. **Heredity in Tuberculosis.**—Achard believes that tuberculosis as a disease is never inherited. A general and a specific predisposition (hypersusceptibility) may be transmitted; whether an actual tuberculosis develops on this foundation depends on exposure to infection. The transmitted predisposition is probably modified by a degree of specific resistance, which may likewise be transmitted. Congenital tuberculosis is exceedingly rare and, therefore, can not be admitted as the principal cause of phthisis in adolescence or adult life. Congenital tuberculosis is not a hereditary disease but it is due to intra-uterine infection by way of the placenta. It is only possible when the placenta is pathologically altered. Congenital tuberculosis is observed only in the infants of women with far-advanced phthisis, the mothers in all cases on record having died soon after delivery. Infants with congenital tuberculosis succumb always to the disease in the first weeks or at most months of extra-uterine life.

72. **Case of Hematoporphyria.**—In spite of the immediate institution of the treatment usually recommended in these cases, Cushing's patient, a woman, aged 69, became progressively weaker, passed urine and feces involuntarily, gradually sank into coma and died ten days after the peculiar color of the urine was first noticed. The urine remained of the same character to the end. The symptoms were characteristic—pigmentation of the urine, acute vomiting, with constipation, progressive weakness, with obscure nervous symptoms, such as ataxia, mental confusion and, finally, incontinence of urine and feces, and death in coma.

79. **Gastro-Intestinal Auto-Intoxication.**—According to Wood, who has gone into this subject deeply, the most diverse views prevail at present regarding the causation, pathology, and treatment of gastro-intestinal auto-intoxication and so-called enterocolitis. The association of the two conditions is frequently observed. A most common symptom of chronic appendicitis is the discharge of mucus by rectum because of the enteritis excited and perpetuated by the inflamed appendix. There is increasing evidence to show that a causal relationship exists between chronic appendicitis, with or without mucus enterocolitis, and gastro-intestinal auto-intoxication. Lesions of the female reproductive organs may also, either by interfering with intestinal peristalsis through direct pressure or reflexly, so interfere with digestion as to cause gastro-intestinal auto-intoxication. In dealing with the symptom-complex of gastro-intestinal auto-intoxication and mucus enterocolitis it is absolutely necessary, in the majority of instances, to have recourse to surgery before permanent relief is obtained. This statement presupposes that intelligent dietetic, hygienic, and medical measures have been faithfully observed previous to operation. Relief following surgical work, when indicated, is usually immediate. It may be necessary, however, to keep the patient, especially if neurotic, under observation and treatment for some months following the operation.

81. **Treatment of Spasticity and Athetosis.**—Frazier believes that without fear of contradiction it may be said unquestionably that section of the posterior roots relieves in most instances spasticity, even when the spasticity is of the most extreme type and of long duration, in adults and in children, whether of cerebral or of spinal origin. This statement is substantiated by all but one of the thirteen cases under consideration. From the practical standpoint it may be said that the spasticity is relieved to such a degree that resistance to passive motion is abolished and we can go still farther and say, that in most instances, the reflex associated movements, often a very annoying and distressing phenomenon, are also abolished usually together, and the reflexes formerly exaggerated become either normally active or less active than normal. They are permanently lost only in exceptional instances.

What is of considerable importance, and in striking contrast to such pre-existing methods as tenotomies and the like, the effects of root section are enduring. Of the thirteen cases cited, voluntary motion was restored to a marked degree in seven cases; in one of these, however, the spasticity was only partially relieved; of the remaining six, in one no mention is made, in another the condition was unchanged, and in one the movements were fairly good on one side but not so good on the other. Theoretically, we abolish the contractures and restore approximately the normal range of excursion in the movements of the limb; we eliminate the disturbing reflex associated movements, which interfere with voluntary individual movements; we make provision for the return of voluntary motion and theoretically we should have brought about a condition which would enable the patient to use the limb for ordinary purposes. Practically, however, this is true only to a very limited degree. It may be that sufficient time has not elapsed in many of the cases for the best results to be attained. Practice, education, and muscular exercise continued over a longer period may accomplish more than has yet been observed.

82. **Management of Breast in Puerperium.**—The proper time to begin the nursing, says Bacon, depends on the needs of the

child, the activity of the gland and the condition of the mother. Premature children must have food shortly after birth, while a developed child can get along without food for two or three days without danger. There is no doubt, however, that the earliest secretion, the colostrum, is of considerable value to the child and should be secured, if possible. A good average rule is to put the child to the breast from three to six times a day for the first two or three days. On the second or third day, when the breast becomes congested on account of the distention of the lymphatics and blood-vessels supplying the secreting gland structures, there is generally more or less discomfort. This can be reduced in most cases by proper bandaging. The object of the bandage is support and not compression. It must be applied always so as to give relief and not cause more pain. This will be accomplished if it is applied so as to hold the breast to the front of the chest.

The best form of bandage, Bacon says, is made of strong muslin long enough to go around the chest and pin in front. It should be about 16 inches in width with notches 7 or 8 inches deep for the shoulders, over which the edges of the notches are pinned. If the patient is very sensitive and not sufficiently relieved by the bandage, ice bags should be applied. Formerly, Bacon frequently employed massage for this purpose, but lately he has almost discarded this manipulation because of the satisfactory results obtained by the ice. The pump is apt to be painful, its use is not founded on the right principle, and it should be avoided. The rules for the frequency and length of nursing, after the establishment of the secretion, depend on the amount of milk obtained by the child and the character of the secretion.

84. Congenital Stenosis of Pylorus.—In every one of 14 patients, 9 of whom were operated on by Scudder, a pyloric tumor having all the classical signs was palpated and inspected. Moreover, in every case the clinical course of the disease manifested itself as an obstruction to the exit of food from the stomach into the duodenum. In all of these cases the baby was gradually starving to death. The object of this investigation has been to determine whether or not gastro-enterostomy performed on these babies with a demonstrative pyloric stenosis modified in any particular the digestion of fat, starch and protein. The chemical and microscopic examinations of these stools show that in most of the cases the digestion is normal. The protein was not markedly increased in any amount in any of the stools and it was normal in the majority of cases. The percentage of fat in three cases was higher than normal. Excepting these the total amount of fat excreted in one day was within normal limits. These facts, Scudder believes, are evidence that the operation of gastro-enterostomy does not materially change the ultimate disposition of the two food components, fat and protein. If to the chemical evidence be added the clinical facts that all these babies without exception are thriving in apparently perfect health, that they have lived several years since the operation was done, have gained in weight, in height, and in every way seemed well and happy; if these carefully observed clinical facts are considered, the evidence is overwhelming that in these babies gastro-enterostomy has no ill effect on metabolism as measured by the digestion of fat, protein, and starch, and normal growth of these babies.

86. Parasitic Myomata.—The general contour of the tumor in Richardson's case, its definite capsule, the large vessels surrounded by myxomatous tissue situated in a position corresponding roughly to that of the pelvis, the peculiar striated appearance of the islands of myomatous tissue surrounding areas of degeneration, together with the general architecture, suggested very strongly a distorted kidney through some developmental anomaly. The resemblance was so striking at operation that microscopic examination was necessary to determine the true nature of the tumor. It was then found that the peculiar appearance was due to focal degenerations.

87. Congenital Dislocation of Hip.—The apparatus described by Feiss consists of an iron band running around the pelvis to just beyond the anterior superior spines; to this band is fastened an iron strip running down the external aspect of the thigh, not quite as far as the external condyle. To this

there are fastened two bands, one for the lower part and the other for the upper part of the thigh. The stock used is wrought sheet iron, not tempered, and ranges from 15 to 18 gage, depending on the size of the child. The width of the various bands also depends on the size of the child, beginning with $\frac{5}{8}$ of an inch for an infant. The pelvic band may be made a little broader than the others.

88. Floating Kidney.—The operation of splitting the capsule and sewing it to the muscles with catgut has been modified by Herff and used on twenty-four patients without a single failure or a return of the affection. The technic of the modified operation is as follows: The usual incision, about six inches in length, is made, extending from the lower margin of the twelfth rib, along the outer edge of the sacrolumbalis group of muscles, downward and forward toward the median line. If the patient is fleshy, the incision may be extended to give sufficient room. The kidney is exposed in the usual manner, the fatty capsule separated from the organ and the kidney delivered. It is best to separate the fatty capsule as completely as possible before an attempt at delivering the kidney is made, as it simplifies the part of the operation very materially. It is unnecessary to remove the fatty capsule in all cases. Should this be well-developed, however, it may be done to prevent its becoming interposed between surfaces that are to be made to adhere. The true fibrous capsule is then carefully incised on a grooved director and separated from the cortical substance from pole to pole, to the extent of an inch and a quarter on either side of denuded capsule and temporarily fastened with hemostatic forceps. Before reducing the kidney, he passes two rubber tubes, through which silk cords have been drawn, under each pole of the kidney, traversing the perirenal fascia and fatty capsule that has not been detached completely at this point, in order to safeguard against a possible slipping of tubes from under the poles. The kidney is then reduced and placed in position. Two punctures are made on either side of the incision, traversing skin, fascia and muscle, which correspond to the position of the tubes under the poles, and are brought out through the aperture on both sides. The catgut sutures in capsules are rethreaded, passed through muscle and fascia and tied. These serve to keep apart the margins of the capsules in order to expose the denuded cortical portion of the kidney to muscle and fascia and insure adhesive inflammation. A few layers of catgut sutures unite the different layers of fascia and muscle that were divided in exposing the kidney. The skin incision is then closed with a continuous horse-hair suture. The suspending rubber tubes containing silk cord are slit open to the level of the surface of the skin and the opposing ends of the cord are loosely tied over a small roll of sterilized gauze, which completes the operation.

101. **Observations on Car Nausea.**—In looking over the cases of the past 4 years, Ayres found that 75 patients gave car sickness as a symptom or sometimes as a chief complaint, and while it was associated in most cases with headaches, asthenopia and stomach trouble, yet it was given prominence by the patient. Stomach trouble was by far the most frequent accompaniment. Before working out the statistics, he had formed the decided impression that the majority of patients would show astigmatism contrary to rule, either simple or compound, and that the proportion was greater in hyperopic than myopic astigmatism. Out of the 75 patients 30 had plus astigmatism contrary to rule and 31 had plus astigmatism with the rule. Only 58 were contrary to rule, or 51 per cent. of the patients with astigmatism against the rule had car nausea while only 3 per cent. of those having astigmatism with the rule complained of it. In myopic astigmatism, both simple and compound, the proportion is decidedly less, and in the few cases of minus astigmatism contrary to rule, only one-fourth of them complained of car sickness, or just one-half as many as found in plus astigmatism contrary to rule. Car sickness was found in every case associated with astigmatism with or without some other forms of ametropia; it was found in mixed astigmatism and it is to be noted also that 55 per cent. of those unusual cases which had astigmatism with the rule in one eye and against in the other complained of it. The adjustment of correct lenses cured the nausea in many cases completely, other cases reported nearly complete cure, with only occasionally a feeling of nausea on the train, and in every case benefit was derived from the lenses, for not only did the train sickness disappear, but with it in most cases the vertigo, the headaches, the asthenopia and, better still, the stomach trouble.

118. **Intestinal Anastomosis.**—The method which Sorel describes he believes eliminates all the inconvenience attributed to the end-to-end anastomosis, and by being the most rapid (more rapid in fact than all mechanical devices), very easy and simple it eliminates the danger common to every other form of anastomosis, namely, long manipulation of the intestine, which makes infection more apt to occur and causes trauma, which facilitates the formation of adhesions. The method has been used by various surgeons in 14 cases in human beings after it was used, always successfully, over 200 times on dogs. This is a suture method in which the cut ends of the intestines are sutured and inverted over a rubber tube. The size of the tube should be one-third less than that of the intestine to be anastomosed, and of about

the same length as its diameter. Any tube of soft resilient rubber, about 0.5 mm. in thickness, can be used.

A plain round, straight or curved needle threaded with silk or linen is passed from within the lumen of either of the two segments of the intestine through the whole thickness of the gut and mesentery, traversing the dead space at a distance of about 3 cm. from the cut edge, avoiding, of course, any blood vessels. The end of silk or linen is held by an artery forceps. The needle is then passed through any one of the catgut loops of the rubber tube; then going to the other segment of the intestine on the same side, it is passed from without in through the mesentery and intestinal wall, again traversing the dead space. The needle is then brought out again through intestinal wall and mesentery, and going back toward the first segment of intestine it is passed under the same catgut loop of the rubber tube, and finally passing through the mesentery and intestinal wall, will come out inside of the intestine at a distance of a few micromillimeters from the point of beginning of the stich. It will be noted that the dead spaces have been traversed four times. The two segments of the intestine are approximated and the two mesenteric angles (dead spaces) are securely closed by gently tying the two ends of silk, the knot being in the inside of the intestine. The two ends of silk are left long, one being held by an artery forceps; the other, armed with the needle, will be brought outside of the intestinal cavity by passing through the whole intestinal wall, close to the attachment of the mesentery and is used for the circular mattress suture of the second stage. The two segments of the intestine are brought over the rubber tube and held in place by one or more temporary stitches, which pass through a catgut loop, thus preventing the tube from slipping and facilitating the circular mattress suture; the temporary stitches should be cut very close to the knot. The catgut loops stand prominently between the two edges of the intestine. The needle is passed through the catgut loop near the attachment of the mesentery, close to the mesenteric angle, and at about 2 mm. from the cut edge of the opposite segment of gut a continuous mattress stitch is begun; the needle goes through the whole thickness of the intestine. As the needle passes from one segment to the other it goes through the catgut loops, the serosa is inverted with each stitch, by tucking it under with a thumb forceps, and gentle traction is maintained so that each stitch is kept taut, and no silk is seen between the two cut edges, which must be closely approximated. Care should be exercised not to pull the silk perpendicularly to the intestine because by so doing it always tears the gut. The traction on the silk must be made by keeping it parallel to the suture line. When the circular mattress stitch is completed the silk is knotted to the end which was held by the artery forceps and the ends are cut close to the knot. The temporary stitches can be cut off when they are reached with the circular suture.

Sorel says that one needs not to be particular as to the regularity of the mattress stitch; the only important points are: to pass the silk under a catgut loop at least once, when going from one segment to the other, and to invert the serosa, keeping the silk taut. The intestine is washed with normal saline solution; and clean pads and towels are put around, the anastomosed gut is taken in one hand and one strand of the catgut is gently pulled until about half the number of loops have disappeared; the ends of the catgut are then knotted and cut close. While pulling the catgut it will be seen that the serosa is inverted.

129 *Myasthenia Gravis. M. G. Schlapp and J. J. Walsh, New York.

129. **Myasthenia Gravis.**—In this case, which was studied rather carefully and had at the beginning some appearances that might lead one to think of hysteria, a story of fright was obtained, followed immediately by the gradual development of all the symptoms of myasthenia gravis. The patient was a young woman of 24, a cashier. She was very sensible, with no caprices, no nervous symptoms, and none of the faults of disposition usually set down as due to a tendency to hysteria. She had been in perfect health, missing no time, undisturbed by the menstrual periods, with regular bowels and a good appetite. She was a favorite in her own family.

One evening in 1906 a brother was brought home dead. She was at home when he was brought in and she suffered severely from the shock, swooning away and then afterward vomiting. She was better after half an hour, but she did not sleep that night and felt nauseated during most of the next day. She was unable to eat much for several days and headaches developed. These headaches were very severe and continued even after her appetite returned to a great degree and when she thought that she was quite well otherwise. When she returned to work after the funeral she found that she was very easily tired and that her eyelids began to twitch. The left one was the first to be affected, but both bothered her after a short time. After the twitching had continued for some time she would find it easy to open her eyes, but rather hard to keep them open and the lids would droop. Speech became very tiresome to her, too, and then after an interval she would be worse, and at the end of six weeks she found it very difficult to hold her eyelids up or to talk much, and some difficulty of swallowing developed. These symptoms of gradual loss of use of the muscles continued to develop for six months with certain variations. She died December 23 from sheer weakness of the respiratory muscles, together with the malnutrition consequent on difficulty of swallowing.

The course of the case was typical of myasthenia gravis, except that the intermissions were perhaps more marked than are usually seen. The authors suggest that the secretion of the thymus gland represents some material that maintains the tone and the vitality of the dark red muscle substance. When this diminishes the white substance overgrows somewhat according to that law which seems to hold in all the tissues, that the disappearance of one form of tissue leads to hypertrophy of neighboring tissues of other kinds in the same order. It is possible that the thymus may have the double function of maintaining the vitality of the dark red muscle substance and inhibiting the light red muscle substance. Such double functions are rather common and are to be expected in nature. The shock or fright that represents the beginning of this case of myasthenia gravis may have disturbed certain trophic nervous influences that enabled the thymus gland to do its work.

133. **Manifestations of the Angioneurotic Group of Diseases.**—The following summary is made by Matthews of his cases:

Case 1. History of attacks of pain and lameness in ankles, calves, knees, hips. Purpuric spots on knees, calves, thighs. Colicky pains in abdomen, at first mild, then very severe. Some edema of feet. Recurring purpura of fingers and foot, with some edema of fingers. Herpes. Nephritis. Endocarditis. Death.

Case 2. At first pains in epigastrium after taking food. Tenderness over epigastrium. Pains increasing in severity

and more generally distributed over abdomen and regardless of food. Marked erythema with here and there urticarial wheals. Localized edema. Recurrence of erythema. Much headache. Albumen and casts and blood in urine. Recovery.

Case 3. Recurrent attacks of urticaria, pains in chest and abdomen twenty years ago. Arthritis. Edema of ankle. Purpuric spots. Fever for a few days. Pains in upper abdomen and chest. Recurring attacks of pain in abdomen, chest, rectum. Glycosuria. Recovery.

Case 4. Sudden attack of croup. Profuse urticaria, followed by prompt relief of the laryngitis. Recovery.

1. **Mechanotherapy in Disease.**—Bryce regards it as very remarkable that the medical profession should so long have neglected the treatment of disease by physical methods or mechanotherapy, especially when in its various branches it has long been exploited by so many irregular practitioners. Speaking of osteopathy, Bryce has no hesitation in saying that the vast majority of his cases are quite capable of being successfully treated by other methods, and that many ailments, especially acute conditions such as typhoid fever, pneumonia, nephritis, "cold in the head," are liable to be seriously aggravated by manipulative attention. It is lamentable that the apotheosis of mechanotherapy should result in such ill-guided enthusiasm as its application to many acute disorders would testify. However, Bryce continues, scientific mechanotherapy has a distinct field of usefulness. He reports several cases which, he says, could not have been treated successfully without some form of manipulative therapeutics. He has used the method in cases of asthma, neurasthenia, neuralgia, and others which have resisted the orthodox methods of treatment, and in some cases he has had beneficial results which could not have been attributed to the influence of suggestion. However, some of the benefit derived may have been due to improved physical condition which naturally results from the treatment, and some of it may have been due to the preliminary relaxation of the muscles and the breaking down of adhesions.

4. **One Cause of Cancer.**—During 25 years, of 4,902 tumors removed by operation in the Kashmir Mission Hospital, Neve found that no less than 1,720 were malignant, and of these 1,189 were epitheliomatous, and 848 were on the thighs or abdomen and were due to the irritation of the kangri, a portable fire basket, carried by the people under their clothes. When sitting down this rests against the inner sides of the thighs or the front of the abdomen. The front of the chest, the breasts and the calves of the leg all are exposed to the irritation of the heat, and these regions are also liable to become the seats of epitheliomatous disease, although much less frequently than the thighs and abdomen. The disease is quite as common in men as in women. The average age of the patients was as high as 55. Epithelioma is extremely rare under 40. Scars from previous burns are often the starting point for epitheliomata. Kangri-burn cancer is a typical squamous-celled epithelioma. In the early stages, the malignancy is slight, it is too slow to infect glands, and is very amenable to operation. In late cases deep glands are involved, and in many cases, owing to adhesions and brawny infiltration of the skin and cellular tissue, it is inoperable. In many cases its origin is in scar tissue. It is demonstrably due to a definite cause, namely, irritation from the constant application of heat. In this respect it is similar to other epitheliomata resulting from mechanical, chemical or thermal irritation. The nature of the cause is opposed to a parasitic theory of origin, and favors a trophic theory of cancer.

6. **Prevention of Scarlet Fever.**—During the first four days in a scarlet fever case commencing at the earliest possible moment, Milne has pure eucalyptus oil gently rubbed in morning and evening, all over the body from the crown of the head to the soles of the feet. Afterward this is repeated once a day until the tenth day of the disease. The tonsils he always swabs with a 1 in 10 phenol solution every 2 hours for the first 24 hours, rarely longer. For 26 years Milne has used pure eucalyptus oil in this way. When this treatment is commenced early, he asserts, secondary infection never occurs and complications are unknown.

18. **Sterility.**—There can be no doubt, says Gibbons, about the gonococcus being responsible for many cases of sterility, but it is useless to endeavor to make it responsible for nearly all. Gibbons draws attention to the fact that certain continuous vaginal discharges, apart from that caused by the gonococcus, which cannot be cured by douching, may yield to vaccine treatment if the organism causing that discharge be separated, cultivated and a vaccine made therefrom. The modern internal treatment by organotherapy requires most careful consideration and much more experience before statistics of real value can be tabulated. In his own experience, Gibbons has had such success by curing ordinary vaginal discharges, conception following thereon, that he has been most seriously impressed by the fact that apparently simple discharge may contain much toxic material which can act on the protoplasm of the spermatozoa. If any disease exists it must be cured, and if it does not yield to ordinary treatment thorough curetting may be advised, or if this will not be entertained, a course of waters may be of the greatest service.

19. **Ehrlich's "606" Specific for Syphilis.**—It appears from the cases McDonagh has treated, that the earlier the syphilis the larger the dose required (0.45 to 0.6 gram), and that 0.5 gram is ample in the late stages. In his cases it was the general rule for the temperature to rise to 100 F. on the night of the injection, and to become normal after 48 hours; sometimes the fever persisted to the third day, but only in those cases which had some of the toxic edema. In only one case was any albumin found after injection, and in this case it was transient. In almost every case an induration could be felt in both buttocks, probably due to a fibrosis caused by the caustic action of the sodium hydrate; whether the induration will ever disappear time alone will show; at any rate, it causes the patient no inconvenience. Beyond the improvement observed by the naked eye, McDonagh was very much struck by the extraordinary change for the better in almost every patient's general condition: they not only appeared brighter, but felt ever so much better and put on weight; this alone is a great achievement, since there is scarcely a patient who does not become depressed, anemic and lose weight under mercurial treatment. It seems that the severer the case the quicker the action, and the results obtained so far, McDonagh says, reach beyond expectation.

20. **Influence of the New Ehrlich Preparation.**—McIntosh found that "606" (dioxydiamidoarsenobenzol) is a specific remedy for European relapsing fever, and thinks it will be equally efficient in the other spirochaetoses.

22. **Isohemolysis in Relation to Cancer.**—It is evident from Upcott's work that the possession of isohemolysis is very far from being pathognomonic of cancer. But then very few signs of the disease in its curable stages will bear this interpretation. A reaction which is positive in 50 per cent. of patients with cancer deserves, he thinks, to be weighed in the balance with other facts in the endeavor to arrive at a diagnosis. The only other conditions likely to be confounded with cancer in which hemolysis is frequently encountered are tuberculosis and pernicious anemia, especially the former. In such cases, if hemolysis be proved, it is possible that one of the forms of tuberculin reaction would be of value. A negative hemolytic reaction can, of course, carry no weight.

27. **Epidemic Summer Diarrhea.**—The authors isolated from the feces, heart's blood and scraping of abdominal organs of cases of epidemic diarrhea, two groups of organisms producing diarrhea in puppies, the one group apparently new, and corresponding exactly with their original strain *Bacillus F.* and the other identical with *Bacillus suipestifer*. These groups are distinguishable from each other, from *B. paratyphoid* and

from *Bacillus suipestifer* by absorption tests alone. They were not present in the stools of 100 normal children.

- 43 Atelosis in a Man, Aged 42: Physical Development Said to have been Arrested at about the Age of 9 Years. F. L. Weber.
- 44 *Rare Congenital Deformity of Nose in an Infant. G. Wilkinson.

42. **Portals of Infection in Tuberculosis.**—In the case of children, Whipham thinks it probable that many patients are infected through the alimentary tract, and that in them the bovine bacillus plays an important, though not exclusive part. It must be remembered that children are very liable to become infected, and when once the disease has gained an entrance it spreads rapidly, as a rule, giving rise to a generalized infection. The tissues in early life show but a slight resistance to the tubercle bacillus, and have little if any power to limit the disease to a given area, or to start reparative processes when once attacked. With age, however, the power of resistance increases. In infancy the lymphatic glands are the first tissues to be involved, the bronchial glands, as a rule, the site of election. The protective power of the gland at this age being but feeble, a generalized tuberculosis in most cases results. After the first year or so the glands are more able to withstand the infection, so that the protection is afforded, perhaps for a time, perhaps permanently. Later, about puberty, the rôle of the lymphatic glands diminishes, and the disease is characterized by lesions in the apices of the lungs as in adult life, but at this age the infection is apt to be more rapid and more virulent than after full maturity has been attained.

44. **Rare Congenital Deformity of the Nose.**—The deformity in Wilkinson's case consisted of a deep depression in the middle line of the nose, with wide separation of the nostrils and flattening and broadening of the whole feature. The nose was 3 cm. wide at the level of the alæ, but only projected about 1 cm., the greatest projection being on either side of the middle line in front of each nostril. These two prominences are separated by a depression of the tip of the nose 2 cm. wide. The nasal bones and nasal processes of the superior maxillæ were flattened. There was no separation between the nasal bones. The columella was 2 cm. broad, and the anterior nasal spine could be felt behind the columella as a broad projection of bone, about 1½ cm. from side to

side. On inspection of the nasal passages the anterior ends of the nasal septum could be seen as a prominent ridge on the inner sides of each vestibule. The two sides of the septum were apparently separated from each other. There was no nasal obstruction. On everting the upper lip there was seen a distinct notch on the buccal surface in the very center of the lip. There was also a well-marked notch in the middle line of the alveolar process. The two halves of the alveolus were not in alignment, but met with a forward-pointing angle. Two uncut incisors could be felt beneath the gum on either side of the mesial notch, showing that this represented a division between the two halves of the premaxillary bone. The deformity arose, no doubt, from failure of fusion of the two mesial masses of the frontonasal process.

Annales de Gynécologie et d'Obstétrique, Paris

- 45 *Treatment of Vaginal Cystocele. (Sur la cure de la cystocele vaginale ou hernie pré-utérine). H. Violet.
- 46 *Anemia of Pernicious Type During Pregnancy. Audebert and Balous.
- 47 Arterial Irrigation of Lower Segment of the Uterus. A. Couvelaire.

45. **Treatment of Vaginal Cystocele.**—Violet distinguishes between (1) primary prolapse of the uterus, which requires hysteropexy or hysterectomy; (2) primary downward displacement of the lower portion of the vagina, corresponding to an actual eversion by way of the perineum, correction of which requires suturing of the levator ani muscles either anterior or posterior to the bladder, and (3) preuterine and retrouterine hernias in the anterior or posterior cul-de-sac of the vagina, by way of the weakest points in the sacro-rectal-genital aponeurosis. He describes the technic which he applies in the latter form, giving the details with illustrations of three cases. The main features of his technic are the closing of the hernial gap by suturing the vesico-uterine ligaments, following this by fixation of the uterus at a point on or just above the isthmus, fastening the uterus thus in physiologic anteversion. As the vagina cystocele is generally associated with sinking of the posterior vaginal vault and elongation of the lips of the cervix, he follows with lozenge-shaped resection of the posterior cul-de-sac and amputation of the cervix before proceeding to reconstruct the perineum by direct suture of the levator ani muscles.

46. **Pernicious Anemia During Pregnancy.**—The case reported is interesting as the extreme anemia of the pernicious type in a ii-para of 26 showed a pronounced turn for the better immediately after the delivery of a macerated fetus about term. The spleen was considerably enlarged, which is not generally the rule with pernicious anemia in pregnancy.

48. Abstracted in THE JOURNAL, September 3, 1910, page 899.

50. **Multiple Lesions of the Kidneys.**—Zimnitzki urges the importance of striving to detect and distinguish the various pathologic processes that may be developing at the same time in an organ. In a case described, a man of 51 with venereal antecedents developed a puzzling syndrome finally revealing itself as a combination of stone in the kidney and mixed pyohydronephrosis with atrophy of one kidney and compensating hypertrophy of the other. He cites several cases of the four types of hydronephrosis: the true internal, the external or false hydronephrosis, the combination of both and the intermittent.

67 Ureter Anomalies. I. E. Papin.
68 Case of Bilharziosis of the Bladder. G. Marion.

66. Technic for Hysterectomy.—Chaput asserts that the drawbacks of subtotal hysterectomy (liability to cancerous degeneration and infection) can be obviated by excising the mucosa lining of the cervix and pushing the entire stump of the cervix down into the vagina and suturing the walls of the latter above it, thus excluding it entirely from the abdominal cavity. He obtains access to the cervix through an incision in the anterior vaginal vault, then slits the cervix, spreads it open flat and resects the mucosa and then sutures it into its cylindrical shape again and invaginates it into the vagina. He also asserts that the drawbacks of total hysterectomy can be obviated by first removing the cervix through the vagina and then removing the rest of the uterus by abdominal section. This is particularly advantageous for the obese. The vaginal operation can be done under local, general or spinal anesthesia. The clamps are removed the second day and the abdominal operation is then done. He describes this technic in detail with illustrations.

Semaine Médicale, Paris

August 31, XXX, No. 35, pp. 409-420

- 69 *Traumatic Neuritis and Hysteria. F. Moty.

69. Traumatic Neuritis and Hysteria.—Moty remarks that as the infectious complications of trauma are becoming of less importance, the nervous disturbances resulting from the traumatism are looming up into constantly greater prominence. Two facts seem to be established by his experience with 161 cases of traumatic neuritis, namely, that the existence of a neuritis can be presumed when the region affected is colder than the corresponding region on the other side, and secondly, that the outcome of the trouble depends in large measure on the individual tendency to hysteria in the patient. If the limb is found colder than its mate, electric tests may confirm the assumption of neuritis. The muscles generally atrophy early and likewise the bones; in some of his patients the sole of the foot was markedly smaller than its mate 3 months after a fracture of the leg with neuritis. In some puzzling cases with chronic arthritis of the knee, the knee was hot, the leg above or below unusually cold, and the diagnosis of neuritis was confirmed by the

asymmetrical shortness of the sole. Trophic ulcerations can be distinguished from tuberculous lesions by this chilliness and atrophy of the limb. When there is traumatic paralysis or contracture there is generally an accompanying neuritis and more or less hysteria, so that he has become convinced that progressive neuritis is a form of what he calls hysterotraumatism. The prognosis, he reiterates, does not depend on the gravity of the trauma but on the degree of hysteria, so that examination of the visual field to estimate the tendency to hysteria and inquiry into the personal and family antecedents will generally afford a basis for the prognosis. In about 10 per cent. of his 161 cases no measures proved more than transiently effectual. If the primary lesion was grave the cure may require years and the limb cannot be expected to regain its former strength after suture of the nerve, although the sensory functioning may be comparatively normal. He commends Weir Mitchell's methods of revulsion in treatment of neuritis; galvanic treatment may also prove effectual. He has witnessed the cure of old trophic ulcers under a few weeks of the continuous current; the sinusoidal current and undulating galvanic current may also render good service. Psychic treatment is of prime importance, he emphasizes; as the course of a neuritis is variable, certain impressions or auto-suggestions may induce at any time a turn for the better. In one of his cases the limb was amputated as a last resort and the intense pains were permanently cured thereby. If the amputation is done while the neuritis is still progressing, the stump is liable to present further neuritic disturbances. In this connection he refers approvingly to Sherren's work in this line (summarized in THE JOURNAL, Feb. 12, 1910, page 571). In 2 cases in which the spinal nerves were involved, he resected the posterior roots of the plexus involved but with only transient benefit. He considers nerve-stretching as practically abandoned now except to release the nerve.

71 and 72. Ehrlich's "606" in Syphilis.—Isaac reports 27 cases, all showing the promptly beneficial action of the drug; in some cases previous systematic mercurial treatment had proved ineffectual. In an average of 10 days the patients were entirely freed from even extremely severe manifestations of the disease. No serious by-effects were observed but in 2 cases there was a febrile and painful local reaction compelling the use of large doses of morphia for several days. The Wassermann reaction was still positive by the sixth week in all but one patient. Michaelis states that he has not encountered any trace of threatening by-effects in his 71 syphilitic patients treated with Ehrlich's "606."

73. Treatment of Large Intestine with Gas or Sprays.—Skaller applies the drug topically in the form of a spray, borne along on a jet of oxygen under pressure. The outflow of the medicated gas is provided for by an aspirating device.

Experiments on dogs, he states, have demonstrated the practicability and harmlessness of this method of medicating the intestines, the oxygen and spray penetrating to a greater distance and into all crevices much more effectually, he says, than is possible with a fluid.

82 *Diagnostic Importance of Ulcerations on the Palate in Typhoid. (Ueber den diagnostischen Wert der typhösen Gaumengeschwüre). M. Lüdin.

82. Ulceration on the Palate as Sign of Typhoid.—The general symptoms and the development of a typical ulceration on one side of the palate in the 2 cases reported suggested typhoid fever, but the further course of the disturbances contradicted this assumption. Both patients were tuberculous but the ulceration had no features characteristic of a tuberculous lesion. In the experiences at the Basel medical clinic these ulcerations of the palate were observed in 11.76 per cent. of the 68 cases of typhoid in the last 3 years, but the 2 cases reported show that they are not pathognomonic of typhoid.

83. Rosenbach's Tuberculin.—Rosenbach produces his tuberculin by the growth of the *Trichophyton holosericum album* on living tubercle bacilli and their culture medium. The toxicity of the tubercle bacilli seems to be materially reduced by the action of this fungus, while the other properties of the bacilli do not seem to be altered. The Rosenbach tuberculin is thus much less toxic, he asserts, while the doses can be larger and the therapeutic efficiency is far greater than that of ordinary tuberculin. He relates extensive experience with it in pulmonary and surgical tuberculosis and lupus at the university polyclinic, at Göttingen, in his charge.

90. Vibration Massage Catheter.—The catheter is closely studded with holes and tap water introduced through it induces a vibration which massages the cavity, as Dreuw explains in detail with illustrations. The catheter can be enclosed in a rubber bag or not as desired. The same principle of vibration massage from running water, he adds, can be applied to instruments of different shapes designed to be introduced into the body cavities.

- 98 *Congenital Hypertrophy and Stenosis of the Pylorus in Infants. P. Dilg.

92. Bacteriology of Surgical Tuberculosis.—Burekhardt found bovine tubercle bacilli in 3 out of 29 cases of tuberculous bone or joint processes, and also in 1 out of 6 cases of tuberculous peritonitis and in 1 out of 9 cases of tuberculous glandular processes in the neck. No bacilli of the bovine

type were discovered in his 4 cases of urogenital tuberculosis. He thus found bovine tubercle bacilli in 5 out of 49 cases of surgical tuberculosis selected at random, the patients being of all ages and of both sexes. He gives a detailed account of his clinical experiences and of extensive bacteriologic study of the 49 strains of tubercle bacilli and 3 from animals. There was nothing in the clinical course or the anatomic findings in the 5 bovine cases to distinguish them from the human type. The outcome, however, was unusually favorable. In the 3 joint cases no special focus could be discovered in the bone, as in the human bacilli cases.

98. Congenital Stenosis of the Pylorus in Infants.—In the case described the pylorus was remarkably thick, the walls encroaching on the lumen which was further obstructed by ridges of mucosa projecting into it. This case emphasizes the importance of early gastro-enterostomy if the threatening symptoms are not promptly alleviated by lavage and dieting.

107. Study of Infant Mortality.—Rosenfeld has been studying the statistics in regard to the infant death-rate in Austria during the last 25 years, comparing the influence of the age of the infants, the mode of feeding, the seasons, etc. His conclusions are that the almost constant drop in infant mortality since 1895 is not to be ascribed to improved hygienic conditions, better feeding, etc., but is the work of certain still unknown, possibly climatic, factors which are at present beyond our control. Nothing else, he declares, will explain the facts observed, especially the almost universal sudden increase in the infant death-rate in certain years and the almost equally universal decline in others, other conditions being apparently the same at both times.

111. Treatment of Syphilis with "606."—Junkermann reports 25 cases in which Ehrlich's remedy was used; no injurious by-effects were observed although in two weakly patients there was a brief change in the heart rhythm with sweating

and anguish, but no nervous symptoms. No spirochetes could be discovered in the lesions after the injections.

113. **Modified Momburg Belt Constriction.**—Gelyi has found that the abdominal aorta can be compressed and the same results obtained as with the Momburg belt by an apparatus consisting of a steel and rubber pad, mounted in a standard fastened to the edge of the operating table. With a screw the pad is lowered to compress the region of the abdominal aorta, as by the Momburg belt, but the waist is not constricted. Compression can be applied as gradually as desired; when it is no longer needed the whole device is unscrewed from the table.

116. **Measurement of the Arterial Pressure.**—The construction and mode of action of von Recklinghausen's tonometer are described in detail with the principles on which it is based and the interpretation of the findings.

119. **Infant Mortality During the Heated Term.**—Klose ascribes the excessive mortality among infants in a large part to the acute loss of water during the summer heat. The heat is not so injurious for the infants when the humidity is high. His experiments and research and comparative study of the work of others confirm the assumption that dry hot summers are particularly injurious for infants.

120. **Pneumonia in Dyspeptic Infants.**—Berend states that the mortality among infants in Hungary is always as high or even higher in the winter and spring than in the summer. Pneumonia is frequent, and he ascribes it to the unhygienic methods of dressing and caring for the infants. Breast feeding is the rule but the spacing is too short and the infants constantly suffer from overfeeding. His experience has shown that when the child loses suddenly in weight the resulting modification of conditions in the circulation favors catarrhal infection. Pneumonia in infants seems to follow an abrupt decline in weight. He found a loss of weight of over 300 gm. in 2 days or of over 500 gm. in 5 or 6 days recorded in 71 out of 400 infants in his service at Budapest in the last 2 years. And pneumonia developed at once in 41 out of these 71 infants. In 41 out of his total material of 78 cases of pneumonia an abrupt decline in weight had preceded the development of the disease. The children were all under treatment for some digestive disturbance. The pneumonia in these 41 cases developed at once after the loss in weight, even when the infants were isolated or there were no other cases of catarrhal affections on hand. His assumption of the causal importance of the abrupt decline in weight in the production of the pneumonia emphasizes the necessity for forestalling and warding off any abrupt decline in weight from loss of fluids, leaving the blood abnormally thick and the viscosity abnormally high, and altering the osmotic processes throughout, thus modifying the natural immunity defenses. In the last 100 infants with chronic digestive disturbances taken into the hospital, 30 had pronounced bronchopneumonia, 30 bronchitis or coryza, and 10 other infectious processes. Only 20 were free from some complicating infection. Even during the summer fully half the infants have a catarrhal respiratory affection when first seen.

122. **Experiences with Ehrlich's "606."**—Fraenkel and Grouven conclude from their experiences with "606" in over a hundred cases of syphilis that it is undoubtedly a remedy which will mark decided progress in treatment of this disease and possibly of others, but they report a fatality after its intravenous administration which they ascribe to an individual hypersusceptibility to arsenic. The patient was a waiter of about 25 who had suffered for years from severe disturbances in speech, word blindness, etc., evidently of syphilitic origin, and had been in the psychiatric clinic for 18 months on that account. The drug was injected in a small amount of water (0.4 gm. to 15 c.c. of water). Fifteen minutes later symptoms of serious arsenic poisoning developed, proving fatal in 3½ hours. Autopsy showed extensive foci of softening in the left temporal lobe and distinct amounts of arsenic were recovered from the spleen, lungs and liver, the only organs examined for this purpose. Since this occurrence the intravenous route is no longer used in the clinic. No appreciable by-effects were observed in any of the other cases. In 30 the fate of the arsenic in the body was investigated and it was found that from 6 to 10 mg. was eliminated daily in the urine during the first week, and from 6 to 8 mg. in the second week, but after this no further traces could be detected except in a few cases in which 2 mg. was found, and up to 9 mg. in one case. The drug induced a decided and early turn for the better, they say, in all the cases except the one mentioned above, surpassing that ever attained by mercury.

124. **Radicular Sciatica.**—Stursberg relates the details of 7 cases which demonstrate that the affection which we call sciatica is not always restricted to the region innervated by the sciatic nerve. Sensory phenomena were observed indicating the participation of roots in the sacral, lumbar and thoracic regions. Some lesion in the posterior roots would explain without difficulty the syndromes observed and this assumption points the way to more effectual treatment. The occasional simultaneous or alternate occurrence of sciatica and lumbago in the same patient confirms this assumption. Lumbar puncture might possibly give relief, or heat applied to the sacral region; measures directed to the sciatic nerve alone are inadequate in this class of cases.

126. **Technic for Amputation for Diabetic Gangrene.**—Kausch cuts straight across the limb in a single plane and leaves the whole wound open. By this means he avoids all crevices and nooks where infection might lurk in extravasated blood, etc. In his first case the soft parts gradually retracted, and after the third week he applied extension to the limb. By the twenty-sixth day the soft parts had nearly covered the bone and they were drawn together with adhesive plaster over the small gap still left, and healing was complete by the end of the third month. The patient was a man of 51. The gangrene and phlegmons had followed a trifling injury of the foot and had not been arrested by amputation of the foot and leg, by the ordinary technic, followed by fistulas, but the whole syndrome subsided immediately after the amputation in a single plane at the middle of the thigh and now with careful diet the patient has no longer any sugar or albumin in the urine. The results were equally good in another diabetic. He attempted in this case during the earlier amputations to wash out clots in the artery by injecting salt solution above. The attempt failed in this instance but he thinks that this might be of advantage in certain cases of gangrene. In his first case the bone projected 6.5 cm. from the soft parts on one side and 2.5 cm. on the other, but the adhesive plaster extension with a weight of from 2 to 4.5

kgm. soon brought the soft parts down to cover the stump. This case exemplifies how a moderate diabetes of long standing can be suddenly transformed into the most serious type by superposed infection; the sugar ran up to 120 gm. with intake of 40 gm. carbohydrates, the urine remaining persistently acid although 18 gm. of sodium bicarbonate were being taken daily. The phlegmons aggravated the diabetes and the aggravated diabetes reacted in turn on the phlegmons—a vicious circle. After the focus had been removed the amputation wound healed as if there had been no diabetes; the soft parts bore as if normal the compression necessary for the extension traction. He insists on the importance of keeping diabetics entirely free from glycosuria. In 2 other cases he was unable to induce the patients to obey his dietetic restrictions after amputation on account of diabetic gangrene, and the other leg became gangrenous. He thinks this might not have occurred if the patients had dieted to keep the urine entirely free from sugar.

127. **Kaolin as Transmitter of Infection.**—Zweifel has been using since 1901 kaolin, fuller's earth or *bolus alba*, as it is variably called, as a dressing for the umbilicus, and always found it satisfactory. He had the kaolin sterilized by baking for several hours in large jars, at a temperature of from 170 to 200 C. Recently, however, 4 of the infants developed tetanus, to which 3 succumbed, and the fourth was saved only by vigorous serotherapy. No cause for the tetanus could be discovered except the possibility that the umbilicus had been dressed with some kaolin which by mistake had not undergone the supposed sterilization. This experience suggests that *bolus alba*, talcum powder, etc., should never be used to dress wounds, dust gloves, etc., in the clinic without thorough preliminary sterilization. He tests the thoroughness of the sterilization by Stieh's technic, that is, the melting of a strip of alloy in a test-tube introduced into the center of the material being sterilized. Unless the alloy is melted he refuses to use the material in question.

128. **Sterilization of Women by the Roentgen Rays.**—Görl reports 9 cases in which the menopause was brought on by Roentgen exposures. Some of the women required 80 exposures for the purpose, and this slow, gradual extinction of the ovarian functioning he regards as one of the advantages of the method. He states that the general stimulating action of the rays was soon evident in the improved general health; no climacteric disturbances were noted in any case, and the heart seemed to be favorably influenced in the myoma cases. The exposure was never strong enough to induce erythema, and thus it cannot act directly on a myoma, but the myomas subsided nevertheless, probably secondary to the sterilization process. The method is especially indicated, he says, for menorrhagia from a cardiac defect, nephritis or myoma when operative treatment is inadvisable for any reason.

130. **Cosmetic Injection of Human Fat.**—In Holländer's case a chorus girl of about 21 became strikingly thin in the face and neck while the rest of the body was well nourished. The progressive loss of adipose tissue was corrected by injection of a mixture of equal parts of tallow and human fat, filling out all the hollows in the face. He has ascertained by experiments that the fat is soon absorbed, leaving a porous scaffolding of tallow which forms an organic combination with the connective tissue. His patient's complexion had been sallow, which he found had been the result of the relaxation of the skin and contraction of the elastic fibers, as at once after the contours had been rounded out the skin became rosy again.

133. **Treatment of Stenosis of the Pylorus.**—Jann advocates resection or exclusion of the pylorus as the only rational treatment of stenosis unless the extent of the lesion and adhesions or the general condition prevents such a serious operation. Gastro-enterostomy he regards as merely a palliative operation, only to be preferred in case of necessity.

134. **Atropin in Gastric Ulcer and in Internal Medicine in General.**—Schiek reports the prompt healing in some very serious, obstinate cases of gastric ulcer under a systematic course of atropin, and he expatiates on the importance of this too much neglected remedy in internal medicine. His experiences parallel those of von Tabora; the atropin evidently soothed and relaxed the musculature of the stomach and pylorus while checking the gastric secretion. When all other measures have failed and operative treatment seems indispensable, he injects subcutaneously, twice a day, from 0.001 to 0.0015 gm. atropin sulphate, morning and evening, keeping this up from 4 to 10 weeks with the patient on a milk-cream diet. The healing of the ulcer in his cases was counteracted by motor insufficiency of the second degree and hypersecretion. The atropin paralyzes the vagus innervation of the stomach, which is evidently functioning abnormally in these cases. The subjective symptoms subside generally at once, and perseverance with the atropin reduces the tendency to excessive secretory functioning. The frequent discovery of vagus irritability with gastric ulcer is more than a casual coincidence; each aids in producing a vicious circle, fostered still further by reflex action. He has found atropin useful also in treatment of spastic constipation, spasmodic asthma, pylorospasm, lead colic, cardiospasm and gall-stone colic. By the relaxation induced by subcutaneous injection of atropin, the walls of the ducts allow the stone to pass along or to fall back into the gall-bladder. This treatment, he believes, might prove useful also in kidney-stone colic; Loewi has reported brilliant results from atropin in reflex vasomotor angina pectoris. Surgeons might find atropin useful also, Jann says, in preparing patients with the status lymphaticus for operation. It is also useful to differentiate spastic contraction of the stomach from organic retraction of the stomach walls; in several cases of hour-glass stomach Schiek noticed various signs indicating extreme excitability on the part of the vagus. Before giving atropin, the condition of the nervous system must be carefully investigated. If the vagus is abnormally irritable the drug can be given with confidence, he states, up to 0.091 or 0.062 gm. a day. In the absence of signs of abnormal excitability of this part of the nervous system the greatest caution is necessary; active delirium and other serious by-effects may be observed when the exact indications for it are not heeded.

136. Bohac and Sobotka discuss further their previously published experiences with "606," mentioned in THE JOURNAL, Sept. 3, 1910, p. 898.

147. **Hemorrhagic Infarct in the Pancreas.**—Hofmann reports a case of hemorrhagic infarct of the pancreas in a woman of 57 who had suffered for years from cramps in the stomach, but she had never presented signs of jaundice. A sudden violent pain in the region of the umbilicus and collapse were the first signs of trouble in the pancreas, but she soon roused, though still complaining of intense abdominal pain. The entire abdomen was tender and slightly distended, the right lower portion bulging, pulse 90, temperature 38.6 C. The areas of greatest painfulness were in the stomach region and below the costal arch on each side; there was nothing to indicate sepsis, however. The pancreas was tamponed and drained, but septic symptoms then developed and the patient died the third day after the operation, which seemed to benefit her at first. Another patient is subject to paroxysmal exacerbations of a chronically recurring pancreatitis. In one such attack the pancreas was felt to be unusually hard and the merely exploratory laparotomy seemed to benefit, as all the disturbances subsided afterward. In this case an obliterating endarteritis is probably responsible for the recurring disturbances. The stormy onset with collapse followed by subsidence of the shock symptoms and relatively good pulse are characteristic of hemorrhagic infarct or apoplexy of the pancreas, especially in combination with the absence of motor restlessness and unimpaired consciousness with the signs of peritonitis—the clinical picture thus differing in these respects from that with perforation of a viscus. Another striking feature in the first case was the enormous distention of the cecum and ascending colon, evidently the result of compression of the transverse colon by the swollen pancreas. Drainage and tamponing are seen to be ineffectual treatment; Hofmann believes that if he had resected the infarcted segment of the pancreas the patient might have survived. At the autopsy this part shelled out readily without loss of blood.

- 150 *Acute Influenzal Urethro-cystitis. G. Ghedini.
151 Alimentary Albumosuria. I. Belfiore.

150. **Influenzal Urethro-Cystitis.**—Ghedini reports what he thinks is the third case on record of acute inflammation of the urethra from the action of influenza bacilli in the blood. The 2 other cases were reported by Cohn and Klieneberger; a large number of cases of cystitis due to the influenza bacillus are on record. His patient was a woman of 35 with acute catarrhal gastro-enteritis and the influenza bacillus in the blood. As the symptoms of this were subsiding, signs of urethro-cystitis developed and the temperature ran up again. It subsided the fourth day with a crisis and the symptoms on the part of the urethra and bladder had all disappeared by the end of the week. Comby has reported 3 cases of painful, rebellious and hemorrhagic cystitis of influenzal origin.

154 Granulated Leukocytes in Pus. M. Abetti.

152. **The Hypophysis Cerebri and Castration.**—Fichera discusses the results of research in this line by various writers, including 4 monographs on the influence of castration in human beings and 10 on experimental work in this line. The hypophysis hypertrophies after castration, suggesting a possible correlation between it and the genital glands. The contradictory findings that have been published he explains as due to the different ages at which the castration was done; a pronounced influence on the size and functioning of the

hypophysis is most likely, he says, when the castration is done in very young individuals.

156 *Pseudocirrhosis of the Liver of Pericarditic Origin. C. Martelli.

156. **Pseudocirrhosis of the Liver of Pericarditic Origin.**—Martelli's patient was a boy not quite 5 years old and the clinical course and autopsy findings were typical of Pick's disease. At the same time, Martelli protests against the assumption that this is a special syndrome; ascites occurs with adhesive pericarditis just as cirrhosis of the liver, compression of the portal vein and peritonitis are liable to be accompanied by ascites. In neither case are there any grounds for setting up the syndrome as a special morbid entity. The child in his case had malaria when quite young and was brought with his family to New York at the age of 4. The emigration authorities did not allow the family to enter the country and they stayed at Ellis Island, he states, during the summer and fall, the heat, the crowding and poor food causing great discomfort. The child in question was taken there with an eruptive fever, probably scarlet fever, the sore throat, swelling of the feet and intestinal disturbances keeping the child in the hospital for 3 months, after which the family was deported to Italy. Signs of adhesive pericarditis developed a year later in the child, proving fatal in 10 months.

THE BACTERIOLOGY OF ACUTE RESPIRATORY INFECTIONS IN CHILDREN AS DETERMINED BY CULTURES FROM THE BRONCHIAL SECRETION

L. EMMETT HOLT, M.D., LL.D.

Professor of Diseases of Children, College of Physicians and Surgeons (Columbia University)

NEW YORK

In December, 1908, an investigation was begun in the Babies' Hospital to determine what information could be gained in respiratory infections from a study of cultures of bronchial secretions. For the first season interest centered on the *Bacillus influenza* to gain, if possible, some definite information as to its frequency and importance in respiratory infections, and also to see what value, if any, could be attached to sputum cultures in the diagnosis of influenza. The first season's observations extended from December, 1908, to June, 1909, and were made on 250 patients and 40 nurses in the

of this paper a detailed report concerning the *Micrococcus catarrhalis* which was found in about two-thirds of the cultures made. Thus far we have not been inclined to consider its presence as significant or important.

During the past season, from the middle of September, 1909, to June 1, 1910, there have been made, from over 500 patients and 30 nurses and attendants, over 1,100 cultures from the secretions of the respiratory tract during life. There have been made, in addition, cultures from the lungs and heart's blood in 85 routine autopsies. It has been our custom to make a sputum culture from every patient admitted to the wards; at intervals to take cultures from all the inmates of the hospital—patients, physicians and nurses. In most of the acute respiratory cases, especially in the protracted ones, repeated cultures were made. Frequent cultures also were made in most of the febrile cases of obscure diagnosis.

The patients were inmates of the Babies' Hospital and for the most part under three years of age. In taking

Babies' Hospital. The method pursued and results obtained have been set forth in a previous paper.¹ They indicated that the *B. influenza* played a very important part in respiratory infections, especially in winter and early spring, being second in importance only to the pneumococcus. Our observations, however, showed that it played no part in these infections during the warm months, for it disappeared entirely toward the end of May, as soon as permanent warm weather came, and it was not found again until about the middle of October. Pneumococcus infections, on the contrary, persisted throughout the summer months.

During the past season the scope of the study has been somewhat enlarged and has included observations on the occurrence in the secretions of the respiratory tract, both in healthy and diseased persons, of the pneumococcus, the *B. influenza*, the *Staphylococcus aureus* and the streptococcus. In our present report we are not especially concerned with the diphtheria bacillus, and it will be mentioned only casually, although it was noted when present. Nor has there been included in the tables

cultures, so far as possible, the bronchial secretion was secured. Control cultures were taken from the nasopharynx, pharynx and nose in about forty-five cases to determine the variations. Anterior nasal and pharyngeal cultures often disagreed with the bronchial cultures, and hence were deemed rather unreliable as representing the nature of the respiratory infection. Results obtained from the naso-pharyngeal cultures in the main corresponded closely with the bronchial cultures, but were much more difficult to obtain. To avoid contamination it was found necessary, if there was much mucus present, first to cleanse the mouth and sometimes even the pharynx. A curved swab was then passed behind the soft palate into the nasopharynx.

The method of taking the bronchial cultures I have already described. It consists in inducing a hard cough by pharyngeal irritation and catching on a swab the secretion excited by the cough. The cultures may, therefore, be considered to represent fairly accurately the bronchial flora rather than the pharyngeal flora.

The results of the clinical cultures made from Sept. 20, 1909, to May 1, 1910, are shown in Table 1.

The patients are divided into four groups:

1. Holt, L. Emmett: The Bacteriology of Acute Infections of the Respiratory Tract in Children, with Especial Reference to Influenza. Arch. Int. Med., 1910, v. 449.

Chart 1.—Temperature in Case 1. Influenza, bronchitis, double otitis and bronchopneumonia.

Chart 3.—Temperature in Case 3. Influenza, bronchopneumonia and otitis.

Chart 2.—Temperature in Case 2. Influenza and slight bronchitis.

1. Those with pneumonia. Most of the pneumonias were of the acute primary type, bronchopneumonia being much more common than the lobar variety. Only a few of the pneumonias were secondary to other infections. A small number were terminal infections in children suffering from marasmus.

2. Those with bronchitis and other respira-

tory infections, laryngitis, tracheitis, etc. The cases included in this group were for the most part rather mild infections.

3. Those with pulmonary tuberculosis.

4. Those with non-respiratory diseases. These were surgical patients, children admitted for disordered nutrition (feeding cases) or other chronic diseases, or healthy infants. In this group are included thirty nurses and attendants.

What a mixed infection the acute pneumonia of early life is, this table shows in a striking manner.

Pure cultures were practically never seen, although a single dominant type of infection was present in very many cases. The table shows in the different groups the frequency with which the different organisms were found in the cultures, and also the number of patients in which they occurred.

In the first group, the pneumonias, and, in fact, in all the groups, the predominance of the pneumococcus and *Staphylococcus aureus* will be noted. The percentage of cases showing the *B. influenzae* falls considerably below that observed in the previous season. The streptococcus was rarely the predominant organism found, although present, usually in small numbers, in over one-half the patients and about one-third the cultures taken. The probable explanation of this small percentage is that few of the pneumonias were secondary to such infections as measles, diphtheria, etc.

That the character of the infection in bronchitis is essentially the same as that in pneumonia is not generally appreciated. In the second group of mild respiratory infections, however, it will be noted that the relative frequency of the different organisms found in cultures is about the same as in the first group, except that the percentage of influenza cases is higher. In the third group, the tuberculous cases, the pneumococcus and *Staphylococcus aureus* still predominate. In the fourth group, non-respiratory cases, it is not surprising to find the *Staphylococcus aureus* in about 85 per cent. of the patients and of the cultures, and the streptococcus in about one-half this number. It is, however, rather surprising to find that 52 per cent. of the patients showed the pneumococcus, but it should be remembered that the season was the winter and spring and the patients were hospital inmates. The proportion of influenza cases falls the lowest in this of any of the four clinical groups; but it was found in 19 per cent. of the patients.

I have appended to the table the results of cultures made from 57 cases of acute otitis after fresh paracentesis, as otitis is so frequently associated with acute infections of the respiratory tract in children. It is noteworthy that while about one-half the patients with otitis showed the *B. influenzae* in throat cultures, in only four patients (both ears in two of them) did the cultures made after paracentesis show the *B. influenzae*; the predominant organism was the *Staphylococcus aureus*.

It is desirable, and we hoped it might be possible, to connect certain clinical symptoms and definite cultural findings. In many cases with experience we were able to predict the predominant type of infection, but in very many others it was impossible. The great difficulty apparently lies in the mixed character of the infection, which has already been emphasized, so that the clinical picture, like the cultural findings, was usually of a mixed type. In one group, for instance, a predominant influenza infection, in another a predominant pneumococcus infection, and in others a predominant staphylococcus infection; but these were seen in all possible combinations. There

were many variations in the clinical course of the infections which could be explained by the cultures. In fact, it became evident that a very extended experience will be required before this can be done with even an approach of accuracy.

Very few examples were seen of what we are accustomed to regard clinically as acute pneumococcus infection of the lung—viz., cases with an abrupt rise in the temperature followed by a steadily high range and a critical fall. The pneumonia cases were for the most part atypical both in course and duration. It is my own belief that it is the other organisms present, especially the *Staphylococcus aureus* and the *B. influenzae*, which are largely responsible for these variations.

In our series of cases we were unable to see any definite modification of the symptoms in those which showed the streptococcus in the cultures, except in a few, which were of exceptional severity.

The *B. influenzae* was often present in small numbers, when it did not appear to have any effect on the symptoms, but many of the most irregular and puzzling cases were associated with its presence. A study of this organism in quite a large series of cases led to the conclusion that when present in numbers it did produce quite definite symptoms. We came to recognize several fairly distinct clinical types associated with influenza infection:

1. Cases with pneumonia often small in extent, sometimes with signs only of bronchitis, but with very wide and irregular fluctuations of temperature which occurred without any apparent cause.
2. Very protracted cases with exacerbations and remissions.
3. Recurring cases of pneumonia in which a succession of attacks followed each other, separated by an interval of days or weeks with partial or apparently complete recovery.
4. Cases showing constitutional symptoms of only a mild infection judging by the pulse, the nervous symptoms and the amount of general prostration, but with quite extraordinary fluctuations of temperature which was usually high and very irregular in its course. A small area of pneumonic consolidation sometimes appeared late in these cases. However, there were in many instances no evidences of consolidation and only râles in the chest; in some cases these were few and inconstant.

The presence of the *B. influenzae* was more frequently associated with symptoms of the lower than with those of the upper respiratory tract. In general, influenza infections were characterized by mild general symptoms, by very irregular physical signs and by wide and irregular fluctuations of temperature.

ILLUSTRATIVE CASES

In the following case-reports examples are given of what we have been accustomed to call influenza infections, together with the evidence on which the diagnosis of influenza rested. The charts have been selected from a great number and are fairly characteristic of the clinical conditions met with.

CASE 1.—*Influenza; bronchitis; double otitis; later bronchopneumonia; death; autopsy.* The patient was a delicate child 9½ months old, admitted December 3 with a second attack of acute bronchitis; previously ill for one week. The entire family at home were reported suffering from coughs and colds at the time. On examination there was found moderate prostration and scattered râles throughout the chest. Three days later, on December 6, double otitis developed and paracentesis was done on both ears. The operation was repeated on both ears on December 13 and again on the left ear on December 15 and 27.

The râles in the chest persisted, but not until December 21 were there any signs of consolidation of the lung and then

only over a small area. These signs never cleared up; the prostration steadily increased and with failing nutrition the child died on January 16 of exhaustion.

During the course of the illness the principal interest attached to the wide fluctuations of temperature, chiefly between December 10 and 20. The daily excursion was at times as much as 10 degrees. There were no chills. Such a temperature occurring in a case of otitis after both ears had been opened and with a constant tendency to close led the surgeon to suspect sinus thrombosis or mastoiditis. Further operation was opposed, partly on account of the child's poor general condition, but also for the reason that as the throat cultures showed the *B. influenzae* it was thought that this might be the explanation of the unusual temperature variations.

At autopsy a very small amount of bronchopneumonia was found. The cultures from the lung showed the *B. influenzae* and the pneumococcus. The mastoid and the sinus were carefully examined by the aural surgeon himself and no trace of disease could be discovered.

CASE 2.—*Influenza; slight bronchitis.* This child was under

Chart 4.—Temperature in Case 4, unresolved pneumonia and influenza.

Chart 5.—Temperature in Case 5, prolonged bronchopneumonia and otitis.

observation for three and a half months and in spite of the recurring attacks of fever he was never very sick and gained steadily in weight, on the average about a pound a month. He was a delicate infant, 9 months old, weighing on admission but 10 pounds. He was brought to the hospital on account of poor nutrition and a slight cough. A few coarse scattered râles in the chest could be heard most of the time during his stay but there were no fine râles and no signs of consolidation were ever present.

During the first period of fever, from October 13 to 23, the digestion was not particularly disturbed; and the pulmonary signs did not increase. No cultures were taken at this time. There followed then an interval of nearly two weeks with normal temperature and no signs of illness except an occasional slight cough.

The second rise of temperature came on without apparent cause, with no obvious disturbance of digestion, and no new signs in the chest. No sufficient explanation of this temperature could be found, and as during the previous attack the patient did not seem very sick even when the temperature was as high as 105 F. The urine was normal, and also the ears though frequently examined. No malarial organisms could be found in the blood. The Widal test was negative and the spleen was normal. The tuberculin test was negative. The leukocyte count was low, the average of several examinations being 7,000; the polymorphonuclear percentage ranged from 31 to 36.6. Influenza was suspected but repeated cultures from the bronchial secretion at this time failed to reveal this organism. The temperature subsided before any satisfactory diagnosis could be made.

After a normal interval of about a week a third period of temperature began which continued nearly three weeks; although it was not quite so high as the previous attack, it was of the same irregular type. During this febrile period the sputum cultures showed the *B. influenza* constantly. There were no more general or local symptoms of illness than during the previous periods of fever. A positive agglutination reaction was obtained with the patient's own influenza organisms. I believe that all the febrile attacks were due to the influenza and that the organisms were missed in the early cultures.

Four injections, 75 millions each, of a polyvalent, heterogenous influenza vaccine were given to this patient on January 7, 13, 20 and 26. The temperature did not rise again and the subsequent course suggests that some benefit resulted from the vaccines, but this cannot be definitely affirmed. As in the previous case a disposition of the temperature to go to subnormal after the marked fall is noteworthy.

CASE 3.—Influenza; bronchopneumonia; otitis; death; autopsy. The patient was a delicate child, 7 months old, admitted December 5 on account of its poor nutrition and cough. No symptoms of acute illness were present. During the first two weeks a slight rise of temperature was noted occasionally as shown in the chart. The temperature was then normal until December 31. With this acute rise in the fever the symptoms of bronchopneumonia developed with a small consolidation in the right lung. There was very little change in the signs or the symptoms for the next ten days. Otitis then developed and both drums were opened on January 12. Three days after this a small spot of pneumonia was discovered in the opposite lung. The signs in the lungs did not increase with the high temperature nor did they diminish with the fall in the temperature which succeeded. The child steadily lost strength, however, and died from exhaustion.

The autopsy showed an ordinary bronchopneumonia of moderate extent; no other lesions of importance. The bronchial cultures during life repeatedly showed the *B. influenza*. Cultures from the lungs at autopsy showed the *B. influenza* but no pneumococci.

CASE 4.—Unresolved pneumonia; influenza. The patient was a boy 2 years old, admitted January 21 with a history of two months' illness with pulmonary symptoms and a diagnosis of pneumonia. Temperature on admission was 103 F. Physical signs pointed to a partial consolidation in the right upper lobe behind. Leukocytosis of 40,000; polymorphonuclear percentage, 79. By January 31 nearly all the signs in the chest had disappeared; leukocytosis 14,000.

The patient continued to improve until February 7, there being present in the chest during this time only occasional coarse râles, bronchovesicular respiration and slight dulness over the area previously noted. Following the rise of temperature on February 7 an increase in the signs in the chest took place. More râles were present; they were of finer quality and over a larger area, but only on the right side. There was no definite consolidation. The leukocyte count ranged from 20,000 to 28,000 during the next few days. This exacerbation was of brief duration and after four or five days the only signs in the chest were those which had been noted before the rise in the temperature. During the following three weeks the irregular fluctuations in temperature shown in the chart occurred with no special change in the local or general symptoms. The child coughed moderately but did not appear very sick at any time.

Repeated sputum cultures showed the *B. influenza*. There was no temperature after that last recorded. Careful and repeated examinations were made in this case of the urine, the ears and the blood, without revealing any other cause for the temperature. The inference seemed a fair one that the temperature was due to the influenza infection.

I think that the cultures which we have made go far toward establishing the fact that the *B. influenza* plays a considerable rôle in the respiratory infections of young children. We have tried the use of influenza vaccines in about half a dozen cases without any very decisive results, but I feel that this is a subject demanding further investigation. Their use is indicated especially in the very protracted or in recurring cases of influenza infection. Such an infection, we have shown, may continue for three months, and may probably last a much longer period.

With reference to the precise influence of the streptococcus and *Staphylococcus aureus* on the symptoms and course of respiratory infections, I feel more hesitancy in expressing an opinion. The *Staphylococcus aureus*, I am convinced, plays a more important part in the bronchopneumonia and other respiratory infections of young children than has usually been accorded to it. We began our investigations with the view, which I believe is commonly held, that its presence was to be expected, not only in the sputum, but in autopsy cultures from the lungs, and that it was not significant. But a wider experience has led us to modify this opinion. When present in numbers the staphylococcus, I believe, modifies the symptoms of pneumococcus infections. In some cases it certainly seems to be the predominant organism. We have found this to be true of some cases characterized by temperature not very high, and with rather narrow fluctuations, and with constitutional symptoms of only moderate severity.

The following case, however, seems worth recording. It made a strong impression on all who followed it:

CASE 5.—Prolonged bronchopneumonia; otitis; cure (?) by staphylococcus vaccines. This patient was a premature infant 7 weeks old, and its weight November 25 when the elevation of temperature began was only 3 pounds, 12 ounces. The temperature continued in this case for more than three and a half months. The complete chart is too long for reproduction but the temperature for the periods omitted was exactly like that which preceded and followed them.

The daily fluctuations were for the most part narrow, the usual range being 100 to 102.5 F.; it never touched 104 F. and very rarely went to the normal line. During the greater part of this time there were localized coarse and fine râles in the right lung behind. These signs persisted and from time to time were heard throughout both lungs. There were no signs of consolidation at any time. The infant had a moderate cough but never seemed very sick. The persistent physical signs and the temperature led to a suspicion of tuberculosis but the skin test was negative and no tubercle bacilli

could be found in the sputum. The blood showed a leukocytosis of from 12,000 to 16,000. The child's weight slowly increased to 5 pounds 14 ounces by March 13. On January 12 otitis developed and the left ear was opened; subsequently the right ear was affected and was opened January 20.

The culture card of this patient for January and February is reproduced in full and shows exactly the findings on the different days. As influenza vaccines were being used at this time in some other cases, and as the influenza bacillus was occasionally present in the cultures of this patient, they were first tried. Three injections of a heterogeneous influenza vaccine were administered on January 29, February 3 and 8; the first dose was 50 millions, the second and third 30 millions each. Although the temperature was not quite so regular in its course during and for a few days after these injections, no real benefit seemed to follow.

During February several quite large furuncles appeared over the chest and abdomen. This circumstance coupled with the persistence of great numbers of staphylococci in the sputum cultures led to the suspicion that the essential process in this patient might possibly be a staphylococcus infection. On February 22, 27 and March 5 and 11, injections were given of a staphylococcus vaccine from a stock culture, each dose being 30 millions. The effect on the temperature was immediate and striking, as is shown by the chart. After each injection there was a fall and after the last injection no further rise occurred; but what was quite as surprising, the long persisting signs in the chest quickly and permanently disappeared. From this time the gain in weight rapidly increased and the child was discharged quite well on April 25.

One hesitates to make any deductions from a single case, but the length of observation of this patient and the close study which was possible makes it worthy of the record. I cannot believe that cases of this kind are so very rare.

POST-MORTEM OBSERVATIONS

Turning now to the post-mortem findings, we have observations on 138 autopsies made during the fall, winter and spring months. I have included those of the season of 1908-1909, not previously published in detail. These autopsies were practically consecutive; cultures were invariably made unless the examination was hurried or partial. As a rule autopsies were made early, most of them within twelve hours and very many within six hours after death. All bodies were immediately placed on ice unless the weather was cold. Post-mortem changes do not, I believe, play an important part in the findings. Cultures were made from the part of the lung showing the most extensive disease and in every instance from both lungs. There was substantial agreement of the findings from the two lungs, so that it has not been thought important to separate them. The main facts are given in Tables 2 and 3.

It will be noted that of the 138 cases there were 76 of pneumonia, 20 of bronchitis, 29 of tuberculosis, and in only 13 was there no disease of the lungs. The small number with no pulmonary disease is accounted for by the fact that no summer autopsies are included.

In general the post-mortem findings correspond with the clinical findings by sputum cultures as indicating the

type of infection. Mixed infections were seen in the great majority of the cases. The *B. influenza* was found in the lungs four times in pure cultures; the pneumococcus was found pure in six cases. In this connection I should like to mention one case in which at autopsy a pure culture of influenza was obtained from a sero-fibrinous pleural exudate, and another in which a pure growth of this organism was obtained from empyema pus drawn by aspiration in a patient who recovered. This patient's bronchial secretion gave also a positive influenza culture.

Omitting the staphylococcus, a single organism was found in but 13 of the 138 cases. The significance of the finding of the staphylococcus alone in 26 cases is somewhat doubtful.

Cultures from the heart's blood were made in 117 cases, in 71 of which there was no growth. The *B.*

TABLE 2.—POST-MORTEM CULTURES

	Lungs, 138 Cases—		Heart's Blood 117 Cases.	
	Cases.	Alone.	Cases.	Alone.
<i>B. influenzae</i>	37	4	1	0
<i>Pneumococcus</i>	53	6	8	5

<i>Catarrhalis</i>	7	0	0	0
<i>Pyocyanus</i>	3	0	3	2
<i>B. coli</i>	1	0	2	1

TABLE 3.—POST-MORTEM CULTURES (138 CASES)

Growth from Lungs.	Pneumonia, 76 Cases.	Bronchitis, 20 Cases.	Pulmonary Tuberculosis, 29 Cases.	Non-Respiratory, 13 Cases.	Total.
<i>B. influenzae</i> alone.....	2	2	0	0	4
<i>Pneumococcus</i> alone.....	4	1	0	1	6
<i>Streptococcus</i> alone.....	1	0	0	0	1
<i>Staphylococcus aureus</i> alone.....	8	6	8	4	26
<i>B. influenzae</i> and pneumo- coccus.....	5	1	0	0	6
<i>B. influenzae</i> and strepto- coccus.....	5	0	2	0	7
<i>B. influenzae</i> and staphylo- coccus.....	7	1	2	0	10
<i>Pneumococcus</i> and strep- tococcus.....	1	0	1	0	2
<i>Pneumococcus</i> and staphy- lococcus.....	11	1	5	2	19
<i>Pneumococcus</i> and catar- rhalis.....	5	0	0	0	5
<i>Staphylococcus</i> and strep- tococcus.....	10	1	7	3	*21

* The remaining 31 autopsies showed various other combinations of the above organisms, or of them with *pyocyanus*, *B. diphtheriae*, or *P. coli communis*, but not more than two cases of any one variety.

influenza was found but once, and then not alone; the pneumococcus in but 8 cases; in 5 of these alone. Only the streptococcus and staphylococcus were at all frequent, being found, respectively, in 22 and in 17 cases.

Cultures such as those which we have been making involve considerable labor. Are they of any practical value to the physician? My own belief, after an experience extending over two years, is that they are of great assistance in diagnosis, especially in influenza infections. In cases where the symptoms led us from our experience to suspect influenza we seldom failed to find the organism, usually in the first or second culture, but occasionally not until repeated cultures had been made. These give much more definite results than the search for tubercle bacilli in suspected cases.

The discovery of the *B. influenza* in sputum cultures in cases of obscure high temperature, in cases of recur-

ring bronchopneumonia, or pneumonia running an unusual course, or of high temperature persisting in cases of otitis in which the ears had been opened, or after surgical operations, of course does not establish the fact that the temperature is due to this infection; but when this organism is found repeatedly and in large numbers associated with such symptoms it is, in the winter and spring season at least, extremely probable.²

Further evidence that the presence of the *B. influenza* in the nasopharyngeal and bronchial secretion is significant is shown by the fact that of three recent cases of influenza meningitis which I have seen, the cultures showed in each case the influenza organism in the nasopharynx, and in two in which the examination was made they were also present in the bronchial secretion.

No one realizes more than I that a much more extended study and many series of observations must be made before it will be possible to establish relationships between bronchial or nasopharyngeal cultures and clinical symptoms in respiratory infections. The separation of the respiratory infections is admittedly difficult, but I believe it to be quite as desirable as in the case of intestinal infections. To what extent vaccines may be found useful it is impossible to say, but it is certain that any form of specific treatment must be based on a knowledge of the nature of the infection.

In conclusion, I desire to express my indebtedness to Dr. Martha Wollstein, pathologist of the Babies' Hospital, and to Dr. Josephine Hemenway, resident physician, for their invaluable assistance in the observations recorded in this paper.

14 West Fifty-fifth Street.

THE NEGRO AS A HEALTH PROBLEM *

H. M. FOLKES, M.D.
BILOXI, MISS.

In the South, regardless of hair-splitting dictionary or legal definitions, it is customary to regard as negro any person who is known to have any negro blood in his veins; this despite the fact that the Supreme Court of Louisiana has lately handed down a decision restricting the term "negro" to those having a greater proportion of negro blood than would occur in an octoroon. This decision, however much it may be law, has not been the custom.

It may not be commonly known in the North that prior to the war it was the custom in the South among the better class of slave owners to give the very best care and attention to the slaves—to the house-servants as well as every other class of laborer generally. Of course, while due credit must be given to the humane motive at the bottom of this, it must be acknowledged that the economic consideration was also largely influential, as each negro, old, or young, possessed considerable cash value. Hence it was decidedly to the interest of the property owner to take care of his investment.

The natural result of this was a higher standard of physical health among negro children than has ever

been attained since the emancipation, for among other unfortunate sequelæ following this perfectly righteous step was the handing over of the lives and care of negro progeny to their more or less fatalistic parents, who, removed from the control of intelligent direction, soon lapsed into their African condition of irresponsibility. The unfortunate creatures (as the negro race has done in all history) then reverted, in a large measure, to aboriginal conditions.

The negro, due to his heredity and environment, is essentially a fatalist, and when moved at all it is by his emotions, and not by judgment.

It must be understood, however, that for the first ten or fifteen years following the war many negroes, especially those who had been most closely associated with the white people, that is to say, the house-servants, continued to follow the training and habits which had been ingrained during their more intimate association. To those of us who have been born and raised in the South, it requires but a few moments' contact with the individual darkey to judge of his earlier training.

That negroes are devoid of love and affection for their offspring is not true, yet I have been repeatedly struck by the fact that they can and do yield a greater degree of affection, solieitude, and attention to white people than they will continuously accord their own family. Mark well the use of the word "continuously," for it is this phase of the problem which is curious from the psychologic standpoint. A striking illustration of this is the devotion so markedly shown by slaves to their owner's family while the master was at the front during the war.

These preliminary remarks are essential to the study of this question, for it must be borne in mind that among intelligent people who have had training in sanitary laws a degree of exemption from infectious diseases among their children may be looked for, whereas this seldom applies to the negro. Exemption is practically a result of unconsidered cause, such, for example, as might apply to the power of resistance as exhibited in heredity, environment, habits, etc. As further proof of this statement there may be noted the well-known fact that in those diseases to which negroes are more immune than whites, this immunity lessens in a marked degree as the negro blood is proportionally diluted by white; as an example of which may be cited the fact that among the blacks there is a relatively larger degree of immunity to malaria, typhoid, intestinal diseases, tonsillitis, mumps, influenza and yellow fever.

Mulattoes, octoroons and quadroons are much more susceptible to the infectious diseases and are especially more susceptible to the ravages of syphilis and gonorrhæa than are their more deeply tinted brethren. Negroes of all shades are extremely susceptible to tuberculosis, and also to measles. In my experience extending over a period of nearly twenty years, I do not recall having seen a case of scarlet fever, diphtheria, mumps or tonsillitis in black negroes, and since beginning this paper I have made inquiries of all the physicians with whom I have come in contact and have received practically the same answer as to the immunity of the pure-blooded negro from these diseases.

Mulattoes, quadroons, and octoroons are decidedly more susceptible to scarlet fever, diphtheria, mumps and tonsillitis, but with rather large experience among the different shades of negro people, I can recall at this moment but very few instances of these diseases among them.

2. Reference has already been made to the fact that in the spring of 1909 our influenza infections disappeared after about May 20. Precisely the same thing happened this year. Thus of 48 cultures taken between May 1 and 19, influenza was found in 19; of 19 cultures made between May 19 and 31, influenza was found but once, on May 23. At autopsy the *B. influenza* was found in cultures from the lungs but once after May 19, this being in a patient who was admitted two weeks previously.

* Read in the Section on Diseases of Children of the American Medical Association, at the Sixty-first Annual Session, held at St. Louis, June, 1910.

It might not be out of place at this point to call attention to the fact that mulattoes, quadroons, and octoroons, as they are at present in the South, are mostly descendants of their own type of people, and not the result of crossing of white and black bloods; in other words, mulatto man and woman have as progeny mulattoes; quadroons present the same as themselves, as also do octoroons. There is, however, a marked tendency toward a decrease in the number of children born to these light-colored negroes and the nearer they approach to pure white blood the fewer the children they have, as a rule.

Within the past ten years there has been a marked improvement in the South, both among the whites and negroes, in educational conditions and in the mode of living. Nearly all classes and conditions of people have better houses, better food, and have paid a larger degree of attention to matters of hygiene. Poverty makes for all the ills of life, but with greater returns for cotton during the past ten years the result has been a vast improvement among all Southern people, and as the white man benefits so also does his shadow, the negro.

One of the gravest problems confronting the whites in the South, however, is trying to find means of preventing tuberculosis among the negroes of all shades and degrees. When it is remembered that practically all household service in the South is rendered by negroes it can be seen how necessary it is that the white people guard themselves against this evil which the negro race carries with it.

Bearing in mind the fatalistic tendency of the darkey, one should easily understand why it is difficult to get them to abandon their habit of carelessly spitting around the house, and the injurious practice of hermetically sealing their sleeping apartments, as nearly all do. Those who have directed much attention to health matters know how difficult it is to get any class of people to fear dangers that they cannot see or realize, and it is a thousand times more difficult to get the negroes to grasp the idea that there may exist anything in microscopic life that could be a menace to their health.

With a population of approximately 10,000,000 negroes living in the South, with every disease-carrying possibility and proclivity, as may be instanced in tuberculosis, uncinariasis and amebiasis, it may be seen that the problem before us is not alone political, but one striking at the vitality of the race. I protest against any attempt made toward keeping these poor unfortunate creatures from being educated. Education in any degree never hurt any race and instead of ceasing the attempt to educate negroes, they should be taught their duty to their neighbor as well as to themselves. It was my privilege and pleasure to advocate ten or fifteen years ago the teaching in the public schools of the natural history of disease and the inculcation of the idea that it is far better to prevent disease than to attempt its cure when once acquired. Hospitals are a great blessing, as are also any other humanitarian projects, but it is infinitely a better and wiser plan to prevent diseases than it is to wait to cure them.

No better place than here can be found to emphasize the sad fact that the negro race, including all shades, is, in this country, at least, an immoral people. There are, of course, exceptions, though generally speaking this statement is correct, and to prove it we have the striking testimony and evidence of one of their own race in the person of William Hannibal Thomas of Massachusetts, who in his "American Negro" says:

My study and questioning of the average negro as he exists in the United States to-day, has convinced me that he is bestial by nature, that he holds in no regard whatever such virtues as may be present in the mothers, daughters, wives, and sisters among them. They revel in lewd conversation, erotic practices, and unlimited sensual pursuits. Especially do they delight in encouraging the approaches of whites among the women of their kind. That such licentiousness is prevalent is not surprising when we reflect that animal impulse is the sole master to which both sexes yield unquestioning obedience.

As illustrating the contradictory nature of the negro, the same writer avers:

While imputations of immorality are resented by the known impure, there is a common disposition to question each other's morals, and rarely is either male or female accorded a clean bill of approval. . . . Marital immoralities are not confined to the poor, the ignorant and the degraded among the freed people, but are equally common among those who presume to be educated and refined.

To one who is a southerner born and bred it is a source of the greatest pride to know that in the South to-day there is found a proportionately larger number of the pure Anglo-Celtic type of people, with fixed determination to prevent that miscegenation which would Africanize this country. As an American who loves his native land from the Atlantic to the Pacific and from the Canada line to the Gulf of Mexico, and as a medical man, I warn the white people of this country against this insidious evil which to-day is sapping the very foundation of that Aryan blood which stands for the republican form of government and the highest type of civilization.

Miscegenation in the North is certainly at this day more in evidence than it is in the South, and if decided steps are not taken against this curse by the white people of that part of the country, they are creating for their descendants a Frankenstein monster indeed. In the South this phase of the question is practically settled. A white man to-day who wilfully lives with a negro woman, be she black or yellow, is ostracized, and in nearly all our southern states severely punished. But from the standpoint of a national menace the negro question is so glaringly in evidence that it is along these lines that this paper is presented.

Howard and Reynoir Streets.

HEMIPLEGIA FOLLOWING ACUTE INFECTIONS *

W. A. JONES, M.D.

AND

ARTHUR S. HAMILTON, M.D.

MINNEAPOLIS

The cerebral palsies of childhood have received considerable attention in certain rather elaborate treatises; such as those of McNutt, Lovett, Osler, Sachs and Spiller in this country, and of several writers abroad, but aside from these not much has appeared on the subject. Thus, even in the most elaborate systems of medicine, paralysis of central origin in diphtheria is given the briefest consideration, or else is not mentioned at all. These facts are thought to justify the publication of the following reports of cases.

CASE I.—*History*.—The patient, a schoolgirl, aged 9, was seen at the University Free Dispensary Feb. 8, 1908. Her

* Read in the Section on Nervous and Mental Diseases of the American Medical Association, at the Sixty-first Annual Session, held at St. Louis, June, 1910.

father was living at 38 and well except that he was nervous; her mother was living and well at 36. She had had two miscarriages, both at about three months. Two brothers and one sister were living and well. A paternal aunt was paralyzed at 24, following labor. Another paternal aunt was extremely nervous. Otherwise the family history is negative. The patient's general health had been good. She was the second child. There was no trouble at her birth. She had croup in early childhood; had never had convulsions, but when a child had a habit of holding her breath when crying. She walked and talked at the usual age, and did as well in school as others. She was never seriously ill up to her attack of diphtheria, and was never seriously injured.

Present Illness.—In September, 1906, she had a severe attack of diphtheria with membrane in her throat and nose. She was given 12,000 units of antitoxin and seemed to progress ordinarily well until the middle of her attack when she developed darting pains in the right arm and leg. They were spasmodic, and each one lasted only two or three minutes. For four days the pain grew steadily worse and finally was very severe. It then began to decline and at the end of the week was practically gone. When present, the pain was worse in the arm than in the leg. There was no tenderness to touch between the attacks, so far as the mother recalled. The mother thought that even during the pain the arm and leg were rigid, and certainly they were so afterward. There was diplopia and some trouble in articulation for a short time following this attack. During the intervening two and one-half years up to the present time there had not been much change. The right arm was spastic with frequent more or less spasmodic contractions. The leg had been less spastic, but was still noticeably stiff, and the patient had slight trouble in walking, and considerable trouble in running. Attention always made the condition worse.

Physical Examination.—The patient was a moderately well-developed, well-nourished girl. The temperature was normal, the pulse 86. The forehead was somewhat low and narrow. The eyes and ears were normal, except for a slight tubercle on the right ear. The vault of the hard palate was high and narrow and very irregular. The teeth were set very irregularly. The arteries were soft. The apex-beat of the heart was in the mid-clavicular line. Otherwise the heart examination was negative. The right leg seemed slightly smaller than the left. The right arm was very firm and muscular and, evidently, better developed than the left. The measurements were as follows: The right forearm, a little below the elbow, 17 cm.; the left forearm, a little below the elbow, 16.75 cm.; the right calf 22.75 cm., and the left calf 23.5 cm. The patient was subject to frequent attacks in the right hand and arm of an athetoid character. The attack started in the hand with hyper-extension of the hand and flexion of the wrist. The hand was rotated until the palm was turned completely outward, when there was a flexion in turn of the second, third and fourth fingers. The arm was then rotated in the opposite direction until the palm pointed inward. The entire right arm and leg became spastic during these maneuvers. There was no pain associated with them. The patient had increased kneejerks, especially on the right side, but there was no ankle-clonus. There was a possible faint right Babinski. She seemed to feel cheerful and happy and was always active, although at times she said she was unusually tired. She had a little frontal headache occasionally.

Course of Disease.—Directly after coming to the dispensary the patient was placed on thyroid extract, 5 grains twice a day, and within a few days her arm and leg had made a very striking improvement—so much so that her parents were convinced of her complete recovery at an early date. The cause of this improvement was not easy to determine, but it was probably not due to the use of the thyroid extract, especially since, after three weeks, there was no further improvement, and within a short time there was a complete relapse to her former condition. She continued coming to the dispensary at more or less long intervals up to about the end of 1908. At that time there was no permanent improvement, but there had been several short periods of temporary benefit. On Dec. 19, 1908, when waked in the morning, she appeared un-

usually drowsy. When eating her breakfast she said that her face on the right side felt numb and later that it felt as if needles were pricking it. After a little time this feeling went to her right hand also. Finally, all the right side felt the same way. This condition of affairs lasted until 10:30 a. m., when the feeling began to go slowly away, but the patient was very sleepy for some time afterward. After the feeling had partially gone, the mother noticed that the hand and arm had lost their spasticity and were scarcely up to normal so far as tonus was concerned. There was also some lack of power in the hand and arm. On the afternoon of the first day of the numbness the patient was brought to our office at 3:30. She was then a little dull and heavy mentally, and there was still some feeling of numbness in the right side. The reflexes were about normal on both sides. The right arm hung rather limply by her side. There was absolutely no trace of spasticity or athetosis and all movements of the right upper extremity were performed with less power than those of the opposite side. There was some headache on the first day, and in the evening this became very severe. The next day she was stupid and weak, but when seen on the following day she seemed as well as ever, except that the condition of spasticity on the right side had returned. Shortly after this time she disappeared from observation and we have not been able to learn anything of her since.

CASE 2.—History.—The patient is a single woman, aged 22. The father is living and well at 51; at times drinks to excess. The mother is living at 47 and has heart trouble and tuberculosis. One sister died of diphtheria. One sister and four brothers are all well. There is no other nervous or mental trouble in the family, but a number of the mother's family have died of tuberculosis. The patient was always delicate but up to 12 years of age was never seriously ill. She had measles in childhood, but never had rheumatism. She walked and talked at the usual age. There was no trouble at her birth. She was uncommonly bright up to the present attack.

Present Illness.—At 12 years of age she had "black diphtheria." She lived twenty miles in the country and had no physician until after her paralysis appeared, and no antitoxin at any time. Three or four weeks after her attack of diphtheria she suddenly developed a right hemiplegia, including the face, arm and leg. There was a complete loss of motor power, including speech. Apparently there was no sensory involvement. The condition lasted one day, when she appeared to entirely recover and remained well for one week, at the end of which time there was a second attack with very much the same symptoms and lasting two days. At the end of two weeks she had still a third attack, following which she was in bed for six weeks. As this history is given by the mother from her recollection, it is not certain that all the facts are accurately stated, including especially the complete recovery between the attacks. The mother says that the patient was not unconscious at any time, but that her mind after the third attack was "just like a baby's," by which she probably referred to the fact that the patient found it necessary to relearn speech. At the end of twelve days she could move her foot a little, and at the end of seventeen days spoke the word "Henry." The mother thinks that at this time she could understand spoken, but not written words. As time passed she gradually acquired control of the right side, first in the face, then in the leg, and later in the hand and arm. Her face apparently recovered completely. There has always been a slight stiffness in the right leg, and the right hand and arm are distinctly spastic. She was a long time in learning to speak, but finally reached the point at which she had very little trouble, though even at present she cannot always recall words as she wishes to. She went to school after recovering from her paralysis and learned readily. She is always cheerful and happy in disposition.

Physical Examination.—The patient is a well-developed and well-nourished young woman. There are no evidences of degeneracy. The pupils are equal and react normally to light and distance. The ocular movements are normal and there is no nystagmus. Vision is good, but the patient says that occasionally when looking suddenly to one side she has double vision. Smell and taste are normal. There is no involvement

of the fifth or eighth nerves, but there is a slight defect in the right lower seventh. Her tongue is normal in appearance and is protruded straight. There is no trouble in swallowing. The heart and lung examination is negative, except for a faint blowing mitral murmur. The arteries are soft. The urine examination is negative. The deep reflexes of the left arm are normal; those of the right are much increased. The right patellar and Achilles reactions are very active, the left patellar and Achilles are normal. There is no ankle-clonus, but there is a faint Babinski reaction on the right side. The patient walks and runs well, but complains of slight stiffness in the right toes in movement, and there is a marked degree of spasticity in the entire right upper extremity. Grip in the right hand measures 17 and in the left hand 27. Muscular power in the right biceps and triceps is fair, but not so good as in the left. The middle finger and the thumb of the right hand are the most difficult to move. The first and little fingers are the easiest to move. The right forearm at its largest point measures 21.25 cm., and the left at a corresponding point measures 22.75 cm. Nothing unusual is noted in the patient's mental condition, except that, contrary to her mother's statement, she does not appear to be a particularly bright girl. Her speech is normal, except that she occasionally has some difficulty in finding the proper word.

CASE 3.—History.—The patient is a boy, aged 4. The father is living at 38; well and temperate; mother living at 37, well. There are no brothers or sisters. There is no tuberculosis, cancer or nervous or mental trouble in the family. There was no special trouble at the patient's birth and instruments were not used. The patient was breast-fed. His general health has been good, except that he has had croup every winter. At two and one-half years he had measles, and one year ago had diphtheria, but was not very ill with either. His appetite has been good, and his bowels regular.

Present Trouble.—On Dec. 28, 1909, the patient became ill with lobar pneumonia involving one lung. He was very ill and his temperature was above 103 for nine days. Three days after his temperature went down he developed a right hemiplegia. At noon he was noticed to have some weakness in the right hand. This slowly increased, and by the next day his hand and arm were completely paralyzed. Later in the same day the leg and foot of the same side also became paralyzed and there was motor aphasia. The face was not affected then or later. There was no sensory disturbance noticed and no disturbance of the sensorium. Thirteen days after the paralysis appeared he began to move the hand and arm, and speech power began to return, and in a few days he could put the hand on top of his head. He now uses the hand as well as ever, and his enunciation is good. A few days after power of movement appeared in the arm he began to use the leg, but improvement was slow, and even now use of this limb is decidedly impaired. There were no eye symptoms at any time. Three days after the paralysis appeared he developed a left middle-ear abscess which broke spontaneously and is now quite healed.

Physical Examination.—The patient is a well-developed and well-nourished boy. His head is well formed and there are no scars or evidences of degeneracy. The temperature is normal, the pulse 94, strong and regular. The examination of the heart, arteries and lungs shows nothing abnormal. The tongue is clean and is protruded straight to the front. The abdomen is protuberant. The pupils are equal and react normally for light and distance. The ocular movements are normal, and there is no nystagnus. Sight and hearing are good. Muscular power in the right arm seems normal. The patient limps slightly with the right leg, but examination shows no muscular weakness of any consequence. The circumference of the right thigh and calf is slightly less than at the same point on the other side. The reflexes in the left arm are normal, in the right moderately increased. The left patellar and Achilles reflexes are greatly increased. There is a slight ankle-clonus and Babinski on the right side. The abdominal and cremasteric reflexes are active on both sides. Sensation is normal everywhere, so far as can be determined. The right fingers are a very little stiff. The right leg and foot are mod-

erately stiff. There is a very slight ataxia in the right hand. Speech and mental condition are normal.

CASE 4.—History.—The patient, a girl of 11, is one of ten children. The family history is good in all respects. The patient has always been considered well and strong, though not large for her age. There is no mention of any of the ordinary children's diseases. Since 5 years of age, she has attended school and has done well there.

Present Illness.—The trouble is dated from Jan. 4, 1910, though the patient had not been quite natural for the two preceding weeks and had seemed to want to be alone and undisturbed. On Jan. 4, 1910, in the afternoon, she suddenly fell over on her side or back. She was unconscious at the time, but remained so for a few minutes only. The same afternoon she was able to walk, but the right hand and arm were almost paralyzed. She attempted to speak, but was unable to do so. She seemed to understand what was said to her, and appeared perfectly conscious. There was no muscular twitching and no pain. At about 8 p. m. she began to talk and her speech was entirely normal, until the next morning at 8 a. m. when there was again the loss of speech power without the other manifestations of trouble. For three days and nights this alternating loss and return of speech power continued, since when she has been unable to utter a word, except "papa" and "mamma." From the date of the onset of her trouble to February 1 she was about the house most of the time. Her mind seemed clear and she comprehended all that was said to her. She attempted to play with the other children, but could not speak. During this time, however, she had occasional "sinking spells" when she would fall, always toward the right side. She always attempted to protect herself in the fall. She was not unconscious, and there were no symptoms resembling convulsions. She slept well at night; had no rash or other sign of illness. During all this time, except the first three days, her mental condition was good. Her appetite was poor. There was no involvement of the right leg at any time, and up to January 29 the improvement in the hand and arm was so marked that she could sweep a room with very little difficulty. The parents noticed no disturbance in the eyes or face. On February 2 at 1 p. m. clonic spasms developed in the right side, involving, at first, the face, shoulder, arm and hand, and toward evening the right lower extremity. Each attack lasted two or three minutes, and was followed by a short period of drowsiness, and then by another attack. The parents think she was unconscious during these attacks, but not during the interval. During the afternoon and night of February 2 and all day of February 3 she was never long free from a convulsion. Toward evening the attacks became a little milder and a little less frequent, but on February 4 she had convulsions about every ten minutes. She complained of no pain, and gave no signs of distress. She could swallow, but apparently had no desire for food. She had little, if any, fever (parents' statement).

She was admitted to the University Hospital February 4 at 8 p. m. Her temperature was then 100.6, pulse 120 and respiration 24. When first seen by one of us the following morning she was lying asleep. There was nothing unusual in her attitude or appearance, except that the right corner of the mouth drooped a little, and there was some fullness of the right upper eyelid. Directly after being awakened a convulsion began, starting in the right face. The eyelids then began to twitch, the right more than the left. The right eyelids during the convulsion were closed and the left about half open. The convulsion then extended to the right arm and then to the right leg. The whole attack lasted about one and one-half minutes. During the next thirty minutes six more attacks occurred, four being general and two limited to the face only. Subsequently they occurred in about the same order of frequency up to the time of her operation. Both facial attacks lasted fifty seconds.

In all the attacks, both eyes were drawn strongly to the right. The pupils were dilated and did not react to light in the midst of the most severe attacks, but did so in the lighter spasms, and toward the end of the more severe convulsions.

All the attacks began in the face save one, which commenced in the right arm. Usually the order was face, arm

leg, and cessation of movement was in the reverse order. She was probably conscious throughout the light attacks and at the end of the more severe ones, but in the midst of a severe convulsion, sharp pricking of a pin produced no response. During the severe attacks the right rectus abdominis muscle was very hard, the left only slightly contracted. The convulsion never spread to the left side, except that the left eyelids twitched decidedly and in the most severe attacks the left arm and leg contracted slightly.

The reflexes varied decidedly. After a severe convulsion no reaction could be obtained in the right arm or leg. This included the plantar reflex, which could not be demonstrated at any time in the right foot during the examination. In the interval between attacks the facial and abdominal reflexes appeared about normal. The deep arm and leg reflexes were somewhat increased, and, though varying considerably from period to period, there was no striking inequality in the two sides, except directly after the convulsion. There was no evident voluntary movement at the time of the examination in the right arm or leg, but on the day preceding the patient was observed on one occasion to move the right arm slightly.

In speaking or swallowing there was no movement in the right face. On request the patient closed the eyes and wrinkled the brows normally. A subsequent careful examination showed very slight response to light in the pupils in the midst of a fairly severe attack. A possible slight Babinski was obtained on the right side. As far as could be told there was no sensory disturbance. She swallowed well.

At times the patient spoke the words "yes" and "no" quite distinctly. She occasionally called the word "nurse" and said "good" for food that pleased her. She never used a complete sentence. She probably comprehended what was said to her and sometimes attended to requests and sometimes did not. She displayed a childish interest in a tie-pin; at times asked for a bed-pan. She screamed repeatedly as if in severe pain.

Dr. Baker, the resident physician, had observed double deviation of the eyes, and had repeatedly seen elevation of one eyeball and depression of the other, with frequent variation and, toward the end of a convulsion, a peculiar oscillatory movement most marked in the right eye.

Urinary examination previous to the operation showed nothing of consequence, except specific gravity of 1036 and a few cylindroids. Two days after the operation a trace of albumin, but no cylindroids or casts, was found. A few days later even the albumin had disappeared. Previous to the operation the leukocyte count was six thousand. The temperature was variable, but frequently up to 103.

Operation.—On February 7 an operation was done by Dr. J. E. Moore under ether anesthesia. A large bone flap was removed from over the left motor area. When exposed the cortex showed some congestion and slight bulging of the brain substance. Beyond this, in a careful examination, nothing was found. The flap was replaced and the skin sutured.

Postoperative History.—On February 10 there was no movement of the right hand or arm, but a very slight movement in the right foot on deep pricking. Sensation seemed greatly lessened in the right leg and foot, but was probably not wholly absent. The mental condition was much better than it was preceding the operation. At 7 p. m. following the operation, the patient had a convulsion lasting two minutes. At 8:15 there was another, very slight, lasting only a few seconds. In the next hour there were two slight convulsions, but at one time she was conscious and answered when spoken to. Up to 7 the next morning, however, there were forty-five convulsions but all much milder and of much shorter duration than previously. The convulsions continued to 8 p. m. February 9, gradually growing less severe and less frequent. Early on the morning of the 10th the patient again had several slight convulsions, but none afterward. When she was sufficiently recovered from the operation it was found that she had a partial sensory aphasia and also visual amnesia.

The wound did nicely until February 16, when the patient pulled her dressing off and infected it, which greatly delayed its healing. Otherwise her surgical convalescence was uneventful, and the return of motor and sensory power in the right side was fairly rapid. No culture was made at the time of

the operation, but when suppuration appeared in the wound the *Staphylococcus pyogenes aureus* was obtained from it.

On March 4 the patient moved her right leg very well; movements of her hand and fingers were also much improved, and she was able to pick up an orange with this hand. On March 16 she was up and walked about. March 23 she walked quite well, except that the right leg was rather spastic. The right arm was greatly improved, but the grip in the hand was feeble. All movements with this arm were performed slowly and were both spastic and ataxic. There was no special atrophy of hand, arm or leg. Sensation for touch, pressure and pain was apparently normal in the tongue, face and extremities. In speaking and laughing the right face behaved about the same as the left. At this time she was also beginning to speak and write a few words and could understand the name of most objects handed her and tell the names of some.

She was discharged April 2, very much improved.

On May 17 she was reported by her home physician as being able to use her leg as well as ever. She had again become able to use her right hand in writing, but the fingers were a little stiff. Her vocabulary was fair, but not so good as before her illness. In all other respects she seemed perfectly well.

CASE 5.—For permission to publish this case we are indebted to Dr. S. Marx White, of Minneapolis, with whom one of us saw the patient in consultation, and to whom we are indebted for many of the notes referring to the case.

History.—Since 1901 the patient, a married man aged 54, had suffered from a bladder obstruction which annoyed and disturbed him to such a degree that, on April 6, 1902, a prostatectomy was done by Dr. J. E. Moore. This relieved the immediate difficulty. Up to about January 12 of the following year the patient was fairly well, but on this date the right epididymis was opened. On Oct. 17, 1905, the right epididymis was opened and removed.

During the year 1906 the patient was obliged to give up one-half of each day for rest. During this time also the urine became cloudy and was found to contain colon bacilli and staphylococci. There were no casts. Some small polypoid granulations sprang up at the margin of a blind pocket or partially closed sinus in the prostatic urethra, with intermittent obstruction to the flow of the urine. It was necessary occasionally to remove the granulations and irrigate the bladder.

In February, 1907, the obstruction became more pronounced and the use of the catheter began. In April, 1908, the patient went to St. Mary's Hospital in Rochester and Dr. C. H. Mayo performed a suprapubic cystotomy. The removal of a V-shaped portion of the fold of mucous membrane relieved the obstruction temporarily and there was some increase in the general strength. Hexamethylenamin (urotrophin) and the catheter with bladder irrigation made up the treatment employed. Occasionally the suprapubic scar would open and drain for a few days. As an illustration it opened spontaneously June 30 and closed July 3, 1909. In spite of the treatment employed, however, the patient's general condition gradually failed. On July 6, 1909, he had a painless contraction of his left forearm, which lasted about an hour. The sinus opened July 19, 1909, and drained to Aug. 4, 1909, and on the last day mentioned, August 4, the patient complained of a peculiar numbness, which extended over his left hand, wrist and forearm, as if a tight glove were drawn over the parts. He did not speak much of this feeling, but would attempt to shake it off.

On August 5, his business partner sent an automobile to the house to take the patient for a ride and he seemed in every way normal mentally. In the afternoon of the same day, about 5 p. m., his wife suggested that he call up his partner and express his thanks. He was unable to recall the name until prompted, but telephoned in the usual manner and expressed his pleasure at the use of the car. A few moments later he turned to his wife and made an irrelevant and irrational remark, and within five minutes had a left-sided convulsion. Dr. White saw him at 6:30 p. m. The convulsions were being frequently repeated, and at the consultation at 8 p. m. the attacks were persistently evident in the left face and arm, while both legs were rigid.

No convulsions occurred except on the left side, but they continued at frequent intervals during the days and nights of August 6, 7, 8 and 9, and were uniform in character. There would develop suddenly a quick, violent, muscular movement of the left face and arm and occasionally of the left leg. The patient was able to talk at times, but his utterance was incoherent. His temperature began to rise with the onset of the convulsions and ranged from 99.8 to 103 F. On August 9, 1909, after a consultation including Drs. Moore, Tibbets, White and Jones, a diagnosis of acute septic encephalitis was made and an operation was advised for exploration and possible relief.

Operation.—The family having assumed the responsibility, on the following day, Dr. Moore removed a large osteoplastic flap from the right parietal region and exposed a large, very much congested and inflamed area in the motor cortex. No gross breaking down of the brain substance was noted, except in the center of the area where a softening process had begun. This area was incised and temporary drainage inserted.

Postoperative History.—There were no further severe convulsions, but slight and abortive seizures continued up to the time of death. The man became stuporous and died sixty hours after the operation. There was no autopsy.

The exact cause of the paralysis in the above cases it is quite impossible to give, and a consideration of the known facts concerning infantile hemiplegia does not serve to clarify the situation wholly.

Hemiplegia due to thrombosis and embolism was established pathologically by Virchow in 1846. In 1876, Huguenin was able anatomically to distinguish clearly between encephalomalacia and encephalitis; and in 1884 Strümpell's article on "Acute Encephalitis of Children" brought out the fact that many of the cases of infantile hemiplegia are due to encephalitis of the motor area and this paper aroused special interest in the subject. In recent years much attention has been given to the histology and bacteriology of encephalitis, including especially in this country the valuable work of Councilman, Mallory and Wright, and of Southard, and his co-workers, Sims, Keene, Stratton and Richards. But up to the present it has been impossible to clinically distinguish the different groups of infantile hemiplegia according to their etiology (Southard), though the work of Openheim, Taylor and Southard will doubtless stimulate our activity and increase our capacity in this direction.

The deleterious influence of the diphtheria toxin on the nervous system has been long and widely known and both clinical and pathologic evidence combine to show that the nerves are much more subject to this influence than the ganglion cells of the cord and cortex. Peripheral paralysis occurs in diphtheria in as high as 5 to 15 per cent. of the cases, while out of 800 diphtheria patients in the Berlin Charity Hospital only three developed hemiplegia and out of Wallenberg's 190 cases of infantile hemiplegia only three were of diphtheritic origin, while of Osler's 120 cases not one was attributed to this cause. The histologic study of material from post-mortem cases of diphtheria shows that changes in the ganglion cells are uncommon, and some authors record their entire absence. A few, however, insist on certain changes in the ganglion cells, though mostly of a light character, and in the small number of recorded post-mortem examinations the paralysis has usually been found to be due to embolus or thrombus. Taylor states that the causes of infantile hemiplegia in order of frequency are: acute encephalitis, thrombosis (arterial or venous), hemorrhage, and embolism. Very rarely a case has been reported in which the paralysis was believed to be partly of central and partly of peripheral origin.

Of the two cases of paralysis following diphtheria, here reported, there was undoubtedly a central lesion in both, but it may be that in Case 1 there was both a central and a peripheral lesion. Whether the cause was acute encephalitis, or one of the other conditions mentioned above, would have been difficult to determine at the time and is quite impossible with the history now at hand, though the prolongation of the symptoms previous to the development of the final and complete paralysis in both cases and the tendency of the symptoms to increase in intensity over a period of some days in one case would suggest encephalitis rather than one of the vascular conditions, which usually develop their symptoms comparatively rapidly.

Contrary to the opinion of the laity, paralysis in diphtheria is not due to the use of antitoxin, though the use of antitoxin does not appear to have lessened the number of cases of paralysis, either of central or peripheral origin.

Paralysis, either of central or of peripheral origin, in the course of pneumonia, is very infrequent. Thus Vanysek, in reporting a case of peripheral neuritis, states that neuritis and polyneuritis after croupous pneumonia is a very rare disease. Enouf reported a case of paralysis of his own and collected five others. In two of these cases, which came to autopsy, one had a meningeal hemorrhage and one a spinal cord softening. The other cases were of uncertain variety, including one case of paralysis of both legs and one arm. All four patients recovered after a duration of some hours to some weeks. Though there is no reason apparent why paralysis of central origin in pneumonia might not be due to true encephalitis, I do not know of a positive case in literature, except in connection with meningitis. There has been so little work done on the subject, however, that definite conclusions cannot yet be reached. As regards the nature of Case 4, in particular, no positive statement can be made. It was looked on previous to the operation as an instance of cerebral tumor or encephalitis. The operation and subsequent course make the diagnosis of tumor impossible and the diagnosis of encephalitis correspondingly more probable. In Case 5 the diagnosis of septic encephalitis seems justifiable.

513 Pillsbury Building.

ABSTRACT OF DISCUSSION

DR. M. L. PERRY, Parsons, Kan.: This question of infantile hemiplegia is one on which there has been division of opinion, especially as to the pathogenesis. When the paper on this subject was presented by Strümpell (in 1874, I believe), in which he took the position that the lesion in these cases was an encephalitis similar to or identical with the process found in anterior poliomyelitis, there were many, especially among the foreign men, who accepted the theory. It has not been accepted as fully in America and I think the weight of opinion among the men in this country has been until recently that these cases were of vascular origin. Dr. Southard, of Boston, has recently done some work that has thrown considerable light on this subject. He has found that the majority of these cases are due to an encephalitis, but the process is a different one from that found in the cord in anterior poliomyelitis. He has made rather extensive bacteriologic studies in such cases and has found that there is no one constant organism. I have myself been of the opinion that a large number of such cases were of vascular origin, until this work of Dr. Southard has convinced me that I have been mistaken. Viewed from a clinical standpoint the subject is of the greatest possible importance from the fact that a large number of such patients develop epilepsy later on. In a study of some nine hundred cases of epilepsy I have been much impressed with the frequency with

which we find a history of attacks, similar to those described by the doctor in his paper, occurring as a precursor of epilepsy. In fact, as a result of a careful study of this subject I am convinced that the brain lesions causing infantile cerebral palsies may be ranked as one of the most important and frequent causes of epilepsy.

DR. SANGER BROWN, Chicago: It is a little doubtful whether these cases admit properly of a classification that would enable them all to be discussed together. According to the essayists the diphtheritic paralysis and encephalitis are adduced as the cause of the hemiplegia. I think the pathology of diphtheritic paralysis is pretty well defined to be a peripheral paralysis, and due to the effect of the toxin of diphtheria acting on the peripheral motor neurons, some being more sensitive than others, but in severe cases all being affected. There are various evidences, such as the usual impairment or loss of the reflexes in the parts concerned. Now I do not think in either of the two cases referred to by the essayists, even though signs of diphtheritic paralysis appeared before hemiplegia, that is, in the paralysis of the palate, or in the power of convergence, or the pupillary condition, even though that had occurred, and afterward hemiplegia occurred, it would be proper to regard the hemiplegia as being caused by the diphtheritic paralysis. It would be, I think, fair to assume that it was due to the general infection, as it might occur in any of the infectious diseases, and as Dr. Sachs has pointed out, or contended for very ably, the hemiplegia would be due to a vascular disturbance, due to the infectious disease, and not to the toxin acting on the peripheral neurons. I would strongly take the view that these two conditions were merely coincident, and I do not think it would be at all proper to regard the hemiplegia as a form of diphtheritic paralysis. Now, I think each case should be considered separately. The only other point that struck me was in the case of the child with the paralytic and sensory attacks in which there was no fever. The symptoms were described, and from the subsequent history I should strongly suspect interstitial sclerosis.

DR. L. H. METTLER, Chicago: I would like to ask Dr. Perry or Dr. Hamilton how they differentiate, aside from the mere difference in location, between the pathology of acute hemorrhagic encephalitis and acute hemorrhagic anterior poliomyelitis. The theory propounded by Strümpell, wherein he classified certain forms of infantile encephalitis, nuclear inflammation, and anterior poliomyelitis as one and the same pathological process, differing only clinically by reason of the different localization of the lesion—a functional more than a pathologic differentiation—has always been more popular in Europe than in America. If Strümpell's condition is the true one, it seems to me that it offers us a distinct advantage in the practical consideration of these affections. Clinical differentiations between diseases, along easily observed lines of function, render the diagnosis and management of diseases easier and more accurate than when those differentiations depend on minute post-mortem pathologic findings. I, for one, would like to be more minutely informed on this matter. As I feel now, it is not the nature of the lesion so much as it is the location of it, that marks the distinction between these inflammatory troubles of the central nervous system, especially its gray matter. I think Starr takes emphatically the same position in his recent work on diseases of the nervous system. If these infantile palsies, cerebral, nuclear, and spinal, are absolutely distinct and dissimilar disease processes, I think the differences, apart from mere location of the lesion, ought to be brought out more clearly by our teachers of pathology. Sarcoma of the brain and sarcoma of the cord are not regarded as essentially different diseases.

In this connection, while speaking of localization differences being made the basis of nosology in the absence of any real pathologic differences, I desire to speak of another matter not wholly irrelevant to the subject of the paper. Until the present time we have been talking a great deal about multiple neuritis, of the alcoholic and infectious types, as though it were a distinct, unique, and *sui generis* disease-process. Many pathologists now, however, are modifying their views, and are inclining to adopt more and more the teachings of Charcot, for which he long ago contended so earnestly and for which he

received so much adverse criticism, namely, that these alcoholic intoxications and infections, when studied under the guise of multiple neuritis, represented mere localization differentiations and not essential diseases. Other organs were always more or less also involved, and the alcoholism or infection was the essential basis on which the cases in practice were to be classified. Present investigations show that in alcoholic polyneuritis, for instance, the degenerative process may be traced up through the nervous system to the very cortex. I cite this as a parallel instance somewhat to the question in hand, and to point out that we must not be too narrow in our conceptions of disease. We must be careful not to refer to clinical manifestations, which represent merely a functional localization, as special diseases.

Therefore, I would like to be informed wherein pathologically, not functionally, hemorrhagic poliomyelitis differs so much from hemorrhagic poliomyelitis as to warrant the consideration of these two maladies as wholly distinct and separate diseases. It is the end and aim of all science to generalize, if possible, to reduce to small groups many related phenomena, and to harmonize apparent discrepancies. It certainly is not the end and aim of science to merely enumerate a vast mass of minute and particular observations that may be closely interrelated.

DR. W. A. JONES, Minneapolis: The object of this paper was to provoke a discussion as to the influence and effect of infections on the central nervous system. The description of the three supposedly diphtheritic cases means that infection is not only peripheral, but of central origin, and not infrequently destructive or inflammatory lesions are found in these so-called peripheral paralyzes. If encephalitis and poliomyelitis are due to infections, I do not see how we can differentiate between these various diseases and their onset.

The two last cases reported, to my mind, are the most important, because they both show a central localized infective and inflammatory process in the cortex, and both cases, which were operated, seemed to confirm the work of Dr. Southard.

The third case, that of the child, was particularly interesting, but we were not able to determine the beginning of the infective process. The lesion was a characteristic one, if we can judge from gross appearances, and the inflammation involved mainly the cortex and did not extend into the white substance extensively. She made a prompt recovery from her peculiar epileptiform attacks and practically complete recovery from the hemiplegia following operation. The character of the epileptiform attacks in the third and fourth cases was distinctive in that the attacks were sudden, violent, repeated muscular contractions without paralysis between the seizures; that they were irritative and cortical I think is undisputed, particularly with our findings.

TUBERCULOSIS IN MARKET MILK OF CHICAGO *

F. O. TONNEY, A.B., M.D.
Director Municipal Laboratories
CHICAGO

During the summer of 1909, a series of examinations of market milk was undertaken in Chicago, at the instigation of the Commissioner of Health, Dr. W. A. Evans. Several similar investigations have been reported in other localities in the United States during the past two years, the results of which bring out clearly the high incidence of tubercle bacilli in milk-supplies and the consequent importance of milk control from the standpoint of public health. It is believed that the results herein recorded, inasmuch as they give insight into the milk situation of one of the large municipalities of the country, will be of interest as adding to the general fund of knowledge on the subject.

* Read in the Section on Preventive Medicine and Public Health of the American Medical Association, at the Sixty-first Annual Session, held at St. Louis, June, 1910.

The work was undertaken during the months of July and August, 1909, and carried out partly in the Bacteriological Department of the University of Chicago under the direction of Dr. P. G. Heineman of that institution, and partly in the Municipal Laboratory of the Department of Health, City of Chicago. The results of the work in both laboratories will be reported jointly, in order that from the larger number of samples thus available for study a more accurate idea of the extent to which the general supply was effected may be obtained. In addition to the reporting of results, it is my purpose to discuss briefly a few of the considerations which naturally arise in connection with the choice of the remedy to be applied.

The samples were collected by health department inspectors, and were brought in partly in original containers and partly in sterilized bottles furnished by the Municipal Laboratory. The effort was made, as far as possible, to deliver the samples to one of the laboratories within a few hours of the time of collection. It was arranged that the dairy inspectors working in the neighboring country districts should submit samples from the country shippers to the Municipal Laboratory. In addition, a milk inspector was detailed within the city limits for collection of market samples from depots, stores, wagons, etc., with the idea of covering, in as representative a manner as possible, all types of places in which milk is sold in Chicago. Samples collected within the city limits were delivered to the Bacteriologic Laboratory of the University of Chicago.

The technic employed in the laboratory at the University of Chicago was as follows: Three hundred c.c. of the sample were centrifugalized for thirty minutes at a speed of about 1,200 revolutions per minute. The layer between the cream and the sediment was then removed by means of a sterile pipette and the sediment and cream thoroughly mixed. This mixture was diluted with sterile saline solution to an amount sufficient for the injection of three guinea-pigs, using from 1 c.c. to 2 c.c. for each injection. All inoculations were made subcutaneously in the abdominal wall, the syringe being cleaned and sterilized by heat after the injection of each specimen of milk. The pigs were kept in clean cages and observed for a period of three months. Animals showing glands at the end of six weeks were separated from the others. Tuberculosis was determined by the gross lesions and by smears prepared from the affected organs. The same general method was followed at the Municipal Laboratory of the health department with no essential differences in detail, except that one animal instead of three was used for each specimen. In the Municipal Laboratory the gross autopsy findings were confirmed by demonstration of the tubercle bacilli in stained sections of the organs, the slides of which are now on file in the health department. It is to be noted, however, that, inasmuch as the clinically negative animals were not subjected to autopsy, but in both laboratories were allowed to live and be used for other purposes, the results of the series must be reported as minimum findings only. No cultural studies were attempted to determine the presence of human and bovine types of the organism.

From a strictly scientific point of view, it is to be regretted that cultures were not made from the organs to exclude the possible presence of Rabinovitsch butter bacillus. It so happened that the autopsies fell due at a time when the laboratories were flooded with other work, and therefore it was necessary to omit this detail for lack of available time. Practically, however, it is

our belief that the positive findings here reported may be considered tuberculosis. The autopsies were in every case well marked and typical, and the findings agree well with the results of observers in other cities in the United States.

Incidentally in connection with the autopsy of the animals, it was decided to mount a few of the guinea-pigs by the Kaiserling method for purposes of exhibition. The value of such exhibits in the fight for purer milk soon became evident, and I believe, should not pass without mention, inasmuch as the suggestion may be of use to others who may contemplate the institution of a similar educational campaign. In the conduct of such a campaign, it is very necessary to have at one's command arguments which are convincing to laymen, many of whom are still doubtful as to the existence of bacteria, and most of whom find it difficult to understand how milk, which is perfectly sweet and pure to all appearances, may still be unfit for use and dangerous to health. In this connection it is hard to conceive of a more concrete object-lesson for the milk-dealer or legislator than to present for his inspection a guinea-pig which has been killed by the milk he is feeding to his children. A normal guinea-pig should also be mounted for comparison, in order that the marks of the disease in the tuberculous specimens may be clearly apparent to any observer.

The total number of milk samples examined in the two laboratories was 163. Of these, fifty-one caused the death of all the animals injected from acute infections within three weeks, before diagnosis of tuberculosis was possible. Eliminating these as lost, there remain one hundred and twelve available for the series, of which ten, or 8.9 per cent., proved tuberculous. Of 144 samples of raw milk, forty-nine were lost within three weeks, leaving ninety-six available for consideration. Of these, ten specimens, or 10.5 per cent., were found tuberculous. Of nineteen pasteurized samples, two were eliminated, leaving seventeen for consideration. None of the pasteurized samples caused tuberculosis in the animals injected.

	No. Samples.	All Animals Died in Three Weeks.	Available for Series.	Per Cent. Found Tuberculous.
Total	163	51	112	8.9
Raw	144	49	95	10.5
Pasteurized	19	2	17	0

With regard to results of other observers, up to the year 1908, a very complete report has been published by Trask¹ of the U. S. Public Health and Marine-Hospital Service, covering chiefly the work of European experimenters. More recently the results of several American observers have been added to the list. Hess,² in 1909, examined 107 samples of market milk in New York City with the result that seventeen, or 16 per cent., were found to contain tubercle bacilli; Anderson³ examined 223 samples taken in the city of Washington and reported sixteen, or 6.72 per cent., as positive. Mohler⁴ has examined seventy-three samples with positive findings in two cases, or 2.7 per cent. The Bureau of Animal Industry⁵ reports two positive out of thirty-six examined, or 5.5 per cent. Goler⁶ reports about 5 per cent. of the milk-supply of Rochester, N. Y., infected,

but does not state the number of samples examined. The incidence of tubercle bacilli in the milk-supplies of American cities, as far as obtainable, is therefore represented by the following figures, which include the results reported in this paper: Total number of samples examined, 551; total found positive, forty-six; per cent. positive, 8.3.

Without entering into the question of the relative prevalence in human subjects of the human and bovine types of infection, which has been extensively discussed in recent literature,⁷ I believe it is safe to say that the problem of tuberculosis in milk-supplies is of sufficient importance to warrant immediate steps for its eradication. Obviously it is desirable and in many instances has been proved practicable to eliminate tuberculous animals from dairy herds by means of the tuberculin test, followed by strict isolation or slaughter of the reacting animals, but this process requires time and also strict legislative support. The difficulties of its accomplishment increase enormously with the size of the community affected and the extent of the dairy districts involved. It has not as yet been proved practical in connection with milk-supplies of large municipalities. But granting its desirability and practicability, it is obvious that the public is entitled to protection during the interim required for obtaining the necessary legislation and enforcing such measures when obtained, both of which must necessarily be slow processes. Briefly stated, there is need of immediate protection of milk-supplies, while the more ideal, but necessarily slowly operating measures are being carried out. Such an immediate safeguard is to be had in compulsory pasteurization.

In Chicago the situation is being met in the following manner: The ordinance of Jan. 1, 1909, provides that all milk sold in Chicago, beginning Jan. 1, 1914, shall be obtained from tuberculin-tested cows. During the interim of five years between Jan. 1, 1909, and January 1, 1914, milk not obtained from tuberculin-tested cows may be sold, provided the said milk is pasteurized according to the rules and regulations of the department of health. Under this ordinance about 54 per cent. of the milk sold in Chicago is now pasteurized and 24 per cent. is tuberculin tested. Before the close of the present season, if existing plans are carried out, the remaining 22 per cent. will be pasteurized, and also much of the tuberculin tested product will be pasteurized. During the summer of 1909, when about 30 per cent. only of the milk was pasteurized, strict enforcement of the ordinance being at that time impossible because of administrative difficulties involved, a decrease of 521 was noted in the deaths reported among children under one year from diarrheal diseases. The average bacterial count of raw milk in 1909 was 5,547,502 per c.c.: of pasteurized samples taken from plants, less than 200,000; of pasteurized samples taken from all sources including the output of plants not yet under satisfactory control, and also street samples, many of which had been kept in stores over night, was 944,000 per cubic centimeter. Results in 1910, so far as obtainable, show a greater difference in favor of pasteurized milk, and seem to indicate that the control of pasteurization is becoming more effective. There is still the problem of preventing the practice prevailing in some retail establishments of selling left-over samples from the previous day's delivery. In my opinion this one detail is responsible for

most of the high counts obtained in pasteurized milk and tends to hold the average bacterial counts far above what they would otherwise be. The correction of this error is the next important problem which must be undertaken in the control of the situation.

It may be well to add a word as to the special applicability of pasteurization as an immediate safeguard to the milk-supplies of large cities. That it is effective in the prevention of milk-borne tuberculosis is fully conceded, but the milk situation in large cities involves so many other factors that tuberculosis of necessity comes to be regarded as only one among many sources of danger, several of which are more important from a public health standpoint. In a large city there must always be present the element of distance between the producer and consumer. Contingent on this necessary condition are the thousand and one sources of contamination occurring as a result of multiplicity of handling, time consumed in transit, improper cooling during transit, etc., all of which factors tend to multiply enormously the common polluting agencies to which milk is subject. The final product, which reaches the consumer, may therefore be dangerous from the standpoint of five or six groups of diseases, of which tuberculosis is probably not the most important. In order of their importance I should enumerate these as follows: First, and by far the most deserving of attention, is the group of infantile diarrheal diseases, which are responsible for about one-third of the death-rate among children under 2 years in our large cities. As to the bacteriology of these conditions we have little satisfactory knowledge, but the evidence furnished by vital statistics is convincing in establishing the important relation of milk thereto. Second is typhoid fever, the relation of which to milk-supplies is now well understood. Third in rank is tuberculosis. Fourth is scarlet fever. Fifth is diphtheria. Sixth is a group of miscellaneous affections not particularly important in this country, such as cholera, foot-and-mouth disease, milk-sickness and others.

As tuberculosis may be eradicated by strict application of the tuberculin test, so may these other infections be eradicated by the strict observance of sanitary rules in the production and handling of milk. But the enforcement of such observance, as in the case of elimination of tuberculosis from herds, is a time-consuming proposition, involving an educational campaign and the development of an adequate inspection system. The public is entitled to immediate protection, while the process is going on, and for this immediate protection we must turn again to pasteurization. There is certainly no one other agency of purification of milk-supplies which is of such wide applicability. That compulsory pasteurization is practicable for towns and cities under proper supervision by health authorities will, I think, soon be established and generally recognized from the experience of the City of Chicago during the past eighteen months.

ABSTRACT OF DISCUSSION

DR. F. O. TONNEY, Chicago: In reply to a question that has been asked: The bacterial counts here reported were all made on plates which had been incubated at 20 degrees C. for five days. As has been pointed out by Dr. P. G. Heinemann of the University of Chicago in a recent publication, this method gives higher bacterial counts in milk than does the method more commonly used in which the temperature of incubation is 37 C. and the time of incubation 48 hours. For

7. An excellent summary by Moss: Bull. Johns Hopkins Hosp., February, 1909, xx, No. 215; Park: Tuberculosis Congress, Washington, D. C., 1910.

this reason the count of 200,000 probably represents a higher result than would have been obtained by the less rigorous method in more general use. The figure of 200,000 per c.c. represents an average of all plants inspected, and of course includes counts made on the product of pasteurizing plants not yet under satisfactory control, the purpose of the inspection being primarily to correct any errors noted in the management of the establishment.

I think, therefore, bearing in mind the two points above mentioned, that we may consider 200,000 per c.c. a very good figure, especially in view of the great difficulty involved in the enforcement of such an ordinance so soon after its passage. I do not wish to be interpreted as saying that a bacterial count of 200,000 per c.c. on an individual sample indicates a safe product, but I believe that this figure, representing as it does an average on samples from all plants both good and bad, is a satisfactory figure for the first year of the life of the ordinance. Probably the average for the second year will show improvement.

DR. W. A. EVANS, Chicago: There is but one way to answer that question; and that is, that 200,000 at the pasteurizer's side is not a satisfactory bacterial count. The usual bacterial count at the pasteurizer's side was around say a thousand—somewhere in there. A great many pasteurizers just started up last summer; and some of them run high. You see how one of them that would run quite high, would pull up the average. Whatever method of counting was employed, 200,000 would be an unsatisfactory count.

PATHOLOGY AND TREATMENT OF ALVEOLAR ABSCESS

AND A PLASTIC OPERATION TO CLOSE NASO-ORAL FISTULA AND A NEW OPERATION FOR MANDIBULAR NECROSIS *

STEWART L. McCURDY, M.D.
PITTSBURG, PA.

The capital operation of dentistry is devitalizing pulp and filling of the root canals, as an abdominal section or the opening of an important joint is the capital operation of surgery.

If the peritoneal cavity or synovial membrane is infected during an operation, serious and dangerous inflammatory processes follow; infections of the former in many instances result in death, and infections of the latter result in ankylosis and even amputation. It is

Fig. 1.—The most common alveolar fistula of the maxilla. Usually persists for years until the tooth is extracted.

Fig. 2.—This represents the method of establishment of naso-oral fistula; a, nasal septum; b, nasal cavity; c, membranous floor; d, abscess cavity; e, denuded root of tooth.

possible for the general surgeon to perform the operations without mortality only because of the great care exercised by him preparatory to and during the opera-

* Read in the Section on Stomatology of the American Medical Association, at the Sixty-first Annual Session, at St. Louis, June, 1910.

tion. On the other hand, the most delicate operation in dentistry, requiring the most technical skill as well as demanding perfect asepsis in its practice, is the devitalizing and extracting of pulps and filling these cavities. If infection occurs on account of carelessness on the part of the dentist, the too common alveolar abscess is the result. Alveolar abscess, or the so-called pus sac so frequently found on the apex of a tooth after extraction, is the forerunner of 90 per cent. of all the destructive diseases of the maxillary bones.

SERIOUS CONSEQUENCES OF ALVEOLAR ABSCESS

The pathologic changes which occur in the so-called alveolar abscess begin at the apex of the root of a tooth. The first change is quite small, beginning in the form of

Fig. 3.—Abscess; a, antral cavity; b, naso-antral septum; c, membranous floor of the antrum; d, abscess cavity ready to rupture into the antrum; e, root of tooth denuded and cause of disease.

Fig. 4.—Alveolar abscess of the mandible; A, abscess cavity; B, roots of tooth; C, external alveolar plate to be removed with tooth; D, point of incision.

an infiltrate, which later liquefies. This change involves the tissues immediately around the apex of the root either destroying or promoting the absorption of the bone. The process of the destruction is in the direction of the least resistance from the root involved, which experience demonstrates to be smaller on the buccal side of the alveolar process. The destruction continues to the surface of the bone when the external manifestation of the abscess is present, namely, a fluctuating infestation on the external surface of the bone. This continues to destroy tissue in proportion to its activity, which depends on the variety of germ responsible for the disease.

The symptoms are well known to every dentist. Pain is in proportion to the rapidity of the course and, as a rule, is not prominent, a slight ache of the face being the most common characteristic.

If the root of the tooth affected is in proximity to the maxillary sinus, this cavity will be infected, resulting in antral disease. Occasionally when the disease is in

because the membranous floor is still intact. If the distention of the abscess cavity is great or if it continues for a considerable length of time, the nasal or antral cavity will be entered and in the former instance the antrum becomes infected, and in the latter instance a nasal fistula established.

When a fistulous opening is established from one of these abscesses, the orifice may be through the alveolus, the external or internal surface of the bone. In cases of fistulas communicating with a cavity in which there was the root of a tooth denuded of its periosteum and apical circulation I have not seen the opening close

Fig. 5.—The above illustration represents Case 1 described in the text; a and b, alveolar process on two sides of tooth; b, denuded; c, detached gingival tissues; d, lingual gingival tissues; e, lip.

the mandible in proximity to the central canal a great portion of the bone will become involved before the surface is reached and the ordinary fluctuating cyst described above is not found.

In many of these abscesses the bony floor of the antrum is destroyed, yet the antral cavity is not entered

without the extraction of the tooth. This applies to chronic openings persisting for three or more months.

An alveolar abscess of the mandible is rather common. It is usual, also, for the abscess to break through the cheek rather than into the oral cavity. It is all a question of dependent drainage. The reason that alveolar abscesses of the superior bone repair better than those below is that the drainage above is superior.

The second serious consequence of alveolar abscess is a more grave variety of destruction of the maxillary bone, when the nasal floor, membranous and osseous, is destroyed, leaving a naso-oral fistula. In this condition we have a very troublesome complication, making it necessary for the patient to keep the opening packed con-

stantly, requiring removal after meals and withal leaving the mouth in a very unsanitary condition.

The underlying factor in nearly all of these cases is syphilis and, after the constitutional treatment has been pushed until all granulating surfaces have repaired, it is very desirable to close the opening permanently.

OPERATION AND CASE REPORTS

An operation which I have done in several instances and which has accomplished this purpose may be described as follows: Assuming that the labial gingival structures are completely destroyed and that the lingual periosteum and mucous membrane extend well down to the normal line, two incisions are made through the lateral structure, either with scissors or knife, back up to the orifice of the fistula and far enough back on the two sides to make the tongue wide enough to cover the opening. The margin of the flap thus made is freshened and the corners made round. The next step is to freshen the orifice of the fistula, denuding well the internal surface of the lip for a distance equal to the

Fig. 9.—Taken after operation in Case 1.

thickness of the flap. The flap is now turned up over the orifice of the fistula and sutured there with silkworm gut. In the three cases in which the operation has been performed (two of which are described below) the results have been perfectly satisfactory.

CASE 1.—Patient.—A man, aged 50, with infection of the mandible. He had lost all of his lower teeth but three, and the cavity included practically all of the mandible on its external surface, the bone being bare throughout. The alveolar process, on its external margin, including the cavities left by the extracted teeth, stood out perfectly nude in the floor of the mouth. It had required just a month for the ease to advance to the condition described.

Operation.—This included a complete removal of the external half of the mandible from the second molar on the right side to the second bicuspids on the left, through the roots of the teeth and to external inferior margin of the bone. This left the internal alveolar plate intact throughout with the periosteum undisturbed. The cavity was mopped out with pure tincture of iodine. The usual method of procedure would doubtless have been to pack the entire cavity, with the hope that the bone would heal by being granulated over from later approximation of the external periosteum. It was decided,

however, that such an extensive cavity should be immediately obliterated. Dependent drainage was absolutely necessary if this was to be accomplished; hence an incision was made from the lowest part of the cavity in the median line through the skin under the chin large enough to admit a rubber drain the size of a lead-pencil. The next step was to stitch together with catgut the labial and buccal gingival margins, thus closing off the field of operation entirely from the oral cavity.

Postoperative History. To my intense gratification the two gingival margins did completely unite and not a drop of pus was ever found in the oral cavity. The drainage established from below was quite sufficient to carry off the small quantity of reparative lymph and detritus and the patient was practically well in ten days after his operation.

CASE 2.—Patient.—A man, aged 30, had extensive infection of the mandible beginning from an infected tooth. Seven or eight teeth had been extracted and the entire external surface of the mandible was bare. The oral cavity was welling full of pus from the extensive suppurating area. The disease had developed rapidly and was running an acute course.

Operation.—This was practically the same as that performed on the above case. After the removal of the external half of the bone and disinfection of the wound, drainage was established through the skin under the chin. The gingival margins were approximated by catgut sutures.

Postoperative History.—The openings did not unite throughout as in the former case; two or three openings communicated with the mouth. This case was no doubt syphilitic and constitutional treatment was administered before the disease could be controlled. It was several months before the system was impressed with the medication and the wound closed.

CONCLUSIONS

1. Dentists should realize the seriousness of the most frequent operation they perform, namely, that of devitalizing and extracting pulps, since infection and serious bone destruction originate from this cause.
2. Destruction of the bony floor of the antrum does not necessarily mean perforation of the membranous floor or infection.
3. An alveolar fistula leading into a cavity where a considerable portion of a tooth is exposed requires extraction of this tooth before complete recovery can be expected.
4. Persistent headaches and general reduction in health are frequently caused by very insidious alveolar abscesses.
5. In destruction of the mandible, requiring removal of bone, it is advisable to establish drainage through the chin and approximate the gingival margins with sutures so as to shut off a pus cavity from the oral cavity.
6. Naso-oral fistula may be closed by a membranous flap from the roof of the mouth.
7. In all suppurative conditions of the mouth pure tincture of iodine should be used as a disinfectant.

624 Pittsburg Life Building.

ABSTRACT OF DISCUSSION

DR. G. V. L. BROWN, Milwaukee: Dr. McCurdy, being a skillful surgeon, has simply applied correct surgical plastic methods to oral operations, and that, I am sorry to say, is something which is not always done in this work. The way Nature is obliged to help out in the closure of openings by granulation and that sort of thing is a matter to be deprecated, and in a corresponding way any suggestions leading to correct surgical closure are in the right direction.

DR. WILLIAM C. FISHER, New York: In this synopsis a statement is made that probably one-half the cases of necrosis of the maxillary bones are due to syphilis. I think probably one thing is lost sight of, and that is that the administration of mercury for syphilis very often starts up symptoms for

which the disease is blamed. We can get the very same symptoms from the administration of mercury that are caused by syphilis.

DR. JAMES E. POWER, Providence, R. I.: To me it seems unnecessary to make an incision such as described by the essayist. As I understand the operation, the doctor draws the flap across the opening at the top, within the oral cavity, and then makes an incision below and on the external surface for drainage. I do not think that one is justified in making an external incision on the face, and surely not in a case like the one described. I do not quite see any disadvantage in proper drainage through the mouth, even in view of the fact that there may be bacteria present which are capable of causing trouble in the alimentary canal. With the external incision, even if he gets union within the oral cavity by first intention, some days will elapse before he gets a sufficiently strong union to prevent back drainage. I believe that the term syphilis is getting to be used in the medical profession about the same as neuralgia in the dental profession. It seems that about every condition which is beyond the diagnostic capabilities of the practitioner is pronounced syphilis. I am conscious of the prevalence of syphilis, but I believe that many mistakes are made. From my experience I would not care to accept the statement in the matter as final, that over one-half the cases of necrosis of the superior maxilla were due to syphilitic conditions. A good many times the argument for the diagnosis of syphilis is simply that the condition improved under potassium iodid. We all know that many conditions will improve under potassium iodid. Without a good history the only true test is the Wassermann reaction, and that is very seldom resorted to by the general practitioner because it is a complex process and requires the skill of a laboratory expert. Dr. Fisher says that he believes that many of the cases of para-syphilitic conditions are due to the drugs. I believe, however, that all conditions that come from treated syphilis are from the disease and not from the drug. We might get a profuse flow of saliva from too much mercury, but I do not believe that we get necrosis of bone, gummata and other pathologic manifestations which are associated with syphilis and which are erroneously attributed to the use of the drug. I believe 100 of the para-syphilitic conditions are due to the disease where but one is due to mercury. My authority for this statement is Dr. Charles M. Whitney of Boston. I am speaking of cases properly treated. Of course, if a practitioner continues to use mercury after symptoms show that the drug should be suspended he is likely to be confronted with serious conditions. Salivation was used as the indicator in the early days of the treatment of this disease, but that day has passed. They are treating syphilis more scientifically to-day. It is seldom if ever that a syphilologist will permit a patient to reach the stage of profuse salivation.

DR. EUGENE TALBOT, Chicago: I have failed to see in any work the proper pathology of alveolar abscess. While I may not be correct, I have an idea of the process taking place and I may be able to add some point which has not yet been recorded, and I have made a number of drawings on the board to give a general idea of what I intend to present. Most individuals who have alveolar abscesses are run down. In case of syphilis, mercurial, or any other drug poisonings, there is a want of tonicity of the nervous system, in all cases, we may say, due to irritation. When irritation takes place the peri-dental membrane becomes involved and inflammation is set up, which causes pressure pain around the root of the tooth. With this pressure, inflammation is set up in the arteries of the bone, the Haversian canals and in the vessels of von Ebner. That inflammation causes absorption of the bone proper, leaving the fibrous tissue (trabeculae) as you see it in the diagram on the board. This might be likened to the plastering on the side of a building. If it were not for the lathing the plastering would not stick. If the lathing (trabeculae) be removed, then the alveolar tissue or bone cannot be restored. The extent of formation of this abscess depends entirely on the amount of irritation and also on the weakened condition of the patient. It may go on, extending down into the bone tissue through these canals,

and the bone proper (that is, the bone-cells which are held together by fibrous tissue) is absorbed, leaving the fibrous tissue intact. This fibrous tissue becomes organized and forms the sac of the abscess. The inflammation extends through these Haversian canals and produces absorption outward, just as when pebbles are thrown into a small lake, the waves enlarge and spread outward, and if you throw several pebbles into the lake at different localities these waves extend until they coalesce. The principle of bone absorption is the same. Absorption goes on around each Haversian canal until the entire area is involved, and we not only have absorption going on in the Haversian canals, but the vessels of von Ebner become involved. These are not so large as the Haversian canals, so the process of absorption takes longer, but the principle is the same. It burrows right through the bone.

DR. FREDERICK NOYES, Chicago: The absorption of bone under the conditions just stated may be considered as a response to a mechanical condition of pressure, which is the result of the exudate which comes from the inflammation, and the absorption occurs in all the spaces of the bone in the neighborhood of the inflammation.

DR. C. W. HARNED, Iowa City, Iowa: There is just one word I would like to say as to closing of these wounds. I think anyone who has made a practice of closing wounds to prevent secretions of the mouth getting into them will never give it up. I never fail to close up a cavity if possible, after removing all necrotic tissue. I think such wounds will seal in 36 hours, so that no saliva will get into the wound. Pus is rarely present after all the necrotic tissue has been removed. I want to commend the essayist for making this point in the matter of drainage.

DR. JAMES E. POWER, Providence, R. I.: The last speaker states that in his antral diseases he cleans the antrum and then closes the opening through which he operated. In all the antral cases which I have treated I have been obliged to follow the curretage treatment with irrigation. I would like to know how he irrigates if he closes the opening, or what procedure he follows.

DR. C. W. HARNED, Iowa City, Iowa: I prefer going in above the bicuspid, when I think disease involves the antrum. Thorough ventilation as well as drainage through the nose on that side is important. I make an opening through the internal wall of the antral cavity into the meatus, after the antrum is cleansed. Close up the mucous membrane on the outside after you have packed. Remove packing the next day through the nostril. Always close mucous membrane on the outside immediately, and irrigate as little as possible. I find that when I irrigate the least the patients get along the best. If all the pus and necrotic tissue is removed, and the cavity sterilized, very little irrigation will be found necessary.

AN IMPROVED METHOD OF GENERAL ANESTHESIA IN HEAD-SURGERY BY MEANS OF GLASS NASAL TUBES *

JOSEPH E. LUMBARD, M.D.

Anesthetist to the Harlem Hospital, the General Memorial Hospital and the Lying-in Hospital; Fellow New York Academy of Medicine, etc.

NEW YORK

Anesthesia for head-surgery certainly presents difficulties for the anesthetist. In order to insure greater safety to the patient and less interference of the anesthetist with the surgeon during an operation on the head, many inhalers have been produced. Nasal tubes for such purposes of anesthesia were introduced in 1908 by Dr. Edwin Pynchon of Chicago and Dr. Stuart B. Blakely of New York independently. Since one of these instruments allows the entrance of too much air

* Demonstrated before the Harlem Medical Association, May 14, 1910, and the Valentine Mott Medical Society, May 24, 1910.

and the other does not provide sufficient air. I have devised an instrument which experience has proved to be more practical than any other on the market.

My apparatus consists of two glass tubes (Fig. 1, A and B) so bent that each will properly fit a nostril. These tips are connected with the mechanism which supplies the anesthetic vapor by means of two soft rubber tubes (Fig. 1, C), joined together at the supply end by a glass Y, which also connects them with the supply tube (C) itself. They are furnished in three different sizes in order to make the apparatus adapted to nostrils of different shapes.

Furthermore, the apparatus which I use for continuing the anesthesia is different from that employed by either Dr. Pynchon or Dr. Blakely. I induce anesthesia in the usual way and then introduce the glass

Fig. 1.—Glass nasal tubes for general anesthesia in head-surgery (A and B); connected with supply tube (C).

nasal tips into the nose. For convenience these may be held in position by means of a small piece of adhesive plaster placed across them transversely on the forehead (Fig. 2). The anesthesia is then continued by supplying the vapor in one of four ways: first, by the Crile method, that is, by the use of a funnel and tube (Fig. 1, C), on the stretched gauze of which ether is dropped; second, by the one-bottle Junker apparatus, as used so commonly in England for head-surgery; third, by the two-bottle modification of the Junker apparatus, as used by Dr. T. W. Brophy of Chicago for work on cleft palates; fourth, by the Gwathmey three-bottle modification of the Junker apparatus. By each of the Junker methods anesthesia vapor is pumped into the nostrils by means of suitable bulbs.

I much prefer the Gwathmey apparatus, as it allows the use of both ether and chloroform, either singly or combined in any proportion, with the greatest safety and ease.

The following are some of the advantages of the glass nasal tips over the long rubber tubes which have been in common use:

1. They are more safely and easily introduced into the nose.
2. They allow the anesthetic vapor on its way to the lungs to become warmed by the nose.
3. Successful use of the instrument is in no way interfered with by a deformed nasal septum or exostosis.
4. They do not cause nasal hemorrhage.
5. They cannot become obstructed with blood and mucus.
6. They remain in position much better than rubber tubes.
7. They are easier to clean and sterilize.

A method very similar to mine has been successfully employed at Roosevelt Hospital in New York City,

Fig. 2.—Glass nasal tubes for anesthesia in use.

where it is now entirely used for head-surgery in place of rectal anesthesia.

The glass nasal tips, as above illustrated, are certainly a most excellent means of producing a safe and continuous anesthesia in head-surgery, not interfering with the surgeon.

1925 Seventh Avenue.

REPORT OF A CASE OF MIDDLE MENINGEAL HEMORRHAGE ACCOMPANIED BY ACTUAL HEMIPLEGIA: OPERATION, RECOVERY

L. L. SMITH, M.D.

Captain Medical Corps, U. S. Army, on Duty at the Government Hospital for the Insane
WASHINGTON, D. C.

The occurrence of middle meningeal hemorrhage, unless accompanied with severe depressed and compound fractures of the skull, is not so frequent but that the following case may be of interest:

History.—About midnight of April 4, 1909, I was called to see a workman who, I was told, was suffering from a

scalp wound inflicted by means of a bricklayer's spirit-level, in the hands of a fellow-workman. On arriving at the scene of the trouble about half an hour later, I found the patient lying on the floor in an unconscious condition. His breath had a very strong odor of alcohol.

Examination.—There was a contused scalp wound about three inches long in the left temporal and parietal regions, which was bleeding profusely. The pupils were equal and reacted to light. On further examination I concluded that the patient was suffering from concussion of the brain and acute alcoholism. I was informed that the man had been drinking heavily before the trouble occurred. The wound involved the skin of the scalp and the superficial fascia. The occipito-frontalis muscle was contused but not divided. Superficial examination presented no local evidence of depressed or other fracture of the skull at the site of injury. In about one-half hour the patient began to show indications of returning consciousness—he had begun to move both legs and arms, but was unable to sit up. He groaned considerably but was unable to speak. I was at first tempted to suture the scalp wound and await development of symptoms, but after reconsidering I decided to explore the bone at the site of the injury for evidence of fracture. This was done, without an anesthetic, about one hour after the occurrence of the injury.

On exploring the bone a fissured fracture involving the left parietal and temporal bones was found. There was some slight oozing of blood from the line of fracture. As there

Patient operated on for middle meningeal hemorrhage, accompanied by actual hemiplegia; from photographs taken on the seventeenth day after operation.

did not appear to be any depression of the bones or evidences of compression, it was decided to close the scalp wound and await development of possible pressure symptoms. As the line of this fissured fracture crossed the branches of the middle meningeal artery, arterial extravasation was feared. The patient vomited several times after being put to bed, and voided urine involuntarily several times during the night. At 8 o'clock the next morning the temperature was 99.2 F.; pulse 76, full, regular and strong; respirations 22. The patient was in a semi-conscious condition, could not speak, but would groan occasionally. Breathing was rather stertorous. The patient moved the left arm and leg occasionally. There was actual hemiplegia of the right side of the body, leg, arm and face. When the arm and leg in question were raised they dropped lifeless. The paralysis of the right side of the face was well marked. The condition of the left side of the face was confusing; the left facial nerve was believed to be involved, as it was afterward found that the line of fracture extended to the base of the middle fossa, and that the facial nerve was probably implicated in the fracture. No twitching of the muscles of the right side of the body was observed, neither were there any epileptiform attacks. The pupils were equal, moderately dilated, and reacted sluggishly to light. The tongue could not be protruded. The patient could not take any nourishment; voided urine involuntarily. He did not appear to understand anything said to him. As the focal symptoms were typical of

an extravasation from the branches of the left meningeal artery, it was decided to operate on him at once.

Operation.—Under chloroform anesthesia an incision was made enlarging the scalp wound, and the anterior branch and trunk of the middle meningeal artery, left side, were exposed by trephining. On removing the button of bone, a blood clot immediately bulged into the wound. This was cleaned out gently, and there at once occurred profuse bleeding from the anterior branch of the artery, which was controlled with considerable difficulty. It was necessary to open the dura, pass a grooved director into the opening and ligate the artery by means of a small, curved needle and fine catgut. The trephine opening was extended by means of a rongeur forceps to the posterior branch of the artery, where there was also considerable bleeding. A large amount of blood-clot was removed. The dura had been found intact, and was compressed inward, with the cerebral cortex, for about two inches. When the dura was opened the cerebrospinal fluid was found to be clear. The cerebral cortex presented no macroscopic evidence of injury beyond compression. There was no evidence of subdural hemorrhage. The dura was closed with fine catgut sutures. The clot covered the dura over the entire motor area of the cerebral cortex of the left side. The wound was irrigated with hot physiologic salt solution until all of the clot had been removed. Soon the brain began to expand, and gradually assumed its normal condition again. The patient's respiration and pulse improved greatly as soon as the blood-clot was removed. As the patient had lost considerable blood, a liter of physiologic salt solution was given at this time intravenously which greatly improved the pulse. The line of fracture was found to extend downward to the base of the middle fossa of the skull. The wound was closed with silkworm gut sutures. Several strands of silkworm gut was the only drainage employed. Only enough chloroform to keep the patient barely under was given, and this was stopped as soon as possible. While the wound was being sutured the patient began to regain consciousness, and moved the arm and leg which had been previously paralyzed.

Postoperative History.—About midnight of the same day the patient regained complete consciousness and spoke for the first time since the injury. He had complete use of his paralyzed side, although the muscles were slightly weaker for about five days than those of the sound side. The patient made an uneventful recovery. Wound healed completely and he was discharged from the hospital seventeen days from the time he was injured. The photographs were taken the day of discharge from hospital. I told him not to go back to work for about one month, and was surprised to find him engaged at his trade of bricklaying on one of the buildings about one week after his discharge from hospital. I heard from him about five months after the injury and he had had no further trouble.

This case is of special interest on account of the actual hemiplegia which occurred. To show that this is not a frequent occurrence I quote from "Surgery of the Head," by Dr. Cushing, in Keen's "System of Surgery:"

Instances of actual hemiplegia from an extradural hemorrhage have also been recorded, but they must be rare, since the centers for the lower extremity lie so far away from the part at which an extravasation of this sort is likely to arise, that a clot large enough to implicate the upper ridge of the hemisphere would in all probability either lead to such deep coma that symptoms of hemiplegia could not be appreciated, or else would cause death before they were appreciated.

Kinds of Nystagmus.—Each canal produces a nystagmus in its own plane and to its own side. As there are three canals, there are three kinds of nystagmus, or nystagmus in three different planes, horizontal, superior and posterior.—J. S. DeMuth, in *Journal of Ophthalmology and Oto-Laryngology*.

THE ETIOLOGY OF ACTINOMYCOSIS

THE PRESENCE OF ACTINOMYCETES IN THE CONTENTS OF
CARIOUS TEETH AND THE TONSILLAR CRYPTS OF
PATIENTS WITHOUT ACTINOMYCOSIS*

FREDERICK T. LORD, M.D.

Instructor in Clinical Medicine, Harvard Medical School, Physi-
cian to Out-Patients, Massachusetts General Hospital.

BOSTON

As I have noted in a previous publication on the etiology of actinomycosis,¹ the failure of true actinomyces to grow at other than body temperature, the lack of any convincing evidence that actinomycosis is a contagious disease and the prevailing location of the affection about the jaws and neck suggest that infection arises from within the individual and probably from the mouth.

As a result of the investigation of material from the teeth, it was shown that organisms having the morphology and staining reaction of actinomyces could be constantly demonstrated in smear preparations (eleven cases) and in serial sections (five cases) of the contents of carious teeth in patients without actinomycosis. They

Fig. 1.—Case 9. Actinomycosis of the omentum in a guinea-pig, fifteen days after intraperitoneal inoculation with material from tonsillar crypts. Nodular tumor attached to the stomach (actual size).

are so abundant as to suggest that they play a fundamental part in dental caries. The intraperitoneal inoculation of guinea-pigs with material from carious teeth gave rise to omental tumors histologically identical with actinomycotic tissue and containing typical club-bearing actinomyces granules in three (60 per cent.) of five animals.

Following the demonstration of actinomyces in the contents of carious teeth, material from tonsillar crypts was investigated.

I. INVESTIGATION OF THE CONTENTS OF TONSILLAR CRYPTS

1. *Method.*—No patients with the lesions of actinomycosis were studied. The investigated material consisted of yellowish, hard or soft masses extracted by means of the platinum loop from the tonsillar crypts of seven

patients. The masses were placed in sterile test-tubes and sent to the laboratory. In addition, material expressed from the crypts of enlarged tonsils, removed by operation, was examined in six cases. These tonsils showed no other lesion than hypertrophy. All instruments used in the manipulations were previously sterilized. The method of animal inoculation, of imbedding and staining the fresh specimens and the tissue obtained from the inoculated animals was the same as in the investigation of the contents of carious teeth.

2. *Serial Sections of the Fresh Material.*—Serial sections of a part of the hard or soft, yellowish masses from the crypts of the tonsils were made in four cases (Cases 6, 8, 10 and M. L.²). Filaments resembling actinomyces in morphology and staining reaction and similar to those in the contents of carious teeth were present in large numbers in all. They appear as an interlacing network or as colonies composed of a dense mass of organisms with radiating peripheral filaments. Club-formation was not observed. The filaments are much mixed with other bacteria. In consideration of the tendency of actinomyces to produce wide-spread connective tissue formation in the typical lesions of the dis-

Fig. 2.—Case 9. Section through two fused nodules showing abscess formation; (A) necrotic pus cells, actinomyces filaments and bacteria; (B) actinomyces granules without "clubs;" (C) connective tissue. In other parts of the tumor (not shown in the photograph) typical club-bearing actinomyces colonies are found. (× 7 app.).

ease, it is suggested that their toxin production is a cause of hypertrophy of the tonsils.

3. *Animal Inoculation.*—Guinea-pigs were inoculated intraperitoneally with material from thirteen cases. Three animals died of general peritonitis within twenty-four hours and are excluded, thus leaving ten cases for further consideration.

Negative Cases: Of these ten animals, post-mortem examination of three (Cases 1, 2 and 3), twenty-one days after inoculation with fluid material expressed from the excised tonsils, showed only slight omental thickening in places and serial sections were negative. A fourth animal (Case 4) inoculated with yellowish, soft material extracted from the tonsil by means of the platinum loop, showed numerous adhesions and three small nodules, one of which contained a small amount of pus. Serial sections were negative.

*This investigation was undertaken under a grant from the Proctor Fund of the Harvard Medical School.

1. Lord, F. T.: A Contribution to the Etiology of Actinomycosis: Experimental Production of Actinomycosis in Guinea-Pigs Inoculated with the Contents of Carious Teeth, Boston Med. and Surg. Jour., July 21, 1910.

2. M. L., aged 25, female. Diagnosis enlarged tonsils and chronic arthritis. Tonsils received July 28. Guinea-pig inoculated with expressed material died within twenty-four hours of general peritonitis.

Positive Cases: The six remaining animals, including one (Case 5) inoculated with fluid material expressed from the excised tonsils and five (Cases 6, 7, 8, 9 and 10) receiving injections of more solid material extracted from the crypts by means of the platinum loop, were killed within from thirteen to forty-five days after inoculation. Post-mortem examination of these animals showed from one to three grayish-white or reddish omental tumors varying in greatest diameter from 1 mm. to 1 and 0.5 cm. Serial sections of one or more of the tumors showed from one to six colonies of branching filamentous Gram-staining organisms, surrounded by a zone of pus cells of variable width, beyond which there was connective tissue in different stages of development. Radially disposed, peripheral, club-bearing filaments were demonstrated about some of the colonies in all the positive cases. In their histologic appearance, the tumors are identical with actinomycotic tissue and with the experimental lesions similarly obtained with the contents of carious teeth. The colonies of branching, filamentous organisms are typical actinomyces granules. Bacteria and foreign bodies were also found in the lesions. Moderate enlargement of the intra-abdominal

a small nodule adherent to pylorus. Serial sections of adhesions and nodules show no colonies of actinomyces.

GROUP II: POSITIVE CASES

A. Animal inoculated with fluid material expressed from crypts of excised tonsils.

CASE 5.—L.H.S., male, aged 27. Hosp. No. 154522. Diagnosis, enlarged tonsils. Guinea-pig inoculated July 28. Killed after fourteen days. Omentum shows three reddish nodules one 3 x 2 mm., the others somewhat smaller. Serial sections show one colony of actinomyces in each nodule. "Clubs" are found about one of the three colonies.

B. Animals inoculated with yellowish, hard or soft material extracted from the tonsillar crypts by means of platinum loop.

CASE 6.—Dr. T., male, aged 25. Office patient. Diagnosis, functional cardiac murmur. Small amount of yellowish, hard material obtained from tonsillar crypts. Tonsils slightly enlarged. Guinea-pig inoculated July 21. Killed after eighteen days. Omentum shows a nodule 2 by 1 mm., containing one colony of actinomyces and two smaller nodules containing foreign bodies. Swollen and at times bulbous filaments project in a radiate manner from the colony. A few club-bearing filaments are found.

CASE 7.—C.J.T., male, aged 24. Hosp. No. 154675. Diagnosis, acute tonsillitis. Small, hard, yellowish mass extracted from one of the crypts of an enlarged right

Fig. 3.—Case 7. Actinomycosis of the omentum in a guinea-pig, seventeen days after intraperitoneal inoculation with material from a tonsillar crypt. Colony of actinomyces surrounded by a narrow zone of connective tissue. ($\times 20$ app.).

glands was frequently noted, but serial sections of these glands failed to show actinomyces.

A brief account of the inoculation experiments in the ten cases is as follows:

GROUP I: NEGATIVE CASES

A. Animals inoculated with fluid material expressed from the crypts of excised tonsils. Killed after twenty-one days. Omentum showed only slight localized thickening. Serial sections showed connective tissue about foreign bodies, but no actinomyces.

CASE 1.—F.M.R., female, aged 12. Hosp. No. 152875. Diagnosis, enlarged tonsils and adenoids.

CASE 2.—V.S.W., female, aged 12. Hosp. No. 11698. Diagnosis, enlarged tonsils.

CASE 3.—R.S., female, aged 12. Hosp. No. 48016. Diagnosis, enlarged tonsils.

B. Animal inoculated with yellowish soft material extracted from two crypts of a slightly enlarged tonsil by means of platinum loop.

CASE 4.—M.T.C., female, aged 35. Hosp. No. 154861. Diagnosis, pelvic adhesions. Guinea-pig inoculated August 1. Died after 13 days with symptoms of arthritis. Autopsy showed adhesions of omentum to liver and intestines. Omentum contains three nodules, the largest 3 mm. in greatest diameter. A small amount of pus expressed from

tonsil. Guinea-pig inoculated July 30. Killed after seventeen days. Omentum shows a nodule 1 and 0.5 mm. in greatest diameter, containing a colony of actinomyces and a foreign body (Fig. 3). The width of the colony at the center of the nodule is more than half the width of the nodule. Club-formation is well marked.

CASE 8.—A.S., male, aged 18. Hosp. No. 152742. Diagnosis, enlarged tonsils. Two yellowish masses, one 3 mm. in diameter, hard and gritty, the other 1 mm. in diameter and soft, extracted from the crypts. Two guinea-pigs inoculated August 2. One animal killed after thirteen days. On the anterior wall of the stomach, a hard, grayish, elongated tumor, 1 and 0.5 cm. in greatest diameter and somewhat constricted toward one end. It is composed of two fused nodules. Omentum adherent to liver by a band of fibrous tissue, between which and the liver is a white nodule 3 mm. in greatest diameter. Sections of the larger mass show six colonies of actinomyces in the larger and two in the smaller nodule. Club-formation is well marked about all the colonies. The second animal was killed after forty-five days. Similar omental tumors containing club-bearing colonies (Fig. 5) were found.

CASE 9.—L.P.W., female, aged 13. Hosp. No. 151963. Diagnosis, enlarged tonsils and adenoids. Two yellowish masses about 1 mm. in diameter extracted from the ton

sillar crypts. Guinea-pig inoculated August 4. Killed after fifteen days. Adherent to the stomach along omental attachment is a hard, grayish-white, nodular tumor, 1 and 0.5 cm. long, 12 mm. wide and 8 mm. high (Fig. 1). Omentum adherent to left kidney between which and spleen is an oval, grayish nodule 5 mm. in greatest diameter. Sections of the larger of the two masses show abscess formation occupying about a half of the diameter of the fused nodules composing the mass. The abscesses are surrounded by connective tissue (Fig. 2). They contain pus cells, actinomyces filaments and bacteria in varying proportion in different parts of the sections. In regions where the bacteria are most abundant, there are necrotic pus cells and numerous isolated and clustered actinomyces filaments with radiating peripheral filaments without "clubs." In parts of the tissue (not shown in the photograph) where bacteria are relatively few in number, typical club-bearing colonies of actinomyces are found. These colonies are surrounded by a narrow zone of well-preserved pus cells beyond which is fibrous tissue. The appearance suggests that the great abundance of bacteria in the larger abscesses has prevented the formation of typical actinomyces granules.³

Fig. 5.—Case 8. Actinomycosis of the omentum in a guinea-pig forty-five days after intraperitoneal inoculation with material from tonsillar crypts. Margin of a colony of actinomyces showing "clubs," some with central filaments and with branches. Fresh specimen. (× 750.)

CASE 10.—A.H., female, aged 7. Hosp. No. 67593. Diagnosis, enlarged tonsils and adenoids. One foul, yellowish mass about 3 mm. in diameter and several smaller masses, extracted from the tonsillar crypts. Guinea-pig inoculated August 4. Killed after fifteen days. In a mass of adhesions, between stomach, liver and several loops of intestine is a grayish-yellow nodule of an oval shape and 8 mm. in greatest diameter. Sections show five colonies of actinomyces (Fig. 4). Only one colony is deeply stained in this section. Club-formation is well marked.

II. SUMMARY

From the investigation of the teeth and the tonsils, it may be stated that organisms having the morphology and staining reaction of actinomyces have been constantly found in smears (eleven cases) and serial sections (five cases) from the contents of carious teeth and in serial sections (four cases) of yellowish, hard or soft material

3. A similar admixture of bacteria and organisms resembling actinomyces, with the formation of multiple abscesses was observed in an animal inoculated with the contents of carious teeth. No typical club-bearing actinomyces granules were found.

from the tonsillar crypts of patients without actinomycosis.

Following the intraperitoneal inoculation of guinea-pigs with the contents of carious teeth (five cases) and the tonsillar crypts (ten cases) omental tumors histologically identical with actinomycotic tissue and containing typical club-bearing actinomyces granules have been produced in 60 per cent. of the inoculations in both instances.

III. BEARING OF THE FINDINGS ON THE ETIOLOGY OF ACTINOMYCOSIS

The constancy with which actinomyces can be demonstrated in the contents of carious teeth and the crypts of the tonsil in patients without actinomycosis indicates the buccal cavity as a source of the disease. Imperfect drainage of a carious tooth, whether arising spontaneously or as the result of filling an incompletely sterilized tooth, may be regarded as favorable to the production of the disease about the jaws or neck, the root canal of the tooth being the channel of infection. Organisms derived from the teeth or the tonsil may also be implanted in neighboring tissues or find lodgment in more remote parts of the body by way of the respiratory tract or the alimentary canal. Actinomyces have been known to penetrate the lymphatic system only in very rare instances and extension from the tonsil by way of the lymph channels is improbable.

In explanation of the infrequency of the disease compared with the numberless chances for infection, it may be noted that in five negative inoculation experiments with the contents of carious teeth,⁴ organisms resembling actinomyces were present in smears from the extracted material and it may be assumed that actinomyces were also present in the injected material, but failed to multiply in the body of the animal. Here, as in other infections, the varying numbers and vitality of the seed and fertility of the soil doubtless determine the result in large measure.

Another factor of probable importance is the number and virulence of the organisms occurring as a mixed infection with actinomyces. As suggested by the findings in one inoculated animal (Case 9) the infrequency of actinomycosis of the jaw compared with simple alveolar abscess may be due to rapid multiplication of pyogenic organisms at the site of infection, thus preventing actinomyces from taking root in the tissue and developing typical club-bearing colonies.

This investigation was carried out in the Clinico-Pathological Laboratory of the Massachusetts General Hospital. I am indebted to Dr. J. H. Wright for his encouraging interest and to Drs. J. L. Goodale, D. C. Green and W. F. Knowles, of the Throat Department, for their kindness in placing material at my disposal. The photographs were made by Mr. L. S. Brown.

Paget's Disease of the Nipple.—E. Jonas (*Interstate Medical Journal*) states that, according to recent investigations, Paget's disease of the nipple is cancerous from the very first, rapidly involving the skin and the breast itself. This disease demands the same prompt attention and radical surgical interference as is accorded all other cancers of the breast. There is a striking parallelism, he declares, between Paget's disease of the nipple and leukoplakia in cancer of the tongue; and also an analogy with cancers of the scrotum and penis, occurring in certain working classes.

COMPLEMENT FIXATION WITH AN ANTI-
GENIC CRYSTAL OBTAINED FROM
LUETIC LIVER*

CHARLES F. CRAIG, M.D.
Captain, Medical Corps, U. S. Army
WASHINGTON, D. C.

Since the observation by Wassermann, Neisser, and Bruck¹ of the value of the complement fixation test in lues, the exact nature of the antigenic substance or substances contained in extracts from luetic and normal tissues has received a great deal of attention, and the re-

Fig. 1.—Antigenic crystals $\times 372$.

Fig. 2.—Antigenic crystals $\times 750$.

sults appear to show that more than one substance, capable of acting as an antigen, is contained in these extracts. It is the purpose of this contribution to describe briefly a crystal obtained from an alcoholic extract of luetic liver which acts as a very efficient antigen when dissolved in alcohol, and which has not, to my knowledge, been

heretofore obtained from such extracts. I regret to state that at the present writing the exact chemical nature of this crystal has not been ascertained, the most that can be said concerning it being that it may belong to the group of crystals which may be obtained from the bile salts.

It is probable that in an alcoholic extract of luetic liver, containing, as it does, a mixture of numerous organic and inorganic substances, there occur chemical bodies which may react one on another, giving rise to modifications resulting in the production of antigenic substances not demonstrable in the fluid until these reactions have occurred. It would appear that the crystal under discussion originates in this manner, as it does not occur in the fresh extract, but only after the extract has been kept for several weeks.

It has been proved that several substances may be separated from animal tissue which, when used alone, may act as antigens. Landsteiner, Müller, and Potzl², as well as Porges and Meier³, found that lecithin acts as an antigen and Noguchi⁴ has confirmed their results, but

Fig. 3.—Antigenic crystals $\times 1560$.

lecithin alone is unsatisfactory in practice, on account of its variability in this respect. Noguchi states that while lipoids are undoubtedly active agents in complement fixation it has not been ascertained just which lipoids are concerned, but his acetone-insoluble lipid antigen is an excellent illustration of the fact that these substances, at least, are capable of acting as most efficient antigens. Cholesterin has been claimed by Fleischmann⁵ to be antigenic, but Noguchi only obtained negative results with this substance. However, the recent work of Browning, Cruickshank, and McKenzie⁶ has shown that when cholesterin is added to an alcoholic solution of lecithin to the point of saturation, the complement-binding power of the solution is greatly augmented, and an antigen is obtained which they say "is a very efficient substitute for the crude organ extract in the Wassermann test, and is probably superior to the crude extract."

The artificial antigen of Sachs and Rondoni⁷, composed of an alcoholic solution of lecithin, oleate of soda, and oleic acid, has received both favorable and unfavorable comment, and is not generally accepted as being as reliable as the crude extract. Of the soaps, oleate of soda has been used as an antigen by Sachs and Altmann⁸, while the salts of the bile acids, sodium taurocholate and sodium glycocholate were proven to be antigenic by Levaditi and Yamanouchi⁹, their work being confirmed by Noguchi⁴, who also found that sodium cholate acts as an antigen.

I have found that sodium taurocholate is absolutely useless in practice, for, while possessing antigenic properties, it is very weak in this respect, and different samples vary exceedingly. My observations confirm those of Noguchi, who found that the bile salts were greatly inferior to the lipoids as antigens.

The antigenic crystal described in this paper is as efficient, when absolute alcohol is saturated with it, as is the crude extract from which it was obtained, but while this is so, I do not consider that this crystal is the only antigenic substance present in the crude extract, or even that it is necessarily the most important in this respect, for to admit this would be to contradict the great antigenic value of other substances obtained from tissue extracts and which bear no resemblance to it in morphology or chemistry.

The important fact determined by observations on the antigenic value of this crystal is that it is practically as efficient, in antigenic strength, as the whole extract, and that a saturated alcoholic solution of these crystals may be substituted for the crude extract with identical results, so far as clinical diagnosis is concerned.

METHOD OF OBTAINING THE CRYSTALS

The crystals under discussion were obtained from an extract of luetic liver made in December, 1909. The liver was macerated in 10 volumes of absolute alcohol for 10 days, the mixture being kept in the incubator at 37° C. and shaken several times a day during that period. The resulting mixture was then filtered and the filtrate at once evaporated to one-third its volume by means of an electric fan, at room temperature. When titrated it was found that 1 drop from a capillary pipette was sufficient to cause total inhibition of 1 c.c. of a 1 per cent. suspension of human corpuscles in the presence of luetic serum (Noguchi's modification of the Wassermann test being used) so that this extract may be said to have been strong in antigenic substances.

A portion of the extract was allowed to remain undisturbed in the ice-box until early in April (about four months) when it was observed that a snow-white precipitate had formed. On microscopic examination this was found to consist of long, needle-like crystals, small coarsely granular masses, and prismatic crystals. On filtering and adding the precipitate to a sufficient amount of absolute alcohol, the granular matter and the prismatic crystals dissolved, leaving the needle-like crystals apparently intact. In order to obtain these crystals in as pure a condition as possible, they were washed from eight to ten times in absolute alcohol and preserved in a small amount of the latter.

CHARACTERISTICS OF THE CRYSTALS

The crystals are long, needle-shaped bodies, having a fractured extremity, and are well illustrated in the photomicrographs (Figures 1, 2 and 3). They are colorless when viewed singly, but *en masse* form a snow-white collection at the bottom of the container. When shaken in alcohol the resulting mixture has a peculiar silky appearance due to the multitude of very delicate crystals suspended in the fluid. The exact chemical nature of the crystals has not been definitely ascertained. They give a positive Pettenkofer's reaction, thus indicating that they belong to the bile salts. I have compared them with taurocholic and glycocholic acids, and sodium taurocholate and glycocholate and find that they differ markedly in appearance and in solubility. While, from the method of preparation, it cannot be proved that the crystals are chemically pure, the great differences that show in solubility and the fact that they are so strongly inhibitory would appear to prove that they are not identical with any of the substances so far investigated. In appearance, they resemble glycocholic acid most closely and because of this I have compared them very carefully with this substance, with the following results:

The sample of glycocholic acid was prepared by Kaulbaum, and was found to be very soluble in absolute alcohol and acetic acid, soluble with difficulty in cold water (300 parts); soluble in acetone and slightly soluble in ether. The antigenic crystal is very slightly soluble in absolute alcohol and very soluble in acetic acid, exceedingly soluble in cold water; insoluble in acetone and ether. The saturated solution of glycocholic acid in absolute alcohol is yellow in color, while the solution of the antigenic crystal in this fluid is colorless. The melting point of glycocholic acid lies between 138 and 140 degrees C.; that of the antigenic crystal is 235 degrees C.

It will be observed that the antigenic crystal differs greatly from glycocholic acid in solubility in different reagents and the melting point, and in addition I have determined that glycocholic acid cannot act as an antigen. If placed under the same conditions as the antigenic crystal, *i. e.* in saturated alcoholic solution, one drop, when added to 1 c.c. of a 1 per cent. suspension of human corpuscles, will cause total hemolysis in a few moments without the addition of complement, while larger doses cause a dirty-gray precipitate. If diluted, in any strength, the acid is unable to cause inhibition, dilutions from 1 to 50 up to 1 to 1,000,000 having been tested. It is therefore my opinion that these crystals are not glycocholic acid or any of the bile salts which have been mentioned.

The very small amount of these crystals which is soluble in absolute alcohol is remarkable, a very minute quantity of the crystals being sufficient to make a large amount of efficient antigen. That the crystals are very slowly soluble is proved by the following observations: A small quantity of the crystals was washed eight times in absolute alcohol, the alcohol being saved after each washing. The washing was done with a centrifuge and it was found, by titration with a known positive luetic serum, that each washing was weakly antigenic. After the last washing the crystals were allowed to remain in a test tube, with a quantity of absolute alcohol, for 24 hours, in the ice-box; the alcohol was then titrated and found to be much greater in antigenic power than the alcohol used in washing. Another titration at the end of 72 hours proved that after this period the alcohol possessed twice the antigenic power that it did at the end

7. Sachs and Rondoni: Ztschr. f. Immunitätsforsch., 1909, 4, 132.

8. Sachs and Altmann: Berl. klin. Wehnschr., 1908, xiv, 494; *Ibid.*, 1908, xiv, 699.

9. Levaditi and Yamanouchi: Compt. rend. Soc. de Biol., 1907, lxiii, 740.

of 24 hours, and that it was as efficient as the crude extract in this respect. No increase in antigenic value was noted after 72 hours.

Owing to the slight solubility of these crystals and the fact that even the small quantity that is dissolved is sufficient to cause absolute inhibition of hemolysis in the presence of luetic serum, it is possible with a small quantity of the crystals to prepare a large amount of antigenic solution. From the very small amount of crystals originally obtained from the crude extract, an amount which was not weighed, but was certainly not over a few centigrams, I have already prepared over a liter of antigen as strong in antigenic properties as the whole extract, and have enough remaining to prepare almost as much more. The original amount of crude extract was 250 c.c.

I mention this in order to show how little of the material is soluble in absolute alcohol, yet is efficient as an antigen. As soon as the alcohol is saturated it possesses practically the same antigenic strength as the whole extract, and in the same amount does not possess either hemolytic or inhibitory properties when used with normal serum. If added in too large an amount it will inhibit hemolysis, as will almost every antigenic substance if used in too large a dose, and if the crystals be added directly to a blood suspension they produce hemolysis. They are very soluble in salt solution and if dissolved in this medium in large amount they produce hemolysis, so that they should not be used in this manner. The amount soluble in absolute alcohol is never sufficient to produce hemolysis and, for practical use, the crystals have to be used in alcoholic solution.

COMPLEMENT FIXATION

The method used in testing the antigenic properties of the crystals has been the same as is used in making the Wassermann test in this laboratory, *i. e.*, Noguchi's modification; and it has been my practice since May, 1910, to run parallel tests of each serum, so far as possible, using the whole alcoholic extract as antigen in one set, and the saturated alcoholic solution of the crystal in the other. It will be understood, then, that the methods of titration, and of performing the tests, are those recommended by Noguchi, and that identical conditions were present in both sets of tests with the exception of the antigenic solution.

The first titration of the original whole extract and of the saturated alcoholic solution of the antigenic crystal resulted in showing that both were practically the same in antigenic strength, the crystal antigen being slightly the weaker of the two, requiring 0.025 c.c. instead of 0.02 c.c. to produce inhibition under similar conditions. The titration was made in May and since then both the crude extract and the crystal antigen have grown gradually weaker, at present 0.06 c.c. of the extract being required to produce inhibition and 0.08 c.c. of the alcoholic solution of the crystal. From this it is evident that neither the crude extract or the crystal antigen are permanent, so that it is necessary to titrate both at intervals. Since May, I have made comparative tests of 160 different sera with both antigens and in every case the results have been practically the same. The sera examined were from patients suffering from primary, secondary, tertiary, and latent lues and from other diseases, and in no instance was a positive reaction given by the whole extract and a negative by the crystal, or *vice versa*. From a clinical standpoint the results may be

said to have been identical, but it was noticed in a few cases that the whole extract gave slightly more marked inhibition than the crystal antigen, while in a few others the crystal antigen gave a stronger reaction. These slight differences caused no confusion in reading the tests, but are interesting because they indicate that substances are present in the whole extract which caused differences in the reaction obtained. The variations were not confined to any one stage of lues or to any particular class of cases, as is illustrated in the following table giving the results in 15 cases, in 10 of which these slight differences in the strength of the reaction were detected. The signs +++ and +— are used to indicate the differences in the reactions, but they should not be interpreted to indicate such great differences as are usually meant by them when used to illustrate the varying degrees of inhibition in the Wassermann test, as in all of the positive cases inhibition was practically complete and the tests were undoubtedly positive with both antigens:

Case.	Diagnosis.	Whole Extract.	Crystal Antigen.
1.	Primary lues.....	+++	++
2.	Primary lues.....	+++	++
3.	Primary lues.....	++	+—
4.	Secondary lues.....	++	+
5.	Secondary lues.....	+++	+++
6.	Secondary lues.....	+++	+—
7.	Secondary lues.....	+	++
8.	Tertiary lues.....	+++	+++
9.	Tertiary lues.....	+—	++
10.	Tertiary lues.....	++	+++
11.	Tertiary lues.....	+	++
12.	Latent lues.....	+	+++
13.	Latent lues.....	+++	+
14.	Latent lues.....	+++	+
15.	Latent lues.....	+	+

It will be observed that in some cases the crystal antigen gave a stronger reaction than the whole extract, while in other instances the opposite is true. In the majority of the sera tested, however, the results were identical, and in none was there any disagreement as to a positive or negative result. The explanation of the slight differences noted is difficult, but they apparently depend on differences in the sera tested, some body or bodies being present having slight inhibitory power over the antigenic action of one or the other antigen. I believe that the whole extract gave slightly better results in the majority of cases, but the crystal antigen gave results which were as dependable as those given by the whole extract and as clinically useful.

The practically identical results obtained with the whole extract and the antigenic crystal, the practically identical titration of both, and the gradual loss in antigenic strength in both as determined by titration would apparently prove that the crystal represents the only active antigenic substance present in the crude extract, but such an opinion is hardly justifiable, for other substances are present in alcoholic extracts of luetic liver which have antigenic properties and which do not appear to be identical with these crystals. I have been unable to obtain the crystals in one lot of acetone-insoluble lipoid antigen, prepared according to Noguchi, and no work has yet been done to determine whether they occur in alcoholic extracts of normal tissues which have been found to have antigenic properties. The crystals are not obtained in every alcoholic extract of luetic liver, for in one such extract, made in the manner described, and now seven months old, the crystals have not appeared. It is interesting to note that this particular extract is very weak in antigenic property, and that it is rapidly losing strength. Of course it is possible that in the original extract from which the crystals were obtained, some con-

dition not usually found was present, or that some particular step in the preparation favored the formation of the crystals, but I believe that further research will demonstrate that they are present in the majority of alcoholic extracts of luetic liver prepared in the manner mentioned. If these crystals can be obtained in most alcoholic extracts of luetic liver, or other tissues, as easily as they were in the extract here described, it will greatly simplify the preparation of antigenic solutions, as so small a quantity of the crystal is needed to make a large amount of efficient solution. It may be found possible, also, to keep the crystals in a dry state, and thus enable us to make up small amounts of antigenic solution as needed.

Until the exact nature of these crystals is determined it is idle to speculate on the relation which these observations bear to the present theories regarding the mechanism of complement fixation in lues, but they would appear to indicate that the purely chemical nature of the process should be more fully investigated, and that the preparation of a reliable artificial antigen may be hoped for in the future.

The most important result of these observations is the isolation of an apparently pure crystalline substance from an alcoholic extract of luetic liver which possesses practically the same antigenic strength as the original whole extract and which can be used with practically identical results in the complement fixation test for lues.

I desire to express my thanks to Dr. Noguchi for helpful suggestions, and to Prof. Frank P. Underhill, of Yale University, for valuable aid in the investigation of the nature of the crystal. Owing to the small amount of material I was able to furnish for this purpose a definite conclusion could not be reached regarding this question.

THE PATHOLOGY AND PROGNOSIS OF INTERNAL EAR COMPLICATIONS RESULT- ING FROM INFLAMMATORY MIDDLE- EAR DISEASES*

J. HOLINGER, M.D.
CHICAGO

In 1907 a paper appeared by Dr. C. J. Blake of Boston under the above heading, as a part of a symposium on suppuration of the labyrinth. Our knowledge of the pathology of suppuration of the labyrinth has been increased since then by a number of valuable contributions, but, as in 1907, the volume of the literature on the clinical part of the subject is out of all proportion more extensive than on the pathologic. This is explained by the great technical and scientific difficulties of pathologic investigation of the labyrinth. The large amount of clinical literature, based on this comparatively small foundation of pathology, creates the impression that the whole structure of our teachings of suppuration of the labyrinth is somewhat top-heavy, and the inevitable consequence will be that our views on some of our clinical teachings, as for example concerning the indications for operation, will probably, sooner or later, have to be modified.

In sketching the pathology and the prognosis of internal ear complications, resulting from inflammatory

middle-ear diseases, I shall try to give a general survey of the status of the subject, only indicating some of the open questions rather than attempting to answer many of the questions, which, to a great extent, can be done correctly only by future careful and patient observation of the living and of the post-mortem material.

Bacteriology will be of little use, as even the differentiation of tuberculous labyrinthitis (which differs in many respects from all other forms of labyrinthitis) is made from pathologic and not from bacteriologic criteria.

Statistics also are admissible only conditionally, since Goerke, for example, puts acute suppurations of the labyrinth and acute exacerbations of chronic suppurations in the same category, drawing therefrom the conclusion that suppurations of the labyrinth in acute suppurations of the middle ear are nearly as frequent as those in chronic suppurations. There is another question which must be decided before we can make use of statistics. If a labyrinth sequestrum is found twenty years after a patient had scarlet fever, during which time the ear had suppurated, this certainly would seem to be a chronic suppuration of the middle ear and labyrinth. But the real course of the disease was probably as follows: The patient was very sick after the scarlet fever, had little power of resistance, and acute scarlet otitis set in which invaded the labyrinth. Thrombosis of one of the large arteries destroyed a part of the labyrinth, so that the so-called chronic suppuration was simply caused by the process of demarcation of the sequestrum, and finally by the sequestrum itself, which induced suppuration, acting as a foreign body. Clinically as well as pathologically such a case is an acute panofitis and cannot be put on a parallel with cases of cholesteatoma, in which one part of the labyrinth is destroyed while the other still shows function. Our position in this matter is not strengthened by the assertion made by some careful and experienced observers, namely, that they never saw a sequester develop in a case that was treated properly from the beginning. It is evident that at present it is too early to give statistics, and only as an apology do I repeat the well-known statement that, according to Hinsberg, there is one suppuration of the labyrinth to every one hundred acute and chronic suppurations of the middle ear.

The best division of my subject, having also clinical value, is the following:

- I. Serous labyrinthitis.
- II. Labyrinthitis in connection with acute otitis media, including scarlet fever, diphtheria and otitis, leading to formation of sequestrum.
- III. Chronic labyrinthitis in consequence of cholesteatoma.
 - A. Circumscribed labyrinthitis.
 - B. General labyrinthitis, earies, necrosis.
- IV. Tuberculous labyrinthitis.

I shall try to give a short description of each of these different forms.

I. SEROUS LABYRINTHITIS

Serous labyrinthitis was first described by Professor Siebenmann and his assistant Dr. Nager in connection with cholesteatoma and tuberculosis of the middle ear. Some of their original specimens from a patient who suffered from tuberculosis of the middle ear show no perforation into the labyrinth. Nevertheless, there are crescent-shaped, slightly opaque parts on the same side of each whorl of the cochlea. Their only explanation is this: In the preparation of the normal specimen the

* Read in the Section on Laryngology and Otology of the American Medical Association, at the Sixty-first Annual Session held at St. Louis, June, 1910.

labyrinthine fluid is lost, and the cavity of the cochlea is empty when seen under the microscope, but this transudation, being of an inflammatory nature, has coagulated. It was compared to the hypopyon in the eye, which is also a gathering of sterile seropus in a cavity close to an inflammatory focus, not in direct connection with the focus, but separated from it by some more or less healthy tissue, such as the cornea in one, and bone and membranous labyrinth in the other locality. Reissner's membrane, the sensory epithelia, Corti's organ, etc., are not very much changed, but they certainly have suffered somewhat.

This form of inflammation may heal by simple absorption of the fluid and consequently the hearing, which is lost during the inflammation, may be more or less completely restored; or it may become organized, and by formation of scars, in the course of time crush out the life of some of the important cell groups, which otherwise might, to some extent, have recovered. Siebmann attributes certain forms of deaf-mutism existing at birth to intra-uterine labyrinthitis of this form.

II. LABYRINTHITIS IN CONNECTION WITH ACUTE OTITIS MEDIA.

The labyrinthitis in connection with acute otitis media is usually the avenue by which the disease advances to a fatal meningitis in those fortunately not frequent cases in which death occurs a few days after the beginning of an acute otitis media. The port of entrance is usually the round or the oval window, or else, though rarely, some defect or dehiscence in the bony wall of the labyrinth. The infection at once invades the whole labyrinth, the cochlea as well as the vestibular apparatus. From the labyrinth the infection has two avenues to the meninges, one along the auditory nerve, the other through the aqueductus vestibuli and the endolymphatic duct. The possibility can certainly not be disputed that, in making a paracentesis, the stapes may be injured and the entrance of infection facilitated, or that instillations of peroxid may force infected material through the highly inflamed and, therefore, brittle membranes of the windows. A short sketch of the history of a case which first drew my attention to this possibility is the following:

A man, 35 years old, was seen at a hospital in an unconscious condition on a Monday evening in November, 1902. There was seropurulent discharge from the right ear, hard pulse and stiffness of the neck. His friend told me that he had developed earache the Friday evening previous. Saturday a paracentesis had been made and in the evening the patient went to bed on account of dizziness. Sunday severe headache and vomiting set in. Monday he became unconscious, and was brought to the hospital, where he died during the night. At the post-mortem examination the base of the brain showed pus along the blood-vessels. The pus was thickest in the locality of the right cerebellum, which corresponded to the place on the posterior surface of the pyramid, where in the reddish dura, the sacculus endolymphaticus was visible as a flabby yellow bag filled with pus. All spaces of the labyrinth contained pus; the crura of the stapes were severed from the foot-plate, surrounded with pus. The oval window was open.

The round window does not become a port of entrance of infection as frequently as does the oval window. Several authors attribute this to the more protected position of the round window. It is difficult to understand from what it is protected, unless it is from direct injury, since hydraulic pressure of the pus will act against the round window in the same way as it does against the oval win-

dow. The perforation of both windows takes place in some cases. Some authors assert that the swollen mucous membrane or granulations in the niches of the windows form a protection of the membranes of the windows; others assert the opposite, and show that a perforation occurred where the granulations caused a retention of the secretion.

Other ports of entrance, dehiscences and newly formed perforations, are much more rarely the cause of acute suppurations of the middle-ear spreading to the labyrinth. The location of the perforation is alone responsible for the course the disease takes. Cases are reported by Yoshii and Goerke of perforation from the Eustachian tube into the top of the cochlea. In these rare instances the suppuration remained confined to one coil.

The forms of otitis media after scarlet fever, diphtheria and measles, leading to labyrinthitis and finally to the formation of sequestrum, seem really to belong to this category, because the initial lesion is an acute otitis media, which, on account of the weak general condition of the patient, is followed by a slow and more or less general labyrinthitis. Lange and Goerke explain that "the cause for necrosis and the formation of a sequester of the whole labyrinth must be sought in the interior of the labyrinth." The demarcation and sometimes spontaneous elimination of a sequester of the labyrinth is usually a very slow process lasting for years, and during all this time it is associated with suppuration from the ear. But it is by no means a unique process, since the formation of large or smaller sequestrations in the mastoid process is not at all rare. The peculiarity of the process is the fact that encasement of new bone is not formed in the labyrinth and in the mastoid, as around sequestrations of, *e. g.*, the tibia.

III. CHOLESTEATOMA

Whenever during a suppuration there is a destruction of a large part of the lining of the middle ear, the defect can be remedied only by a scar and covered by epidermis; or when the tympanic membrane has become adherent to the inner-wall of the middle ear or aditus ad antrum, from long contact caused by being drawn inward, the result in both cases is a displacement of the normal lining of the middle ear by a cholesteatoma membrane. Underneath this membrane the bone becomes gradually absorbed. If this process takes place on the medial wall of the middle ear and antrum, it will lead to absorption of the capsule of the labyrinth. The result is a fistula of the labyrinth, which, however, is still covered by the cholesteatoma membrane. This membrane is often reduced to a simple layer of epidermis. It is important to remember that this process is often combined with suppuration in other parts of the middle ear, but it may also occur without even a trace of inflammation or suppuration or granulation being present. In the antrum and aditus it leads to a fistula of the horizontal or superior semicircular canal. The bone around it is ivory-like, white, and shows either a fine hole, a groove, or two separate holes, according to whether the semicircular canal is just opened or its wall has been partially or entirely worn away by the absorbing process. A protecting wall of granulations often, but by no means always, protects the remainder of the labyrinth. The result may be as follows:

1. Circumscribed labyrinthitis, which is usually confined to one or two semicircular canals. Other peripheral parts of the labyrinth are rarely affected. Herzog

stated that the first step in a circumscribed labyrinthitis is always a general serous labyrinthitis, and in this way he explains a number of symptoms, while others contradict him.

2. General labyrinthitis. A labyrinthitis is likely to remain local and circumscribed only if it concerns peripheral parts. Whenever the perforation takes place in the vestibulum the result is general labyrinthitis. This leads to destruction of all the important parts of the organ and therefore leads to total deafness. The process may be acute or chronic. An acute general labyrinthitis in connection with cholesteatoma is often connected with some therapeutic means, syringing or operation, whereby the cholesteatoma masses are forced through a fistula, or one of the windows is injured. The result is usually complete destruction of all important parts of the labyrinth and is often a stepping-stone to meningitis. In exceptional cases small circumscribed parts of the cochlea may recover.

Labyrinthitis in connection with cholesteatoma of the middle ear is by far the most frequent form of labyrinthitis associated with suppuration of the middle ear. Aside from the simple absorption of the capsule, the process may invade the labyrinth by caries, that is, destruction by granulations or by necrosis. In long-standing cases both processes take place side by side, and it is usually difficult or impossible, even under the microscope, to decide which of the two is the more prominent.

IV. TUBERCULOUS LABYRINTHITIS

Tuberculous labyrinthitis was investigated by Bezold, Scheibe, Siehenmann, and Nager. They found that its chief characteristic is the absence of all attempts at regeneration, as the disease occurs in patients who are in poor general condition, owing to the advanced stages of the disease of the lungs. A great resemblance was found between these processes and those in scarlet fever, in which, as was seen before, the disease attacks individuals whose power of resistance is greatly reduced. The most harmless form of disease of the labyrinth is the infiltration of the annular ligament of the oval window, or of the membrane of the round window combined with a few granulations on the inner surface of the ligament, and a serous labyrinthitis. It occurs in scarlet fever as well as in tuberculous otitis. The sensory epithelium is comparatively slightly affected and recovery with little loss of function is therefore possible, if the general condition improves. The more serious forms are clinically, as well as pathologically, even more interesting. In looking over the reports of Dr. Heinrich Herzog, we find deafness usually very pronounced, but the other labyrinth symptoms, dizziness, vomiting, nystagmus, etc., are rarely mentioned by the patients. The pathologic changes, on the contrary, are very extensive. Tuberculous processes usually enter through the windows into the labyrinth. The labyrinth fluid is changed, and contains many cast-off cells, the membranous labyrinth is destroyed, the sensory epithelium is swollen and cast off or changed to unrecognizable heaps of cells, and the nerves are atrophied and extensively infiltrated. But the process does not spread beyond the boundaries of the labyrinth, and death from meningitis rarely occurs in tuberculous labyrinthitis.

PROGNOSIS OF INTERNAL EAR COMPLICATIONS

The prognosis of internal ear complications, resulting from inflammatory middle-ear diseases, consists of the prognosis concerning the hearing, and the prognosis con-

cerning the life of the patient. In serous labyrinthitis the life of the patient will rarely be jeopardized, nor will the hearing. Much more dangerous, in fact the most dangerous of all forms of labyrinthitis, is the labyrinthitis in connection with acute otitis media. The so-called acute panotitis usually terminates fatally, as the meninges are invaded almost simultaneously. An operation in these rare cases can scarcely ever be premature, provided the diagnosis of labyrinthitis is certain, since the process, if left to itself, is liable to end fatally after a very few days. Scarlet fever and diphtheria otitis, complicated with labyrinthitis, progress more slowly, owing to the poor general health of the patient, and, therefore, the life of the patient is often spared, though the hearing of the ear involved is destroyed.

The prognosis of labyrinthitis in consequence of cholesteatoma of the middle ear is best given in Dr. Karl Grünberg's words: "Pathology teaches us that the suppurative inflammation of the labyrinth has a pronounced tendency to heal, provided life is not extinguished by other complications. After the acute stage has passed the exudations become organized and form a scar." The final result as to hearing depends on the extension of the destruction and the extremely varying power of restitution. Goerke, in connection with a case of perforation of a cholesteatoma through the annular ligament, is even more sanguine. "The number of cases of labyrinthitis which heal in this way cannot be estimated, hardly can they be suspected, if we consider how many ears of deaf-mutes show similar changes. It must be repeated over and over again that the most serious forms of labyrinthitis show attempts at recovery which—and this is important—really give the protection which we expect of them."

In view of these quotations taken from some of the most modern writers, the large death-rate in connection with operations on the labyrinth is rather surprising. It is now known that many lives have been sacrificed on account of the lack of knowledge of pathology, lack of experience on the cadaver, and lack of clinical experience. Recognizing this fact, it is evident that operations on the labyrinth ought to be performed only by qualified operators. This restriction must be extended beyond the labyrinth operations proper, as it is beyond question that many a death, after a simple mastoid operation, finds its explanation in the curetting of a few granulations on the medial wall of the antrum, aditus or middle ear. These granulations often cover a fistula in the labyrinth and their removal opens the avenue for infection of the whole labyrinth and the meninges. Trained assistance also is important, since an incompetent handling of a retractor may, by luxating the stapes, lead to the same consequences.

Pathology has shown that Nature is able to cope with a suppuration of the labyrinth, provided she has sufficient time to throw out her safeguards.

109 Randolph Street.

Treatment of Nervous Diseases.—The first essential for the successful treatment of any disease is a correct diagnosis; the second is a full recognition of the source from which the disease has flowed; and the third is a clear conception of what we desire to accomplish. Given this information, curable nervous diseases may be shaped toward recovery by such physical measures as rest, occupation, and exercise; by water, electricity and massage; by exhortation, persuasion and explanation, and by medicines.—J. Collins, in *Interstate Medical Journal*.

DISCUSSION OF THE SYMPTOMS AND DIAGNOSIS OF INFECTION OF THE LABYRINTH RESULTING FROM SUPPURATIVE OTITIS MEDIA *

J. R. FLETCHER, M.D.
CHICAGO

Infections of the labyrinth from suppurative otitis media may be classified as (1) circumscribed, (2) diffuse, (a) manifest (circumscribed or diffuse), (b) latent (diffuse), (3) perilabyrinthitis.

Circumscribed labyrinthitis is qualified thus: with erosion, fistula or stapes subluxation, or without either.

Diffuse labyrinthitis is qualified as suppurative, serous or hyperemic.

By manifest labyrinthitis is meant an inflammatory disease of the labyrinth, showing characteristic spontaneous symptoms.

Latent labyrinthitis signifies a like disease, showing no characteristic manifest spontaneous symptoms.

Perilabyrinthitis is an inflammatory disease of the cellular bone surrounding the labyrinth capsule. It can cause suppurative, serous and hyperemic labyrinthitis, or necrosis with sequestration of a part or the whole of the cochlea.

This cellular bone may be either diploetic or pneumatic. When pneumatic the cells have a mucous lining and communicate with the antrum and mastoid cells. A pneumatic structure must be frequent, as Wales¹ speaks of the membranous lining as being constant.

In those cases of chronic suppurative otitis media which progress to infection of the labyrinth, the otoscopic pictures which I have seen are as follows: The drum is perforated, usually below Shrapnell's membrane. If the perforation is central, granulations may be observed springing from the promontory or from around the oval or round windows, or from all of these points at the same time. Some part of these granulations may pass through the drum perforation, even filling most of the external canal. Their attachment can then be determined only by the probe. If the whole drum has been destroyed or the perforation is marginal, cholesteatoma will be seen, especially in the neighborhood of the windows and antrum, provided the exudate is not great enough to wash away the epidermal cells, of which the cholesteatoma is largely composed. The third picture shows the inferior portion of the drum attached to the lateral labyrinth wall and the perforation, which was central, thus made marginal. Cholesteatoma either will be seen or may be washed out. In these cases a fistula through the posterior-superior part of the external auditory canal will sometimes be seen, which communicates with the antrum.

The symptom-complex is changed according to routes of infection, of which there are three:

1. Through some part of the lateral labyrinth wall (usually circumscribed labyrinthitis).
2. Through the blood-vessels (usually diffuse suppurative labyrinthitis).
3. Through the perilabyrinthine bone cells (usually diffuse serous labyrinthitis).

CIRCUMSCRIBED LABYRINTHITIS

Circumscribed labyrinthitis is characterized by the following symptoms: defective hearing, even to total

deafness, or no defect of hearing referable to the cochlea; tinnitus, with or without cochlear impairment of hearing; cochlear impairment of hearing with or without tinnitus; vertigo coming in attacks, of which Barany says there are two types.

The first comes without outward cause, while the patient is quiet or even during sleep. The attacks are severe and of long duration, lasting from half an hour to several hours, and are more frequent than those of the second type. They are accompanied by nausea and vomiting, almost always, and by disturbances of equilibrium and spontaneous vestibular nystagmus. The nystagmus is rotary or compound, horizontal and rotary; directed as a rule to the diseased side only, but sometimes to the sound side also, but strongest to the diseased side.

Such attacks are probably due to hyperemia, as I have noticed marked impairment of hearing during attacks of this character. It is probable that diffuse hyperemic labyrinthitis occurs only in the course of circumscribed and perilabyrinthitis and acute suppurative otitis media.

The second type comes from without, especially from rapid movement of the head, arising from bed, looking upward, bending forward, etc., and going from a hot to a cold room, and *vice versa*. They are not severe or of long duration, lasting from a few seconds to some minutes only. Nausea and vomiting are wanting. Spontaneous nystagmus and disturbances of equilibrium are always present.

In both kinds of vertigo the fistula symptom and cochlear symptoms may be found. Between attacks these patients frequently feel quite well and have no manifest symptoms. If examined between attacks the reaction to both the turning and the caloric tests are quite normal, as a rule. Exceptionally when the caloric test is normal the rotary nystagmus from turning lasts longer than the horizontal. This never occurs in the perfectly healthy; it is, therefore, pathologic. When the reactions between attacks are normal the spontaneous nystagmus during attacks is strong and directed to the diseased side only. When the reaction is subnormal the spontaneous nystagmus may be strong and directed to both sides when the eyes are in the corresponding lateral position, though strongest to the diseased side. It is compound, as a rule, rotary and horizontal. Between attacks throwing the head backward causes vertigo and rotary nystagmus to the diseased side for fifteen seconds. This procedure cannot be repeated for ten minutes. Inclining the head to the shoulder of the diseased side causes strong rotary nystagmus to the diseased side. The same procedure to the well side seldom causes nystagmus. When it does occur it is weak, rotary and directed to the sound side. The fistula symptom can often be demonstrated. Failure to find it does not preclude the presence of fistula, because cholesteatoma over or granulations around the fistula sometimes prevent compression and aspiration of the membranous canal. To be certain that eye movements are a reflex response to artificial opening in the labyrinth wall the examination must be made by placing in the auditory meatus a Siegel otoscope or a perforated olive tip, with rubber tubing and bulb attached and then making compression and aspiration without removal of the tip. If a slow eye movement occurs in one direction by compression, and in the opposite direction by aspiration, fistula may be confidently diagnosed. A quick eye movement in the opposite direction to the slow, constituting nystagmus, is not essential. If the Eustachian tube is

* Read in the Section on Laryngology and Otology of the American Medical Association, at the Sixty-first Annual Session, held at St. Louis, June, 1910.

1. Baurnbill and Wales: *Modern Otology*.

open it must be closed, if possible, with a plug of cotton, otherwise the cavity will not be air-tight and the test will fail.

When the reaction to the turning and caloric tests are subnormal the eye movement is very small, requiring the closest inspection, at times, to detect it. The quick component, that is to say, nystagmus, does not occur in response to the compression and aspiration test. Ten turnings right and left give the following pathologic results: The after-nystagmus to the diseased side lasts half as long as that to the good side. This symptom alone cannot be considered pathologic unless the difference is at least as two to one. This is the typical subnormal reaction to turning.

When patients are in bed during severe attacks of vertigo they lie on the diseased side because in looking at objects in the room they look away from the quick component of the nystagmus, thus lessening its activity.

MANIFEST DIFFUSE LABYRINTHITIS

Manifest diffuse labyrinthitis is ushered in by the circumscribed becoming diffuse through intratympanic operation or acute exacerbation of the otitis media; (first route) by direct infection through the blood current; (second route) or by the perilyabyrinthine route. It is of first importance to distinguish between the suppurative on the one hand and serous and hyperemic on the other. In the suppurative the cochlear symptoms are absolutely negative, and hearing is quickly and completely lost. In the serous and hyperemic some hearing remains, the small a_1 Bézold fork will, at least, be heard. Spontaneous recovery of hearing takes place in serous and hyperemic labyrinthitis. From our present knowledge all cases in which hearing is recovered belong to these types. The vestibular symptoms are exceedingly stormy. Vertigo is so marked that frequently the patients are unable to stand. Objects within the visual field seem to move to the sound side; when the eyes are closed the body of the sufferer seems to him to rotate to the sound side. Nausea and vomiting nearly always accompany the vertigo. Horizontal and rotary nystagmus (compound) is marked. If the disease is left-sided, the nystagmus is to the right; if right-sided, the nystagmus is to the left, especially when the patient is looking in these directions. When he is looking straight ahead or to the opposite side to the quick component the nystagmus is invariably present, but weaker. Looking to the sound side and movement of the head increases the nystagmus. The position in bed is directly the reverse of that in severe attacks during circumscribed labyrinthitis. They lie in the sound side. The caloric test of the diseased ear is negative. Cold irrigation of the sound side stops the spontaneous nystagmus to this side and causes rotary nystagmus to the diseased side for a few seconds. Hot irrigation of the good ear increases the spontaneous nystagmus and the severity of the accompanying symptoms. The spontaneous nystagmus can also be increased by turning, head erect, to the diseased side. It is lessened or stopped for a few seconds by turning toward the good side. Turning with the head 90 degrees forward produces corresponding results. In either case the increase lasts just twice as long as the reduction.

Vestibular ataxia or reactionary body movements are the same as in experimental physiologic nystagmus, namely, always in the opposite direction to the quick component of the nystagmus. For instance, a patient with spontaneous, rotary nystagmus, that is, nystagmus in the frontal plane, to the left; standing facing for-

ward, head erect, feet together and eyes closed will fall to the right. With head rotated to left shoulder the nystagmus is directed backward and the falling is forward. With head rotated to the right shoulder the nystagmus is directed forward and falling is backward. With the head inclined 90 degrees forward the nystagmus is horizontal with relation to the earth. Falling cannot take place in this plane, therefore the reactionary movement is rotation around the vertical axis to the right, very unsteady and staggering. These reactions occur in 50 per cent. of cases. Practically all neurasthenics react, but not by the above rule. They usually continue to fall in the same direction or sink to the floor, irrespective of change of direction of the nystagmus. Their reaction does not characterize the nystagmus but does characterize the neurasthenic. The nystagmus known as horizontal causes no reactionary body movement.

LATENT LABYRINTHITIS

In latent labyrinthitis the history is of the utmost importance, as these patients must have had repeated attacks of vertigo and nystagmus or one storm of long duration, or both. Either total deafness exists or rest of hearing only will be found. The spontaneous nystagmus is small and weak and is directed to both sides when looking in these directions. There is none when looking straight ahead, unless opaque glasses are used so that fixation of vision cannot occur. In such a case it is minimal and directed to the sound side. Fistula and caloric tests are negative. Movements of the head have no effect. The utmost care should be exercised in the diagnosis of these cases, because they may be mistaken for acoustic neuritis of long standing. Ten turnings give the same pathologic results as in circumscribed labyrinthitis. The ataxic symptoms are very slight when present.

To diagnose latent labyrinthitis all tests must be made. The negative are quite as important as the positive. The latter are usually under the normal.

PERILABYRINTHITIS

Perilyabyrinthitis is most frequently associated with acute suppurative otitis media, but not infrequently with acute exacerbations of chronic middle-ear suppuration. The mastoid is always, and probably first involved. Systemic diseases, especially diabetes mellitus, predispose to it. When the process is acute the endolabyrinthitis is hyperemic, as is shown by rapid recovery of hearing following the simple mastoid or radical operation. When the perilyabyrinthitis is of longer standing the type of endolabyrinthitis is more apt to be serous. The recovery of hearing in the serous type is relatively slow, depending largely on drainage of the perilyabyrinthine spaces. Suppurative endolabyrinthitis can occur and does, especially in the course of diabetic mellitus. Sequestration is then most liable to follow. Otherwise this type can be differentiated from that occurring by other routes only by the history or post-mortem.

The above are for the most part late diagnostic symptoms. The earlier symptoms are those of mastoiditis and the middle ear, plus the following, which may be grouped as positive and negative.

POSITIVE

Slower gradual onset of diffuse endolabyrinthitis.

Recurrent deafness with manifest vestibular symptoms accompanying acute exacerbations of chronic middle-ear suppuration.

Pain on pressure located particularly over superior part of mastoid process.

Frequency of associated facial paralysis.

Weber test localized in the diseased ear, as pointed out by Neumann.

NEGATIVE

Absence of the fistula symptom or attacks of vertigo such as occur in circumscribed labyrinthitis.

Infrequency of intracranial complications.

It is difficult to diagnose perilabyrinthitis really early. The importance of the diagnosis relates particularly to operative interference; that is, to the kind of operation.

Perilabyrinthitis is an extension of mastoiditis into cells which communicate directly with the mastoid cells. A typical theoretic case is as follows:

Spontaneous nystagmus first directed to the diseased side probably in the frontal plane, accompanied or not by nausea and vomiting. Reactionary falling backward, forward or side-ward—progressive rather quick loss of hearing, but not absolute. In the meantime change of plane of the nystagmus to compound horizontal and rotary and directed to both sides but strongest to one side; finally rotary and directed to the good side only, with reactionary movements characteristic of rotary nystagmus. Absence of fistula symptom, probable absence of intracranial complications, unless it is of tuberculous origin; facial paralysis coming on late in the disease. Weber test localized in bad ear. Frequent association with systemic disease. Probable recovery of hearing after simple mastoid or radical operation. Possible recovery of facial palsy in the course of a year after radical operation if the systemic disease, when present, is cured or improved.

This is a new subject and I advance this picture for what it may be worth to those who may have opportunity to observe cases frequently from the very beginning. Acute severe cases of mastoiditis are very promising for such observations. In conclusion, for the sake of brevity I will say only that the conclusion arrived at is that the study of symptoms set forth enables us to make an earlier and more exact diagnosis.

100 State Street.

THE PRESENT STATUS OF VERTIGO CONSIDERED FROM A DIAGNOSTIC STANDPOINT*

GEORGE E. DAVIS, M.D.
NEW YORK

In the discussion of suppurative labyrinthitis before this section at the Chicago meeting in June, 1908, it was my privilege and good fortune to present the first paper to appear in the medical literature of this country, reporting the recent progress made in the diagnosis and treatment of labyrinthine diseases, as taught in the Vienna schools. Since then the literature on this subject has been added to very materially, notably by Mackenzie¹ of Philadelphia, Fridenberg,² and Richards³ of New York, and Mr. Scott⁴ of London, the last contributing some valuable new research data relating to the functions of the semicircular canals.⁵

* Read in the Section on Laryngology and Otology of the American Medical Association, at the Sixty-first Annual Session, held at St. Louis, June, 1910.

1. Mackenzie: *Homeop. Eye, Ear and Throat Jour.*, 1909, xv, 17.

2. Fridenberg: *Ann. Otol., Rhinol. and Laryngol.*, St. Louis, 1908, xvii, 670.

3. Richards: *Ann. Otol., Rhinol. and Laryngol.*, St. Louis, 1907, xvi, 561.

4. Scott: *Proc. Roy. Soc. Med., Otol. Sec.*, p. 41, 1909.

5. From Scott's most excellent paper on "The Problems of Vertigo, etc." (*Proc. Roy. Soc. Med.*, April, 1909.) I have quoted freely and adopted his tables, showing the detailed results of his research illustrating the three main types of labyrinthine nystagmus and comparing the hypotheses of convection currents and momentum currents.

My first contribution was rather a foreword, very briefly outlining the methods of functional tests of the semicircular canal system developed by the researches of Barany, Alexander and Neumann of Vienna. The basis of these tests was founded on the fact that stimulation of the peripheral end-organs of the eighth nerve produces vertigo, nystagmus, and disturbances of equilibrium. It is in the interest of the solution of the mechanism of these several manifestations, when dependent on pathologic conditions, that the present discussion is undertaken.

For a correct interpretation of vertigo, a phenomenon ubiquitous in extent and protean in type, it is necessary, first of all, to have a clear conception of the term. Equilibration, or the adjustment of the individual to space, and orientation, or the recognition of that adjustment, are very complex functions.

ORIENTATION

The faculty of orientation is exercised through the central and peripheral sense organs and any marked or sudden disturbance of this function, induced experimentally or pathologically, creates that disagreeable sensation of confusion, known as vertigo, due to a false conception of one's relative position to space or motion, and relatively its concomitant sensation of disturbance of equilibrium. It is self-evident that vertigo and disequilibration are made manifest through the same sense organs as are equilibration and orientation. For convenience of discussion these peripheral sense organs may be classified into three subdivisions: (1) the static labyrinth, the special equilibrium sense organ; (2) the eyes, or visual sense organs; (3) the deep muscles, joints, viscera, etc., the kinesthetic sense organs.

It is a well-recognized fact that the impulses conveyed by these several peripheral sense organs and their centripetal tracts are correlated in the cerebellum, by which the function of equilibration is established and maintained. It is a further well-recognized fact that a perversion of this function, when occasioned by a permanent lesion in one of these three sets of sense organs, will eventually be corrected by the other two, perhaps not absolutely but sufficiently for all practical purposes. It follows also that with a loss of the function of two sets of these sense organs there will be a relative increase in disturbances of equilibration and orientation.

This paper will be chiefly concerned with the type of vertigo (rotatory) which results from stimulation or irritation of the static labyrinth, the special sense organ of equilibration. Since pathologic phenomena are better comprehended when we have a clear conception of the physiologic functions and anatomic structure and arrangement of the particular organs or tissues involved, perhaps it were well, from a diagnostic standpoint, to make a brief reference to this phase of the subject—particularly as to the arrangement of the semicircular canals and the origin and distribution of the nerve and blood supply to the same. As regards the blood supply to the labyrinth the works of Shambaugh, Siebenmann, Schwalbe and Eichler should be consulted, and a most excellent paper by Shambaugh⁶ treating this subject from a clinical standpoint, is worthy of consideration in this connection.

The geometrical arrangement of the semicircular canals in three principal directions of space gave rise to the original theory as to the functions of the labyrinth. At first the assumption was that the canals were asso-

6. Shambaugh: *Arch. Otol.*, New York, 1906, xxxv, 11.

ciated with audition, and they were supposed to mediate sensations of sound coming in any of the three main directions corresponding to their axes, or to analyze atypical sound directions by a proportional representation in the three dimensions.

Later investigations, from the time of Purkinje to Barany, by careful experiments on animals and man, developed the theory of a specific equilibristic function of the labyrinth. In analyzing the mechanism of this function it is important to bear in mind the anatomic structure, arrangement and relation of the labyrinth, and to remember we have to do with a bilateral, symmetrical structure; that each canal of a side corresponds in the same plane to a canal of the opposite side; the two external canals in the horizontal plane, the anterior or superior canal of one side with the posterior canal of the other side; that the ampullary bulbs of corresponding canals are at opposite ends; the ampulla of the right horizontal canal being on the right, while that of the contralateral canal is on the left; the ampulla of the right superior canal being in front, above and beyond that of its synergist, the left inferior being behind and below.

The anatomic structure, and the relations of the membranous labyrinth to its corresponding bony container, the osseous labyrinth, may be had by reference to the texts, and I will not discuss this phase of the subject more than to call attention briefly to the origin and communications of the eighth nerve. We shall appreciate the fundamental significance of this when we undertake to differentiate the manifestations or impulses due to stimulation or irritation of the static labyrinth, or the special equilibrium sense organ, from correlated manifestations or impulses originating from stimulation of the visual sense organs, the eyes, and the kinesthetic sense organs, the deep muscles, joints, etc.

The auditory nerve really consists of two nerves, the cochlear and vestibular, and has its origin from three roots situated in the medulla. The cochlear division has its origin from the accessory nucleus and is distributed to the cochlea. The vestibular division has its origin from the chief nucleus and Deiter's nucleus and is distributed to the vestibule and semicircular canals. The peculiar arrangement of the distribution of the labyrinthine nerve end-organs, or the hair cells, in the maculae of the utricle and saccule and ampullae of the semicircular canals, bears a basic relation to the mechanism of the phenomena of vertigo, nystagmus and disturbances of equilibrium. The last two manifestations can be readily understood when we remember that the portion of the vestibular nerve which arises in Deiter's nucleus communicates fibers to the nucleus of the motor nerves of the eye muscles and to the motor nucleus of the spinal cord on either side. Nystagmus is caused by impulses conveyed to the former, and disturbances of equilibrium by impulses conveyed by the latter.

THE TYPE OF VERTIGO AND THE VARIETIES OF NYSTAGMUS RESULTING FROM LABYRINTHINE STIMULATION

Labyrinthine vertigo, whether produced experimentally or pathologically, is always rotatory.

Labyrinthine vertigo is always associated either with nystagmus, or disturbances of equilibrium. The reverse of these phenomena does not hold, however, as disturbances of equilibrium may occur without vertigo.

All forms of vertigo may be associated with nystagmus, but some forms of vertigo may not be associated

with nystagmus; that is, the ocular and kinesthetic forms.

Moreover, while rotatory vertigo associated with nystagmus is characteristic of labyrinthine irritation or lesion, it is not pathognomonic of it, for, as pointed out by Stewart⁷ and Panse,⁸ and verified by other observers, we may have rotatory vertigo and nystagmus during convalescence in cases of paresis of the eye muscles. In the latter instance the mechanism of the vertigo and nystagmus may be plausibly explained by assuming that the labyrinth is reflexly influenced by the stimulation resulting from the innervation of the eighth nerve communicated through Deiter's nucleus to the oculomotor muscles. The nystagmus occurs when the patient endeavors to turn the eyes attentively in the direction of the partly paralyzed muscle's action. I have recently observed a case with this rotatory type of nystagmus occurring during convalescence following paralysis of the left abducens muscle.

LABYRINTHINE NYSTAGMUS

We may conveniently divide labyrinthine nystagmus into three main types according to the direction of the excursive movements; however, there may be subdivisions as a resultant of a combination or association of the main types.

The three main types are designated, respectively, as horizontal, vertical and rotatory, according to the planes of direction of the nystagmus. A combination of the horizontal and vertical types results in a compromise between the two, or oblique nystagmus, or frequently we find the horizontal and vertical associated but not combined.

In discussing the directions of the planes of excursive ocular movements reference is had in relation not to space but to the planes of the orbit or eyeball. Thus in horizontal nystagmus the plane of oscillation is horizontal in relation to the horizontal plane of the orbit; in vertical nystagmus the plane of the oscillation is in relation to the vertical plane of the orbit; whereas in rotatory nystagmus the plane of oscillation is in the meridian of the eyeball at right angles to the antero-posterior axis.

Labyrinthine nystagmus is characterized by rhythmic movements and consists of a rapid and slow component. The direction of the nystagmus corresponds to the direction of the quick component. Thus we designate horizontal nystagmus as horizontal nystagmus to the right or left, according to the direction of the rapid movement. Similarly in regard to the vertical nystagmus according to the direction of the rapid movement up or down we designate it as vertical nystagmus upward or downward. The same rule applies to rotatory nystagmus.

The rapid movement is usually referred to as the major movement; however, the slower movement is the primary movement, or the true labyrinthine reflex, while the rapid movement is secondary or voluntary.

MECHANISM OF NYSTAGMUS

"Stimulation of only one ampulla produces a simple, primary reflex deviation of the eyes in one direction without nystagmus. If now the endeavor is made to turn the eyes in the opposite direction a sequence of fleeting images sweeps across the retina in the opposite direction and the eyes are jerked in rapid pursuit of the

7. Stewart: *Dentsch. med. Ztg.*, 1895, p. 511.

8. Panse: *Arch. Otol.*, 1902, xxxi, 467.

seemingly moving object which is momentarily fixed; but instantly the primary labyrinthine movement again gains control, a repetition of the fleeting images across the retina occurs, followed by the secondary rapid or major movement of pursuit, and thus continues until the stimulation is annulled and the nystagmus ceases."⁵ We have an illustration of this in the phenomenon *déviaton conjuguée*, which represents a true reflex phase of nystagmus produced by unilateral irritation in the semicircular canals, vestibular nerve, or Deiter's nucleus. This may be demonstrated by placing the patient with a rhythmic nystagmus under general anesthesia, or may be observed sometimes in the comatose stages of cerebral abscess complicating labyrinthine suppuration. In both instances we have deviation of the eyes in the direction of the slow movement, proving that it is the primary or unconscious reflex movement, occurring during the unconscious state, while the quick movement, though the rapid and more intense, is the secondary or voluntary movement occurring during the conscious state. Therefore, the slower movement represents the vestibular reflex, while, on the other hand, the rapid movement represents the voluntary or cortical one. The maximum intensity is experienced when the eyes are turned in the direction of the quick component, and *vice versa*.

With ocular vertigo and nystagmus, closure of the eyes affords marked relief, but in the rotatory or vestibular form it has no influence; whereas in the kinesthetic form both the vertigo and the disturbance of equilibrium are exaggerated. This is a most important differential diagnostic test in the several forms of nystagmus.

Before discussing the pathologic forms of labyrinthine nystagmus let us get a physiologic view by analyzing the mechanism of some of the functional tests in developing experimental nystagmus: (1) thermal tests; (2) momentum tests.

The physical effects of the thermal stimulus depend on the variations in density of the watery solutions at different temperatures. According to well-known physical laws, when water cools the density of the cooler particles increases and they fall, and conversely, when water is heated the density of the heated particles is decreased and they rise. If we cool the surface of a bowl of water we get a descending convection current, and if we heat it we get an ascending convection current. The walls of the labyrinth and the fluid therein—the perilymph and the endolymph—are no exception to this rule. By cooling or heating the middle ear and outer wall of the labyrinth we get descending or ascending convection currents passing through the ampullæ of the superior and external semicircular canals, respectively, depending on the position of the head; through the former when the head is erect and through the latter when the face is directed upward or downward. On account of the depth of the ampullæ of the posterior semicircular canal the thermal tests are not practicable. The intensity of the convection currents, and reactions (vertigo, nystagmus and disturbances of equilibrium) resulting therefrom, depends on the suddenness, degree and duration of the alteration of the temperature of the outer wall of the labyrinth and the fluid adjacent thereto.

The momentum tests have a wider field of application than the thermal tests. The character of the physical effects of momentum depends on the direction of the motion, either in curved lines and circles or in more or less straight lines, vertically, antero-posteriorly, or laterally; also on the position of the head.

In case of the circular motion or rotation the semicircular canals, with their ampullæ, are affected, and the intensity and extent of this effect depends on the angular velocity, tangential speed and duration of rotation. As observed by Scott:⁵

Viewing the matter physically in order to estimate the momentum set up by rotation we must pay regard to the angular velocity, tangential speed and duration of rotation. The angular velocity is determined by computing the time of one complete revolution of 360°, and stated as so many degrees per second. If we adopt a uniform angular velocity of, say, 360° in five seconds, the approximate tangential speed varies directly with the distance between the semicircular canals and the axis of rotation; this distance can be obtained by measuring the radius of the curve of revolution described by the external auditory meatus, which will give the approximate relative position of each set of the semicircular canals. It will be obvious that when the patient reclines on the turntable with the head half a meter from the axis of rotation, and the table is turned at the uniform angular velocity of 360° per five seconds, the tangential speed of the head, and therefore the labyrinth and of the endolymph, will be greater than when the head is only a quarter of a meter from the axis of rotation. Similarly, if the patient be seated over the axis of rotation with the labyrinths equidistant from the axis of rotation, the tangential speed will be equal in the two labyrinths.

The theory most accepted now as to the effects of thermal stimulus and rotation on the semicircular canal system is that they cause currents of endolymph through the canals, either from the canal through the ampulla to the utricle or from the utricle through the ampulla to the canal. These currents, pressing or dragging on the hair cells in the ampullæ, stimulate the cells and provoke nystagmus, vertigo and disturbances of equilibrium. Owing to the observation that it requires greater effort to provoke nystagmus by rotation in one direction than by rotation in the opposite direction, particularly if the labyrinth on one side is destroyed or not functioning, the theory has been advanced that the several ampullary nerves have a principal and subordinate function. The more plausible assumption is, considering the marked inequality of the sectional areas of the semicircular canal and its ampulla, the ratio being about 1 to 25, that it requires more effort and time by rotating the head in one direction to establish a current from the ampulla to the canal—that is, from a broad to a narrow channel—than when rotating the head in an opposite direction to establish a current from the canal to the ampulla—from a narrow to a broad channel.

In case of motion in more or less straight lines the semicircular canals and ampullæ are not affected, but the utricle and saccule and their contents, i. e., the endolymph and the sensory hair cells of the maculae of the utricle and saccule. In this instance the intensity and extent of the effect depends on the suddenness, speed and duration of the motion. We may cite as an illustration the nystagmus and vertigo of *mal de mer* or sea-sickness. Ordinarily the arc described by the rolling and pitching of a ship is too small and the angle of velocity and tangential speed too slow to occasion momentum currents in circles as in the semicircular canals, but such currents as are established are in more or less straight lines in the sacs of the utricle and saccule, corresponding to the direction of the lines of the motion of the ship but opposite in direction, and the vertigo, nystagmus, etc., is due to the irritation occasioned by the increase or diminution of weight on or dragging of the hair cells of the two maculae.

The following tables from Scott illustrate the methods of provoking the three main types of labyrinthine nystagmus and indicate the direction of the deflection of the three sets of fibrillae which would be produced in accordance with the laws of convection and momentum considered in relation with known anatomic structure:

TABLE 1.—ROTATORY (COUNTER-CLOCKWISE) NYSTAGMUS OBSERVABLE DURING ATTENTIVE DEVIATION AND FIXATION OF THE EYES TO THE RIGHT *

BY THERMAL METHODS		
Cold water irrigation.....	Left ear.....	Head erect
Hot water irrigation.....	Right ear.....	Head erect
Hot water irrigation.....	Left ear.....	Head inverted
Cold water irrigation.....	Right ear.....	Head inverted

BY ROTATION AROUND A VERTICAL AXIS		
Rotation counter-clockwise.....	Face directed downward	
Rotation clockwise.....	Face directed upward	

* For an account of technic adopted by Barany see Thomas Guthrie's digest (Brain, 1906, p. 383); also Mackenzie's abridged translation (Jour. Laryngol., Rhinol. and Otol., xxiv, No. 2). The present series of observations was carried out by methods evolved independently of Barany's, though essentially similar. The conclusions were also formulated before the results of Breuer's investigations were studied.

TABLE 2.—ROTATORY (CLOCKWISE) NYSTAGMUS OBSERVABLE DURING ATTENTIVE DEVIATION AND FIXATION OF THE EYES TO THE LEFT *

BY THERMAL METHODS		
Cold water irrigation.....	Right ear.....	Head erect
Hot water irrigation.....	Left ear.....	Head erect
Hot water irrigation.....	Right ear.....	Head inverted
Cold water irrigation.....	Left ear.....	Head inverted

BY ROTATION AROUND A VERTICAL AXIS		
Rotation clockwise.....	Face directed downward	
Rotation counter-clockwise.....	Face directed upward	

* The effect of rotation on the eye-movements depends on the angular velocity and tangential speed. A certain minimum velocity is necessary, and this varies somewhat in different persons. Given the appropriate angular velocity and appropriate tangential speed, one finds that rotation will induce the same type of nystagmus with the same directional characters whether both labyrinths are functional or whether one labyrinth had become defunctive.

TABLE 3.—HORIZONTAL NYSTAGMUS OBSERVABLE DURING ATTENTIVE DEVIATION AND FIXATION OF THE EYES TO THE RIGHT *

BY THERMAL METHODS		
Cold water irrigation.....	Right ear.....	Face downward
Hot water irrigation.....	Left ear.....	Face downward
Hot water irrigation.....	Right ear.....	Face upward
Cold water irrigation.....	Left ear.....	Face upward

BY ROTATION AROUND A VERTICAL AXIS		
Rotation counter-clockwise.....	Head erect	
Rotation clockwise.....	Head inverted	

* Inversion of the head was conveniently obtained by complete backward extension of the head over the end of a special rotating table, so that the head was about 10 in. from the axis of rotation.

TABLE 4.—HORIZONTAL NYSTAGMUS OBSERVABLE DURING ATTENTIVE DEVIATION AND FIXATION OF THE EYES TO THE LEFT

BY THERMAL METHODS		
Cold water irrigation.....	Left ear.....	Face downward
Hot water irrigation.....	Right ear.....	Face downward
Hot water irrigation.....	Left ear.....	Face upward
Cold water irrigation.....	Right ear.....	Face upward

BY ROTATION AROUND A VERTICAL AXIS		
Rotation clockwise.....	Head erect	
Rotation counter-clockwise.....	Head inverted	

TABLE 5.—VERTICAL NYSTAGMUS OBSERVABLE DURING ATTENTIVE DEVIATION AND FIXATION OF THE EYES UPWARDS (IN RELATION TO THE ORBIT)

BY ROTATION METHODS		
Rotation counter-clockwise.....	Right side of head downward	
Rotation clockwise.....	Left side of head downward	

TABLE 6.—VERTICAL NYSTAGMUS OBSERVABLE DURING ATTENTIVE DEVIATION AND FIXATION OF THE EYES DOWNWARD

Rotation clockwise.....	Right side of head downward	
Rotation counter-clockwise.....	Left side of head downward	

TABLE 7.—DEFLECTION OF THE FIBRILLE OF THE SUPERIOR SEMICIRCULAR CANAL ON ONE SIDE *

BY THERMAL METHODS				
Direction of Deflection of Superior Fibrillae.	Produced By	Position of Head.	Resulting Type of Nystagmus.	Direction of Maximum Intensity.
From canal to utricle.	Cold.	Erect.	Rotatory.	Non-stimulated side
From canal to utricle.	Hot.	Inverted.	Rotatory.	Non-stimulated side
From utricle to canal.	Hot.	Erect.	Rotatory.	Stimulated side
From utricle to canal.	Cold.	Inverted.	Rotatory.	Stimulated side

* No reactions are obtained where the method is applied to a defunct labyrinth.

TABLE 8.—DEFLECTION OF THE FIBRILLE OF ONLY ONE SUPERIOR SEMICIRCULAR CANAL BY ROTATION WHEN ONLY THE RIGHT LABYRINTH IS FUNCTIONAL, THE LEFT BEING COMPLETELY DEFUNCT

Direction of deflection of superior fibrillae in right side.	Direction of rotation.	Position of head.	Type of nystagmus.	Direction of maximum intensity.
From canal to utricle.	Clockwise.....	Face downward.	Rotatory.	Left
From canal to utricle.	Counter-clockwise.	Face upward.	Rotatory.	Left
From utricle to canal.	Counter-clockwise.	Face downward.	Rotatory.	Right
From utricle to canal.	Clockwise.....	Face upward.	Rotatory.	Right

TABLE 9.—DEFLECTION OF THE FIBRILLE OF ONLY ONE SUPERIOR SEMICIRCULAR CANAL BY ROTATION WHEN ONLY THE LEFT LABYRINTH IS FUNCTIONAL, THE RIGHT BEING COMPLETELY DEFUNCT *

Direction of deflection of superior fibrillae in left side.	Direction of rotation.	Position of head.	Type of nystagmus.	Direction of maximum intensity.
From utricle to canal.	Clockwise.....	Face downward.	Rotatory.	Left
From utricle to canal.	Counter-clockwise.	Face upward.	Rotatory.	Left
From canal to utricle.	Clockwise.....	Face downward.	Rotatory.	Right
From canal to utricle.	Counter-clockwise.	Face upward.	Rotatory.	Right

* Deflection of the fibrillae of both superior semicircular canals simultaneously. The nystagmus evoked by rotation clockwise and counter-clockwise with the face upward and face downward is precisely the same in type and directional characters when both labyrinths are intact as when only one is functional.

TABLE 10.—DEFLECTION OF THE FIBRILLE OF THE EXTERNAL SEMICIRCULAR CANAL, EITHER SIDE SINGLY

BY THERMAL METHOD				
Direction of Deflection of External Fibrillae.	Produced By	Position of Head.	Resulting Type of Nystagmus.	Direction of Maximum Intensity.
From canal to utricle.	Cold water.....	Face downward.	Horizontal.	Stimulated side.
From canal to utricle.	Hot water.....	Face upward.	Horizontal.	Stimulated side.
From utricle to canal.	Hot water.....	Face downward.	Horizontal.	Non-stimulated side.
From utricle to canal.	Cold water.....	Face upward.	Horizontal.	Non-stimulated side.

TABLE 11.—DEFLECTION OF THE FIBRILLE OF ONLY ONE EXTERNAL SEMICIRCULAR CANAL BY ROTATION WHEN ONLY THE RIGHT LABYRINTH IS FUNCTIONAL, THE LEFT BEING COMPLETELY DEFUNCT *

Deflection of the External Fibrillae.	Direction of Rotation.	Position of Head.	Type of Nystagmus.	Direction of Maximum Intensity.
From canal to utricle.	Counter-clockwise.	Erect.	Horizontal.	Right
From utricle to canal.	Clockwise.....	Erect.	Horizontal.	Left

* The corresponding reactions are reversed when the rotation is made with the head inverted

TABLE 12.—DEFLECTION OF THE FIBRILLÆ OF ONLY ONE EXTERNAL CANAL BY ROTATION WHEN ONLY THE LEFT LABYRINTH IS FUNCTIONAL, THE RIGHT BEING COMPLETELY DEFUNCT *

Deflection of the External Fibrillæ.	Direction of Rotation.	Position of Head.	Type of Nystagmus.	Direction of Maximum Intensity.
From utricle to canal.	Counter-clockwise.	Erect.	Horizontal.	Right
From canal to utricle.	Clockwise.	Erect.	Horizontal.	Left

* The corresponding reactions are reversed when the head is inverted. Deflection of the fibrillæ of both external semicircular canals simultaneously when both labyrinths are functional. The nystagmus produced by rotation clockwise and counter-clockwise with the head erect or with the head inverted is precisely the same in type and directional characters when both labyrinths are intact as it is when only one labyrinth is functional.

TABLE 13.—DEFLECTION OF THE FIBRILLÆ OF THE POSTERIOR SEMICIRCULAR CANAL, EITHER SIDE SINGLY, THE ONE BEING DEFUNCT, OR BOTH SIDES SIMULTANEOUSLY, BOTH LABYRINTHS BEING FUNCTIONAL

Direction of Deflection of the Inferior Fibrillæ, i. e., of Posterior Canal.	Direction of Rotation.	Position of Head.	Type of Nystagmus.	Direction of Maximum Intensity.
From utricle to canal.	Clockwise.	Right side downward.	Vertical.	Downward
From utricle to canal.	Counter-clockwise.	Left side downward.	Vertical.	Downward
From canal to utricle.	Clockwise.	Left side downward.	Vertical.	Upward
From canal to utricle.	Counter-clockwise.	Right side downward.	Vertical.	Upward

DEDUCTIONS FROM THE TABLES

Study of the accompanying tables reveals that stimulation of the ampullæ of the horizontal and posterior semicircular canals or deflection of the fibrillæ from utricle to canal, or *vice versa*, imparts similar impulses, provoking deviation of the eyes in attentive fixation, and, when the stimulation is sufficiently intense, nystagmus in the direction of the deflection of the fibrillæ. With stimulation of the ampullæ of the superior semicircular canals the conditions are reversed: the nystagmus provoked takes place in the direction opposite to the deflection of the fibrillæ. Thus in the former instances of the horizontal and posterior canals, deflection of the ampullary fibrillæ from the utricle to the canal produces nystagmus toward the opposite side or in the direction of the deflection of the fibrillæ; but in the latter instance of the superior canal, deflection of the fibrillæ from the utricle to the canal produces nystagmus to the same side, or in the opposite direction to the deflection of the fibrillæ.

The diagnostic importance of this observation is evident from a clinical viewpoint. Thus spontaneous horizontal nystagmus to the left would indicate some probable lesion in the right vestibule, while rotatory nystagmus to the left would indicate some lesion in the left vestibule. A combination of horizontal nystagmus to the left and rotatory nystagmus to the right would be stronger evidence still of some lesion of the right vestibule. Again, rotatory nystagmus to the right, associated with oblique nystagmus downward and to the left (the latter being a combination of horizontal and vertical nystagmus), would indicate some irritation or lesion in the right vestibule. Similarly other deductions may be drawn from a study of the directional character of nystagmus. We must be careful in our analyses, however. For instance, in a case of spontaneous nystagmus associated with labyrinthine fistula outside the vestibule (say the fistula is situated in the right osseous horizontal canal), provided the membranous canal and ampulla are intact, thermal and momentum tests will give the

normal reaction (see tables); but in this case should spontaneous nystagmus be present it would be horizontal in character and directed to the right or to the same side as the lesion, whereas usually with spontaneous horizontal nystagmus to one side we would infer vestibular lesion on the opposite side. The confusion occasioned in such cases, particularly if bilateral middle-ear suppuration or involvement exists, is strikingly illustrated in a similar case cited by Scott. In such a condition, however, if the osseous fistula happens not to be protected by cholesteatomatous masses, etc., meatal air compression will elicit horizontal vertigo to the same side and clear the diagnosis. The mechanism of spontaneous nystagmus in this case, according to the above tables, Ewald's experiments and other clinical observers, is due to the impulse proceeding from the canal to the ampulla. Scott explains the mechanism of the nystagmus in these cases by assuming that the impulse is produced by the vascular granulation tissues situated at the seat of the fistula. Should the fistula be situated in the superior canal under like conditions (vascular granulation, and ampullæ functioning), if spontaneous nystagmus occurred it would be rotatory, but to the opposite side. With the fistula situated in the vestibule, under like conditions, the presence of spontaneous nystagmus would be rotatory to the same side and horizontal to the opposite side.

Furthermore, functional tests, in cases of normal labyrinths, have shown that if the stimulation be the same on either side no nystagmus results, however intense the stimulation. This may be demonstrated by the thermal test, by using hot or cold water from the same container, to which is attached two tubes, one tube being inserted in either ear, and the injections made simultaneously. In other words, to produce vertigo, nystagmus and disturbances of equilibrium, there must be a preponderance of stimulation on one side sufficiently intense to imbalance the function of the mediating sensory organs and cause a perversion or misinterpretation of the impulses produced by said stimulation.

This brings us to the consideration of a new hypothesis promulgated by an eminent London authority in explanation of unilateral ablation nystagmus.

ABLATION NYSTAGMUS

Preliminary to an analysis of this hypothesis attention may be called to some of the characteristics of ablation nystagmus. It is well known that spontaneous nystagmus does not occur after removal of the labyrinth in children, rarely after ablation in adults of 35 or 40 years of age who have normal vascular systems, but that it is more or less frequent for a limited period following destruction of the labyrinth in persons over the latter age—provided the remaining labyrinth is functioning. The character of the nystagmus may be rotatory, horizontal or oblique, or a combination of these, and vary in intensity and duration. If there is but one of the types present it is usually the rotatory, and directed toward the sound side; if two types are present they are the rotatory and horizontal, the rotatory directed to the sound side and the horizontal to the side of the ablation; if all three types are present the horizontal and vertical are usually combined into the oblique.

As time lapses the sensory end organs of the sound labyrinth become inured to one-sided stimulation and gradually acquire a disregard of the disproportionate unilateral impulses, and then the nystagmus begins to

lapse also. If the three types are present the vertical element disappears first, the horizontal next and the rotatory last.

An analysis of the characteristics, directional and otherwise, of ablation nystagmus (see tables) shows that it corresponds to the type of nystagmus resulting from vestibular stimuli causing a simultaneous deflection of the ampullary fibrillæ of a normal labyrinth (from the utricle toward the superior, horizontal and posterior semicircular canals respectively); the deflection being upward in the superior ampulla, and backward and downward in the horizontal and posterior ampulla. Hence the question arises, Whence the origin of the stimuli or impulses provoking ablation nystagmus? Scott attributes the source of these stimuli, in many instances, to the influence of carotid pulsation. On account of the relation of the internal carotid artery to the labyrinth, in its passage through the petrous portion of the temporal bone, particularly where it bends sharply forward and upward in front of the cochlea, the assumption is that the force of the heart-beat transmits impact waves to the walls of the vestibule, and that the direction of such waves is chiefly upward and backward, being reflected from the convex arch of the carotid artery. Should such impaction waves occur they would be directed upward and backward and therefore cause deflection of the fibrillæ of the superior ampulla upwards, and of the fibrillæ of the horizontal and posterior ampullæ backwards, associated with the type of nystagmus such deflection would produce (see tables) rotatory nystagmus to the stimulated side, horizontal and vertical nystagmus (or combination of the last two—oblique nystagmus) to the non-stimulated side. And we would naturally infer that the intensity of the nystagmus would be proportionately exaggerated the stronger the impulse wave thus transmitted; and *vice versa*, the weaker the impulse waves, the less pronounced the nystagmus. Clinical observations and experiments have abundantly confirmed this deduction and furnished the foundation for Scott's hypothesis of impaction waves causing spontaneous nystagmus. In corroboration of the approximate correctness of this hypothesis he cites cases in which the spontaneous nystagmus following unilateral labyrinth destruction was enhanced when the force of the circulation was increased by bodily exercise and violent muscular exertion, and a diminution or cessation of nystagmus when the body was put at rest. But especially convincing was the report of the influence of the carotid pulsation on the spontaneous ablation nystagmus in eight consecutive cases. On compression of the common carotid on the side of the destroyed labyrinth no effect was noted, whereas non-compression of the common carotid on the side of the normal labyrinth showed a complete arrest of the nystagmus in each case, continuing as long as compression was maintained and returning when the compression was stopped. The direction of the nystagmus was toward the side of the destroyed labyrinth.

Furthermore, corroborative evidence of a negative character is furnished in cases where a unilateral defunct labyrinth is of long standing. In such cases the cessation of the nystagmus results from the ampullary end-organ becoming accustomed to or acquiring a disregard of the impulses conveyed by the impaction waves, which in the beginning deflected the fibrillæ from the ampullæ toward the canal. Latterly, after the cessation of the nystagmus, if we compress the carotid on the side

of the normal labyrinth, by obviating the impaction wave, we create an impulse in the opposite direction or a relative deflection of the fibrillæ from the canals toward the vestibule. In this instance we should have rotatory nystagmus toward the negatively stimulated side or the side of the destroyed labyrinth, or in the direction opposite to the deflection of the fibrillæ. We find this so in practice.

Other evidence in favor of this theory is the occurrence of spontaneous nystagmus comparatively only after the age of beginning hardening or loss of elasticity of the arteries, whereby the force of the impaction waves is increased and correspondingly the intensity of the nystagmus. Mr. Scott's hypothesis of the impaction wave causing unilateral ablation nystagmus, considered from a physiologic, anatomic and experimental viewpoint and supported by evidence of a collateral nature, is plausible, and the greatest step in advance made in the solution of the problem of vertigo and the explanation of the mechanism of nystagmus since the contributions to the subject by Barany and Alexander.

CONCLUSIONS

The internal ears are the special sense organs of equilibrium. With the internal ears we recognize (orientation) and maintain our relations to space (equilibration).

The visual sense organs (the eyes), and the kinesthetic sense organs, (the muscles, etc.), are accessory sense organs of equilibrium and are coordinated with the special sense organs of equilibrium (the internal ears), through the mediation of the cerebellum.

The two special sense organs of equilibrium (the internal ear of either side), are normally symmetrical in structure and function, and any factor whatever, whether it be physiologic, experimental or pathologic, which innervates, stimulates or irritates one of these twin organs in excess of the other (or on the other hand accomplishes the same thing through enervation, depression or destruction of one in excess of the other), in that measure tends to or creates proportionately a disturbance of their joint functions—equilibration. If the disturbance of equilibration is sufficiently marked or intense we also get nystagmus and that unpleasant and complex phenomenon termed vertigo.

Finally, it must be acknowledged that not yet unravelled is the mystic arcanum of the mechanism of the complex labyrinthine function of equilibration and orientation, or the mechanism of the perversion or disturbance of that function as manifested by vertigo, nystagmus and disequilibration; but the great interest in research work now being directed along these paths augurs a satisfactory solution soon.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRs. HOINGER, FLECHER AND DAVIS

DR. A. B. DUEL, New York: I have watched with keen interest the rapid advances which have been made during the past few years in this branch of our specialty. From an unknown and unexplored field, surgery of the labyrinth is rapidly developing into a well-known and well managed one. This is due to the fact that this small and difficult field harbors the end-organs of two most delicate special senses, viz., those of hearing and orientation. By perfection of methods of examining these functions and careful observation of the alterations in them produced by various diseases affecting the

labyrinth we have learned to fix accurately the position and extension of these lesions. We are able to say with much certainty, this patient has a perilyabyrinthitis; this, an acute circumscribed suppurative labyrinthitis; this, an acute diffuse suppurative labyrinthitis; this, a manifest lesion; this, a latent one; this patient has a fistula; this probably has not a fistula.

Operative indications have been laid down in a most dogmatic way, depending on the presence or absence of certain definite indications. It needs no wise man to predict that these indications, exact as they may seem at present, will, when matured by long experience, be somewhat modified. We are too prone to be satisfied with a few rules which may be easily observed without knowing the reasons why these rules were made. Too many cases of patients operated on after observation of certain symptoms are being reported by men who have not given sufficient attention to the more difficult question of why these symptoms appeared. The phenomena of vertigo, nystagmus, ataxia, for instance, bear the same relation to the lesion or irritation in the vestibular apparatus as the absent patellar reflex and spastic gait of locomotor ataxia do to pathologic lesions in the cord causing it. No one would contend that he understood tabes because he recognized these characteristic symptoms, and likewise he should not feel that he understands suppurative labyrinthitis because he observes certain prominent features of the disease.

The function of orientation is a nice sense presided over by the vestibular apparatus; it is intimately associated with equilibration and brings this about by impressions through Deiters' nucleus, to the oculomotor centers on one hand, and to the motor neurones of the cord on the other. To accomplish this with perfect accuracy a double system is essential, just as binocular vision is necessary for judging distance, and binocular hearing for judging direction. In other words, angulation is necessary to nicety in sight, hearing, or orientation.

If the position of the semicircular canals be carefully observed, it will be noticed that the superior verticals lie at right angles to each other, the direction of their planes being from behind, forward and outward in either direction. The posterior verticals, at a lower level, are at right angles to the superiors on the same side and to each other, the direction of their planes being from before, backward and outward. The horizontals are so arranged that movements sidewise produce a current by the same movement, in one toward the ampulla, in the other away from it. As a result the canals work in pairs, and it becomes impossible to think of experiments by movements of the head, or whirling of the individual, which do not influence more than one canal at the same time. In fact, in the normal individual all forward and backward movements of the head must produce impressions from all four vertical canals at the same time and all coordinate movements of the eyes and muscles are the resultant of all these impressions. Now all impressions of motion in space resulting normally from orientation (the vestibular sense), come from currents set up in the endolymph by these motions. This impression results reflexly in movements of the eyes and a certain tension in the muscles to maintain equilibrium. Any upset in this delicate sense will result in subjective sensation of motion and reflex efforts to compensate for them, thus bringing about the phenomena of acute vestibular irritation—vertigo, nausea, vomiting, nystagmus—the direction and character depending on the nature and extent of the irritation.

Equilibration can soon be accomplished by practice, without orientation, by compensation, by means of vision and muscle sense. Hence the phenomena of acute vestibular irritation soon disappear and altered reflex phenomena have to be sought after and brought about by the special tests, as you have heard.

The man with only one labyrinth learns to do without the missing labyrinth just as he would without one eye or one ear, and he does without both just as he would without both eyes or ears. He learns to equilibrate without orientation. Is he just as well off? Certainly not; he feels the need of the faculty in any new environment or situation. Try a man

who has just lost one labyrinth and acute symptoms have disappeared—vertigo, nystagmus, ataxia, in ordinary situations—ask him to walk up or down an incline. He will be unable to do it at first, but by repeated trials he will soon learn. He has, in other words, learned to equilibrate with faulty orientation. After he has learned to do these things in the light, try him in the dark. He will fail again, but will learn with practice. His education in compensation for lack of sense of orientation will be analogous to that of a blind man learning to walk with confidence and just as difficult. We have only touched the outside edge of the subject of labyrinthine phenomena, although we have already learned to interpret them sufficiently to recognize danger signals and have grown so bold as to invade the domain of the labyrinth with impunity.

PROF. HOLGER MYGIND, Copenhagen, Denmark: So far as etiology is concerned, there is one point which I do not think has been brought out, and that is the traumatic cause—suppuration produced through operation, and especially due to radical operation. I have seen a considerable number of these cases, and I think that the labyrinthine suppuration caused by radical operation is much more frequent than most of us think. These cases that occur after radical operations have a very different course. I may divide them into three groups:

1. The very light cases in which no symptoms at all are observed by the patient or by the medical man. Even if such patients are asked if they feel at all ill after operation, they often reply, "No, I did not notice anything at all." As Dr. Fletcher pointed out, there is no proof that labyrinthine symptoms have not been present, only they have been overlooked, and the physician observes that there has been labyrinthine involvement; perhaps a week or more after operation he discovers that the patient is totally deaf in that ear and if the function of the labyrinth be examined it is found that it is lost. These cases, I think, teach a great deal; especially that we should be careful with our indications for radical operation. My experience is that our indications for simple mastoid operation ought to be very wide, for I believe the risk we run in acute cases is very small considering the risk the patient runs when he is not operated on. On the other hand, my indications for radical operation are very limited, so limited that in a discussion with Prof. Körner of Rostock I had even a more conservative view than he has, and he is very conservative on the whole. I think that when a patient with chronic suppuration of the middle ear has fairly good hearing we should be careful about performing the radical operation. If both ears are affected, we should be exceedingly careful and only do the operation when occasion demands it very strongly.

2. In postoperative labyrinthine suppurations in which there are distinct labyrinthine symptoms, the patient, shortly after operation, or sometime after, gets distinct labyrinthine symptoms—nausea, vomiting, noises in the ear, etc.—and in these cases one not infrequently sees paralysis of the facial nerve. What I say now it is not necessary to say to surgeons of great experience, but to the younger members here I say: After an operation, either radical or simple, if in the course of a few days a facial paralysis develops, look well to the labyrinth. It is often said that paralysis is due to blood-clot; pressure of the dressing, or something like that, but in my experience it is frequently caused by labyrinthine suppuration; and, of course, there is a close anatomic connection between the facial nerve and the labyrinth.

3. There is a group of cases of postoperative labyrinthitis, which is not so large, but which is very important; this is a class in which the labyrinthine suppuration develops explosively and leads to diffuse meningitis. The prognosis in these cases is very grave indeed; I have seen only one such patient recover. That was a boy of sixteen who had labyrinthine suppuration and diffuse leptomeningitis and recovered after craniotomy, excision of the dura, etc.

I consider an operation on the labyrinth a very difficult operation. One of the greatest difficulties is to avoid breaking down the bony wall of the Fallopian canal.

DR. GEORGE F. COTT, Buffalo: An interesting point raised by Professor Mygind is the question of traumatic cases, following the radical operation. Some operators have been luckier than others. In 10 years I have done 102 radical operations and have had only one patient die. How often do these cases occur?

There are not many reported in this country. In the last 3 or 4 years there have been some isolated cases, but I suspect that there are many more than have been reported. I have seen 8 or 9; 3 of these patients were operated on, and the labyrinth drained; and in 3 the radical operation was done; the others are still under observation with no operation. If that number occurs in a city of 450,000 why have not large numbers occurred in cities like Chicago and St. Louis? They no doubt do occur, but are overlooked. I do not know whether the otologists will be more conservative or not; I am afraid not. I think these patients will have to go to operation, although it is extremely difficult, or they will die. To wait until the patient is *in extremis* is bad policy. The physician must take the chance and so must the patient. Of course, everything must be thoroughly considered.

In this country we have not yet decided the question of time to operate. Jansen in Berlin two years ago read a paper in which he told of over 100 operations on the labyrinth which he had done with a death-rate of 29 per cent. In the next 100 cases he will have no such death-rate, because now we have more definite symptoms and the patient has a much better show.

As to the question of diagnosis, no man would think of operating on the labyrinth unless deafness were present. When deafness is complete and the other definite symptoms are present it is well to operate. The operation necessarily belongs to the otologist and not to the general surgeon, and I believe the general surgeon will never perform it as he does other operations about the ear, nose and throat.

Suppose a patient has caries of the middle ear, with a very long history; suppose he has had perilyabyrinthitis, and is in the latent condition in which the least irritation will set up further trouble—what are you going to do? If you operate radically the chances are ten to one that he will die unless the labyrinth is drained. Such cases have occurred and I do not doubt that they are the cases to which Professor Mygind refers in which the patient died after radical operation from involvement of the labyrinth.

Another point, as to the hearing after exfoliation of the cochlea in suppuration of the labyrinth: I find in Bezold's writings that he cites a number of cases in which a certain amount of hearing existed after the cochlea had been cast off. Politzer mentions that it may be possible for some hearing to exist without the labyrinth. Before Bezold's death I think he made the claim that it is absolutely impossible to hear anything after the labyrinth has been destroyed. In this country, Dench and some others have operated in a certain number of cases, drained the labyrinth, and after the patient has recovered found that there was a certain amount of hearing left. I take the stand that it is impossible to hear after destruction of the labyrinth. Bezold says that in the cases reported, bone conduction on the other side has been neglected.

DR. CULLEN F. WELTY, San Francisco: I wish to show a specimen of the complete labyrinth operation, and to call attention to the large amount of dura that is uncovered, giving free access to any operation of the cerebellum, also to call to attention the facial nerve in the canal; the cochlea and canals have been entirely destroyed. This operation is not so difficult as Prof. Mygind would have us believe. I have seen ten or twelve similar operations and have done three myself, and have not seen a case of facial paralysis. My patients are all well. Dr. Ducl hit the nail on the head when he said: "On the careful examination depends the whole condition." In the various ear hospitals it has been repeatedly demonstrated that there is a mortality of from 10 to 12 per cent. Prof. Mygind says that 65 per cent. of the cases of meningitis are infected by way of the labyrinth. When to operate and when not to operate is the all-absorbing question.

OPERATIVE CHART *

	Cochlea.	Excitability of Vestibular Apparatus	Fistula.	Spontaneous Nystagmus.	Operation.
I	+	+	+	+	No No
II	—	+	+	+	Eventual No
III	+	—	—	+	Operation Eventual
IV	+	—	—	—	Eventual Eventual
V	—	—	+	+	Operation Operation
VI	—	—	—	—	Operation Operation
VII	—	+	—	—	No No

* Neumann, Heinrich: Indikationen für die operative Eröffnung des Labyrinthis.

I here submit an operative chart. Grouped with the other a mistaken diagnosis is almost impossible. Use this last chart until you thoroughly master the situation from a pathologic standpoint and by that time it will be very clear indeed. There is a test that has not been spoken of; indeed, it is very important for those of us who will dare to operate without a proper examination, as I did in one case only recently. However, I operated under stress of circumstances that does not often happen. As I was completing my operation I found a good-sized fistula of the horizontal canal; besides, the facial nerve was uncovered, posteriorly. I had never seen the patient prior to operation and was leaving the following morning to attend the American Medical Association Session. By removing the anesthetic for a short time so that the patient might sufficiently recover for the reaction, a stream of cold water was directed into the ear. In a short time there was a steady pull of the whole eye to the opposite side; this is the reaction of functioning canals. This cleared the diagnosis wonderfully. Dr. Shambaugh says that a patient should not be operated on so long as there is hearing left. I am sure he has not thought of this in a serious way.

At the Otologic Congress at Budapest, Dr. Neumann reported a large number of cerebral complications showing conclusively that 75 per cent. of such cases were the result of acute exacerbation of chronic ear suppuration. Now should we follow Dr. Shambaugh's suggestion we should do the radical operation on patients with a latent labyrinth suppuration (patients who hear and do not react to the caloric test). As I have shown by Neumann's publication that the acute exacerbations are particularly dangerous, so it will be seen by this radical ear operation an acute exacerbation of the latent labyrinth suppuration is produced with possible fatal termination. According to the Vienna school of otology the labyrinth should be removed at the time the radical operation is done or left alone entirely. The disturbances of equilibrium and the *tinnitus* that one of the speakers refers to following the labyrinth operation are due to incomplete operation; in other words all other operations except Neumann's will be followed by more or less disturbance of equilibrium and by *tinnitus*—such as happened to me years ago! With more definite pathologic findings we are accorded the privilege of changing our conclusions in regard to various operations.

DR. G. E. SHAMBAUGH, Chicago: Several points have been brought up in this symposium which I should like to emphasize. In the first place, we must keep in mind that in suppurative otitis media a number of different types of internal ear complications may occur, all of which give rise to distinct labyrinth symptoms such as vertigo, nystagmus, *tinnitus* and deafness. It is important that we make a correct diagnosis of the type of complication in a particular case because the treatment is different for the several complications. In some of these complications giving rise to labyrinth symptoms, a simple mastoid operation is indicated; in others, the labyrinth itself should be opened up, and in still others nothing beyond the treatment of the otitis media by the ordinary measures is called for. Most important is it that we differentiate between cases of diffuse suppuration of the labyrinth and cases of labyrinth fistula, or the so-called circumscribed labyrinthitis, be-

case in the latter we do not open the labyrinth, whereas the opening of the labyrinth may be called for in the diffuse suppuration. The diagnosis between diffuse suppuration of the labyrinth and diffuse serous labyrinthitis is also important because it is not advisable to open the labyrinth in cases of serous involvement. We should never open the labyrinth when there is any function retained in the labyrinth such as a remnant of hearing or a vestibular apparatus that can be stimulated. It is a much graver mistake to open a labyrinth when no adequate indication exists than to neglect to open it when the diagnosis would seem to indicate an operation. Many of the patients with diffuse suppuration of the labyrinth will recover spontaneously without operation, whereas to open into a labyrinth not the seat of diffuse suppuration experience has shown to be of danger to the patient. It is not possible to interpret intelligently the various symptoms arising from the several complications of the labyrinth without a clear understanding of the physiology of the inner ear and without a clear idea of the pathology of these complications.

I cannot agree with Dr. Welty that the disturbances that occur after operation on the labyrinth occur because it has not been entirely destroyed. The function should be destroyed before we operate. If symptoms of labyrinth irritation occur after operation it means that we have operated when we should not have done so, because there was still function there.

In my experience I have not yet observed the condition which Professor Mygind points out, in which there is apparently after a radical operation a destruction of the labyrinthine function, without our being able to recognize it from the symptoms. He said we might recognize it perhaps weeks or months afterward. That it is possible for a patient to have a rapid destruction of the labyrinth without symptoms I have not observed. It would seem to me that such a case might be explained by the fact that before operation we did not go through the complete tests. There might have been destruction of the labyrinth without the patient being aware of it dating back perhaps many years.

DR. ROBERT BARCLAY, St. Louis: Whatever the condition of the ear—whether or not there be suppuration of the middle ear, with or without extension to the labyrinth—vertigo may arise from, and should be attributed to, another source. My attention was directed to this when the cause of vertigo was being discussed; and that it might be borne in mind in every case I thought it well to speak of the influence of the inferior cervical ganglion. From that ganglion arise not only the inferior cardiac nerve but also vasomotor fibers that control the contraction and dilatation of the vertebral artery, of which the labyrinthine artery is a branch, and from which alone the arterial supply of the labyrinth is drawn. The effect of tobacco, acute tobacco intoxication—especially in enfeebled persons or in young persons beginning to smoke—largely affects this very nerve center, the inferior cervical ganglion and its arterial and nervous distribution. Such an attack resembles the pure labyrinthine inflammatory invasion very closely; and I wish to call attention to it and emphasize the necessity for considering this possibility in all cases of vertigo.

DR. C. M. BROWN, Buffalo: I agree with Dr. Shambaugh that it is not wise to operate on the labyrinth so long as we have any function left there. The greatest problem is when to operate and when not. We are all doing mastoid work and I believe that it is not right to do it without first making an examination to find out if the semicircular canals and cochlea are functioning. We can all examine the internal ear. The caloric test is always at hand and should be used in every acute as well as in every chronic case of mastoiditis in which we are going to operate. It is a well-established fact that in syringing an ear with cold water one gets nystagmus to the opposite side if the labyrinth is functioning. Every patient can be so examined in order to ascertain if the labyrinth is functioning or not.

Recently I had a case of double otitis media in which there was a question concerning which side to operate on. Both sides were examined thoroughly; on one side the vestibular apparatus was not functioning at all—

no result on turning and no result with cold water. There was chronic suppuration on both sides following scarlet fever at the age of 2. I did not operate on the side that was not functioning. If I had I should have expected meningitis, if I had not at the same time removed the internal ear.

Do not operate in a mastoid case without testing the condition of the vestibule, and if you cannot do an operation on the internal ear leave that mastoid alone which has a non-functionating labyrinth. If the cochlea and vestibule are destroyed it may be well to remove both. We should not quibble too much on when to operate on the internal ear, but on when to leave it alone.

DR. LOUIS K. GUGGENHEIM, St. Louis: The statement was made by Dr. Fletcher that with a diffuse suppurative labyrinthitis, say of the right side, he got a spontaneous rotatory nystagmus to the left. On syringing the left ear with cold water this nystagmus is decreased, and if syringing is continued long enough we get a rotatory nystagmus to the right (diseased) side. A vestibular nystagmus to the diseased side in a case of diffuse suppurative labyrinthitis without an intracranial complication I believe to be impossible, for the following reason: Normally the two vestibular apparatuses exert a certain equal influence over the eye-muscle nerves through the vestibular nerves, Deiter's nucleus, the fasciculus longitudinalis posterior, and the nuclei of the abducens and oculomotor, and any disturbance in the equilibrium of this influence results in nystagmus. Now in a diffuse suppurative labyrinthitis of the right side the influence normally exerted by that side is lost, the left vestibular apparatus acts alone, the result being a vestibular nystagmus to the left side. If we now syringe the left side with cold water the influence exerted by the left vestibular apparatus is temporarily lessened by the paralyzing effect of the cold water. The result is a decreased nystagmus to this side. If the syringing is continued long enough, the stimuli which normally pass from this side to the eye muscles may be entirely lost. The result will be complete cessation of nystagmus. Now, no matter how long the syringing with cold water is continued, a vestibular nystagmus to the right (diseased) side is, I believe, impossible, for the simple reason that the right vestibular apparatus is no longer functioning. In other words, with the right vestibular apparatus destroyed by the diffuse suppuration and the left vestibular apparatus temporarily paralyzed by cold water, we again have vestibular equilibrium restored. Therefore, there can be no nystagmus of the vestibular variety, as this depends on a disturbance of vestibular equilibrium for its existence.

PROF. HILGER MYGIND, Copenhagen, Denmark: I think the difference of opinion between Dr. Welty and myself may be explained by the difference in our operations: I do the operation more radically. Dr. Welty has passed round a temporal bone on which he has made resection of the labyrinth. Now, I want to state that Dr. Welty has not opened the whole of the superior semicircular canal. That is just where the difficulty comes in. It is important to have a very small chisel and a very sharp one. To Dr. Shambaugh I would say, the reason the labyrinthine symptoms are overlooked is likely because these postoperative suppurations often come in the course of the first twenty-four hours after operation when the patient is still suffering from the effects of the anesthetic.

DR. ORTO GLOGAR, New York: A few years ago, when I was assistant to Professor Politzer in Vienna, Dr. Neumann said: "When you go to America tell them about this labyrinthine work; you will find that they do not know very much about it." A few months ago when Dr. Neumann was here he was astonished to find how much was known about it in this country. Three years ago I suggested that all cases of chronic suppuration of the middle ear be examined before radical mastoid or labyrinthine operation, as is done in Politzer's clinic, that is, by the so-called labyrinthine schema. I am in accord with Professor Mygind that we must be conservative in the radical operation, but we can only do this by following up the cases, every day making a new test and thus detecting labyrinthine symptoms at the very onset of the inner ear involvement. There is another disease which simulates lab-

yrinitis and is caused by pressure symptoms only. A retention of pus or cholesteatoma behind a fragment, adherent to the promontory, or behind a new membrane formed in place of the destroyed tympanic membrane may cause all the symptoms of labyrinthine suppuration; these will readily disappear, however, when the primary cause is treated properly. I consider Dr. Neumann's method of operating on the labyrinth the best.

DR. J. R. FLETCHER, Chicago: The fibrous connective tissue formations in the area of the oval window aid in the production of fistulas. In relation to the matter of operation on the labyrinth, the statement has been made that it is not difficult; my experience has been mainly on cadavers, and I opened the facial canal in many of them. I have made no report of operations on the living. Every test that is mentioned in this paper I have repeatedly confirmed, and I believe that I have not deceived myself. I think they are correct.

DR. G. E. DAVIS, New York: I do not know whether I understood Dr. Duclouet in regard to the loss of orientation with the destruction of one ear. I tried to make it clear in my paper that the ear serves the purpose of audition, orientation and equilibration. I also mentioned two other sets of accessory sense organs, the eyes and the muscles. It goes without saying that with the loss of one ear a man may have orientation and equilibration just as when one eye is lost he may have vision. With the loss of one set of these sense organs the other two sets in a short period will enable the individual to re-establish these functions. Orientation is the recognition of our position in space and equilibration is simply the faculty of assuming and maintaining position in space. With the loss of one ear, if a man can stand, he appreciates that he is standing, and if he reclines he appreciates that he is reclining, and that is the function of orientation. Maintaining that is equilibration. Now with the loss not only of one ear, but the visual organs also, a man soon learns to appreciate his position in space and to maintain it.

Dr. Shambaugh has, I think, fully answered Dr. Welty as to the destruction of the labyrinth. I wish to answer another point of Dr. Welty's in regard to his statement that the caloric test was negative after either the cochlea or semicircular canal system is out of commission. Now, if the cochlea is out of commission and the semicircular canals are in commission and the caloric test be made, a reaction is manifested by nystagmus, with nausea and vomiting, showing that the semicircular canals are still functioning.

FOIBLES IN SPECIALISM*

C. F. WAHRER, M.D.
FORT MADISON, IA.

One of the easiest tasks is to find fault with existing things, whether they be right or wrong. There is but one other thing as easy, and that is to go wrong, as nearly all the nations of the earth were tempted to depart from the paths of right, and thus prepare the way for their enemies to encompass their destruction. Even after a short season of right-doing the Israelites, as soon as Moses was out of their sight up the mountain, made them a golden calf and worshiped it. They were not the only ones who did this. Some of the most powerful nations of the earth, drunken with the wine of material success, became unmindful of their morals, and departing from the virtues of the fathers, indulged in riotous living, became vain and arrogant, and thus soon went to their destruction. As with nations, so with individuals. Their foibles are their ruin.

Thus it might fare with the foibles of specialism. Not that specialism is not a good thing; on the contrary, it is indispensable. The realms of knowledge are so large that it is no longer possible to follow the teachings of a Chesterfield: "to be a gentleman it is necessary to know a little of everything, and know all about some things." Science asks too much of us now to follow the above teaching. This is the era of specialism, and we must be content with a choice of careers. Medicine is but a branch of the natural sciences, namely, biology, and we are not able to learn all even of this one branch. We have found it needful to study more particularly some of the parts of medicine in order to do justice to our patients' needs. This leads us to medical specialism.

May I suggest that, if we could eliminate all pseudo-science, or else if we could establish a censorship of that part of our literature which masquerades as scientific, many of our burdens would be lightened and much of our precious time would be saved. Our library shelves groan under the weight of verbosity, prolixity, tautology, and literary dust, straw and chaff. This pseudo-science has begotten pseudo-specialism and specialism gone mad.

This paper is not to be construed as the usual diatribe of a generalist against specialism, as I am an admirer of true specialism, for I recognize it as an absolute necessity; but it is a warning against the foibles of the pretender and some of the better ones even, whose zeal has exceeded their discretion. The earnest and true scientific specialist also, at times, succumbs to the foibles of his class, which is an easy thing to do when off guard. For instance, it is very easy to fancy that all affections of man must fall under this or that particular branch of practice, so that, one might think, the other specialities do not amount to much. For example, I recently heard a man, who fancied he is a major surgeon and who does some creditable surgery, stigmatize some other men as finger-and-toe surgeons. You know, of course, what he meant to express, though there is some surgery about the fingers and toes that may tax the skill of the best of surgeons.

There are those in our own Section on Diseases of Children who act as if all there was to pediatrics was the artificial feeding of infants—as if all babies were fed out of bottles! Those inclined to mathematics want to reduce infant-feeding to algebraic or logarithmic formulas, the results of which, of course, agree with some children, the same as almost anything else would agree with them. Others, in writing of the management of the infant, would make us infer that all the babies they treat are the children of millionaires. They describe the duties of the first nurse, those of the second nurse, then that of the nursery maid. They then tell us when the child should spend its time in the nursery, when in the solarium, and when in the tent on the housetop, when it should have a ride in the grounds, when in Central Park, and when it should take a sea voyage. This makes us heave a sigh and exclaim "lucky dog."

I really think that the specialist spoke from his usual habit and daily practice; only he forgot that there were some mothers who do not have two nurses, no solarium except the back porch of the flat, no sea, except the mud puddle in the alley, no housetop where the little sufferer with pneumonia may be put in a tent, and no tent. The moral is obvious. It may not be amiss to say that in the rural districts most children are fed on the moth-

* Read in the Section on Diseases of Children of the American Medical Association, at the Sixty-first Annual Session, held at St. Louis, June, 1910.

er's breast, and the artificially fed babies are given cow's milk, often augmented with cream, and they thrive. I do not mean by this that the rules for artificial feeding should be disregarded; but they receive too much emphasis on the floors of pediatric societies. What the majority of mothers need is such directions as they can follow and practically carry out in their homes, according to the dictates of common sense, and not according to the vaporings of a specialist of the ethereal cult, which, be they ever so valuable for the clinical laboratory of a multimillion-endowed hospital, are not within reach of the average mother's ability to execute.

Another foible is the idea that it is always necessary to give the history of the affection under discussion, its bibliography, pathology, etiology and antiseptic technic, how to wash the hands, etc., until the few grains of truth the author wishes to present are so mixed with chaff, straw, dust and debris that what would have been a modest book or paper, becomes a bulky mass that is scarcely worth while to peruse for the worth it may contain.

The history of disease, if worth the reading, can be found in special books; we also have works on antiseptics, pathology, etiology and the other trimmings, so that it is not only unnecessary to mention these things in every paper or book, but also a clumsy method of exhibiting one's exaggerated ego at the frightful expense of the money, time and bookshelves of the unfortunate reader.

Another foible of which the specialist should beware is considering the attendant who calls him an *ignoramus*. The consultant rightfully is supposed to have special knowledge in the case, else he would not have been called. But this does not by any means make the attendant an inferior man. The general internist is often the better man of the two, and, if the specialist were to measure up with the internist, he would find himself very often the smaller man. In his specialty he is assumed to be the better man, but that should not cause him to put on airs, become pompous, or otherwise conduct himself so as to disparage the attendant. Though some may question if this is ever done, it is almost as much the rule as the exception. Then the attendant gets tired, and softly swears to himself, "Never again."

Another foible very common and damaging to specialism is the too close application to specialism. It is almost as impossible to be a specialist without keeping informed in the cognate branches, as it is to keep well informed in the whole field of medicine. Yet a certain amount of general information must be kept up in order to be a specialist of the broad school, so as to be comprehensive, not narrow, as it is easier for a man to have a larger horizon from the top of a hill than from the bottom of a well. Now we all concede that specialism, as exhibited in the Section on Diseases of Children, is for the good of mankind, including the members of the Section, and that only the highest motives impel all of us to contribute what we do. Yet, lest we forget, I sound this note of warning to all who specialize, that things too highly specialized may exceed their sphere of usefulness, and become merely ornamental and ideal from an academic point of view, rather than useful and practical.

The physician must, in the larger number of cases, entrust his directions not to trained nurses, but to mothers of varying grades of intelligence, and hence he must

learn to give such instructions as any particular mother may be able to execute, so as to obtain the greatest good to her child. These instructions are simple when compared with those issued to a staff of nurses in one of our teaching hospitals, equipped with a clinical laboratory, yet it requires no great stretch of the imagination to see that the one may lead to better results when issued to a mother of average intelligence than the other. Here is where that peculiarly indefinable quality of the mind, called "common sense," makes itself especially felt. Not that I want to establish it on a throne above science, but I would place it on a level in conjunction with experience, one on the right, the other on the left of science, so as to make that glorious trinity the ally of the physician, which makes for success in the treatment of disease and puts to flight the bizarre and finicky vaporings of the evanescent etherealist.

No word has been more abused than the word "practical," unless it is the other word "specialist." When taken together in their larger sense they are scarcely susceptible of abuse, and for this I make a plea. And whether we prescribe for a sick baby, or write a book on the subject, let us not make it encyclopedic with the accumulated dust of the ages, but rather let us follow the authors of mathematical works, who do not insert the multiplication table into every book, but let it suffice to appear in one of the primary books of the series. For instance, the bacteriology of one part of the body is very similar to any other part; hence the antiseptics or asepsis of one is similar to that of any other part; so there is no need to mention these and their tedious details in everything medical that is read and published. The author's learning will be in evidence without these tiresome details, and our time may be spent more profitably in reading rather than hunting for the little new and instructive matter we seek and need. Of course, publishers must live, but they should serve us and not we them. I have a few small monographs in my library, less than half the size of the ponderous volumes we are now offered, that contain more solid meat than many a book three times their size. Then there is a system of four volumes with a ponderous 1100-page supplement two years later, which are so stuffed and padded with the history, bacteriology, case histories, aseptic technic, prescriptions, pharmacology, quotations from obsolete authors, parallel opinions from more modern authors, hazardous opinions not yet proved, long bibliographies, and doubtful statistics, that it takes endless time to find anything if it is wanted ever so much. These things are really not foibles but crimes, and should be punished, if it were possible.

My excuse for reading this paper in this Section is not its special fitness for the Section on Diseases of Children, but the fact that we have no section especially appropriate for the reading of such a paper unless it be appropriate for any section. We must read, not scientific papers only, but papers on anything that may be of benefit to the medical profession. The two divisions of the American Medical Association into legislative and scientific do not nearly cover the legitimate field of our activities. We should have a time and place in general session where such things as medical economies could be taken up and briefly discussed. I trust as we progress we may grow broader, and then we shall have fewer foibles in specialism as well as in all things medical.

A CASE OF COLLOID CARCINOMA OF THE SKIN

A. BAMBERGER, B.S., M.D.

Resident Physician, Cook County Hospital
CHICAGO

I report this case, first, because of its rare occurrence, as I am unable to find a similar condition reported in literature, and secondly because it emphasizes the importance of laboratory work in cases of obscure diagnosis.

History.—Miss C. G., unmarried, aged 35, a clerk, entered my service at the Cook County Hospital, June 8, 1910. She had always lived in Chicago and was apparently of good habits. Menstruation began at 14 years, was regular and of the twenty-eight-day type.

Present Illness.—The patient stated that two weeks before entering the hospital a blister appeared on the lower third of the right leg and that after a few days it opened, and an ulcer followed, for which she sought treatment. She denied having injured the leg or having applied any drug locally. With the exception of the ulcer she said she was in good health.

Past History.—She was well up to the present illness, except that her legs occasionally swelled, which condition a physician told her was due to nephritis. She had diseases of childhood and malaria ten years ago, but denied typhoid and all venereal infections. Family history was negative, except that the patient's mother died of heart disease.

Examination.—The patient was an obese white woman, quite nervous, but apparently having no pain; no cyanosis or icterus. The pupils were equal, reacted to light and accommodation; the mouth was negative, except for a few decayed teeth; there was no thyroid enlargement. The lungs were negative. The heart showed no enlargement; tones strong, regular, no murmurs. There were no ascites, no abdominal masses, no tenderness on palpation. The liver was not enlarged; the spleen not palpable. The lower half of the right leg was edematous. About 2 inches above the ankle was a superficial, irregularly shaped ulcer about 2 inches in diameter. The parts surrounding the ulcer were inflamed and tender. The femoral glands of the right leg were moderately enlarged; there was a slight varicosity of veins of both legs; pulsation of posterior tibial and dorsalis pedis was less marked on the right than on the left leg. The uterus was in good position and not tender; there were no masses or tenderness in pelvis. Knee-jerks were present; Romberg and Babinski absent. The urine was clear, amber, specific gravity 1020, acid, no albumin, sugar, casts, leukocytes or red-cells. Blood examination showed 15,000 leukocytes; no malarial parasites.

Course of the Disease.—On first examination I thought the condition was a dermatitis with infection and ulceration, and accordingly applied hot dressings, which failed to alleviate the symptoms. During the first three weeks in the hospital the patient ran an irregular temperature, ranging from 99 to 101 F., with no special evening rise. The ulcer gradually extended until it involved the entire anterior third of the leg and laid bare the tibia. It was very foul and sloughing. On the ninth day after admittance a bluish discoloration of the toes appeared which gradually increased in intensity and extension until there was a well demarcated gangrene of the entire foot and lower third of the leg on the twenty-second day. The leg was then amputated just below the knee. During the patient's entire stay in the hospital she had a severe diarrhea of greenish, liquid stools, containing small amounts of blood, but no parasites, and also continually lost weight. After the operation the patient grew steadily worse, the diarrhea becoming uncontrollable and the emaciation being very rapid. Three weeks after the operation she became irrational and very weak, and three days later, on the forty-sixth day after admittance, died. I was uncertain as to the cause of death and as no post-mortem examination was permitted I made the tentative diagnosis of tuberculous enteritis.

Pathologic Finding.—At the time of amputation I excised a piece of the involved tissue for examination, which the hospital pathologist diagnosed as colloid carcinoma.

As colloid carcinomas occur most frequently in the intestines it is most probable that the patient had a colloid carcinoma of the intestines with a secondary growth in the skin.

THE PATHOLOGY OF JOINT TUBERCULOSIS:
TUBERCULOUS SINUSES

LEONARD W. ELY, M.D.

DENVER

In numerous articles in the past I have called attention to the importance of avoiding secondary infection of the walls of tuberculous sinuses and abscesses by the germs of suppuration, and have pointed out the danger the patient incurs if this secondary infection take place. In this I have followed the teachings of others and my own experience, an experience gathered in treating many cases of joint tuberculosis. On the other hand, the custom of opening, scraping and packing tuberculous abscesses is still widespread, and those who practice it do so either from ignorance or because their experience teaches them that it is correct. Now, the experience of one man may be said to be as good as that of another, and until we can bring proof to sustain us we shall hardly convince our opponents. A very suggestive case of tarsal tuberculosis has recently furnished us with additional evidence of the truth of our contentions, and I shall quote it at length. Before doing so, however, I wish to call attention to one or two points in the pathology of joint tuberculosis.

Pure tuberculosis does not, possibly with very rare exceptions, attack ordinary connective tissues of low grade of organization. They must contain some peculiar cellular elements in addition.

The red or cellular marrow of bone and the cellular synovial membrane, tendon sheaths, lymph nodes, epithelial structures, etc., are vulnerable; but cartilage, ligaments, fatty or yellow marrow, fibrous connective tissue, etc., escape direct infection. If, however, a secondary infection by pus germs be added, tissues that were immune before, now are open to attack.¹ An ordinary tuberculous abscess, starting from a focus in a bone, making its way toward the surface along the fascial planes, travels along a path of ordinary fibrous tissue which is not open to attack. So long as these abscesses remain uninfected the patient does not suffer from constitutional involvement nor from other symptoms except possibly those due to pressure. If a secondary infection be added the entire picture is changed, and forthwith the constitutional symptoms of pain, fever, etc., become prominent, the danger to the patient is greatly increased and his chances for recovery are seriously impaired.

What is the reason for this? Why are these tracts once infected so difficult to heal? No matter how vigorous our method of drainage, their course is never that of a simple infected abscess. They may exist for years. One reason is that the secondary infection has changed what was a small localized tuberculous focus into a widespread tuberculous area, and has added a mixed infection. In an old tuberculous sinus tubercles may be seen under the microscope deep in the walls, inaccessible to any curette, but in an uninfected sinus no tuberculosis is present. In other words, the walls of an uninfected

1. Ely: Surg., Gynec., and Obst., July, 1910.

tuberculous sinus are not tuberculous; the walls of an infected tuberculous sinus are tuberculous. By permitting infection of a sinus with pus germs we are at the same time infecting it with tuberculosis. This fact, though not new, is not generally known. The following case illustrates it:

The patient was a man of forty-four years, a driver. He had suffered from pain and disability of his right foot for twenty months, and these symptoms had increased to such an extent that he was compelled to go about on crutches. He had been treated with plaster of Paris and strapping, and had never had any open sinuses. Examination showed moderate swelling over the dorsum of the foot, and considerable sensitiveness to pressure. The foot was in eversion. The lungs were involved. The evidences of the disease were so small that the wisdom of an amputation was doubted, but, acting on the theory that tarsal tuberculosis in the adult seldom if ever is cured without an amputation, and especially in view of the patient's pulmonary disease, this operation was decided on and was performed at the Roosevelt Hospital. During the performance of a Syme's amputation, the knife of the operator cut through a sinus on the dorsum of the foot, leading upward, but not communicating with the surface. From this sinus pus oozed.

By courtesy of the house staff I secured the specimen. On dissection it was found that the comparatively mild symptoms were caused by an extensive tarsal tuberculosis which had involved two of the tarsal joint cavities with their ramifications, and the talus, navicular and cuneiform bones. The cartilages were roughened, mottled and eroded at their periphery. The synovial membrane was thickened and inflamed, and showed under the microscope typical tuberculosis, but the walls of the sinus from this tuberculous lesion showed, not tuberculosis, but the ordinary evidences of inflammation—round cells, polymorphonuclears, edema, arterial thickening, dilated capillaries, etc.

If one will picture to himself this extensive bone tuberculosis penetrating the bones of the tarsus, covered up as it is by ligaments running in every direction, with numerous tendons passing over these, and with blood vessels and nerves added, he will appreciate the utter absurdity of an attempt by a partial operation to eradicate under all these a disease of whose extent he cannot possibly have any idea. Any other operation than an amputation would have been worse than useless.

Special Article

TYPHOID FEVER IN DETROIT

BY THE SPECIAL COMMISSIONER OF THE JOURNAL

The reports of the municipal board of health show that in certain years typhoid fever has prevailed in Detroit to an extent that must be called excessive. The death-rates from this disease for 1887, 1888, 1892, 1893 and 1907 are so high that they might well have been the occasion for grave concern to the inhabitants of any modern civilized city. The facts are set forth in Tables 1, 2 and 3.

NATURE OF THE AVAILABLE STATISTICS

Other than these bare records of deaths, there is little to throw light on the extent, distribution and age incidence of typhoid fever in Detroit. The first report of the health department was published in 1882; so late as 1894 we find 83 deaths recorded under the head of "febris," and in a footnote these are said to include: "febris intermittens 8, perniciosa 1, puerperalis (!) 10,

remittens 4, typhoides 64, typho-malaria 6;" it was not till 1904 that typhoid fever was added to the list of diseases that must be reported to the health officer. Even now it is plain that only a small proportion of the typhoid fever cases are regularly reported to the authorities. In 1905-6, 70 deaths and only 87 cases were reported. It may be recorded in passing that the system of recording vital statistics on the basis of the fiscal year (July 1-July 1) rather than the calendar year does not facilitate comparison with conditions in other cities.

It must not be supposed that Detroit is peculiar in most of the practices above mentioned. Until recently few American cities have had a satisfactory system of nomenclature, and certainly very few have at the present time any adequate record of typhoid fever cases. Detroit can hardly be said to be much different in this respect from the average American city of its class.

An exception must here be noted to the aforesaid meagerness of record. One particularly severe outbreak

1895-9	19.1		

of typhoid fever—in 1892—was made the object of special investigation by a competent observer,¹ and his conclusions were published in a supplement to the annual report of the Michigan State Board of Health, 1898.

THE CAUSE OF THE 1892 OUTBREAK

The extensive epidemic of the summer of 1892 carried the typhoid death-rate for that year to the highest figure known in the sanitary history of the city (93.8) and is one of the severest recorded in any American city during the last twenty-five years. Professor Williams' careful study of the distribution of the deaths and the age of the decedents, together with other data, led him to the belief that nothing but the public water-supply could be the general vehicle of infection. All the facts obtainable at the time pointed to this conclusion, and it is indeed difficult to explain so explosive an epidemic and one of such magnitude in any other way. The discussion that followed the reading of Professor Williams' paper in the sanitary convention at Detroit in December, 1897,

1. Gardner S. Williams, at the time civil engineer to the Board of Water Commissioners of Detroit.

showed that leading sanitarians were ready to accept the explanation of a water-borne origin.

The source of the unusually heavy water infection responsible for the epidemic of 1892 was made the object of special investigation in the study just cited. The conclusion was reached that the excessive numbers of typhoid bacilli in the Detroit water at that time had come from the sewers at Port Huron, the only city on the American watershed having a system of sewerage. Computations made from the best available data indicated that not more than twelve or less than six days would probably be required for the water to flow from Port Huron to Detroit. A fact thought to be of special significance was the circumstance that extensive dredging operations in the channel of the Black River, the small stream into which all the sewers of Port Huron emptied, had been conducted by the United States government in the spring of 1892 and, therefore, just prior to the outbreak in Detroit. The material excavated was loaded on scows and dumped in St. Clair River about a mile below Port Huron. It is supposed that the sewage deposit thus added to the water of the St. Clair contained typhoid bacilli which found their way in from

wide and 800 feet long, with an average capacity of about 30,000,000 gallons. The daily per capita consumption is estimated as averaging from about 160 to 180 gallons. The total amount pumped daily ranged during the year 1907-8 from about 59,000,000 to over 91,000,000 gallons, an amount equivalent to from two to three times the capacity of the settling-basin.

The character of the water-supply is tested at intervals by the city analyst and bacteriologist. The results in general appear to be satisfactory. In the report of the health board for 1907-8 we read: "The bacterial count varies from 96 per cubic centimeter to 720 per cubic centimeter, the latter count only existing for a day or so in the spring. At no time this year have colon bacilli, or other evidence of sewage contamination, been observed." No statement is made in the published reports as to quantities examined or methods employed in the attempt to detect sewage contamination.

On September 21 and 22 of the current year (1910) your commissioner examined specimens of the Detroit water-supply drawn from a tap in the business district of the city. On September 21 two 0.1 c.c. samples and two 1 c.c. samples did not show the presence of *B. coli*,

* Seventeen deaths reported up to September 26.

one to two weeks to the Detroit water intake. While this explanation leaves unaccounted for the large amount of typhoid fever in Detroit in March and April, 1892, and throughout the whole year 1893, the evidence in Professor Williams' paper must be studied in detail to be appreciated at its full value. It may be added that this instance of alleged long-distance water conveyance of typhoid bacilli was cited in the Chicago Drainage Canal case and was the subject of comment by witnesses on both sides of the controversy.

While it may be admitted that the precise origin of the Detroit epidemic of 1892 was not indisputably ascertained, there can be no doubt that in some way typhoid bacilli had gained access to the public water-supply in that year. There was no difference of opinion in regarding the water-supply at fault.

DESCRIPTION OF THE WATER-SUPPLY

The water-supply of Detroit is drawn from the American channel of the Detroit River at a point near the northeast corner of the island of Belle Isle (see diagram). There are three inlet pipes, one 1,000 feet and two 1,500 feet long, one 5 feet and the other two 6 feet in diameter. These run from the channel of the river to an open settling basin. The settling basin is 365 feet

but in a third 1-c.c. sample two *B. coli* organisms were present. On September 22 *B. coli* was not present either in two 0.1 c.c. or in three 1 c.c. samples examined. Litmus lactose agar was used as the isolating culture medium and the nature of the red colonies verified by sub-cultures. Four 1 c.c. samples taken direct from the settling-basin showed the presence of *B. coli* in one case.

These bacterial examinations do not afford any marked evidence of contamination at the time the samples were collected. On the other hand, their generally negative character does not necessarily imply that the water is at all times and under all conditions safe. A dangerous infection of such a water-supply as that of Detroit might exist for a day, or even a few hours, and remain undetected unless examination of the water was searching and frequent. It is noted above that in one sample of tap-water colon bacilli were demonstrably present.

A MENACE TO DETROIT'S WATER-SUPPLY

Reference to the topographical diagram shows a small stream known as Connor's Creek, which empties into the Detroit River on the American side a short distance above the water intake. This stream flows through a large cemetery and receives the drainage from a part

of Fairview (estimated to contain about 400 families at the time of its annexation to Detroit, in 1907). The situation thus created seems to have been a cause of anxiety to some of the Detroit authorities for a long period. In the discussion of the 1892 epidemic, already referred to, it is stated that as a rule the water of Connor's Creek does not mix sufficiently with the main current of the river to reach the intakes, but flows past nearer shore.² Even if this is the case, however, there is certainly danger from this source when an intake pipe nearer shore is used, as seems sometimes to be the case.³ There is some evidence, furthermore, that the water at the main intake crib may be affected. One observer⁴ is on record as follows: "When there is a flood in Connor's Creek basin the foul waters of the creek can be readily seen all the way from its mouth in the river to the opening of the city sewers. It is not unusual after heavy rainfalls and consequent floods of the creek basin to find the city water as drawn from the house faucets contaminated with quantities of organic matter."

officer of Detroit, Dr. Guy L. Kiefer. In the 1903-7 report the statement occurs that Detroit is "reaching a death-rate which will soon cast suspicion on our water-supply." In the same report an appropriation is urged "sufficient to carry the sewage of Fairview to a point in the river beyond the intake of Detroit's water-supply. This precaution is the least we can take . . ." Similar statements and recommendations are made in the 1908 report, and filtration of the public supply is again earnestly advocated.

THE PRESENT SITUATION

During the current year, particularly in the latter part of August and in early September, typhoid fever was said to be excessively prevalent in Detroit. It was estimated at one time (see Detroit daily papers of Aug. 30, 1910) that 900 cases of the disease existed in the city, and much concern was expressed over the outlook. An appeal for a more complete notification of cases was at that time issued, and as a result 240 cases were

Diagram of Detroit to show the relation of water-supply and possible sources of contamination.

A recent visit to Connor's Creek by your commissioner shows that the stream at the present time is heavily laden with sewage. A hundred yards south of Jefferson Street, near the large manufacturing establishment of the Chalmers Motor Company, the conditions are substantially those of an open sewer. Grease and paper float on the surface and the bubbles of gas which are rising to the surface testify to the active decomposition of organic matter taking place on the bed of the stream. The current is in most places exceedingly sluggish, but rapid flushing out may occur after heavy rains. An examination of the water of Connor's Creek at its mouth was made by your commissioner, and showed respectively 12 and 11 organisms of the *B. coli* group in each of two 0.1 c.c. samples. Immediately below the mouth of the creek on Detroit River are several large ice-houses.

The recent growth of population in the vicinity of Connor's Creek naturally increases the danger of specific infection entering the water. The gravity of the situation has been clearly recognized by the present health

reported to the board of health up to September 10. Thus far the death-rate has not shown any striking increase over the figures for 1909 or 1908. At the present writing (end of September) there is little reason for believing that typhoid fever cases are relatively much more numerous than at this season for four or five years past.

All this does not mean that typhoid fever has not been and is not unduly high in the City of Detroit. While the rates for 1906-9 are not perhaps alarmingly high (Table 1), they are by no means so low that they can be contemplated with equanimity by any Detroit resident. In 1909, for example, there were 94 deaths from typhoid fever in Detroit, as compared with 45 in Cincinnati, a city that has recently purified its water-supply, or a rate of 24 compared with Cincinnati's rate of about 12.

Perhaps the most disquieting feature of the typhoid fever situation in Detroit is the failure of the disease to diminish in recent years or, to speak more correctly, its tendency to increase. In the face of a steadily lowering typhoid death-rate throughout the country generally, Detroit has shown an actual and substantial increase in the last five years as compared with the two preceding quinquennial periods (Table 2).

2. Williams, G. S.: Ann. Rep. Michigan State Board of Health, Supplement, p. 106.

3. See Detroit Times, Aug. 17, 1910.

4. Wyman, H. C.: In discussion of Williams' paper: Ann. Rep. Michigan State Board of Health, Supplement, p. 100.

As to the causes of typhoid fever in Detroit there seems every reason to consider the public water-supply responsible for some of the cases.

1. The general typhoid death-rate for the city is higher than would reasonably be expected in a city situated as is Detroit, but with a pure water-supply.

2. The typhoid rate in the city has risen in recent years, corresponding with the growth of population in the environs of the city, and the consequent increased pollution entering directly above the water intake. This increase in typhoid fever has occurred during a period when the disease has been decreasing in the country at large.

3. The deaths from typhoid fever tabulated by months (Table 3) show not only the general autumnal increase, but also seasonal irregularities which indicate water-borne infection. Such, for example, are the relatively large number of deaths in March and April, 1892 and 1893, in December, 1906, and January, 1907, in May, 1907, and in July, 1908. In 1904 almost as many deaths were recorded in the first half of the year (28) as in the second half (30).

4. The annual death-rates show marked fluctuations, far greater than would be expected in a city of this size if the water-supply were not exposed to irregular pollution. Instances are the rate of 19 in 1890, followed two years later by a rate of 93, and the rate of 21 in 1898, followed the next year by a rate of 12. Such fluctuations betoken varying degrees of pollution of the water-supply.

5. One extensive epidemic of typhoid fever in Detroit (1892) has been definitely traced to the public water-supply. The source of supply is now no better protected against occasional contamination than it was 18 years ago; as a matter of fact, the danger from near-by infection (Connor's Creek) is considerably greater.

6. The character of the watershed, with its considerable population draining into Lake St. Clair, the fact that large boats sometimes pass close to the intake crib, the existence of a small stream which discharges raw sewage a few hundred yards from the intake demonstrate the possibility of occasional water infection.

7. As could be anticipated from the environmental examination, the water-supply gives occasional bacterial evidences of contamination. If the analyst of the health board is correctly quoted,⁵ considerable variation occurs: "some days the water will be very poor, but on the next day following it improves."

It is obviously impossible to discover just what proportion of the typhoid fever cases in Detroit are due to water, to the milk supply (which, judging from the investigations of the health board, is now in bad condition), to contact or to other factors, without an intensive study of the situation such as that carried out in Washington and Pittsburg. There seems to be urgent need for such a study. A fuller notification of cases is a necessary preliminary to this inquiry and should be instituted at once. In the meantime the alleged use of an old intake pipe near the shore should be investigated. The Connor's Creek nuisance can hardly be done away with immediately, but some action looking to the speedy removal of this sword of Damocles would seem to be worth while. If the present conditions are allowed to govern Detroit's water-supply a much more serious outbreak of typhoid fever than that occurring this autumn is simply a question of time.

Therapeutics

EPILEPSY

Epilepsy shares with tuberculosis the distinction of being a common chronic disease which has received an unusual amount of study and investigation during the last decade or two. But, in spite of all that has been done, our practical knowledge of the disease is not much greater than it was fifty years ago. It is true that in connection with the phenomenal expansion of modern operative surgery, and of brain surgery in particular, some convulsive conditions, commonly designated as Jacksonian epilepsy, have become amenable to operative treatment. These cases, however, although commonly included in the category of epilepsy, might not unfairly be excluded from such a classification, as their phenomena, in spite of striking superficial resemblances, are considerably different from the usual cases of epilepsy, and their pathologic lesions differ in their gross characteristics from the almost speculative pathology of real epilepsy.

The most important thing which the modern study of epilepsy has taught is that some patients who have convulsive attacks may be cured by operative treatment, and to that end that it is obligatory to study every detail of the past history and present condition of each patient to decide whether he may be included in this operative class. Also, we are now able to class as epileptic (or at least to recognize the close resemblance to epilepsy) many patients who do not exhibit convulsive seizures at all.

This subject has been very carefully and exhaustively elucidated in the "Morison Lecture" on epilepsy, delivered before the Royal College of Physicians of Edinburgh by Dr. William Turner, physician of the King's College Hospital and of the National Hospital for the Paralyzed and Epileptic, London (*British Medical Journal*, March 26, April 2 and 9, 1910).

Turner divides the cases commonly called epilepsy into four classes:

First: The organic epilepsies, including (a) those due to "traumatic lesions of the skull, brain or membranes; (b) those associated with or sequential to focal organic disease of the brain, such as tumors or thrombosis."

Second: The early epilepsies, those of infancy and early childhood, characterized by "the marked degree of mental impairment, amounting to imbecility or even idiocy, found in most cases." Many of them are caused by "focal lesions, encephalitis, hemorrhage and thrombosis."

Third: The late epilepsies, including (a) "the epilepsy associated with degenerative cardiovascular disease;" (b) "the intoxication epilepsies, of which alcoholic epilepsy is most common;" (c) that occurring later in "dementing psychoses;" (d) that resulting from "clamptic conditions, such as uremia and puerperal eclampsia."

Fourth: Idiopathic epilepsy. Of this condition he gives the following definition: "Idiopathic or genuine epilepsy may be defined as a chronic disease of the brain characterized by the recurrence of seizures in which interference with consciousness is an essential feature, associated either with convulsions or transient psychical phenomena, occurring usually in persons with an hereditary neuropathic endowment and eventually leading to more or less permanent mental impairment and dementia."

5. Detroit Free Press, Aug. 26.

It is to a consideration of this idiopathic or genuine epilepsy that the three lectures are limited, and the entire third lecture is devoted to the treatment.

It is a curious circumstance that, although epilepsy is a common disease and the paroxysms usually occur not infrequently, physicians outside of institutions do not often see patients in the convulsive seizures, except in the more severe forms of the disease, distinguished as serial epilepsy and status epilepticus.

The question of what to do for a patient who is having an epileptic convulsion or fit is one which the physician must be prepared to answer without hesitation, as it certainly comes under the head of medical emergency. The most important thing to be done at once is to do such obvious things as will prevent the patient from being injured by the involuntary movements incidental to the convulsion.

This does not involve trying to limit forcibly the convulsive action by holding the limbs or trying to open the hands. Some have advised inserting a wooden plug between the jaws, so as to prevent the biting of the tongue, but this is a procedure of doubtful efficacy. It is not necessary to pour water on the patient, or into his face, or to slap or pinch him. Neither is it of advantage to give him inhalations of ammonia or nitrate of amyl, as ordinarily the convulsion soon ends. Hence it is generally unnecessary to telephone for an ambulance, as the patient can soon be taken home in a carriage.

In ordinary fits, after the convulsive action has ceased, the natural tendency of the patient to sleep should not be combatted, but he should be allowed to rest as comfortably and with as little disturbance as possible until his own inclination leads him to get up and move about. This rest undoubtedly allows the nervous system to recuperate, in at least some degree, from the serious perturbation to which it has been subjected. These suggestions are applicable to ordinary cases of epileptic fits which occur occasionally, not daily, in individuals who walk about the streets at their pleasure and are not in any sense confined or restrained.

In contrast to these must be discussed those cases in which a number of convulsive attacks occur during a short interval, distinguished as serial epilepsy, and that grave form of the disease in which the convulsive seizures follow each other at short intervals, during which, ultimately, consciousness is not regained and in which, after the convulsions cease, a condition of coma usually persists until death ensues. In this latter condition very active treatment is indicated. Turner advises larger doses of bromid, supplemented by chloral; for example, 20 grains (1.30 grams) of bromid of sodium with 10 grains (0.60 gram) of hydrated chlorid may be given every 2 or 3 hours. This is especially applicable to serial epilepsy and to the milder grades of status epilepticus. The chloral and bromid may be combined in one prescription, or two prescriptions may be written and the doses combined, as desired, as:

R	Gm. or c.c.	
Chlorali hydrati	5]	ʒiiss
Sodii bromidi	10]	ʒiij
Elixiris aromatiei	50] or	fl.ʒij
Aque	ad. 100]	ad. fl.ʒiv

M. et Sig.: As the physician directs.

[Each teaspoonful of the above, i. e., 5 c.c., represents 0.50 gram (7½ grains) of bromid and 0.25 gram (4 grains) of chloral.]

Or, if ordered separately:

R	Gm. or c.c.	
Chlorali hydrati	10]	ʒiij
Tinctura cardamomi comp	50]	or fl.ʒij
Aque	ad. 100]	ad. fl.ʒiv

M. et Sig.: As directed.

[Each teaspoonful, i. e., 5 c.c., represents 0.50 gram (7½ grains) of chloral.]

and

R	Gm. or c.c.	
Sodii bromidi	10]	aa. ʒiij
Potassii bromidi	10]	or fl.ʒij
Essentie pepsini (N.F.)	50]	ad. fl.ʒiv
Aque	ad. 100]	ad. fl.ʒiv

M. et Sig.: As directed.

[Each teaspoonful, i. e., 5 c.c., represents 0.50 gram (7½ grains) each of the sodium and potassium bromid.]

In the more serious forms of status epilepticus, morphin, either in combination with the bromid and chloral or by subcutaneous injection, is sometimes useful. If, in spite of these remedies, the convulsions continue severe and frequent, inhalations of chloroform must be given and continued until complete anesthesia is produced. The convulsions will thus be held in check temporarily. Turner has seen good results from the hypodermatic injection of from 1/75 to 1/100 of a grain of hydrobromid of hyoscin. There has also been recommended (Clark, Turner) the hypodermatic injection of 10 per cent. sterile solution of bromid, repeated until 60 or 100 grains have been administered. Also "injection of the bromids by means of lumbar puncture has been advised, in sterile solutions of 30 grains to the ounce, 10 or 15 c.c. of the cerebrospinal fluid being withdrawn before 10 c.c. of the bromid solution are injected."

In high temperature Spratling (*Modern Medicine*, vii, page 670) reports great benefit from the cold bath.

After the convulsions have ceased and while the patient is lying in a comatose condition the treatment should be of a supporting character. Ammonia, alcoholic stimulants and digitalis or strophanthin should be given in order to strengthen the action of the heart. Nutrient enemas of peptonized milk may be given until the patient regains the power of swallowing, after which easily digested liquid nourishment should be given regularly at not too long intervals.

Another important question in connection with the convulsive seizure is: Can anything be done to prevent the full development of the attack when its first premonitions, the aura, are felt by the patient? In other words, can the fit be arrested? On the assumption that the convulsion is directly due to a sudden temporary disturbance of the cerebral circulation, inhalations of nitrate of amyl have been recommended. They are believed to be especially efficacious when the warnings are of cephalic character, "and particularly in those with olfactory sensations (Gowers)." To facilitate this use of the drug it is furnished in small glass globules enclosed in silk and cotton, which can be quickly broken and the vapor inhaled without delay. When the warning sensation first appears in the hand, it was long ago suggested that the wrist be encircled with a band which should be quickly tightened when the first premonition is felt. Forced extension, rubbing of the limb and biting of the finger are expedients of perhaps occasional but usually of doubtful efficiency. In patients who have visceral aura, pressure on the epigastrium, drinking cold water, swallowing a few drops of ether, inhalation of ammonia and, finally, autosuggestion—"a strong determination to overcome the attack"—are expedients which are all

believed to have been proved efficacious in individual cases.

The next questions in the management of epilepsy are: What can be done to prevent the attack? And what is the treatment of idiopathic epilepsy?

During recent years there has been a strong movement in various parts of the country toward the establishment of colonies for epileptics. For those epileptics who are also imbeciles or idiots, and who at present are confined in jails, almshouses and in hospitals for the insane, this is a most praiseworthy and useful undertaking. But when these institutions are fully established and the busy and well-meaning but not very thoughtful or well-informed practitioner recommends every epileptic he finds to be sent to an institution, and when every family which includes an epileptic who occasionally has a fit, and who consequently has difficulty in securing steady work, eagerly seizes the opportunity to rid itself of the burden of feeding and watching its unfortunate member, incalculable harm will be done.

It would be presumption to attempt to teach the officers of these institutions how to manage their patients, but those physicians who have the care of epileptics who are retained in their own homes should have the following suggestions in mind:

First, the general hygienic surroundings of the unfortunate invalids should be looked after and made as good as possible. Many are able to undertake and are benefited by some manual occupation, preferably out of doors, such as farming or gardening. This exercises the brain and helps to keep it in more normal condition, and also exercises the body and promotes those metabolic changes which are so necessary to its welfare. Physical exercise increases the elimination of all of the eliminative organs and glands, and as a result prevents the accumulation in the body of the toxic products of metabolism which are believed to have some action in predisposing to epileptic convulsions. This out-of-door work is especially adapted to patients of robust constitution. Frail, delicate patients may do well at less strenuous, in-door occupations, such as bookkeeping or drawing.

If it is impracticable for an epileptic to work he should at least take out-door exercise, and Turner recommends "walking, running, tennis, golf, croquet and football" as especially suitable, while "bicycling, rowing, swimming and riding" should be avoided.

The patient should not be left alone, but should, so far as possible, always be in the company of some member of the family, a friend or an attendant, who understands his condition and who will not be greatly disturbed if the emergency arises demanding coolness and composure.

Bathing is a most desirable adjunct to work and exercise, strengthening the habitually sluggish circulation, promoting assimilation and nutrition and increasing elimination.

The diet of the epileptic is a subject concerning which a great deal has always been said and written. In considering this question Turner points out that "in any attempt to formulate the principle which ought to guide the physician in considering the dietetic treatment there ought to be kept in mind that nervous energy has its source chiefly in the albuminous and nitrogenized principles of food stuffs." Since nervous energy seems to be in excess in epilepsy it is not strange that many observers, including Turner, have found it desirable to exclude albuminous foods from the diet of epileptics. Or, to use

the more recent nomenclature, a "purin-free" dietary is advantageous in epilepsy. "A purin-free diet," writes Turner, "is made up of those foodstuffs in which the 'purin' or alloxur bodies are absent, or present only in such small quantities as to be negligible. Purin bodies exist in all forms of meat, both the white and the red, commonly used as food. They are present in large quantities in such substances as sweetbread, liver and beef-steak. They are not present in milk, eggs, bread, butter, cheese, the farinacea, most fruits and some vegetables. They exist to only a moderate degree in most forms of fish, peas, beans, lentils, tea, coffee and oat-meal."

Concerning the medicinal treatment it must be conceded that after more than fifty years of use, since its introduction by Laycock, no drug equals a bromid salt in general usefulness and efficacy. Turner's experience has been that in approximately half of the cases of epilepsy the bromids caused either arrest of the fits or a notable lessening of their frequency and severity, while in the other half they seemed to exert no influence at all. When they produce a favorable influence this is generally apparent within a comparatively short time after their administration is commenced.

Turner believes that too large doses are usually given. He finds that daily doses exceeding from 45 to 90 grains (from 3 to 6 grams) are rarely useful. The sodium salt is usually preferable to the others.

Rather recently it has been found that the bromids prove more efficacious in epilepsy if the amount of sodium chlorid in the food is reduced. Turner points out that, "Hoppe (*Neurol. Centrabl.*, 1906, p. 993) has shown that one-third of the chlorin of the blood serum has to be replaced by an equivalent amount of bromin before any therapeutic result is obtained." This diminution of sodium chlorid in the food has been found particularly useful in cases in which large doses of the bromids seemed to be necessary, and also in those instances in which the patients seemed to be especially susceptible to the toxic action of the bromid. It has been found that very much smaller doses of the bromids prove efficacious in connection with a "salt-free" or "salt-poor" diet. Turner has found that very substantial benefit has been derived from a combination of a "purin-free" diet with "salt-starvation."

It remains to consider only one final practical question. How long shall systematic administration of the bromids be continued? And it must be confessed that this question cannot be answered definitely. Some writers have advised that treatment should be continued for two years after the last fit. Others, like Turner, teach that this period, at least in some cases, is insufficient, some of his patients finding that even after years of freedom from fits, if the bromid is stopped, "a return of giddiness or of 'sensations'" indicates that there is still a liability of the more serious attacks to return. In all apparently cured patients the bromid should be discontinued only very gradually. It should never be stopped suddenly after it has been used for a long time. During the gradual withdrawal the patient should be carefully watched in order to detect, if possible, the earliest indication of a return of the fits. Finally it must be urged that for some epileptics it is wise to substitute a moderate dose of the sodium bromid for the usual amount of sodium chlorid in the food, even for many years after the occurrence of the last epileptic convulsion.

CULTIVATION OF THE LEPROSY BACILLUS

Although it is now nearly forty years since Hansen discovered in leprosy tissues the small rods which are now universally conceded to be the cause of leprosy, yet the cultivation of this bacillus has been an unattainable goal for the bacteriologist. On a number of occasions successful results have been reported, but none of these claims has been accepted, although it has always seemed possible that in this respect injustice may have been done, since it has not hitherto been impossible to prove the identity of any suspected acid-fast bacillus as *B. lepra* because there was no known susceptible animal on which its pathogenicity could be tested.

Two recent achievements in this problem have overcome some of the greatest obstacles, and taking advantage of them Duval¹ of New Orleans has succeeded, he believes, in securing pure cultures of the leprosy bacillus. The first of these discoveries was made by Clegg in the Philippines, who reported last year that he had succeeded in growing on artificial media an acid-fast bacillus obtained from leprosy tissue, by means of inoculating this tissue on culture media already inoculated with amebas and their symbiotic bacteria. Of necessity, in this case, the supposed leprosy bacilli were not in pure culture, and there were then available only morphologic means of identifying them. The latter deficiency has been supplied by Sugai, who found that the Japanese dancing mouse was susceptible to infection with leprosy bacilli coming from human tissues, the lesions showing the histologic characteristics of the typical leprosy lesion. Duval confirmed both these observations, and by means of special complex media has been able to obtain in pure culture, without the presence of either amebas or symbiotic bacteria, an organism with the morphologic and tinctorial characteristics of *B. lepra*, which when inoculated in pure culture into the Japanese dancing mouse produced typical lesions.

It is to be hoped that the correctness of Duval's claims will soon be established by other observers, for then the door will be opened to rational prophylactic and curative treatment of this historically incurable disease.

CAUSE AND EFFECT

There is a type of newspaper journalism which causes the thinking to grieve and the decent to shudder; it has neither conscience nor honor; it glorifies indecency and envelops immorality with sickly sentimentality and a maudlin moralizing; its advertising pages are open to anything that will go through the United States mails—and to many things that would not, if they were brought to the attention of the authorities. The habitat of such papers is confined to no locality; they are to be found in most of the large cities of this country. While what follows deals only with a California example, the subject-matter may easily fit any other of the same type.

A correspondent on the Pacific Coast recently sent to THE JOURNAL a clipping from a San Francisco paper of this kind, in which appeared the most shameless and openly worded abortion advertisements. One of these described how a "Dr. F. E. Grant" at 1293 Golden Gate Avenue was prepared to:

"GUARANTEE to cure the longest and most obstinate female cases in 24 hours by STRICTLY up-to-date, ANTISEPTIC, SAFE and PAINLESS methods, WITHOUT DELAY from home or work."

"TRAVELERS can be treated and return home the same day. We have never had a failure. Confinements and adoptions arranged."

And more of the same tenor. This, it should be remembered, was but one of many similar advertisements. These filthy, criminal and wicked notices are what this San Francisco paper serves up to its readers for the money there is in it. They constitute a *cause*; the *effect* follows:

San Francisco, within the past two weeks, has been shocked by the details of a crime which bids fair to outdo in gruesome details the Crippen tragedy. According to the reports, a young school-teacher who had loved not wisely but too well found herself pregnant and went to San Francisco to be relieved of the consequences of her indiscretion. She sees the Grant advertisement boldly offering to perform the criminal act she desires and she places herself in his hands. While on the operating table she expires and Grant, the police claim, to hide the consequences of his crime, dismembers the body, packs it in a trunk and, renting a house for a short time, buries the body (saturated with nitric acid) in the cellar. After a few months had elapsed—during which time the Grant advertisement and others similar to it continued to outrage decency—the crime is discovered and the San Francisco public is served with the details of the tragedy. Note what happens: The very paper, which by every moral law is, at least indirectly, responsible for the poor girl's death and is an accessory before the fact to the crime which has been committed, comes out with "scare heads", double-leaded type, and all the "yellow" accessories which go with this type of journalism. Page after page is devoted to the gory details of the crime—more than half a page being given to a picture of the murdered girl.

1. Duval, C. W.: Jour. Exp. Med., 1910, xii, 649

In the abortionists' column of the same issue of the paper in which these sickening particulars are printed, Dr. Grant's advertisement is missing, but the others—thirteen of them—are there. In the editorial columns, also of this issue, the editor thunders virtuously against those "who make their money by catering to depraved tastes and have no scruples against corrupting the young"!

How much longer will the American people permit the pages of the daily press to be thus prostituted and debauched? The trade of criminal abortion is vile enough at any time even when carried on in secret and hidden from the public gaze. When, however, this villainous traffic is exploited brazenly and openly through the columns of the daily press it is time for the decent element of society to take a hand, if only to protect the integrity of the social fabric itself.

THE USE OF BACTERIA TO KILL RATS

Under different names there are now offered for sale several preparations of living bacteria for the purpose of exterminating rats and mice. The bacteria in question are supposed to be highly virulent for these animals, and directions are given for spreading the infectious material about so that the animals may infect themselves and die. Aside from the question as to the effectiveness of this method of extermination—and it is still an open question—attention may be called to the fact that the method is far from being free from danger to human beings. In some cases at least the bacteria employed are paratyphoid bacilli or closely related thereto. This is the case with the so-called "ratin." According to the published statements¹ of the promoter of "ratin," the bacillus was first obtained from the urine of a child, 2½ years old, suffering with cystitis. When first isolated the bacillus had only slight virulence for rats, but mice died from feeding on material contaminated with it. On passage of the strain through rats, its virulence for these animals was increased, so that here also fatal infection would occur on feeding.

Naturally special efforts are made—at least one would think so—to maintain a high degree of virulence, but it seems that the various preparations on the market do not cause death of more than 50 or 60 per cent. among the wild rats exposed to infection. It is asserted that "ratin" has been ingested by human beings without injury. Absolute harmlessness to human beings has not been established, however, and hence special care should be taken in the use of this and other preparations of the same nature, especially because of the great danger of contamination of food substances and utensils used in the preparation of food. The following instance from recent British journals may be cited as suggestive of human infection from this rat virus:

Acute diarrhea attacked a number of persons who on a certain day had eaten dinner at the same place. On careful sanitary inspection of the premises, many dead mice were found, and it was also discovered that shortly before "ratin" had been spread about. We know that bacteria of the paratyphoid group may cause acute human infections and intoxications, and the above instance may well have been the result of food contamination with "ratin."

In view, therefore, of the reasonable doubt which exists both of the effectiveness and of the harmlessness for human beings of such viruses as the one mentioned, their indiscriminate employment is to be condemned. Indeed, it would seem self-evident that the first requisite of a virus to be used for the extermination of vermin which are capable of contaminating foodstuffs for human consumption, must be absolute lack of pathogenic power for man.

Current Comment

OSTEOPATHS AND VITAL STATISTICS

The *Springfield Republican* makes this remark in a recent issue: "The New York Supreme Court has denied the osteopaths the right to issue death certificates. They can cure patients; the regular physicians keep the monopoly of burying them." Since the *Republican* is recognized as one of the most ably edited newspapers of the country it would show a lack of the sense of humor if we failed to regard this as a joke, for the *Republican* must know why the court made this ruling. We may be excused, however, if we use the joke as a text for a preachment, since it presents the general conception of the reason for the issuance of death certificates. Laws requiring death certificates as a preliminary for the burial or removal of a body were not enacted and are not enforced for the benefit of the medical profession or for the persecution of osteopaths. It is of no advantage to a physician, and is frequently a decided annoyance to be required to fill out a death certificate setting forth the cause and manner of death. This is required, not for the benefit of the physician but as a safeguard to the community. As Professor Huxley long ago pointed out, it is necessary for the protection of the individual and of society at large that a record should be made of the manner and cause of death of each human being, as a means of preventing and detecting crime as well as to preserve records of causes of death. The value of such data is recognized in all civilized communities. The carelessness of Americans regarding birth and death records is looked on with astonishment by our European neighbors. Cattle, dogs and horses are carefully registered. The birth of even an Angora kitten is considered worthy of record, yet we have practically no birth records while, in nearly half of the United States, human beings die and are buried without any record being made of the fact. The properly educated physician recognizes the importance of death certificates and

1. Bahr: *Centralbl. f. Bakt.*, 1905, p. 263.

furnishes them without compensation, not as a privilege, but as one of his duties to the state. Such legal documents should be certified only by those properly qualified to determine the cause of death.

A LAYMAN'S ADVICE TO PROSPECTIVE MEDICAL STUDENTS

An excellent article on "How to Study Medicine," by Dr. Henry S. Pritchett, president of the Carnegie Foundation for the Advancement of Teaching, appears in last week's issue of *The Outlook*. It would be of undoubted advantage to medical education if many such articles could appear in lay periodicals. This article calls attention to the excessive number of medical schools, to the alluring advertisements of commercial medical colleges, to the generous educational opportunity now open to anyone, including the poor boy, and to the problem of sectarian medicine. President Pritchett refers particularly to the fact that medicine has been practically made over in the last twenty years; that its practice to-day rests on certain fundamental sciences, such as bacteriology, physiology, physiologic chemistry and the like, which were unknown, or scarcely touched on, twenty-five years ago, and that it is absolutely necessary for the physician of this generation to have a broader general and professional education than was formerly required. The student who is looking toward the medical profession, therefore, should secure, first of all, a good general education and then should obtain a medical course in a college which is sufficiently equipped and prepared to teach medicine in accordance with modern standards. Before deciding on the medical school he shall attend, President Pritchett urges the prospective student to seek advice from some well-informed practitioner in his neighborhood, one who is acquainted with the medical teaching of to-day, and not to allow himself to be misled by alluring advertisements. With the amazing confusion which surrounds medical education in this country to-day, the choice of a medical school is a serious problem, especially for the student who desires to do honest work. Such an article as that by President Pritchett, therefore, is to the prospective medical student as a compass to a sailor in a stormy sea.

STATE BOARD EXAMINATIONS IN MATERIA MEDICA

The National Confederation of State Medical Examining and Licensing Boards is to be congratulated on its action in advising the constituent boards to restrict examinations for licensure in materia medica and therapeutics to questions on the more important drugs. The confederation is also to be felicitated on its adoption of a list of these drugs.¹ While the list selected will hardly please everyone, just as Dr. Eliot's five feet of books failed to win universal approval, it is restricted to drugs in more or less common use, and was considered by the committees which had charge of this matter to meet the requirements. If the various examining boards should decide to follow the plan outlined by the confederation, they would be able to make fairer tests of

the knowledge of remedies possessed by applicants for license to practice, and students would be compelled to acquire a thorough and useful knowledge of essential drugs instead of the superficial familiarity with the action of preparations which are almost never used—a pseudo-knowledge which is not only useless but dangerous. This point is worthy of emphasis. The medical student, or even the physician, in trying to gain a knowledge of the ridiculously large and bewildering number of drugs on the market, is attempting the impossible. He acquires real practical knowledge of none. In consequence, his knowledge of the action and uses of even the most important drugs is often vague and imperfect, and he becomes a routine prescriptionist, copying his prescriptions from text-books and journals. If the recommendations of the confederation were adopted, the student could devote the time allotted to this study to the acquisition of a more thorough understanding and scientific application of the more important drugs, to the immense betterment of the practice of medicine in general. The practicing physician also would do well to ponder the subject, for this action of the confederation points the way to the salvation of therapeutics. Therapeutics can never be an exact science, but there is no reason why it should not be based on thorough knowledge, on exact and critical experimental and clinical observation, and on sound reasoning. The discriminating use of a few drugs, well-studied and thoroughly understood, will accomplish vastly more good than the indiscriminate abuse of the numberless drugs which have never been subjected to any real clinical investigation, and which, in many instances, differ but little from nostrums. It is gratifying to note that the confederation has officially recognized and endorsed this necessary reform. It now remains for the various state boards to give it practical effect.

EARLY HISTORY OF RENAL SURGERY

Ekehorn, who recently became professor of surgery in the university at Upsala, devotes his inaugural lecture¹ to an account of the early history of renal surgery. He follows its development back to the oldest civilization of which we have any record. While there is reason to believe that surgical operations of consequence were performed in Egypt and Babylonia during the height of culture in those ancient countries, no trace of any operations on the kidney has been discovered. The first historical record of renal surgery is found in the writings of Hippocrates (450-370 B. C.), who recommends well-indicated and rational operations in the regions of the kidneys and on the kidneys themselves. Then came a long and deep silence on this subject, which lasted until the end of the middle ages, when the interest in it again awakened, and yet the field of renal surgery remained practically the same as that marked out by Hippocrates until as late as 1869. In the latter part of the summer of that year, Simon, a Heidelberg surgeon, had as patient a woman, 46 years old, who had been subjected to ovariectomy, after which there developed a ureteral fistula which caused great suffering. After thorough prepara-

1. See report of the committee, page 1302

1. Upsala Läkaref. Förh., 1910, xv, 343.

tion by means of anatomic and experimental studies, he removed the corresponding kidney and thus restored the patient to perfect health. This operation marks the beginning of the new history of renal surgery.

ANTITUBERCULOSIS WORK IN MASSACHUSETTS

The work against tuberculosis is becoming well organized in many states and is being systematically carried out. The fifth annual report¹ of the Associated Committees of the Massachusetts Medical Society for the Prevention and Control of Tuberculosis is an interesting revelation of the sort of work that is being done. The report of the chairman states that the chief difficulty in obtaining control of the tuberculosis situation in Massachusetts (and this will apply to the work in other states as well) is that of getting hold of the patients early in the disease, and to overcome this the profession must render more assistance, and the use of visiting and school nurses must be extended. Employers of labor must also assist, and outdoor schools for puny children must be established. In the way of educating the public, pamphlets and school exhibits are employed, and employers have helped by distributing cards of caution and instruction with pay envelopes. Registration and disinfection of premises where patients have died are also measures to be encouraged. The pamphlet contains the report of the secretary and the detailed reports of the work done by the committees in the eighteen districts of the state.

Medical News

CALIFORNIA

Pay of Interns.—The supervisors of Los Angeles county have voted to pay interns of the County Hospital an annual salary of \$100.

Itinerant Practitioners Taxed.—A new license ordinance has been adopted by the city council of Porterville, by virtue of which itinerant doctors will be obliged to pay a license of \$50 per day.

First-Aid Boxes on Streets.—The chief of police of Berkeley has made requisition for twenty-five Red Cross, first-aid-to-the-injured boxes, to be placed near the police and fire alarm boxes. The bicycle policemen will also carry first-aid boxes on their bicycles.

Personal.—Dr. Francis M. Pottenger, medical director of the Pottenger Sanatorium, Monrovia, writes to deny the report which has been circulated to the effect that he is starting or contemplating starting a sanatorium for tuberculosis at Tucson, Ariz., as a branch of the Pottenger Sanatorium. —Dr. H. C. McLanahan, Belmont, who recently returned from Europe, has been elected associate to the chair of mental disease and legal medicine, and assistant in clinical neurology at Cooper Medical College, San Francisco. —Dr. Edwin H. Wiley, Los Angeles, surgeon on the Receiving Hospital staff for nearly three years, was tendered a farewell dinner by the staff of the hospital, September 9. Dr. Wiley has left for Hermosillo, Sonora, Mexico, to take charge of the hospital there. —Dr. Frank W. K. Kidder has been appointed assistant police surgeon of Los Angeles. —Dr. Edward E. Baumeister, Chico, has been commissioned assistant surgeon in the National Guard of California with rank of first lieutenant. —Dr. Ernest E. Thompson, Red Bluff, has succeeded Dr. A. P. Carter, Red Bluff, resigned, as health officer of Tehama county.

GEORGIA

Sanitarium Opened.—Dr. James N. Brawner, formerly head of the Pasteur Institute, Atlanta, has opened the Oak Grove Sanitarium near Smyrna, for the treatment of nervous and mental diseases, with accommodation for more than forty patients.

Medical College Opens.—The Atlanta School of Medicine opened for its fall term September 20. The dean, Dr. George H. Noble, presided, and addresses were made by Hooper Alexander, Ex-Governor Northen, and Drs. William S. Kendrick and E. C. Thrash.

Scholarships in Medical College Bestowed.—Under the law making the medical college of Augusta a branch of the state university, the governor made the following bestowals of beneficiary scholarships, September 9: The state at large, T. B. Brantley, Sylvania; W. W. Meadows, Helena; Ollie D. Thompson, Augusta, and Mark E. Perkins, Millen; First Congressional District—J. Felton Burkhalter, Daisy, and T. F. Grooms, Statesboro; Second Congressional District—Jack G. Standifer, Blakely, and T. P. Brown, Beachton; Third Congressional District—W. T. Lanier, Cordele, and C. C. Frederick, Wellston; Fourth Congressional District—J. E. Taylor, Newman, and Homer L. Barker, Franklin; Fifth Congressional District—C. Mell Smith, Monroe, and Erle Thornton Newsome, Union Point; Sixth Congressional District—C. B. Brookins, Milledgeville, and L. C. McAfee, Macon; Seventh Congressional District—Egbert M. T. Tilton, and M. A. Acree, Calhoun; Eighth Congressional District, E. F. Griffith, Eatonton, and James W. Payne, Monticello; Ninth Congressional District—T. L. Holcombe, Staham, and Howard Kennedy, Gainesville; Tenth Congressional District—John T. Logue, Augusta, and D. L. Murray, Lincolnton; and Eleventh Congressional District—Warren Hall, Nicholls, and W. B. DuVall, Homerville.

ILLINOIS

Chicago

Law Violators Fined.—In the United State District Court, September 23, the Semrad Chemical Company and Allen B. Wrisley Company, charged with misbranding and adulterating flavoring extracts, are said to have been found guilty and fined \$200 each. —J. Gartenstein, an "herb doctor," is said to have been found guilty on September 27, of practicing medicine without a license and fined \$100 and costs.

Personal.—Dr. Alexander H. Ferguson announces that he has sold his equity in the Chicago Hospital and henceforth will do his surgical work at St. Luke's Hospital on Tuesday and Thursday at 2 p. m. —Dr. Janet Gunn has been elected president of the Board of Managers of the Mary Thompson Hospital, vice Mrs. Charles Fitz Simons, who has been a member of the board for thirty years, but recently resigned on account of illness and who has been made president emeritus. —Dr. John S. Marshall, chief of the dental service of the United States Army, who has been in Manila for three years, is visiting in Chicago, en route to Columbus Barracks, his new station. —Dr. B. C. Corbus has returned from Europe, where he went to investigate Ehrlich's new specific for syphilis. He brought back a quantity of the substance.

INDIANA

New Hospitals.—At Columbus the sanatorium formerly occupied by Dr. A. P. Roope was opened October 3 as a City Hospital, with Dr. Roope as chief surgeon. —At Linton the county council has appropriated \$25,000 for a city hospital, which will take care of the numerous miners injured in the district.

Personal. Dr. J. A. Wooden, Gosport, was elected president of the National Association of Mexican War Veterans, September 6. —Dr. William Engle has resigned as house surgeon at the Wabash Railway Employees' Hospital at Peru, Ind., and has gone to Evansville to locate. —Dr. E. L. Swedener, formerly assistant physician at the Indiana State Reformatory, Jeffersonville, has returned from Nebraska and assumed his old position, succeeding Dr. Walter Levy, who resigned to engage in practice in New Albany.

State Association Meeting.—The annual meeting of the Indiana State Medical Association was held in Fort Wayne September 28-30. A state inebriate hospital was recommended, the creation of a national department of health was advised and the State Board of Health was endorsed in its fight on benzoate of soda. Indianapolis was selected as the meeting place for 1911. The following officers

¹ Paper, 46 pages, September, 1910, 3 Joy Street, Boston.

were elected; president, Dr. Frederic C. Heath, Indianapolis; vice-presidents, Drs. John N. Hurty, Indianapolis; Andrew S. Dickey, Tipton, and James P. Salb, Jasper; secretary, Dr. Charles N. Combs, Terre Haute; treasurer, Dr. David W. Stevenson, Richmond; and councilors—Third District, Dr. Walter J. Leach, New Albany; Sixth District, Dr. C. S. Hoagland, Milroy; Ninth District, Dr. William H. Williams, Lebanon, and Twelfth District, Dr. Budd Van Sweringen, Fort Wayne, and delegates to the American Medical Association, Drs. Miles Porter, Fort Wayne, and Frederick A. Tucker, Noblesville.

IOWA

Suggests Epileptic Colony.—Dr. Charles F. Applegate, superintendent of the State Hospital, Mount Pleasant, at a meeting of superintendents of state institutions in Des Moines, September 27, suggested the establishment of a colony for Iowa epileptics. He said there were 4,000 of these unfortunates in the state.

Medical College News.—A new medical building is to be erected during the year on the campus of Drake University, Des Moines. A number of changes have occurred in the faculty. Dr. John Hyren Peck has been made instructor in theory and practice of medicine; Dr. Walter Lawrence Biering, instructor in medicine; Dr. Arthur Steindler, professor of orthopedic surgery, and Dr. Alexander Roche Robinson, professor of pathology.

Elections.—The Iowa Public Health Association, at its meeting in Waterloo, September 21, elected the following officers: president, Dr. Fred Albert, Mason City; vice-president, Dr. Samuel Bailey, Mount Ayr, and secretary-treasurer, Dr. William G. Carhart, Marion.—The Des Moines Pathological Society, at its annual meeting, September 23, elected Dr. James Taggart Priestley, president; Dr. Francis A. Ely, vice-president; Dr. Lawrence P. Piper, secretary-treasurer, and Dr. Alva P. Stoner, member of the executive committee.

KENTUCKY

Antituberculosis Work in Schools.—The Louisville Antituberculosis Association has arranged by the employment of a trained nurse and with the permission of the school board to have lectures given throughout the school year in all of the public schools. The nurse will visit each room and lecture as to the manner of the spread of tuberculosis, its prevention and cure. The superintendent of the public schools has assured the association that every effort will be made to have an open-air school for tuberculous children.

Good Milk Campaign.—The illustrated Sunday supplement of the *Courier-Journal* of September 25 published ten photographs of dairies producing certified milk under the rules laid down by the commission of the Jefferson County Medical Society. Much prominence has been given the Edison moving picture film entitled: "The Man Who Learns," which is being shown at a local moving picture show under the auspices of the distributors of certified milk and the Babies' Milk Fund Association of Louisville, which distributes only certified milk to the babies under its care. This film is educational and contrasts the intolerable conditions prevailing in many dairies before certified milk methods became generally known, with the improvements after they cleaned up. In addition to this film are shown pictures of the adapted milk laboratory of the Babies' Milk Fund Association, a distributing station, with child being weighed and the picture of the baby who gained eight ounces a week while being fed by the Association.

Violators of Food and Drugs Act.—Fifty retail druggists of Louisville appeared before R. M. Allen, chief of the State Food and Drug Division of the Experiment Station to answer charges of alleged violations of the Kentucky Food and Drugs Act of 1908. There were about eighty cases heard, some of the druggists being charged with more than one violation of the act. Among the drugs alleged to have been sold in violation of the act are tincture of opium, camphor, liniment, essence of peppermint, lime water, spirits of niter, witch hazel and tincture of iodine. The department claims that these preparations were deficient in strength, ranging from 10 per cent. to 60 per cent. of the standard strength as prescribed in the United States Pharmacopoeia. In view of the fact that these were first offenses and that there were extenuating circumstances in many of the cases, it is likely that only three or four cases will be presented in the courts. Second violations of the act will not be excused and the violators will be prosecuted.

MARYLAND

New Hospitals.—Plans have been completed for the annex to the State Hospital for the Insane, Sykesville (Springfield Hospital). The new building is a two-story brick and stone structure, and is to be devoted to feeble-minded patients.—The Centerville Emergency Hospital, with accommodation for sixteen patients was opened October 1. It is in charge of Dr. Laura Redding, and is under the patronage of the Queen Anne's County Medical Society.

Baltimore

Colleges Open.—The College of Physicians and Surgeons opened October 3, for its annual session. The opening address was made by Dr. Emil Novak.—The Department of Medicine of the University of Maryland opened October 3, without formality.—The session of the Baltimore Medical College began with an address by Dr. Tilghman B. Marden, September 20.—The freshman class of Johns Hopkins Medical School contains fifteen women.

The Herter Foundation Lectures.—The fifth course of lectures of the Herter Foundation was delivered in the auditorium of the physiologic building of Johns Hopkins University by Dr. Hans Chiari, professor of physiologic anatomy in the University of Strassburg. The first lecture was delivered October 5, and was on "The Significance of the Amnion in the Origin of Human Monstrosities," the second on October 6, was on "Necrosis of the Pancreas," and the third on October 7, was on "Spondylolisthesis."

Free Tuberculosis Hospital Urged.—The report has been made to the Municipal Tuberculosis Commission urging a free hospital for tuberculosis patients to accommodate 300 patients, and to cost about \$300,000. The report also recommends that children suffering from tuberculosis be excluded from the public schools, that a colony for the care of tuberculous negroes be established, and that a separate ward building for the treatment of children with early tuberculosis be instituted at the Maryland State Sanatorium, Sabilla-ville. It is suggested that this hospital as well as the Municipal Tuberculosis Hospital, a department of the Almshouse, be placed under the care of the board of health. At present the provision for the care of the tuberculous consists of the Municipal Hospital, the Phipps Dispensary at Johns Hopkins Hospital, a special dispensary at the University of Maryland, and Christ Church.

MASSACHUSETTS

Antituberculosis Tag Day.—The Newburyport Antituberculosis Society netted about \$1,000 from a "tag day," September 14.

Ether Day.—The trustees of the Massachusetts General Hospital announce that the exercises of the sixty-fourth anniversary of Ether Day will be held, October 15. The principal address will be delivered by Dr. George W. Crile, Cleveland.

Hospital Opened.—Dr. Philemon E. Truesdale, at the opening of Highland Hospital, Fall River, for patients, September 7, entertained about sixty guests. The address of the occasion was delivered by Dr. J. Riddle Goffe, New York City, on "Modern Surgery." Dr. Goffe also held a clinic in the afternoon.

Personal.—Dr. Thomas F. Donoghue, Boston, has returned from Europe.—Dr. John F. Moore has been appointed police surgeon of Worcester.—Dr. Harry H. Nevers, Lawrence, was recently operated on for appendicitis.—Dr. Burdette L. Arms has been appointed director of the bacteriologic laboratory of the Boston Health Department, vice Dr. Francis H. Slack, who resigned to accept a position at the Kansas State Agricultural College.—Dr. Patrick J. Timmins, Boston, has returned from Europe.

MISSISSIPPI

Personal.—Dr. Richard M. Boyd, Houston, has moved to Aberdeen.—Dr. Edgar D. Craft, Laurel, has passed the examination and been admitted to the Medical Corps of the United States Army.—Dr. William G. Allen, Newton, has been appointed physician for the Rockefeller Fund for the counties of Newton, Neshoba, Lauderdale, and Jasper.

MISSOURI

Medical Journals Consolidated.—The *Kansas City Medical Index-Lanct*, after thirty-two years, has been consolidated with the *Medical Herald* of St. Joseph. The new editor-in-chief is Dr. Charles Wood Fassett, St. Joseph, and the editorial staff includes Drs. S. Grover Burnett, John Punton and Otto L. McKillip, all of Kansas City.

Baby-Farmers Convicted.—Dr. Joel B. McDaniel and Mrs. Mary Rail, Kansas City, tried by the municipal court September 24, on the charge of having operated a "baby farm" are said to have been found guilty. Dr. McDaniel, who, it is alleged, has failed to report the births of infants he had attended, was fined \$50, and Mrs. Rail was fined \$25 for keeping more than one infant under two years of age for pay.

Free Medical Services at University.—An announcement is made by the president of the University of Missouri that every student in attendance at the university this year will receive medical attendance free. Dr. Woodson Moss, Columbia, is to be university physician. Free care at the hospital is to be given to students, excepting those suffering from communicable diseases, who will be treated in their quarters or in suitable hospitals.

The State Tuberculosis Commission.—The Missouri Commission on Tuberculosis met at the Hotel Jefferson, September 24 and organized and elected Archbishop John J. Glennon, chairman; Dr. Edward W. Schaudler, Kansas City, vice-chairman; J. H. Lynch, secretary, and Dr. William A. Clark, Jefferson City, treasurer. The other members of the executive committee are Dr. George Homan, St. Louis; Mrs. Philip N. Moore, St. Louis; W. K. Bixby, St. Louis; A. A. Speer, Chamois, and Dr. Jacob Geiger, St. Louis. It was decided to make inquiry at once in every feasible manner to locate the extent of tuberculosis throughout the state, and investigate all the public institutions on this point, instituting searching physical examination of patients to determine the fact of the disease, and enlisting the aid of practicing physicians, health officers, registrars of vital statistics, editors of newspapers, etc., to get as complete information on this subject as possible. The funds for the purpose have been subscribed by private individuals. As the result of this it is expected that the public health service of Missouri will be placed in excellent condition. A report will be sent to the governor in December, on which it is expected he will base recommendations to the general assembly for new legislation.——Governor Hadley, on September 24, appointed a negro tuberculosis commission to investigate the prevalence of tuberculosis among the colored race. The members of the commission are Drs. J. T. Caston, Jefferson City; John E. Perry, Kansas City; William S. Carrion, St. Joseph, and George S. Jackson, St. Louis; S. P. Covington, St. Louis, and Mrs. Nevada Kenner, Marshall.

St. Louis

The New Barnes Hospital.—At the meeting of the American Hospital Association, held in St. Louis, September 20, plans for the new Robert A. Barnes Hospital were shown for the first time. The new hospital is to be erected on Kingshighway near Forest Park, and is to cost about \$1,500,000, the funds for which were bequeathed by the late Robert A. Barnes who died about fifteen years ago. The hospital buildings, consisting of ten in all, will consist of a children's hospital, the Barnes Hospital proper, a service building, pathology building, school building, nurse's training school, superintendent's residence, power house, and laundry. The other buildings of the group are those of the Medical Department of Washington University. The hospital will have twenty wards and many private apartments, and will accommodate 360 patients.

NEVADA

Personal. Dr. Charles E. Swezy has been appointed division surgeon of the Western Pacific Railroad with headquarters at Winnemucca.—Dr. Willis W. Stockham has purchased the Duckworth Hospital, Pioche, from Dr. Theophilus D. Duckworth, taking immediate possession.

State Medical Society Meeting.—The Nevada State Medical Association held its seventh annual convention at Lake Tahoe, September 19-21, and elected the following officers: President, Dr. Sidney K. Morrison, Reno; vice-presidents, Drs. William H. Hood, Reno, and Donald McLean, Carson City, and secretary, Dr. Martin A. Robinson, Reno.

NEW JERSEY

To Prevent the Tuberculous from Teaching.—The Camden Board of Education has adopted rules, which will make it impossible for a teacher, suffering from tuberculosis, to enter or to continue in the service of that city.

Personal.—Dr. George Cunningham has been appointed borough bacteriologist of Vineland.—Dr. Fred M. Corwin has succeeded Dr. Henry D. Abbott as medical inspector of public schools of Bayonne.—Dr. Alonzo L. Leach has been elected president of the board of health, and Dr. Virgie M. D'Marcy, health officer, of Cape May.

NEW YORK

Personal.—Dr. J. Clarence Sharp and Dr. and Mrs. Isador Abrahamson have sailed for Europe.—Dr. John W. Braman has returned from Europe.

School Out of Doors.—A portico is being built in connection with Public School 33 at Ninth Avenue and Twenty-Seventh Street where forty anemic school children will study out of doors this school year.

The Straus Milk Stations.—A committee consisting of Mr. Homer Folks, Dr. Abraham Jacobi, and Mr. V. Everit Macy, with Mrs. J. Bordeu Harriman as chairman, waited on Mr. Straus recently. He has consented to further discussion of the subject with the committee and will keep the milk stations open in the meantime.

For Charity.—It has been announced that \$6,000 was raised by the bazaar given in August for St. Joseph's Hospital, Far Rockaway.—Father John A. Keller, late rector of St. Gabriel's church, New Rochelle, N. Y., in his will bequeathed \$2,000 to St. Joseph's Hospital for consumptives and \$1,000 to St. Francis Hospital, N. Y.

Undersized Nursing Bottles.—At the Pure Food Show in Madison Square Garden, Dr. Reichmann recently produced a number of nursing bottles and showed that they were undersized and not correctly graduated. He stated that more than one-half of the bottles tested were found to be 26 per cent. short of the size for which they were sold, thus depriving the infant of more than one-fourth of the food it was supposed to get.

Crocker Bequest Held Up.—The Supreme Court has granted an injunction to the stepchildren of the late George Crocker, restraining the executors from selling property which was bequeathed to Columbia University, that the proceeds of the sale of this property might be used for a cancer research fund. The litigants claim that they were induced to make over their interest in the property to Mr. Crocker during his lifetime, and that he left their property to Columbia University.

The Truth About City's Milk Supply.—The Health Department is preparing an exhibit for the budget show that will tell as nearly as possible the exact truth in regard to the city's milk supply. Because of inadequate funds the department has not done all that should have been done to guard the supply. There are at present only 57 men employed for the purpose of inspecting 44,000 farms, 12,000 stores, 5,500 wagons, 1,100 shipping stations, 75 milk depots, and 15 receiving points. At least 125 men would be required to do the work satisfactorily.

Auto-Ambulance Service for Insanity Cases.—For the first time in the history of the hospital an automobile ambulance service for the handling of cases for the psychopathic ward has been installed at Bellevue Hospital. Hitherto insane patients have been brought to the hospital in patrol wagons by the police, but henceforth the police will have nothing to do with the handling of such cases. This innovation has been made at the suggestion of Dr. Minus S. Gregory, who has been in charge of the insane department at Bellevue for the past nine years.

Hospital Staff Resigns.—The seven doctors who constitute the staff of the Beth David Hospital, until recently known as the Yorkville Hospital, have resigned at the request of the board of directors, owing to a reorganization of the hospital which has come under the control of the Federation of Polish Jews. This organization has appointed a committee to look for a new site and contemplates building a hospital five times as large as the present one, which accommodates only thirty patients. It is said that resignations were asked for because the federation wishes to fill up the staff with its own physicians.

NORTH CAROLINA

Medical College Opens.—The eighteenth annual session of the North Carolina Medical College opened in Charlotte, September 14. Addresses were made by Rev. P. R. Law, D.D., Drs. John R. Irwin, Walter O. Nesbit, and the president and founder of the college, Dr. John P. Munroe.

Personal.—Dr. Charles L. Minor, Asheville, has gone to Europe.—Dr. William D. MacNider, Chapel Hill, has returned from Chicago and resumed his duties at the University Preparatory Medical School.—Dr. John C. Rodman has been appointed a member and chairman of the board of health and city physician of Washington.

Convicted of Abortion.—In the Guilford County Criminal Court, September 23, Dr. William L. Vestal, High Point, who was arrested July 3, charged with the death of Miss Bessie Thomason, Statesville, from criminal abortion, and charged with a like offense, but without fatal results, in the case of May Owen, Linwood, on advice of counsel is said to have pleaded guilty to manslaughter in the first case and to criminal abortion in the second, and to have been sentenced to ten years' hard labor in the state prison.

NORTH DAKOTA

Personal.—Dr. Thomas M. McLachlan, Bismark, has returned from Europe.—Dr. Louis B. Baldwin, superintendent of the State Hospital for the Insane, Jamestown, has been appointed superintendent of the new University Hospital, Minneapolis.

District Society Officers.—At the annual meeting of the Grand Forks District Medical Society, the following officers were elected: President, Dr. W. H. Bates, Grand Forks; vice-president, Dr. Benjamin D. Lemery, Inkster; secretary, Dr. William C. Wilson, Grand Forks; treasurer, Dr. George W. Williamson, Grand Forks, and censors, Drs. James Grassick and Gudmund J. Gislason, Grand Forks.

OHIO

Medical Society Meets.—The McDowell Medical Society, at its annual meeting in Cincinnati, September 15, elected the following officers: President, Dr. S. Cary Swartzel; vice-president, Dr. William L. Shollenbarger; secretary, Franz Miketta, and treasurer, Dr. Peter F. Kilgour.

Tuberculosis Hospital Opened.—As the result of a meeting in Urbana of the members of the joint hospital board, the district tuberculosis hospital, known as the Kinnane District Hospital, has been opened. This hospital is to accommodate tuberculosis patients from Champaign, Addison, and Clark counties.

OKLAHOMA

State Board Appointments.—Dr. George H. Truax, Stone-wall, has been appointed a member of the State Board of Medical Examiners, vice Dr. Joseph Hensley, Oklahoma City, and Dr. Harry L. Lott, Oklahoma City, has been appointed an alternate member of the board.

Medical College Opens.—The formal opening exercises of the Medical Department of the University of Oklahoma, Oklahoma City, were held September 15. Addresses were delivered by President A. Grant Evans of the university and Dr. Arch. K. West, dean of the medical school.

PENNSYLVANIA

Poliomyelitis Report.—County reports to the State Health Department show that since the first of July, 830 cases of infantile paralysis have been reported in the state. Of this number, Philadelphia showed 112 cases; Northampton, 130; Allegheny, 32; Lehigh, 11; Lancaster, 148; Berks, 15, and Westmoreland, 30.

Personal.—Dr. Jonathan C. Biddle, superintendent of the State Hospital for Injured Persons, Fountain Springs, was badly injured, October 1, when in endeavoring to avoid a boy his automobile went over an embankment.—Drs. Lawrence Litchfield, Irwin J. Moyer, John W. Boyce, Thomas D. Davis, and Percival J. Eaton have been appointed members of the examining board of the Civil Service Commission of Pittsburg.

Hospital Dedicated.—The St. Margaret's Memorial Hospital, Lawrenceville, Pittsburg, was opened for public inspection October 1. The hospital, which has been closed for ten years, has been newly equipped and can accommodate about eighty patients. The attending staff includes Drs. Percival J. Eaton, Elwood B. Haworth, Sidney A. Chalfant, Evan W. Meredith, William C. White, William W. Blair and William P. Barndollar.

Philadelphia

Veterans as Guests.—The next reception held by the Medical Club of Philadelphia at the Bellevue-Stratford, October 23, will be given in honor of the members of the profession throughout the state who have been graduated in medicine fifty years or more.

Trachoma Institute Report.—The report of the Trachoma Institute, 227 Pine Street, shows that 680 patients were treated for this disease during the month of August. Of these, 240 were new cases. This clinic is open daily and the treatment is free.

Officers Elected.—At the meeting of the Medical Society of the fifth censorial district, composed of Adams, Cumberland, Franklin, Fulton and New York counties, held at Hanover,

August 17, the following officers were elected for the ensuing year: President, Dr. Alexander C. Wentz, Hanover; vice-president, Dr. J. Burns Amberson, Waynesboro, and secretary and treasurer, Dr. George E. Holtzapple, York.

Personal.—Drs. J. William White, Arthur J. Brewe, and McCluney Radcliffe have returned from Europe.—Dr. Alan L. Diefenderfer was the guest of honor at a dinner given September 30 by the medical staff of the German Hospital to celebrate the completion of his term as intern in the hospital.—Drs. Cheney M. Stinson, Harry A. Streckert, and A. C. Luhr have been appointed to the gynecologic staff of Jefferson Hospital.—Dr. Adam Klemm sailed for Europe September 27.

TEXAS

Personal.—Dr. David J. Hardin, Kirk, was shot and seriously wounded at his home September 20.—Dr. Duren, Utopia, was seriously injured in a runaway accident in San Marcos, September 23.

New Society Organized.—It is announced that at a meeting of the City and County Health Officers of Texas, at Houston, a society known as the Tropical Disease Research Society was organized. Its membership consists of health officers and others interested in the study of tropical diseases.

WYOMING

Personal.—Dr. J. W. Garard has been appointed house surgeon of the State General Hospital, Sheridan. Dr. John B. Hynds, house physician at the hospital, has resigned.—Dr. Darwin E. Brown, Laramie, has succeeded Dr. Herman E. McCollum, Laramie, as physician of Albany county.

State Society Meeting.—At the twelfth annual meeting of the Wyoming State Medical Society, held in Casper, September 28 and 29, the following officers were elected: President, Dr. Albert G. Hamilton, Thermopolis; vice-presidents, Drs. T. A. Dean, Casper; William H. Roberts, Sheridan, and Samuel B. Miller, Laramie; secretary, Dr. Marshall C. Keith, Casper; treasurer, Dr. Neil D. Nelson, Shoshone, and editor of the Wyoming Department of the *Western Medical Review*, Dr. Fred W. Phifer, Wheatland. The next meeting will be held in Thermopolis.

GENERAL NEWS

Coming Fraternity Banquet.—The seventh annual banquet of the Nu Sigma Nu Alumni Association of New York will be held December 3, at the Yale Club, 30 West Forty-Fourth Street, New York City.

Personal.—General Health Officer J. S. B. Pratt, Honolulu, of the Territorial Board of Health of the Hawaiian Islands, is making a three months' visit to the United States.—The Department of State has selected the following delegates to the International Conference on Tuberculosis, to be held in Brussels: Dr. Hunt, Dr. Mazzyk P. Ravenel, Madison, Wis.; Dr. Arnold C. Klebs, Chicago, and C. H. Baldwin, Washington, D. C.

Advisory Board Called.—The gravity of the situation regarding the possible introduction of cholera from the infected sections of Europe has been made evident by the call issued for the Advisory Public Health Board of the Public Health and Marine-Hospital Service to meet in Washington, October 10. This board is composed of Drs. Simon Flexner, New York City, director of the Rockefeller Institute of Medical Research; Dr. William P. Sedgwick, Boston; Dr. Victor C. Vaughan, Ann Arbor, Mich., president of the Michigan State Board of Health; Dr. Frank F. Westbrook, Minneapolis, and Dr. William H. Welch, Baltimore.

FOREIGN NEWS

Personal.—Dr. Dawson Williams, London, editor of the *British Medical Journal*, who was seriously injured in an automobile accident July 9, is still disabled, but improving slowly.

Mexican Hygienic Exposition and Congress.—The exposition to show the progress of Mexico from a sanitary point of view, during the latter part of the last hundred years, was opened in the City of Mexico, September 2. Charts, models and photos of six of the larger cities and especially the City of Mexico, illustrate the progress made comparatively recently in supplying potable water and in draining large centers of population. A model modern hygienic hacienda building is one of the exhibits and has its walls covered with charts illustrating the progress made by Mexico in the last twenty-five years in fighting infectious diseases, such as typhus, scarlet fever, yellow fever, small-pox, consumption, etc. A

section of the exhibition shows the precautions taken against the introduction of foreign diseases and unhealthy immigrants, models of sanitary stations, the lodging houses for immigrants, etc. Another section shows models of rural hospitals in Mexico for the use of consumptive patients, and models of the general hospital in Mexico City and in Mexico, also models showing the evolution of baths, laundries, and dwelling houses from the most rudimentary conditions. Two large rooms are devoted to the exhibition of the progress which has been made in Mexico in the public schools, by photographs of the schools in the capital and in the cities and towns throughout the Republic.

Other Deaths in the Profession Abroad.—Aside from deaths mentioned by our foreign correspondents, we note the following: Marc Dufour, M.D., professor of ophthalmology at Lausanne, Switzerland, and a leading figure in specialist and medical circles and a public-spirited citizen, died recently, aged 67. He was an honorary member of numerous scientific societies at home and abroad and was president of the international ophthalmologic congress held at Lucerne in 1904. Two years later he took a trip around the world. For some years he has been the editor of the *Revue Médicale de la Suisse Romande*.—The chief of the medical service in the Swiss army, Dr. A. Mürset, recently succumbed to cerebral hemorrhage, at the age of 50, while on a vacation trip near home.—The death of A. A. Rubio, M.D., at an advanced age, is reported from Cuba. It is stated that all the public places of amusement in his city, Pinar del Rio, closed on the days of his death and funeral as a token of respect.—Italy has recently lost two prominent otolaryngologists, Drs. F. di Colo of Pisa and C. Seechi; also the director of the maternity at Verelli, G. Raineri, M.D., from infection during an operation; and P. Mantegazza, M.D., professor of anthropology at Florence and president of the Italian Ethnologic Society, formerly professor of general pathology at Pavia and author of numerous popular scientific works.—M. Dominguez, M.D., professor of therapeutics at the University of Mexico, died recently.—Mary A. Marshall, M.D., one of the oldest medical women in Western Europe, died at Cannes, aged 73.—E. Malzeva, a young Russian woman physician succumbed at Yskor to cholera, and the provincial authorities have founded a scholarship in her name at the Woman's Medical College at St. Petersburg in appreciation of her services during the epidemic.

Cholera in Europe.—An Italian exchange states that the daily papers in the department of Apulia announced that some of the district physicians there fled when cholera became epidemic. The national board of health has appointed a committee to investigate the matter. The president of the association is chairman of the committee, which includes, besides three other physicians, a representative from each of the two newspapers involved. In discussing the matter it was proposed that the district involved in an epidemic should temporarily insure the lives of non-medical men whom the authorities call on for medical services, and that better provision should be made for the families of sanitary officers dying at their posts in times of such epidemics. The Prussian government, by Robert Koch's advice, installed bacteriologic laboratories at the points where the Vistula and Memel rivers enter the country from Russia, and examine all the crews of boats and rafts passing down the river. Over 5,200 persons were thus examined during the five weeks after July 1, and three healthy germ-carriers were discovered by this means and rendered harmless. It is stated that there are over thirty institutes prepared to make bacteriologic examinations of the kind in Germany, all under the control of the national health authorities and the Berlin Institute for Infectious Diseases.—Free postgraduate courses on cholera have been organized at Vienna and elsewhere.—The last official reports from Russia place the number of cases of cholera at 170,353 with 77,466 deaths. A letter from Dr. A. Dworetzky of Moscow in the *Münchener med. Wochenschrift* just received, states that of the 1,082 cities throughout the Russian empire only 192 have a public water supply and only 38 a sewerage system. This includes 762 cities in European Russia; only 149 have a public water supply and 27 a sewerage system. He describes the features of the present epidemic of cholera and adds that he would hail with gratitude the carrying into effect of the suggestion mentioned in the Berlin Letter, page 1212, that the other European governments should bring pressure to bear on the Russian government to take more effectual measures against cholera, as the Russian epidemics are a perpetual menace to other lands.

MANILA LETTER

(From Our Regular Correspondent)

MANILA, Aug. 16, 1910.

The Civil Hospital

The famous "case of the Civil Hospital" has been disposed of at last. The Governor-General has said the final word in regard to an investigation of the management of the institution, and has let it be understood that the affair is to be considered disposed of. This case had its origin last May when a disgruntled American nurse resigned and made public severe charges against the institution. Others also who were more or less dissatisfied were induced to give their opinion. As the season was dull (the government bureaus being removed temporarily to the summer capital at Bagio) and the newspapers were short of news the incident was given much publicity, and became a topic of general conversation. In the absence of the Governor-General, the Secretary of the Interior and the Director of Health, the Assistant Director of Health ordered an investigation into the conditions and management of the hospital—a procedure which seems to have been irregular. The Civil Hospital is an institution maintained by the government for the benefit of its employees in Manila and the neighboring towns. Government employees and members of their families are given medical attention, prescriptions and medicines free of charge. Nor is there any charge for hospital and nursing services, other than the cost of meals served to patients. Some time ago, for the sake of economy and the efficiency of the service, it seemed desirable to make certain changes in the management and staff of the hospital, since, as in the opinion of the Governor-General, "there is no doubt whatever but that under the previous management of the hospital the care of government property and supplies was lax and there was greater consumption than the conditions justified, and that a change in the method of accounting for property was necessary. It is also found that some of the criticisms leveled against the new system which has been established are unjustified; that some of the nurses have purposely tried to make the new system unpopular and fail by not taking the trouble necessary to comply with the new regulations and then informing the patients that the resultant lack of facilities was due to the stinginess of the administration, a course which does not commend itself highly to fair-minded people. In the main, however, it is believed that the nurses of the Civil Hospital are high-minded, hard-working and faithful and that they may be depended on to cooperate in everything which is required of them for the good of the service and the success of their work. It is believed that the criticism of purposely trying to make the new system fail is one which can be leveled at so few individuals as to make it by no means a charge against the nursing force in general, and that repetition of such practices need not be apprehended for the future." It has been maintained by many that keeping competent American nurses in the Philippines will always be a difficult problem. Indeed, if American nurses were the only ones available this might prove a very serious drawback to hospital work and medical education in the islands, but the experiment of training the Filipina girls to be nurses has turned out so well that perhaps in the near future the services of very few American nurses will be required in the Philippines.

LONDON LETTER

(From Our Regular Correspondent)

LONDON, Sept. 24, 1910.

Fees for Insurance Examinations

The practice of some insurance companies of offering very low fees for the medical examinations of applicants for life insurance when the sum assured is small is a standing grievance and subject of controversy in the medical profession. It is pointed out that whether the sum assured be small or large the trouble is exactly the same if the examination is to be thorough, and all insurance companies desire this. The usual fee for examination paid by good companies, who generally insure for sums ranging from \$2,500 upward, is \$5, but in the case of the postoffice (which undertakes insurance for small amounts) and the companies which among the working classes insure for sums as low as \$500 or even less, the fees are as low as \$1, even \$0.50. The pressure of competition enables the companies to get examinations made for these very low fees, but practitioners in good position often decline the work, and there is strong feeling in the profession that they should be refused by everyone. The subject has again

come into prominence in consequence of the attempt of the Pearl Insurance Company to obtain medical examinations, and reports at the following rates: If the sum assured is \$125, \$0.75; if over, \$125, but not exceeding \$250, \$1; if over \$250, but not exceeding \$500, \$1.50. The temptation is held out that the number of proposers will be large, and therefore it will be worth while to undertake them. The scheme is strongly condemned by both the *Lancet* and the *British Medical Journal*. The former suggests that if it is not possible for actuarial reasons to pay larger fees, the company should ask only for a medical examination and carrying no responsibilities; the latter states that if such fees are accepted there will be tendency for the value of the reports and the amount paid for them to assimilate.

Decline of the Antivaccinationists

Though, as shown in previous letters, a lamentable decline has taken place in the number of children vaccinated in Great Britain in consequence of the reduction of the obstacles to those who obtain exemption for their children on the grounds of conscientious objection to vaccination, it is of some satisfaction to know that the militant antivaccinationists are a dwindling body. The income of the National Antivaccination League has so much declined that in the current year it was only \$100 a month. In 1909 the amount was 200; in 1908 over \$300 and in 1907 over \$400 a month. Other evidences of failure are shown in dissensions among the leaders and in the repeated withdrawals of odious charges against the profession in connection with vaccination which the official organ of the league, the *Vaccination Inquirer*, has been compelled to make.

New Methods of Treating Cancer

The ninth report of the cancer research laboratories of the Middlesex Hospital contains an account of the trial of new empirical methods of treating cancer in the cancer wards of the hospital. (This hospital alone among the general hospitals of London has special cancer wards and special cancer research laboratories.) The patients were all the subject of inoperable malignant disease. Seven cases were treated with arylars-onates—6 with soamin and 1 with atoxyl. The treatment was pushed until symptoms of arsenical poisoning were produced. In no case was there any benefit, not even relief of pain. Three patients were treated with the neoformans vaccine without any result than recurrent jaundice in 1 patient. Coley's fluid was used in 3 cases of sarcoma and in 1 of carcinoma. In the latter there was slight relief of pain; in 2 of the former there was no beneficial action, but in the third the result was remarkable. The patient was a healthy-looking girl, aged 20, who was admitted for a large primary sarcoma of the inguinal glands. It measured $5\frac{1}{2} \times 4 \times 4\frac{1}{4}$ inches. The margin was nodular and irregular. It was firmly fixed to Poupart's ligament and also adherent to the skin. She was given 28 injections of Coley's fluid, beginning with a dose of quarter of a minim, which was increased until 25 minims were reached. The injections produced recurring febrile attacks, which resulted in progressive anemia that threatened to be fatal, and therefore led to the stoppage of the treatment. On the other hand, the effect on the tumor was for a time remarkable. Within a fortnight from the commencement of the treatment there was distinct diminution in size in all its diameters. At the end of a month the improvement reached a maximum. The tumor was mobile and free from the skin and had diminished to one-fourteenth of its former cubic content. The overlying skin was white, soft and supple. Enlarged glands, previously incorporated in its margins, gradually separated from its retracting borders and were found mobile and discrete on either side. By this time, however, 25 minims of the fluid were required to produce any reaction at all and the general toxemia was marked. The injections, which at first were painless, caused great suffering and were often followed by local suppuration. Further treatment was abandoned at the patient's request. The growth again rapidly enlarged, ulcerated through the skin and caused death 3 months later. The necropsy showed primary glandular sarcoma and metastases in the portal mesenteric, bronchial and cervical glands.

Pitchblende (from which radium is extracted and which consists mainly of uranium oxid) was used in 14 cases. In some beneficial results but no cures were obtained. The pitchblende diminished concomitant acute inflammatory reaction and appeared to encourage fibrosis of the tumor. If pain was due to infiltration of skin it gave great relief. Its effect on enlarged cervical glands causing pressure symptoms seemed

worthy of further trial, but was less hopeful. Pain due to pressure on deeper structures was not relieved. Hence there was no marked relief in cases of uterine cancer, for the pain is mainly due to infiltration and pressure on the pelvic nerves and viscera at a distance from the primary growth. In rectal cancer, in which the growth usually becomes annular and the pain is due to fecal obstruction and resulting proctitis, the pain was relieved and the obstruction diminished.

PARIS LETTER

(From Our Regular Correspondent)

PARIS, Sept. 23, 1910.

Metallic Radium

Up to the present, the substances known under the name of radium have been in reality only salts of that metal, such as radium bromid and chlorid. In one of the last sessions of the Académie des Sciences, Mme. P. Curie made a report from which it appears that, in collaboration with M. A. Debierne, she has succeeded in obtaining pure radium. For this purpose, 106 mg. of radium chlorid were electrolyzed with an anode formed of 10 gm. of mercury. The radium amalgam thus obtained is unstable in air; it decomposes in water. After having been dried it is rapidly introduced into an iron combustion boat, previously reduced in pure hydrogen. The boat is then placed in a quartz tube and a vacuum is immediately produced in the apparatus. Distilling is done in a hydrogen atmosphere and under a pressure superior to the pressure of mercury vapor. The radium thus obtained presents the form of a white, brilliant metal, adhering strongly to the iron of the boat. This metal makes a blackened mark like a burn on paper. It decomposes in water energetically, becoming completely dissolved, especially on the addition of a very little hydrochloric acid. Mme. Curie intends to study the radioactive qualities of metallic radium.

Monument to Professor Cornil

At Cusset, near Vichy, the native city of Dr. Victor Cornil, former professor of pathologic anatomy at the Paris college of medicine, who died April, 1908, a monument has just been dedicated to his memory. The monument represents Professor Cornil standing with a book in his right hand and a microscope in his left. Bas-reliefs represent the professor teaching. The dedication ceremony was presided over by M. Doumergue, minister of public instruction.

The Stage of Undergraduate Pharmacists

The new organization of studies leading to the diploma of pharmacist has introduced important modifications into the conditions under which the *stage* of students in pharmacy has been taken. Under the regulations hitherto in force the *stage* has lasted three years; hereafter it will be only one year long. Up to the present it has been possible to take it in any laboratory whatever, hereafter it can be taken only in laboratories designated by the rectors of the universities on the recommendation of the superior schools or the mixed colleges of medicine and pharmacy. The *stagiaire* will be obliged to keep a record of the *stage* endorsed by the secretary of the school or the recording clerk of the justice of the peace at the time of entrance and at every change from one laboratory to another.

For Uniform Methods of Analysis of Potent Drugs

The tenth International Congress of Pharmacists, which has just been held at Brussels, and to which official delegates were sent from the United States, France, Italy, Spain, Russia, Sweden, Norway, Denmark, Hungary, Holland, Greece, Japan, China, Argentina, Chili, etc., has made a request of the Belgian government to invite other governments as soon as possible to an international conference for the uniformity of methods of analysis of potent drugs. Following the example of the International Congress of Medical Sciences held at Budapest last year, the International Congress of Pharmacists decided to form a permanent international association, the seat of which shall be the Hague.

Prize of the Society for Infantile Hygiene

The Société d'hygiène de l'enfance has announced a competition for 1910, the subject of which is "The Temporary Sojourn of Children Away from the Family in France or in Foreign Countries." Memoirs should be addressed to the president of the Société d'hygiène de l'enfance, at 10 rue Saint Antoine, Paris, and should be received before Dec. 31, 1910.

BERLIN LETTER

(From Our Regular Correspondent)

BERLIN, Sept. 15, 1910.

Personal

The fiftieth anniversary of his professional career was celebrated Sept. 14 by the eminent physiologist, Professor Hering of Leipsic, who is still an active member of the university faculty. He was presented by his pupils and friends with a *Festschrift* on the occasion of his jubilee.

Sterilization of Street Clothing in the Public Hospitals

The municipal authorities of Berlin, after investigation of the subject in other hospitals in the country, have issued the following regulations in regard to the clothes worn to the hospital by the patients: 1. On admittance all articles of clothing infested with vermin are to be sterilized, also the clothing from persons with contagious disease or coming from a family or close environment in which contagious disease is known to prevail. 2. The clothes and linen are to be sterilized with steam, except leather, rubber and fur articles and hats, which are to be sterilized with formaldehyde. 3. The clothing is to be kept hung up, enclosed in a separate clothing bag; the linen and shoes are to be wrapped separately and placed inside the other bag. 4. The body linen is not to be washed unless especially soiled. 5. The clothing is not to be ironed before being returned to the patient.

Health in the German Navy

According to the recently published sanitary report for the German navy from October, 1907 to October, 1908, the number of sick out of about 50,000 men were, on board ship, 15,000 or 501 per thousand, and on land 13,500, that is, 672 per thousand. The largest number of admissions was on ships in East Africa, 961 per thousand. Fully 816 per thousand of all those treated were dismissed as fit for duty, 1.5 per thousand died (0.88 per thousand of the entire force); 2,144 men (45.4 per thousand of the entire force), were dismissed as unfit for service. Among the diseases which led to dismissal on account of an affection already present before treatment, the first place was taken by heart disease, 9.75 per thousand; 18 committed suicide, and 58 died by accident. The largest number of deaths from disease were due to appendicitis, 11; next to tuberculosis of the air passages, 10, and pneumonia, 7. Death by accident ensued most frequently from drink, 28, and explosion, 20. The mortality of the entire force amounted to 3.1 per thousand, which was smaller than in the English navy for 1908 (3.37 per thousand) and in the American 5.76 per thousand. Among individual diseases those of the digestive tract were the most marked. The morbidity figure for gonorrhoea (26.4 per thousand), and that for syphilis (17.3 per thousand), was greater than in the previous year. The number treated on account of mechanical injuries was 4,078 (92.2 per thousand); 339 were attacked with appendicitis (6.8 per thousand) and 3,414 with affections of the respiratory organs (68.3 per thousand).

The Berlin System of Prompt Aid for the Sick and Injured

The organization of the system of prompt aid for the injured has now been completed at Berlin. Besides the 13 emergency stations in the large hospitals, there are 17 auxiliary stations and a central information and record bureau to supply information as to vacant beds in the various hospitals, to which the sick and injured can be referred, and also to centralize all the sanitary emergency work, including the lifesaving stations along the river, etc. The assistant to the mayor, the *weiter Bürgermeister*, is in charge of the whole system and the executive details are in the hands of the *Magistratssekretäre*, who is in constant local and telephone control of all the stations at any moment, day and night. The auxiliary stations are designated by uniform signs, and about 12,000 metal signs have been posted throughout the city, giving the location of the nearest emergency station, and transparent signs for the same purpose have been installed on the lamp-posts at numerous points in the more crowded streets. In connection with this first-aid work, uniform provisions have also been made in case that many are injured at one time; the central station in the city hall is to be the organized center for all the single and collective rescue work. The police and fire department have all received instructions to this effect. The importance of the organization is shown by the constant demands made on the various stations. For example, last month the auxiliary emergency stations cared for 5,000 cases, thus about 166 every day.

VIENNA LETTER

(From Our Regular Correspondent)

VIENNA, Sept. 20, 1910.

Suicides in Vienna

The statistical report of the board of health of this city cites, among other interesting items, the figures on suicides. It appears that the numbers are constantly increasing at a higher rate than the average increase of the population, for 1,203 persons attempted to take their lives in 1907; in 1908, the figure was 1,236, and in 1909, it was 1,373. Of the last number 520 succeeded. Eight hundred and fifty-eight men and 515 women tried to kill themselves, but only 378 men and 146 women attained their object. The oldest candidate for suicide was 88 years old, the youngest only 12. Seven hundred and eighty-four persons hanged themselves, this being the favorite method of suicide in this city. One hundred and twenty-two shot themselves; three persons attempted self-destruction by pouring oil, spirits or gasoline on the clothes and setting fire to them. The motives were generally, in the order of frequency, misfortune in love, incurable disease or poverty. It is interesting to note that the frequency of attempts at suicide lessens in winter (in December only 30 cases), while it increases in summer, and is at its height in autumn (in October 50 cases).

The Cholera in Hungary

In spite of every active and energetic measure, the outbreak of sporadic cholera could not be prevented in Hungary nor in Austria. Vienna has so far had 7 cases, which were dealt with accordingly, and there is every reason to hope that that will be the last of it. In Hungary the opinion of nearly all epidemiologists favors the idea that the Danube is the means of distribution of the disease. In a certain mining district in Mohacs, the center of infection has been found, and thence it was conveyed by the coal to the Danube ships, which in turn brought it to Vienna and Budapest. The majority of the cases—hitherto 99—have been found amongst the coal miners. Naturally prophylaxis and quarantine interfere greatly with the normal course of business life. The majority of the Hungarian population is agricultural, which makes prophylactic measures very difficult. Just now the harvest of fruit and grapes causes often gastro-intestinal troubles, and as every such case is brought invariably to the hospital for the sake of diagnosis and eventual isolation, much unpleasantness has been caused. But altogether, there is no reason to regard the country as infected, since the sporadic cases have been well controlled, and the other districts where suspicious cases have appeared are very few in number. Instructions have been issued to inform the people officially of the necessity of calling in a medical man at the earliest symptoms of trouble of the alimentary canal.

Marriages

HARRIS GOLDMAN, M.D., to Miss Lena Goldstein, both of Baltimore, August 21.

FREDERICK F. ZELLE, M.D., to Miss Amelia E. Maunder, both of St. Louis, September 28.

J. C. S. BROWN, M.D., to Miss M. Ethel Hunter, both of Sutherland, Sask., September 21.

HOWARD DAVIS LEWIS, M.D., Baltimore, to Miss Floride Lewis, at Baltimore, September 22.

JOSIAH H. HOLLAND, M.D., U. S. Army, to Miss Margaret Clark of Evanston, Wyo., September 22.

ARTHUR HOWARD DOUGE, M.D., U. S. Navy, to Miss Eleanor Creason, at San Francisco, September 6.

JAMES GOLDEN STEWART, M.D., to Miss Dorothy Jane Sedgwick, both of Grover, Colo., September 21.

WILLIAM RAVINE, M.D., to Miss Hannah C. Shilt, both of Cincinnati, at Long Island, N. Y., September 21.

GEORGE G. GANDY, M.D., to Miss Clemantine Rousek, both of Humboldt, Neb., at London, England, September 5.

EDWARD TOPHAM, M.D., San Francisco, to Miss Cecil Belle McLellan of Beresford, Cal., at Richmond, Cal., September 15.

LUCIUS AUGUSTINE FARNHAM, M.D., to Miss Edwina Daniell, both of Calumet, Mich., at London, England, September 20.

WILLIAM HENRY WALSH, M.D., Philadelphia, to Miss Eugenia Gray McIntosh, at Longwood, near Glenwood, Md., September 22.

Deaths

Joseph Gilman Jarrell, M.D. Tulane University, New Orleans, 1892; a member of the Medical Association of Georgia; for several terms president of the Georgia Medical Society, and vice-president at the time of his death; consulting physician to St. Joseph's Hospital, Savannah; assistant surgeon of the First Georgia Infantry, U. S. V., during the Spanish-American War, with service in Porto Rico; later major and surgeon of the First Infantry Georgia National Guard; and chief surgeon of the hospital corps of the Savannah Volunteer Guards; for one term a member of the city council; died in Savannah Hospital, September 20, from septicemia, due to an operation wound, aged 42.

Carey Kennedy Fleming, M.D. Northwestern University Medical School, Chicago, 1886; a member of the American Medical Association; and formerly president of the Denver Clinical and Pathological Society; secretary of the Colorado State Board of Medical Examiners; major and surgeon, N. G., Colo.; professor of obstetrics and gynecology in Gross Medical College, and later professor of abdominal surgery in the Denver and Gross Medical College; gynecologist to St. Anthony's, Mercy and St. Luke's hospitals, and the Herman Strauss Free Clinic, Denver; died suddenly at his home, September 24, from cerebral hemorrhage, aged 46.

Charles Augustus Rahter, M.D. Long Island College Hospital, Brooklyn, 1864; of Harrisburg, Pa.; a member of the American Medical Association; some time president of the Dauphin County Medical Society; vice-president of the Medical Society of the State of Pennsylvania, and president of the Harrisburg Academy of Medicine; acting assistant surgeon in the Army during the Civil War, and surgeon in the German army during the Franco-Prussian War; United States pension examiner, and president of the Harrisburg board from 1885 to 1889; died in Atlantic City, September 21, from cerebral hemorrhage, aged 71.

James A. Young, M.D. Eclectic Medical College of Pennsylvania, Philadelphia, 1868; a member of the Kentucky State Medical Association; for one session adjunct professor of theory and practice of medicine in the St. Louis Homeopathic College; and assistant professor of diseases of children in the Southwestern Homeopathic College, Louisville; died at his home in Hopkinsville, September 24, from tuberculosis, aged 64.

William Gibbons Daggett, M.D. University of Pennsylvania, Philadelphia, 1884; a member of the American Medical Association; lecturer on bacteriology and later on clinical medicine in Yale Medical School; attending physician to the New Haven Hospital, and secretary of the New Haven General Hospital Society; died in the New Haven Hospital, September 18, a week after an operation for appendicitis, aged 50.

David Arthur Fletcher, M.D. State University, College of Homeopathic Medicine, Iowa City, 1895; died at his home in Hartley, Iowa, August 19, from the effects of carbolic acid, believed to have been self-administered with suicidal intent while suffering from mental aberration, aged 37.

C. J. Christensen, M.D. University of Nebraska, Omaha, 1902; of Broken Bow, Neb.; a member of the Nebraska State Medical Association; who had started for the Pacific coast six weeks before on account of ill health; died in Portland, Ore., September 15, from heart disease, aged 35.

Frederick L. Gage, M.D. Long Island College Hospital, Brooklyn, 1876; a member of the Ohio State Medical Association; health officer of Delaware, Ohio, in 1907 and 1909, and coroner of Delaware county since 1904; died at his home September 19, from arteriosclerosis, aged 63.

Annie Marie Selee, M.D. Boston University School of Medicine, 1882; one of the founders of the Boston Homeopathic Hospital; at one time a member of the Melrose school board; died at her home in that city, September 24, from injuries received in a fall ten days before, aged 77.

Norman A. MacNab, M.D. McGill University, Montreal, 1907; a surgeon of the Grand Trunk Pacific Railway in its construction work west of Edmonton, Alberta; died at Mile Forty-two Hospital on that line, near Edmonton, September 16, from typhoid fever, aged 24.

Anthony Romig Finck, M.D. University of Pennsylvania, Philadelphia, 1871; for many years supreme medical examiner of the Shield of Honor; and for more than half a century a practitioner of Philadelphia; died at his home September 19, from pleuropneumonia, aged 77.

John H. Cowles, M.D. Castleton (Vt.) Medical College, 1862; a surgeon of New York Volunteers during the Civil War; and a pioneer practitioner of Furnas County, Neb.; died at his home in Weeping Water, Neb., March 23, from cerebral hemorrhage, aged 78.

Orlando Logan, M.D. University of Buffalo, 1882; a member of the American Medical Association; for fifty-four years a practitioner; surgeon in the Army during the Civil War; died at his home in Girard, Pa., August 20, from chronic heart disease, aged 81.

Joseph Chamberlain Caldwell, M.D. Medical School of Maine, Brunswick, 1870; a member of the Maine Medical Association; of Buckfield; died while making a professional call on a patient at East Sumner, June 17, from heart disease, aged 67.

Thomas C. Green, M.D. Medical College of Indiana, Indianapolis, 1882; a veteran of the Civil War; and formerly a practitioner of Albion, Ind.; died at the home of his son in Fort Wayne, September 15, from abscess of the lung, aged 65.

John Philip Phillips, M.D. New York Medical College, New York City, 1859; surgeon of the Eleventh New York Volunteer Infantry during the Civil War; died at his home in New Haven, Conn., September 20, from senile debility, aged 77.

William C. Dodds (license, years of practice, Iowa, 1887); for sixty years a practitioner of medicine and for fifty years of that time a resident of Cedar Bluffs, Iowa; died at the home of his son near that place, September 15, aged 88.

Hugh P. Credille (years of practice, Texas); a member of the State Medical Association of Texas; for more than thirty-five years a practitioner of Commerce; died at his home in that city, February 21, from nephritis, aged about 60.

Francis A. Bryant, M.D. Worcester (Mass.) Eclectic Medical College, 1856; for fifty-two years a practitioner of Cedar Falls, Iowa, and three times mayor of the city; died at his home, September 4, from senile debility, aged 84.

Oren Newton Dages, M.D. Harvard Medical School, 1910; an intern in Massachusetts General Hospital, Boston, was drowned September 21, in Lake Magog, N. H., in an attempt to rescue two girls who were drowning, aged 25.

John A. Fuson (license, Tenn., 1889); of Dowelltown; for more than half a century a practitioner of DeKalb County, Tenn., and twice a member of the state legislature; died at the home of his son in Liberty, April 19, aged 74.

Horatius Latto, M.D. Long Island College Hospital, Brooklyn, 1890; formerly a member of the Medical Society of the County of Kings; died in Brooklyn Hospital, April 18, from cerebral hemorrhage, aged 50.

Elijah G. Tracy (license, Bedford County, Ind., years of practice); a member of the Medical Society of the State of Pennsylvania; died at his home in Sylvania, August 30, from senile debility, aged 85.

James W. Ferguson (license, Kansas, 1901); formerly of Thayer and Stafford, Kan.; a pioneer physician of Neo-ho county; died at the home of his son in Chamite, September 16, from cancer, aged 62.

Joseph Thomas Dupuy, M.D. Jefferson Medical College, 1861; a member of the Medical Society of Virginia; of Laurel Hill; died in Memorial Hospital, Richmond, September 7, from dysentery, aged 75.

Percy Benton, M.D. University of Louisville, Ky., 1882; a member of the Kentucky State Medical Society; formerly of Brodhead; died at his home in Mount Vernon, Ky., May 28, 1909, aged 47.

James Mostyn McCarter, M.D. University of Toronto, 1896; of Verona, Ont.; died in the Kingston General Hospital, September 15, four days after an operation for appendicitis, aged 37.

Edward A. Wilcox, M.D. Rush Medical College, 1857; who served his district as representative and senator in the state legislature; died at his home in Minouk, Ill., September 23, aged 80.

Thomas F. Phillips, M.D. University of Nashville, 1874; a member of Bradley County (Tenn.) Medical Society; died at his home, September 5, from the effects of the kick of a horse, aged 63.

John Beverly Crowell, M.D. College of Physicians and Surgeons, New York City, 1873; died suddenly at his home in East Orange, N. J., September 21, from heart disease, aged 60.

William G. Lloyd, M.D. University of Tennessee, Nashville, 1890; formerly of Kingston, Ark.; died at his home in Rocky, Okla., August 3, from ptomain poisoning, aged 48.

Pharmacology

YONKERMAN'S "TUBERCULOZYNE"

International Quackery—A Comparison of the Protection That is Accorded the British and the American Publics

Time was when the United States was the dumping ground for the British quack and nostrum vender. The absence of medical practice acts, or the inadequacy of such as existed, made many of the states a fertile field for the quack from across the water or for the discredited British physician. The lack of enforcement of such state food and drug laws as existed and the absence of any federal law on the subject left the American people at the mercy of as heartless a gang of quacks and "patent medicine" exploiters as ever plied their disreputable trade.

This influx of quacks and nostrum makers from over seas has been largely diminished since the advent of the Federal Food and Drugs Act. In fact the current has set in the other direction and now instead of the American public being fleeced by the English medical fakers the American quack is fleeing the English public "good pickings."

It is surprising to those who have kept in close touch with the "patent medicine" question, how many medical and medicinal frauds of American origin are now being vigorously exploited in Great Britain.

The reason for this improved state of affairs is to be found in the activities of the federal, and to a certain extent the state, authorities in this country, in prosecuting various

Great Britain, on the other hand, has a Food and Drugs Act that is neither as broad nor as specific as our own. The British courts, too, have shown a decided tendency to treat the "patent medicine" faker with a leniency that is compatible neither with good sense nor public policy.

That this attitude is largely due to a lack of appreciation on the part of the judiciary of the evils inherent to the nostrum traffic is evident from the remarks made by the judge before whom was tried the case of the British agents for that cocain-containing nostrum, "Tucker's Asthma Cure," *versus* the *Lancet*. It may be recalled that this leading legal light in referring to the cocain habit made the following statement: "Surely, it must be infrequent. I thought it was chiefly to be found among the Indians of South America." The indiscriminate sale of habit-forming "patent medicines" is not likely to be very greatly restricted in the British Isles while such monumental ignorance exists in high places.

An interesting example of the greater laxity on the part of the authorities in Great Britain in controlling quackery may be found by comparing the "literature" issued by Derk P. Yonkerman of Kalamazoo, Mich., and London, England, for use on opposite sides of the Atlantic. Yonkerman runs a "consumption cure" of the usual quack type, consisting chiefly of a potassium bromid mixture and a full set of "follow-up" letters and other "literary" accessories in the way of testimonials, etc.

Free samples of the nostrum are sent out by both the American and English branches of this fake and a comparison of the respective labels is interesting:

Page 11

Consumption Can be Cured

Dr. Derk P. Yonkerman, Who Has Discovered a Wonderful Cure for Consumption.

At last a positive cure for Consumption has been found! A wonderful specific has been produced which destroys the tubercle bacilli—the germ of Consumption—without injury to even the most delicate constitution. This remarkable discovery has already been tested in countless cases with such marvelous success that Consumption can no longer be considered an incurable disease. Consumption in its advanced stages, aggravated cases of bronchitis, asthma, and catarrh have been quickly cured by this new treatment, even after a change of climate and the use of emollients and all the usual remedies brought no relief whatever.

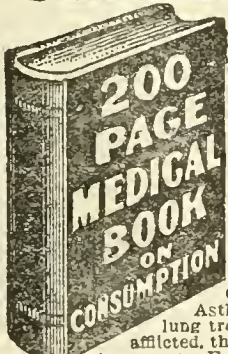

In order to place this treatment in the hands of every sufferer, both rich and poor, the discoverer has organized a distributing company. Through this company he has arranged to supply a generous

FREE TRIAL TREATMENT

only to those having Consumption or any other Consumption of the Lungs.

Fig. 2—A much reduced photographic reproduction of a typical British advertisement of Yonkerman's "Tuberculozyne." From the London *Daily Mirror*.

Consumption Book

FREE

This valuable medical book tells in plain, simple language how Consumption can be cured in your own home. If you know of any one suffering from Consumption, Catarrh, Bronchitis, Asthma or any throat or lung trouble, or are yourself afflicted, this book will help you to a cure. Even if you are in the advanced stage of the disease and feel there is no hope, this book will show you how others have cured themselves after all remedies they had tried failed, and they believed their case hopeless.

Write at once to the Yonkerman Consumption Remedy Co., 4195 Water Street, Kalamazoo, Mich., and they will gladly send you the book by return mail free and also a generous supply of the New Treatment, absolutely free, for they want every sufferer to have this wonderful remedy before it is too late. Don't wait—write today. It may mean the saving of your life.

fraudulent medical concerns. This, coupled with the campaign of enlightenment against the great American fraud that has been consistently carried on by the American Medical Association for the past few years through THE JOURNAL, the Association laboratory, and the Council on Pharmacy and Chemistry has resulted in a steadily narrowing field of operations for the quack and the nostrum seller in the United States.

ENGLISH LABEL

AMERICAN LABEL

Tuberculozyne Yonkerman.	Tuberculozyne (Yonkerman)
The New Remedy for Consumption.	The New Remedy for Consumption.
The Only Known Remedy for all forms of Consumption.	Not a Patent Medicine.
An Antitoxin Acting Agent of the Greatest Therapeutic Value.	

It will be noticed that the statement "The Only Known Remedy for all Forms of Consumption" which is to be found on the English labels, is absent from the labels on the American samples. The reason is plain. The American Food and Drugs Act declares that lying on the label is illegal—and as the statement in question is a palpable falsehood, the company, doubtless, will not risk a possible prosecution by putting it on the American product. Probably for the same reason the other untruth, viz., "An Antitoxin Acting Agent of the Greatest Therapeutic Value" is also omitted from the American labels.

Fear of the postoffice fraud-order is doubtless responsible for the generous pruning of the "literature" sent out by this

concern from its Kalamazoo office, resulting in a corresponding protection to the American public. For instance, a booklet is sent out purporting to describe "Tuberculozyne" and its use in consumption; in England this brochure bears the title:

"TUBERCULOZYNE (YONKERMAN) CURES CONSUMPTION"

This, of course, is an untruth as vicious as it is cruel. The expurgated American edition, therefore, goes through the mails with this title

"CONSUMPTION, ITS DIAGNOSIS, TREATMENT AND CURE"

Many other little twists, omissions and modifications are found that indicate the value of the American postoffice fraud-order.

ENGLISH EDITION

AMERICAN EDITION

"There have been found *cures* for small-pox . . ."

"There have been found *safe precautions, such as vaccination*, against smallpox . . ."

"Consumption remained as *mysterious* and deadly as ever."

". . . consumption has remained as *insidious* and deadly as ever."

"Tuberculozyne (Yonkerman) the most wonderful and marvellous medical discovery of the age, cures consumption."

[Not in the American edition.]

". . . the Tuberculozyne treatment introduces copper into the blood . . ."

[No mention is made, in the American edition, of the "copper salts" said, in the English edition, to be the essential element of the "cure." The omission is probably due to the fact that copper is present at all in this fake exists in such infinitesimal quantities as to have no appreciable therapeutic action.]

"Tuberculozyne is a combination of certain salts of copper . . ."

"Tuberculozyne — the Copper Cure for Consumption" . . ."

There are numerous other details in the American edition of the Tuberculozyne booklet that have been toned down from the English version so as more nearly to correspond, if not with the facts, at least with probabilities. In giving the "life history of Dr. Derk P. Yonkerman," for example, we find that Englishmen are asked to believe that Yonkerman

". . . won prizes for proficiency in every study in the curriculum."

Americans, fortunately, do not have their credulity strained to the same degree for in the United States edition we read that Yonkerman merely

". . . won many prizes for proficiency in his studies."

Whether this modification is a tribute to the natural skepticism of the American public or to the stricter postal laws that obtain on this side of the water is not known. That modesty had anything to do with it is unthinkable. Many other equally interesting differences between the claims made on opposite sides of the Atlantic might be quoted but the whole matter can be summed up by saying that in England the style of the Tuberculozyne booklet is that of "the Lie Direct," while in the United States it approximates "the Lie with Circumstance."

A word in closing regarding the composition of this fake. The nostrum comes in two solutions which have been analyzed in this country by Dr. L. F. Kebler of the Bureau of Chemistry, U. S. Department of Agriculture, in Australia by the Board of Health of Sydney, N. S. W., and in Great Britain both by the public analyst and by the British Medical Association. Like every nostrum, the formula seems to vary at the whim of its exploiter. We give the latest analysis, that made for the British Medical Association and published in "Secret Remedies."

"No. 1 was a bright red liquid; analysis showed it to contain in 100 fluid parts, 3.4 parts of potassium bromid,

12 parts of glycerin, a trace of a pungent substance, sufficient oil of cinnamon (or oil of cassia) to give a flavor, a very small quantity of alcohol, and cochineal coloring matter darkened with a trace of alkali; no copper was present. The following formula gave an exactly similar liquid:

Potassium bromid	3.4	parts
Glycerin	12.0	parts
Oil of cassia	0.1	part
Tincture of capsicum	0.17	part
Cochineal coloring	q. s.	
Caustic soda	0.06	part
Water to	100	fluid parts

"No. 2 was a brown liquid, one specimen being bright and another containing a little sediment. Analysis showed it to contain in 100 fluid parts, 18 parts of glycerin, sufficient essential oil of almonds to give a flavor, and a coloring matter which appeared to be burnt sugar. No copper was found in the small free sample, but the larger bottle of No. 2 contained 0.01 per cent. of copper, and a trace of sulphate; this quantity of copper is equivalent to 1/48 grain of crystallized copper sulphate in each fluid dram. As regards the other ingredients the following formula gave an exactly similar liquid:

Glycerin	18.0	parts
Essential oil of almond	0.1	part
Burnt sugar	q. s.	
Water to	100	fluid parts

"The estimated cost of ingredients for No. 1 and No. 2 together is 2½ d." (5 cents).

Yonkerman has two prices for his "Tuberculozyne;" in England he asks £2 10s. 0d. (\$12) while his own countrymen get the same thing for \$10. Not altogether the same, either, as the "literature" sent out in Great Britain is typographically more elaborate and, as has been shown, the claims are more preposterous.

Tuberculozyne, we are told, is sold, "at a very moderate advance above actual cost." If selling 5 cents worth of drugs for \$10 or \$12 is Yonkerman's idea of "a very moderate" profit, we shudder to think what might have happened if instead of electing to follow quackery as a trade he had turned his talents toward the field of "high finance."

SIMPLIFICATION OF MATERIA MEDICA EXAMINATIONS

Report of the Committees on Materia Medica of the National Confederation of State Medical Examining and Licensing Boards and of the Council on Medical Education of the American Medical Association

With a view to fostering a more thorough knowledge of the really important drugs, the National Confederation of State Medical Examining and Licensing Boards, at its last meeting in Atlantic City, June, 1909, authorized the appointment of "a committee of three, to confer with the Council on Medical Education of the American Medical Association and to compile and to report to this Confederation a list of the more important drugs and their preparations, to which the examinations of the constituent boards may be confined, this list to be published in THE JOURNAL of the American Medical Association as with the approval and endorsement of the confederation."

In accordance with these instructions, the two committees have conferred by correspondence, and herewith submit a list as requested. Since the instructions of the committee of the Council on Medical Education applied only to the drugs generally used by the profession, it was not deemed advisable to prepare at this time an official list for examinations in homeopathic materia medica.

In presenting to you the official list of drugs for state board examinations in materia medica, we wish to emphasize the fact that it will accomplish its purpose most effectively if the individual state boards will publicly record their inten-

tion of confining their examinations to this list. The chairman of either committee will be glad to receive such assurance.

For the Confederation:

M. G. MOTTER, *Chairman*,
J. C. GUERNSEY,
GEORGE MACDONALD.

For the Council on Medical Education:

TORALD SOLLMANN, *Chairman*,
BERNARD FANTUS,
EGBERT LE FEVRE.

OFFICIAL LIST OF DRUGS FOR STATE BOARD EXAMINATIONS IN
MATERIA MEDICA

The following list has been framed with the view of including only those drugs which are commonly conceded to be practically indispensable in the general practice of medicine and as many preparations as are needed to bring these into play.

It does not aim to contain all the drugs which are of some interest or even of some importance, but, as has been said, only those which are indispensable. The others can scarcely be deemed fair subjects for license examinations. Their selection, for purposes of instruction, may be safely left to the individual teachers, who, if they wish, can obtain suggestions in the list of the Committee of One Hundred of the Council on Medical Education of the American Medical Association.

The drugs marked with an asterisk (*) are introduced for their toxicologic importance.

LIST OF DRUGS AND PREPARATIONS

FLAVORS:

Syrupus
Syrupus Glycyrrhizæ
Aqua Menthæ Piperitæ
Elixir Aromaticum
Spiritus Menthæ Piperitæ

LOCAL IRRITANTS:

Sulphur Lotum
Ichthyolum
Tinctura Iodii
Liquor Iodii Compositus
Iodoformum
Aqua Hydrogenii Dioxidii
Acidum Tannicum
Oleum Terbinthinæ
Copaiba
Oleum Santali
Ceratum Cantharidis
Aloe and Aloinum

PURGERS, VEGETABLE CATHARTICS AND

Tinct. Gentiana Comp.
Syrup Rhei Aromaticus Fldext
and Arom. Fldext. Rhamni
Purshiana
Santonium
Thymol
Resina Podophylli
Pulvis Jalapæ Comp.
Oleum Ricini
Oleum Tiglii
Oleo-resina Aspidii
Pelletierinæ Tannas

EMOLLIENTS AND PROTECTIVES:

Oleum Olivæ
Glycerinum
Petrolatum (also Album and
Liquidum)
Oleum Theobromatis
Adeps Benzoinatus
Adeps Lanae Hydrosus
Acacia (and mucilage)
Collodium flexile
Oleum Morrhuæ (and
Emulsum)
Pepsinum

ALKALOIDAL DRUGS:

Strychnina Sulphas
Tinctura and Extr. Nucis Vomice
Caffeina Citrata
Theobromina Sodio-Salicylas
Opii, Pulvis, Extr., Tinct., and
Tinct. Campb.
Pulvis Ipecac. et Opii

dum.
Physostigmina Salicylas
Apomorphina Hydrochlori-
dum
Ipecacuanina, Pulvis, Fld-
ext. and Syrupus
Aconiti Tinctura and
Aconitine
Quinina Hydrochloras and
Sulphas
Tincture Cinchona Comp.
Fldext. and Ext. Colchici
Colchicin

RENZOI DERIVATIVES:

Acetphenetidinum
Acetanilidum
Sodii Salicylas
Phenol and Phenol Liquefactum
Phenylis Salicylas
Resorcinol
Creosotum

BIOLOGIC PRODUCTS:

Epinephrin
Gland. Thyroidea Siccæ
Serum Antidiphtheriticum
Serum Antitetanicum
Vaccina Variolæ

HYDROCARBON NARCOTICS:

Alcohol (and Sp. Frumenti and
Sp. Vini Gallici)
Ether
Chloroformum
Nitrogen Monoxid
*Carbon Monoxid
Chloralum Hydratum
Sulphonmetbanum
Liquor Formaldehydi
Hexamethylenamina

NEUTRAL PRINCIPLES:

Digitalis, Pulv., Infus. and Tinct.
Strophanthi Tinct.
Strophanthinum
Ereofa, Fluidextr. and
Ext.

SUNDRY:

Spir. Camphoræ (and Linim.)
*Acid. Hydrocyanic. Dil.
Spir. Glycerilis Nitratiss
Amylis Nitris
Oxygen
*Carbon Monoxid

SALINES:

Sodii Chloridum
Magnesii Sulphas
Liquor Magnesii Citratiss
Sodii Phosphas
Saccharum Lactis
Ammonii Chloridum
Calcii Chloridum
Potassii Bromidum and
Sodii Bromidum
Potassii Iodidum
Potassii Acetas
Potassii Chloras
Potassii Permanganas
Sodii Boras

ALKALIES AND ACIDS:

Aqua Ammonia (and Aromatic
Spiritt)
Ammonii Carbonas
Sodii Bicarbonas
Creta Preparata
Liquor Calcis (and Lin.)
Acid Hydrochloricum Dil.
Acidum Boricum

METALS:

Arseni Trioxidum
Liquor Pot. Arsenitis
Antimonii et Potas. Tart.
Bismuthi Subcarbonas and Sub-
nitri.

tum
Hydrargyri Oxidum Flavum
Hydrargyri Chloridum
Corrosivum
Hydrargyri Chloridum
Mite
Hydrargyri Iodidum Flava-
um and Rubrum

Correspondence

Postgraduate Study of Pediatrics in Vienna

To the Editor:—The fact that we find so few American physicians who are interested in the diseases of children, studying in the medical centers of Europe, makes it seem probable that the opportunities for work in Europe along the line of pediatrics are not fully understood in America. This fact, taken in connection with the effect produced on me by a very discouraging editorial in THE JOURNAL (July 25, 1908, li, 320), has made me think it possible that a few words from one who has recently been on the ground are not wholly uncalled for. I feel this the more strongly in view of the difficulties I myself experienced in my efforts to obtain information about European work in children's diseases before starting on my trip. The reason for this was twofold: the men who had recently come back had worked along lines other than my own, whereas the men who had worked in pediatrics had been away so long that their details were, in the main, hazy and indefinite. I can speak, at first hand, only of Vienna and conditions there; for there I spent most of the short time at my disposal. What I shall have to say, also, will be entirely from the point of view of the man who desires, primarily, pediatrics. Furthermore, I naturally look at things through the eyes of a "short-term" man.

First, a word as to the general system of graduate work in Vienna. The American Medical Association of Vienna may

well be likened to a graduate college in connection with a large university. It boasts a floating membership of one hundred students, graduates in medicine, chiefly Americans; arranges for courses by university professors, docents, instructors and assistants; and through the dean of the University of Vienna grants a *Zeugniss*, or certificate, for work done and courses taken.

The courses, embracing all the branches of medicine and surgery, general and special, are posted on a bulletin board at the Café Klinik, which serves as headquarters and general rendezvous for the American physicians in the city; and membership in these courses, up to the number of vacancies announced, is, with a few unimportant exceptions, granted in the order in which applicants have signed their names to the announcing slips. The courses run, as a rule, for one month, starting generally on the first. They cost from \$10 to \$20 a month, and occupy from one to two and a half hours a day, five or six days in the week. They may be taken for a month single, or as often as desired, the changing clinical material doing away with any danger of tiresome repetition.

And now for the work especially in children's diseases. Professor Escherich of the University of Vienna has gathered around him a coterie of young men, of whom Professor von Pirquet, until very lately of Vienna, now of Johns Hopkins University, is perhaps the most widely known. These men give courses in pediatric diagnosis, infant-feeding, laboratory methods especially applicable to children, etc., and hold themselves in readiness to give courses in any special work that may be desired. Special work in the dispensary, where two men handle the actual work, with and constantly under the instruction of the assistant, has been considered by many men one of the best courses in Vienna, and must usually be spoken for one, two, three or even more months in advance. When I say that I have seen more than a hundred patients (children under 12 and infants) treated in the two small dispensary rooms of the Heilige Anna Kinderspital, of an afternoon, after a morning's work of similar proportions, and add that the wards are rich in feeding cases, infectious diseases and the usual line of the diseases of older children, it will be seen that (thanks to the Austrian social system that sends so many cases to the hospital and the dispensary that with us would go to private physicians) these men have no lack of material to demonstrate. I feel that it would not be fair to speak specially of Docent Hamburger, whose never-failing courtesy and good nature were even more notable than his excellent, idiomatic English, without acknowledging as well a debt of gratitude to Messrs. Schick, Reuss and Sperck, who were never too busy to stop their most important work in order to clear up a doubtful point or to show an interesting case, no matter how long past the hour for closing it chanced to be. Docent Knöpfelmaier's course, at his own Karolinen Kinderspital, must also be mentioned here, as well as the very valuable short courses in tracheotomy and intubation—theory, manikin and actual practice—which are to be had with any one of several of the assistants.

Hardly less important, to the man fresh from his hospital, but lamentably "stale" as to his memory of the specialties which he "learned" (save the mark!) in the six-weeks courses of his fourth year in medical school, are the opportunities given for reviewing these often slighted, because too little understood, branches of medicine. Skin and ear especially, eye, nose and throat perhaps to a less degree, orthopedics most of all, are very important "minors" for the man who has chosen pediatrics as his "major." The opportunities for a casual or more thorough review of any or all of these subjects are many and valuable. I need not say cheap, when a little calculation, on the basis of some statements made above, will show the prevailing rate for such courses to be from 40 to 60 cents an hour! (See catalogues of some of the post-graduate schools in this country, or of the medical schools that give graduate summer courses, for comparison!)

As to what can be found in other cities, I can only say, from a very short experience in Berlin and from the conversation of men I have met who have worked there, that the "course" system is not so fully developed in the German capital as it is in the Austrian; and that at the latter center

it is much easier to fill up one's schedule for the entire day than it is at the former. Munich, a delightful city to live in, has the "course" system not at all; but work can easily be arranged for there to the extent of the clinical material available; and Professor Pfaundler's kindness to Americans leaves nothing to be desired.

Board and room in Vienna can be obtained for \$1.20 a day up, or down, if one can prevail on an Austrian friend to act as his business agent, and can prevail on himself to put up with the lack of some of the things that most Americans insist on having. The more one knows of German, the more valuable, naturally, will be one's experience here; but not a few men in Vienna to-day speak no German, but what they have learned since leaving home—and that, in more instances than one, is woefully little!

Perhaps more men than we realize have the opportunity of taking a few months of study abroad after leaving their hospitals and before settling down to practice, but are deterred from a feeling that nothing of value can be obtained in so short a time. Of course, this a matter that every man must decide for himself; and yet, to my mind, the mental broadening, the inspiration, the refreshing brushing away of intellectual cobwebs that one gets in a few months or even weeks in a foreign city, leave no shadow of doubt that the short-term man is well repaid for any sacrifice that he may have to make in order to gain his short time abroad.

F. H. RICHARDSON, M.D., Brooklyn.

Registration of Foreign Physicians

To the Editor:—Kindly allow me a few words in final answer to Dr. Nathan, who is laboring under some delusion. I regret very much the personal tone this matter has taken, but for the sake of an understanding by Dr. Nathan let me say:

First, I never alluded to Canadians or their registration.

Second, I never wrote about practicing in Canada nor of the difficulty American physicians find in qualifying to practice in that country.

Third, I alluded solely to the difficulty South-African-born medical men have in obtaining the right to practice in South Africa. German, French and Russian physicians of the highest standing were forced, after years of practice in South Africa, to proceed to London (directly after British occupation) to obtain the British certificate to continue practice. Surely the egotism of British physicians is not so great as to suppose that all physicians except those of British colleges are poorly informed and trained. I knew whereof I spoke, and would refer Dr. Nathan to my only communication in THE JOURNAL September 3. If Dr. Nathan re-reads the various communications that have appeared in THE JOURNAL during the last six weeks I think he will find that he has been answering an article which I did not write.

JAMES A. HONELL.

[COMMENT: We have received a number of other communications on this subject, some of them decidedly personal in character, and for this reason we think it best to close the discussion. No objection can reasonably be raised to the requirements fixed for the right to practice medicine in any country unless there is a clear discrimination against the physician of other countries. The requirements in Germany, although severe, are apparently equally enforced for all applicants, whether they are educated in Germany or elsewhere. Likewise in Great Britain the requirements seem to be the same for all candidates regardless of nationality. A country may be slow to recognize foreign educational institutions, but this is justifiable owing to the greater difficulty of securing accurate information regarding them. It is worthy of note, however, that in Great Britain the diplomas of no less than twenty medical colleges in the United States are now recognized. It is true that the requirements to practice medicine in most foreign countries are more severe than they are in the United States, but the reason is that in many of our states the requirements are ridiculously low or are not prop-

erly enforced. The requirements to practice medicine in most of our states should be made more thorough, not for the purpose of preventing foreign physicians from obtaining licenses, but to protect the public from illiterate and untrained doctors no matter where they come from.—Ed.]

A Visit to Ehrlich

BERLIN, GERMANY, Sept. 13, 1910.

To the Editor:—Not since the announcement of Koch's tuberculin has there been such an onslaught of medical men on Germany.

Going down on the train from Berlin to Frankfort with me there were no less than five physicians, all eager to be the first to see Professor Ehrlich and to obtain a supply of the now famous "606."

To those who are fortunate enough to become acquainted with Dr. Marks, the first assistant, the task of seeing Professor Ehrlich is not difficult. But without his good services one would have to wait at least three or four days, for the waiting list daily is from thirty to forty physicians. These men, coming from all parts of the globe, think that Professor Ehrlich should receive each one personally, and at once give him a supply of the new specific. On his refusal to do so, they at first entreat and later become indignant, and some have become little short of violent. It is no wonder one finds the little man nervous and distracted; but notwithstanding, he treats all visitors who are gentlemen with the greatest courtesy and consideration.

As the substance is given out entirely for experimental purposes, Professor Ehrlich is exceedingly careful into whose hands it goes, feeling that the only persons competent to use it are trained syphilographers with laboratory affiliations.

Professor Ehrlich was greatly disturbed by the numberless letters and cablegrams which poured in from all over the world, some of them from men who were not in the least qualified to administer the new remedy. He asked me, in consequence, to cable you to advise all American doctors to stay at home and not write, as the drug would be on the market in due time.

Ehrlich is a little disturbed over the accusation that he is about to make a fortune out of this new substance, for such is not at all the case.

This specific, as well as all others that have been invented in the laboratory under the direction of Ehrlich, was patented, not from any selfish motive, but to protect his discovery.

Around Ehrlich in Frankfort are a large number of chemical factories which hold many valuable patents on some of our well-known preparations. So if Ehrlich soon after discovering the true nature of atoxyl, and after having made his first three substitute products, had not secured patents on these, which are but the initial steps to three distinct fields of chemical possibilities, these factories would have obtained patent rights which would forever have closed this field of research to Ehrlich, and there would have been no "606."

Ehrlich personally is not to profit at all from the discovery. Before he was positive of the result of his work, he arranged that should it be a success 55 per cent. of the proceeds should go to his laboratory (which is sorely in need of funds) to continue along in this research work, and that the other 45 per cent. should go to the manufacturer.

By the patenting of the remedy we are assured of the following: first, the substance will be made with great care and with absolute uniformity, guaranteed by Ehrlich. Second, he has assured me that the substance will be put on the American market at exactly the same price for which it is sold by the European trade, plus the duty.

The amount of clinical work seen in Frankfort is limited to Herxheimer's clinic, where it is most thoroughly done, though on a small scale.

It might be interesting to you to know that the representative of *McClure's Magazine* was in Frankfort very recently, and that an article will appear in the November and

December issues treating syphilis in all its phases from a layman's standpoint, and that the lay press here in Frankfort, as well as in Berlin, keep the public informed from time to time on the results of this discovery; and further, that it is a common occurrence for a patient infected with the disease to come to a clinic and ask to have the new remedy administered to him.

In Berlin at the Virchow Krankenhaus, Wechselmann's clinic at the present writing offers the largest amount of material for observation. Here over 900 cases have been treated, and the results are on the whole most gratifying.

At this clinic one can see treated syphilis in every form, from babies 10 days old to an old man in his eighty-fifth year, who was so unfortunate as to contract a specific primary lesion at this late date.

Most brilliant are the results which are obtained in tertiary lesions. In these, gummatous distinctive processes begin to heal at once, but in order to continue this improvement it has sometimes been necessary to repeat the injection, and in one instance the injection was given three times.

The work of Lesser and Citron, while not conducted on such a large scale, is equally interesting, and the reports that come from their clinic should be most valuable.

In regard to the administration of diamido-arsenobenzol, Ehrlich is most particular that no patient who has any retinal changes, cardiac lesions or kidney disease shall receive any of the substance.

The modes of administration are numerous, as every clinician is trying to attach his name to Ehrlich by the application of his own special technic. These different methods will have to be tried out, and the fittest will be the longest survivor.

A word in regard to the Wassermann reaction for diagnosis. In all cases that have been previously treated with mercury the test still holds good, but in cases that have been treated with "606," the test, for a short while after the injection, has no value, as some report an early negative reaction and some the contrary. It will be a long time before any statistics on this point will be available, so until then we shall have to wait.

In general, one would say:

First, "606" is a specific agent against spirochetes.

Second, one injection will not cure every case of syphilis, but it seems possible to destroy the spirochetes by one injection, if it be given sufficiently early.

Third, it is absolutely contraindicated to administer "606" without first having made a positive diagnosis, by finding spirochetes or by the serum diagnosis of Wassermann.

B. C. CORBET, Chicago.

Cholera Among British Troops During Indian Mutiny

To the Editor:—Your notices of the rise of Asiatic cholera to epidemic proportions in certain parts of Europe, with comments on the means by which it is spread, recall a fact mentioned by a British officer in a new book which gives an account of the siege of Delhi, as it came within his personal observation. The officer, Griffiths, says that the British troops employed in the siege were scourged by cholera, and that the camps were plagued by myriad swarms of flies, this fact being regarded as a coincidence merely. The mortality from cholera exceeded the losses caused by the ferocious fighting at the front, which continued many weeks between combatants maddened by racial hates and wrongs and under a midsummer sun, neither side giving or asking quarter.

With our present knowledge it would appear only too plainly that the relation between the flies and cholera was not a coincidence, but rather cause and effect. A hint is given as to the food supply of the British by the story the officer tells, that when the city was finally taken, after days of severe street fighting, he was returning to quarters one morning through avenues cumbered with torn and rotting bodies. He asked his servant what there was for breakfast and was told "fried liver." This was the last straw, and it was only after some weeks that he was able to return to duty.

He also mentions, as an eye-witness, the peculiar psychic and physical effects attending the blowing of men from the muzzles of cannon, a form of military execution employed at that time to punish Sepoy mutineers.

GEORGE HOMAN, M.D., St. Louis.

"The Stomach Whistle: Who Blew It First?"

To the Editor:—The question of priority discussed in THE JOURNAL, September 3, p. 879, by Drs. Spivak and Kemp, recalls to my mind that as early as 1884 Dr. S. J. Meltzer of New York, in connection with his studies of the deglutition sounds, carried on experiments with a stomach tube having a whistle at one end and a balloon for blowing in air at the other end. One incident remained vivid in my mind. At his request I introduced such a tube into his esophagus. On one occasion the procedure brought on an alarming attack of spasm of the glottis which Dr. Meltzer relieved by swallowing sips of water in rapid succession, a method of treatment described by him a few years previously. I am not delegated by Dr. Meltzer to claim any priority for him; I simply wish to record the fact and thus contribute to the history of the invention of the stomach whistle.

JUSTIN WOLFFARTH, M.D., Asheville, N. C.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

SIMPLE GOITER AND ITS TREATMENT

To the Editor:—Has the recent advancement in knowledge regarding the functions of the thyroid thrown any light on the subject of simple goiter? Just how are the iodids used in what has been called the "interrupted method?" Having used iodin externally and sodium iodid internally for three months without improvement, would it be wise to continue the treatment, and if not, does this exhaust our armamentarium? The patient is a young girl of fourteen with a small, simple goiter affecting mainly the right lobe and isthmus. She is otherwise normal. J. A. R.

ANSWER:—Recent studies of the thyroid and its functions seem to indicate that enlargement of the gland up to a certain point is a compensatory process. On account of an increased demand of the system for thyroid secretion the glandular elements proliferate. A moderate amount of hyperthyroidism, due to sexual development, is not infrequent in girls at puberty. This is often true also of the normal thyroid during pregnancy. At such times there is a hypertrophy of the gland which may be called a goiter but which is only physiologic and will subside of itself within a shorter or longer period. In cases in which the enlargement persists or increases, it is probably in the beginning a compensatory process, as stated, the increase beyond a doubling of the size of the gland being probably due, according to Dr. C. H. Mayo, to the fact that portions of the hypertrophied gland lose their function, the latter being taken up by the more newly formed gland tissue. In case this hypertrophy extends beyond the point of compensation and too much secretion is taken up by the system, the symptoms of hyperthyroidism or exophthalmic goiter may be produced; the condition is no longer a simple goiter. Thus there may be a distinct relation between simple goiter and the exophthalmic form. Wilson says that from the clinical standpoint exophthalmic goiter is caused by an enlargement of the gland with hypersecretion, while a simple goiter is enlargement of the gland without symptoms of hypersecretion, and that if a patient lives long enough every case of exophthalmic goiter will become a case of simple goiter. It must be remembered, however, that the case may be one of exophthalmic goiter or Graves' disease apparently from the beginning, and that there may be scarcely any noticeable enlargement of the gland; also that the enlargement may be due to a cystic condition and not to hypertrophy of gland tissue. The etiology of the condition which induces the enlargement has not been definitely determined, but in certain portions of the mountainous country of Europe, where goiters are unusually frequent, it is attributed to the water.

It seems to be the opinion of many authors that the iodids are the best agents for the condition, though a number of other drugs and measures are employed. We understand by the "interrupted method" of using the iodids the giving of the proper dosage of

some iodid three times a day, for a period, for instance, of three months, and then allowing a rest of a week, or two weeks, or even a month before resuming the treatment. While most physicians do not believe in the use of external applications, some recommend them, as for instance, the use of an ointment of the red iodid of mercury, iodin, etc. In view of the possible etiologic relation of water the patient may be directed to drink only boiled water. Ergot and belladonna have been given, and electrolysis by means of needles plunged into the substance of the gland, the tapping of cysts, incisions of the isthmus, ligation of arteries, partial thyroidectomy and the administration of the thymus of sheep, are measures that have been employed. Thyroid extract or thyroid feeding is also effective in some cases of simple goiter.

In the case mentioned by our correspondent, while the enlargement on one side might seem to indicate that the gland may be cystic, yet it may only be a case of physiologic hypertrophy due to the advent of puberty, and measures directed to the establishment of normal menstruation by the administration of iron, and by other roborant treatment, with the lapse of a little time, may be all that is necessary to effect a cure.

BISMUTH-VASELIN PASTE

To the Editor:—Please inform me where I can procure literature on the history, success and merit of the bismuth-vaselin paste treatment, more particularly when applied to suppurating sinuses.

GEORGE L. BATES, M.D., Morrisville, Vt.

ANSWER:—The following are a few of the many articles on this subject:

- Beck, E. G.: *Fistulous Tracts, Tuberculous Sinuses and Abscess Cavities*. THE JOURNAL, March 14, 1908, p. 868.
- Harris, H. H.: *Bismuth-Vaselin Paste Injections*, *Lancet-Clinic*, Sept. 26, 1908.
- Discussion on Bismuth Treatment of Tuberculous Sinuses at meeting of American Orthopedic Association, reported in THE JOURNAL, July 25, 1908, p. 342.
- Beck, J.: *Bismuth Paste in Treatment of Suppuration of the Ear, Nose and Throat*, THE JOURNAL, Jan. 9, 1909.
- Swindt, J. K.: *Bismuth Paste Diagnosis and Treatment of Fistulous Tracts*, *South California Pract.*, January, 1909.
- Robitschek, E. E.: *Beck's Bismuth Paste Treatment, with Report of Nine Cases*, *Jour. Minn. Med. Assn.*, Feb. 15, 1909.
- David, V. C. and Kauffman, J. R.: *Bismuth Poisoning Following Injection of Bismuth-Vaselin Paste*, THE JOURNAL, March 27, 1909, p. 1035.
- Bacus, V. J.: *Bismuth Poisoning*, THE JOURNAL, April 17, 1909, p. 1273.
- Stern, W. G.: *Bismuth Injections for Treating Old and Secreting Fistulas*, *Cleveland Med. Jour.*, April, 1909.
- Ridlon, J., and Blanchard, W.: *Bismuth Paste Treatment of Tuberculous Sinuses*, paper read before American Orthopedic Association; abstr. in THE JOURNAL, Aug. 7, 1909, p. 478.
- Baer, W. S.: *Results of the Injection of Beck's Bismuth Paste in Treatment of Tuberculous Sinuses*, *Bull. Johns Hopkins Hosp.*, October, 1909.
- Anderson, A. B.: *Poisoning by Bismuth Subnitrate in Bismuth Paste*, *West. Med. Rev.*, January, 1910.
- Shober, J. S.: *Treatment of Tuberculous Sinuses by Beck's Bismuth-Vaselin Paste Injections*, *Ann. Surg.*, May, 1910.

LIST OF PRIZES OPEN TO COMPETITION

To the Editor:—A list of prizes to be competed for by physicians during the next twelve months would doubtless prove of interest to those of your readers who are carrying on investigations.

PHYSICIAN.

ANSWER:—We gave a list of prizes in THE JOURNAL, Feb. 19, 1910, page 636. We did our best to make that list as complete as possible and since we specified which prizes are for annual award, the list ought to be still good for reference. Competition is not in all cases limited to physicians.

The Public Service

Medical Department, U. S. Army

Changes for the week ended October 1, 1910.

- Wheate, J. M., M.R.C., Sept. 19, ordered to proceed from Fort Lincoln, N. D., to Fort Yellowstone, Wyoming, for temporary duty.
- Marshall, John S., E.S. and D.S., Sept. 20, reports on three months leave of absence.
- Pyles, Will L., capt., Sept. 23, on expiration of his present leave of absence, ordered to Fort Mackenzie, Wyoming, for duty.
- O'Connor, R. P., major, Sept. 23, granted 5 days leave of absence.
- McCord, Donald P., M.R.C., Sept. 23, granted 3 months leave of absence about Oct. 1, 1910.

McIntyre, Henry B., capt., Sept. 23, granted leave of absence from date of his relief from duty in San Francisco, to and including Oct. 25, 1910.

Hoffenger, A. C., C.S., Sept. 24, granted 14 days leave of absence. Pidd, Peter C., capt., Sept. 26, left Fort Slocum, N. Y., with recruits en route to Fort McDowell, California.

The following named first lieutenants, Medical Reserve Corps, will report Oct. 1, 1910, to Col. Louis A. La Garde, Medical Corps, President, Army Medical School, for a course of instruction at that school: Robert H. Gantt, Henry P. Carter, Francis X. Strong, Hatley J. Hallett.

Slater, Ernest F., M.R.C., Sept. 24, is honorably discharged from the service of the United States, to take effect Oct. 13, 1910, his services being no longer required.

Weed, Mark D., lieutenant, Sept. 24, ordered to proceed to West Point, N. Y., for temporary duty.

La Garde, Louis A., colonel, Crosby, Wm. D., lieutenant-col., and Keifer, Frank R., lieutenant-col., Sept. 24, 1910, appointed members of a board for the examination of medical officers for promotion.

Bailey, Edward, M.R.C., Sept. 24, relieved from duty at Fort George Wright, Washington, and report in person to the Med. Supt., Army Trans. Service, at that place, for duty, with station at Seattle, Washington, relieving 1st Lieut. James E. Maloney, M.R.C., from duty on the transport *Burnside*.

Maloney, James E., M.R.C., Sept. 24, will, on being relieved from duty on the trans. *Burnside*, proceed to Fort George Wright, Washington, for duty.

Lamb, Wm. P., M.R.C., Sept. 27, 1910, honorably discharged from the service of the United States, his services being no longer required.

Roberts, Ernest E., M.R.C., Sept. 16, ordered to accompany Battery C, First Field Artillery from Fort Sill, Oklahoma, to San Francisco.

Davis, A. O., lieutenant, Sept. 27, left Fort Oglethorpe, Georgia, with 11th Cavalry on 21 days practice march.

Wheate, J. M., M.R.C., Sept. 27, left Fort Lincoln, N. D., en route to Fort Yellowstone, Wyoming, for temp. duty.

Gridis, F. C., M.R.C., Sept. 20, left Fort D. A. Russell, Wyoming, with the 9th Cavalry on practice march.

Trinder, John H., M.R.C., Sept. 28, orders directing him to report on Oct. 1, 1910, at Army Med. School, Wash., D. C., for a course of instruction at that school, revoked.

Willcox, Charles, major, Sept. 28, ordered to report at Washington, D. C., for examination for promotion on Oct. 18, 1910.

Bustion, Joseph E., lieutenant, Sept. 28, granted 30 days leave of absence.

Kierulff, H. Newton, M.R.C., Sept. 28, 1910, is honorably discharged from the service of the United States, to take effect Oct. 29, 1910, his services being no longer required.

Carswell, R. L., capt., Sept. 29, relieved from duty at the Army General Hospital, San Francisco, ordered to Manila, P. I., for assignment to duty on the transport sailing from San Francisco, December 5, 1910.

Miltenberger, Val E., M.R.C., Sept. 29, relieved from duty at Fort Riley, Kansas, and ordered to Manila, P. I., for assignment to duty on transport sailing from San Francisco, Dec. 5, 1910.

Barney, F. M., M.R.C., Sept. 29, relieved from duty at Fort Clark, Texas, and will proceed home. Lieut. Barney is relieved from active duty in the M.R.C., to take effect on the expiration of leave of absence granted him this date, for one month and seven days.

De Witt, Wallace, major, Sept. 29, relieved from duty at Fort Yellowstone, Wyoming, and ordered to Schofield Bks., H. T., for duty.

Leslie, S. H., D.S., Sept. 23, ordered to proceed from Fort Leavenworth, Kansas, to Fort Meade, S. D., Robinson, Nebraska, and Fort Mackenzie, Wyoming, for temporary duty.

Medical Corps, U. S. Navy

Changes during the week ended Oct. 1, 1910.

Wentworth, A. R., medical inspector, detached from the Naval Academy and ordered to the navy yard, New York.

Lung, G. A., surgeon, detached from the navy yard, New York, and ordered to duty on board the *Connecticut* as fleet surgeon of the Atlantic fleet.

McCormick, A. M., surgeon, detached from duty on board the *Connecticut* as fleet surgeon of the Atlantic fleet and ordered to the Naval Academy.

Hayden, R., P. A. surgeon, detached from the naval proving ground, Indian Head, Md., and ordered to duty at the naval hospital, Norfolk, Va.

Stratton, R. J., P. A. surgeon, detached from the Naval Medical School Hospital, Washington, D. C., and ordered to the naval proving ground, Indian Head, Md.

Lane, H. H., asst.-surgeon, detached from the naval station, Hawaii, and ordered to duty at the naval hospital, Canacao, P. I.

Acting Assistant Surgeons E. E. Woodland, R. B. Pratt, A. L. Jacoby, J. J. Lynch, O. J. Miller, W. H. Halsey, W. E. Eaton, L. P. Pratt, C. C. Hightower, J. V. Howard, J. G. Omelvina and E. P. Halton, ordered to instruction at the Naval Medical School, Washington, D. C.

Grow, E. J., surgeon, detached from the Naval Medical School, Washington, D. C., and ordered to the *Solace*.

Rennie, W. H., P. A. surgeon, ordered to duty at the naval hospital, Annapolis, Md.

Baker, M. W., P. A. surgeon, detached from the *Connecticut* and ordered home to wait orders.

Steadman, W. G., P. A. surgeon, detached from the naval recruiting station, Hartford, Conn., and ordered to the *Dirie*.

Smith, H. W., P. A. surgeon, detached from the Naval Academy and ordered to the *Connecticut*.

Stuart, M. A., P. A. surgeon, commissioned passed assistant surgeon from May 4, 1910.

Curtis, E. E., P. A. surgeon, commissioned passed assistant surgeon from July 12, 1910.

Hermesch, H. R., P. A. surgeon, detached from duty at Knoxville, Tenn., and ordered to the naval recruiting station, Minneapolis.

Trible, G. B., asst.-surgeon, ordered to duty at the naval hospital, Norfolk, Va.

Olson, G. M., asst.-surgeon, detached from the naval recruiting station, Minneapolis, and directed to wait orders.

Lynch, J. J., acting asst.-surgeon, resignation accepted to take effect Oct. 1, 1910.

U. S. Public Health and Marine-Hospital Service

Changes for the week ended Sept. 28, 1910:

Williams, L. L., surgeon, leave of absence for 7 days from Sept. 19, 1910, amended to read 3 days.

Gardner, C. H., surgeon, leave of absence for 1 month from Sept. 1, 1910, amended to read 22 days from Sept. 1, 1910.

Sprague, E. K., surgeon, granted 1 month's leave of absence from Sept. 28, 1910.

Rucker, W. C., P. A. surgeon, relieved from duty in connection with the suppression of plague in California, and detailed for temporary duty in the Bureau, effective Sept. 22, 1910.

Creel, R. H., P. A. surgeon, detached from U. S. R. C., *Tahoma*, and ordered on shore duty at Unalaska, as fleet surgeon, Aug. 9, 1910.

Guthrie, M. C., P. A. surgeon, granted 1 month's leave of absence from Oct. 1, 1910.

Hunt, Reid, Professor, Chief Division of Pharmacology, Hygienic Laboratory. Detailed to attend the Second International Conference for the Study of Cancer to be held in Paris, Oct. 1-5, 1910, and the Conference of the International Antituberculosis Association to be held in Brussels, Oct. 5-8, 1910.

Porter, Joseph Y., Quarantine Inspector, granted 30 days' leave of absence from Sept. 20, 1910.

Barnes, W., acting asst.-surgeon, granted 30 days' leave of absence from Oct. 5, 1910, with pay, and 1 month's leave of absence from Nov. 5, 1910, without pay.

Clark, E. S., acting asst.-surgeon, granted 30 days' leave of absence from Sept. 13, 1910.

Clerborne, A. B., acting asst.-surgeon, granted 7 days' leave of absence from Sept. 24, 1910. Paragraph 210 Service Regulations.

Gill, S. G., acting asst.-surgeon, granted 1 day's leave of absence Sept. 17, 1910. Paragraph 210 Service Regulations.

Kimmel, W. A., acting asst.-surgeon, granted 30 days' leave of absence from Sept. 25, 1910.

Rnsh, John O., acting asst.-surgeon, granted 10 days' leave of absence from Sept. 24, 1910, without pay.

Schuster, B. L., acting asst.-surgeon, granted 1 day's leave of absence Sept. 10, 1910.

Stuart, A. F., acting asst.-surgeon, granted 30 days' leave of absence from Oct. 1, 1910.

Wakefield, H. C., acting asst.-surgeon, granted 14 days' leave of absence from Oct. 10, 1910.

Society Proceedings

COMING MEETINGS

- Am. Ass'n. for Study and Prev. Infant Mort., Baltimore, Nov. 9-11.
- American Association of Railway Surgeons, Chicago, October 19-21.

KENTUCKY STATE MEDICAL ASSOCIATION

Fifty-fifth Annual Meeting, held at Lexington, Sept. 27-29, 1910

The President, DR. JOSEPH E. WELLS, Cynthiaana, in the Chair

Diagnostic Significance of Headache to the Internist

DR. J. W. KINCAID, Catlettsburg: Pain is a subjective symptom and headache is an attack of diffuse pain, affecting different parts of the head and not confined to a particular nerve. Headaches must be considered in connection with the patient's personal and family history, and this should be obtained as a matter of routine, like making a physical examination. The number of lives sacrificed, owing to cerebral syphilis and nephritis untreated, except by "patent medicines" and headache tablets, until the crisis comes like a thunder-clap out of a clear sky, will never be known. History of migraine or epilepsy is very suggestive; as is also a previous history of a weak nervous system. One should never fail to inquire about a former luetic infection and also regarding the use of alcohol and drugs. The duration of the headache, its periodicity, the character of the ache, and accompanying symptoms during an attack and the presence of cardiac pulmonary, renal or gastro intestinal systems must be investigated. Another point is the hour that the headache occurs.

In the physical examination the first point is to exclude the neuralgia and migraine. Neuralgic pain is distinguished by

sharp pain referred to certain points along the course of the nerve with sensitiveness of the epicranial structures to which these nerves are distributed. The patient will often state that the pain is relieved by hot applications.

Examination of the urine is most important, headache being a frequent early symptom of nephritis; the headaches of uremia are easy to diagnose. Nephritic headaches are often associated with symptoms of arteriosclerosis, with the addition of nausea, vomiting and possibly somnolence. Headache in the pregnant woman should excite suspicion at once and demands an immediate examination of the urine. It is often a premonitory symptom of an approaching eclampsia, which may be forestalled by vigorous eliminative treatment.

Examination of the nervous system is, perhaps, the most important of all. Collins says that 40 per cent. or more of all headaches are due to neurasthenia. Headache is of common occurrence in the early stages of infectious diseases. As an initial symptom of typhoid it is often so severe and persistent as to demand opiates for its relief.

Diagnostic Significance of Headache to the Surgeon

DR. A. DAVID WILLMOTH, Louisville: In headache we are called on to minister to one of three conditions, the aim of all surgery: to relieve suffering, to restore function and to save life. Every case of frequently recurring headache calls for very careful and painstaking examination, not only of every organ in the body, but of the urine, blood and blood-pressure as well. The reflexes, sensations and other nervous functions must be tested out either by the surgeon himself, or, better, by a competent neurologist. An accurate history should be obtained and a continued series of observations made, this being necessitated by the loss of memory that frequently accompanies headache. Surgical headaches may be divided into two classes as regards cause: those in which the pathology is located in the brain, membranes, skull or scalp; and those in which the lesion is located elsewhere in the body and the head symptoms are secondary, the so-called reflex headaches. Headaches must also be classified as to the character of pain experienced by the patient, and, last, they must be divided as to their location on the head.

Patients recognize five kinds of pain: (1) Pulsating and throbbing; (2) dull and burning; (3) constricting, squeezing and pressing; (4) hot and burning; (5) sharp and boring. Under the first head come the vasomotor troubles, such as migraine; to the second belongs the toxic and dyspeptic headache; to the third the neurotic; to the fourth the rheumatic and the anemic, and to the fifth the hysterical and epileptic.

The pain may be frontal, occipital, parietal, vertical, diffuse, or combinations of any of these. Localized pain, with tenderness on pressure, suggests strongly that the pathology is superficial, and that the bones or membranes are affected. If all the branches of the fifth nerve are affected, it is strong presumptive evidence that the trouble is intracranial, while, when only one branch is affected, it is generally extracranial. If headache be accompanied by epileptiform phenomena, disturbances of speech and facial paralysis, at or near the period of adolescence, we probably have to do with organic disease. The correctness of the diagnosis is enhanced if there is vomiting and inability to retain food, in the absence of gastric symptoms, and certainly if the vomiting is projectile in character. The following points of significance should be attached to vomiting due to organic brain disease: (1) the influence of the position of the head, the vomiting being frequently arrested in the horizontal and recurring in the erect position; (2) the absence of premonitory nausea; (3) the peculiar character of the vomiting, the contents being ejected without strain of retching, just as in babies at the breast; (4) the irregularity of the radial and cardiac pulse which will be augmented by the vomiting. It may be said, however, that vomiting is only to be looked for in the early stages.

In organic disease the pain is generally constant; there are rarely periods of perfect freedom. At times the patient will shriek from the suffering. This may be said of migraine, but in migraine the paroxysms are separated by days or weeks of freedom, comparative or complete. The pain of organic disease persists during the night, preventing sleep

or arousing the sufferer. Functional headaches rarely prevent sleep, which indeed often ends the attack. If sleeplessness is a symptom, optic neuritis, vertigo and vomiting should be looked for. If the three constitutional states, marked anemia, kidney disease and lead poisoning can be excluded, optic neuritis with headache is almost pathognomonic of organic disease. Much can be done for patients with headaches found by exclusion to be entirely surgical. If due to adhesions, or any of the conditions not cancerous, relief can be promised. I have found that, if the brain is dealt with gently, it lends itself kindly to almost any amount of handling.

The Diagnostic Significance of Headache to the Specialist in Eye, Ear, Nose and Throat

DR. M. C. DUNN, Henderson: The two most important facts to keep in mind in endeavoring to interpret the significance of headache are, first, that it is an important symptom of a number of functional and organic diseases; and second, that the location, character and duration of the pains are often the means of suggesting the condition or disease on which it depends. We have much yet to learn respecting headache and the remote effect of a disturbed nervous equilibrium on the organs of the chest and abdomen. We also have much to unlearn, many inherent prejudices to overcome and many clinical conclusions to discard before our patients can derive the full benefit of our own advancement.

Discussion on Headaches

DR. D. M. GRIFFITH, Owensboro: Eyestrain as a cause of headache is now universally accepted by the profession, but the credit of intelligently and persistently bringing the subject before the profession is largely due to S. Weir Mitchell. In persistent headache in a patient under 40 in whom there is no assignable cause, the refraction and muscular balance of the eye should be carefully inquired into by a competent oculist and with the use of a cycloplegic. In my experience the small errors of refraction are those that produce the reflex we call headache, because Nature keeps up a persistent effort to overcome this small error in order to secure good vision, while with a large error she abandons herself to poor vision and secures thereby freedom from the nerve strain. In chronic simple glaucoma, pains may be the only symptom recognized except at the hands of those of considerable experience; and I would admonish the general practitioner not to use cycloplegics in these cases, as the result is always disastrous. I have found that the most frequent cause of one-sided headache is the nose or the accessory sinuses; and in this order of frequency with the sinuses—the frontal, ethmoidal, sphenoidal and lastly maxillary. Many of the worst headaches come from pressure in the middle turbinate region, and I have given relief to many patients by operations which secured relief of pressure. Contrary to the general opinion, diseased tonsils may be the cause of headache, as proved by several of my own cases during the past year. A school teacher, who had suffered from headaches for three years, was given complete relief by removal of the tonsils in their capsule.

DR. J. D. KISER, Lexington: In a case of periodical pain, which may involve any region, if the headache is one sided, it may be due to trouble with the frontal and sphenoidal sinuses. If the sphenoidal sinus is involved, it is deep seated, going back toward the attic to the head, and often the removal of the middle turbinate will relieve the troubles. In these cases it is essential to secure free drainage. There may be blocking of the ostium, with obstruction to ventilation, the condition being brought about by a swollen condition of the membrane. In case of sphenoidal involvement, a condition may develop in the sphenoidal sinus which will undermine the sella turcica; and pressure on the optic nerve may produce blindness. From an ophthalmologic standpoint, there is temporal, frontal and occipital pain or discomfort extending into the neck, and sometimes down into the shoulders themselves, indicating eyestrain or asthenopia. It may be due to muscular imbalance, to retinal asthenopia, or if due to muscular imbalance the internal muscles may lack the power of con-

vergence. Especially is this the case when there is hypermetropic astigmatism due to failure of the ciliary muscle to act in adjusting the accommodation. The majority of these patients can be absolutely cured or greatly benefited by correcting the refractive error and adjusting properly fitted glasses.

DR. F. H. CLARK, Lexington: I believe that toxemia is the largest of any one cause of headache, but more than one cause is involved in the production of headaches. These toxemias are of two general types, like lead poisoning and acid intoxication, due to a defective liver or kidneys. In many so-called neurasthenias, I believe that the headaches are modifications of migraine.

DR. CURRAN POPE, Louisville: If headache is a symptom and symptomatic, how can we come to a conclusion about headache, unless we, like the jury, are in possession of all the facts? No practitioner has a right to diagnose headache until he first possesses all the facts in any given case. The history of syphilis may be the most unreliable that was ever given. Do not believe it. Do not accept it. You are given scientific methods of approximating an accurate diagnosis through the methods of Wassermann and Noguchi. I do not accept the question of specific headache unless it is based on the serum diagnosis. A headache may disappear when the patient's mental attitude is corrected, without the use of either hypnotism or suggestion. In my opinion, the question of eyestrain, of the various other reflexes arising from the sinuses and otherwise, occupies a very definite, clear, well-defined position. If a condition exists, correct it. My principle has always been to refer these patients to some good specialist, in order that the causal condition may be removed if it really exists. The principal thing is to lift any burden from the individual, and it is only by eliminating one after the other of the possible causes and getting down deep into the question of headache that we will cure these patients. I am not speaking of organic lesions, which are questions for diagnosis and operative work, if possible.

DR. JOHN J. MOREN, Louisville: I want to go on record as saying that true migraine has never been cured by properly fitting glasses. The number of attacks may be lessened and the amount of pain influenced, but these true cases of migraine are never stopped. That has been my experience. My method is to try to distinguish, if I can, the character of the pain. In a patient with pain over the fifth nerve, a true darting, actual pain, the location of the pain being very definite, what is causing it? Is it something in the blood? Is it something irritating the nerve? That should be our line of thought. If an individual complains not of headache, but of the sensation of having a band around the head, or a sensation of weight, it is not a pain, but a sensation, and that will give a clue in looking for hysteria or neurasthenia so called. Look for eyestrain. Look out for various reflex causes. I would emphasize the importance of studying the character of the pain, and there is nothing that will help us more in this than the location of pain.

DR. J. A. STUCKY, Lexington: It is evident that this great bugbear which confronts the medical profession, headache, is not clearly understood, and that after all the diagnosis must be made by elimination. Undoubtedly, toxemia is the basis of the majority of cases of headache. But what causes the toxemia? It may be intestinal. It may be due to trouble in the accessory sinuses. If the sinuses are involved, how does that produce toxemia? Not by production of pus. When the sinuses begin to suppurate, the headaches begin to get easy. It is the negative pressure; it is the rarefaction in the anterior ethmoid cells, in the sphenoidal sinus, in the frontal sinus, and it is necessary to relieve the negative pressure before opening the sinuses. How do refractive errors produce headache and toxemia? By lowering vitality, lowering the power of resistance. I can take a little cotton and give any of you toxemia in twenty-four hours by blocking up the attic of the nose. There is pain as the toxins result from retained secretions. Retained secretions become pus or purulent after a while. We should bear in mind the possibility always of intracranial complications.

(To be continued)

AMERICAN ASSOCIATION OF OBSTETRICIANS AND GYNECOLOGISTS

Twenty-third Annual Meeting, held at Syracuse, N. Y., Sept. 20-22, 1910

The President, DR. AARON B. MILLER, Syracuse, in the Chair

Officers Elected

The following officers were elected for the ensuing year: president, Dr. Herman E. Hayd, Buffalo; vice-presidents, Drs. Henry Schwarz, St. Louis, and Lewis C. Morris, Birmingham, Ala.; secretary, Dr. William Potter, Buffalo (re-elected); treasurer, Dr. X. O. Werder, Pittsburg, Pa. (re-elected).

Louisville, Ky., was selected as the place for holding the next annual meeting; time, Sept. 25-27, 1911.

The President's Address: Gynecology

DR. AARON B. MILLER, Syracuse, N. Y., after speaking of the recent advances that have been made in obstetrics, gynecology and abdominal surgery, said in part: The scope of work of the members of this Association has gradually increased since the knowledge of bacteriology has illumined the way to a more accurate diagnosis and given us a known pathology. In 1882, Dr. J. Marion Sims made the prophetic statement that it would become possible to open the abdomen in gunshot and stab wounds, to repair and thereby lessen the mortality attending these injuries. In the master mind of Sims the seeds of advancement had taken lodgment. His observations and associations abroad had given him an oversight into the possibilities of the future, the possibility of surgery becoming a science, founded on findings that were indisputable. With the advent of bacteriology came a new school of surgeons, whose knowledge was founded on facts, not theories, and like the mariner who consults his compass, had known laws to direct them: The field of gynecology, the pelvis, with the abdomen appended, was their hunting ground, and like an army marching to victory, the field was soon taken. Now all the organs of abdomen and pelvis have felt the results of advancement and have yielded of their pathology abundantly. The knowledge of the real etiology of disease robbed surgery of its terrors and opened the pelvic and abdominal fields for investigation through a perfected technic, with but little fear of serious consequences attending thorough exploration, thereby revealing the living pathology and rendering the arrest or elimination of disease possible. In obstetrics, marked results have been obtained through a knowledge of infection. From a heavy death-rate following confinement, the technic carried out in hospital practice has almost eliminated the mortality.

In the field of gynecology, the disease that stands as a lone sentinel against the advancement of science is cancer. Having existed since the earliest history of medicine, it has withstood all investigation. While all forms of maladies have crumbled in ruins about it, it has continued its ravages until many thousands of people in the United States are dying annually of this disease. Cancer of the breast, recognized and treated in its inception by early operation, has resulted in a greater percentage of cures, and materially lessened the mortality. It is the consensus of opinion that cancer of the stomach has its origin on the site of an ulcer. Prophylactic treatment prevents the cancer by curing the ulcer. Prophylaxis must be introduced in the prevention of cancer of the uterus by early repair of lacerations. Traumatism is the accepted factor in inducing cancer of the breast.

Gynecologists have been slow to impress on the public, and to enlighten women especially, as to the great dangers that threaten them through ignorance of venereal diseases that are liable to be brought to them by unsuspected avenues. This subject has been enshrouded in such mystery that boys and girls have grown to mature manhood and womanhood, ignorant of the laws that should govern their lives, for fear that the knowledge of sexual diseases might lead to contamination. Proper environment should be placed about the growing child to aid in development and to protect when dangers threaten, thereby promoting stronger, healthier bodies.

Present Status of the Colon Tube

DR. H. WELLINGTON YATES, Detroit: Seldom, if ever, are soft rubber tubes admitted into the normal colon. When an endeavor is made to force the tube upward, even by the gentlest manipulations, it is found to coil itself up in the rectum and there do positive harm, because of pressure irritation and the consequent inability to retain the enema. In perhaps half the instances it is impossible to tell when the tube is coiling up on itself, even when we suspect it. Colon tubes as such are of no value, because they do not reach the colon, and they are mischievous in that proportion as we endeavor to force them high up. Water or fluid injected four or five inches into the rectum is carried upward into the colon and may be found at the cecum in ten minutes. There is good reason to believe that a reversed peristalsis is set up when fluids are injected into the rectum. The introduction of a tube more than five inches for colonic irrigation or therapeutic enemata is useless and likely to defeat the object desired.

DISCUSSION

DR. L. S. McMURTRY, Louisville, Ky.: It has been discovered that what we formerly called high enemata were not high enemata; that if we introduced a soft rectal tube into the bowel and kept on passing and passing the tube it reached to the sigmoid and then began to coil on itself and did not pass into the bowel. Years ago, therefore, I abandoned all efforts at what is known as high enemata, recognizing that it was a deception. It seems that this has an important bearing on some important features of treatment of the colon, especially ulcerative conditions. For instance, if the cecum be opened the colon can be irrigated from below or above, but if there is no opening in the caput coli it is almost impossible, no matter what position the patient is in, to get water up into the transverse and ascending colon, but if an opening is there and water is thrown in the gas will pass out of the opening in the cecum. An opening also provides a means of medicating the entire mucous surface of the colon, but without such an opening it is impossible to do it.

DR. J. G. SHERRILL, Louisville, Ky.: It has been demonstrated by Dr. Hanes that fluids pass with difficulty into the colon and cecum because of the amount of gas found in this portion of the bowel, and that if an opening be made in the cecum or appendix the gas will pass out and fluid will go in. Dr. Hanes uses coal oil in the treatment of amebic dysentery with gratifying results.

DR. LOUIS FRANK, Louisville, Ky.: I wish to emphasize the therapeutic value of injections of fluids for medication in high bowel lesions by the use of the inverted posture.

DR. FRANCIS REDER, St. Louis: Dr. Soper and I have done considerable work in the field of rectal intubation and the injection of water into the lower bowel, endeavoring to get it as high up as possible, and we found that if we took an ordinary colon tube and introduced it into the bowel it was impossible to get above the promontory of the sacrum. The ordinary soft tubes coil on themselves and the fluids injected do not reach beyond what is called the shelf of the rectum.

DR. W. YATES, Detroit: The purpose of my paper was to show the possibility of not only medicating the rectum, but the sigmoid and colon with fluids.

Diagnosis of Chronic Surgical Lesions in the Upper Abdomen

DR. C. N. SMITH, Toledo, O.: The diagnosis of these lesions is made with accuracy by the anamnesis alone. Differentiation of cholelithiasis from ulcer demands recognition of the initial symptoms which are frequently overlooked. The accepted symptomatology of cholelithiasis and ulcer is largely that of their terminal events. The most striking feature of ulcer is periodicity of painful attacks, alternating with intervals of relief. As complications occur, the attacks are more severe, becoming nearly continuous. In cholelithiasis the stomach distress, compared with the pain of ulcer, is of much less intensity, occurs sooner after the taking of food, is the pain of a full stomach and does not progressively increase and reach its height in from two to five hours after meals. In cancer of the stomach, generally a sequence of ulcer, symptoms of

the latter gradually merge into those of the former. Vomiting may or may not be a dependable symptom in cancer; anemia is a most important symptom. Chronic pancreatitis being largely a terminal event in cholelithiasis, the diagnosis of the former is facilitated by recognizing the initial symptoms of the latter. Valuable pancreatic symptoms are found in the feces. Chemical and microscopic examinations are necessary. The Cammidge reaction is of questionable value. In movable kidney during Dittel's crises, the swollen and tender kidney, especially when jaundice is present, may be mistaken for an inflamed and distended gall-bladder. Differentiation is made from appendicitis, rupture of the gall-bladder and renal colic. The appendix may mimic successfully many of these lesions.

DISCUSSION

DR. R. T. MORRIS, New York: We cannot always make a diagnosis of the presence of gall-stones. We should not fall into the trap of speaking of cholelithiasis. We should not make that diagnosis. It is a dangerous thing. We should speak of cholecystitis, as the gall-stones are merely incidental to cholecystitis.

DR. J. PRICE, Philadelphia: If the internists made diagnoses in these cases early and referred them to surgeons for operation promptly, many more lives could be saved than are now saved.

DR. R. E. SKEEL, Cleveland: If one wishes to secure as complete and certain a history as is necessary to make a diagnosis in the class of cases under discussion, unusually intelligent patients must be met with, but I do not see any possibility of the average patient giving such an accurate history of his case as will lead the surgeon to make a diagnosis from that alone.

Problems in Uterine Cancer

DR. WALTER B. CHASE, Brooklyn: In the present state of our knowledge, early extirpation of the uterus offers the best chance of cure. Where there is considerable involvement of the vaginal structures, the first indication is high amputation of the cervix and removal of the vaginal involvement. If the uterine stump does not heal hysterectomy should usually be undertaken, providing there is normal mobility of the uterine body. Vaginal hysterectomy subsequent to cervical amputation is difficult if not impracticable; fixation of the uterus, if not dependent on other coexisting causes, contraindicates hysterectomy. If the parametria are involved radical measures are contraindicated. When subsequent to the removal of the cervix and the vaginal growth hysterectomy is expedient, the abdominal route should be chosen, because vaginal hysterectomy is neither easy nor practicable and because there should be as little interference as possible with the remaining cicatrix. The value of hysterectomy for cancer of the body of the uterus as a secondary operation, though not recognized by the average practitioner, has a value which cannot be gainsaid in a certain class of cases. I object to the palliative treatment of uterine cancer by potent escharotics, both on account of the inability to limit the area of their destructive influences, and the violent pain attending their application. The thermo-cautery is the palliative measure *par excellence*. The electric cauterizer leaves nothing to be desired, but if one is under the necessity of using a Paquelin cauterizer, which is practically as satisfactory, it is hazardous to attempt the operation with a single apparatus. A variety of straight and curved platinum knives and home-shaped instruments are needful. For securing the best results, care is needed in protecting the vaginal walls from excessive heat and skill in removing all diseased structures compatible with the anatomic relations of the healthy and diseased structure. My results from the use of the thermo-cautery have been satisfactory. The *modus operandi* seems to be, first, it has the power to destroy or inhibit specific germs beyond the area of actual destruction of tissue; second, it closes the lymphatics, thereby limiting absorption; third, it promotes healing, diminishing hemorrhage and purulent discharges; fourth, when the destruction of malignant growth extends to normal structure, it facilitates the advent of healthy cicatrization; fifth, by

following the use of the cautery, by daily gentle irrigation with an antiseptic of not more than one dram to a quart, always avoiding peroxid of hydrogen, and dressing with antiseptic gauze, the suffering is greatly lessened and sometimes almost wanting, until the inevitable end; sixth, well authenticated cures have followed this treatment, in which no expectation of cure was suggested.

Such information should be disseminated among women as would teach them the necessity of seeking assistance early in cancer. Public interest should be awakened among philanthropic men and women, in order that as much may be done for cancer patients as has been done for those suffering from tuberculosis, and that facilities may be provided for the care of the numerous patients with uterine cancer who are without financial resources.

Statistics of Cancer in the Female

DR. K. I. SANES, Pittsburg, Pa.: This paper is based on statistical data collected from the latest 8 annual reports of the Bureau of the Census and the latest reports of 219 hospitals. The figures show that the proportion of deaths from cancer to the total number of deaths from all causes are in females, 1 to 17.7; in males, 1 to 33.4; the proportion of deaths from cancer in the past 35 years, to the total number of deaths in the same period, are, in females, 1 to 9.8; in males, 1 to 18.5. Taking the relative frequency of cancer in both sexes, it is found that according to the mortality statistics of the United States Bureau of Census, 62 per cent. of those that died of cancer are females and 38 per cent. males; according to the hospital statistics, 66.5 per cent. are females and 33.5 per cent. males. We see then that cancer is an exceedingly common disease in the female and is seen about twice as frequently in females as in males. Whether based on mortality figures or on population figures, there is clearly shown an increase in cancer from 1900 to 1908. In the 8 years there was an increase in cancer mortality from 1 in 22.8 deaths to 1 in 16.6 deaths, or from 63 per 100,000 population to 74.3. The question is frequently raised whether the gradual increase in mortality is not due to changes in the methods of reporting deaths and to the greater accuracy in the diagnosis of cancer, especially in view of the slight variation for the 5 years between 1903 to 1907. Hospital statistics, if carefully and properly compiled, can be utilized to great advantage by the profession in many ways. The modern hospital organization and facilities, the gradual increase of the number of hospitals all over the country, the more general use of the hospitals by the sick, the greater readiness by the profession and patients to adopt surgical measures for surgical diseases—all this makes the hospital the most valuable source of statistical medical information. But to get accurate information, not only must each hospital have a careful conscientious statistician, but the visiting members of the hospital staff must see that their diagnoses are carefully reported in the hospital records.

Discussion on Cancer

DR. W. H. HUMISTON, Cleveland: I have had but five cases of the so-called inoperable cancer of the uterus, and in these I resorted to the Wertheim operation, making a very wide dissection. Four of these patients are still living.

DR. R. WALDO, New York: A decided advance has been made in operative work for the treatment of cancer of the uterus. I believe to-day that almost any one, who is competent to pass judgment, will advise a radical operation on any woman 45 or 50 years old, who has a persistent hemorrhage from the uterus, unless there is a polypus or something of that kind which he can thoroughly demonstrate is the cause of the hemorrhage. Occasionally a uterus will be removed at that age which is not cancerous, but many more uteri will be taken out that are the seat of incipient carcinoma. Generally I prefer the vaginal route in operating in these cases.

DR. M. I. ROSENTHAL, Fort Wayne, Ind.: The early symptoms of cancer of the uterus are hemorrhage and discharge, and when we get a case of cancer of the uterus early it is a pure accident. The only saving point we have is the fact

that some carcinomata are less malignant than others, or some are more malignant than others, and when we are dealing with carcinoma of the fundus of the uterus we are ordinarily dealing with a carcinoma that is less malignant, and a destructive operation through the vagina in such a case is uncalled for. When we are dealing with carcinoma of the portio vaginalis we are dealing with that form of cancer which is not so malignant. In such cases, ordinary hysterectomy done with cautery will give as good results as any other method. When we are dealing with carcinoma of the portio uteri, which begins in the endometrium higher up, we are dealing with a serious malignant growth in which practically no operation will do good. I have done the Wertheim operation, and reported fifty-seven cases in the *New York Medical Journal* some years ago, with good results in that class of cases.

DR. J. H. CARSTENS, Detroit: I agree with Dr. Rosenthal and Dr. Waldo that it is largely a question of early diagnosis. When a woman has cancer which is so far advanced that the lymphatics and other structures are involved, it is better to let her alone and trust to the *vis medicatrix naturæ*.

DR. T. B. NOBLE, Indianapolis: I look on cancer of the cervix or of the uterus as an analogue to carcinoma of the breast. It should be so considered and diagnosed, and decidedly so with regard to treatment.

DR. J. PRICE, Philadelphia: I look on the vaginal operation as one of the simplest in surgery, but in operating for the removal of carcinoma of the uterus, in which adjacent structures are involved, and wide and deep dissection is necessary, it is better to operate through the abdomen.

DR. F. REDER, St. Louis: The whole question resolves itself into early diagnosis, skilled operative measures, and education of patients.

DR. E. J. ILL, Newark, N. J.: In operating for cancer of the uterus no surgeon can open up an extensive area of cellular tissue without spreading the cancer cells. The safest operation in cervical carcinoma is to start from above, separate all adhesions, separate all attachments to the uterus and to its surroundings, and then go from below and lift the mass right out and cut it off with a cautery, as has been suggested by Werder.

Treatment of Intestinal Obstruction Due to Malignant Neoplasm

DR. M. I. ROSENTHAL, Fort Wayne, Ind.: The general results from operations for cancer of the bowel, as shown by a review of 328 cases from the literature, are as follows:

1. Obstruction of the bowels due to carcinoma is not hopeless as to cure by radical operation. Incomplete excision of all cancerous tissue must necessarily result in recurrence of the growth.
2. Anastomosis without resection of the malignant growth should be the operation of election in obstruction due to cancer, when the radical operation, that is complete excision, is impossible.
3. Anastomosis without resection low in the pelvis, when the bowel is accessible with difficulty, can be successfully accomplished by the assistance of the Murphy button.
4. Anastomosis without resection probably bears the same relation to cancer of the bowel as does gastroenterostomy to cancer of the pylorus.
5. The clamp and suture method of bowel anastomosis is practical, rapid and trustworthy, and applicable in a large variety of bowel cases requiring resection or anastomosis.

Diagnosis of Tubal Abortion and Rupture

DR. C. E. CONGDON, Buffalo: The general indication for operative interference as promptly as possible cannot be gained. Schauta, for example, after a careful study of the literature, collected 123 operative cases, with a mortality of 5.7 per cent. and 121 cases treated palliatively, with a mortality of 86.89 per cent., although in another series of more carefully selected cases, he found the mortality by palliative treatment to be only 65 per cent. To recapitulate the diagnostic features:

1. There is sudden pain, nearly always, the exceptional cases being those with sudden collapse, as in two cases which I reported in July, 1909.
2. Florine hemorrhage occurs within 48 hours after the initial pain. This symptom and sign is common to all cases of ruptures or abortive tubal pregnancy.
3. If to this we add collapse the diagnosis is complete. If collapse is lacking or slightly marked it is on account of gradual internal hemorrhage when on examination the cul-de-sac will show a progressive bulging.

Results at Lebanon Hospital of Deferred Operations for Extrauterine Pregnancy

DR. RALPH WALDO, New York: Many patients are brought into the hospital in a desperate condition, and in the 81 cases that I report there have been but 3 deaths. It was thought that 2 or 3 patients would die in the ambulance. They were freely stimulated and reached the hospital moribund. At no time after reaching the hospital would they have stood an anesthetic or the slightest operation. Necropsies proved the diagnosis of ruptured extrauterine pregnancy to be correct. The third patient who died presented one of these unfortunate cases, occasionally encountered by all surgeons, in which the patient was making an absolutely normal convalescence, when she suddenly died from pulmonary embolism. Seventy-eight other patients were operated on by the abdominal route, and recovered. After a severe hemorrhage another does not take place in less than from a week to ten days. In from two to seven days, depending on the condition, the abdomen is opened from above. The clots and free blood are rapidly removed with the hand and dry gauze sponges, but the abdominal cavity is never irrigated. Formerly, when the patient had lost a large amount of blood we put a quart or two of normal saline solution in the abdominal cavity, and left it there to be absorbed. More recently, this saline solution has been given in rare instances in the cellular tissue by hypodermoclysis, or more frequently in the rectum. In one instance only in the above cases was the abdomen drained; in all others it was closed. The entire operation required from eight to twenty minutes. I prefer the abdominal route, because the operation can be performed much more quickly, and, when the mass is high up and the vagina small, much better. I perform many operations on the tubes and ovaries through the vagina. So I am not prejudiced in favor of the abdominal route.

Discussion of Extrauterine Pregnancy

DR. L. F. SMEAD, Toledo, O.: A woman, aged 25, was brought to me with a diagnosis of ectopic pregnancy. This was her second pregnancy. In her first pregnancy she was cared for by the physician who brought her to me, so that we knew the exact condition. There were no abnormal symptoms. The history of the case was that for two or three days there was slight pain in the right side and during the night preceding the day on which I saw her there was a slight flow. There was no tenderness in the abdomen particularly and on vaginal examination I found a slight mass over the right cornu of the uterus. The question was whether it was ectopic pregnancy. First, I considered the pregnancy possibly tubal, with a slight rupture into the broad ligament; second, I thought of interstitial pregnancy in the cornu, and third, I considered the possibility of a simple development of the placenta in the right horn of the uterus. The uterus was fully as large as it should be at about three months. As the examination was satisfactory with the abdominal muscles quite relaxed, I decided later that probably a threatened abortion was taking place with the placenta in the right cornu of the uterus, and I decided to treat the case in that light, as I was not anxious to open the abdomen in a normal pregnancy or to overlook interstitial pregnancy in the cornu of the uterus. Two months have elapsed since I saw her. The symptoms have disappeared and apparently a normal pregnancy is progressing.

DR. H. W. LONGYEAR, Detroit: This matter of deferred operation in extrauterine pregnancy in the presence of shock has been threshed out in this association several times and, if I remember rightly, the consensus of opinion has been decidedly in favor of immediate operation. It is my opinion that operation should be done in these cases even in the presence of extreme shock. I know of no other class of cases in which we wait in the presence of hemorrhage for shock to cease. We operate primarily for the stoppage of hemorrhage, and to wait for shock to cease in some cases would be fatal.

DR. J. H. CARSTENS, Detroit: Dr. Longyear has struck the keynote. In hemorrhage from a leg that has been cut off, we do not wait for shock to subside, but we stop the hemorrhage. I believe in operating in these cases promptly.

DR. W. H. HUMISTON, Cleveland: I have had an unusual record in cases of ruptured tubal pregnancy, that is, I have

yet to have my first fatal case, and I operate on these patients as soon as I can get them ready for operation, or get my instruments there and assistants. I do not care what condition the patient is in, whether in shock or not.

DR. H. S. LOTT, Winston, N. C.: I want to emphasize the character of the pain. Several times I have made a diagnosis of ectopic pregnancy in the early weeks by sitting by the side of the bed of the patient and watching her for several hours, and the pain is always recurrent, rhythmic, and explosive, whereas if the appendix is the seat of trouble the pain is continuous without intermissions, and often without remissions.

DR. J. G. SHERRILL, Louisville, Ky.: I agree with Drs. Carstens and Humiston. If we have a ruptured vessel internally we consider it one of the most dangerous forms of hemorrhage with which we have to deal. If we had a case of gunshot wound of the abdomen we would not wait to open that abdomen. The same course therefore should be pursued in cases of ruptured extrauterine pregnancy.

DR. E. GUSTAV ZINKE, Cincinnati: There are exceptional cases. Extrauterine pregnancy is not always the same in every case. Some of these patients recover without operation. We find these symptoms when we operate for other conditions. Tubal pregnancy terminates in three different ways, namely, tubal abortion with absorption of the ovum rupture between the layers of the broad ligaments and tube ruptured into the peritoneal cavity. In the case of rupture between the layers of the broad ligaments we have a well-defined tumor form. In rupture into the peritoneal cavity we have sudden shock and all the signs of internal hemorrhage, and in such a case prompt action is indicated, and it is for the operator to decide whether an operation should be performed at once or whether he has time to wait. In cases in which the tube ruptures into the peritoneal cavity with severe hemorrhage, with all the symptoms of shock, we do not see the patients in the hospital, but usually at their homes or in places where opening the abdomen is prohibited. It would mean death to operate at once, because neither the surgeon nor the patient is prepared. Experience has taught us that by putting these patients in the recumbent position, and keeping them there with an icebag over the abdomen and lowering the head, often within half an hour or an hour, improvement takes place. The pulse begins to get stronger, and with the appearance of a stronger pulse, or digital examination, we feel the formation of a tumor through the vagina. In cases in which that tumor does not appear the vaginal vault becomes more or less flattened. There is no resistance. You feel nothing apparently. In these cases hemorrhage goes on. In the cases in which a tumor forms we can afford to wait longer and encapsulation will take place and the patient can be operated on with absolute safety within a few days or even weeks.

DR. L. S. McMURTRY, Louisville, Ky.: The diagnosis is easy in these cases. I have known women who have had one attack of tubal pregnancy and who were then operated on make the diagnosis themselves in the second instance and call the physician and tell him the condition that existed. I have one instance of that kind in mind now, and there is no trouble with the diagnosis and the treatment. When a woman is bleeding to death inside there is only one indication and that is to operate as soon as possible.

DR. C. L. BONFIELD, Cincinnati: I want to emphasize the point that in these cases, by the time the operator gets to the patient, usually the hemorrhage has taken place and the surgeon does not operate to stop hemorrhage, but to relieve shock, because in the majority of cases the hemorrhage has already stopped.

DR. W. B. CHASE, Brooklyn: Every member of this association believes he is grounded in the principles of surgery, but we have different methods of reaching the same end. We cannot make a universal rule which will apply to every case of tubal pregnancy. The man who attempts to do it will go wrong more than half of the time. Every case must be treated according to the findings, and according to whether the physician is prepared to treat it at the time.

DR. J. PRICE, Philadelphia: I feel that cases of ruptured ectopic pregnancy and all perforative forms of disease belong to the calamities, and we should be prepared to operate

promptly. The surgeon should be the cleanest and most prepared man living.

DR. C. E. CONGDON, Buffalo: It is not my policy to cross swords with my friends, but when they make the assertion that the diagnosis of ectopic pregnancy is always easy and that any one can make it without any preparation I certainly must take exception to the statement. The members of this association mean that they can make a diagnosis, but not the average general practitioner.

DR. R. WALDO, New York: A mistake made much more frequently than any other is that the patient is suffering from incomplete abortion.

The Breast of the Expectant Mother; Its Care Before and During the Period of Lactation

DR. FRANCIS REDER, St. Louis: To prepare a nipple properly the expectant mother is instructed to use soap and water freely. After drying the breast, gentle friction with a rough towel or flesh brush is made for about five minutes. Following this rubbing, the nipple is massaged by rolling and kneading it between the fingers, gentle traction being made during these manipulations. Olive oil may be used freely during the process of massage, which is to be done twice daily. It is surprising how an almost hopeless appearing nipple in a comparatively short time will assume the characteristics of a normal one. The application of alcohol and astringent lotions is to be condemned. A nipple cared for with these agents will become large, hard and inelastic, presenting deep corrugations, which will impede the healing of any excoriation or fissure, should such a lesion occur. The pain accompanying such a lesion brings many hours of suffering to the mother. A nipple prepared by systematic massage will usually withstand the strain of the nursing period without mishap. Its care after the child has commenced to suckle is one of simple cleanliness. Thorough ablutions after each nursing, to free it from any accumulated secretions, and liberal dusting with boracic acid, which is washed off when the child is put to the breast, are all that is necessary. This treatment must be diligently adhered to. The care of the breast is as important as that of the nipple. Its anatomic structure gives evidence of how readily this organ is amenable to culture, if only instituted properly and at the right time. The breast of a healthy girl that does not show development conforming to the incentive given by puberty should after an elapse of three years be subjected to the stimulating influences of systematic massage, to be continued until a normal equipoise has been attained. By developing the breast at this stage of womanhood, many of the obstacles pertaining to a normal motherhood may be overcome. The massage in reality is an exercise most simple in character. By placing a breast in the palm of each hand and locking the fingers across the chest, the young woman is told to walk about in a well-aired room, and with a full inspiration force the hands apart. This exercise is to be repeated for at least fifteen minutes daily. It is most conveniently carried out on rising and before retiring, and should be continued until satisfactory results show themselves. The normal breast of the expectant mother should receive some attention as soon as the physiologic changes manifest themselves. The breast during the pregnant state does not require the judicious management that the breast demands after lactation has established itself; it is of the greatest import, especially if the breast gives evidence of great fulness and tension with tenderness, that the lactiferous ducts be maintained in as patulous and healthful a state as possible. In short, the secretions in the tubes should not be allowed to become stagnant. It has been demonstrated that the *Staphylococcus albus* and the *Staphylococcus aureus* find entrance into the milk ducts from the skin. It seems to me that this so-called milk fever is the result of these micro-organisms having gained entrance into the lactiferous ducts, and having been stimulated into great activity by finding a proper medium in the milk for their propagation.

DISCUSSION

DR. THERESA BANNAN, Syracuse, N. Y.: I have been looking for milk fever, referred to by Dr. Reder, for 20 years in

practice and have not found it. The question of the care of the nipple of the expectant mother is of far-reaching and tremendous importance. It solves 50 per cent. of the problems of pure milk. It means not only the health of the mother, but the life not only of the first child, when most of the difficulties arise, but of all her subsequent children.

DR. WILLIAM G. DICE, Toledo, O.: It is the general practitioner who is at fault to a great extent. I think most patients are willing to take proper care of the breasts if given proper instruction. I do not recall seeing in my own practice more than two cases of abscess of the breast in ten years.

DR. A. J. RONGY, New York: I thought that the term milk fever had been eliminated from the vocabulary of our obstetrical work. In a record of 6,000 cases, in both hospital and maternity work, we practically do not have what is known as mastitis. We never have cases of suppurative mastitis. It seems to me that the trouble with these engorged breasts, or with so-called milk fever, is in doing too much for the patient rather than doing too little.

DR. J. H. CARSTENS, Detroit: I am opposed to the application of alcohol or tannic acid and other astringents to the breast. The nipple of the mother should be soft and pliable.

(To be continued)

CITY NEWSPAPERS AND SANITARY REFORMS

Thanks to a broader knowledge and a developing public sentiment, it is no uncommon thing to-day to see a great city newspaper stand squarely for sanitary progress. In this respect none ranks higher than the Philadelphia *North American*, whose editorial utterances on public health are sane and sound from both an economic and scientific standpoint. An editorial in a recent issue takes as its text a statement made by one of the candidates for governor of the state. THE JOURNAL is not especially interested in state, local, or party politics, but the editorial in question contains so many good things that it is deserving of reproduction in full had we the space. Strange and well nigh unbelievable as it may seem, the time has apparently arrived, in Pennsylvania at least, when the utterances of a candidate for political preferment on the subject of the health and life of the people are regarded as almost as important as his views on the tariff or on the crime of '73. Such papers as the *North American* are doing a great work in arousing and guiding public sentiment in support of life-saving measures. Under the title, "Grim Advocate of Death," the editor says:

Not in the credulous days of the witch-burners, nor in the dark ages when dirt was considered a corollary of holiness, but in this presumably enlightened year of our Lord 1910, before an audience of sane citizens of Pennsylvania, a man who has not the excuse of illiteracy dared declare this doctrine:

"I shall have something to say in the campaign about our health department. It is the best illustration of what Tilden said was the meddling into the affairs of an individual. It is sumptuary legislation with a vengeance.

"Common-sense application of the rules of education along hygiene has been taught in the public schools for twenty-five years, and we are just now realizing the fact that we know nothing at all about it.

"Of all the cranks in the world, the scientific crank is the worst to deal with, because, while he has truth on his side, he sees nothing but the naked facts. He finds bacteria and germs everywhere, and if you give him enough latitude, he will find impurity everywhere.

"He closes your country school because some one with a case of mumps or German measles has attended.

"He will not allow you to expectorate for fear that some germ will be started upon its deadly mission.

"He objects to having your barnyard drain into the rivulet for fear some germ will contaminate the creek miles below.

"He is just now engaged in working up a sentiment to get the next legislature to require you to erect sun parlors for your cows and biplanes for your chickens. Hogs will be something of the past. Your cows will be required under penalty of the law to drink nothing but filtered water, and their milk must be pasteurized before shipment. He intends to send inspectors into every dairy in the state.

"Not content with an army of 1,200 men on the state payroll with an expenditure nearly as great as the whole expenses of government during Pattison's first administration, he is looking for new worlds to conquer, and soon the veterinary department and the pure food department will form new regiments in the army of the employed."

Had Rip Van Winkle gone to sleep an office-seeking politician and slept a century instead of napping only twenty years, he might have been excused for such a speech. But it is difficult to understand how any man who has been awake and honest during any portion of the past twenty years could so play the part of a voice both from and for the tomb.

Yet that plea for dirt, ignorance, disease and death was made only two days ago as an appeal for votes by a man who knows how to read and write, whom we do not think even intellectually dishonest, who has been elected to the senate of this state, and actually hopes, even after those utterances, to be elected governor of a self-respecting, twentieth-century American commonwealth.

The farmer is studying fertilization, alternation of crops, selection of seeds, retention of the fittest and elimination of the unfit among his livestock, the application of the germ theory to the soil beneath his feet, which has given to Europe three times the grain product per acre that our virgin lands produce.

And here comes a man asking for their votes by such an insult to their intelligence as lies in asking them to go back half a century in consideration of those nearest and dearest to them. . . .

We do not think Mr. Grim ever harbored a thought of murder of his fellow-man or woman. He is simply a victim of the ignorance which he mistakenly supposes is shared by the farmers of Pennsylvania.

It might be well for him to ask the oldest war-time farmer whom he meets about gangrene in hospitals and about how not only a gunshot wound, but any internal abdominal ailment, meant death before the advent of scientific meddlers like Pasteur and Lister.

It might be well for him to ask some farmer's wife, who saw a long-lost but unforgotten baby choke to death in her arms, and later saw a child quarantined from school and saved to health and strength by antitoxin.

He talks of "cranks"—scientific, meddlesome, official cranks—who forbid the pollution of streams and the drainage of poisonous filth into drinking water. And this to the families that, one day each year at least, put fresh flowers on the grave of one whose life was heedlessly wasted by typhoid.

Actually, in this stage of the world's progress, a man dares assert that it is an infringement on personal liberty to put restrictions on expectoration.

Let the man spit where he pleases—in or out of the executive offices of the capitol at Harrisburg. But, in the name of God and Mount Alto and White Haven, and the memory of all the dead innocent victims of dried tuberculosis sputum, blown from the dust under their feet into their nostrils, let there be an end of such noxious demagoguery.

This is not a matter of politics. It is a matter of state shame that a department of Pennsylvania's government, that is the admiration of the other states and not a hissing and a byword to the rest of the country, should be so assailed by a would-be governor. . . .

And the farmers of Pennsylvania know, as well as we know, as well as Mr. Grim should know, the ideal of the health department, the "microbe cranks," the plan that is the one thing

for which this state has earned and is earning the admiration of the civilized world:

A Pennsylvania in which there shall be no young men and women languishing away with tuberculosis; a Pennsylvania in which no children shall die of diphtheria; a Pennsylvania in which there shall be no typhoid, no scarlet fever, no small-pox, no meningitis, no dysentery, no malaria—this is the kind of Pennsylvania which the state department of health hopes ultimately to create.

It does not expect to reach this goal in a year, or ten years, perhaps not in a single generation, but this is the ideal that it has constantly in mind. It recognizes the fact that, so long as any of these diseases exist, their prevalence is a distinct reproach to the state. It is a reproach simply because the method of eliminating them is known.

The old theory of government as a power which protects its citizens only from foreign foes and native marauders is giving way to new standards of civilization. The greatest enemies to the state are those which are unseen, and the first duty of an enlightened commonwealth is to protect its people against them.

POSTGRADUATE COURSE FOR COUNTY SOCIETIES

DR. JOHN H. BLACKBURN, DIRECTOR
BOWLING GREEN, KENTUCKY

[The Director will be glad to furnish further information and literature to any county society desiring to take up the course.]

Second Month—Fourth Weekly Meeting

DISEASES OF THE VEINS

VARICES, PHLEBECTASES

ETIOLOGY: Anatomic and mechanical factors. Age, sex, occupation.

PATHOLOGY: Gross and microscopic changes.

SYMPTOMS: Local and secondary disturbances.

VARICOSE VEINS OF LOWER EXTREMITY: Veins involved. Local changes. Secondary disturbances. Complications.

TREATMENT of veins; of ulcers.

VARICOCELE: Causes. Symptoms. Indications for surgical treatment. Methods of operation.

Monthly Meeting

Etiology and Early Diagnosis of Arteriosclerosis.

Prophylaxis of Diseases of the Arteries.

Surgical Treatment of Aneurism.

State Boards of Registration

COMING EXAMINATIONS

GEORGIA: Regular, The Capitol, Atlanta, October 11. Sec., Dr. I. H. Goss, Athens.

ILLINOIS: Coliseum Annex, Chicago, October 19-21. Sec., Dr. James A. Egan, Springfield.

KANSAS: Topeka, October 13. Sec., Dr. H. A. Dykes, Lebanon.

LOUISIANA: New Orleans, October 18-19. Sec., Dr. A. B. Brown, 108 Baronne Street.

MICHIGAN: Lansing, October 11-13. Sec., Dr. B. D. Harison, 504 Washington Arcade, Detroit.

MISSISSIPPI: Jackson, October 11-12. Sec., Dr. S. H. McLean.

NEW JERSEY: State House, Trenton, October 18. Sec., Dr. H. G. Norton.

NEW MEXICO: Santa Fé, October 10-11. Sec., Dr. J. A. Massie.

OKLAHOMA: Muskogee, October 11. Sec., Dr. Frank P. Davis, Edft.

WYOMING: State Capitol, Cheyenne, October 12-14. Sec., Dr. S. B. Miller, Laramie.

Virginia June Report

Dr. R. S. Martin, secretary of the Medical Examining Board of Virginia, reports the written and oral examination held at Richmond, June 21-24, 1910. The number of subjects examined in was 9; total number of questions asked, 100; percentage required to pass, 75. The total number of candidates examined was 110, of whom 97 passed, including three

osteopaths, and 13 failed. Eight candidates were licensed through reciprocity. The following colleges were represented:

Book Notices

LES GREFFES OVARIENNES ENVISAGÉES AU POINT DE VUE DE LA PRATIQUE CHIRURGICALE. Etude critique, expérimentale et clinique. Par le Docteur Louis Sauré, Prosecteur à la Faculté. Travail de la Clinique de M. le Professeur Quenn. Papier. Price, 3,50 francs. Pp. 96, with 4 illustrations. Paris: G. Steinheil, 2, rue Casimir-Delavigne, 1909.

The author of this work has set out to discover the value of ovarian grafting in surgery and has collected, classified and subjected to careful criticism the various results hitherto obtained from human and experimental surgery. Holding that it has been well established by Limon that there are present in the ovary two kinds of glandular cells and two kinds of secretions, that of the corpus luteum and that of the interstitial cells, and believing that the failure of the latter by removal of the ovary or by their destruction by disease leads to pathologic phenomena, the author concludes that it is reasonable to assume that grafting of the ovary may be of value if it can be successfully done. He then subjects the results of both surgical and experimental operations to clinical and histologic tests.

He arrives at the following conclusions: 1. Autografting, that is, transplanting the whole or a portion of one ovary from its normal seat to another location in the same individual, intraperitoneal or under the skin or intramuscular, is practical, especially when done with a simple technic. The method of grafting with a vascular anastomosis, however, is considered too dangerous. 2. Heterografting, that is, transplanting an ovary from one individual into another, fails in the great majority of cases. To what degree the internal secretion of the ovary is established in the graft is uncertain. 3. The clinical benefit of the grafts are rarely appreciable. 4. The practice of human ovarian grafting is at present very limited, its most enthusiastic advocates having had not more than a score of cases in the last ten years. The booklet closes with a complete bibliography.

THE LAWS OF LIFE AND HEALTH. By Alexander Bryce, M.D. Cloth. Price, \$2 net. Pp. 421, with illustrations. Philadelphia: J. B. Lippincott Company, 1910.

While the layman is interested as never before in the subject of health preservation, the number of books which satisfactorily treat it are lamentably small. Books there are by the score that professedly have been written to meet this need, but the great majority of them are entirely inadequate. Many have been written by those whose literary attainments far outstripped their scientific knowledge, with the result that accuracy has been sacrificed in the attempt to "popularize" the book. On the other hand, not a few are all that could be desired scientifically, but the language is so technical and the style so abstruse as to render the works worthless for lay perusal. Bryce in his "Laws of Life and Health" has managed to steer clear of the Scylla of inaccuracy on the one hand and to avoid the Charybdis of technicality on the other—not that the whole of the book would be intelligible to the ignorant, but the ignorant are not as a rule interested in the subject with which it deals. To the average layman of ordinary intelligence and education, however, the subject-matter will be perfectly lucid. One of the interesting features of the book is the eminently fair and impartial way in which the author deals with what may be called the controversial questions of hygiene and dietetics. Each chapter of the book is prefaced by a "law" in which is expressed the principle underlying the subject-matter of that chapter; furthermore, at the end of each is given a brief and succinct summary. Dr. Bryce's work is one that the physician can conscientiously recommend to his patients, because of the sterling common sense which characterizes it and the absence of "fads" and "notions."

HOOKWORM DISEASE. Etiology, Pathology, Diagnosis, Prognosis, Prophylaxis, and Treatment. By George Dock, M.D., Professor of the Theory and Practice of Medicine, Medical Department Tulane University of Louisiana, New Orleans, and Charles C. Bass, M.D., Instructor of Clinical Microscopy and Clinical Medicine, Medical Department, Tulane University of Louisiana, New Orleans. Cloth. Price, \$2.50. Pp. 250, with 50 illustrations. St. Louis: C. V. Mosby Co., 1910.

Uncinariasis is a historical disease and has been the subject of preventive and remedial measures in European countries for many years. Though it had been suspected or hinted

at as the cause of morbidity, in the South, particularly, and a few cases had been actually demonstrated previously, "the era of productive discovery" in regard to uncinariasis in this country began in 1895 when Smith found the ova in human feces in Texas, and thence knowledge of the disease advanced rapidly through the work of Ashford, King, and Gutierrez in Porto Rico in 1899 and subsequent years, and through the studies of Stiles, who has developed the subject thoroughly and named the parasite most frequently found in this country, *Necator americanus*. The great prevalence of the parasite in Porto Rico and the South has led to a wide study of the subject and the production of a large literature in the weekly and monthly medical publications and its discussion in conferences and medical meetings. Now come the textbooks. This book by Doek and Bass is the result of a study of the literature and of their own work in Louisiana and Mississippi, and describes concisely the history, distribution and zoologic features of the hookworm, the modes of infection and the pathology, symptomatology, prophylaxis, diagnosis and treatment of the disease. Not much space is devoted to treatment, since this is comparatively simple and confined almost entirely to the administration of thymol, although other drugs are mentioned. The chapter on diagnosis, however, is complete, and gives clear and explicit directions for examining the feces for the worms, the larvæ and the eggs, the diagnosis depending on the finding and identification of the ova, as the worms are rarely if at all found in the feces unless oteniacide has been given. The history of ground-itch, the appearance of the patient and the presence of eosinophilia also indicate the presence of the parasite. The subject of prophylaxis is perhaps the most important, on account of the wide distribution of the disease and the production of so much incapacitating morbidity. One of the first and most important prophylactic measures is the cure of those affected. The continuance or extension of the disease depends entirely on the human host who alone harbors the human parasite and deposits the ova in the feces. The prevention of soil pollution is important but secondary, and a full discussion of the subject is given. The book makes free use of the literature and the work of others and well covers the subject of this important disease, which has incalculably retarded the development of an immense and rich section of our country. It contains numerous charts showing the rapid improvement in the blood picture following treatment. It is a practical working book in the management of this disease.

SURGICAL AFTER-TREATMENT. A Manual of the Conduct of Surgical Convalescence. By L. R. G. Crandon, M.D., Assistant in Surgery at Harvard Medical School. Cloth. Price, \$6 net. Pp. 803, with 265 illustrations. Philadelphia: W. B. Saunders Co., 1910.

One of the many advantages of a hospital training or an internship in a large hospital is the opportunity it affords of learning the details of many minor procedures relating to the care of patients both before and after operations, which, heretofore, have formed in a sense an unwritten book and which have descended by word of mouth or by precept from senior to junior members of the house staff.

In this volume appears much of this "unwritten" matter, so that the younger members of the profession need no longer be altogether dependent on their senior brothers for the acquisition of this knowledge. But the contents of this volume are much more comprehensive than might be inferred from the above, as it contains much that is essential for the nurse to know, such as how to prepare the patient for the operation, or for catheterization; how to give enemas; formulas for nutritive enemas; proctocolysis; lavage of the stomach; bandaging; care of bed-sores; invalid and convalescent food receipts; massage and movements, etc.

There is also much that is of great value to the older surgeon, such as the details of many operative procedures; methods of after-dressings, splints, bandages, casts, fixation appliances, etc., and a most interesting and instructive chapter by Sanborn on "Therapeutic Immunization and Vaccine Therapy," in which are taken up the principles of immunization; the role of opsonins; the opsonic index in health and disease; theories relating to infection; auto-inoculation by Bier's method; technique of the preparation, care and use of vaccines in which the clinical side of the subject is quite extensively presented, etc.

It will thus be seen that the volume is more comprehensive in its subject-matter than might be supposed from the title. It is an excellent work and can be heartily commended.

A SYSTEM OF SYPHILIS. In Six Volumes. Edited by D'Arcy Power, M.B., and J. Keogh Murphy, M.C. With an Introduction by Sir Jonathan Hutchinson, F. R. S. Volume IV, Syphilis of the Nervous System. By F. W. Mott, M.D. Cloth. Price, \$13.50. Pp. 502, with 57 illustrations. New York: Oxford University Press, 1910.

This volume of Power and Murphy's series is by one author, and it gains greatly in continuity and balance thereby. Dr. F. W. Mott, to whom the task of writing on syphilis of the nervous system has been entrusted, is notably suited for it, and the editors are to be praised for their wisdom and courage in assigning the entire subject to him, instead of, as is usual, parceling the topics around among numerous writers. After an introductory chapter in which a broad survey of the subject is made, he considers his special topics in the following order: general pathology of syphilis of the nervous system; general symptomatology of brain syphilis; syphilis of the spinal cord; parasymphylis; the cerebro-spinal fluid in relation to syphilitic diseases of the nervous system; the etiology of tabes; general paralysis of the insane; diagnosis of syphilis of the nervous system; tabes; nervous diseases in congenital syphilis; specific treatment of syphilis of the nervous system; general treatment and prognosis of syphilitic diseases of the nervous system. These chapter headings indicate the broad view of the subject which the author takes, and the details are worked out not only with an intimate knowledge of the symptomatology and pathology of syphilis in its multiform attacks on the nervous system, but with an equal familiarity with the recent advances in the subject which have come from the study of experimental syphilis in apes, from the discovery of the *Spirochæta pallida*, and from the application to syphilis of the complement fixation test. Altogether the volume is a very valuable addition to the literature of syphilis and a credit to British scholarship.

GRUNDRISSE UND ATLAS DER SPEZIELLEN CHIRURGIE. Von Georg Seltan, M.D. Second Edition. Lehmann's medizinische Handatlasen. Vol. xxxvii. Cloth. Price, 16 marks. Pp. 624, with 261 illustrations. München: J. F. Lehmann's Verlag, 1910.

The author says that in preparing this work he had two objects in view: first, to present an atlas on surgery which should form a part of Lehmann's "Medical Atlases;" and second, to present a text on surgery which should come in between the too condensed compends and the more elaborate works on surgery, the idea being to condense as much as possible, yet to omit nothing which is essential.

The atlas consists of 80 full-page handsomely colored plates from life and 479 illustrations in the text, many of which are in two and three colors, and all of which are said to be original. As an atlas the work is a good one, and the artists and the publishers are to be congratulated on the excellence of the plates and illustrations. The text is concise and to the point, but possesses no other special advantage.

PROCEEDINGS OF THE EXERCISES AND CONFERENCES OF THE NATIONAL ASSOCIATION FOR THE STUDY AND EDUCATION OF EXCEPTIONAL CHILDREN. Inaugurated on the occasion of the Tenth Anniversary of the Groszmann School for Nervous and Atypical Children, April 1, 1910. Waldemar H. Groszmann, Secretary. Plainfield, N. J. Paper. Price, \$1.50. Pp. 141. 1910.

This pamphlet contains the proceedings, including papers, of the first conference of the organization. The papers describe work being done in the education and training of exceptional children in New York City and other places, and the problems presented by such children in the schools. Other papers are on biologic variations causing retardation, congenital symbol amblyopia, hysterical states in childhood, a comparison of the psychologic and chronologic ages in children, hereditary and general causes of exceptional development, the exceptional child and the law and many other papers on allied subjects. With the present tendency to differentiate in the school courses between the normal pupils and those varying from the normal standard these papers and those prove of interest to educators, school authorities and those interested in child study.

MICHAEL SERVEYUS. HIS LIFE AND TEACHINGS. By Carl Theophilus Odner, Professor of Church History, Academy of the New Church, Bryn Athyn, Pa. Cloth. Price 50 cents. Pp. 96, with illustrations. Philadelphia: J. B. Lippincott Co., 1910.

Probably no more remarkable man ever lived than Michael Serveyus; but, hounded by both Catholics and reformers, and

by Calvin especially, his books destroyed almost as soon as printed, and himself burned at the stake in his early manhood, he accomplished practically nothing, and his influence on his own and succeeding generations has been *nil*. Finding opposition and persecution on every hand, he temporarily gave up his theologic writings and studied medicine, and for several years had a large practice. But the temptation was too strong and he again became involved in a fight with the theologians. In the present work Professor Odlner discusses and defends not only Servetus the theologian, but Servetus the man. The book is of medical interest simply because Servetus was a physician; it will appeal especially to theologians and has a value as a historical contribution to the subject of martyrs to religion.

ESSENTIALS OF LABORATORY DIAGNOSIS. Designed for Students and Practitioners. By Francis Ashley Faight, M.D., Director of the Laboratory of the Department of Clinical Medicine, Medical-Chirurgical College, Philadelphia. Second Edition. Cloth. Price, \$2 net. Pp. 336, with illustrations. Philadelphia: F. A. Davis Company, 1910.

This treatise covers the methods of laboratory diagnosis. The directions are clear and concise and sufficient for carrying out the ordinary methods of examination demanded in clinical investigations. In the preparation of the new edition, the material has been brought up to date without materially increasing the size of the book. The book is excellently illustrated. In an appendix a description is given of the author's private laboratory equipment; a number of useful tables are also added.

HYPNOTISM AND TREATMENT BY SUGGESTION. By J. Milne Bramwell, M.D., Author of "Hypnotism: its History, Practice and Theory"—etc. Cloth. Price, \$1.75 net. Pp. 216. New York: Funk & Wagnalls Co., 1910.

Dr. Bramwell, who is one of the principal English advocates of the use of hypnotism in medicine, in this little book gives a summary of his experience and views. A brief history of hypnotism, especially in its development in England, is given. The body of the book is largely taken up with case histories in which the author's successes are reported. He discusses the various theories of hypnosis and gives his objections to them, but says that unfortunately he has none of his own to offer. The book is a pretty good summary of the subject, though not a very elaborate or detailed one.

PRAKTISCHE WINKLE FÜR DIE CHLORARME ERNÄHRUNG. Von Dr. H. Strauss, Dirigierender Arzt der inneren Abteilung des Jüdischen Krankenhauses in Berlin. Paper. Price, 1 mark. Pp. 47. Berlin: S. Karger, 1910.

In this little pamphlet Professor Strauss has given a supplement to his other publications on the salt-poor diet in which practical directions are given for the carrying out of the treatment. The indications and principles of the method are not discussed. A large number of recipes and suggestions for the preparation of various foodstuffs in palatable form without salt are given and the book is completed by extensive tables based on the analyses of Strauss and Leva, giving the percentage of salt in the raw material of different foodstuffs.

A MANUAL OF OPERATIVE SURGERY. By Sir Frederick Treves, Bart, F.R.C.S., Sergeant-Surgeon to H.M. the King, and Jonathan Hutchinson, F.R.C.S., Surgeon to and Lecturer on Surgery at the London Hospital. Third Edition. In Two Volumes. Vol. II. Cloth. Price, \$13. Pp. 821, with 495 illustrations. Philadelphia: Lea & Febiger, 1910.

The previous editions of this book met such general favor that it is merely necessary to point out new and enlarged features. Considerably more space is given to the chapter on operations on the skull and brain, middle ear and mastoid antrum, and a new chapter on tendon surgery is added. The mechanical features of the book deserve special mention. The type is clear and clean-cut, the paper is not glossy and the illustrations are numerous, well made and descriptive.

ÜBER DIE NATUR UND DIE HERKUNFT DES TRACHOMERREGERS UND DIE BEI SEINER ENTSTEHUNG ZU BEOBACHTENDE ERSCHEINUNG DER MUTIERUNG DES GONOKOKKUS NEISSER. Von Dr. Hans Herzog (Refln). Paper. Price, 5 marks. Pp. 56, with illustrations. Vienna: Urban & Schwarzenberg, 1910.

Herzog considers the work that has been done on the "trachoma bodies" of Halberstadter and Prowazek, and gives a fairly complete bibliography. In his opinion the "trachoma bodies" are mutation forms of the gonococcus of Neisser. His theory and his work are very entertaining but not completely convincing.

Miscellany

REPORT ON OBSTETRIC TEACHING

The report of a special committee appointed by the American Gynecological Society to investigate the present status of obstetric education in Europe and America and to make recommendations for the improvement of obstetric teaching in this country appears in the *American Journal of Obstetrics and Diseases of Women and Children*, August, 1910. The committee consisted of Prof. B. C. Hirst, of the University of Pennsylvania, Medical Department, chairman; Prof. E. B. Cragin, of Columbia University, College of Physicians and Surgeons; Prof. J. Clifton Edgar, Cornell University Medical College; Prof. C. M. Green, Medical School of Harvard University; Prof. E. P. Davis of Jefferson Medical College; Prof. J. W. Williams of Johns Hopkins University Medical Department, and Prof. J. Clarence Webster of Rush Medical College (University of Chicago).

RECOMMENDATIONS

A detailed statement of the methods employed in certain medical colleges of Great Britain, Germany, Austria, Switzerland, France, and Italy is given, and, by way of comparison, of the courses given in the American colleges represented by the members of the committee.

Length of Instruction.—It is recommended that the teaching of obstetrics occupy at least two years of the medical course, and that those expecting to practice obstetrics should be urged to avail themselves of elective opportunities. The committee also recommended that the number of labor cases personally attended by each undergraduate student should be at least six, under supervision and instruction.

Character of Instruction.—The committee also recommended all the known methods of teaching this branch of medicine, namely: didactic lectures, clinical lectures, clinical conferences, ward classes and touch courses, hospital and out-patient instruction, manikin practice in operative obstetrics and recitations. Of the first three methods, it recommended specially clinical lectures and conferences, and that ample facilities should be afforded students to make antepartum examinations, including inspection, abdominal palpation, pelvimetry, fetometry, vaginal examinations, etc. A two-weeks' hospital residence should be required, the committee thinks, before the out-patient practice.

Scope of Instruction.—It is recommended that as obstetrics at present includes pregnancy and parturition, their complications and consequences, and the complete recovery of the women after labor, that obstetric instruction should include the medical and surgical treatment of these conditions.

The tendency of obstetrics to become more surgical in practice and to require a surgical training is evidenced by the fact that in the medical schools of Europe and in more than one-third of the first fifteen medical colleges of this country, the chairs of obstetrics and gynecology are combined under one head.

The Individual Study of the Young Criminal.—The anti-social acts which we call criminal are just as much the outcome of physical and mental capabilities, of emotions, desires, obstinancies, weaknesses of character, imitation, submission to psychologic influences of the crowd and other definite results of environment as are the more socially desirable aspects of conduct. For this reason William Healey (*Jour. Am. Inst. of Crim. Law and Criminology*, May, 1910) believes that a scientific inquirer is early forced to doubt the efficacy of investigating the causes of crime by any generalized method and must question the system of treating the criminal through institutional life; but much, he thinks, can be gained by an intensive investigation of the individual. There is considerable analogy all the way through between crime, a so-called social disease, and bodily disease. To understand each there must be estimation of the normal as well as of the pathologic, there must be study of etiology, symptomatology, diagnosis and, finally of treatment. But the analogy must not be carried so far that crime is likened to a specific disease

and the hope aroused that there may be found a specific treatment. In this paper, Healy deals only with the diagnosis of the underlying causes and attempts to show the great complexity of etiologic factors and the hopelessness of treating the cases wholesale. After reciting the histories of a number of young offenders, Healy analyzes the causes of juvenile criminality as follows: bad companions, immoral mother, poverty, mental subnormality, cheap plays and nickel shows, bad heredity, very poor education, bandit ideas from books, morbid impulsions-kleptomania, mother away working—no one to look after the children, bad sexual habits, congested neighborhood, defective antenatal conditions, neglectful father, innate laziness, epilepsy, difficult birth, degeneracy with stigmata, feeble-mindedness, recent immigration, densely ignorant family, desire for finery, careless not ignorant parents, hypersensitiveness, stepmother, mental peculiarities—perhaps the beginning of a psychosis—teasing by other children, alcoholism of parent, high mental capacity out of all proportion to the environment, nervous irritability, poor general health, defective vision, defective hearing, great love of excitement and adventure. The above study shows that delinquents have immensely varying needs, capabilities and adaptabilities, and the system which has mainly attempted reformation by mere restraint or, recently, somewhat by efforts at formal education or other classwork in custodial institutions is not effective. We know by court records that old methods are largely a flat failure as a deterrent to crime. In place, then, of any policy of repression or effort at reformation in large groups, what are the more constructive methods that offer greater chances of success? The amount of alterability in the whole situation is, plainly enough, the sum total of the alterabilities of the individuals concerned. Then it follows that if, as we have seen, the needs and possibilities of these individuals are extremely various, greatly varying methods of meeting those needs and developing those possibilities must be inaugurated, if the full amount of modification of the situation is to be realized. Just how much alleviation the entire crime situation can be subjected to is, of course, altogether unknown, and it certainly will remain unknown until the most rational procedures of treatment follow the most rational methods of diagnosis—especially until the importance of the young criminal as a factor is realized, his importance as an individual at the age when the twig is bent, needing individualistic study and individualistic treatment.

Medicolegal

Injured Person Not Responsible for Malpractice

The St. Louis Court of Appeals says that the case of Scholl vs. Grayson (127 S. W. R. 415) was brought to recover damages for a man being negligently run down by an automobile. He was first treated for his arm by a physician whom he afterwards discharged and sued for unskillful and careless treatment. The petition in that case was offered by the defendant in this case as an admission against the interest of the plaintiff. But the offer of the petition in the action filed by the man against his first physician for wrong treatment was not accompanied by an offer to prove the physician was not of good reputation, or that he fell short of due care in consulting him. The duty of a party injured by the tort (wrongful act) of another to use reasonable care to obviate, as far as possible, bad results from the injury and thereby diminish the damages, extends no further in the matter of selecting a physician to treat the injury than to select one of good repute. For lack of care and skill shown by such a physician in his treatment, the patient is not answerable; nor is the circumstance admissible to mitigate the damages for which the tort-feaser (wrongdoer) is liable. The petition filed against the physician was therefore properly excluded in this case because it tended to establish no fact favorable to the defendant in this case.

Reciprocity Provision in Medical Practice Act—Powers of Board and Their Limitation

The Court of Appeals of the District of Columbia says that the case of United States vs. Custis and others, brought on the relation of one Thompson (38 W. L. R. 396), was to compel the defendant, the Board of Medical Supervisors of the District of Columbia, to grant the relator a license to practice medicine and surgery in the District of Columbia.

The statute regulating the practice of medicine and surgery in the District of Columbia authorizes and directs said board to license to practice medicine and surgery in the district, without examination, any applicant for such license who has been engaged in the practice of medicine and surgery in any other jurisdiction (state, etc.), on condition, among other things, that the applicant acquired the right to practice medicine and surgery in such jurisdiction under conditions equivalent to those with which he would have had to comply in order then to have practiced medicine and surgery in the District. "And said Board of Medical Supervisors is further authorized to determine all matters of fact required to be determined in the execution of the provisions of this section."

It was conceded that the material provisions of the Maryland statutes were the same as those of the District of Columbia; that the relator was regularly admitted to practice medicine and surgery in Maryland, and practiced thereafter for a period of two years; that he presented satisfactory evidence of good character, paid the fees required and complied with all the requirements of the statute. The board, however, claimed the power, by rules and regulations, to determine what should constitute "conditions equivalent" under the statute, before reciprocal relations between Maryland and the District of Columbia could be said to exist. But the court thinks equivalent conditions exist under this statute by virtue of the provisions of the law, and not under the rules of the board.

The rules which the board are authorized to make are, the court says, for its guidance in carrying into effect the provisions of the law in the District of Columbia, and not in the State of Maryland. The Maryland board may have an entirely different set of rules for carrying into effect substantially the same statute as that of the District of Columbia; but that is a mere matter of local procedure, which cannot affect the reciprocal rights of practitioners of one jurisdiction to practice in another, provided they meet the requirements of the board in the state where originally admitted and the provisions of the statute in the jurisdiction where they desire to practice. If the contention of the board be correct, it lies within its power to prescribe conditions of admission to the boards of all states and territories in order to entitle any of their licentiates to practice in the District of Columbia, thereby absolutely annulling the express provisions of the statute. It is against public policy to place such arbitrary power anywhere, much less in a mere medical board.

The object of this statute was to open the doors to reputable practitioners, and, to this end, give full faith and credit to the acts of the board of a neighboring state having equivalent conditions, until it is clearly shown that the applicant does not come up to the requirements of the statute as to two years' practice or good moral character, or that he wrongfully obtained his original license to practice, either through his own fraud or through the fraud of the board. These are matters which the board would have authority to investigate, matters of fact on which they could pass, and their decision would not be subject to review in a proceeding of this kind. But no such showing was here made. The whole action of the board was based on the fact that they had a different system of grading for admission to practice than that adopted by the Maryland board. About the most inequitable test of ability that can be applied is the comparison of examination grades derived from either the same or different sources. It would certainly be dangerous to make arbitrary power dependent on such a deceptive test. It is well settled that licensing boards are not vested with personal or arbitrary power, but are subject to the control of the courts when it appears that they have acted arbitrarily in refusing a license.

This power is inherent in the court, and no statutory authority is necessary for its exercise.

If a board or officer deprives a citizen of a legal right, to which he is clearly entitled, and the citizen has no right of appeal or other adequate remedy, the proper court will review the action and see that justice is done and legal rights preserved. The rule is well expressed in *Spelling on Injunctions and Other Extraordinary Remedies*, 2d Ed., sec. 1433: "But, while the action of an officer clothed with a discretion is not reviewable, if exercised on matters left to his discretion, yet his judgment as to the extent of his discretion under the law, and the matters on which it may be exercised, are reviewable on mandamus; and where a discretion is abused, and made to work injustice, it may be controlled by mandamus."

The answer of the board totally failed to set forth any legal justification for its refusal to grant the relator a license. The rules and regulations of the board were its sole defense. As the court has observed, this was insufficient. The relator had complied with all the requirements of the law and the board had no discretion left in the premises. It was its duty to have acted favorably on the application. Refusing to do so, the relator availed himself of the only remedy afforded him, and the court below should have sustained the relator's demurrer to the board's answer to his petition and issued the writ of mandamus he asked for to compel the board to grant him a license to practice medicine and surgery in the District of Columbia.

2. Treatment for Chronic Intestinal Putrefactions.—After having studied the problem experimentally and then trying it out clinically in thirteen cases, Bassler is convinced that in cases of chronic intestinal putrefaction wherein such conditions as carcinoma, colonic obstruction, abnormal organic disease of the pancreas or stomach, or gastrointestinal atrophy, etc., are not responsible for the condition, much benefit can come from raising the content of *B. coli communis* in the gut by instillation of either the autogenous mixed forms or strains from other individuals. An individual who has high Gram-positive stools can by the autogenous mixed or *B. coli* instillations quickly have the running proportion between the Gram negatives and Gram positives raised to a proportion equivalent to normal, this being due to raising the number of *B. coli* and also to diminution in the putrefactive Gram positives as the first-named become more numerous. With this more equal proportion between the two types of organisms, the conjugate sulphate of the urine diminishes and substantial improvement occurs. From his experience Bassler is led to believe that these injections are a valuable method of treating these patients, being quick and effective in the majority, and not harmful in any. It is his belief that when anatomic conditions causing stagnation exist the results from these treatments are not capable of giving such good or substantial benefit. As regards the permanency of the benefit brought about it is apparent that in about half of the patients who do not respond to simple treatments, the condition clears up inside of from one to three months of this

treatment, but that the other half may not remain substantially benefited even when the instillations are kept up for longer periods. These latter patients show relapses when the instillations have been stopped for a week or more, quickly responding again when the injections are re-established. Bassler thinks it probable that in the relapsing cases some permanent anatomic mischief preventing the establishment of a normal bacterial intestinal condition is present, which is either the cause of the development of the condition in the first instance and then of its prolongation, or that there is present some anatomic or permanent functional change affecting normal secretions and motility of the digestive canal in asthenic ways. All patients with putrefactive conditions should first be treated by the routine methods of treatment for those conditions (diet, hygiene, tonics, etc.) before instituting the instillations. When, however, the latter are begun, the autogenous mixed bacteria should first be used, always employing fresh specimens of stools for inoculation of the media. This treatment should be kept up for about 4 weeks before a change to the strains of *B. coli* is employed for a length of time: when benefit has been established autogenous mixed bacteria may again be used. If no benefit is noted on the *B. coli* alone the *B. lactosus aerogenes* may also be added to them, the two grown together in the single media, and these tried for a length of time. If after these, no sustained or apparent benefit is achieved, then there is present some anatomic and permanent complication affecting the function of the gut, and the best he has hoped for is a resort to surgery in some of the cases, or a longer interval continuation of instillation of whatever form of culture has shown the best results in that particular case.

3. Acute Anterior Poliomyelitis.—On a warm day in August, 1891, when 25 months old, after an indiscretion in diet, and without antecedent traumatism, Eshner's patient was seized with fever lasting three days, and associated with pain in the right leg and the back. There had been no vomiting and no diarrhoea. On the fifth day the right lower extremity was found to be paralyzed, without apparent alteration in sensibility. The paralysis increased in severity for a week, and then it began gradually to diminish. The upper extremities, the left lower extremity, and the face were unaffected. The general nutrition was preserved, but the right lower extremity was moderately wasted. Intelligence was good and sensibility was unaffected. The gait was wobbling, the feet being held rather far apart in walking. There were no contractures and no deformity. The knee-jerk was normal on the left, enfeebled on the right. The circumference of the right leg was $7\frac{1}{4}$ inches, that of the left $7\frac{1}{2}$ inches. The muscles of the right leg responded less well to faradic stimulation than did the muscles of the left leg, but there was no degenerative reaction. The patient occasionally had nocturnal enuresis, but there was no evidence of rachitis. Under treatment with massage and electricity for eight months practical recovery took place. Eleven years after this illness, in March, 1903, a day after a fall, resulting in injury to the left shoulder and the left elbow, the patient developed weakness in both hands, more marked on the left. She had not been feeling well at this time and was "nervous," although she was attending school and had no fever or nausea or vomiting. While the symptoms manifested were those of acute anterior poliomyelitis, Eshner points out that some one might attribute them to peripheral nerve injury in consequence of the fall. The development of the symptoms a day following and not immediately after the accident, the involvement of both hands primarily, even though in slight degree and but transitory in character on the uninjured side, the absence of sensory alterations, certainly entitle the possibility of a spinal, rather than a peripheral lesion a poliomyelitis rather than neuritis—to serious consideration.

4. Three Unusual Cases of Retropharyngeal Abscess.—The first of these cases of retropharyngeal abscess was associated with evidence of pressure on the pneumogastric nerve. The two striking points in connection with this case were the initial torticollis and external cervical adenitis, and the remarkably low pulse (60) that could be explained only on

the basis of pressure on the pneumogastric. The second case was followed by general pyemia and death. The history of this case was typically that of a general pyemia following a retropharyngeal abscess, and strikingly emphasizes the importance of making a prompt diagnosis of the latter condition and of instituting early drainage. The third case was associated with edema of the glottis. The patient recovered.

7. Treatment of Chronic Specific Urethritis.—Persson found that secretions present in the infected urethra inhibit the growth of a common strain of lactic acid bacillus. Suspension in physiologic salt solution of lactic acid bacilli grown on slant agar was injected into the infected urethra and cultures obtained by means of a sterile platinum loop from the urethra—these cultures were planted in milk at the following intervals: First culture, 1 minute after injection; second culture, 5 minutes; third culture, 10 minutes; fourth culture, 15 minutes; fifth culture, 20 minutes; sixth culture, 30 minutes. After 48 hours' incubation there was complete coagulation in cultures 1 and 2; slight coagulation in culture 3; in culture 4, acidity but no coagulation; in cultures 5 and 6, no growth. It was observed that the disappearance of the gonococci bore a constant relation to the length of time the lactic acid bacilli retained their virulence in the urethra. In each of 6 unimproved cases the bacilli were killed almost immediately after injection and although several different cultures were tried, none proved effective. Cultures of lactic acid bacilli grown in nucleinic acid media, retain virulence when injected into the infected urethra for a much longer period of time. In a number of instances cultures which coagulated milk in 36 hours were obtained from the urethra of the patients under treatment 10 hours after the injection was made.

9. A Practical Blood-Sticker.—This sticker is made of a two-dram vial, cork, and a straight surgical needle. The eye end of the needle should be stuck into the small end of the cork. The needle should not be stuck through the cork. The vial contains alcohol or some other antiseptic solution.

15. Standardization of Blood Pressure.—After the most careful investigation Sallom found that normally the blood pressure does not vary more than about 0.3 millimeters of mercury and to be expressed by the following equation:

$$\text{mm. Hg.} \div (\text{W.C.} \times \text{C.}) = \text{P.};$$

in which mm. Hg represents the height of the column of mercury; W. C. the width of the cuff employed; C. the circumference of the arm, and P. the pressure. He says that it is a well-known fact that the pressure exerted by any fluid depends entirely on its height and the size of its base. The size and shape of the vessel play no part whatever. With this in mind it at once becomes evident that the area on which the pressure is exerted plays a most important rôle and must be taken into consideration with every observation. Of course, this is obtained by multiplying the width of the cuff by the circumference of the arm. Knowing the height of the column of mercury and the area or base on which the pressure is exerted it at once becomes a simple mathematical problem to compute the actual pressure employed. For example, in the case of a person, age 22, the circumference of the arm being 8 inches, and the width of the cuff 3 inches, therefore: $-8 \times 3 = 24$ sq. in. = area over which the pressure is exerted.

The systolic pressure in this case was found to be 125 mm. Hg. If, therefore, 125 millimeters of mercury were sustained over an area of 24 square inches, 1 square inch will support a column of mercury 1.24 of 125 mm. Hg or 5.21 mm. Hg.

By computing in this manner the actual pressure employed the results have been startling and of great importance.

Age has been found to have no influence on blood-pressure, it being the same in the child and the adult. In making this statement Sallom says that he is aware of the great importance laid by all observers on age. The error is due to the fact that the circumference of the arm was not taken into consideration. It being smaller in the young the blood-pressure readings were necessarily lower than in the adult, which, however, when standardized gave the same ratio for each square inch. The same is true in regard to sex. It is somewhat inconvenient to speak of the pressure in terms of 4.82 mm. Hg per sq. in.; 6.25 mm. Hg per sq. in., etc. On this account and in order to place the blood-pressure readings on a definite standard it has been found convenient to express them in terms of units. Such a method is simple and practical. It is obtained by taking the figure or figures before and the first figure after the decimal to represent the number of units. For example:—4.82 mm. Hg per sq. in. would be spoken of as 48 units; 6.25 mm. Hg per sq. in. as 62½ units, etc. By such a system the readings are simplified and we become better able to appreciate slight differences.

16. Dr. Pohly's Cases of "Anemic Ulcer" of the Throat.—Lydston takes exception to Pohly's diagnoses of anemic ulcer in three cases on the ground that the cases were not investigated sufficiently. He seems to be inclined to regard them as cases of syphilis.

20. Influence of Exhaustion on Puerperal Morbidity.—A review of the clinical records of 5,000 cases has shown Williams that it is evident that exhaustion during labor has a distinct influence toward increasing puerperal morbidity. He says:

1. A temperature of 100 F. or above occurs at some time during the first twelve hours after delivery in about 20.5 per cent. of all cases.
2. The temperature curve during this period in the majority of cases corresponds with the diurnal variation.
3. This elevation of temperature does not necessarily correspond to the duration of labor, but probably does to its severity.
4. The pulse-rate is a less reliable index of exhaustion than the temperature. It most commonly falls during the first twelve hours, a rise in the majority of cases accompanying a corresponding rise of temperature.
5. Puerperal morbidity, with the exception of mastitis, increases in direct proportion to the duration of labor.
6. This increase affects equally all the more common complications of the puerperium.
7. Cases in which there is an elevation of temperature during the first twelve hours after delivery are followed by a higher morbidity than those in which there is not; and when this temperature reaches to 101 F. or over, the subsequent morbidity is 38.09 per cent.
8. An elevation of pulse at the end of labor is of comparatively slight prognostic importance from this standpoint, but is followed by a slightly increased morbidity.
9. The morbidity is greatest after the high operations, but here, as is also true of the low operations and spontaneous delivery, the morbidity increases in direct proportion to the duration of labor.
10. The morbidity after low forceps is less than after spontaneous delivery, presumably because labor is shortened and exhaustion lessened.

25. **Simple Bursitis.**—Binney says that a chronic bursitis may recover when rest is given, but the gross anatomic changes in the walls of the bursa and in its surroundings are usually so great and so well established that more active treatment may be necessary. Various irritating or alterative liquids or emulsions have been injected into bursæ and have often given good results, but such treatment must be used with great caution, as bursæ frequently communicate with joints and such treatment may produce a dangerous arthritis. Excision is the treatment of choice in chronic bursitis; it not only gives the best prospect of a prompt and permanent cure of the simple, non-infective variety of the disease, and is also the best possible method of treatment if the lesion is due to tuberculosis or similar infection.

35. **Unusual Case of Hysterosalpingostomy.**—The uterus and tubes in Jewett's case were exposed through a short median abdominal incision. The inner portion of each tube, about one-third its entire length, was found impervious, being reduced to a mere cord. The outer two-thirds was normal. The malformation was believed to be congenital. Each tube was resected from the uterine cornu and the entire atresic segment removed, care being used not to injure the vascular supply of the sound portion remaining. The fundal incision was lengthened transversely till the endometrium was easily accessible. The proximal end of the sound segment was split for one-half inch and each flap thus formed was fixed with a single catgut suture to the uterine mucosa close to its cut edge. The uterine musculature and peritoneum were then closed securely, except where traversed by the tube, and the latter was still further secured by two or three sutures passed superficially through the uterine wall and engaging the peritoneal coat of the tube. Free communication through an oviduct of ample lumen was thus established between each ovary and the uterine cavity. The fundus was restored to its normal position by the round ligament operation of Webster and the abdomen closed. The patient was out of bed within less than two weeks.

36, 37, and 38. Abstracted in THE JOURNAL, Feb. 27, 1910, pp. 732 and 735.

40. **Death from Electric Currents.**—Stanton and Krida claim that the two great causes of death are cardiac fibrillation and respiratory paralysis. Low-tension currents tend to kill chiefly by producing cardiac fibrillation. As the tension is

increased the effect on the heart becomes less pronounced, but at the same time the effect on the central nervous system becomes more and more certain as the tension is increased so that in the case of the high-tension currents death is more likely to be caused by respiratory failure, although if the contact is prolonged the heart is also stopped. The authors have been unable to find any reliable data concerning the action of commercial currents of more than 4,500 volts, but all evidence points to the central nervous system as being the chief sufferer from the effects of currents of more than 4,800 volts. Cardiac fibrillation is fatal under known methods of treatment. In cases of simple respiratory paralysis, the patient may be kept alive by artificial respiration until the nervous system recovers from the effects of the shock.

49. **Roentgen-Ray in Diagnosis of Pulmonary Tuberculosis.**—As a means of early diagnosis the fluoroscope, says Minor, while useful, is, save in the case of bronchial gland shadows, by no means equal to an expert use of standard physical diagnostic methods. In Germany where several distinguished diagnosticians have used the Roentgen-ray freely, extreme claims for its early diagnostic value are not so common as in this country. Hence, the statement that any given case was negative on physical examination and showed shadows with the Roentgen-ray is of no great value unless one knows who made the physical examination. Systematically used, it will be found to throw wonderful light on the work, and there are few cases, save the extremely incipient ones, in which it is not useful. Further, as has already been noted, there is no other procedure which can give such information as to the topography of the disease, while again and again it will call to one's attention slight foci of trouble which would otherwise have been overlooked. There is no diagnostic measure in which it is more essential to master fully the use of apparatus, and the first few months of fluoroscopy will be well spent if in them one thoroughly masters the idiosyncrasies of the electrical apparatus which one has to use.

50. **Effect of Diminished Blood Supply to the Intestines on the General Circulation.**—The author found by experimentation that compression of the superior mesenteric artery and celiac axis gives rise constantly to an elevation of general blood pressure which may last for at least an hour. This is not dependent on a reflex for there is no compensatory constriction of the other vessels of the body and the rise in pressure occurs after section of the splanchnic nerves. On the contrary, there is a slight compensatory dilatation of the other organs of the body which, however, is not sufficient to compensate for the increased blood pressure. Intravenous injections of salt solution, either through diminishing the viscosity of the blood or by dilating the vessels or through both means, increase the efficiency of the anastomosis of the splanchnic area after ligation of the superior mesenteric artery and celiac axis. Intravenous injections of blood do

not have this effect and therefore result in a sustained elevation of blood pressure due to the increased bulk of fluid in the general circulation. The rise of blood pressure following constriction of the superior mesenteric artery and celiac axis is due to an increased amount of blood in the general circulation. The pressure remains elevated until the excess of blood accumulates in the ramification of the splanchnic vessels by way of the collateral anastomosis.

51. **Physiologic Mechanism of Anaphylactic Shock.**—Manswaring defines the acute anaphylactic reaction in dogs as an explosive auto-intoxication of hepatic and intestinal origin, which is modified, inhibited and overcome, by a more or less efficient antianaphylactic mechanism, part, at least, of which is situated in other organs. As to the nature of this hypothetical auto-intoxication, whether it consists of split or conjugation products of the injected proteid, of liberated hepatic or intestinal enzymes, of an unusual amount of the normal internal secretion peculiar to anaphylaxis, can only be determined after extensive histologic, chemical and biochemical studies. The facts at present do not warrant the formation of even a working hypothesis on this point.

53. **Peculiar Degeneration Found in Heart Muscle Cells.**—The degeneration in question was seen in tissue fixed in 10 per cent. formalin and in tissue fixed in Zenker's fluid. In sections stained with hematoxylin and eosin it is readily recognized with the low power lens and appears as a small round, oval, or irregular pale blue area inside of a single muscle cell. No particular cells or particular regions of the heart muscle were observed in which this degeneration seemed to occur more markedly than in other portions. It occurs where there is marked proliferation of connective tissue and where there is evidence of pressure atrophy; it occurs also where there is no connective tissue proliferation and the cells appear slightly hypertrophied. It also occurs near the endocardium, near the pericardium, and deep in the heart muscle. In some of the cells in which this degeneration occurs the nuclei are quite prominent, in others no nuclei are to be seen. With the high-power lens these degenerations show a slight bluish mottling, somewhat irregularly defined. Across some of them may be seen fine pink-stained lines that are continuous over into the muscle cell. These are apparently unaltered muscle fibrillae. They sometimes occupy only a portion of the cell, at other times almost the whole of the cell is filled with blue staining material, but always enough of the cell remains to show that it is a heart-muscle cell.

Besides hematoxylin and eosin, the only distinctive stain Hewitt has so far found for these degenerations is iodine in the form of Lugol's solution. These areas when so stained and examined in water appear of a terra cotta pink color, somewhat mottled and rather irregularly defined, fading away gradually at the periphery into the substance of the cell. Other cells are seen in which this degeneration appears, when stained with Lugol's solution and examined in water, of a blackish brown color with a dirty pink base. On washing again in water these areas become more and more pink. In many of the pink-stained areas brownish areas may be seen. On treating sections stained with Lugol's solution with water to which a mere trace of ammonia is added the pink and brownish colors in these degenerated areas disappear; treating sections with slightly acidulated water produces no particular change. As to the nature of this degeneration, Hewitt thinks that it is that of a hyaline change allied to hydropic degeneration with the presence of some mucin.

54. **Bactericidal Power of the Blood Serum of a Typhoid Carrier.** The results of Meader's work may be summarized briefly as follows: 1. The bactericidal power of the blood-serum of a typhoid carrier may be that of a normal person. 2. A typhoid carrier may be actively immunized to *B. typhosus* by the use of autogenous vaccines, and in so doing the bactericidal substances in the blood may be markedly increased. 3. A typhoid carrier if vaccinated so as to bring about an increase of bactericidal substances may cease to harbor the typhoid bacillus. 4. The best therapeutic dose, from an investigation of one case, seems to be from 75 to 400 million

65. Abstracted in THE JOURNAL, Feb. 26, 1910, p. 742.

70. **Unusual Case of Lead Poisoning.**—Three months before the onset of foot drop, the patient had suffered an attack of lobar pneumonia and had been very ill. Many years previous to this, he had had occasional attacks of "rheumatism." With the exception of the rheumatism he had not been ill for 16 years. This sickness had been an unusually severe attack of lead poisoning which he had developed while working "in a sheet lead factory" where he had been foreman. After repeated attempts to continue his work there he had been obliged to resign a very lucrative position and discontinue this kind of work. He had had "colic" so severely that the physician in charge had despaired of his life and had expected him to die. Recovery had been tedious and he had never been well since. Still in the last years he had not shown symptoms of lead poisoning and had considered his ill health due to rheumatism.

It was difficult to imagine this present foot drop to be directly due to "leading" sixteen years ago, and the history of his past illness was again reviewed. Special inquiry was made of the attack of pneumonia, which condition the present trouble has so closely followed. Apparently he had had a frank attack of lobar pneumonia but said that the physician in charge thought the lung had not returned to its normal condition, and that he had taken medicine for some time after he was up and about. He was asked to describe this medicine which he did as follows: "The medicine was bitter drops, made my nose run as though I had the hay fever, and I took ten drops after each meal. The medicine formed a white scum over the neck of the bottle and turned the label brown." The explanation of the case seemed clear to Lazell. The lead deposited sixteen years before in some insoluble form in the bones, had been thrown into solution by the iodids given for an unresolved pneumonia and acute lead poisoning had resulted. The patient was given a good prognosis, saturated with sodium iodid and made a complete recovery.

86. Serotherapy of Gastric and Duodenal Ulcer.—Mayhew reports five cases which he treated successfully according to the method of E. C. Hott of London by the internal administration of an anti-ulcer serum. The important factors in the treatment are: 1. Absolute rest in bed is ordered from two to three weeks. 2. No drugs are given except a simple purgative. 3. Diet is dry throughout; no milk, soup or fish is allowed. Meals may be given every two hours, consisting in rotation of stale bread, yolks of lightly cooked eggs, white meat of chicken. Only liquid allowed is 10 ounces of hot water at 7 a. m., 11 a. m., and 1 p. m. The dietary is doubled in five days and on the seventh or eighth day pounded meat, lightly cooked, may be added. By the end of the second week meat forms the chief article of diet and soon a return to full diet is gained, but alcohol, soup, tea, coffee, and all starchy puddings are forbidden for six months. 4. The serum is given by mouth three or four times a day, immediately after food in one-half ounce of water. In cases of severe pain or hemorrhage 60 c.c. to 80 c.c. can be given in 24 hours. The usual dose is 10 c.c. The serum is continued for from 4 to 6 weeks. The results Mayhew has noted are: 1. Early relief from pain. This was true in all cases and allowed a generous diet in many cases much earlier than is usually considered possible. 2. Chlorosis improved rapidly. 3. Nausea and vomiting stopped earlier than in other forms of treatment. 4. Nutrition of patients was maintained at a higher level than by other methods.

98. Pathology and Bacteriology of Acute Anterior Poliomye-
litis.—Acute anterior poliomyelitis is a specific infectious
disease characterized pathologically by general toxemia affect-
ing the parenchyma of the heart, liver and kidneys and the
lymphoid tissues of the body, but spending itself locally on
the structures of the spinal cord. The authors found that
grossly the cord is congested and on transverse section shows
softening and often hemorrhages in the gray matter of the
anterior horns. In the cord the infectious agent is located in
the perivascular lymph-channels of the anterior portions,
especially invading the gray matter, but extending to the
white matter and pia and occasionally to the posterior horns.
The brain stem and basal ganglia may be involved. In the
cord the medulla and cervical and lumbar swellings are par-
ticularly affected.

The characteristic lesion consists of collections of cells in
the peri-vascular and pial lymph-channels and tissue spaces
of the anterior horns. Of these cells the polymorphonuclear
leukocytes appear early and are relatively few in number.
They are soon displaced by endothelial cells arising from pro-
liferation of the lining and endothelium and lymphocytes
coming from the blood and lymph streams. Edema of the
interstitial tissue and degeneration and destruction of the
ganglion cells are always present. The vessels are congested,
their walls degenerated, and the capillary branches in the
gray matter are irregularly distended and often ruptured,
giving hemorrhages, which always intensify markedly the
amount of destruction. Thrombosis was not observed. Early
degeneration of nerve fibers from the anterior roots is a
constant feature. Stains for micro-organisms were uniformly
negative.

99. Phagocytosis of Red Blood-Cells After Transfusion.

Immediately following transfusion in a patient suffering from
an extreme anemia, resembling the primary pernicious type,
smears of the peripheral blood made by Hopkins showed
great numbers of the polymorphonuclear neutrophil leukocytes
containing red blood-cells. About six hours after the opera-
tion the patient became comatose, developed hemiplegia and
died three hours later. Hopkins believes that the shape, size
and staining properties of the ingested red cells make it seem
probable that many of them were from the donor; while the
fact that the phagocytes were so numerous and that many
of them were atypical, makes it certain that some, at least,
were from the recipient; so that what was observed was
probably a phagocytosis of the transfused red cells by the
phagocytes of the recipient. This might be explained in two
ways: As a washing out into the peripheral blood of phago-
cytes from the blood-destroying organs, or as a phagocytosis
due to the presence of hemopsonin in one of the serums. In
regard to the first possibility, there is ample evidence that
some such "washing out" of bone marrow elements occurred,
in the presence of numerous erythroblasts and the bone-mar-
row giant cell. Moreover, there are two factors present which
are known to increase the phagocytosis in these organs, per-
nicious anemia and transfusion.

100. Pulse-Pressure Changes During Hemorrhage.—While
there are interfering factors which may at times mask the
significance of pulse-pressure changes, Wiggers believes that
the deduction may be drawn that many cases of hemorrhage
must occur in practice in which these pulse-pressure changes
may be of value in following the course of bleeding. The
following series of procedures may then be recommended for
following the course of a suspected or diagnosed internal
hemorrhage:

1. Eliminate so far as possible psychological factors in the patient
by the administration of the customary dose of morphin.
2. Determine the systolic and diastolic pressures by means of the
sphygmomanometer at intervals of not more than ten minutes, and
more frequently if possible. By subtraction obtain the pulse-pres-
sure, and also determine the rate of the pulse and respiration.
3. Tabulate the data as the observations continue.

If the respirations undergo little or no change, the follow-
ing deductions may be drawn: (A) A progressive decrease in
pulse-pressure and decrease in the product of the pulse-pres-
sure and the heart-rate indicate a continuance of the bleeding.
(B) An increase of both, if permanent, after several determi-

nations, indicates a cessation of hemorrhage. (C) A temporary increase of both, followed by a marked decrease on subsequent examinations, indicates an exacerbation. If it is true, however, that such determinations possess a clinical value, the fact should be capable of demonstration in a similar manner on animals.

Wiggers says that he has not yet had time to test his skill in following the course of a sufficient number of such hemorrhages to draw final conclusions, but the results incorporated in a table appended give an indication of the close correspondence in a number of cases. In these experiments hemorrhages were produced in dogs by an assistant, at intervals and times unknown to him. With maximal and minimal manometers, Wiggers determined at various intervals the data, incorporated them in the table, made his predictions, and compared them with the actual date of hemorrhage.

102. Trichinelli Found in Blood.—The patient had been ill since Aug. 17, 1909. On August 24 a diagnosis of trichinosis was made on the basis of edema of the face, together with a differential count, showing 9,100 white cells and 20 per cent. of eosinophils. On August 20 the white cells numbered 10,100 eosinophils, 38 per cent. On August 27 the white cells numbered 11,200, with 44 per cent. eosinophils. On the twenty-fifth and twenty-sixth the stools were examined carefully for trichinae, but none was found. Excision of a piece of muscle for examination could not be done, and on the twenty-fifth it was determined to examine the blood for parasites and preparations were made to take a quantity of blood from a vein; it was not feasible, however, to get a needle into a vein, and, as an experiment, an ordinary puncture was made in the lobe of the ear and 1 c.c. of blood squeezed out by continued effort; this was laked with 12 c.c. of 3 per cent. acetic acid, centrifuged, and the sediment examined under low power. One trichinelli was easily found, two others were not so clearly marked.

103. Uncinariasis in Southern Whites.—The results of this investigation demonstrate that hookworm infection is prevalent not only among the working class and poor people, but also among the upper classes in infected districts, and that in the country and smaller towns at least 30 per cent. of young adults between the ages of 15 and 25 are infected. Judging from the number who give a history of ground itch, a much larger proportion of people under this age harbor the parasite. The authors emphasize the value of the washing and centrifugalizing method of examination in detecting mild infections. Their results would indicate that two-thirds of the mild infections are overlooked in the ordinary stool examinations.

104. The Intracutaneous Tuberculin Test.—The authors feel that in the intracutaneous test we have a method of more exact dosage than in the other methods of cutaneous application. It has been their experience that the general reactions subsequent on the subcutaneous test have been avoided. They urge a more general application of this test, bearing always in mind that tuberculin tests, however applied, become a source of error when they are given a more prominent and important diagnostic place than painstaking and thorough search for physical signs.

105. Has Ovarytherapy an Experimental Basis?—The result of Frank's investigation can be summed up briefly as follows:

1. Corpus luteum extract, injected intravenously in sufficient concentration, proves rapidly fatal in consequence of intravascular thrombosis.
2. Corpus luteum extract of a heterologous species, given subcutaneously, by mouth, or by a combination of these routes, does not replace the normal action of this gland of internal secretion. The injections do not suffice to "sensitize" the uterus and enable it to produce Loeb's d-oidiomata and do not bring about such epithelial changes as are noted after follicular rupture.
3. Corpus luteum extract injections call forth no recognizable reaction in the hypophysis.

106. Anterior Poliomyelitis.—This article deals with attempts to find a method of diagnosis from the blood or cerebrospinal fluid in cases of anterior poliomyelitis, both in monkeys and in human beings. The acute stage of anterior poliomyelitis, as it occurs in human beings, and as it is produced experimentally in monkeys, is characterized by the occurrence of adistinct leukopenia. The differential count

shows a relative increase in number of eosinophils and lymphocytes. As studied experimentally in monkeys, the leukopenia of the acute stage is not preceded by any constant leukocyte picture. The spinal fluid in poliomyelitis monkeys shows more marked and characteristic findings. There is a marked increase in the number of cells during incubation and prodromal stages and the early days of the acute period, being highest in the prodromal stage. The increased cells are at first mononuclear in type and are later replaced by polymorphonuclear cells. A fibrin clot appears in the prodromal and early acute stages, but disappears later. These findings in monkeys agree with the findings in human beings, so far as the author's observations extend. Tests for antibodies to the poliomyelitis (blood of animal repeatedly inoculated with active and then inactivated virus) were made by means of the Bordet-Gengou fixation reaction. There was no evidence of antibodies in the serum of monkeys taken at intervals during the acute disease or in the serum of unsuccessfully inoculated monkeys. There was no evidence of the antigen in the spinal fluids of monkeys or of human beings at various stages in the disease, or in the blood-serum of monkeys suffering from the disease. These latter results corroborate and extend the negative findings of Wollstein.

114. Determination of Saccharin in Urine.—The method presented by Bloor is a colorimetric one, depending on the transformation of the saccharin into what is probably phenolsulphonephthalein or sulphurein, by treatment with a phenol-sulphuric acid mixture, the nitrogen having been split off during the treatment with the strong mineral acid. The color obtained is reddish in strong acid solution, purple-red in alkali and a bright clear yellow in weak acid solutions. It was first attempted to use the reaction directly on the urine, but the phenol-sulphuric acid reagent gives color with so many of the urinary constituents that the direct treatment had to be abandoned and an extraction made. In trying out the various solvents which have been suggested for the purpose it was found that benzol was the most satisfactory, in that it extracted the least foreign matter which interfered with the color. The benzol used must not leave any residue which gives a color with the reagent. Urine containing about 3 milligrams of saccharin is measured off into a 250 c.c. Florence flask, evaporated to about 5 c.c., cooled and strongly acidified with concentrated sulphuric acid (about 18 drops). Clean quartz sand is then added until the whole of the liquid is taken up. About 125 c.c. of benzol are poured in and the whole boiled gently with a return condenser for two hours, with occasional shaking. The benzol is poured off and the extraction repeated with about 100 c.c. of the solvent. After this extraction the solvent is poured off, the sand shaken out into a Buchner funnel, sucked dry and washed two or three times. The combined solvent with washings is set aside to cool to allow water to separate, then is poured through a dry filter into a clean flask. The benzol is now distilled off, using a long brass tube as condenser, until 1 or 2 c.c. is left. This remnant must be removed carefully, with gentle heat and a slow current of air, because saccharin is readily volatile

above 100 C. To the flask containing the saccharin extract are added about 5 c.c. of the phenol-sulphuric acid reagent and the whole heated at a temperature of from 140 to 150 C. for two hours. This temperature must be accurately maintained, since the speed of reaction drops off very rapidly below 140 C., while at much above 150 C., although the reaction goes more rapidly, there is danger of overheating, with destruction of part of the color. The flask is then cooled somewhat and about 150 c.c. of hot water are added.

After the syrupy residue is dissolved the solution is neutralized by the addition of sodium acetate crystals in slight excess, recognized by the disappearance of the pinkish tinge, leaving the liquid clear yellow. The mixture is allowed to stand some hours or preferably over night. The neutralized liquid is transferred to a 500 c.c. graduated flask and diluted up to the mark. A small amount (from 25 to 50 c.c.) is filtered off for colorimetric reading. This filtrate should be clear yellow, with not more than a trace of smokiness. It is then compared with the standard color in a Duboscq colorimeter, setting the standard at 20 mm. The following solutions are required: 1. Reagent: Equal parts by weight of concentrated sulphuric acid and pure crystallized phenol (equimolecular proportions with 5 per cent. excess of phenol) are stirred together until dissolved. The solution should be only slightly colored and a blank determination with the reagent should give only a negligible tinge to the solution. If crystals separate on standing they may be re-dissolved by gentle warming. 2. Standard color solution: Weigh out accurately about 3 mg. of pure saccharin into a 250 c.c. flask, add 5 c.c. of the reagent and digest at from 145 to 150 C. for two hours. Dissolve in hot water, neutralize with sodium acetate and make up to 500 c.c. Check the accuracy of the solution by comparison with other similarly treated amounts of saccharin. These should check to within 0.2 mg. The results of these experiments show that small amounts of saccharin may be determined in the urine by this method with a reasonable degree of accuracy.

115. Estimation of Saccharin in Urine and Feces.—In the course of his work Wakeman took occasion to modify Bloor's procedure in more or less essential details. The main points of difference from the procedure reported by Bloor are the use of ethyl acetate as a solvent instead of benzol and of lead acetate in the place of sodium acetate, and the use to some extent of different apparatus.

2. Duty of General Practitioner to Deaf Child.—It is claimed by Yearsley that something like 50 per cent. of the cases of congenital deaf-mutism are the result of marriage either (1) among those who have such cases, either direct or collateral, in their families, or (2) among those who are blood relations. Here, then, becomes apparent an obvious duty of the general practitioner, and one which he will not infrequently have an opportunity of bringing into action. He should, whenever the occasion occurs, do all he can to discourage such marriages. It may be, says Yearsley, that when we, as a nation, are more alive to the urgent necessity for race culture, when we more fully realize that national wealth is not gold, but healthy, normal citizens, we shall discourage consanguineous marriages in tainted families by law. Until then it will remain the paramount duty of every medical man to do his utmost in this direction and to foster in his patients the feeling that we have a bigger duty toward future generations than we have to ourselves. There is also a duty to deaf children, whether the deafness be congenital or acquired, whose defect lies, in the majority of cases, only in the absence of the sense of hearing. That duty is to impress on the parents that to obtain the best results from education by the oral system (which is the only system which can give the deaf child anything approaching normal intercourse with his more fortunate brethren), such education must begin as early as possible, while brain and larynx are still plastic; that attendance at the deaf school must be as regular as possible; and that the oral training carried out by the trained teacher of the deaf must be continued, supplemented and amplified at home by treating the child as a speaker and not a signer.

3. Blood-Pressure in Toxemia of Pregnancy.—For the last five years Starling has made a rule of taking the blood-pressure as often as possible of every pregnant woman under his care, especially in the last three months of pregnancy. It was impossible to secure identical conditions of observations in these cases, but the mere fact that most of the observations were made, not on patients resting in bed but on patients who either were working in their homes or else had walked to his consulting-room, would prove that these estimations of blood-pressure were too high a reading rather than too low. In spite of the conclusions arrived at by Vogeler and other writers Starling is convinced that during the whole period of normal pregnancy the blood-pressure is normal—that is, from 110 to 120 mm. Hg. Any rise of blood-pressure above 125 mm. Hg would make him suspect that the pregnancy was not quite normal and would put him on the lookout for some degree of toxemia. Any rise of blood-pressure at the commencement of and during normal labor is due entirely to the pain or muscular exertions consequent on labor.

4. Cesarean Section in Eclampsia Gravidarum.—The indications for operation are regarded by McCann to be the following: 1. When the fits are severe and recur in rapid succession. 2. When labor has not commenced. 3. When the cervix is difficult to dilate from elongation, hypertrophy or excessive rigidity. 4. When the mother is moribund and the fetus living and viable. 5. When labor has commenced and there is found considerable disproportion between the size of the child and that of the pelvis. 6. When the surroundings of the patient are suitable for a major surgical operation and when the services of an operator skilled in pelvic surgery can be obtained. Eclampsia, as a rule, is not encountered before the second half of pregnancy, and becomes more frequent the nearer term is approached. Zweifel has, however, reported a case occurring in the third month. When it does occur in the latter half of pregnancy the disease is usually severe, a favorable termination occurring generally in the cases in which premature labor has rapidly supervened. In such cases, when the fits are severe and rapidly succeed one another, the indication is to empty the uterus at once, and this, McCann holds, is best accomplished by the Cesarean operation, in which the bleeding resulting therefrom is also beneficial. Too much time should not be spent in such cases in attempting to dilate the cervix. Unless the cervical tissues rapidly yield to the

methods of dilation adopted it is a matter of common experience that such manipulations tend to increase the fits, and unless the procedures are carefully carried out there is further risk of septic infection. Infection has already claimed many victims in this disease. The wearing of sterile india-rubber gloves should be made compulsory for all those who engage in the practice of obstetrics, and special precautions should be taken in eclamptic cases to disinfect all instruments used.

Whatever views may be held with regard to the first three indications for this operation, McCann thinks that all agree that when the mother is moribund and the child alive an attempt should be made to save the child's life, and that this is best done by rapid Cesarean section. Eclampsia, which is associated with disproportion between the size of the child and that of the pelvis, is a further indication for this operation, as in such cases it is undoubtedly the most rapid method of effecting delivery. The surroundings of the patient and the surgical ability of those in attendance are important factors in deciding what course is best to pursue in the interests of the patient. If a patient can be removed to a well-ordered hospital or nursing home and can command the services of a competent operator the chances of her recovery will be increased, or if her apartment is clean and skilled assistance at hand the simple technic of the operation may be carried out in her own home. Should, however, the patient be in an insanitary dwelling, and no skilled surgical assistance available, her interests are best served by the adoption of expectant methods of treatment. The Cesarean operation under modern conditions is practically free from risk and is, in McCann's opinion, much to be preferred to the other methods of rapid delivery, including vaginal Cesarean section. In properly selected cases it offers the best chances of saving the life of both mother and child, although death of the fetus *in utero* is not infrequent on account of severe convulsions.

9. **Chronic Constipation Treated by Faradism of the Large Intestine.**—The treatment employed by Burroughs consists in the application to the large intestine of a faradic current of a high degree of penetration and capable of very exaggerated interruption. The method positively resolves itself into putting the abdominal and intestinal muscles through a variety of physical drill, by which they daily can gain in strength and efficiency till their restoration is positively complete. In one case cited the patient was placed in a sitting position, leaning slightly forward. Two flat leaden electrodes were adjusted next to the skin over about the middle of the ascending and descending colon respectively. A faradic current of about 9 volts, with an amperage adjusted to the requirements of the patient, was passed for 15 minutes and the current then reversed for another 15 minutes, at the end of which the first seance closed. The patient had about 30 treatments at ever-increasing intervals until the evacuations became normal in consistency and frequency.

11. **Epistaxis in Cerebrospinal Meningitis.**—During an epidemic which came under Rimbaud's observation during the past winter at the penitentiary colony at Aniane (Herault) there was epistaxis in 4 out of 12 cases. In the 3 first cases the attacks of epistaxis determined an immediate improvement of the symptoms. In the first case the bleeding took place on the second day, and was followed by a sharp fall of the temperature, and on its repetition in the evening the fever fell, the delirium ceased, and recovery was complete in a week. In the second case the epistaxis did not occur until the fifth day and recurred 3 times in the 24 hours. Here, again, there was marked and immediate improvement, with rapid subsidence of the symptoms of meningitis. Much the same thing occurred in the third case, the disease only lasting 6 days. In the fourth case the effects were not so marked and recovery

was delayed for 3 months. Here, then, are 4 cases of cerebrospinal meningitis with epistaxis, in all of which the patients recovered. In this particular epidemic the mortality was comparatively low, viz., 25 per cent. In only 1 case was anti-meningococcus serum employed, so that it looks as if the low mortality were due to the epistaxis. The cases may be classified as follows: Meningitis without epistaxis, 8, with 3 deaths, 37.5 per cent.; meningitis with epistaxis, 3, with no deaths.

Clinical Journal, London

September 7

- 15 Diseases of the Colon. W. J. Hadley.
- 16 *Case of Cerebral Tumor. J. A. Ormerod.
- 17 Value of Vaccination. F. M. Sandwith.

16. **Case of Cerebral Tumor.**—The principal points about Ormerod's case are these: The tumor was a sarcoma; its position as found at necropsy was in the right frontal lobe, where it was diagnosed during life. Yet, though it was correctly localized during life, the localizing symptoms were very scanty. The patient was operated on, i. e., the skull was trephined and the dura mater was opened. No tumor was found, but the relief was very complete for the time. However, the symptoms recurred and finally the man died. The first symptoms began in May, 1906. He was under observation on and off in the hospital for the last 11 months of his illness, and the total illness, as estimated from the first symptoms, lasted three and a half years. The first symptoms were fits of a kind called by friends "fainting fits." In these fits there were no convulsions, only loss of consciousness. They began in May, 1906, and he had about one a week for 2 or 3 months. After this he had an interval of 9 months without a fit. Then, in May, 1907, he had an attack in which he lost consciousness and fell off a ladder and hurt himself. After this he seems to have had an interval of a year without any symptoms at all.

In June, 1908, other symptoms began, namely, headache and vomiting. The vomiting, as is usual in such cases, had no relation to food. The headache was intermittent; at any rate, at first. It was said to be brought on when the patient went into a bright light. The headache and vomiting became worse, and 2 weeks before admission he had another fainting fit, which seems to have been the signal for all the symptoms to get worse. Optic neuritis was more advanced on the right side than on the left. The man had an incomplete paralysis of the left side of the face, affecting only the lower part of the face, not the orbiculis oculi nor the occipitofrontalis. This facial paralysis had a character which is peculiar and which is not often seen, that is, the paralysis was more marked in reflex muscle movements of his face than in volitional movements. About the end of January or the beginning of February he developed a transient diplopia, due to weakness of the right external rectus muscle. At this stage he began to get rather dull; he developed a certain fine tremor of his hands. His headache became persistently worse and the symptoms appeared to increase steadily, and, as anti-syphilitic treatment seemed to bring about no permanent benefit, the operation was performed. At the post-mortem examination a sarcomatous tumor nearly as large as an orange was found in the right frontal region.

23. **Malignant Endocarditis of the Tricuspid Valve.**—The little girl in the case reported first complained of abdominal pain, which had come on apparently rather suddenly on March 11. There had been no vomiting, and no blood had been passed by rectum; the bowels had not been moved since the onset of

the illness. The child had not suffered from any recent illness and there was no history of scarlet fever or chorea. At the time of complaining of abdominal pains she had also complained of pains in the leg. Temperature was 104.2 F.; pulse regular, but weak and rapid. The abdomen was much distended, movements with respiration were very slight, and the walls were rigid, and whenever touched she cried out, "Oh, my belly!" The percussion note was resonant. Nothing abnormal could be felt on rectal examination. On examining the chest no abnormal physical signs were detected. There was no albumin in the urine. The abdomen was opened, but beyond some meteorism and one or two small fecal masses nothing abnormal was observed. On the following day the child still complained of constant abdominal pain and cried out very frequently; the legs were now somewhat rigid and no knee-reflex could be obtained. On March 17 considerable dyspnea was present, and on percussion over the thorax the note over both bases was impaired and an area of tubular breathing was noted over the left base. The abdominal pain was still complained of and on March 18 the child's face was of a dusky color. Dyspnea was much increased and there was evidence of bronchopneumonia of both lungs. Later in the day the child died, three days after admission. No cardiac murmur was detected at any time. On opening the abdomen the stomach was found to be distended. The mesenteric glands were enlarged. There was no peritonitis, no collapse of bowel and no occlusion of the mesenteric vessels noticed. The mitral and aortic valves were normal. On the auricular surface of the middle cusp of the tricuspid valve a whitish-grey, rounded nodule, about one-eighth of an inch in diameter, was seen, which was found to be inflammatory in origin and crowded with Gram-staining micrococci. The lesion was very suggestive of an ulcerative endocarditis.

- 34 Points Concerning Typhoid Vaccine. W. B. Leishman.

33. **Certain Urinary Reactions.**—According to Higgins, Joulié's reaction gives information of the power possessed by a given urine of holding calcium sucrate in solution which would be modified by one of the following conditions: (1) The presence of so large an amount of calcium that it exhausts its power of holding calcium in solution, an absence of bodies which hold it in solution, or the presence of bodies which precipitate; (2) the calcium chlorid reaction precipitates a number of bodies closely associated with calcium; (3) Jacquemet's reaction also tends to be exaggerated when there is marked hypoacidity; (4) it has been mentioned that the reduction of copper varies with the amount of calcium in the ammonium filtrate. Higgins has found the following plan useful in ascertaining the variations in the quantitative distribution of calcium magnesium in the urine [100 c.c. is preferably used for each reaction]: (1) Total calcium ammonium hydroxid is added until a precipitate forms, acetic acid is added till it dissolves, ammonium oxalate is then added. This precipitate is collected, washed, burnt with the addition of a little sulphuric acid, the sulphate is then weighed and estimated by multiplying the weight found by 0.4116. (2) By dissolving the precipitate after adding ammonium hydroxid in acetic acid and adding ammonium oxalate the calcium precipitated by ammonium hydroxid can be separately weighed. By estimating the magnesium phosphate and subtracting the amount from the total of the phosphorus pentoxid in combination with the early phosphates one obtains the amount of calcium phosphate present which can be estimated as calcium so as to ascertain how much of the calcium previously estimated in the ammonium precipitate is in combination with

organic acids. (4) The amount of calcium in the ammonium filtrate is obtained by subtracting the weight of the calcium in the ammonia precipitate from that of the total calcium.

No benefit was derived in either case, the lesions being too far advanced. The reduced blood-pressure and the atheromatous state of the internal wall of the artery explain the failure of such operations for senile gangrene. To have any chances of success they should be done early.

- 39 Operative Treatment of Chronic Urethritis. Carle.
- 40 *Cancer of the Body of the Pancreas. R. Leriche.

38. **Operative Treatment of Exophthalmic Goiter.**—Jaboulay reports 28 cases in which he resected the cervical sympathetic. Of the 23 patients surviving the operation, 5 died from intercurrent disease after great improvement and 11 have been lost to sight; 7 have been under observation for from 8 months to 12 years, and the cure has been complete except for slight tachycardia on effort. He gives the details of 2 cases in which the cure has persisted for 12 years; in one of these the sympathetic was merely stretched for a minute. He found that after partial thyroidectomy all the symptoms subsided except the enlargement of the gland, and for this he applies supplementary electric or thyroid treatment. He says that treatment should be by medical means for the exophthalmos and palpitations; if these fail, operative measures are in order. The cases in which operation on the sympathetic is indicated are the recent active forms of exophthalmic goiter and the forms without enlargement of the thyroid. Partial thyroidectomy should be preferred for the old cases and for the forms with great enlargement of the goiter and mild symptoms on the part of the eyes and heart.

40. **Carcinoma of the Body of the Pancreas.**—Leriche calls attention to the peculiar painfulness of these cancers and the special clinical picture as he shows by 3 case histories. Exploratory laparotomy showed that the growth was inoperable although the pain was much relieved by it. This brings to 16, he says, the number of cases on record in French literature; the youngest patient was 37. A number of the other patients were between 40 and 45. In the majority the first symptom was a sudden intense pain above the umbilicus, commencing on the left under the ribs but spreading toward the center and radiating to the back, chest and shoulder. The paroxysms occur more and more frequently, resembling the crises in tabes. In some cases, however, gastric disturbance was the first symptom and in others merely weakness and progressive cachexia. A tumor was palpable in only 9 of the cases. The patient may die without any signs of jaundice. All but 5 of the patients were men. Leriche discusses the possibility of operative treatment and the technic.

41. **Streptococcus-Carriers in Maternities.**—Fabre and Bourret have found the strains of streptococci inducing hemolysis in certain parturients never presenting puerperal complications. They also found them in some with only slight, transient fever. These comparatively healthy streptococcus-carriers may yet prove a source of contagion of other parturients in whom this strain of streptococci may induce serious

complications. They therefore urge prompt bacteriologic examination of every parturient and measures to exclude the possibility of contagion if streptococci of the hemolytic type are encountered. The blood-agar method (Lenhartz and Schottmüller) they have found the simplest and most practical means for cultivating these streptococci from the lochia.

46. **Pathologic Importance of the Trichocephalus.**—Stecherbak reviews the literature on this subject and then gives the details of a case of neurasthenia with severe gastro-intestinal disturbances, rebellious for 2 years to all treatment until the discovery of trichocephalus eggs and a course of thymol rapidly induced a complete cure. In another case, neurasthenia and anemia promptly improved under thymol treatment. In 11 other cases the trichocephalus was undoubtedly responsible for convulsions and other nervous symptoms observed and disappearing after thymol treatment. These patients were all between 19 and 26 years old except 3, aged 7, 14 and 16. The epileptiform convulsions, hemichorea, neurasthenia, cephalalgia and migraine all disappeared or essentially improved under treatment for the helminthiasis. The convulsions in some of the cases had certain hysterical traits, and he has noticed this feature also in intestinal auto-intoxication and with tape-worm. In most of the cases the patients and their families refused to admit the helminthiasis as the cause for the nervous troubles until convinced by the success of treatment. In another series of 20 cases of severe neurasthenia or epilepsy in which helminthiasis was suspected but not proved, tentative systematic thymol treatment did not benefit in the least. He gave from 0.5 to 2 or 2.5 gm. of thymol a day to adults (7½ to 37½ grains), keeping this up for several weeks or months. The drug was suspended for 5 or 6 days after taking it a week, and this intermittent method has proved effectual and harmless in his experience in hundreds of cases. The patient takes the thymol in a capsule, fasting after a purge, and drinks at once a large amount of hot tea and then does not eat for 2 hours. He gradually begins with the smallest doses to test the patient's tolerance for the drug, except in urgent cases of pseudomeningitis or appendicitis, and then he sometimes supplements it with rectal injections with 5 or 10 drops of benzin to the liter of water. He does not ascribe pathologic importance to the trichocephalus unless the eggs are found in unusual numbers. Even when this is the case, the patients may be entirely free from gastro-intestinal symptoms.

49. **Permanent Cure After Resection of Carcinoma of the Upper Jaw.**—In the 8 cases reported the patients are in good health to date or died from other cause, 10, 18, 19, 21 and up to 26 years after the resection of the carcinoma. These are the survivors out of 48 operations of the kind; the immediate mortality was 19 and 2 died of intercurrent disease and in 2 other cases the operation was recent. The other patients all succumbed to recurrences. König believes in extremely radical operation.

51. **The Thymus.**—Nordmann reports experimental research on a large number of puppies in which he removed the thymus or implanted thymus tissue in other young dogs. He used an apparatus similar to Meltzer's intratracheal insufflation apparatus. The thymus was removed in the third and sixth week of life; none of the animals lived longer than a year and the entire heart was found enormously dilated, especially the right half, but there was no hypertrophy—the wall was nearly as thin as paper. He accepts the suprarenals as the antagonists of the thymus.

52-55. **Chondrotomy.**—Freund describes the basis for the method of mobilizing the rigid thorax which he regards as responsible for the development of morbid processes in the lungs in many cases or at least provides conditions favoring their development. Velden describes the ultimate outcome in 10 cases in which Freund's operation was performed, giving the autopsy findings in one case. He emphasizes the necessity for postoperative physical exercises to fasten and enhance the benefit derived. Hansemann discusses the indications; he restricts the operation to cases with stenosis of the superior thoracic aperture and an apical process not yet extending beyond the second or third rib. With emphysema he advises doing the operation early, and he appeals to practitioners and clinicians to give their patients the benefit of chondrotomy in time. The cure of the apical tuberculous process and emphysema is possible only when patients learn to permit surgical intervention of this kind, as for cancer, in the early stages. Mohr gives some skiagrams to illustrate the prevailing types of indications for Freund's chondrotomy.

58. See abstract 40 above.

60. **Treatment of Air Embolism.**—Clairmont suggests exposing the heart and aspirating the air from the right side of the heart when air has been drawn into an open vein under negative pressure. No benefit can be expected unless this is done at once, immediately after respiration has ceased, while the heart is still pulsating. It should be followed by saline infusion into the right ventricle or intravenously or by direct transfusion according to Crile, with stimulants and direct massage of the heart and artificial respiration.

62. **Local Anemia and Hyperemia by Artificially Altering the Distribution of the Blood.**—Sauerbruch gives an illustrated description of his method of inducing negative or positive pressure in parts of the body by a box with devices for differential pressure. The box can be applied to different parts of the body. It has proved possible thus to suck the blood from

part of the body and permit bloodless operations. He has tested the device on himself, lying for a long time in the box, but experienced no disturbances or untoward by-effects. The veins in the fundus of the eye were found engorged but the arteries did not seem to be much affected. He has applied the method in removing a carcinoma of the orbit, for a mastoid operation and for operations on the neck and hand. The benefit was particularly striking in a case of intradural traumatic intracranial hemorrhage. Under slight differential pressure the blood was all aspirated out of the soft parts and bones. Any air cabinet can be used for the purpose.

63. **Thymectomy and Its Consequences.**—Klose operated on puppies ten days old and concludes from the results observed that the thymus is a vital organ that should never be removed in young children. The symptoms following its removal are the results of an acid intoxication, presumably from nucleic acid, and a deficiency of lime, with resulting changes in the bones and brain. Partial removal of the thymus during its most active phase of existence or complete removal during the phase of involution did not seem to cause permanent injury. He believes that the spleen is the organ which acts vicariously for the thymus. Treatment with thymus preparations is unable to counteract the effects of thymectomy. More logical is the administration of alkalines to counteract the acid intoxication or means to stimulate production of alkalies. Harm is done by thymus treatment, as this merely increases the acid intoxication. Rational surgical treatment is by autoplasmic operations.

65. **Exophthalmic Goiter Coming on During Iodid Treatment.**—Kocher thinks that excessive iodid treatment is responsible for the development of exophthalmic goiter in more cases than is generally recognized. He says that this iodine-Basedow, as he calls it, is a frequent and important form of exophthalmic goiter. Treatment should be prophylactic, removing all goiters which do not yield in a few weeks to careful treatment with iodid in small doses. Once developed, all iodid medication should be stopped and all factors avoided that might act unfavorably on the nervous system. In a case described, the thyroid weighed over 160 gm. and contained no less than 0.00368 gm. of iodine. If the other cells of the body had stored up iodine in the same way, there would have been 18.4 gm. in the body. This patient had a goiter for nearly 7 years and then applied local injections of an advertised mixture containing iodine. In four weeks she lost 16 pounds and the typical Basedow syndrome developed. Suspension of the drug and removal of parts of the goiter were followed by gradual recovery.

81 Suicide in the Past and Present. (Ueber den Selbstmord.) A. Münzer.

70. **Vaccination Against Cholera.**—Aaser reports his protective inoculation of the medical and nursing force at the Christiania isolation hospital, 31 persons in all. The vaccine was made according to the Pfeiffer-Kolle technic. The reaction was moderately severe, but was entirely over by the evening of the second day. A few patients said they had never been so sick before in their lives. The moderate fever never lasted more than twenty-four hours. Diuresis was common but no diarrhea was observed. He gives the results of determination of the bactericidal property of the blood serum as followed through several months; the serum has persisted bactericidal for over a year to date.

72. **Sponge for Obtaining Contents of Small Intestine.**—Sarnizyn experimented with various capsules but now uses a little silver capsule. A piece of sponge is placed in the silver capsule and on this a little disc of cork. The whole is then enclosed in a glutoid capsule which passes unmodified through the stomach. When the capsule reaches the small intestine the outer capsule is dissolved. The sponge then becomes impregnated with the fluid contents in the intestine; as it swells it presses the disc of cork against its open end, which is smaller in diameter than the cork. This plugs the opening completely and when the capsule is voided in the stool the sponge can be pressed without removing it from the capsule, and we thus obtain the undiluted fluids from the small intestine. He relates his experience with this procedure at Kasan, Russia, having found it extremely instructive. A glutoid rather than the silver capsule is preferable on suspicion of a stricture of the intestines.

74. **Hemorrhagic Cystitis After Operations on the Rectum.**—Hadda has been impressed with the frequency of cystitis after operations on the rectum. It occurs even when the patients have not been catheterized. At it is usually of a hemorrhagic character, he thinks it is probably the result of thrombosis in the bladder veins. In 153 operations on the rectum, 61.4 per cent. of the patients required catheterization and cystitis developed in 50 per cent. of these. It came on between the third and sixth day as a rule, and in about half the cases of this hemorrhagic cystitis the trouble began with severe hemorrhage. Postoperative cystitis developed in only 12 of 46 patients requiring catheterization in a series of 239 laparotomies in the last three years, and in none of these was the cystitis hemorrhagic.

77. **Ehrlich's "606" in Syphilis.** Kromayer reports 27 cases. In 3 cases some of the symptoms persisted after the injection and in 5 others there has already been a recurrence. A positive Wassermann reaction became negative in only 25 per cent. of the cases. His experience confirms the rapid reabsorption of the pathologic tissue of the syphiloma and the rapid healing over of ulcerations from the stimulation of the epithelium to proliferation.

85. **The Blood-Pressure During Spa Treatment.**—Ritter reports the findings in regard to the blood pressure in patients taking a course of treatment at Carlsbad, and insists on the importance of keeping constant supervision over the blood pressure during spa treatment. The blood-pressure declined systematically in all but 2 of the cases, and this decline, he thinks, is unmistakably due to the influence of the hypotonic mineral waters. This assumption is sustained by the decline in the blood-pressure observed in animals injected with solutions of salts of varying concentration, the conditions approximating those in the patients.

87. **Behavior of the Kidneys in Diabetes Insipidus Secondary to Organic Brain Disease.**—Finkelnburg reports a case of diabetes insipidus accompanying cerebral syphilis; in another it was consecutive to fracture of the base of the skull, in a third to polydipsia with epilepsy in a hard drinker; in a fourth case the diabetes insipidus followed concussion of the brain. In the 2 latter cases restriction of the intake of water restored the urinary secretion to approximately normal. The concentrating power of the kidneys did not seem to be materially impaired in these cases of primary polyuria with an organic brain affection.

88. **The Blood in Poisoning with Arseniureted Hydrogen.**—Joachim gives the details of 2 typical cases of industrial poisoning with arseniureted hydrogen. One patient had had 2 similar but milder attacks 1 and 3 years before. In both cases the olive green tint of the skin was striking; it was probably the result of the combination of anemia and jaundice. Both patients were taken suddenly with headache, chilliness, vomiting, fever, hemoglobinuria, large amounts of bile in the stool, slight enlargement and tenderness of the liver and enlargement of the spleen. The symptoms came on after working for a few hours plating lamps with a mixture containing hydrochloric acid, zinc and arsenic. The patients lay in a state of stupor for a week, but then one rapidly recovered. The other displayed more of a hemorrhagic diathesis and intercurrent typhoid the third week brought him to death's door, but he finally recovered, although convalescence was delayed by a hemorrhagic nephritis. A special feature of the blood picture was the large numbers of erythroblasts, up to 3,544 per cmm. in the first and 43,377 in the second case.

89. **Outcome of Pulmonary Tuberculosis After Tuberculin Treatment.**—In Penzoldt's 10 cases a systematic course of tuberculin treatment was given in 1890, and he now reports the later history of the patients and urges other physicians to overhaul their old records and compare them with the ultimate outcome. In 7 of his 10 cases tubercle bacilli had been found in the sputum and in the others the unmistakable general reaction testified to the nature of their pulmonary trouble. His patients were men between 19 and 40 and 2 young women, all well-to-do and stopping in the Alps at the time of treatment, where Penzoldt himself was stopping on account of an apical process. All entirely recovered or the tuberculosis passed into a mild state permitting survival to date. One patient succumbed to an intercurrent disease after 15 years. Penzoldt's principle was to keep the dosage low to avoid reactions.

91. **Atypical Pneumonia.**—Gross reports 17 cases distinguished by their insidious and gradual onset, the severe subjective symptoms suggesting typhoid at first—absence of objective findings in the lungs for days, sputum thin, copious

and hemorrhagic, inefficiency of antipneumococcus serum and epidemic character of the disease. It passed finally into the typical croupous pneumonia type and all the patients recovered.

92. **Pathology of the Suprarenals.**—Bittorf reports 2 cases of Addison's disease with amyloid of the suprarenals or obstruction and with hypernephroma in 2 others. In 4 other cases the bronze pigmentation was explained by changes in the suprarenals. In some the lesions were evidently of later date than the pigmentation and a functional disturbance had probably preceded them.

110. **Typhoid Fever After Gall-Stone Operations.**—Aruspberger discusses the cases in which cholecystitis appeared in the course of or soon after typhoid, and also typhoid bacillus-carriers in general. He then reports a case which can be explained only by assuming that the patient was a bacillus-carrier and auto-infection after a gall-stone operation resulted in the development of typhoid fever. She was a woman of 42, the wife of a baker, and had had typhoid 15 years before. Recurring gall-stone colic finally compelled removal of the gall-bladder and drainage of the hepatic duct. Sixteen days after the operation typhoid developed. No typhoid bacilli could be found in stool or urine when the patient was discharged. He has found records of 3 similar cases, and suggests that the possibility of the patient having been a bacillus-carrier must be borne in mind in the puzzling cases in which typhoid develops after operations on the biliary passages.

111. Ehrlich's "606" in Syphilis.—Herxheimer has now used "606" in treatment of 200 syphilitic patients. There has been recurrence in only one. The effects were most striking in the malignant cases. No injuries by-effects were observed in any instance.

119-121. Ehrlich's "606" in Syphilis.—Spiethoff states that his experiences with 50 cases were all favorable although the reaction of the drug was rather severe in a number of the patients. In one case, a man of 31 with secondary syphilis, stupor and positive Wassermann reaction had an attack of convulsions resembling an epileptic seizure 4 hours after injection of 0.3 gm. of the "606," with abolition of the corneal reflex and exaggeration of the knee-jerk. There was no history of epilepsy in this case but at the age of 14 he had had a period of psychic disturbances similar to the stupor observed before the injection. Spiethoff had a similar experience with a psychosis developing in a patient during a course of treatment with arsacetin—in these cases the brain was evidently the point of less resistance. In 2 cases he observed sudden total blindness for a few minutes; one in a tabetic 50 hours after the injection of the "606." In the second case an otherwise healthy syphilitic reported sudden blindness in the right eye and ptosis of the lid, the whole lasting for 10 minutes and coming on 8 weeks after the injection. In a few other cases scotoma was noted on the day of the injection. But in all these cases the eye disturbances were briefly transient and never alarming. Tachycardia was also observed in a few cases but subsided if the patients lay down. The treatment had an unfavorable action in the case of an anemic woman of 28, who was very poorly nourished, and had tertiary lesions in the throat. Three years before she had been treated with atoxyl for the same lesions. An injection of 0.5 gm. of the "606" was made in the afternoon, followed in the evening with 0.01 gm. of morphin. The patient was found dead in bed the next morning. Autopsy showed cicatricial stenosis of the throat and healed gummas in the liver, with hypoplasia of the heart and aorta, but no signs of arsenic intoxication could be detected. Ehrlich attributes the death in this case to shock from the local painfulness at the site of injection. Duhot reports an experience similar to that of Taege's, summarized in these columns September 24, page 1154. The infant was transformed under the influence of "606" taken by the mother nursing it. Ehrlich discusses the mode of application of the "606," stating that he has records of 300 cases in which it was given intravenously, while in the 3 fatalities of which he knows the route was different in each case, intravenous in Grouven's case, subcutaneous and intramuscular in the others. It is possible, he adds, that first an intravenous, followed in 48 hours with an intramuscular injection, thus dividing up the amount, may prove the preferable technic.

122. Morbidity of the Puerperium.—Jaeger states that the experiences in 67 cases of febrile puerperium at the Kiel clinic for women show that syphilitic parturients are particularly liable to infection. Consequently internal examination and other interfering measures should be systematically avoided

for them. In 28 of the 50 women in this class there were no signs of syphilis on the external genitals, but the Wassermann test was positive.

126. Floating Capsule Test of the Motor Functioning of the Stomach.—Kaestle has the patients swallow 3 capsules, hardened so that they do not dissolve in the stomach, and filled with bismuth. They float on the surface of the fluid in the stomach and under fluoroscopic examination they can be seen descending as the fluids pass out of the stomach. He found that a glass of water did not entirely pass out of the stomach under 110 minutes, and a glass of warm milk under 2½ hours; the same amount of cocoa required 2¾ to 2 hours and 55 minutes, tea sweetened but without milk passed out of the stomach in 1½ hours. His tests were made on healthy persons of both sexes.

133. Decapsulation of the Kidney in Eclampsia.—Gobiet reports 2 cases in which he did decapsulation of both kidneys. The first patient was a iv-para and no benefit was derived from the operation; the kidneys showed acute hemorrhagic nephritis. The other patient was a i-para and there were no further convulsions after the decapsulation, which seemed to restore normal functioning on the part of the kidneys. When the changes in the kidneys are exceptionally severe, even this intervention is liable to fail, he regretfully remarks.

140 Treatment of Placenta Praevia. J. Olow.

139. Curvature of the Spine in Children.—Haglund makes an impressive plea for the earlier detection and proper treatment of scoliosis in children. He found in examining the 1,600 children in a certain public school at Stockholm that 25 of the children had scoliosis to such an extent as imperatively to require specialist orthopedic treatment and that 86 others also needed it greatly; 158 others needed it but not so imperatively, and 85 others displayed a tendency to curvature of the spine but were scarcely in need of specialist measures. A more or less pronounced tendency to scoliosis was thus evi-

dent in 354 of the 1,599 children, and the boys were slightly in the majority. He gives illustrations of the various types of curvature encountered, discussing the causes and urging more active prophylaxis. The ideal would be, he says, to have a medical man or woman connected with each school—giving up private practice—to take charge of the physical training of the pupils and gymnastic exercises and diagnose incipient curvature. There should also be an orthopedic polyclinic to which those requiring special orthopedic treatment but unable to pay for it should be referred. Or, perhaps better yet, every medical student should be given training in orthopedics as part of his regular course. Physicians then would appreciate better, he says, the important matters of physical training, prevention, diagnosis and care of deformities and the necessity for and technic of orthopedic treatment.

 147 *Digitalis-Camphor in Treatment of Pneumonia. A. W. Schiander.
 148 *Rapid Determination of Albumin Content in the Urine. (Hurtigbestemmelser af eggehvitemængden i urin.) N. B. Koppang.

141. **Causes of Death in Diabetes.**—Hanssen states that of the 33 diabetics dying at the Rigshospital at Christiania in the last 20 years the fatal coma developed once each after pneumonia, the excitement of a journey, diarrhea, alveolar periostitis or rhinitis, twice during otitis media, three times after abrupt changes in the diet and once, in a patient free from sugar at the time, after a diagnostic injection of tuberculin. In 13 of the 23 patients examined post mortem no traces of tuberculosis could be detected and no clinical evidences of tuberculosis had been noted during life in the 10 other cases that did not come to autopsy. In only 9 of the total number of cases were signs of gross disease found post mortem; in this group was a patient with acute dilatation of the stomach, another with edema of the larynx, another with perforation peritonitis and 4 with a combination of pulmonary and heart disease. Seven of the 24 patients dying in coma were between 10 and 20 years old, 7 between 20 and 30, and the others between 30 and 70.

142. **Sudden Death After Lumbar Puncture.**—Hanssen states that there are about 30 cases on record of fatalities soon after lumbar puncture. Autopsy generally reveals excessive pressure on the brain from accumulated fluid and more or less obstruction of the communication between the fluid in the skull and in the spinal canal. In a case he reports, fatal paralysis of the respiration came on 6 hours after the puncture, done to relieve severe intracranial trouble. The heart action remained regular for nearly 20 minutes after the patient had ceased to breathe. In another case evacuation of pus from a cerebellar abscess was followed by similar arrest of the respiration while the heart continued to beat for 15 minutes. In another case, a few hours after a lumbar puncture an operation was done for sinus phlebitis in a boy 5 years old. As the wound was being dressed after the operation the child stopped breathing but under artificial respiration the heart continued to beat for 55 minutes longer. Alcoholism seems, he says, to favor the development of serous meningitis and this should warn against lumbar puncture in hard drinkers. Grøndahl has recently reported an instructive case of this kind; a sailor who was found later to have had a cyst in the membranous roof of one of the ventricles of the brain developed signs of severe pressure on the brain after drinking some liquor and was found dead in bed the next morning.

143. **Acute Dilatation of the Stomach.**—Hanssen discusses eleven cases of fatal acute enlargement of the stomach

observed at the Christiania Rigshospital, and calls attention to the danger of its occurrence with deformities and fractures of the spine; he says that in several cases on record it has followed the application of a correcting corset. In 5 of his cases the enlargement of the stomach was a terminal phenomenon in constitutional disease, but in another case the acute and promptly fatal enlargement occurred in a healthy boy of 15 who swallowed his dinner hastily and hurried back to his employer over a mile away. Notwithstanding lavage and incision of the stomach, releasing explosively the air which was ballooning it, the patient died the next day. The evidence seems to be in favor of the dilatation being due to paralysis; collapse, vomiting and oliguria are the main symptoms. There was no dilatation of the abdomen in six of his eleven cases; the stomach contained from 1 to 8 liters of fluid.

147. **Digitalis and Camphor in Treatment of Pneumonia.**—Schiander states that 7 died of the 25 patients treated according to Quisling's method of combining digitalis and camphor. The mortality was thus 28 per cent., but he adds that the results might be better in private practice.

148. **Determination of Albumin in Urine.**—Koppang reports comparative tests with various methods and technics, his conclusions being most favorable to Aufrecht's method of centrifugating the urine, mixing with 4 c.c. of urine 3 c.c. of an aqueous solution of 1.5 per cent. picric acid and 3 per cent. citric acid. The results, he says, are reliable while the method is simple, rapid and practical and can be applied to any organic fluids and also for determination of propeptones in urine after filtering out the albumin, cooling and centrifugating anew.

THE RELATIONSHIP OF NEUROLOGY TO PREVENTIVE MEDICINE*

JOSEPH COLLINS, M.D.

Physician to the Neurological Institute of New York
NEW YORK

The neurologist is concerned with a branch of internal medicine which at first sight does not appear to have much relationship to public health, but, in reality, not only does such relationship exist, but it is a very intimate one. Though public health seems to concern itself with sanitation and pure food, epidemics and health-menacing noises, public hygiene is, in reality, public education. Its aim should be to teach people, not only how to live long, but how to live happily, and my first contention is that, until the present time, preventive medicine has concerned itself exclusively with the former, whereas, if the object and aim of life is the pursuit of happiness, personal and general, preventive medicine is but half accomplishing its purpose. Following its principles, we direct our efforts to stamping out diseases which kill, leaving unnoticed and unattacked those which maim and incapacitate. The victims of these often find life insupportable, and they not only menace the happiness of their families, but stain the escutcheon by the crime of self-destruction.

I shall attempt a discussion of the relationship of neurology to public health under two captions: first, our obvious duty in dealing with certain infectious diseases of the nervous system, and second, our privilege in attempting to overcome certain incapacitating mental states.

OUR DUTY

Certain infectious diseases of the nervous system, especially poliomyelitis and epidemic cerebrospinal meningitis should be considered reportable, quarantinable diseases. The former is not yet so considered by many health boards; the latter, fortunately, is. The epidemic prevalence of poliomyelitis has been recognized for nearly twenty-five years, the first epidemic having been studied in Norway in 1887, and the second in Vermont in 1894.¹ Since that time, more than fifty epidemics have been carefully described. As the result of the investigation of these epidemics, and particularly of the epidemic that occurred in southern Norway in 1905, the epidemic in New York in 1907, and the epidemic in York County, Nebraska in 1909, we are now in a position to state that the disease is communicable; that contact with a person sick of the disease is not necessary that another person may contract

it; that the period of incubation is from four to ten days; that the contagiousness of the disease varies with the epidemic, and that the mortality rate is liable to great variation, in some instances being as low as 5 per cent., in others as high as 46 per cent. In addition, we know that the seasonal occurrence is very extraordinary; that it occurs, practically only in the warm weather; and that unhygienic surroundings, density of population and conditions of health have little or no bearing on the occurrence of the disease.

The experience of Dr. G. P. Shidler² of York, Neb., shows that the disease can be readily controlled by quarantine, and boards of health should be urged to place poliomyelitis on the list of reportable diseases and to formulate measures which may be quickly enforced to constitute the strictest quarantine.

We must bear in mind that it is an acute and infectious disease of the cerebrospinal axis and its covering, the pia, with a pronounced and inexplicable predilection for the gray matter of the anterior portion of the spinal cord, which it nearly always succeeds in affecting before its pathogenic impetus is satisfied. It affects the gray matter in one case profoundly, in another triflingly, and the symptoms that result in any case must, of necessity, vary with the intensity of the infection and with the portion of the cerebrospinal axis that bears the brunt of the lesion. The most important factor in stamping out the disease is that we learn to recognize it early and that we interpret correctly the so-called atypical cases. In many of the epidemics the experience has been that milder cases and cases in which the paralysis was neither profound nor lasting were looked on as cases of grip or rheumatism. I need not say that these mild and difficult cases are as potent to disseminate the disease as are the severer cases.

The necessity for quarantining epidemic cerebrospinal meningitis is generally conceded. Here we are dealing with a disease that fights in the open, as it were. We know the natural history of the *Diplococcus intracellularis*, we know its mode of entrance into the system; and fortunately, thanks to the brilliant investigations of Flexner, we are in possession of a serum which, given early and properly, is adequate to control the disease, and, in any case, to rob it of its terrors. More than this, epidemic cerebrospinal meningitis is a disease that either kills its victim or allows him to recover, while poliomyelitis nearly always maims, and pitifully so, those that it does not kill.

Other varieties of infectious nervous diseases that come within the scope of the neurologist are epidemic polyneuritis and pellagra. The former is of such rare occurrence in this country, save in our tropical possessions, and the latter is now having its natural history

and pathology so carefully studied by those to whom the opportunity is given, that I shall make only this cursory reference to them here.

Preventive medicine has not given the attention that it should to certain diseases of the nervous system that flow out of occupation and especially of occupation in foundries, blast furnaces and rolling mills. There is a widespread or generalized intoxication of the nervous system that occurs in bronze workers. It is not possible in every instance to say whether the disease is a neuritis, a myelitis, or an encephalitis. A patient that I have had recently in the Neurological Institute will best illustrate this point and will, likewise, indicate how necessary it is to apprise workers in such foundries of the dangers to which they are exposed.

A man, 47 years old, who had lived a continent, healthy life, and who was by occupation a foreman in a bronze factory, was sent to me from Bellows Falls with the diagnosis of pernicious anemia. His story was that in the winter of 1909 he had had two or three attacks of dysentery without attributable cause. Careful inquiry revealed that during the previous summer he had an attack of salivation, that his mouth had been sore, that his breath was extremely offensive, smelling of garlic, and that he had a craving for raw onions, an article of food which he had not been accustomed to eat. In July 1909, and some time after the third attack of dysentery, he noticed that he would often be stricken with uncontrollable drowsiness, while talking to his men in the shop, while sitting at table, while in church, etc. In addition to this, he became forgetful and stupid. About two months later, he first noticed a sensation of numbness and weakness in the extremities, phenomena that increased until he was wholly paralyzed. It was also noted that his speech became somewhat indistinct, and on two occasions he was incontinent of urine. After three months this paralysis began to disappear gradually, and when I saw the patient in March, 1910, he was able to walk with the aid of a cane and supported by another person. The examination showed that there was no marked muscular atrophy. The station and gait and the purposeful movements of the hands were all ataxic. The knee-jerks, the ankle-jerks and the elbow-jerks were lively and the patient had the Babinski phenomenon (extension of the big toes on irritation of the soles) on both sides. There was no detectable disturbance of the various forms of sensibility nor were the special senses disordered. The pupils responded readily to light. Examination of the urine failed to reveal either arsenic or lead.

I interpret this case as an example of intoxication of the nervous system, the peripheral as well as the central, probably by arsenic, although it is quite possible that it was the result of more than one metallic poison. The odor of garlic that was attached to the breath, the ptialism, and the attacks of dysentery, might all be accounted for by arsenic, but arsenical poisoning has rarely been followed by symptoms indicative of implication of the spinal cord and brain such as existed in this case.

The point that I particularly wish to make, however, is that workers in factories such as this should have their health safeguarded.

There is a form of neuromuscular affection which occurs in workers exposed to high degrees of dry heat, such as stokers, puddlers, etc. Its most conspicuous symptom is what we neurologists call myokymia associated with generalized weakness. This condition has been

studied by Edsall of Philadelphia, and I myself have encountered several instances of it. What its pathogenesis is, whether an intoxication by products developed within the system as the result of application of intense heat, or whether it is due directly to the heat, cannot as yet be said.

I purposely refrain from any discussion of the relationship of syphilis to diseases of the nervous system and to the bearing of this problem on preventive medicine. Everyone knows that there are certain organic diseases of the nervous system that flow out of syphilis, and that, if syphilis were conquered, tabes and its twin, general paresis, syphilitic spinal paralysis, and syphilitic endarteritis and meningitis would cease to exist. Syphilis is a social evil which must be dealt with in some other way than by science. The dominant instinct of man will be appeased illicitly, so long as the race exists and so long as alcohol is used. Education will do something toward diminishing its frequency, but a small amount of alcohol, taken at one time, quickly inhibits the effect of education. My personal belief is that we must check the ravages of syphilis by an adequate cure properly administered.

OUR PRIVILEGE

An incalculable part of all the misery, suffering and incapacity in the world is contributed by those functional nervous diseases that are now commonly called the psychoneuroses. They are the diseases that furnish the pabulum on which the rank growth of supernaturalism in therapy, in the shape of Eddyism and Emmanuelism in this country, has occurred. They are the diseases on which the quack fattens; they are the diseases whose existence is a constant reminder of our inadequacy to give proof of the reason for our existence, namely to heal the sick.

We do not successfully combat psychoneuroses, hysteria, psychasthenia, obsessive and anxiety states, because we do not prevent them. We do not prevent them because we do not know their cause. We know that they occur in individuals of neuropathic and psychopathic heritage, that is, in those whose ancestral endowment to resist strain and stress is below the normal, and we know that they are immediately conditioned, in persons thus predisposed, by normal and physical trauma.

During the past few years, a theory or hypothesis of the causation of the psychoneuroses has been evolved and put forth by Freud of Vienna, which is deserving of the most careful investigation and consideration. Although it does not, at first sight, seem to concern the physician who devotes himself to preventive medicine, in reality it does, for on him will devolve the devising of ways and means to prevent them.

The enormous importance of sexual factors in pathologic states as well as in normal conditions, has always been conceded, at least tacitly. It is Freud's merit to have opened up a wider vista into the delicate and hidden connections between the erotic element and nervous disease. His explanation of functional neuroses as the result of a mass of suppressed sexual desires has fallen like a bombshell into this era of sexual hypocrisy; and his ruthless application of the so-called sexual symbolism in all cases has naturally led to a strong, though by no means universal, reaction against the proposed remedy, psycho-analysis.

The question has been raised: Why should the sexual emotions alone, among the manifold equipment of the psyche, give rise to disturbances? In other words, why

regard the sexual emotion as the root of all other emotions? In answer it may be urged that there is only one thing in life which is desirable and pleasing enough in itself to induce human beings to sacrifice all else for it, and for which such sacrifices are constantly being made, namely, love, and its sexual gratification. The suppression of sexual life by sexual ethics is a deplorable concomitant of culture. In the interest of the public the individual is forced to immolate a part of his personality, especially his sexual instincts, and, among these, more particularly the heterosexual desire.

Under favorable circumstances, which include elements ranging from a trained will-power to sedative surroundings, the sexual instinct may be sublimed, that is, directed towards a spiritual instead of a carnal goal. It is then devoted to the amelioration, rather than the propagation of the species. Sublimation processes are the basis of artistic and scientific activities, and in more than a few cases, an unflagging diligence along a chosen line of work is the result of a transformed unsatisfied sexual desire. The sublimated sexuality finds its highest expression in adaption to circumstances, the harnessing of the plunging horses of instinct to the chariot of reason. But it is only the direction of the desires that is changed, not their strength; and unless a certain measure of direct sexual activation be left, the sublimation will lead to disease.

Psychoneuroses are the price of sublimation, the negative of the perversions, according to the teachings of Freud. The self-indulgent, who compromise between desires and gratification, are often blessed with iron "nerves," whereas the would-be ethereal and sexless are proverbially high-strung and nervous. The hysteric, beyond the boundary line of psychic equilibrium, cling so tenaciously to the desire as to renounce peace and happiness, preferring silence to confession. They exhibit an exaggerated tendency to sublimation, but their symptoms are abnormal sex manifestations.

Other psychoneurotic states, which, in the opinion of Freud, are mainly due to sexual abstinence, or rather, suppression, with or without masturbation, are the phobias and obsessions. The pathologic condition is, again, the outcome of the disproportion between the sexual demands and the sexual suppression.

A sexual etiology is common to all neuroses, and, in the psychoneuroses proper, dates back to childhood (Freud's infantile sexual traumatism). Such psychoneurotic states, on the basis of psychic traumatism, besides the phobias and obsessions, include neurasthenic fears with their sequelae, disturbances of sleep, such as nightmare, and of speech such as stammering; nervous affections of the heart, the sexual heart, phrenocardia; hypochondriacal conditions; a number of sexual perversions, fetichism, sadism, masochism, psychic impotence, homosexuality and vaginismus. In his modified views, Freud holds that the factors of constitution and heredity regain their supremacy in proportion as the accidental experiences of sexual adventure recede into the background. Nevertheless, the customary term "neuropathic disposition," according to him, really means "sexual constitution" of the individual. The undeniable fact that sexual traumatism also plays a part in the life history of individuals who are apparently free from neurotic taint is ingeniously explained as the correct balance of the sexual equation.

In his later teachings Freud admits that the accidental effect of a psycho-traumatic experience on the infantile sexuality is not so far-reaching or relevant in

its bearing on the origin of a psychoneurosis as is the individual reaction of the sexual constitution. His original view that a morbid fear is a sexual desire diverted from its natural course has been extended by the acceptance of other possible causative factors, namely a congenital diathesis expressed by psychic inadequacy for the control of the somatic sexual tension. The onset of a neurosis is governed by the original resistance of the nervous system, and facilitated by the ordinary emotional shocks of the individual's life, such as fright, grief, psychic fatigue; but the specific cause, the factor which determines the form of the neurosis, is sexual in character.

Hysteria, according to Freud's interpretation, is the result of the conflict between the sexual desire and the sexual suppression. The hysterical symptoms have the value of compromises between these two psychic currents. The sexual desire is confronted with internal resistance, notably modesty and physical aversion. Sexual abstainers (teetotalers in the *ars amandi*) accumulate a mass of unassimilated memories, suppressed reminiscences and converted emotions. In the course of time, the original feelings are blurred, and finally vanish from the realm of consciousness, to become replaced by the familiar hysterical symptoms of globus, palsies, fits, etc. Provided the source of the disturbance can be reached, the suppressed emotion will find its natural solution, and the symptoms will disappear. Having a sexual etiology, hysteria is never associated with so-called innocence of thought, and hence the danger of corruption does not exist. Being of psychogenic origin, the disease requires fundamentally psychic measures for its control. The symptoms must be literally reasoned away.

I trust that I have said enough to convince everyone that the relationship between neurology and preventive medicine is a close one, and that the neurologist of the future must be one who works diligently in the field of preventive medicine. I venture to express the opinion that the expert in preventive medicine would profit from some training in neurology.

But the subject that I venture to bring to attention in the second part of my address, namely that of the psychoneuroses, is one that must be dealt with entirely from the pedagogic standpoint. We, as physicians, however, must devise ways and means for giving such instruction. It certainly cannot be given, and should not be given by the teachers in our schools. I regret to say that the vast majority of them that I have encountered have an ignorance of the principles of sex knowledge and sex hygiene that is almost abysmal. In fact, I am not at all sure that we physicians, as a class, take the trouble to acquaint ourselves as intimately with the principles of sex physiology as we should, and, of course, we cannot expect to teach that which we do not know, and we should not permit ourselves to get a knowledge of it while teaching, because the experiment is too dangerous to those with whom we are dealing. It seems to me that plain wholesome lectures on sex physiology given to small classes and in many instances individually, should be a part of the curriculum of every public and private school, and that these lectures should be given by physicians, men and women, whose sanity, honesty, earnestness, and ability have been testified to or vouched for by their appointments from the executive medical officer of boards of health.

PAPILLARY CYSTADENOMA OF THE KIDNEY,
ASSOCIATED WITH MYOMA OF THE
UTERUS AND SPINAL CARIES *

GEORGE ERETY SHOEMAKER, M.D.
Gynecologist to the Presbyterian Hospital
PHILADELPHIA

Summary.—The patient presented an unusual series of lesions, namely, uterine myoma with hemorrhage, spinal caries and kyphosis, together with a large bleeding tumor of the

Fig. 1.—A papillomatous pedicle springing from modified kidney structure ($\times 100$).

Fig. 2.—A loosely spread portion of a papillary growth ($\times 100$).

kidney. Hysterectomy was first done for the myoma. The kidney hemorrhage filled the bladder with firm clots which decomposed; a vesicovaginal incision gave exit to the offensive

clots and averted infection of the kidney growth. The latter was removed by nephrectomy and later under local anesthesia the vesicovaginal fistula was closed. The patient recovered.

History.—M. J., aged 27, married, sterile, was an overall thin mulatto woman. On admission to the Presbyterian Hospital she was able to give little history except that of irregular hemorrhage from the vagina for a year, at times severe. The day before admission the urine was bloody also, but she had not clearly distinguished the uterine from the urinary bleeding in the past. For two months she had noticed a tumor in the left upper abdomen. There had been a little pain for a month in the left lumbar region, over the left iliac crest and in the left thigh and the legs. There were well-marked syphilitic scars about the anus and legs. The urine was negative except for abundant blood. As the hemoglobin was 28 per cent, and she was losing blood freely from the uterine tumor, abdominal hysterectomy was done as a first step. An interstitial uterine growth reached nearly to the navel, which the pathologic laboratory reported as a myoma of the uterus with no unusual features.

Recovery from the hysterectomy was aseptic, but about two weeks afterward the hemorrhage from the tumor of the left kidney, which had been absent since admission, began again and soon became serious. The bladder filled with firm clots,

Fig. 3.—Shows cyst wall and areas of hemorrhage ($\times 100$).

which became infected and highly offensive. The cystoscope showed blood coming from the left ureter, and, while it might have been possible to break up and remove clots with an evacuator, the process was not without danger and would probably have to be repeated. With the large mass present involving the lumbar spine as well as apparently the left kidney, not the slightest chance of infection through the bladder could be taken. Therefore a large vesicovaginal opening was made, attaching together the mucous membrane of the bladder and vagina. Removal of the clots and irrigation through this fistula promptly cleared up the bladder infection and maintained a clean field while the kidney was attended to.

Examination of Tumor.—What appeared to be a kidney tumor reached 2 inches below the navel on the left side, filled the whole left upper quadrant and was lost under the ribs, which were forced outward and forward. The enlargement produced by the tumor continued around behind where it joined another swelling to the left of the three upper lumbar vertebrae. These projected backward out of line. The swelling immediately to the left of the diseased vertebrae was deep-seated between the ribs and the spine. There was tenderness, but no definite fluctuation and no redness of the skin. The

* Read in the Section on Obstetrics and Diseases of Women of the American Medical Association, at the Sixty-first Annual Session, held at St. Louis, June, 1910.

questions for decision were whether the abdominal tumor was directly continuous with the tumor of the spinal column; or whether the spinal disease was a caries and separate from the other tumor, while lying in contact with it; and, as the masses could not be separated by examination, whether an attempted nephrectomy would open up the spinal area or not. A well-marked bruit and thrill behind suggested an aneurism eroding the vertebrae, but it was found that these symptoms appeared only when the patient lay on the right side. Indeed, the kidney tumor proved to be suspended from its upper portion with some range of mobility below, so that with change of the patient's position it would swing against the aorta, giving rise to the bruit. The skin test of von Pirquet for tuberculosis was negative. The x-ray photograph showed necrosis and posterior displacement of the three upper lumbar vertebrae, apparently from intrinsic disease and not from erosion. Aspiration to a depth of 2 inches in the swelling to the left of the spine yielded dark, thin, bloody fluid. On this the report of the pathologic laboratory by Dr. Canby Robinson was sterile blood with excess of serum. Cultures and smears were negative for tubercle bacilli and other organisms. In the determination of the sufficiency of the other kidney, indigo-carmin solution was injected into the buttock muscles by Dr. Laws. The cystoscope then showed active spout-

ing followed. Eighteen days after the nephrectomy, the vesicovaginal fistula was successfully closed with no pain under local anesthesia. Two per cent. eucain solution and 1 to 20,000 adrenalin solution were injected into the tissues of the vesicovaginal septum.

When studying the kidney functions prior to nephrectomy in this patient, the presence of the vesicovaginal fistula prevented the distention of the bladder with water or air to facilitate cystoscopy. As reported to the Philadelphia Academy of Surgery¹ I overcame the difficulty by introducing a finger-cot partly through the fistula and then distending the cot

Fig. 4.—A small cyst and papillary growth inside (X 100).

Fig. 5.—A portion of a cyst, and a portion of modified kidney cortex which contains Malpighian bodies and numerous tubules cut in various directions (X 100).

ing of blue urine from the right ureter in eighteen minutes, while the blue stain appeared much more slowly on the diseased side, and the spurts were very feeble and infrequent. The blue stain was very faint on the left. This proved the relatively greater activity of excretion on the sound or right side, and as there were no casts, while the total twenty-four-hour quantity was good, nephrectomy appeared safe. Dr. Willard concurred in the opinion that the main mass was a renal tumor, probably separate from the tender swelling near the spine and that this was secondary to spinal caries. Operation proved the correctness of this view.

Operation.—Through an incision 8 inches long forward over the tumor from the edge of the quadratus lumborum, the entire tumor was enucleated and proved to be a greatly enlarged left kidney. There was no evidence of infiltration of surrounding tissues. Owing to the inaccessibility of the stump, two curved hemostatic forceps were left attached to it, no ligatures being applied.

Postoperative History.—At the end of forty-eight hours these were unfastened, one being removed entirely on the third day and the other, which had appeared to be adherent, on the fourth day. There was no hemorrhage, and aseptic heal-

Fig. 6.—After hysterectomy and nephrectomy; spinal deformity from caries of three upper lumbar vertebrae.

with water. This tightly closed the fistula for the time and made cystoscopy easy. Four weeks after the nephrectomy, when the patient, wearing a plaster jacket for the spinal caries, was nearly ready for discharge from the hospital she

1. Shoemaker, G. E.; *Ann. Surg.*, December, 1909.

suddenly developed a motor paralysis of both lower extremities without impairment of sensation. She had previously been moving freely about the bed. This impairment increased rapidly for seven days after which some improvement in motion occurred. The patient became unwilling to wear a plaster jacket and was discharged at her own request forty days after the nephrectomy.²

Microscopic Examination of Tumor.—Dr. G. Canby Robinson, the pathologist of the Presbyterian Hospital, kindly contributes the following description of the microscopic appearances of the renal tumor: "The tumor mass, which measures 18 by 12 by 9 c.m., takes roughly the shape of an irregularly enlarged kidney. It is roughened by slightly bulbous swellings, especially at the lower end. These swellings have a dark red and purple color. The tumor is firm in consistency. In one place there is a cavity which appears to be the remains of the pelvis of the kidney. On section the kidney is found to be almost replaced by a tumor mass and only at the upper end is kidney tissue seen. Here the cortex is pale, almost white, and swollen, and glomeruli cannot be seen. The tumor structure is pinkish-yellow in color and rises slightly above the cut surface, through which fine bands of connective tissue run. At places the tissue is opaque, while in some areas it is translucent and colorless, resembling hard starch. Microscopic sections show kidney tissue only occasionally. When it is seen, there are a few glomeruli and compressed tubules scattered through large masses of connective tissue. The tumor is composed of fine strands of connective tissue, which grow out apparently from the increased connective tissue of the cortex, and which extend in a branching papillomatous manner in all directions. The connective tissue forms a stroma of the main tumor cells which lie on both sides of the fine connective tissue strands. There are large euboid or columnar epithelial cells, practically always lying in a single layer, possessing large vesicular nuclei with nucleoli, and resembling large tubular epithelium. Tubule-like structures are often seen. Cysts formed by the walls of connective tissue and epithelium are frequent, and small masses of blood are present. The epithelial cells do not appear to have undergone malignant changes, but in one or two places small nests of cells are arranged in a rather suspicious manner."

Diagnosis.—Papillomatous cystadenoma of the kidney. No definite signs of malignancy.

Watson and Cunningham³ state that the adenomas of the kidney are both malignant and benign.

The papillary type usually prevails, but the alveolar is likewise common. The relation between the benign and malignant adenoma is obscure. The majority of pathologists believe that the two are identical, and that they differ from each other only in a clinical sense. There are transition forms from adenoma to carcinoma, although the transition is not a sharp one. It is probable that many of the malignant adenomata are benign in the first place, and that malignancy supervenes. It is impossible to say how long the disease has existed in the benign form, because the tumor may be unrecognized for many years.

In a series of ninety-one tumors of the kidney examined at the Massachusetts General Hospital, four were of the type of large papillary cystadenomata of the kidney.⁴

The accompanying photomicrographs of the tumor tissue illustrate many of the characteristic features of the disease.

Respiratory Signs of Surgical Anesthesia.—Though marked deepening of the respiration may precede, be synchronous with or follow whatever emotional excitement there may be, at any rate it is generally indicative of the early accomplishment of surgical anesthesia.—J. B. Bogan, in *New York Medical Journal*.

² August, 1910, ten months after nephrectomy, patient is reported as doing light housework.

A COMBINED FORCEPS AND TONSILLAR SEPARATOR

A NEW TONSIL SNARE

CULLEN F. WELTY, M.D.

SAN FRANCISCO

In the enucleation of the tonsil I have found this combined forceps of value. Because of its length, all parts of the pharynx can be easily reached without interfering with other instruments. Because it can be used as a tonsil separator as well as a sponge carrier, not losing time consumed in changing instruments, the work is more quickly done. Because of the bluntness of the instrument the capsule of the tonsil cannot be punctured.

Fig. 1.—Combined forceps and tonsillar separator.

Fig. 2.—Showing parts of combined forceps and separator.

In order to use this instrument it is necessary that the tonsil be drawn taut with another forceps. An incision is then made at the point where the mucous membrane joins the tonsil, which will uncover the capsule, and should begin in front and be carried posteriorly until it begins to descend. Through this incision the tonsil is easily dissected or peeled out.

Directly after removal of the tonsil there is usually considerable hemorrhage. This forceps on account of the bend in the end is useful in making pressure to prevent an excessive loss of blood.

I have never been called to the hospital because of subsequent hemorrhage except in one instance, and in that the tonsil was not entirely removed. I am certain that

the blunt dissection with this instrument has given the good results obtained.

The features recommending this new snare are as follows: 1. It is strong, heavy and will not get out of order. 2. It locks together, instead of having screws or fasteners. 3. It is easily kept clean. 4. It is easily and quickly threaded. 5. It has an entirely new device for fastening the wire; when once clamped the harder you pull the tighter it becomes.

DIFFUSE IDIOPATHIC HYPERTROPHY OF THE MAMMARY GLANDS OF THE FEMALE *

A REPORT OF A NEW CASE AND A CONSIDERATION OF THE ETIOLOGY AND PATHOLOGY BASED ON DATA OF RECORDED CASES

HENRY ALBERT, M.D.
IOWA CITY, IOWA

REPORT OF CASES

The following clinical history of the case was furnished by Dr. H. Matthey of Davenport, Iowa:

Patient.—The patient, a girl 13 years of age, when examined August, 1903, was 5 feet and 5 inches tall, weighed 101 pounds and was found to be of a nervous temperament.

Fig. 1.—Patient with mammary hypertrophy; from photograph taken shortly before amputation of the left gland.

Family History.—The patient's parents were both living and well, her father being 39 years of age and her mother 36. She had one brother and one sister, both living. In none of these other members of the family was there any undue enlargement of the mammary glands.

Personal History.—The patient had had the usual diseases of childhood. Enlargement of the breasts began in the early part of June, 1903, and continued at such a rate that in August she was taken to a physician who estimated that each breast weighed about 8 pounds. Pressure applied by means of a bandage and maintained for several months was without benefit. In October when the patient first consulted me, the breasts weighed about 12 pounds each. Operation was advised, but refused. She now drifted into the hands of quacks who treated the condition in various ways, without giving any relief. In July, 1904, she returned to me in poor general condition, feeble, anemic and emaciated. Her weight was 106 pounds, a little more than half of which was contributed by the breasts. Because of these facts, it was deemed advisable to remove only one breast at a time (Fig. 1). The first operation was undertaken July 14, 1904. The amputated left breast weighed 28 pounds. After being two weeks in the hospital, she was allowed to go home to recuperate for the

second operation. At this time her weight was 79 pounds. During the following two weeks she gained 13 pounds and returned for the operation, weighing at this time 92 pounds. The right breast was amputated Aug. 12, 1904. It weighed 26 pounds. Recovery was uneventful, healing being by primary intention. Patient remained in hospital two weeks and returned home in good general health and weighing 75 pounds. Six weeks after the second operation she menstruated for the first time and has been regular since. She was married in 1909 and has been delivered of a six-months developed child since. At present the general health of patient is good; weight, 115 pounds; height, 5 feet 9 inches.

PATHOLOGY OF SPECIMENS

This was essentially the same for the two glands.

Gross Pathology.—Shape: Both glands, which were rather spherical in shape and pendulous while attached to the body of the patient, became considerably flattened out between the skin surface and the base after their removal.

Size: The left gland, which was the larger, was, after removal from the body, 18 inches in diameter and 8 inches in thickness. Its greatest circumference was 58 inches and it

Fig. 2.—Case of left gland, showing lobulated and encapsulated appearance.

weighed 28 pounds. The right gland was 14 inches in diameter, 7½ inches in thickness; its greatest circumference was 45 inches and weighed 26 pounds.

Surface Contour: The skin surface was smooth, being tightly stretched over the underlying gland substance. The nipple of each of the glands had become flattened out and the areola more diffuse, but less distinct than normally. The bases of the glands were distinctly lobulated; the lobulated areas varying from one to four inches in diameter (Fig. 2). The outlines of the glands at the base were so distinct as to be apparently well encapsulated.

Consistency: The glands were moderately soft in consistency. This was quite uniform throughout the gland mass, although on cut section certain areas were found to be much more firm than others. These were not distinct and circumscribed, but fused gradually with the more soft areas. A number of rather large ducts, some with a diameter of as much as 1/8 of an inch were visible on the cut surface. The

* Read in the Section on Pathology and Physiology of the American Medical Association, at the Sixty-first Annual Session, held at St. Louis, June, 1910.

subcutaneous adipose tissue had entirely disappeared. Only a small amount of fat was still noticeable about the base of the gland (Fig. 3).

Color: The cut surface of the tumor was of a whitish-pinkish gray color. The pinkish tint was more marked in the firm than in the soft areas.

Microscopic Pathology.—Section from Firm Portion of Gland: The section consisted principally of full developed fibrous connective tissue with a fair number of capillary blood-vessels. The gland elements were found somewhat grouped in areas, corresponding to the lobules; the acini, however, were much more widely separated than in the normal gland. The acini which were of variable size, some quite large and many dilated, were lined by a single layer of a low columnar (almost cuboidal) gland epithelium, resting on a basement membrane consisting of flat cells. The lumen was free from

Fig. 3.—Cut surface of right gland, showing dark areas of glandular tissue, light areas of more pure connective tissue, and open spaces representing dilated ducts.

contents, except in a few in which debris, consisting of degenerated and desquamated cells, was found.

Section from Soft Light-Colored Portion of Gland: This section consisted almost entirely of fibrous connective tissue with only a very few gland elements. The connective tissue, which contained only a few widely separated nuclei, was somewhat edematous. There were numerous capillary blood-vessels and a number of fat cells.

Section through Skin, including a Portion of the Gland Substance of Medium Consistency: This section showed the connective tissue of the hypertrophied gland to be continuous with that of the subcutaneous tissue and the corium. Except for a few fat cells, the subcutaneous adipose tissue had entirely disappeared. The elastic fibers of the corium were fully as abundant as in the normal skin. I was unable to find any elastic fibers in the substance of the gland proper except, of course, in the larger blood-vessels.

Section from Base of Gland, Including the "Capsule": The "apparent" capsule of the gland was found to consist of condensed gland substance consisting of both gland and connective tissue elements. The glands were somewhat flattened.

Summary of Pathology.—The process was a diffuse hypertrophy affecting all parts of both glands rather uniformly and involving both the glandular and connective tissue elements, the increase affecting principally the latter. The gland acini were lined by a single layer of low columnar (almost cuboidal) epithelium, were larger than normal and more widely separated by intervening connective tissue, which was of the fully developed fibrous type. Capillary blood-vessels were numerous.

REVIEW OF CASES REPORTED

Diffuse idiopathic hypertrophy of the mammary glands is a rare condition. Several authors have collected data from a number of cases, but no attempt to collect all cases reported has been made for some time. In 1902 Kirchheim¹ collected most of the cases reported up to that time. I have reviewed the literature and have

Fig. 4.—Photomicrograph of dense glandular portion of right gland showing irregular variously shaped acini lined by a single layer of low columnar epithelium.

made an attempt to collect all cases reported to date and have summarized the essential data from these cases, so far as such has been available. In some instances I have not been able to secure the original report. In many more the data was very meager. In the majority of cases no description of the pathologic process was given, and I have little doubt but that I have included some cases that are not instances of "true" hypertrophy. I have purposely omitted a case of excessive adiposity of the mamma, diagnosed clinically as diffuse hypertrophy, of which I have the specimen, and another case concerning which I have been informed but of which no pathologic examination was made. I have not included in this paper the cases of mild degree of hypertrophy of the mammae of the male (gynecomastia), or of senile parenchymatous hypertrophy (Bloodgood²), partial or

1. Kirchheim: Arch. f. Klin. Chir., 1902, lxxviii, 582.

2. Bloodgood: Surg., Gynec. and Obst., 1906, lii, 721.

localized hypertrophy, and the still more mild types of so-called hypertrophy occasionally seen associated with pulmonary tuberculosis.

Although I have summarized the principal data from the cases reported, I shall in this paper limit the consideration to the etiology and pathology of the condition.

Number of Cases Reported.—Aside from the one which I have just described, I have been able to collect reports of sixty-nine other cases of diffuse hypertrophy of the female mammae. Of these seventy cases sixty-two were bilateral and six unilateral, three affecting the right and three the left gland. In two instances I was unable to learn which glands were affected.

Age.—Although Bittner³ reported a case of hyperplasia (probably not true hypertrophy) of the mammary gland in a girl 6 months old, the age limit of the reported cases of true hypertrophy extends from 11 to 42 years, with practically every intervening year represented. The vast majority begin to develop about the time or soon after puberty or during gestation. Fifty-eight per cent. of the cases not associated with gestation developed between the ages of 11 and 16 and 40 per cent. during the fourteenth and fifteenth years of age.

Classification of Cases.—Cases of idiopathic hypertrophy may be classified into (1) those associated with gestation and (2) those not associated with gestation, most of which are closely related to puberty.

1. *Gestation Idiopathic Hypertrophy.*—Of the seventy cases eighteen were of this type. Fourteen of these were bilateral and four unilateral. The relation to gestation is clearly indicated by the fact that, after the termination of pregnancy, the condition subsides, although it does not return completely to the normal, and that it frequently reappears during subsequent pregnancies. The enlargement usually begins during the first pregnancy. Sometimes, however, it occurs for the first time during the second or third. In one instance it did not develop until the eighth pregnancy.

2. *Cases Not Associated with Gestation.*—The relation of puberty to cases of hypertrophy is suggested by the fact that 58 per cent. of the cases not associated with gestation developed between the ages of 11 and 16, the period during which puberty ordinarily occurs, and that in a large number of cases menstruation did not set in until after the enlarged glands were removed. In many cases, however, there seems to be no association with either puberty or gestation.

Etiology.—The real cause of this condition is unknown. Such factors as heredity, traumatism, undue sexual activity, general malnutrition, etc., which have been mentioned in connection with the process, seem to have nothing to do with it. Pathologically the process appears to be simply an excessive development of the normal enlargement as seen especially at puberty and during gestation. Presumably the causes which produce the normal enlargement are also at work on this pathologic form, the latter being produced either because of a large amount (or undue activity) of the same cause, or a lack of the inhibitory influences which, under normal conditions, limit the extent of the enlargement.

Recent experimental work has shown that the normal enlargement of the glands is not always due to the same cause. The work of Lane-Clayton and Starling⁴ in producing an increase in the size of the mammary gland of

virgin rabbits by the injection of extracts from the body of rabbit fetuses has shown very conclusively that the enlargement of the mammae during gestation is through the action of a hormone produced in the fetus. That this may also be the cause of the idiopathic gestation hypertrophy is very probable, especially inasmuch as that condition subsides after the termination of the pregnant state.

The cause of the normal enlargement of the glands at puberty is not so well understood. The evidence at hand seems to indicate that a hormone in the ovaries is the principal factor responsible for the development of the mammary glands outside of pregnancy. If this proves to be the case it would seem that removal of portions of the ovaries would be indicated in the treatment of the condition. Up to the present time the only treatment that has been of value is amputation of the glands. Removal of portions of the ovaries has not been tried, so far as I know.

It is very doubtful whether or not the cessation or irregularity of the menses, noticed shortly before and during the hypertrophy in many of the cases not associated with gestation, is of etiologic significance. This may simply be a symptom of the condition, as it is a symptom of other diseases in which the vitality is lowered. On the other hand is to be noted the fact that the general health is usually not affected until after the disease is well advanced, whereas the cessation of the menses is frequently of sudden occurrence several months before the glands begin to enlarge.

Gross Pathologic Morphology.—Shape: The enlarged glands stand out prominently from the chest wall for some time. Later their weight causes them to become pendent and often pedunculated, the gland substance assuming a rather spherical mass, drawn away from the muscles of the chest and hanging over the front of the abdomen, sometimes as far down as the knees. Their large size frequently causes the patient much discomfort and sometimes necessitates the patient remaining in a recumbent position.

Size: The size of the different glands may be compared (1) by their greatest circumference and (2) by their weight.

1. The greatest circumference of the individual glands for which figures are available varies from 20½ inches to 51½ inches, the average being 31½ inches. The average circumference of the hypertrophied left glands is one inch more than the right.

2. The weight of individual glands varies from 1½ pounds to 64 pounds with an average per gland (of all cases) of seventeen pounds. The weight of the combined glands of cases of bilateral hypertrophy varies from three pounds to 124 pounds (Durstons's⁵ case) with an average of 37 pounds. In most cases and on a general average, the left gland weighed a little more than the right. The average weight of the gland in the cases of unilateral hypertrophy is 15 pounds. In the cases reported by Durston⁵ and myself the weight of the two glands exceeded the weight of the remainder of the body.

Surface Contour: The surface of the glands is quite smooth, and skin tightly drawn. The stretching of the skin usually causes the nipples to be flattened out. In one instance they were reported as being retracted; in two, as having become enlarged—in Delfis's⁶ case, as large as a hen's egg. The pigmented areas also become less definite and distinct as the skin becomes stretched. The

6. Delfis: Jour. de physiol. exper. de Magendie, 1825.

skin remains quite freely movable over the underlying gland even though the subcutaneous fat tends to disappear and the connective tissue of the skin gradually fuses with that of the gland. In the later stages, the skin may become thick and hard. In many instances the superficial veins become very large and stand out prominently as blue streaks.

Consistency: During the early stages the hypertrophic glands are firm and elastic, as they are during the normal enlargement at puberty or during the early part of gestation. Later, when they become larger and pendent, they also become flaccid. At first the glands usually feel somewhat nodular; later, however, these tend to disappear. Even when the process feels quite diffusely uniform through the skin, the cut surface may show areas considerably more firm in consistency than others. Such areas diffuse into one another gradually.

Color: The color of the cut surface of the hypertrophic gland in the few cases in which it has been noted, is apparently the same as under normal conditions.

Microscopic Pathologic Morphology.—Unfortunately, microscopic examinations of the specimens were made in only about twenty of the cases. In all of the cases not associated with gestation, it is recorded that there is an increase of both the glandular and the connective tissue elements. In most instances the connective tissue is reported as being principally increased, although in four cases special mention is made of the marked glandular increase. The gland acini are usually described as being larger than normal, more widely separated and sometimes found to be lined with several layers of gland epithelium. I am inclined to think that this last-mentioned phenomenon is due principally to the thickness of the section and the cutting of the acini in an oblique manner. In many instances the glands are considerably dilated and contain granular degenerated material. Such changes in the glands have been likened to the changes that occur in the glands during the early stages of pregnancy. The fibrous connective tissue is usually described as being of the fully developed type with, as a rule, very few nuclei, although some are mentioned as being quite cellular—which may, of course, have been due to an associated inflammation. In the three cases of idiopathic gestation hypertrophy in which a microscopic examination was recorded, the microscopic findings were like those of the mammary gland during pregnancy. Such findings, indeed, may reasonably be expected.

Pathological Physiology.—Gestation hypertrophic glands usually functionate as do the normal ones, although it is often difficult to nurse the infant because of the flattening out of the nipple. Those not associated with hypertrophy are functionless during non-pregnant conditions, although it has been possible to squeeze colostrum-like fluid from the ducts in some cases. Usually, also there is no lactation after the birth of a full-term child. In several instances, however, there was normal lactation in the glands that had been enlarged before the pregnant state. In one case associated with gestation, there was marked galactorrhoea of eight months' duration.

Nature of Pathologic Condition.—Idiopathic hypertrophy has been regarded variously by different authors as a circulatory (edema), an inflammatory, a neoplastic or as a simple hypertrophic process.

In favor of its being an edematous process is the rather sudden onset that has been reported in several cases. In the cases of Durston⁵ and Delbet,⁷ for in-

stance, the patients retired in the evening, slept quietly as usual and in the morning on awaking found themselves scarcely able to turn around. When they tried to get up, the weight of the suddenly enlarged glands caused them to sink back. Usually, however, the onset is very gradual.

Opposed to its being a circulatory process is the fact that there was no mention made of pitting on pressure in the cases reported, nor has the tissue of the glands removed been reported as edematous. For a long time the enlarged glands are firm and elastic and stand out prominently from the body; this would not be the case in edema. The increase in connective tissue following edema is in the nature of a fibrosis rather than an increase of all of the tissue elements. The slight edema which I found in my specimens and which accounts in part for their great shrinkage when placed in formaldehyd solution may readily be explained by the interference with circulation caused by the pendant glands.

There is really no evidence in favor of its being an inflammatory process. The pain sometimes noticed may readily be accounted for on the basis of pressure and a stretching of the nerves.

The neoplastic theory has several supporters. In Porter's⁸ case, in which the glands weighed 17 and 43 pounds respectively, the diagnosis made was intracanalicular fibroma. Kirchheim¹ regards it as a diffuse fibroma. It is true that a section of the hypertrophic gland may be like one from a case of adenofibroma, but a tumor is usually thought of as a more localized and circumscribed process, especially if it is benign. The idiopathic hypertrophy, however, which pathologically is benign, is a diffuse process involving all parts of the gland. The fact that it may begin as a rather localized process, limited to a certain part of the gland, simply means that such represents the beginning point, probably the most susceptible tissue, just as one gland sometimes becomes involved before the other.

Considered from all standpoints, it must be regarded as a simple hypertrophic process involving all of the elements of the gland, but especially the part which at the time, is the most actively growing tissue, namely, the glandular tissue during gestation and the connective tissue at other times, especially during puberty.

The question has been raised as to whether or not cases of unilateral enlargements are cases of true hypertrophy. With a clinical history like those of bilateral hypertrophy, with the same pathologic condition, so far as we know, and an average weight of 15 pounds as against 17 pounds in case of the bilateral type, there is no reason, it seems to me, why they should not be regarded as identical. Indeed, in Van Swieten's⁹ case, the unusual enlargement of one breast which occurred during pregnancy subsided after the termination of gestation. During the second pregnancy it again enlarged.

Associated Pathologic Conditions.—When the glands become of large size, the friction of the glands against a bracing bandage or supporting clothing frequently causes an excoriation of the epidermis chiefly at the most dependent portion. Such friction is apt to be followed by inflammation, abscess and fistula formation, eczema, erysipelas and gangrene. In one case, there was a hernial protrusion of gland-substance through an excoriated opening. Although Billroth¹⁰ reported a case

9. Van Swieten: Commentaria in H. Boerhaave Aphorism de cognoscendis et curandis morbis, Leyden, 1764, A. IV.

10. Billroth: Krankheiten der Brustdrüsen, Deutsche Chirurgie, 1880, Instalment xii, 69.

of sarcoma and Bloodgood² a case of carcinoma in a gland idiopathically hypertrophied, such glands do not appear to be any more prone to malignant tumor formation than under other conditions. In several cases the axillary lymph-nodes were found to be enlarged. In the majority of these cases, there was some acute inflammation of the mammae which readily accounted for the involvement of the lymph-nodes. In several, however, there was no recognizable acute inflammation of the mammae. Even in such cases, the lymph-node enlargement was of a fibrous (chronic inflammatory) character. In no case has there been any metastatic formation of the hypertrophic mammae.

GENERAL SUMMARY

1. Of the seventy reported cases of diffuse hypertrophy of the female mammae, in eighteen the enlargement occurred during gestation; most of the others occurred about the time of or soon after puberty.

2. Of the seventy cases, sixty-two were bilateral.

3. Fifty-eight per cent. of the cases not associated with gestation developed between the ages of 11 and 16 and 40 per cent. during the ages of 14 and 15.

4. The etiology of the condition is obscure. It is very probably due to the action of the same hormones that produce the physiologic enlargements.

5. Pathologically, the condition is a simple diffuse hypertrophy, involving both glands and connective elements. The increase in the gland elements occurs principally in the cases occurring during gestation, whereas the connective tissue increase usually predominates in those not associated with that condition. The process appears to be essentially an exaggeration or continuation of the enlargements that affect the gland normally at puberty and during gestation.

6. The weight of the glands varies from 1½ to 64 pounds, the average per gland of all cases being 17 pounds. In one instance, one of the glands weighed 64 pounds and both glands, 124 pounds. In two instances the combined weight of the two glands exceeded the weight of the remainder of the body.

7. In cases associated with gestation, lactation is, as a rule, normal. In those hypertrophies not associated with gestation the glands seldom functionate, even after pregnancy.

Dubuque and Jefferson Streets.

ABSTRACT OF DISCUSSION

DR. A. S. WARTLIN, Ann Arbor, Mich.: I should like to ask Dr. Albert whether this woman was able to throw her mammary glands over her shoulder; a similar hypertrophy of the mammary gland is often seen in Hottentot women, who are able to throw their breasts over their shoulders and suckle their children, who are carried in slings on their backs. I should also like to know to what type of man this woman corresponded. Did she have any features that go with the Australoid type or Negroid type? Would there be any anthropologic interest in this case as an instance of reversion?

DR. JAMES J. TERRILL, Galveston: Was there any pain associated with the condition? I remember seeing specimens from a somewhat similar case in the early part of this year. The patient, a girl aged about eighteen, had what was diagnosed as diffuse virginal hypertrophy of the breast. Both breasts enlarged but did not weigh more than two pounds each. One breast had to be removed, however, on account of excessive pain, the cause of which was never discovered; but on removal of the first breast, the pain disappeared and the other breast gradually grew smaller in size. Sections pre-

sented an appearance practically identical with that of the sections in Dr. Albert's case.

DR. GREER BAUGHMAN, Richmond, Va.: I saw a case in November, 1903, with Dr. George B. Johnson, in a young white woman. The left breast weighed 10¼ pounds; the right 7¾. The microscopic findings were almost the same as those in Dr. Albert's case—a true hypertrophy of the mamma—non-functionating, except that there was not so much dilatation of the acini and very little fat.

DR. HENRY ALBERT, Iowa City, Iowa: The patient was not able to throw her breasts over her shoulders. I did not see the patient; but I made careful inquiry of the clinician as to any peculiarities suggestive of reversion and was informed that there were none; nor did her parents present any unusual appearance. There was no pain except that which may be readily explained by the enlarged size of the breast. In the reported cases, however, there are a number associated with severe pain, and in a few instances pain was present from the beginning of the process.

A patient whom I saw three or four weeks ago presented considerable enlargement of the mammary glands. A diagnosis of diffuse hypertrophy was made. The process began about a year ago, but it was only during the last three months that the pain had become extreme. On examining the glands microscopically after removal we found nothing but fatty and a little fibrous connective tissue. One of the cases in the literature contains a reference to the fact that the hypertrophy was not due to glandular, but to fatty increase.

A STUDY OF MISTAKEN DIAGNOSES

BASED ON THE ANALYSIS OF 1,000 AUTOPSIES AND A COMPARISON WITH THE CLINICAL FINDINGS *

RICHARD C. CABOT, M.D.
BOSTON

The subject of this paper was suggested by my experiences in a weekly conference with senior medical students at the Harvard Medical School. At this conference the organs obtained from all the autopsies performed at the Massachusetts General Hospital during the week preceding are brought before the class. Before the demonstration of each set of organs I discuss with the students a typewritten summary of the clinical findings in the corresponding patient, including the history, the physical examinations, the reports on blood, urine, stomach contents and feces, the x-ray plates and all other data on which diagnosis was based during life. I never let anyone inform me beforehand of the autopsy findings. After we have committed ourselves definitely regarding the pathologic changes which we expect to find the hospital pathologist, Dr. Oscar Richardson, reads the autopsy protocol and demonstrates the organs.

In this exercise I have been forced once a week for three years to compare my diagnoses with post-mortem findings. It has proved so salutary and instructive, especially when I have been mistaken, that it has seemed to me well to summarize the results of a large series of comparisons between the judgments arrived at by a careful study of clinical data and the anatomic conditions revealed post mortem.

I. METHODS USED IN THE STUDY

I must first explain, as nearly as I can, the plan followed. It is not a simple matter to collate ante-mortem

* Oration in Medicine read before the Section on Practice of Medicine of the American Medical Association, at the Sixty-first Annual Session, held at St. Louis, June, 1910.

* Because of the space required, the article is slightly abbreviated in THE JOURNAL. It appears in full in the Transactions of the Section and in the author's reprints.

and post-mortem data in an intelligent way. One cannot simply read off the clinical diagnoses and note their correspondence or lack of correspondence with the anatomic findings, for:

1. It is often obvious when one reads the clinical record that the diagnosis has been copied from the autopsy protocol.

2. The clinical diagnosis may be so abbreviated as to omit important facts known during life. For example: When death occurs from heart disease the clinical diagnosis is often recorded merely as "mitral stenosis" without any statement regarding cardiac hypertrophy, dropsical effusions or terminal infections. Yet on reading the details of the record one may find evidence that the heart was enlarged, that a large amount of serous fluid has been removed from the abdomen and, perhaps, that some micro-organism had been isolated during life from the circulating blood. These facts warrant us in filling in the clinical diagnosis by the addition of a number of details. My comparisons, then, have been made between the diagnosis warranted by the recorded clinical data and the autopsy protocols.

3. In some cases it has been clear, after a little study, that the clinical diagnosis actually written on the records had been hurriedly filled in by an intern and did not represent the opinion of the attending physician. I recall one case in which the clinical diagnosis still stands as "neurasthenia" although the autopsy record shows that the patient died of cancerous pleurisy.

My comparisons, then, have been far from literal. In each case I have gone behind the recorded diagnoses and endeavored to reason out what diagnosis was justified by the facts as known during life. No other course was open to me if I was to avoid some quite ludicrous mistakes.

II. TYPES OF ERROR

In the accompanying tables I have attempted (a) to separate correct diagnoses from mistaken ones and (b) to subdivide the mistakes into errors of omission and errors of commission. By an "error of omission" I mean failure to find some lesion which in all probability contributed to kill the patient; for example, the failure to find a pneumonic solidification.

"Burnt-out" or obsolete lesions are often undiscovered during life and lead, therefore, to a discrepancy between ante-mortem and post-mortem findings, a discrepancy of interest but different from what I am now defining as an "error of omission." If, for example, the autopsy revealed pleural adhesions, and I am convinced from the written record and from my knowledge of the methods used in the hospital wards that these lesions did not contribute materially to the patient's last illness, and that no attempt was made to find these adhesions by testing the mobility of the lung borders or by any other method of investigation, I do not class the resulting discrepancy between anatomic and clinical results as an error of omission.

By an "error of commission" I mean the diagnosis during life of a lesion—such as cancer of the stomach—which autopsy shows is absent. This type of error is defined in contrast with some discrepancies regarding which we need not consider the autopsy as the court of last appeal. If, for example, a diagnosis of mitral regurgitation is recorded on the clinical record but not in the autopsy protocol, I consider this no proof that the clinical diagnosis is wrong. It is quite conceivable that the valve was insufficient during life owing to a muscular relaxation of which no convincing evidence is left

after death. I have, therefore, attempted no comparison between the clinical and anatomic findings regarding mitral regurgitation. On the other hand, if mitral stenosis exists during life it should be demonstrable after death.

I shall now take up some of the statistics which represent our experience in the last thousand autopsies coming from the medical wards of the Massachusetts General Hospital.

III. DIAGNOSTIC ERRORS IN CERTAIN DISEASES OF THE HEART AND VESSELS

MITRAL STENOSIS

Correct diagnosis in	49 cases or 69 per cent.
Error of omission in	16 cases or 22 per cent.
Error of commission in	6 cases or 9 per cent.
Total,	71 cases

Most of these errors of omission were due to the fact that the patients were seen first within twenty-four hours of death, i. e., after the murmur had disappeared and at a time when very little evidence remained on which a diagnosis could be based.

Cases in which we mistakenly supposed that mitral stenosis existed are not so numerous as I had anticipated. Apparently we have learnt pretty well the lesson taught by Austin Flint nearly half a century ago. It seems to me well to emphasize here a fact often recorded, especially by English observers, but not sufficiently realized in this country. I refer to the presence of a presystolic murmur at the apex of the heart despite a sound mitral valve, not merely in cases of aortic regurgitation (as noted by Flint), but in any disease which has resulted in marked enlargement of the heart. In cases of chronic nephritis, pericardial adhesions, arteriosclerosis and hyperthyroidism, or any other cause, we often hear the murmur formerly identified with mitral stenosis. The murmur may be constant or transient. It may or may not be associated with a sharp, snapping first sound and an accentuated pulmonic second. It cannot be distinguished with any certainty from the murmur produced by mitral stenosis and will continue to lead us into error from time to time until some other and more accurate methods of diagnosis are discovered.

I have found it best systematically to disregard all presystolic murmurs heard at the apex of a markedly enlarged heart, unless the case has been under observation long enough for us to have recorded the murmur before the heart became markedly enlarged or unless we have a clear history of a long-standing infectious process, presumably involving the heart valves. In renal cases, arteriosclerotic cases and, indeed, in most patients beyond their fiftieth year, presystolic murmurs are of very little significance.

AORTIC STENOSIS

Correct diagnosis in	19 cases or 61 per cent.
Error of omission in	11 cases or 36 per cent.
Error of commission in	1 case or 3 per cent.
Total,	31 cases

I have been surprised to note that the diagnosis of aortic stenosis (always accompanied in this series by a regurgitant lesion) was correctly made in nearly two-thirds of our cases, and especially was I amazed that in only one case did we commit ourselves wrongly to this

diagnosis during life. It used to be a standing joke among our pathologists that the clinician always diagnosed aortic stenosis when only a roughening of the aortic arch was demonstrable post mortem. On the other hand, I have been equally astonished to learn that the pathologists found aortic stenosis so frequently where we had overlooked it during life. I am quite convinced that this lesion is often impossible of diagnosis by our present methods of physical examination. In this connection the following points have recently been impressed on me:

1. Aortic stenosis may exist despite the presence of an accentuated aortic second sound, although, as a rule, this sound is diminished or absent.

2. Aortic stenosis may exist in association with a "water-hammer" or "Corrigan" pulse, though the rule is against this. How these two facts are to be accounted for I have no idea.

3. With long-standing cases of "rheumatic" endocarditis involving the aortic valve in patients under 35 years of age, aortic stenosis is almost always present (as proved post mortem) whether there are any characteristic physical signs pointing to it or not.

AORTIC REGURGITATION

Correct diagnosis in	57 cases or 84 per cent.
Error of omission in	5 cases or 7 per cent.
Error of commission in	6 cases or 9 per cent.
Total,	68 cases

It will be noted that in the present series, as in that previously mentioned in my "Physical Diagnosis," our largest percentage of correct diagnoses in diseases of the cardiovascular system concern aortic regurgitation. This percentage was possible only because we have made it a rule to disregard diastolic murmurs unless there were vascular phenomena to correspond ("water-hammer" pulse, capillary pulse, etc.). Diastolic murmurs without these vascular phenomena have generally turned out, post mortem, to be associated with a sound aortic valve. I appreciate that the figures here presented regarding aortic regurgitation have less value than those relating to the stenoses, since it is impossible to deny that the aortic ring might stretch during life sufficiently to produce regurgitation and yet show no evidence of such stretching post mortem. Yet, for reasons which I cannot here take the space to present, I do not believe that the error attributable to this possibility is a considerable one.

CHRONIC MYOCARDITIS

Correct diagnosis in	13 cases or 22 per cent.
Error of omission in	15 cases or 26 per cent.
Error of commission in	31 cases or 52 per cent.
Total,	59 cases

I have given up making the diagnosis of chronic myocarditis, and I believe that the term should be stricken from our text-books on the practice of medicine. It is an anatomic condition, like acute interstitial nephritis, having no corresponding manifestations recognizable during life. A correct diagnosis of chronic interstitial myocarditis, of acute degeneration of the myocardium such as occurs in fevers, or of the fatty change observable in most cases of pernicious anemia, is wholly a matter of luck. There are no clinical symptoms and no physical signs constantly associated with any one of these conditions.

When a patient has suffered from well-marked angina pectoris and shows clear evidence of arteriosclerosis in

the brain, the kidney or the peripheral arteries, we may guess that his coronary arteries are somewhat narrowed and that a fibrous myocarditis has resulted. But even then we may be wrong, as I have often been convinced post mortem. The evidence on which the diagnosis of myocarditis is ordinarily based points merely to a *myocardial insufficiency* such as may be produced by a great variety of causes without the presence of any granular, fatty or fibroid change in the heart. Further, the anatomic diagnosis of fibrous myocarditis post mortem is satisfactory only when it is positive. To say that a fibrous myocarditis does not exist one must have cut the heart into mince-meat and then sectioned and stained each morsel of the hash. The absence of gross fibroid changes demonstrable after a few knife-cuts into the ventricular walls, by no means excludes an extensive though microscopic fibroid change.

One of the most surprising things in this series of autopsies has been the not infrequent occurrence of gross fibroid myocarditis in hearts which were perfectly sufficient during life, and the still more frequent absence of any demonstrable lesion post mortem in hearts that were markedly insufficient during life. As will be seen by the figures quoted above we were wrong in more than four cases out of five in our diagnosis of myocarditis.

ARTERIOSCLEROSIS

Correct diagnosis in	131 cases or 60 per cent.
Error of omission in	77 cases or 35 per cent.
Error of commission in	12 cases or 5 per cent.
Total,	220 cases

Most of the correct diagnoses in this group rested on inferences from general knowledge of pathology rather than on physical examination. If a patient has symptoms pointing to a non-traumatic cerebral hemorrhage it is fairly safe to assert that cerebral arteriosclerosis will be found, especially if the sufferer is middle-aged or older. If angina pectoris has tortured a man for months, it is very probable that his coronary arteries are diseased.

THORACIC ANEURISM

Correct diagnosis in	12 cases or 50 per cent.
Error of omission in	10 cases or 42 per cent.
Error of commission in	2 cases or 8 per cent.
Total,	24 cases

In two cases a mistaken diagnosis of aneurism was made owing to too great reliance on *x*-ray findings, in the absence of other important evidence. In one case I believe that the mistake cost the patient his life. Supposing his malady to be incurable, we allowed him to use narcotics for pain to an extent that ultimately proved fatal. At autopsy there was no trace of aneurism or of any other sufficient cause for death.

The classical difficulty of deciding between thoracic aneurism and mediastinal tumor has occurred five times in this series; in every case the autopsy showed aneurism. As a result of these and other experiences in this field I have come to use the following rule: When still in doubt between aneurism and tumor after all proper methods of investigation have been exhausted call it aneurism.

Abdominal aneurism is distinctly rare in my field of work, occurring but three times in 2,000 autopsies. Our autopsy material includes a relatively small number of syphilitics. Possibly it is for this reason that I have been taught by experience that when we have our

annual or semi-annual discussion about the bed of a hospital patient who complains of epigastric pulsation ("aneurism or dynamic aorta?") the doubtful cases always turn out not to be aneurism, i. e., the patients recover and remain well when reassured.

CARDIAC HYPERTROPHY AND DILATATION

Correct diagnosis in	223 cases or 66 per cent.
Error of omission in	113 cases or 33 per cent.
Error of commission in	3 cases or 1 per cent.
Total,	339 cases

Had we relied wholly on palpation, percussion and auscultation for the estimation of the heart's dimensions I feel sure that our failures would have been far more numerous. Blood-pressure estimations have helped us greatly, and if we could have employed fluoroscopy in every case we could doubtless have done far better.

The distinction between dilatation and hypertrophy has not been successfully made in this series. What clinically seemed an acute dilatation has usually turned out after death to be a chronic hypertrophy and dilatation.

It will be noticed that in six of the seven types of cardiovascular disease thus far discussed, the percentage of failures ranges in the neighborhood of 33 per cent.; thus:

Aneurism	48 per cent.
Arteriosclerosis	40 per cent.
Aortic stenosis	39 per cent.
Hypertrophy and dilatation....	34 per cent.
Mitral stenosis	31 per cent.
Aortic regurgitation	16 per cent.
Average	34 per cent.

In the acute infectious lesions presently to be discussed our record is so different as to indicate that from the diagnostic standpoint they belong in a different and less accessible class. But before passing to the consideration of these more difficult diagnostic problems I wish to return for a moment to some of the difficulties attending the diagnosis of mitral regurgitation. I have not attempted to estimate the number or the nature of our failures in the diagnosis of this lesion because we have, in my judgment, no standard by comparison with which we can get our bearings. But the study of hearts before and after death has further convinced me that mitral regurgitation (that commonest of all cardiac diagnoses) is not only an unverifiable but usually a superficial judgment—about as definite as tachycardia. What we chiefly need to know about mitral regurgitation is what is behind it. Does the orifice leak because of an infectious process involving the myocardium, because of a chronic nephritis which has thickened and stretched the heart, because of hyperthyroidism, beer or arteriosclerosis? Or, rarest of all, is there a purely mechanical deformity of the valve or valve curtains? In all cases, except those belonging to this last group, i. e., in at least nine-tenths of all cases in which we are likely to make the diagnosis of mitral regurgitation we should add it, like an appendage, to some other and more fundamental designation. Thus, such diagnoses as "chronic nephritis, hypertension, cardiac hypertrophy and dilatation with mitral regurgitation," or "arteriosclerosis, myocardial insufficiency, relative mitral incompetence," or "infectious arthritis and myocarditis with mitral leakage," should, I think, replace the great majority of those now standing on our record-books simply as "mitral regurgitation."

The origin, prognosis, course, probable complications and treatment—all that is most important about the case—is suggested not by the leakage but by the diseases which have produced it and are indicated in the earlier parts of the diagnoses above suggested. As I look over the annual reports of our hospitals and note the great number of cases recorded merely as mitral regurgitation, it seems to me hardly more sensible than if one made so many diagnoses of "short breath" or "cough."

ACUTE ENDOCARDITIS AND ULCERATIVE ENDOCARDITIS

Correct diagnosis in	23 cases or 39 per cent.
Error of omission in	32 cases or 54 per cent.
Error of commission in	4 cases or 7 per cent.

Total, 59 cases

ACUTE PERICARDITIS

Correct diagnosis in	11 cases or 20 per cent.
Error of omission in	38 cases or 70 per cent.
Error of commission in	5 cases or 10 per cent.

Total, 54 cases

Most of the errors listed in these two groups are, I believe, inevitable at the present time. There are usually no distinctive physical signs either of acute endocarditis or of acute pericarditis, especially when they occur in the terminal stages of chronic disease. Fortunately it makes at present very little difference in our treatment whether we recognize these items of a general infection or not.

IV. RESPIRATORY SYSTEM

LOBAR PNEUMONIA

Correct diagnosis in	116 cases or 74 per cent.
Error of omission in	23 cases or 15 per cent.
Error of commission in	18 cases or 11 per cent.

Total, 157 cases

Regarding these cases of lobar pneumonia two comments seem to me worth making. First, it should be explained that some of the successful diagnoses of lobar pneumonia were made without distinctive physical signs of a process of reasoning which issued in the judgment "That is the sort of case in which a terminal pneumonia might well occur." This sort of reasoning works backward from familiar disease-groups previously encountered post mortem. One recognizes during life one or more members of such a group and infers the presence of another. Alcoholism and trauma with an unexplained fever and leukocytosis is a familiar group pointing in the majority of cases to a larval pneumonia not revealed by the pulmonary signs. Such an inference is very far from being inevitable, yet experience has convinced many that reasoning of this type is valuable if used cautiously and provided it always goes hand in hand with a thorough study of the patient's history and of the present condition.

Another observation is suggested by the numerous diagnoses of pneumonia when this condition was not actually present. Such mistakes were especially common in patients who were comatose or partially so. The type of congestion or "settling" often found post mortem in the lungs of such sufferers may produce all the classic signs of a full-blown lobar pneumonia though absolutely no solidification; nothing but a soggy lung is discoverable after death. I have often had a similar experience in cases involving marked cardiac insufficiency with or

without a considerable degree of hydropericardium. The signs apparently of solidification at the left base (in the so-called "pressure area" of pericardial effusion) associated with fever, leukocytosis and cough have often led me to a false diagnosis of pneumonia no sign of which was discernible post mortem.

BRONCHOPNEUMONIA

Correct diagnosis in	31 cases or 33 per cent.
Error of omission in	60 cases or 64 per cent.
Error of commission in	3 cases or 3 per cent.
<hr/>	
Total,	94 cases

One might imagine that the very large percentage of error in our diagnoses of bronchopneumonia arose from the inclusion of infants and young children whose lungs are notoriously apt to show after death (from whatever cause) unsuspected areas of bronchopneumonia. But this table contains only cases of adults. I excluded all the cases of younger patients because I felt from the start quite hopeless of successful prediction in this field.

I feel convinced, however, that we may apply to adults the old adage of the pediatric specialists: "When you have the signs of bronchitis but the patient is obviously too sick for (simple) bronchitis, call it bronchopneumonia."

I have been much impressed by a series of typhoid patients dying with the signs only of bronchitis but showing extensive bronchopneumonic areas post mortem, and I am inclined to believe that in many "bad colds" the patch of "sticky râles" which hangs on for a week or more in one or another lower lobe posteriorly represents in fact a bronchopneumonia.

PHTHISIS (ACTIVE)

Correct diagnosis in	32 cases or 59 per cent.
Error of omission in	16 cases or 30 per cent.
Error of commission in	6 cases or 11 per cent.
<hr/>	
Total,	54 cases

MILIARY TUBERCULOSIS

Correct diagnosis in	28 cases or 52 per cent.
Error of omission in	20 cases or 37 per cent.
Error of commission in	6 cases or 11 per cent.
<hr/>	
Total,	54 cases

In explanation of these tables we must note that:

1. I have left wholly out of the account the numerous cases of obsolete or healed phthisis.

2. The 30 per cent. of unrecognized cases was made up mainly of cases seen for the first time within a few hours of death, when all distinctions are blurred.

3. In the effort to recognize doubtful incipient cases we have frequently used radiography, but so far without getting any reliable information not obtainable by other methods. An increased resistance to the passage of x-rays is an excessively delicate but also a very general indication, capable of a multitude of explanations and produced by a multitude of causes other than tuberculosis and often indistinguishable from each other by radiographic evidence.

The correct diagnoses of miliary tuberculosis would have been much fewer had we not adopted some years ago the rule, "When a case is clinically one of tuberculous meningitis, call it miliary tuberculosis and you will rarely be contradicted at autopsy." Tuberculosis

is practically never confined to the meninges, though in many cases miliary processes make themselves apparent only in the central nervous system.

V. URINARY SYSTEM

ACUTE NEPHRITIS

Correct diagnosis in	5 cases or 16 per cent.
Error of omission in	20 cases or 62 per cent.
Error of commission in	7 cases or 22 per cent.
<hr/>	
Total,	32 cases

Some years ago I undertook a critical study of the urinary reports and post-mortem findings in the different types of nephritis. I was much impressed at that time with the large percentage of mistaken diagnoses of acute nephritis—especially the errors of omission. In the present study of another series of cases, the same facts claim attention. It must be stated at the outset that our material contains no cases of scarlet fever; very few of diphtheria and that, as we have no maternity department, our cases of the puerperal type are confined mainly to eclampsia. In the material so limited we find almost no recognizable cases of acute nephritis. Most of those which in former years we called acute we now recognize (thanks to blood-pressure measurements) as chronic with acute exacerbations. For prognosis, and in a lesser degree for treatment, this distinction is important.

Our cases of acute nephritis, recognized and unrecognized, belong mostly in one of three groups:

1. Those due to pneumococcus infections.
2. Those due to infection by the organism of septic endocarditis.
3. Those due to mercurial poisoning.

Our verified diagnoses of acute nephritis have been made chiefly by following these etiologic hints and not from the urinary findings. Given a case of mercurial poisoning, of general pneumococcus infection or of "malignant endocarditis," with or without arthritis, and it is fairly safe to predict that an acute nephritis will develop and will be demonstrated post mortem if the issue is fatal. But this is not a secure basis for diagnostic structures, and we have not yet been able to build much on this or on any other foundation. We doubt whether others can do better at the present time.

CHRONIC GLOMERULAR NEPHRITIS

Correct diagnosis in	53 cases or 74 per cent.
Error of omission in	9 cases or 12 per cent.
Error of commission in	10 cases or 14 per cent.
<hr/>	
Total,	72 cases

CHRONIC INTERSTITIAL NEPHRITIS

Correct diagnosis in	25 cases or 50 per cent.
Error of omission in	19 cases or 38 per cent.
Error of commission in	6 cases or 12 per cent.
<hr/>	
Total,	50 cases

In marked contrast with our failures in acute nephritis, our large percentage of success in chronic glomerular nephritis¹—the type often termed chronic diffuse, chronic parenchymatous nephritis or secondary contracted kidney (Senator). Most of our errors were in

1. Judging by the averages of this whole study I consider anything over 66 per cent. of verified diagnoses as a "high" percentage of success, though I admit that even our best is far from brilliant.

patients seen only in the moribund state and the same is true of the failures recorded in chronic interstitial nephritis.

In distinguishing these two types of nephritis (i. e., those due probably to the results of early infection and those due to arteriosclerosis, wear and tear and senility) I have noticed that most of those associated with any considerable degree of anemia usually turn out to be of the glomerular type. Anemia and uremia are, perhaps, due to the same metabolic poison, while in the interstitial cases we have less anemia and less uremia—the symptoms being chiefly those of circulatory failure.

VI. NERVOUS SYSTEM

CEREBRAL HEMORRHAGE

Correct diagnosis in	34 cases or 67 per cent.
Error of omission in	4 cases or 7 per cent.
Error of commission in	13 cases or 26 per cent.
Total,	51 cases

CEREBRAL TUMOR

Correct diagnosis in	8 cases or 72 4/5 per cent.
Error of omission in	2 cases or 18 1/5 per cent.
Error of commission in	1 case or 9 per cent.
Total,	11 cases

"Cerebral hemorrhage" is here used in the broad sense of "apoplexy," including all sudden attacks of coma and paralysis due to thrombosis, to acute softening or to embolism of the cerebral arteries. It is confessedly impossible to distinguish hemorrhage, rapid thrombosis and embolism by any study of the resulting disturbances of function. With this understanding it may be said that our diagnostic campaigns in this field have obtained an average degree of success. I have been struck, however, with the very considerable proportion of cases which presented during life the ordinary features of apoplexy but showed after death only an arteriosclerotic degeneration of the cerebral arteries without hemorrhage, embolism, thrombosis or acute softening. These cases are like some of those on which Pal based his interesting theory of vascular crises² as an explanation of apoplectic seizures without demonstrable gross lesions post mortem.

Of the small group of cerebral tumors here studied. I will merely say that although we usually were correct in predicting the presence or absence of tumor somewhere within the skull, the attempts at localizing the growth were failures in most cases.

SEPTIC MENINGITIS

Correct diagnosis in	23 cases or 64 per cent.
Error of omission in	8 cases or 22 per cent.
Error of commission in	5 cases or 14 per cent.
Total,	36 cases

TUBERCULOUS MENINGITIS

Correct diagnosis in	26 cases or 72 per cent.
Error of omission in	5 cases or 14 per cent.
Error of commission in	5 cases or 14 per cent.
Total	36 cases

Under the general title of "septic meningitis" I have included the epidemic meningococcus cases, together with those due to the pneumococcus and the pyogenic organisms, whether invading the meninges from the

middle ear or elsewhere. I shall omit discussion both of this group and of the tuberculous cases following.

VII. DIGESTIVE SYSTEM

GASTRIC CANCER

Correct diagnosis in	30 cases or 72 per cent.
Error of omission in	7 cases or 17 per cent.
Error of commission in	5 cases or 11 per cent.
Total,	42 cases

PEPTIC ULCER (GASTRIC OR DUODENAL)

Correct diagnosis in	9 cases or 36 per cent.
Error of omission in	14 cases or 56 per cent.
Error of commission in	2 cases or 8 per cent.
Total,	25 cases

HEPATIC CIRRHOSIS

Correct diagnosis in	19 cases or 61 per cent.
Error of omission in	9 cases or 30 per cent.
Error of commission in	3 cases or 9 per cent.
Total,	31 cases

Our relatively successful dealing with the neoplasms in this table forms a sharp contrast with the shocking failures which were the rule when the diagnosis of peptic ulcer was attempted. Among the fourteen ulcers which we failed to recognize during life nine were gastric and five duodenal. In two cases (Autopsies 637 and 1077) the patient had cirrhosis of the liver (ante-mortem and post-mortem diagnosis) and the gastric hemorrhages were attributed to this. Two patients (Autopsies 2278 and 3441) entered the hospital with the history, symptoms and signs of meningitis, which was confirmed at autopsy. In one case the history distinctly suggested ulcer; in the other, a tuberculous case, there were no symptoms pointing to the gastro-intestinal tract. Seven patients (Autopsies 526, 1161, 1829, 1861, 2024, 2135, 2388) entered the hospital acutely ill with disease outside the gastro-intestinal tract (lobar pneumonia, cancer of the uterus with extensive metastases, cardiovascular degeneration, uremia, congenital syphilis, apoplexy, diabetes). One of these patients, a diabetic boy of 17, had had for three months stomach symptoms quite compatible with gastric ulcer though not characteristic of it. I doubt whether any surgeon would have wished to operate on him in his toxemic and emaciated condition. The other six of the seven patients last referred to had no gastric signs or symptoms whatever.

There remains a group of three cases out of the fourteen in which a diagnosis should, perhaps, have been made. One of them (Autopsy 1586) was seen twice by Drs. Maurice H. Richardson and F. G. Balch, who could make no diagnosis and advised against exploration on account of uncompensated heart disease (autopsy showed insufficiency of the mitral, aortic and tricuspid valves). The second case (Autopsy 1601) had a typical ulcer history, but the abdominal symptoms were obscured or disregarded on account of what was taken to be an acute pneumothorax. Autopsy showed a "subphrenic hypopneumothorax" pushing the diaphragm up to the level of the third rib in front. In view of the frequent occurrence of this type of subphrenic abscess after perforation of a peptic ulcer I think this diagnosis should have been made. The third patient (Autopsy 1064), a woman of 68, would permit no examination, far less exploration of her abdomen.

2. Pal: Gefässkrisen, Berlin, 1905.

In two men, each 35 years old (Autopsies 1238 and 1405) we made the diagnosis of peptic ulcer and were contradicted at the autopsy. One had had "dyspepsia" for four years and was seized the night before he entered the hospital with violent epigastric pain and tenderness not associated, however, with muscular spasm. At autopsy next day a cyst of the pancreas was found to have ruptured into the peritoneum with a resulting general peritonitis. The other man came to the hospital for persistent vomiting of ten days' duration. Soon after entrance he vomited 10 ounces of pure blood. He had also marked cerebral symptoms attributed by a neurologic consultant to cerebral syphilis. At autopsy the stomach showed nothing abnormal. Death was due to chronic interstitial nephritis.

VIII. MISCELLANEOUS

TYPHOID FEVER

Correct diagnosis in	53 cases or 92 per cent.
Error of omission in	0 cases or 0 per cent.
Error of commission in	5 cases or 8 per cent.
Total,	58 cases

DIABETES MELLITUS

Correct diagnosis in	19 cases or 95 per cent.
Error of omission in	0 cases or 0 per cent.
Error of commission in	1 case or 5 per cent.
Total,	20 cases

In typhoid and diabetes the percentage of errors is notably smaller than in the previous groups. This is what one would expect from the sharply cut symptomatology and semeiology of these diseases. Had these cases included any prior to the discovery of the Widal test the proportion of mistakes in the typhoid group would no doubt have been much larger.

The error in the diagnosis of diabetes occurred in a case which was under observation only a few hours before the fatal termination. What seemed to be diabetic coma turned out to be apoplexy with symptomatic glycosuria. It was afterwards learned that the urine had been examined previous to his seizure and had contained no sugar. His previous history showed nothing pointing to diabetes. It must be noted, however, that post-mortem examination is not capable of refuting a well-fortified ante-mortem diagnosis of diabetes.

The five cases in which typhoid was erroneously supposed to exist are of considerable interest and warrant brief analysis did space permit. They confirm the assertion which I have elsewhere made³ that typhoid is simulated (in New England) by only two other diseases, tuberculosis and general septicemia. In this series two of the five cases supposed to be typhoid turned out to be cases of miliary tuberculosis; the other cases were general septicemia.

SYPHILIS

Cerebral syphilis is a diagnosis quite frequently made at the Massachusetts General Hospital, but so far as I know it has never been both made and confirmed during the years (1899 to 1909, inclusive) covered by this report. Two cases with all the traditional evidences of cerebral syphilis, one of which had a positive Wassermann reaction, turned out to be tuberculous meningitis at autopsy; another case showed only chronic

interstitial nephritis; in a fourth case multiple thromboses had occurred in the great venous sinuses of the cranium without any of the recognized causes for such thrombosis. In the only case actually characterized by intracranial syphilitic lesions post mortem they were not recognized in life.

Two other cases of syphilis have recently taught me lessons. One had the ordinary evidences of Banti's disease, splenomegaly and marked anemia followed some months later by ascites. The history gave no hint of syphilitic infection. Dr. Wilder Tileston found a perforation of the nasal septum and suggestive irregularities in the surface of the scalp and of the shin bones, just in time to save the patient from splenectomy. Under potassium iodid and mercury the ascites and anemia disappeared, the spleen shrunk to one-half its former size and the patient made a complete and lasting symptomatic recovery.

The other patient, said to have malaria, had chills, intermittent fever, enlarged spleen and malarial organisms in the blood. I found the liver also enlarged, no malarial organisms in the blood, and obtained a full history of previous syphilitic infection. All symptoms promptly disappeared a year ago under antisyphilitic treatment and have not recurred since.

In order to keep this paper from extending beyond its already inordinate length, I shall try to condense the rest of my data into maxims which should have the merit of brevity if not of wit or clearness, incorporating my summary and conclusions with them.

SUMMARY AND CONCLUSIONS

1. Never make a diagnosis of uremia in a patient seen for the first time in an acute illness characterized by coma or convulsions. Such diagnoses rarely turn out right.
2. Never make a diagnosis of ptomain poisoning without definite chemical evidence. General peritonitis or a tabetic crisis is usually the correct diagnosis.
3. Make no diagnosis of hysteria, neurasthenia or psychoneurosis in a patient whose symptoms begin after the forty-fifth year. The actual diagnosis is likely to be arteriosclerosis, hyperthyroidism, dementia paralytica, or pernicious anemia.
4. Diagnoses of tertian malaria in patients whose symptoms resist quinin more than three days are almost invariably wrong.
5. Bronchial asthma beginning after 40 usually spells heart or kidney disease.
6. Epilepsy beginning after 40 usually means dementia paralytica or cerebral arteriosclerosis.
7. Typical migraine is often a symptom of unrecognized brain tumor or chronic nephritis.
8. Most cases of "bronchitis" mean tuberculosis, bronchopneumonia or multiple bronchiectasis cavities.
9. Aside from the immediate results of acute infections (such as scarlet fever, diphtheria, tonsillitis and pneumonia) "acute" nephritis usually turns out to be chronic.
10. Acute gastritis and gastralgia usually mean appendicitis, gall-stones or peptic ulcer.
11. Pus in or near the liver is often mistaken for serous or purulent pleurisy, for it produces identical signs in the right chest posteriorly.
12. An x-ray of the shin-bones may give the first hint of an active syphilitic process in the joints or internal viscera.

3. Cabot: The Three Long-Continued Fevers of New England, Boston Med. and Surg. Jour., 1908.

13. Systolic or presystolic murmurs, heard best at the apex of a markedly enlarged heart, rarely mean valve lesions.

14. Diastolic murmurs at the base of the heart are very uncertain evidence of aortic disease unless there are characteristic jerking in the peripheral arteries.

15. Myocarditis is a diagnosis which should never be made clinically.

16. Besides the direct evidence afforded by the history and the various methods of physical and chemical examination, diagnosis profits much by taking account of certain familiar pathologic chains or groups of them. Given one or two members of the group it is often wise to act as if the other were present, provided, of course, that the direct evidence in no way contradicts us.

17. Cerebral localization applied to tumors, hemorrhages and the like is still in its infancy.

18. The clinical diagnosis of the so-called diseases of the blood is the easiest and safest in medicine.

190 Marlboro Street.

THE ELECTROCARDIOGRAM IN CLINICAL DIAGNOSIS *

L. F. BARKER, M.D., A. D. HIRSCHFELDER, M.D.,

AND

G. S. BOND, M.D.

BALTIMORE

In the study of cardiac function by instrumental means, a number of methods have been employed, each of which has yielded information which was not obtainable with the others. The study of the arterial pulse has taught us much regarding the relation between cardiac output and peripheral resistance; the study of the blood-pressure has taught us to estimate accurately the force of the heart-beat and the factors which control it; the *x*-ray examination has given us a means of observing the changes in volume of the four chambers of the heart; and the study of the venous pulse has enabled us to detect many changes in the origin and propagation of the cardiac contraction. In spite of the great additions which these methods have made to the study of the heart, there is still much information that they are unable to furnish, and some of this is yielded by studying the electric variations produced in the body at each beat of the heart.

Considered electrically, the human body may be regarded as a battery with the two arms and two legs as its natural and most convenient poles. Owing to processes going on in the body and in the skin, the potential at each of these poles is different; hence, if any two of these limbs are dipped into zinc pans containing salt solution and connected with one another by wires, a constant current is generated; and if a very sensitive galvanometer is placed in the circuit it is deflected by this "body current"—or, as it is usually termed, "rest-current."

The rest-current is due simply to the difference of potential between any two parts of the body and is independent of any muscular contraction. Besides this, another current (action-current) is set up whenever any muscle acts, and this action current adds its effect to that of the body current already present and

causes the galvanometer to swing each time that it is generated, that is, every time the muscle acts. Action of any muscle can cause such action-currents, and even small movements of the fingers placed in the salt solution are accompanied by very large deflections; but if the patient is kept perfectly quiet and there is no tremor the only important deflections are those caused by the cardiac action.

The electric variations accompanying the cardiac action have an intensity of from 1/1000 to 3/1000 of a volt, and consequently could not be studied accurately until an extremely delicate galvanometer had been invented. Professor Einthoven of Leyden has invented such a galvanometer, which consists of a very fine quartz

Fig. 1.—Diagram of a simplified electrocardiograph, showing also the distribution of the electrical changes about the heart. The patient is supposed to be seated with his hands immersed in the jars of salt solution (+ and —).

or platinum thread, so fine that it is barely visible and so light that it can scarcely be weighed by the most delicate balances. This thread is suspended in the field of a permanent magnet or of an electromagnet. When the current from the body passes through the thread, it charges the latter and causes it to be attracted or repelled by the poles of the magnet, and the thread is so light that it is deflected without delay by these changes in the electromagnetic field. The movements of this thread are magnified with a powerful microscope, illuminated with an arc-lamp, and the shadow is photographed on a moving drum 6 or 8 feet away (Fig. 1). By this method, it is possible to study very small currents.

Fig. 2.—Typical electrocardiogram from a normal man. Current led off from right hand and left foot (D 2). Upper line, timer marking fifths of seconds.

It is even possible to connect distant points with the galvanometer and thus to record the hearts of patients who are lying in their beds in the wards, or to connect the laboratory with distant hospitals; but grounded circuits cannot be used for this purpose. Professor Einthoven has made most of his tracings from patients in Professor Nolan's wards of the Leyden hospital, a mile and a half away from his galvanometer.

Even 1/1000 of a volt is sufficient to cause a marked deflection. 4 mm. with our instrument, 1 cm. with the larger instruments. In Baltimore we have worked with the small permanent magnet and a platinum filament. This has given in the main very satisfactory results, but we hope, next year, to have the larger and more delicate apparatus.

* Read in the Section on Practice of Medicine of the American Medical Association, at the Sixty-first Annual Session, held at St. Louis, June, 1910.

The electrical changes during each cardiac cycle are quite characteristic and correspond to the successive activities of the atrium and the ventricle. The base where the atria are situated becomes negative before the atrial activity, which is followed by another, due to the ventricular activity.

As will be noticed, the variations in potential are a little different if they are led off at different parts of the body, and the curves thus derived differ slightly from one another. Since Einthoven's first work, it has been customary to take records from three different derivations: the right hand and left hand—designated as the first derivation (D1); the right hand and left foot, the second derivation (D2); and the left hand and left foot, third derivation (D3). The second derivation shows the greatest oscillations; the third derivation is the most important for determining hypertrophy of the left ventricle.

The typical form of electrocardiogram is shown in Figure 2. As can be seen, the first wave (P) is a small

Fig. 3.—Diagram showing the time relations between the waves of the electrocardiogram, the heart sounds and the contractions of auricles and ventricles.¹ Vertical divisions indicate tenths of a second.

The most recent investigations of Kahn in Hering's laboratory indicate that the electrical variations and the mechanical action are synchronous, and that the electrical variations do not precede the contractions as was first supposed, although the former slightly precede the rises in intra-atrial and intra-ventricular pressures. We have, however, used the term "activity," rather than contraction in the above descriptions, as this leaves the matter open pending confirmation of Kahn's work.

The mode of origin of the T wave is more obscure, as there is no separate contraction which corresponds to it, but the two ventricular waves (R and T) correspond closely to the first and second waves of the di-phasic variation which is seen in the contraction of any

Fig. 5.—A, venous and carotid arterial pulse from a patient with complete heart-block and pulse-rate of 33 per minute. B, electrocardiogram from the same patient. Upper line, timer in fifths of seconds, lower line, electrocardiogram. The rate of the atria is about twice that of the ventricles but the complete dissociation between the two is more readily discernible in the electrocardiogram than in the venous tracing.

Fig. 6.—Electrocardiogram showing extrasystoles which probably arise in the right ventricle. Upper and lower lines as before.

Fig. 4.—Upper line, timer, marking fifths of seconds; lower line, electrocardiogram. Inversion of the R and T waves due to hypertrophy of the left ventricle. Current led off from left hand and left foot (D3). The P wave, due to the atrial activity, is absent.

Fig. 7.—Electrocardiogram showing extrasystoles which probably arise in the left ventricle. Upper and lower lines as before.

one due to activity of the atria (P wave). This is followed by a very small depression of the curve below the base line, Q depression. Then comes the wave due to the action of the ventricles, a large wave (R), which sets in suddenly and as suddenly subsides, falling below the base line (S depression), and this wave in turn is followed by a small second wave (T) which occurs during the middle of systole (Fig. 3).

1. The short interval between the beginning of the R wave and the beginning of the rise in intraventricular pressure is interpreted by Kahn as due to the phenomena of conduction within the heart. In experimental ventricular extrasystoles the electric and mechanical changes are absolutely synchronous.

muscle whatever. Moreover, the form of the electrical curve is scarcely due to the algebraic sum of the curves of the two ventricular contractions, as claimed by Kraus and Nikolai, since the same curve was obtained by Sanderson and Page and, more recently, by Gotch in the frog and tortoise, although these animals have only one ventricle (Fig. 3.)

So much for the normal electrocardiogram. When the left ventricle is hypertrophied, the electrocardiogram undergoes a very definite change, and the first ventricular wave (R) becomes inverted (Fig. 4). Occasionally the T wave is inverted also.

The electrocardiogram is also particularly useful in the diagnosis of heart-block. Figure 5A shows a venous

and arterial tracing from a case of permanent, complete heart-block with the auricular rate about twice the ventricular. Figure 5B is an electrocardiogram of the same case, in which, as will be seen, the complete dissociation is much more easily made out.

One of the most interesting variations is that which is obtained from the extrasystoles, as is seen in Figure 6. It will be noticed that the wave accompanying the extrasystole is unusually large and slow. It is so different from the normal beats which precede and follow it that one can tell by merely watching the string just when an extrasystole takes place. It will be noticed that the first wave is very large, that it subsides very slowly and is followed by a very large depression (Fig. 6). Kraus

Fig. 8.—Electrocardiogram showing fibrillation of the auricles in the portion underlined. Upper and lower curves as before.

and Nikolai have shown that this type of curve is given by extrasystoles which arise in the right ventricle, whereas if the extrasystole arises in the left ventricle one obtains the exact inverse of this curve (Fig. 7). Recent investigations by Kahn have shown that stimuli which arise near the apex give about the same form of curve in either ventricle, in whichever ventricle they may arise. These types are not absolutely distinctive.

If the extrasystole arises in the atria, the curve is preceded by a P wave, and it often resembles the normal electrocardiogram much more closely.

Occasionally one encounters cases in which the P wave due to the atrial activity has disappeared, and is replaced by irregular waves of a frequency varying from 300 to 900 beats per minute (Fig. 8). As Rothberger and Winterberg and, more recently, T. Lewis have shown, this form of curve is associated with fibrillary

Fig. 9.—Scheme of simplified arrangement for the recording of the heart sounds. *Steth*, stethoscope; *Microph*, microphone; *Prim*, primary coil; *Sec*, secondary coil.

contractions of the atria, and is especially frequent in the permanent, absolute arrhythmia. This curve is obtained most frequently when the current is led off from the third right interpace and left interscapular regions—that is, when the circuit passes through both atria. Our own curve is obtained from the second derivation in the same patient as the left-sided ventricular extrasystoles, a patient with paroxysmal tachycardia between attacks.

Evidences of atrial fibrillation cannot be obtained with venous pulse, as the fibrillating auricle does not give any wave on it; and so the only evidences of this state can be revealed by the electrocardiogram. The

studies of Cushny and Edmunds, of Hirschfelder, of Rothberger and Winterberg, and of Thomas Lewis indicate that this may open up an entirely new field in our knowledge of the permanent irregularities of the heart and of paroxysmal tachycardia, and in the study of many functional disturbances which are at present quite mysterious.

It seems probable, therefore, that this new method will enable us to penetrate one step further into the

Fig. 10.—Graphic records of the heart sounds from a normal individual. Upper line, timer in fifths of seconds; lower line, phonogram.

problems which cannot be solved by the older procedures, and will bring us closer to a perfect understanding of what goes on in the diseased heart.

It is also possible to obtain graphic records of the heart-sounds by means of Einthoven's galvanometer. This procedure has nothing to do with the electrocardiogram and there is no direct connection between the galvanometer and the patient's body. The galvanometer is merely connected in circuit with the secondary coil of a very delicate telephone, or rather a microphone, so that it takes the place of the telephone receiver.

A stethoscope is held on the patient's chest and the heart-sounds are led to the microphone through a rubber tube. The sound waves cause telephone currents which are transmitted to the galvanometer and cause the string to vibrate. The vibrations of the string are photographed and graphic records of the heart-sounds are thus obtained (Fig. 9).

Figure 10 shows such records of normal heart sounds. It will be noticed that vibrations of the first sound last only about 8/100 to 1/10 second. The short pause is about 15/100 to 25/100 and the second sound lasts 5/100 to 8/100; while there is a long pause in diastole.

Fig. 11.—Graphic record of heart sounds from a patient with mitral stenosis and insufficiency. *Pre*, presystolic rumble; *Sys*, systolic murmur. Upper and lower lines as in Figure 10.

Figure 11 shows a record from a little girl with a presystolic rumble and a systolic murmur at the apex. The small vibrations correspond to the rumble just before the first sound, and the large vibrations correspond to the heart sounds.

1035 North Calvert Street—2243 Linden Avenue.

ABSTRACT OF DISCUSSION

Dr. J. A. LICHTY, Pittsburg, Pa.: I should like some information regarding the lettering of these waves; have the letters used any significance? I should like to know more, too, regarding the A-wave in particular; the A-wave is always mentioned and looked for, and I should like to know if the

lettering of the A-wave is an arbitrary lettering, or if it possesses some special significance.

DR. JOHN H. MUSSEY, Philadelphia: I should like to call attention to the importance of all these studies, not only the studies with the apparatus which has just been presented, but also the studies with the ordinary Jaquet instrument by which it is made possible to differentiate the various myogenic functions of the heart. This is very important in diagnosis and prognosis. It has also occurred to me that we can draw excellent conclusions as to methods of treatment. When we find in one man that there is an excess of stimulus production or of excitability, a depression of conductivity or contractility or a loss of tonicity, when coupled with certain blood-pressure changes, we have a guide at once for methods of treatment that is not based on empirical grounds, but is actually scientific. In the discussion on the question of heart failure and the reports of the various investigations concerning it, I had in mind to call attention to the value of morphin as a remedy in the earlier periods of heart failure, for two reasons. First, we realize, of course, that in the prevention of heart failure we should take into consideration the fact that there is a failure as well occurring in other portions of the organism, and particularly the nervous system. One of the first indications of heart failure perhaps is undue excitability or excess of stimulus production. Second, there is the immediate action of morphin on the heart. If we can uplift the condition of the nervous system, or reduce its wear and tear, both of which may be factors in the production of cardiac failure, by the use of a remedy such as morphin, we are going a long way in the prevention of cardiac exhaustion. I think therefore that morphin is a valuable aid directly and indirectly: directly by its action in lessening excitability or perhaps stimulus production; indirectly, through the nervous system. Other remedies or measures may be employed to control these disturbed myogenic functions. Furthermore, when we find that there is depression of conductivity, the remedy to be employed—atropin or belladonna—and other remedies come to our minds at once. For the depression of contractility the nitrites, among many other remedies, are necessary, and in loss of tonicity, digitalis and other heart tonics are of avail. In differentiating the remedies required, the degree of tension of the vessels is a valuable aid. I have been at sea recently and frequently in regard to the employment of remedies for the complicating conditions present in cardiac exhaustion. I have had great satisfaction resulting from studies such as these in determining the lines of treatment, and for this reason I wish to call attention to the importance of observations which help us in this matter.

DR. RICHARD WEIL, New York: I think it would be of interest to analyze the evidence offered by this new method with reference to the question of nodal rhythm. It seems impossible to determine definitely by the older sphygmographic method whether the coincidence of the jugular and the radial impulses was due to synchronous contractions of the auricle and ventricle—the nodal rhythm theory—or whether it was due simply to the propagation of the systolic ventricular impulse through the paralyzed auricle into the jugular. I should like to know whether the galvanometer method has in such cases determined the presence or absence of a true auricular contraction.

DR. A. D. HIBSCHFELDER, Baltimore: The A-wave is so called because the wave is caused by the auricular contraction. The letters P, Q, R, S and T of the electrocardiogram are purely arbitrary, but the P-wave is probably so named because it is a presystolic wave. I know of no significance of the lettering of the other waves, except possibly the letters of the alphabet following the P were used for the sake of convenience. P was selected first because it was the first letter of presystolic.

I agree with Dr. Mussey that the most important thing for us at present is carefully and with accuracy to analyze the possible effects drugs are having or are producing, studying the maximal and the minimal blood-pressures, the venous pressures, the electrocardiograms, and also any changes in the cardiac outline. We should study the changes in force and the venous blood-pressure, the tendencies to overfilling

of the heart, the changes in the tonus of the heart muscle (*i. e.*, the tendency of the heart to resist overfilling), and we should study as well the electrical changes which accompany changes in the cardiac impulses.

Many of the venous tracings, especially those having to do with the wave due to synchronous contraction of the auricle and ventricle, admit of doubtful interpretation. Some of the waves which appear during ventricular systole coincide with the C-wave and appear to be due to a fling of the lever. The electrocardiograms taken so far have not shown any evidences of nodal rhythm. Experiments with animals show simultaneous contractions of auricle and ventricle. On the frog's heart we can show contractions of the muscle ring that corresponds to the His bundle. The muscle ring can be seen contracting. When an abnormal stimulus acts first on this ring it contracts first and the auricular and ventricular contractions follow directly the contraction of the ring. The auricle and ventricle then contract simultaneously. However, this does not prove that a similar phenomenon occurs in all the cases which MacKenzie has ascribed to it in man. This whole subject is a matter for further careful investigation.

RACHITIS*

J. W. VAN DERSLICE, M.D.

Assistant Professor of Pediatrics, Rush Medical College
CHICAGO

Rachitis is a dystrophy with which the pediatrician comes into contact with a frequency which breeds contempt; on the other hand there are a certain number of physicians to whom the condition of rachitis is sufficient explanation for any and all pathologic conditions. To what may be attributed this great variation of opinion among medical men? It is undoubtedly due to the fact that there is no definite limitation in the symptomatology of this condition. The definition of rachitis as set down in most of the text-books is the following:

Rachitis is a condition of malnutrition affecting all structures and systems of the body with characteristic defects of nutrition, chiefly manifested in the bones. It is this last phrase of the definition that has caused the many errors in the use of the name. Rachitis is a dystrophy, therefore a constitutional disorder, and though the chief macroscopic and known microscopic changes do affect the bones, there are other changes which are as constant as those of bone growth. With the name "rachitis" there is indelibly associated this so-called softening of the bones, and it follows that many are apt to rely on these changes only as the basis for diagnosis of the condition. It is because of this apparent diversity in the writings of pediatricians that this subject is brought to the attention of this Section, so that the use of the term may be confined to a certain definite symptom-complex.

ETIOLOGY

In no other pathologic condition are there so many theories as to the causative factors as in rachitis. While in the main there is a degree of uniformity, there are many theories of many authors which as yet are both unproved and not disproved. It is not within the province of this paper to go into the myriad of theories or into the various factors that seemingly favor the development of rachitis. Rachitis is a diet disease; to this statement most authors will subscribe. The dietetic errors which have received the greatest emphasis have been the arrangement of the percentages in the various constitu-

* Read in the Section on Diseases of Children of the American Medical Association, at the Sixty-first Annual Session, held at St. Louis, June, 1910.

ents of the foods: to this I cannot subscribe. Admitting that it is possible to develop this condition in the lower animals when fed on various foods, the important point is that by feeding on such mixtures there is certain to be developed a disorder of digestion; and it is this factor which is the important etiologic element in this dystrophy. While it is a daily occurrence to see rachitic infants which have been fed on any of the mixtures that are emphasized as causes for rachitis, on the other hand it is a too common experience to find this dystrophy present in infants which are being given a breast-milk in which all our present-day knowledge in milk analysis can show no shortcoming; hence the constitutional idiosyncrasy of the baby is made to serve as the excuse. It is admitted that there are many contributing factors in these cases the importance of which have not been fully interpreted.

The various contributing causes embraced within the term "malnutrition" are no doubt of vast importance but the point which should be emphasized is that many cases show this or that contributing cause, yet in each and every case there is found an indigestion.

Rachitis is a dystrophy occurring usually between the sixth and thirtieth month, and in a few exceptional cases prior to this period. It is a condition for which the advice of the physician is not sought *per se*. These cases of persistent indigestion will, when occurring at an earlier period, develop the marantic type of dystrophy and in a large percentage of the cases terminate in the dystrophy known as infantile atrophy. There is still another age in which there is apt to occur a dystrophy with characteristic symptomatology, *i. e.*, chlorosis.

CLINICAL HISTORY

The usual clinical history of rachitis is that the child is restless and more or less fretful, the sleep is disturbed, the child shows a tendency to throw off the coverings, there is a slight rise of temperature, especially at night; with this there is the tendency to profuse perspiration about the head and face. When the child is picked up after a sleep it is noticed that the pillow is wet and the perspiration stands in beads on the forehead. Hand in hand with this there is a general tenderness; this tenderness may not manifest itself in the milder type of cases. The child repels advances, manifesting a desire to be let alone. If a careful inquiry is made, it is found that the child has had some disturbance of digestion. There is flatulence, frequently large foul-smelling bowel movements, with either diarrhea or constipation.

This indigestion is always present. The reason that more stress has not been laid on it is that the disorder is not a summer disorder but is met more frequently in the other seasons. The summer diarrheas frequently usher in an attack, but as these attacks of indigestion in the summer are of a more acute type the advice of a physician is sought early and the dietetic disorder is immediately remedied, while the low-grade digestive disturbances of the colder weather are allowed to go on untreated for an indefinite period.

This group of symptoms antedates any bone changes that are demonstrable clinically, but soon the beading of the ribs and the horizontal depression just below the nipple line may be noted; later on the wrists, knees, and ankles enlarge. The enlargements of the ends of the long bones follow certain definite rules and it is found that such bones as are active during their active growth show the greater deformity. The shape of the head is often characteristic. The bones become flattened and

the general appearance is that the head is large but does not simulate the hydrocephalic head, in which there is bulging rather than flattening. The bony prominences are thickened. The head shows other characteristics—the veins on the forehead stand out prominently; the fontanel bulges and is unduly open; the frontal suture in cases occurring early is open.

Craniotabes is not a frequent accompaniment of rachitis but is found in enough cases to call for special mention. Craniotabes is that condition found in the postero-parietal region by which under moderate pressure of the fingers the bones cave inward with a feeling like that of stiff parchment. The question as to the significance of craniotabes is still a mooted point, and many still hold that it is rather associated with syphilis than with rachitis, but that it does occur in cases of simple rachitis there is little doubt. Craniotabes is quite frequently associated with laryngismus stridulus. The skull of a child affected with craniotabes shows shallow depressions at the diseased areas smoothly beveled off into the surrounding bone.

Changes occurring throughout the skeleton will be passed over, as they are too familiar to all to bear repetition.

Muscular Symptoms.—There is general muscular flabbiness and weakness. The patient may be fat and plump but the muscles feel lax and flabby. It is to this condition of the musculature that many of the deformities may be attributed, as kyphosis, scoliosis, knock-knee and talipes.

Nervous Symptoms.—Convulsions, tetany and laryngismus are more prone to occur in the rachitic. Tenderness, irritability, restless sleep, head rolling are common to the disorder and may be attributed to a nervous system rendered unduly irritable by the dystrophy.

Lymph-Glands.—These glands are usually palpable all over the body and in the prolonged and exaggerated cases the spleen is also enlarged.

Teeth.—Dentition may be delayed or irregular. The teeth are more apt to decay.

Blood.—The blood shows constant findings simulating chlorosis. This is especially true in the more severe types.

Complications.—In rachitis there is a tendency toward catarrhal disorders. All mucous membranes are prone to inflammation and many disorders of the upper respiratory tract, bronchitis and bronchopneumonia are encountered.

PATHOLOGY

In spite of innumerable opinions this question is still enveloped in a certain obscurity. The differences of opinion in regard to the causes of the disorder are reflected in a variety of opinions as to the manner in which they act. Identical conditions receive absolutely contradictory interpretations. Probably no organ or tissue of the body is exempt from changes due to this dystrophy, although the only changes which are demonstrable as caused by this condition are seen in the bones.

On examination of a long bone by making a longitudinal section of it and its adjacent cartilage, comparatively healthy bone is found on one side of the epiphysis, healthy cartilage on the other and between the two a layer, more or less thickened, of bluish translucent cartilage. The end of this bluish cartilage toward the healthy cartilage is regular, but the end toward the bone is very irregular—so much so in some cases that the cartilage appears within the bone as islands of cartilage. This

is the spongy tissue which has been considered by many as the characteristic lesion of rickets. The dimensions of the medullary are notably augmented. The modifications as revealed by histologic survey lie especially in the chondroid zone, which is manifestly thickened. At the juncture of this zone with the spongy bone there are numerous structures enveloped in a thin layer of embryonic tissue; the cartilaginous cells are proliferous; only their disposition in series is not regular and the intercellular substance which separates them is not distributed as in the normal bone. It is probable that concurrent disorders do affect the findings in many cases. For example, it is easy of demonstration that if a child passing through a mild attack of rachitis is subjected to an attack of one of the acute infectious disorders, there occurs an exacerbation in the enlargements at the ends of the long bones; so in cases coming to post-mortem from intercurrent diseases, it is not infrequent to find the specific bacteria of the acute disorder lodged in great numbers at points in proximity to the cartilage of the long bones. So it may be said that an intercurrent disorder may have special effect on bones which are undergoing rachitic changes.

The bones show a deficiency of inorganic material. In normal bone the greater portion consists of inorganic material, but in rachitis these proportions may be reversed. By reason of the changes mentioned the entire bone becomes light, spongy, and plastic, and greenstick fractures are prone to occur.

From the stimulation caused by the greater blood-supply, the enlargements at the ends of the long bones are most marked in the epiphyses subject to the greatest motion. From their constant motion in respiration the enlargements are first seen at the anterior ends of the ribs, the so-called rachitic rosary; these enlargements are greater at the fifth and sixth ribs by reason of greater range of movement. It is well to remember that these enlargements are always larger on the pleural side and may not be noticeable externally. After the termination of the rachitis the normal bone development resumes and the newly formed bone becomes harder than the normal bone.

DIAGNOSIS

No disease of early life is so common as rachitis, nor is any disorder so frequently overlooked. It is far commoner for the diagnosis to be made after the cessation of the disorder when there remain but the results of a past rachitis than to have the diagnosis made during the attack.

Rachitis is a disorder insidious in its onset with a very definite symptom-complex described under "Clinical History." This clinical history occurs before any changes in the bones can be demonstrated clinically. There may be a persistence in any or all of these symptoms until the bone-changes appear; or any of them may subside. The chief object of this paper is to call attention to the misuse of the term "rachitis" as applied to the resultant deformities rather than to the disorder itself. The term "rachitis" should be applied only to the symptom-complex above described. The misuse of the term is now so general that in the use of the word it has become necessary to qualify it by a phrase indicating what phase of the disorder is under discussion. The term "acute rickets" is now of more or less general use but this is not applicable as the disease is an insidious disorder, running an indefinite course, and there is no definite disease which may be classified as chronic rick-

ets. At just what point in the disorder it can be said that the rachitis has terminated and that there remains but the results of the rachitis may often be a debatable point, but it is obvious that in many cases of so-called rachitis the disorder has long since been overcome. That this point is well taken is evidenced by the fact that many of the history cards used by the various health authorities in the examination of the school child have this question: Has the child rickets?

It may be set down dogmatically that rachitis is a dystrophy, usually occurring between the sixth and thirtieth months, the symptoms of which are digestive disturbance, restlessness, profuse sweating, especially about the head and face, in severe cases general tenderness; and with these there occur manifold changes in the various systems of the body, with most marked macroscopic and known microscopic changes on the bones.

Of the mistakes in diagnosis most frequently made one is failure to recognize inflammatory and sanguinous effusions beneath the periosteum for simple rickets. This undoubtedly brought the term "acute rickets" into use. Another is mistaking the bone changes of congenital syphilis for those of rickets and a third considering the pseudoparalysis of rickets essential paralysis. Infantile scurvy may complicate rickets, and some authors have a classification including scurvy-rickets; but the disorders should never be confounded, as each has its distinct clinical picture.

PROGNOSIS

Children rarely die of rickets *per se*. It is usually some concomitant or intercurrent disorder that terminates life. Of these the pulmonopathies find in the rachitic child most favorable conditions, and, if survived leave the patient with permanently damaged chest and respiratory organs which may eventually terminate in an invasion of tuberculosis.

Patients with marked splenic enlargement and profound anemia may become marantic with a grave prognosis. Convulsions cause death in a large number of these cases. Laryngismus stridulus appears as a causative factor in many of the fatal cases but it is impossible to say to what extent the rachitis may be held responsible.

The active rachitic process usually ceases by the end of the second year, the length of the disorder depending largely on the ability to remove the indigestion and give an appropriate diet. In many cases the rachitis appears to develop with the advent of an improvement in diet and a clearing up of the digestive disturbance; this can easily be explained by the fact that at the beginning of the treatment of the digestive system the patient was in a condition of athrepsia and with the better hygiene the dystrophy took on a lower grade of malnutrition, namely rachitis. This form of the disorder is usually transient, lasting but a few weeks.

TREATMENT

From the above it is readily seen that rachitis is a preventable disease. The diet is of the first importance. In breast-fed children it becomes necessary to influence the mother in such manner as to make her milk suitable for the child. In many of the cases it becomes necessary to supplement the breast by suitable artificial foods. As the lack of fats has so long been emphasized as a causative factor there is danger of putting too much stress on this phase of the diet and of undoing good efforts by adding more fat than can be handled with

advantage by the child. Good hygiene with plenty of fresh air is a prerequisite. No diet can be set down that can be recommended in these cases. As a general rule cow's milk should be given, but as these cases occur in children fed on the starchy foods it must be remembered that the stomach will need much education in the digestion of this food and the initial use of milk must be in very attenuated doses. Expressed beef juice, raw eggs, orange and lemon juice all have a place in the dietary.

The use of drugs should be limited to the needs of the individual. Syrup of the iodid of iron is frequently indicated. For the digestive weakness the addition of malt or of molasses gives very favorable results. In clinical use the addition of a considerable amount of New Orleans molasses has the same effect as an extract of malt. The intercurrent disorders should be given appropriate treatment.

The tendency to deformities, such as bow-legs, knock-knee and spinal curvatures, must be borne in mind and precautionary steps be taken by preventing undue strain on these parts. In regard to remedying these deformities, it is well to remember that they are very common in childhood and rare in adult life. The tendency of Nature is toward repair.

ETIOLOGY, DIAGNOSIS AND TREATMENT OF COLONIC, SIGMOIDAL, RECTAL AND ANAL AFFECTIONS IN INFANTS AND CHILDREN UNDER TWELVE YEARS OF AGE

INCLUDING REPORT OF THREE HUNDRED AND SIXTY-
NINE CASES

WITH A DESCRIPTION OF A METHOD OF CECOSTOMY
WHICH PROVIDES A MEANS OF IRRIGATING THE
LARGE AND SMALL INTESTINE SEPARATELY OR
AT THE SAME TIME *

SAMUEL GOODWIN GANT, M.D., LL.D.

Professor of Diseases of the Rectum and Anus in the New York
Post-Graduate Medical School and Hospital
NEW YORK

A fairly large experience in the treatment of colonic and anorectal affections has convinced me that the discomfort and pain from which infants and children suffer is to be found in these localities much more frequently than is suspected by the internist, pediatricist or surgeon. When an adult suffers from a colonic or rectal ailment he is usually advised to have it treated or operated on just as soon as its nature has been determined, but this rule is not always followed when an infant or child becomes so afflicted. In many instances pathologic conditions of the colon and rectum go unrecognized; in others they are considered of minor importance, and in still others, even when serious and after diagnosis, the physician not infrequently does nothing but advise the mother to let the child alone, telling her that it will outgrow the trouble.

Now and then a case of abdominal disease is encountered in which a diagnosis cannot be made, except by ex-

clusion. Usually, however, the nature of the intestinal lesion can be determined by palpation, percussion, succussion, the x-ray, or by inflating or distending the colon with air, fluid or a bismuth solution, after first obtaining a complete history. There is no reason, however, why diseases of the rectum should not be accurately diagnosed by the physician who has perfected himself in modern methods of examination.

Most rectal ailments are located in the lower inch and a half of the rectum; consequently they can be identified by inspecting and palpating the anus and surrounding parts and by making a careful digital and anoscopic examination; but when the disease is in the middle and upper rectum, at the rectosigmoidal juncture or lower sigmoid flexure, it can be seen only through the proctoscope or sigmoidoscope.

In many quarters the opinion prevails that a digital and proctoscopic examination is impossible in very young children. Such, however, is not the case, since the sphincter can be made to relax and the rectum is sufficiently large to admit the finger or a small proctoscope.

I have treated many young people and adults for very extensive procidentia recti, invagination, mechanical constipation, colitis, stricture, abscess, fistula and other serious diseases of the lower bowel who had suffered since infancy or childhood, affections which could have been speedily cured had they been correctly diagnosed and treated in their incipiency. It would seem that the time has now arrived when physicians should take on themselves the responsibility of treating the anorectal affections of children as soon as diagnosed and no longer permit them to drift, as has been customary, with the hope that they will outgrow the lesion if it does not heal spontaneously.

The treatment in this class of cases does not necessarily mean an operation, for, in many instances, a cure can be effected by regulating the stools, keeping the bowel in a hygienic condition and by making topical applications. When surgical intervention is necessary it should cause no anxiety, because in the vast majority of instances the operation will be devoid of danger, can be quickly performed, postoperative suffering is slight and convalescence is short.

Instead of discussing at length the etiology, symptoms, diagnosis and treatment of the various colonic and anorectal diseases of infants and children twelve years of age or less, I have subdivided and tabulated my work in this field, which includes 368 cases, to show the large variety of affections encountered in these regions and the results which followed their treatment. Three tables with their summaries have been compiled: the first includes the cases of rectal diseases, the second those of anorectal obstipation and the third those of abdominal obstipation. After calling attention to the salient features of these tables and outlining the treatment of the various diseases, I shall describe my method of cecostomy which permits the small and large intestine to be irrigated separately or at the same time, a reliable procedure to employ in all cases where direct bowel treatment is indicated.

Remarks.—The age of these patients varied from birth to 12 years of age; the majority were more than 6 years old. None of the five deaths recorded is chargeable solely to the treatment instituted, because they occurred in infants afflicted with acute congenital bowel obstruction (2), cancer (2) and diphtheritic colitis (1), and the patients were moribund or in a deplorable condition when first seen.

* Read in the Section on Diseases of Children of the American Medical Association, at the Sixty-first Annual Session, held at St. Louis, June, 1910

TREATMENT OF ANORECTAL AFFECTIONS

The majority of operations performed in this series of cases required less than ten minutes, and local anesthesia induced by sterile water, normal saline or a 0.125 per cent. eucain solution was employed more frequently than general narcosis, and the treatment of the different affections was in the main as outlined below.

Fissure in Ano.—Recent fissures were cured by securing daily semisolid movements and by cleansing and placing a small gauze pledget previously saturated in ichthyol or a silver nitrate solution in the rent for the purposes of drainage and stimulation. Palliative measures are of little avail in the treatment of old fissures accompanied by sphincteralgia because they do not put the muscle at rest. Divulsion of the muscle is sometimes effective, but I have discarded it in favor of division of the sphincter because the latter puts the sphincter at complete rest during the treatment and also serves to widen the anal canal and act as a prophylactic against future tears. My operation consists in anesthetizing the tissues posterior to the rent by injecting them with sterile water or a 0.125 per cent. eucain solution until white. The sphincter is then severed by scissors, one blade of which has been placed posterior to and the other in the rectum in front of the fissure, or with a bistoury.

Ulcers of the Anal Region.—Ulcers which incite sphincteric contraction are treated as fissures unless they are syphilitic, when anti-syphilitic remedies are added. Extensive ulcers in the middle and upper rectum are treated through the proctoscope with stimulating applications, the cautery or caustic. When they are numerous, superficial and scattered throughout the rectum, irrigation daily with a mild solution of ichthyol 1 per cent., permanganate of potash 1 per cent., or weak solutions of boric acid or silver nitrate. Carlsbad salts or krameria and soda work well, but when the ulcerated areas are chronic and deep, as indicated by frequent evacuations containing a large amount of pus, blood, mucus and other debris, stronger solutions are employed until there is improvement, and in addition a warm emulsion composed of olive oil, bismuth and iodoform is injected in small amounts at night for the purpose of allaying tenesmus and pain. In aggravated cases in which the colon and sigmoid are involved, and the above measures fail, appendicostomy or cecostomy is performed.

Procidencia Recti.—Where the mucous membrane only protrudes, a cure can sometimes be effected by (a) correcting a cough, diarrhea, constipation or other cause of straining; (b) securing semisolid movements; (c) having the child stool while in the recumbent posture; (d) injecting an alum, zinc or other astringent solution after each action, and (e) placing a pad of gauze over the anus and tightly strapping the buttocks.

When this treatment fails, I infiltrate the mucosa with water or a eucain solution at a number of points until glassy white welts are formed; these in turn are seized, pulled down, ligated and left to slough off as in hemorrhoidal operations. The procedure is nearly always successful because a sufficient exudate is thrown out to glue the mucous and muscular coats together, and shortening and narrowing of the rectum ensues as healing of the ulcerated areas takes place.

Where both the mucosa and muscularis protrude, I (a) remove a cuff of the mucous membrane, (b) fold and suture the muscular tunic on itself and (c) complete the operation by suturing the divided edges of the mucosa. In very extensive cases of procidencia complicated by invagination of the sigmoid flexure into the rectum, I proceed as follows: (a) the abdomen is opened, the bowel pulled up until taut and then anchored to the anterior parietes by my method of sigmoid-opexy; (b) linear cauterization is made to the middle and upper rectum through the proctoscope, and finally (c) a diamond-shaped piece of tissue, including a part of the lower rectum, the sphincter and the postanal tissues, is removed to narrow the bowel, shorten the muscle and tighten the external parts about the rectum.

Polyps.—These, when located at or near the anus, are ligated and excised after having been anesthetized at their attachment.

When situated higher up, where the mucosa is less sensitive, each in turn is exposed by the aid of the proctoscope, a Gant valve clamp is snapped on their pedicle and they are left to slough off. This method of removing polyps is admirable because it takes but a moment, is certain, causes no pain or bleeding and does not require ether. The older procedure of removing them by torsion is to be condemned because it is painful, extensively lacerates the mucosa and is frequently followed by copious bleeding and a lengthy convalescence.

In cases of long standing in which the growths are numerous, large, ulcerated and scattered throughout the colon or sigmoid flexure, nothing short of cecostomy and lavage or extirpation of the diseased bowel effects a cure.

Internal Hemorrhoids.—As will be seen by a glance at Table 1, internal hemorrhoids occur in infants and children almost as rarely as cancer. These tumors are painlessly removed in a moment by ligation after having been infiltrated with water or eucain.

Thrombotic Piles.—These are transfixed at their base with a curved bistoury, split open and packed with gauze, which arrests bleeding and acts as a drain to prevent their refilling.

Cutaneous Hemorrhoids.—These are snipped off with scissors and the wound is allowed to heal by granulation.

Stricture.—In cases in which the lumen of the intestine is diminished through swelling of the mucosa or exudates in and outside the rectal wall, the discomfort arising therefrom is lessened or completely overcome by regulating the stools, irrigating the bowel, making soothing and stimulating topical applications to the diseased intestine and by dilating the constricted bowel with the fingers or bougies.

Moderate cicatricial strictures are improved by divulsion gradually with bougies or forcibly with the fingers, but their division is preferable because more lasting results are obtained and the operation takes no longer. The technic consists in guiding a probe-pointed bistoury through the stricture and severing it and the sphincter posteriorly as it is withdrawn, and in packing the wound with gauze. Both divulsion and division are contraindicated when the stenosis is located above the peritoneal attachment, because peritonitis will surely follow rupture or perforation of the intestine.

There is but one cure for a scar stricture and that is complete extirpation, a procedure which entails some danger. Where there are multiple constrictions or a very long stricture and much perirectal thickening, extirpation will take considerable time, cause much shock and would likely prove fatal in young children, and for these reasons it is advisable to substitute colostomy for excision until the child has grown older and stronger, when the artificial anus may be closed and the stricture removed.

Congenital Deformities.—The treatment of imperforations of the rectum and anus in the newly born is varied according to the deformity. When the outlet is partially or completely blocked by a fold of skin or fibrous tissue, it is caught in forceps and removed with scissors; but when the anus is abnormally narrowed by connective tissue, it is split and the wound is drained and occasionally stretched as healing takes place. In cases of deformity in which the feces find a free exit through the vagina, bladder, buttock or elsewhere, operation is postponed until the child is older, but when the opening is small and there is danger from obstruction, it is enlarged or a temporary vent is formed in the interischial or inguinal region.

Imperforate Anus: If the cul-de-sac terminates low down and the sphincter is intact, the anus is formed at the usual location, but if the muscle is absent the anus is made further forward or backward according to indications. The operation is begun by an incision extending from the perineum in front to the coccyx behind, which splits the sphincter. The wound is deepened upward to the blind rectum, which, after being freed, is brought down and sutured to the anal skin, after which the sphincter and wound are sutured about it. The coccyx is removed when additional room is necessary, but the peritoneal cavity is not opened except when imperative, and is then closed before the bowel is anchored. When the intestine cannot be brought down to the perineum, it is sutured to the skin of the sacral or coccygeal regions. In all cases a fair-

sized rubber tube is left projecting from the rectum through which the meconium, gas and feces escape.

Imperforate Rectum: The anus may be normal and an obstruction may not be suspected until dangerous symptoms arise. In such cases, when the terminal extremity of the intestines is near the surface, it is incised, evacuated and washed out, but when the condition of the patient permits, the rectum is brought down and sutured to the anal region.

In distressing cases in which a part of the rectum is obliterated, it is freed and anchored at the most available point or a permanent artificial anus is established. When colostomy is performed, according to my intermuscular plan, the patient has fair control over the evacuations and often requires a laxative.

Sequelæ.—Sequelæ frequently need treatment to overcome constipation and prevent obstruction. Usually the trouble is caused by the small size of the original opening or a long narrow stricture which has formed where the intestine has retracted. In both conditions the lumen of the bowel is increased by incising and subsequently dilating it, or in cases where no previous attempt has been made to bring the end-sac to the anus this is done if feasible. When neither of these procedures is possible a permanent artificial anus is formed.

Fistulas.—Fortunately in children fistulas are superficial, short, and of the complete variety and require but a slight operation under local anesthesia. The following are the steps in my operation for complete fistula: (a) enough of a 0.125 per cent. eucain solution is injected into the sphincter and tissues overlying the tract to form a white line, which indicates desensitization; (b) the lower blade of a Gant probe-pointed scissors is then introduced into the outer opening and made to travel along the sinus, which, together with the sphincter, is rapidly divided by a succession of cuts, and (c), after which the wound is packed with gauze.

Abscesses.—Irrespective of their extent and location, abscesses are freely incised, curetted, cleansed and drained to relieve pain and prevent burrowing of the pus.

Pruritus Ani.—This is more frequent in children than is suspected, and may be induced by local lesions which incite a discharge, worms and foreign substances which get caught in the anal, mucous or skin folds. When due to the former the condition causing the discharge is corrected, and when to the latter, frequent cleansing of the anus with plain or salt water will afford the necessary relief. In cases in which itching has existed for a considerable time and there is a chronic dermatitis, this is remedied by applying iodine or a nitrate of mercury ointment.

Impactions.—All these are treated alike, whether composed of feces, seeds or fruit-stones, but little or nothing is accomplished toward their dislodgment or expulsion by means of oils or cathartics internally administered. Recent fecal impactions are occasionally softened and evacuated by repeated enemata of warm water, oil or glycerin alone or in combination, but these measures have no effect on mucus-covered masses. Hydrogen peroxid in full strength when injected in liberal amounts has a decided tendency toward the breaking up of the fecal concretion into numerous smaller masses so that it can be washed out. Marked impactions, which cannot be dislodged by friction, massage and enemata, are removed by force. When low they are broken up or penetrated by the finger or handle of a spoon, but when high up in the rectum or sigmoid this is accomplished through the proctoscope with a gouge, after which the impactions are quickly evacuated by irrigation. Fecoliths which become eneysted and cannot be dislodged by treatment instituted from below or by way of the mouth, are removed by enterotomy or an outlet is made above them.

Venereal Warts.—These are removed with scissors without anesthesia, or they are dried up with a mixture of equal parts of calomel and tannic acid.

Hypertrophied Anal Papillæ.—When causing pruritus and tenesmus they are snipped off under infiltration anesthesia.

Hypertrophy of the Anal Sphincter. This condition, if inducing sphincteralgia and constipation, is quickly and successfully treated by dividing the muscle exactly as in fissure

operations, and painful defecation resulting from an abnormally small anus is treated in a similar manner.

Hypertrophied Rectal Valves.—The valves are divided by placing Gant's valve clamps on them and allowing them to slough out.

Fecal Incontinence.—This condition following injuries or operations is improved either by narrowing the anus through cauterization and the production of scar tissue or by isolating and approximating the ends of the divided muscle.

COMBINED STATISTICS OF TABLES 2 AND 3

Anorectal mechanical constipation (obstipation)....	70	43	27	54	10	2	4
Abdominal mechanical constipation (obstipation)....	36	19	17	12	16	8	0
Total (35 affections).....	106	62	44	66	26	10	4

My case of posterior proctoele was relieved by removing a section of the bowel and suturing the edges of the wound, and the bifurcated rectum was treated in the same way.

Foreign Bodies.—Small, smooth and sharp-pointed objects are removed with the finger or through the proctoscope with forceps, but when large or encysted, much annoyance is saved by splitting the sphincter muscle under eucainization so that they can be quickly removed without pain.

Diseases, Injuries and Deformities of the Coccyx.—When the coccyx is displaced, fractured or inflamed and causes discomfort or painful defecation, its removal is indicated. The steps in my method of coccygeal excision consist in the following: (a) the tissues are folded between the thumb and fingers and divided transversely and down to the tip of the coccyx with one cut of the seissors; (b) a Gant coccygeal elevator is hooked in the bone and it is lifted upward, freed and removed by four cuts made at the sides, beneath and transversely through the base of the coccyx; and (c) finally the wound is closed with interrupted sutures. This procedure is superior to the older excision operation because it requires but three minutes, is practically bloodless, primary union is obtained and the only paraphernalia required are strong, blunt-pointed seissors, a needle and a piece of catgut. The success of the operation is due to the fact that the cuts are made without injury to the blood vessels, since the seissors point upward, outward and away from the rectal vessels at all times.

Sacrococcygeal Cysts and Tumors.—These require skilful handling, and routine treatment is impossible because of their variable size, composition, method of attachment and the fact that they may contain fluid, sebaceous matter, hair, or supernumerary limbs. They have been treated with phenol and iodine injections, and with the cautery, but without success. Tapping and their partial removal has given temporary relief, but when feasible the tumor or cyst is carefully dissected out and the wound drained and closed.

Sacral Dermoids.—Indicated by a dimple or moisture over the bone, sacral dermoids are operated on by infiltrating their overlying tissues with eucain or water, removing the sac and draining the wound.

Malignant Growths (Sarcoma and Carcinoma).—Malignant growths require a difficult and prolonged operation and in children recur quickly after extirpation; for these reasons the little patients should be made comfortable by palliative measures and not be subjected to operation except in very favorable cases.

From what has been said it may be correctly inferred that rectal diseases, with the exception of cancer and congenital deformities of the bowel, are readily curable, and further, that the treatment required is simple, devoid of danger, leaves few sequela and causes little suffering. If such good results are so easily obtained, has not the time arrived when the family physician and pediatricist should prepare for and treat this class of affections in a more satisfactory manner than has heretofore been done? Should they do this, I believe that much unnecessary discomfort and pain could be saved to infants and children and that many of the serious bowel affections now encountered in adults could be prevented.

COMMENTS ON TABLES TWO AND THREE (OBSTIPATION)

I wish now to direct attention to some statistics relating to mechanical constipation, a condition which is often congenital, or acquired early in life, owing to the anatomic arrangement of the bowel in infancy and early childhood (Tables 2 and 3). In Table 2 are tabulated the cases of anorectal, and in Table 3 those of abdominal obstipation.

In studying these statistics of 106 cases of obstipation, it is interesting to note the large number (35) and widely varying conditions which have entered into its causation.

In nearly all the cases of anorectal obstipation the patients were cured or very greatly benefited; in only two instances was there no improvement, and only four deaths occurred in the seventy cases. The results obtained are no better than one would expect because of the simple nature of the rectal ailments causing the trouble and their easy curability. Of the four deaths, two were due to cancer and the others to acute obstruction from congenital deformities, and all four patients were beyond saving when seen.

Fourteen different lesions were found to account for the thirty-six cases of abdominal obstipation and the results in this series show that twelve patients were cured, sixteen improved and eight not benefited. The results obtained were very good, but not so flattering as those following the treatment of rectal obstipation, but this is not to be wondered at, because the lesions were more serious and laparotomy was necessary.

About one-half of the constipated infants and children examined suffered from mechanical obstructions of one kind or another. This appears to be a startling statement to make, since habitual constipation is usually thought to be the most common type of costiveness, but it must be remembered that my work is largely surgical and for a number of years I have taken a great interest in the treatment of surgical constipation and have written much on this topic. This would naturally lead to my getting a considerable number of these cases, whereas the internist would get the atonic type. My experience, however, warrants the belief that the cause of constipation is of a mechanical nature very much more frequently than physicians and surgeons at present recognize, and occurs in about 25 per cent. of the cases.

TREATMENT OF MECHANICAL CONSTIPATION (OBSTIPATION)

The therapeutic measures, medical and physical, employed to relieve and cure ordinary or atonic constipation are, as a rule, unreliable in obstipation, because here we have a surgical disease, and nothing short of an operation will permanently correct or remove the impediment to the fecal current.

I have elsewhere¹ fully described the surgical procedures indicated in the treatment of the various forms of mechanical constipation and need not do more here than to state how the operations are performed without giving their steps.

Dilatation of the Colon and Hirschsprung's Disease.—These are corrected in the very young by scarifying and plicating the colon and sigmoid flexure longitudinally to narrow the bowel, after which it is sutured to the anterior abdominal wall at one or more points to overcome ptosis; but when there are other complications, or the bowel is paralytic, I make it a practice to sever the ileum near the cecum, close the divided ends and anastomose the proximal extremity with the sigmoid flexure or rectum (ileosigmoidostomy, ileorectostomy). In older children, who can withstand a capital operation, in whom the intestine is enormous in size, its walls thin and the propulsive power destroyed, the ileum is joined to the sigmoid flexure or the colon is resected or excised.

Colonic Ptosis and Inagination of the Sigmoid Flexure.—These conditions are easily corrected in most instances without danger by scarifying the abnormal portion of bowel, lifting it upward and anchoring it to the anterior parietes at as many places as required by suspensory sutures tied across rubber tubings.

Adhesions.—These are dealt with according to their character. When a segment of intestine is glued to another piece

of intestine or organ by exudates, separation is accomplished by wiping the intestine loose with gauze. When it is attached by fibrous bands, they are divided with scissors, but when the adhesions are extensive the bowel is carefully freed by dissection while in view, after which raw surfaces are covered with peritoneum.

Angulations and Twists (Volvulus).—Angulations and twists of the colon are straightened out by dividing adhesions, the abnormal mesentery or other structure which pulls on the bowel, or when induced by a misplaced organ or tumor, the former is replaced and the latter is removed.

Enterospasm.—When caused by impacted seeds, fruit-stones or a foreign body, enterospasm is often relieved by catharsis, belladonna, hot fomentations and enemas, but when these measures fail the offending object is removed through an opening made in the intestine.

Narrowing of the Bowel.—Narrowing, resulting from a hypertrophied O'Beirne's sphincter or stricture, is sometimes relieved by dieting, irrigation and medication, when the cause is inflammatory or ulcerative, but when the obstruction is due to cicatrization, division or excision of the stricture is practiced.

DIRECT BOWEL TREATMENT WITH DESCRIPTION OF A NEW ENTERO-COLONIC IRRIGATION

Up to the present physicians know that better results are obtained in the treatment of inflammatory, ulcerative, parasitic and other bowel affections when medication is carried directly to the lesions than when it is made to reach them indirectly, as when given by mouth.

Enteroclysis and irrigation may be accomplished from below through the anus or from above through an opening made in the intestine, and however done it will prove successful provided all the lesions are reached. Treatment from below would be ideal if this could be satisfactorily accomplished, because the patient could remain at home and not be subjected to operation. But unfortunately it cannot be so done, because of the difficulty frequently encountered in passing the tube sufficiently high to carry the fluid to all parts of the diseased intestine.

Appendicostomy, cecostomy and my operation, which provides a way of irrigating both the small and large intestine, were originated with the object of procuring a means of through and through irrigation.

Appendicostomy, once so popular, is fast falling into disrepute, because the appendix is frequently bound down by adhesions, blocked, strictured, too short, or diseased, which makes it unfit for irrigating purposes; it sloughs off, or its opening closes. When appendicostomy is practiced, the appendix should be opened and a Gant appendiceal irrigator introduced during the operation so that irrigation can be started immediately.

Ordinary cecostomy may be employed when the disease is limited to the colon, but is not effective when the small intestine is involved.

I believe that the method of cecostomy with a provision for small and large bowel irrigation as described below is superior to other operations devised for the purpose of carrying the treatment directly to the bowel, because it is applicable in the treatment of lesions located in the small intestine, the large bowel or both. The operation is simple, devoid of danger, requires but a few minutes, and provides a certain means by which the physician, intern or nurse can irrigate all parts of the bowel immediately or later according to indications. Concisely described, the steps in Gant's cecostomy are as follows:

1. Through an incision made over it the cecum is brought into the wound and three purse-string sutures are introduced

1. Gant: Constipation and Abdominal Obstruction, 1909.

into its outer surface opposite the ileocecal valve and the intestine opened within the suture line.

2. The Gant metal, or preferably rubber, enterocolonic irrigator, is now pushed across the cecum and guided through the ileocecal valve into the small intestine by means of the thumb and fingers of the left hand and is held there by an assistant until the infolding purse-string sutures are tied and a circular cone-shaped valve is formed around the tube.

3. The cecum is scarified and two suspensory sutures are introduced at the sides of the irrigator and then carried through the abdominal wall by means of a long-handled needle, where they are tied across rubber tubings.

4. After the wound has been closed by the layer method the metal irrigator is retained in position by attached pieces of tape which encircle the body, but when the rubber tube is used it is fastened in the same way, or to the skin by an adhesive strip after the irrigating tubes have been closed with cravat clamps.

5. The dressings, including an outer covering of rubber tissue, are now applied after having been split to allow the irrigator to project through them.

COMMENTS ON AND INDICATIONS FOR GANT'S CECOSTOMY

I have employed this operation since January, 1906, and published it with indications Aug. 15, 1908,² but since then slight improvements have been made in the technic.

I have performed the operation twenty-two times on adults in the direct treatment of inflammatory, ulcerative, parasitic, specific and other affections involving all parts of the intestine, and the results following this procedure have been most flattering.

It has been performed but three times on children under 12 years of age. In all instances good results were obtained, and from this experience with the operation I am convinced that it has a wide field of usefulness in the treatment of intestinal affections in infants, children and adults, and that it should take precedence over enterostomy, colostomy, appendicostomy and ordinary cecostomy in this class of cases.

In a paper read before the Medical Association of Greater New York, April 20, 1908, and since, I have maintained that cecostomy is indicated in the treatment of enteritis, enterocolitis and catarrhal, tuberculous, dysenteric, syphilitic and gonorrhoeal colitis, ptomain poisoning, intussusception, paralytic ileus, peritonitis, cholera, typhoid fever, intestinal parasites, the manifestations of intestinal autointoxication, ordinary and pernicious anemia, intestinal feeding, malnutrition; following operations on the mouth, throat or stomach, and in gastric stricture, ulcer, cancer or other disturbances where rest of the organ is desirable. I also called attention to the fact that by means of cecostomy various intestinal diseases could be investigated, and that the procedure could be used to determine the amount and nature of the intestinal juices and discharges, the character of the feces, the direct action of salines and other cathartics when injected directly into the small and large bowel, the marked, immediate vasomotor effect following hot and cold enteroclysis, to diagnose angulation, twisting, ptosis or dilatation of the intestine by x-raying the bowel after it has been coated with bismuth solution injected for the purpose, and for the study of many other interesting problems.

150 East Thirty-Fifth Street.

ABSTRACT OF DISCUSSION

DR. LOUIS J. HIRSCHMAN, Detroit: I believe with Dr. Gant that most of us have been a little more remiss in investigating rectal diseases in children than we have been in adults. It is surprising to find in how many of the little patients brought to us the examination of the rectum has been neglected by the physician. These children are brought to the rectal specialist as a last resort, but it is seldom that even ocular inspection has been employed by the attending physician. By means of the proctoscope we can make an ocular examination very readily, and we can make an examination of the rectum in an infant of one year through a female cystoscope. Digital examination will give a practical understanding of the condition in the whole abdominal cavity. One can even examine the condition of the appendix, the colon and sometimes the gall-bladder can be reached with the finger. I do not know that I agree with Dr. Gant about leaving a "buttonhole" in young children. A child has less resistance, and we must be more careful how we employ major surgery. But I believe that many patients with intestinal disturbance, who have not responded to drug treatment, have responded to colonic irrigations with simple saline solution when everything else has failed. Often a crying child that is not helped by any treatment will be found to be suffering from anal fissure. Again, often following infectious diseases, acute hemorrhoids may develop. In cases of apparent prolapse, it is well to be certain that there is not an invagination. Recently I saw a child who had a complete extrusion of the entire colon in whom a diagnosis had been made of prolapse of the rectum. The child had gone down from 18 to 12 pounds in weight in six weeks. I think children are just as often subject to disease of the lower part of the abdomen as are adults.

DR. C. F. WAHNER, Fort Madison, Ia.: I have seen men introduce colon tubes all the way up to four feet in length, presumably past the ileocecal valve; in some cases, however, the end returned and even protruded from the rectum; large quantities of solution were therefore thrown into the rectum. Does Dr. Gant consider insertion of a high rectal tube a possibility or an impossibility? In most instances, I think, it is a mere dream.

DR. G. S. HANES, Louisville, Ky.: A frequent affection of the child is constipation, and the chief cause for constipation in children, and one which is easily overlooked, is intestinal obstruction. This means irritation of the outlet of the bowel—that is, of the sphincter muscle. There are ten cases of constipation due to irritation around the anal canal to one due to all other causes combined. The next trouble we most frequently find is diarrhea. The diarrheas that occur in childhood are usually due to fermentation of food, a catarrhal condition or ulceration. Constipation and diarrhea, of course, are symptoms of other conditions. When a child has eaten food that has fermented and produced irritation, as soon as the canal is cleared out the diarrhea will disappear. But when it is due to ulceration, or to a catarrhal condition, we must be more careful in treatment. Not long ago, a child of 4 years was brought to me with persistent diarrhea that had lasted for 14 months. I found that it was a case of amebic dysentery. The rectum was dotted thickly with small ulcers. I introduced the proctoscope and curetted one of the ulcers and examined it under the microscope and found it seething with amebas. In the last two years I have treated more than fifty cases of amebic dysentery, most of which have come from Kentucky. Of this number, six patients were children under 10 or 12 years of age. All physicians know how difficult it is to cure a case of amebic dysentery in any patient. In fact, we do not know whether they are cured or not. I told the family physician what to do, and if the child was not cured it was greatly relieved. I have never found appendicostomy at all difficult. To do an ordinary appendicostomy, when there is diarrhea or constipation, or other condition that prevails in the lining of the intestine, there need be no difficulty in introducing the instrument through the appendix. One can pick up the appendix and determine whether or not it is patulous. The best treatment of amebic

2. Gant: Local and Surgical Treatment of Chronic Diarrhea, with Description of a New Operation for Irrigating the Large and Small Intestine, New York Med. Jour., Aug. 15, 1908.

dy-entery is ordinary coal oil. I have put in as much as half a gallon and allowed it to remain as long as possible. It is a sedative and does not set up peristalsis, and the patients can retain twice as much oil as they would water. I have had patients return after 24 hours and state that they were still passing coal oil. In the diarrhea, as a rule, the diseased condition is usually in the lower bowel and it can be treated through the anus.

DR. E. H. THRAILKILL, Kansas City, Mo.: Some time ago, in a paper before the Missouri State Medical Association, I said that the obstetrician before handing the child over to the nurse should examine the anus. I have seen children with stricture of the anus which would be relieved by just a little treatment by dilatation and there would be no further trouble. I have seen a number of cases of constipation due to fissure around the anus. With a very small dilator one can cure this, but the little child will have for some time fecal matter remaining there and irritating the bowel and he will not have a movement. Intussusception occurs because the colon and sigmoid are rather long in infancy, and this part of the bowel grows slowly during the first few years and is down low in the iliac region, and thus the invagination of the sigmoid into the rectum takes place. I recently saw such a case in which the child had a prolapse or invagination of the sigmoid to the third degree. If these little children are put into the knee-chest position the bowel will often drop back and the little sufferer will be relieved. As to cases of pericolicitis due to extra-colonic conditions, I think that is true of the majority of cases of constipation.

DR. S. G. GANT, New York: All proctologists agree that it is extremely difficult to introduce the proctoscope and sigmoidoscope because of the curves of the rectum and the angulations of the sigmoid. Pressure should never be exerted in their introduction. I know of three deaths from intestinal rupture and peritonitis caused by forcible attempts to push long, unyielding tubes through the sigmoid flexure. Had I the time I should like to comment on the more common types of rectal diseases occurring in infancy and childhood. A summary of them, however, has been given in the papers. I agree with Dr. Thrailkill that sometimes extra intestinal pressure may be the cause of diarrhea (obstructive type) and constipation (obstipation), but do not agree with him that it is the most common factor, because in my experience the seat of the trouble is most frequently found within the intestine.

It is difficult to understand why constipation is not more frequent when we come to study the points of difficult passage to the feces under normal conditions and appreciate the condition of affairs when they become abnormal. Such obstructive points named from below up are the anal sphincter, levator ani muscle, rectal valve, O'Beirne's sphincter, angulations of the sigmoid, swinging transverse colon, and splenic and hepatic flexures, to say nothing of the difficulty encountered by the solid feces from the cecum perpendicularly upward. Some physicians make a universal practice of divulsing the sphincter muscle in all cases of constipation—a most pernicious practice. Dilate or cut the sphincter when the anus is tight and a good result follows, but to do this when the muscle is relaxed does no good and may do considerable harm.

Surgical intervention is unjustifiable in obstinate diarrhea until medication, dieting and enteroclysis from below have been tried without benefit. Of the procedures devised for this purpose my ecostomy, which provides a quick, safe and sure way of healing the lesions causing the frequent stools, is preferable to all others, because by means of it the medicated fluid can be made to reach all parts of the entire intestinal tract. Two conditions prevail in chronic diarrhea: The first is the laxity of the bowel and surrounding tissues, which permit the easy introduction of instruments, and the second is the constantly dilated state of the rectum by gases. In these cases the finger passes into a dilated cavity, an opposite condition to that found in persons who suffer from constipation.

TUBERCULOSIS OF THE FEMALE ORGANS OF GENERATION AND THE PERITONEUM*

J. RIDDLE GOFFE, M.D.

Professor of Gynecology, New York Polyclinic; Attending Surgeon Women's Hospital, and Gynecologist to New York Polyclinic Hospital; Consulting Gynecologist to New York City, St. Joseph's, Mt. Vernon and Lawrence Hospitals

NEW YORK

HISTORICAL SUMMARY

The study of tuberculosis of the female genitalia was secondary to that of tuberculosis of the peritoneum, although Morgagni, in making a necropsy in 1744 on a young woman who had died from tuberculous peritonitis, found the uterus and Fallopian tubes filled with caseous material and considered these organs as being the primary focus of the disease. Similar conclusions were reported by others who had found similar conditions. At this time, however, tuberculosis of the female genitalia was found only in patients suffering from a constitutional invasion. The local condition was discovered only at autopsy and had no clinical interest; it was considered simply as a pathologic curiosity. This antedated the year 1825.

Christian Fenger divided the history of our knowledge of this disease into three periods. The first embraces everything antedating 1825, which I have described. The second includes the period from 1825 to 1884; during this period peritoneal tuberculosis became better known and more frequently recognized. It was thought at that time that simple peritonitis terminated in recovery; that is, in certain recognized cases of peritonitis the patients did recover, and this fact led to the conclusion that they must be simple, while tuberculous peritonitis was thought to be always fatal. The third stage, from 1884 to the present time began when Koenig proposed laparotomy as a cure for tuberculous peritonitis. It is interesting to note that Koenig reached this attitude of mind from a *priori* deductive reasoning. He had had extensive experience in successfully opening and draining knee-joints and other articulations for tuberculosis. These joints are, as we know, closed cavities lined by a serous membrane; reasoning by analogy, therefore, he concluded that, if incision and drainage cures tuberculosis of a serous membrane in a joint, it should be equally as effective in the abdomen. Acting on this conclusion he submitted four patients suffering from tuberculous peritonitis to operation, and published a paper describing the procedure, in which he reported three recoveries and one death. In 1889 he presented a second paper in which he reported 131 similar operations collected from literature and his own clinic. The results showed 107 in satisfactory condition on leaving the hospital. Of these 107, seventy-four were cured and thirty-three improved. This was the beginning of the new era in the study of this disease, and to Koenig the modern world is indebted for an entirely new concept in its treatment. Many operators in various parts of the world followed in his footsteps and thus an experience was gained that changed materially the prognosis. It was learned that cures occur sometimes spontaneously; especially is this the case with children. In the crusade for eradication of the scourge of tuberculosis the search light is being turned on every phase of the disease, and vigorous means of stamping it out are being applied wherever its head appears.

* Read in the Section on Obstetrics and Diseases of Women of the American Medical Association, at the Sixty-first Annual Session, held at St. Louis, June, 1910.

PRIMARY FOCUS OF TUBERCULOSIS

The possibility of tuberculosis of the genitalia being a primary focus is a question of which most diverse views are entertained. Some of the most careful investigators positively deny it, while others as positively assert that it is possible, although all admit that it is very rare. The readiness with which women of the present day are submitting to gynecologic examinations, and the careful discriminating diagnostic acumen that is being directed to this line of research have brought to light cases in which the only lesion to be found in certain cases has been confined to the cervix, the vagina, or the uterus. The order of frequency with which the generative organs proper are involved is as follows: Fallopian tubes, uterus, ovaries, vagina, vulva.

Genital tuberculosis may be either primary or secondary. By the former it is generally understood that the focus in the genital organs is the primary seat of invading infection. Of necessity an ascending infection is generally primary, and a descending is secondary. According to Hegar the primary ascending infection is produced by penetration of germs from the outside directly to the mucosa of the vagina, uterus, tubes, and finally the peritoneum and ovaries; and the secondary, by penetration of germs into lymphatics through minute breaks in the continuity of the tissue of the genital canal, the germs being so carried to the Fallopian tubes directly or by way of the pelvic peritoneum into the tubes at the fimbriae.

The source of the infection may be the seminal discharge of tuberculous men during intercourse. This has been strongly advocated by some investigators and seems *a priori* to be quite reasonable. But so many cases of tuberculosis of the epididymis with tubercle bacilli in the urine and seminal discharge in married men are known without the wife becoming infected that the chances seem to be against this theory. Even granting that this might be the source it would require unusually favorable conditions for its success. The preparation of the soil for the implantation of the infection by gonorrhoea becomes a prerequisite. The puerperal state with its attendant traumatism offers favorable soil for primary infection. Martin has noted the fact that there is frequent coincidences between tubal pregnancy and tubal tuberculosis indicating a previous lesion.

Dührssen has had a case, mentioned by Amann, in which catheterization of the uterus to overcome sterility was followed by acute tuberculosis of the tube and peritoneum; whether infection was carried in by the catheter or whether the operative interference was simply the occasion for the acute outburst is a question.

It is possible that the street dust loaded with tubercle bacilli and swept up by a woman's skirts and thus deposited on the external genitals may be a source of infection.

TUBERCULOSIS OF THE PERITONEUM

Method of Invasion.—Tuberculous invasion of the tubes and ovaries may precede that of the general peritoneum, be contemporaneous with it or follow it. They are frequently found existing together and probably have the same origin. In tuberculous peritonitis, the disease reaches the peritoneum by three channels: first, hemic, through the blood-current, which gives rise to the acute miliary form of general tuberculosis; second, by contiguity, which form is secondary to tuberculosis of the lymphatic

system, or to ulcers of the bowel which have not yet perforated the peritoneal coat; third, by continuity, which form arises from extension of ulceration in the bowels or Fallopian tubes. This is spread over the peritoneum by lymph-currents or, as some assert, by gravity along the serous surface. The direct primary hemic method is believed to be extremely rare.

Treatment.—There is practically a unanimity of opinion among all who are experienced in handling this disease, that, if possible and practicable, the focus of infection should be removed. On this point William J. Mayo says: "The treatment of tuberculous peritonitis should embrace not only the treatment of the peritonitis, which is symptomatic, but the removal of the source of infection, which in the majority of cases will be found in the Fallopian tubes, appendix or intestine." Murphy says: "The surgical treatment of tuberculosis of the peritoneum involves the following propositions: (1) to remove or shut off the source of supply to the peritoneum of new tuberculous debris; (2) to remove the products of the infective process from the peritoneum; (3) to increase the tissue proliferation for the encapsulation of the foci already present; and (4) to avoid mixed infection."

It is therefore desirable, to say the least, that a diagnosis of the presence of tuberculosis be made in advance of operation. The investigation should embrace a careful examination of the genital organs by touch, so as to determine their exact condition. The fact that this malady is frequently discovered in young girls should be kept in mind. The history of the case with relation to heredity, loss of appetite and weight, and the possibility of venereal infection, should be carefully considered. Martin recommends the application of Koch's tuberculin injection test. He also lays great stress on the subconjunctival instillation of Pirquet-Calmette. He considers this especially important in cases of tuberculosis complicating pregnancy, for the reason that the reaction determines the amount of resistance being offered by the patient, and thereby indicates the wisdom of allowing pregnancy to continue.

But when all these precautions have been taken into consideration, surprise may await the surgeon, on opening the peritoneal cavity. Allport has voiced this in his forceful and characteristic style when he says: "Uncertainty is the characteristic element in the preliminary diagnosis of all tuberculous infection of the peritoneum; surprise inevitably awaits the surgeon as he opens the abdomen; and the unexpected sits ever at the elbow of the pathologist as he examines the specimen in the laboratory."

Operation.—In dealing with any individual patient the method of procedure must be adapted to the condition presented and so may vary with every case. Experience has evolved some pretty definite and fixed rules. First, it must be constantly kept in mind that spontaneous recovery is often possible; at the same time, it must not be forgotten that Nature in her effort to overcome the disease can be greatly assisted in many cases by the surgeon. When the operator has made the abdominal incision and recognizes that he is in the presence of a more or less extensive tuberculous peritonitis, even with distinct foci in the uterine appendages, what shall be his rule of procedure? He should not be led astray by the protean forms of the disease that reveal themselves in successive cases. The whole situation becomes clear when he recalls the fact that there is but one basic lesion

of which the case in hand is one of its stages. Nature is ever waging her war of resistance. Her line of defense may be overwhelmed in the first onset and a condition of hopeless route and annihilation may be presented. This condition obtains in cases of ulceration, perforation, cheesy degeneration, and mixed infection, with resulting hectic fever. On the other hand, we may have a picture of disseminated miliary tubercles accompanied by abundant ascites; this exudate is indicative of a protective process due to irritation of the unaffected peritoneum. If in this process the individual has gained advantage in the fight, this irritation becomes an obliterative peritonitis, the final process resulting in fibrous or cobweb adhesions. Another picture is presented when the infection has invaded the peritoneum from contiguous organs, and presents an ulcerative or cheesy form which is accompanied by fibrous nodules, cicatrizing ulcers, masses of plastic exudate possibly here and there organized into obstructing bands of fibrous tissue. Adhesions and obstructing bands may form sacculated receptacles containing tuberculous debris known as pseudocysts, which may contain pus; this indicates mixed infection, possibly a colon bacillus. The omentum may also be matted together, being an extension of the same process.

As has been said, positive diagnosis is difficult and uncertain, hence the surgeon must be ready to deal wisely with the condition found. In the practical handling of these cases they may be divided into three classes, first, the ascitic; second, the adhesive; and third, the cheesy, attended usually with debris and pus.

In the first or ascitic variety the serum should be evacuated and the wound closed without drainage. These are the cases that recover so mysteriously and so permanently. As a sequel to this surgical intervention, the patient should receive the benefit to the fullest extent of such therapeutic measures as climate, hygiene and diet. These are usually cases of general miliary peritonitis. If a definite focus is discovered in the tubes or the appendix, its removal is desirable. But quiescent adnexa which have been long buried in protecting adhesions should not be disturbed.

In the second class, or adhesive variety, if the plastic exudate is quite universal, and a tendency to organize into adhesive bands is apparent, no interference should be attempted unless a distinct focus can be easily reached and removed. The wisdom of attacking this for its removal will depend on the general condition of the patient. The wound should be closed without drainage.

In the third class of cheesy deposit, with collections of debris, some operators, acting on Koenig's suggestion of the analogy between articular joints and the peritoneal cavity, have advocated curetting, excision, suture, and dissection of the tuberculous masses. This is too radical surgery. Experience has shown that it is disastrous. Adhesions that presumably shut in intestinal ulceration should be carefully preserved, but collections of debris and pus should be as carefully cleansed and the cavity drained with cigarette drains of gutta-percha tissue. Gauze drains should be proscribed. Allport says: "Gauze drainage is a snare of the devil and is especially apt to be followed by serious and often fatal fecal fistula in the dry forms of tuberculous peritonitis. Statistics show conclusively that its practice leads to evils which are worse than the original disease."

Parker Sims in summing up an article read before the New York Surgical Society, March 13, 1907, says:

We have learned that operations should not be undertaken during the first year of infancy; we have learned that surgery offers but little hope in the adhesive variety of the disease; we have learned that the serous variety offers the best prognosis under the various forms of treatment and that the surgical treatment of this variety offers the best results obtainable in this disease. But the most important lesson we have learned is that the scientific operation of today is the one which has for its foundation the removal of the original focus of the disease, as the tuberculous Fallopian tubes, vermiform appendix, mesenteric gland, etc.

CASE REPORTS

My experience embraces seven cases widely distributed through my years of practice.

CASE 1.—Miss R. T., aged 32, referred to me as a subject of chronic general peritonitis, May, 1887. Without any suspicion of tuberculous I opened the abdominal cavity for the purpose of drainage, and with the expectation of finding pus foci in the Fallopian tubes. The entire peritoneum was covered with a moist grayish exudate agglutinating universally the omentum and the coils of intestine. Never had I seen such a case before. There was almost no literature on this subject at that time, and in my ignorance I separated the adhesions and drained freely in all directions with gauze. The result, of course, was a prompt fatality.

CASE 2.—Mrs. S. M., at the New York City Hospital, came into my service May, 1894, as a case of double adnexal disease, the adhesions filling the entire pelvis. The patient's general condition was bad, with a daily temperature of 101 F. I performed a vaginal pan-hysterectomy. On examining the specimen during its removal miliary tubercles were apparent on the peritoneum surface of tube; the uterus and ovaries were cheesy. As the patient was in no condition to withstand a laparotomy, I elevated the patient in the Trendelenburg posture, and with retractors opened wide the vaginal opening into the peritoneal cavity, after which the pelvis was drained vaginally with iodoform gauze. The patient died in less than a year.

CASE 3.—Mrs. G. L., City Hospital, June, 1894, had symptoms of almost constant pain in the left ovarian region; diagnosis, salpingitis. On opening the abdominal cavity I found a condition of general miliary tuberculous. The left tube and ovary were bound together by adhesions, the tube being large and covered with tubercles. There were no other adhesions, and no ascites. The left adnexa were removed, the patient was wheeled into the sunlight and the direct rays of the sun were allowed to pour into peritoneal cavity through the widely opened incision. The wound was closed without drainage. The patient made a complete and permanent recovery.

CASE 4.—Captain — of the Salvation Army, presented herself at my office December, 1908, giving a history of constant pain in the right ovarian region, which had grown steadily worse for about a year, with the pain intensified at menstrual periods. There was loss of strength and flesh. The abdomen was distended and tympanitic, with dullness in the flanks. A hard nodular mass filled the right pelvis, crowding the uterus to the left side. I made a diagnosis of probable tuberculous, and subjected the patient to a laparotomy at the Woman's Hospital, January, 1909. On opening the abdominal cavity I found coils of intestine firmly agglutinated together and firmly attached to the right adnexa, forming a large mass. The surrounding peritoneum and the fundus of the uterus, where the right horn could be seen peeping out of the coils of intestine, were dotted with miliary tubercles. In attempting to separate the intestines, I found that their walls were thoroughly invaded and quickly felt that the part of wisdom was to desist from further interference. I therefore sponged the cavity dry and closed the wound without drainage. Temperature ran daily to 101½ F. for about a week. Under careful and enforced diet, strength returned rapidly, and the patient left the hospital in four weeks. Outdoor life, day and night, and good nourishment were enjoined, and one year later she reported at my office greatly improved and ready to go back

to the ranks of the Salvation Army. There was no ascites and the pelvic mass had diminished to at least one-half of its former proportions. I have not seen the patient since.

CASE 5.—Miss E. D. M., aged 22½ years, was a private patient of Dr. Weiss, Mt. Vernon, N. Y., who has kindly furnished me the following history:

"I first saw the patient on Dec. 1, 1906, and found her suffering with an attack of acute lobular pneumonia (lower left lobe), with no cough but felt oppression in chest, had high temperature and felt sick.

"The history leading up to this acute condition in brief was this: The patient had been more or less tired for some five or six weeks; but still went to work, when she was suddenly taken down on or about December 1 with a chill and the acute condition above spoken of. The pneumonia took the usual course and on Jan. 24, 1907, some seven weeks after the beginning of the original illness the patient returned to work. At this time the pneumonia had resolved and, while her general condition was fair, she was still weak. The patient continued to go to her work (that of a stenographer), from Jan. 24, 1907, to Feb. 28, 1907, about five weeks, when she again noticed that she had severe pain in the left lower abdomen. She persisted in going to work, however, until February 28, when the pain became so great that she remained at home. Examination at this time showed nothing special in the thorax. There was a general swelling and distention of the abdomen. Percussion of the flanks showed some slight evidence of liquid in the abdominal cavity. There was thickening of left Fallopian tube with considerable pain on pressure; otherwise the patient's condition was negative.

"The usual hygienic and tonic treatment was instituted, the tentative diagnosis being tuberculous peritonitis. On March 18, 1907, Dr. Goffe kindly saw the patient with me and gave his opinion that an absolute diagnosis was difficult to make and advised close observation.

"Four days later patient was transferred to the Mount Vernon Hospital. The distention at this time had improved somewhat, the pain, however, in the lower left side persisted, and there was more or less fever with increased pulse-rate.

"During the following two weeks patient appeared to improve. In consideration of this fact, on consultation with Dr. Goffe, it was decided to do an exploratory laparotomy. Accordingly on April 3, 1907, under the direction of Dr. Goffe, I opened the abdomen and found the peritoneum studded with many patches, congested, and all the organs adherent. The parietal peritoneum itself was fully ⅜ of an inch thick. The left tube was found considerably enlarged and adherent. It was decided to close the abdomen without drainage and institute a sustaining and tonic line of treatment. After a few days the abdominal wound broke down and large quantities of pus came from the sinus.

"During the summer of 1907, the patient had chills with continued rises of temperature, sweats, lost considerable weight, and drained a great deal of pus. Examination showed some of these sinuses extending from 5 to 6 inches under the abdominal wall, one in particular, running up from the wound on the right side toward the liver.

"From April until October the fresh-air and hygienic treatment in every sense of the word was carried out to the letter: not only were the windows of the patient's sleeping apartment kept open day and night, but she was carried daily down to the lawn, where she passed her time either on a couch or in a hammock, thus enjoying the benefit of the outdoor treatment continuously. In addition to this she was given tonics and proper food.

"About August 1, 1907, the heretofore weak and bed-ridden patient began to show perceptible signs of improvement and, while her weight at that time could not very well be taken, her general appearance, in spite of the large amount of drainage from the wound, showed considerable weekly improvement. This went on continuously until in September the patient was permitted to walk about and take exercise. The improvement continued along these lines until October 6, when in addition to the pus drainage there were evidences of a fecal fistula.

"From October, 1907, until April, 1908, in spite of the inclement winter weather, the same open-air treatment was contin-

ued. By April 1, 1908, the patient had improved to such a degree that it was decided to transfer the patient to her own home. On the day of transfer (April 6), the patient's weight was found to be 102 pounds, as compared with 104 or 105 pounds, which was her best previous weight in health.

"From April 1 until August 1, 1908, she remained at home continuing in about the same general condition, with an occasional chill and a small break-down possibly of some gland or pus pocket as shown in the increase of drainage, improving, however, in general condition.

"She was permitted to take up some of her previous business duties. Accordingly, she accepted a position which permitted her four to six hours light work, with the coincident exercise of walking daily back and forth to her place of business. This test she stood remarkably well and, with the exception of one or two minor colds during the winter, improved to such an extent that on April 6, 1909, she appeared sufficiently recovered to be able to take up her more arduous duties as chief stenographer in a large law office in a town about ten miles away. This, of course, included not only walking to the station, but twenty miles' railroad travel as well. She stood the strain of this new occupation very well until mid-summer when she began to lose in weight. She then took a three weeks' vacation in the Adirondacks and returned to work in August considerably improved.

"From that time, August, 1909, to the time of the present writing, March, 1910, she has enjoyed very good average health, with the exception of an occasional attack of bronchitis, generally the result of some indiscretion in dress. She looks well, eats well, and is able to carry out all the duties of her position and, while she tires from time to time, it cannot be said that she does so to any greater extent than any other person might under similar circumstances.

"During this time, namely, from about July, 1907, to March, 1910, an effort has been made at all times to carry out the open-air treatment, and particular attention has been paid to regular meals, largely of the proteid type, with very little medication. An occasional tonic or emulsion or a little ordinary cough medicine has been about all the medical remedies employed. No alcohol has been used. The patient has been advised to rest as much as possible and also to get as much sleep as circumstances will allow.

"The patient now looks well, has a good color, is strong and eats and sleeps well. She weighs at time of writing 103 pounds. There remains a small fistula which discharges some pus daily and occasionally some fecal matter, showing that the fecal fistula is not entirely healed. The only trouble the patient now experiences is that, when the sinus closes, the fecal matter seems to accumulate between the intestines and the abdominal wall and, until relieved, there is more or less pain and distress. Other than that the patient has no discomfort.

"In February, 1907, just subsequent to the attack of pneumonia, when the patient again went to bed, she menstruated continuously for about three weeks before being removed to this hospital. From about March 22, 1907, to Jan. 4, 1908 (a period of ten months), menstruation ceased entirely. On Jan. 4, 1908, it recommenced and has remained regular ever since in time, quantity and quality.

"A recent internal examination showed no especially abnormal conditions, except that the uterine organs and adnexa are fixed and there is some thickening and fulness in the left broad ligament and tube.

"Examination of pus made by our pathologist, Dr. Goldhorn, showed nothing of interest.

"My interpretation of the general low-grade peritonitis which commenced in March, 1907, is that the infection was due to the pneumococcus germ secondary to the original attack of pneumonia.

"In closing a word might be said in regard to the treatment. It will be noticed that after the original laparotomy it has been entirely medical and that there has been no surgical interference. This has been done advisedly, for the reason that the patient showed continuous improvement, and the condition and the internal conditions, so far as they could be interpreted from the laparotomy and subsequent course of

the disease, were such that any surgical procedure would be fraught with so much danger that the inconvenience of a small fecal fistula was considered preferable to a possible unfortunate outcome, the result of a surgical interference."

CASE 6.—Mrs. S. R. H., aged 26, had been married five years, had never been pregnant and had always been a great sufferer from dysmenorrhœa. Four years ago the patient had an attack of pleurisy, being in bed ten days. During the following two years she complained of painful breathing and a stitch in the side. She lost flesh and became very weak. For the past two years she has suffered pain in both ovarian regions, at intervals so intense that morphin had to be used. Dec. 25, 1909, the patient entered Lawrence Hospital, Bronxville, N. Y., where I operated for salpingo-oophoritis. The adnexa of each side were bound together with plastic exudate and the tubes, as well as the neighboring coils of intestines, were freckled with miliary tubercles. The adnexa were removed with the exception of the left ovary which was apparently free from disease. There was no ascites. Recovery was prompt. Three months later, April 11, the patient reported a gain of 5½ pounds; she was never so fat in her life. She can walk now without pain, but tires easily, is living out of doors and sleeping on the veranda.

CASE 7.—Mrs. E. D., aged 44, was subjected to laparotomy for constant pain in the abdomen, which was accounted for by adhesions. There was also an old hardened chronic condition of the left adnexa. The omentum was attached to the sigmoid flexure and the fundus uteri. These adhesions were separated and part of the omentum removed, as was also the ovary and tube of the left side, which were bound firmly together. There was no evidence of tuberculous present, but the pathologist reported that the walls of the tube were pretty generally invaded with tubercles. The patient made a prompt recovery and has been relieved of her pain. This case undoubtedly stands as an example of spontaneous recovery.

616 Madison Avenue.

ABSTRACT OF DISCUSSION

DR. EMIL NOVAK, Baltimore: The possibility of tuberculous peritonitis should always be borne in mind in any obscure abdominal condition, especially in the presence of an abdominal tumor. An illustrative case is that of a colored woman whom I saw about four years ago. She was brought into the hospital several weeks after delivery. Her only complaint was that the abdomen was just as large after delivery as before. After examination, we decided that there was probably an ovarian cyst complicating pregnancy. Not until the patient had been anesthetized and placed on the operating-table did we notice a deep-seated mass high up in the abdomen, which made us think that the condition was not one of ovarian cyst, but possibly one of tuberculous peritonitis. At operation, we found the woman suffering from tuberculous peritonitis with an encysted ascites, while the deep-seated mass proved to be a much infiltrated great omentum. The case was particularly interesting, in view of the fact that the presence of one abdominal tumor, the encysted ascites, had misled us, and that the other tumor, the infiltrated omentum, had put us back on the right track.

In estimating the good results following operative treatment in this disease, one must bear in mind that there is a strong tendency in many cases toward spontaneous recovery. This is well illustrated in a case reported by Louis, of a young man suffering with very advanced tuberculous peritonitis, with marked ascites, emaciation, etc. In this condition he fell a victim to Asiatic cholera, and recovered not only from the cholera, but also from the tuberculous peritonitis.

DR. C. C. FREDERICK, Buffalo: Patients with acute tuberculous peritonitis sometimes do not survive the shock of operation. With the exception of that one source of fatality following operation, I have never seen a patient die as a result of operation nor fail to see a patient apparently completely recover. I have seen many who have passed through the same course as that given by Dr. Goffe in the history of his patient. I have seen them go for a period of from six

months to a year or a year and a half or two years with a stormy career, but eventually recover. I have never seen one left with a permanent fecal fistula or any other fistula, although the infection of the abdominal scar as the result of contact of the tuberculous infection with the wound at the time of operation is sometimes a source of trouble for several weeks or months after the operation. Four or five years ago, I began using drainage through Douglas' pouch in these cases almost as a routine procedure. I broke up all the adhesions in the adhesive cases in which the intestines had been lifted into the upper part of the abdomen by the accumulations of fluid beneath them and the peritoneum, all the mesentery having become adherent, so that one could see simply a mass composed of intestine in such condition that one could not see a convolution of the intestine. I free the adhesions completely, sometimes the operation being 30 or 45 minutes in duration. All the tuberculous surface is exposed to view and to contact. The abdominal cavity is sponged out. In women usually the focus of infection is the tube. Then a drain is passed down through Douglas' pouch. I always put in a big drainage tube with fenestræ at the top. The tube is kept in for weeks so as to insure free drainage from the lower part of the pelvic cavity even after the upper part may be shut off by adhesive inflammation and lymph. Such treatment is almost invariably followed by recovery in cases of tuberculous peritonitis.

DR. ROBERT T. GILLMORE, Chicago: Recently, I have been unfortunate enough to have three cases of tuberculous peritonitis or salpingitis. The symptoms are much the same as those of tuberculous in other parts of the body, though not quite typical as regards the evening rise of temperature and the night sweats. In some cases the condition comes on insidiously with slight pain if the disease originates in a tube, and it may not be greater on the side on which operation shows the greater pathologic condition. The pain is dull and there is usually some tympanitis. Besides those symptoms I have been able to get nothing characteristic. The temperature may be normal; the pulse rapid. A diagnostic point which should not be neglected is the von Pirquet reaction. This is not a positive reaction, and in adults is of negative value. If old tuberculin is used and the reaction does not occur it may be assumed that the condition is not tuberculous. Another diagnostic point is leukopenia instead of leukocytosis, which occurs with any of the pus-producing organisms. One of my patients had been treated for three months for typhoid fever; owing to similarity of the clinical picture the diagnosis was not inexcusable, but had the indefinite bilateral pelvic mass been palpated the diagnosis would have been easier. Still another point is the finding of fluid in the abdomen. Sometimes there is postural accumulation of fluid, such as is seen in non-compensated cardiac conditions or in lesions of the kidneys. If disease of these two organs can be eliminated tuberculous peritonitis may be suspected.

DR. A. MILES TAYLOR, San Francisco: I have been working along these lines for some years, and I agree with Dr. Goffe that it is very difficult without a thorough knowledge of pathologic conditions to make a correct diagnosis. However, with the means we now possess in the laboratory, and with long experience, we should be able to overcome this. I am much interested in the case of tuberculous tube with ectopic gestation, this being the only case reported so far, other than those which I reported in a monograph written ten years ago, and in a paper which I read on May 10, 1910, before the San Francisco County Medical Society, entitled "Tuberculosis of the Fallopian Tubes as an Etiologic Factor in Extra-Uterine Pregnancy," wherein I reported 64 patients operated on, and 42 of whom were proved, by pathologic laboratory examination, to have tuberculous tubes. I believe that the primary infection may be, and is, introduced through the vagina, either by examination with finger, by coitus, or through abrasions of the vulva. In the secondary form it is introduced by foci in some other organ of the body, as the lung, hip, or knee joint,

or any other organ infected with this disease. The monthly congestion of these organs certainly is a field inviting to the tubercle bacilli, as well as to any other pus-forming micro-organism. Many surgeons have reported tuberculous disease of the tubes even in girls of 17 and upward. Such men as Kaufmann, Amann, Kleinhaus, Tuffier, Pozzi, Delbet, Hartman, Faure, Sick, Bier, Murphy, Ochsner, Tuholske, Riolaus, Vassall and Regnier de Graf have reported this condition, but none of these gentlemen has associated tuberculosis of the tube as a cause of ectopic gestation previous to this time.

DR. H. T. BYFORD, Chicago: When we separate extensive adhesions in cases with but little effusion we often get ulceration and breaking down of the intestinal walls. Hence, I think, it will not do to recommend the separation of adhesions in all cases. In view of the fact that many recover without operation, we should look at the matter from a conservative standpoint. These adhesions are Nature's method of limiting the disease, and, usually, form again. You cannot drain any part of the peritoneal cavity longer than a day or two. As a rule I drain only long enough to let out the excess of material which Nature has not been able to take care of. In most cases it is enough to let out the fluid and remove the septic focus, and, if desired, let in a little air or sprinkle in a little iodoform as a local stimulant. Although the ovaries and tubes may not be the primary focus, they usually require removal in cases of pelvic tuberculosis, because the monthly congestion seems to favor the development of germs.

DR. TOD GILLIAM, Columbus, O.: I presume that most of us are influenced by our own experience in these affairs. A few years ago, Dr. Byford and I were pitted against each other in Chicago on this same subject. I am a strong advocate of operative interference in tuberculous peritonitis with effusion. I am an advocate principally from my own experience, which has been most favorable, and because one gets immediate and convincing results. When the abdomen is opened and the fluid let out, usually that is the end of the trouble. I have sometimes had reaccumulation, but even this would disappear and almost every patient with uncomplicated tuberculous effusion has been cured. I never interfere with the adhesions of tuberculous peritonitis if I can help it, and I am very particular not to do any damage to the intestines. I have never known an intestinal tuberculous fistula to heal, and I dread them greatly. If I find that the tubes are involved, and I can get them out without damage to the intestines, I remove them. In cases of this class I have had excellent results.

DR. J. R. GOFFE, New York: I believe in the conservative method of treating these patients as I indicate in my paper. In one of the cases reported, the young woman had been suffering from one to two years and was finally obliged to give up her work in the Salvation Army. I made a diagnosis of tuberculous peritonitis, with the focus probably in the right appendages, and did a laparotomy. There was considerable serum, which I carefully sponged out. In attempting to separate the adhesions about the diseased appendages on the right side, I found that the walls of the intestine were involved, and, after separating just a few "of the uppermost coils of intestine," I desisted and restored them to their original position and closed the abdomen without drainage. She made a beautiful recovery, the most satisfactory convalescence I have ever witnessed. I take the stand that in all these cases conservative work is the best. Remove the focus, if easily and safely reached, but refrain from all serious damage to the tissues, drain out the fluid and close the wound.

Rectal Fistula. Pelvi-rectal fistula may even track round and invade the bladder. In other cases the fistula may cause inflammation of the peritoneum, and from the peritoneum the inflammation may spread on to adjacent coils in the small intestine. The small intestine may even be adherent to the inflamed peritoneum in the pelvic area. F. C. Wallis, in *Clinical Journal*.

A FORECAST OF THE UNITED STATES PHARMACOPEIA IX *

M. I. WILBERT, M.D.
WASHINGTON, D. C.

It is generally well known that the Pharmacopeia of the United States of America had its origin in the desire of the leading men in the medical profession of a century or more ago to secure for their patients medications of uniform strength and activity and to eliminate from the practice of medicine, so far as possible, drugs and preparations of unknown value or of recognized uselessness. In accordance with these intentions the first edition of the Pharmacopeia of the United States was devised by capable, broad-minded men as a safeguard to the health of the American people, and the preface to that work outlines, at some length the objects and the ideals of the founders.

As an illustration of the aims of the originators I may be permitted to quote from the initial paragraphs of the preface to the first U. S. P.:

It is the object of a pharmacopeia to select from among substances which possess medical power, those, the utility of which is most fully established and best understood, and to form from them preparations and compositions, in which their powers may be exerted to the greatest advantage.

The fault of the lists of the materia medica which have been adopted in different countries has always been their redundancy, rather than their deficiency. The number of articles necessary in the management of diseases is always far short of the catalogue afforded by most pharmacopeias.

The value of a pharmacopeia depends on the fidelity with which it conforms to the best state of medical knowledge of the day. Its usefulness depends on the sanction it receives from the medical community and the public, and the extent to which it governs the language and practice of those for whose use it is intended.

The assertion has been made that the materia medica of a century ago might be considered as "lilliputian" when compared with the variety of the materials available at the present time.

This statement should not go unchallenged in view of the fact that, despite the principles laid down in the preface quoted above, the founders of the U. S. P. nevertheless saw fit to include in that book more than 600 drugs and preparations, which they considered to be of sufficient merit to warrant continued use. In addition to this, a review of the "International Pharmacopeia," compiled by A. J. L. Jourdan, first published in 1828, will convince anyone that the materia medica of that early day was both complex and varied.

An interesting reflection of the direct effect of the compilation by Jourdan, just referred to, is found in the preface to the U. S. P. for 1830, which says in part:

It is highly desirable that uniformity in the preparation of medicines should everywhere prevail, for the benefits accruing from the mutual interchange of the medical writings of different civilized nations must be greatly affected by any material difference in the nature or composition of the remedies employed. . . . It is a duty, therefore, which we owe to the cause of pharmacy to throw our own weight into that scale which already preponderates, and thus contribute to the production and maintenance of the desired uniformity.

The introduction of proprietary medical schools in the earlier decades of the nineteenth century appears to have been accompanied by a decadence of the high ideals

* Read in the Section on Pharmacology and Therapeutics of the American Medical Association, at the Sixty-first Annual Session, held at St. Louis, June, 1910.

once dominant in American medicine and the United States Pharmacopeia was among the lines of effort to be most seriously affected. Without discussing this particular influence further, it may be pointed out that the variance of opinion regarding the field of usefulness for a pharmacopeia that has been manifested in this country during recent years, has led us to overlook the rather limited field occupied by the Pharmacopeia of the United States during nearly fifty years of its existence.

From 1830 to 1880 the chief and, practically, the only direct use for the Pharmacopeia was as the basis for a commentary, the U. S. Dispensary, which was developed and continued by the chief editors and the publishers of the Pharmacopeia. During all of this period, the history of the Pharmacopeia is so intimately associated with that of the Dispensary, that many otherwise intelligent medical practitioners did not know, or at least, did not appreciate that the two books were not identical.

We should not forget, however, that the thanks of all who are in any way interested in the development of the science of medicine in this country is and ever will be due to the originators and editors of the "United States Dispensary," Dr. George B. Wood and Dr. Franklin Bache for their far-sighted policy of continuing the Pharmacopeia along the high plane on which it was founded.

The really slow deviation from the original intent of the founders of the Pharmacopeia is well illustrated by Table 1, showing the comparative number of vegetable, chemical and animal drugs and the number of Galenical preparations in the several editions of the U. S. P.

TABLE 1.—THE NUMBER OF DRUGS AND GALENICAL PREPARATIONS IN THE VARIOUS EDITIONS OF THE U. S. P.

	1820.	1830.	1840.	1850.	1860.	1870.	1880.	1890.	1900.
Vegetable	254	260	281	297	312	321	264	255	220
Chemical	109	116	124	140	176	192	233	239	268
Animal	12	15	17	19	18	18	15	18	21
Galenical	246	229	266	312	367	440	481	473	443
General Formule	4	5	6
Total	621	620	688	768	873	971	997	990	958

It will be noted that, in the first revision of the U. S. P., the number of official articles was actually reduced and that, following this date, the sum-total of articles increased rather rapidly to 1870 and apparently reached a maximum in 1880, from which time the number of official articles appears to be again gradually decreasing.

The evident causes for the increases in the number of articles official in the U. S. P., in the decades from 1810 to 1870 inclusive, are of course varied. Not the least among these causes, however, is the part taken by pharmacists in the several revisions including and following that of 1840, and the influence that the introduction and increase of eclectic, botanic and other "new" schools of medicine had on the practices of medicine, as well as pharmacy, in these United States.

Altogether, the several editions of the Pharmacopeia appear to reflect the decadence of the medical instruction and medical ideals in this country in a way that as yet, has not been sufficiently well recognized.

The U. S. P. VI, or that of 1880, as it is more generally known, represents a revolution in Pharmacopeia-making in this country, but, unfortunately, the revolution was originated and carried out by pharmacists, and medical men took little or no part in it.

Dr. E. R. Squibb,¹ in commenting on the U. S. P. VI, says:

It is by far the best Pharmacopeia of the time, because it is the result of more labor and research than any other, and by hands as skilful as any other.

In its general complexion and tone it is pharmaceutical rather than therapeutical. That is, while its general tendency is to both polypharmacy and polytherapy, its greatest redundancy is in its pharmacy; and this is not to be wondered at, from the constitution of the committee of revision and from the fact that the pharmacists did almost all of the work.

Since 1880 the pharmacists of the country have continued to bear the burden of pharmacopeial revision with little or no assistance from the medical profession, and the U. S. P. has continued to be, primarily, a pharmaceutical reference-book, with little or no regard to therapy or therapeutic needs.

Some indication of the comparative scope of the Pharmacopeia of the United States is evidenced by Table 2, showing the number of titles included in fourteen of the leading pharmacopeias of the world, with the comparative number of general headings, crude drugs, chemicals and Galenical preparations.

TABLE 2.—NUMBER OF TITLES, ETC., INCLUDED IN THE SEVERAL NATIONAL PHARMACOPEIAS

Pharmacopeia.	Published.	Total Titles.	General Headings.	Drugs.	Chemicals.	Preparations.
British IV.....	1898	826	0	189	186	451
German IV.....	1900	626	23	193	176	234
United States VIII..	1905	958	6	241	268	443
Spanish VII.....	1905	1073	0	269	260	544
Dutch IV.....	1905	673	17	200	182	274
Japanese III.....	1906	706	14	204	207	281
Belgian III.....	1906	722	25	185	173	329
Austrian VIII.....	1906	698	19	232	160	287
Danish VII.....	1907	489	22	142	144	181
Swiss IV.....	1907	853	29	244	227	353
Swedish IX.....	1908	583	19	144	179	241
French V.....	1908	1122	48	271	293	510
Italian III.....	1909	669	18	164	194	294
Hungarian III.....	1909	551	18	142	183	294

Excepting the pharmacopeias of Spain and France, which are dominated by conditions not prevailing in other countries, it will be noted that the U. S. Pharmacopeia excels in the total number of official titles.

Another interesting fact is that the two pharmacopeias, the Swiss and British, having the next highest number of official titles are, like the U. S. P., in a way controlled by the dispensing interests involved. The Pharmacopeia of Switzerland is published under the auspices of the Swiss Pharmaceutical Society, while the British Pharmacopeia is largely dominated by the Society of Apothecaries, which represents the more numerous and more influential "general practitioner" who, with the assistance of the "chemist and druggist" is well able to dictate the scope and content of the Pharmacopeia.

Eliminating the pharmacopeias published in countries where special conditions appear to make a large number of official articles necessary or desirable, our own Pharmacopeia is the most prolix, and, as constituted at the present time, does not reflect a satisfactory development of medical science so far as pharmaceutical therapy is concerned.

Recognizing the old adage that "a multiplicity of remedies is an indication of incompetency or ignorance" physicians and others who are interested in divorcing the science of medicine from the possible domination of commercial interests looked forward rather anxiously to the outcome of the United States Pharmacopeial Con-

vention held in Washington on May 10, 11 and 12 of this year.

That this outcome is not altogether promising, from a progressive point of view, is evidenced by the reports of the convention which have appeared in the several medical and pharmaceutical journals. Thus the *New York Medical Journal*, (May 14, 1910, p. 1020) in commenting on the outcome of the Pharmacopeial Convention, says regarding the scope of the Pharmacopeia:

The convention took the ground that the extent to which a drug was used is a safer criterion of its availability for introduction into the Pharmacopeia than the expression of opinion regarding its therapeutic value. Consequently the use rather than the therapeutic value of a drug will be taken as a guide by the committee regarding admissions and deletions.

This expression of opinion is justified by the fact that the limiting clause that, "there should not be included rarely used substances or those whose value and use has not been established" was, on motion, eliminated from the first paragraph of the general principles to be followed in revising the Pharmacopeia.

The paragraph on scope of the Pharmacopeia as finally adopted provides essentially that the Committee of Revision be authorized to admit into the Pharmacopeia any medicinal substance of known origin; but no substance or combination of substances shall be introduced, if the composition or mode of manufacture thereof be kept secret, or if it be controlled by unlimited proprietary or patent rights, and the list of substances should be carefully selected, with standards for identity and purity as far as possible.

So far as the physician is concerned, this one paragraph involves the important features of the revision of the Pharmacopeia, as the interpretation put on it by the majority of the Committee of Revision will determine whether the Pharmacopeia of the United States is to be developed solely as a legal standard for the many thousands of medicaments used by man in the treatment of disease, or whether it shall continue as a basis for medical prescribing and contain only descriptions, formulas and standards for therapeutically active or useful medicines.

In this connection, it may be well to point out that the Committee of Revision has been made responsible for the nature and content of the U. S. P. IX and that the members of the committee will not be in a position to shirk criticism should the result of its work not comply fully with the wishes of the interested owners of the Pharmacopeia or the accepted facts that are clearly evidenced at the time.

It goes without saying, therefore, that the members of the medical profession still have an opportunity to demonstrate the validity of the claim that the Pharmacopeia, being issued under the joint authority of physicians and pharmacists, should be an authoritative list of remedial agents representing the best and most active therapeutic agents known to physicians and of the purest and most reliable quality that can be furnished by pharmacists.

The question frequently heard, "Who is to determine the medicinal value or usefulness of a medicine?" is based on sheer sophistry. The value or usefulness of a medicament is to be determined according to the best light of the day, and no one will believe for a moment that the substance thought useful to-day will continue to be considered so for all time to come.

The radical nature of the changes which have been brought about in our ideas regarding the usefulness of

medicaments can be well illustrated by the following items from the materia medica of a century or more ago:

"Toad powder" was at one time a valued medicine and was said to "provoke urine and cure the dropsie, if curable. Outwardly applied, it draws out the poison of carbuncles. Blown up the nostrils, it stops their bleeding. Applied to the soles of the feet, it draws away distempers from the head, helps frenzies and fevers. It is also good against old ulcers and fistulas and biting of serpents."

Spermaceti, an article known to modern medicine less than three hundred years, was landed during much the greater portion of this period as "the sovereignst medicine on earth for inward bruises resulting from falls and similar injuries." It was also asserted to be "of considerable use in pains and erosions of the intestines, in coughs proceeding from sharp defluxions, and, in general, in all cases where the solids require to be relaxed or acrimonious humours to be softened."

No medical practitioner to-day uses toad powder as a diuretic or spermaceti as a never-failing remedy for "inward bruises," and yet he would be rash indeed who would assert that the practitioner of old was absolutely wrong and that toad powder did not contribute, in a way, to the progress of the science of medicine.

The frequently made assertion that "the Pharmacopeia is the law of the land so that its first valuation and its greatest function is to provide a standard for purity and for strength" is based on a misconception of fact and a misinterpretation of the letter as well as the spirit of the Food and Drugs Act of June 30, 1906, which specifically mentions the United States Pharmacopeia and the National Formulary.

In the discussion on the scope of the U. S. P. no one appears to have been willing to concede the fact that in law, in name and in possible scope these books are equal, with, perhaps, a number of counts in favor of the legality and usefulness of the National Formulary. In this connection we should not forget that, technically at least, the "United States Pharmacopeia" does not as yet exist.

Without going into a detailed discussion of the merits of the two books as an available legal standard it may be permissible to call attention to the Standard Dictionary definitions, as follows:

Pharmacopeia: "A book, usually published by authority, containing the formulas and methods of preparation of medicines etc. . . ."

Formulary: "1. A compilation or collection of forms, formulas, doctrines or precedents. . . 3. A ritual or formula."

As designating titles for a treatise on medicinal substances the two words are practically synonymous apart from their derivation, one being Greek, the other Latin.

So far as the practicability of developing either book as a legal standard for any and all substances is concerned, it would appear that the owners of the Pharmacopeia are, at least, divided as to the desirability of having their book used exclusively for this purpose, while the owners of the National Formulary are unanimously in favor of providing standards for all articles not included in the Pharmacopeia of the United States.

Thus the American Pharmaceutical Association in deciding on the scope of the National Formulary held that the therapeutics or therapeutic incompatibilities of the National Formulary preparations are not within the province of the National Formulary committee. "The physician may reasonably be expected to know what he wants, and if he chooses to prescribe preparations which are therapeutically incompatible it is the duty of the

pharmacist to supply what is ordered. The Committee on National Formulary feels it to be its duty to supply formulas for medicaments which may be prescribed by physicians, if the demand is sufficient to justify our attention and if an acceptable formula can be devised or obtained."

With the need for developing the Pharmacopeia as an all-embracing standard for drugs and medicines eliminated, and with at least a fair-sized minority of the members of the Pharmacopeia convention opposed to such use, it would appear as though the Committee on Revision would certainly be going contrary to the best interests of the American people in deviating from the time-honored scope and use of the Pharmacopeia.

Physicians have long since recognized that the practice of medicine is not limited to the administration of drugs and preparations of drugs, and that the prevention of disease and the prevention of further spread of disease, when it does occur, are among the requirements that the medical practitioner should not and dare not lose sight of.

With these varied requirements to prepare for it is obviously impossible for the medical student, in the limited time at his disposal, to acquire a working knowledge of all the drugs and preparations which have been used at one time or another, and it would appear that no more important public health measure could be introduced at the present time than the outlining of a therapeutically active materia medica as a basis for the instruction of medical students and for reference by physicians now in practice.

In conclusion allow me to call attention once more to the quotation from the first edition of the Pharmacopeia which asserts that "the value of a Pharmacopeia depends on the fidelity with which it conforms to the best state of medical knowledge of the day. Its usefulness depends on the sanction it receives from the medical community and the public, and the extent to which it governs the language and practice of those for whose use it is intended." Can we, on the eve of the corresponding decade of the twentieth century, do better, or will we do less?

Twenty-fifth and E Streets, N. W.

ABSTRACT OF DISCUSSION

DR. A. S. LOEVENHART, Madison, Wis.: Since the Pharmacopeial Convention left the matter to the Committee on Revision to decide, I think it would be proper for this Section to express its wish that all substances be omitted that have not a recognized therapeutic value and that are unnecessary duplications.

DR. C. S. N. HALLBERG, Chicago: I take decided objection to Mr. Wilbert's statement in reference to the makeup of the Pharmacopeia. I made a special study of the makeup of the European pharmacopeias last year. The British Pharmacopeia is dominated by the Medical Council and there is not a pharmacist on it. The council delegated the revision to Professor Atfield.

The U. S. Pharmacopeial Convention absolutely refused to listen to some of the medical delegates, because they knew that they did not have back of them the practices of 140,000 physicians of the United States. We pharmacists must cater to the physicians who write prescriptions and use medicine. While it is interesting that there are medical men, in Baltimore particularly, who have wonderful ideas on drugs, seldom write prescriptions, and rarely, if ever, prescribe medicine, they have our sympathy, but they have not our real heartfelt thanks, because they do not act as real pharmacologists. To give a concrete example: I have been told that

out of Kansas alone last year there were shipped 200,000 pounds of echinacea, nearly every pound of which went into regular and proprietary pharmaceutical preparations, to be used by physicians. Yet the Council on Pharmacy and Chemistry will not admit echinacea to New and Nonofficial Remedies. When such an army of medical men is using it as an antiseptic and astringent, by what right do you say that these men do not know how to practice medicine, or do not know what kind of medicine to use?

DR. A. S. LOEVENHART, Madison, Wis.: If usage is to be the criterion, then Peruna should be in the Pharmacopeia. I claim that we cannot afford to let certain articles go into the Pharmacopeia on the basis of usage. We do not limit physicians; they can use what they wish, but a book that is supposed to represent, as Mr. Wilbert said, the best medical thought and to have the medical profession behind it, must not include drugs on the basis of usage.

DR. C. S. N. HALLBERG, Chicago: After the U. S. P. Convention is past you cannot do anything by any action taken here to influence the committee. The committee of this Section, and I believe the committee of the American Medical Association on the Pharmacopeia, engaged in a campaign for six months trying to test the medical sentiment of this country in order to get crystallized the ideas and bring them before the convention. What was the result? Not one idea did they carry through, because the Pharmacopeial Convention represented the actual state of pharmacy and medicine in this country as near as it could be formulated, and that is why they stuck to the original principles. The Pharmacopeia is for a standard of strength, purity and quality of medicinal substances and gives directions for their preservation, valuation, preparation and compounding, and not one more syllable about it, nor can you, by any stretch of imagination, add another attribute to it, so that I do not see that any good can be accomplished by our expressions of opinion.

DR. F. E. STEWART, Philadelphia: In 1880, this whole subject came up in a discussion with Dr. Squibb, and I remember what he said, and thirty years' experience confirms it, namely: "A large part of the demand for new remedies is a fictitious demand, caused by advertising. Take antipyrin: on account of advertisement it was widely used, but after the patent expired the demand fell flat."

DR. A. S. LOEVENHART, Madison, Wis.: We want the Pharmacopeia to represent the best medical knowledge as to what drugs are useful in the treatment of disease. We would rather let much-used drugs, which are worthless according to general medical opinion, go in the National Formulary and let them be in the hands of the pharmacists who come in contact with the physicians who are handling this class of drugs. Dr. Hallberg states that the United States Pharmacopeia should be a standard for medicinal substances and that it contains nothing about therapeutics. The mere proposition that it is a standard of medicinal substances proves that there is a large element of therapeutics concerned in it. The definition of medicinal substances is: "those useful in the treatment of disease." Dr. Hallberg puts the interpretation that anything sufficiently used by the medical profession is useful in the treatment of disease. I hold that we should accept the best obtainable medical opinion as to what should be included in the Pharmacopeia. That is a simple statement of the difference between us.

Dr. Hallberg has said that the medical profession has lost its chance for the next ten years. I disagree with him; the whole thing is entirely open. The Committee on Revision can include drugs to meet the needs of the people whom it is trying to serve. Now if we, as a part of their constituents, state that we hope these things will not be continued, it will strengthen them to leave out drugs which have been included merely on the basis of usage. With regard to those who shall say what drugs are useful, we can leave them to the general trend of recognized therapeutic value. We must leave to the revision committee to determine by the general trend of medical literature and by methods which they must work out. It should be pointed out that the medical men on the revision committee are in the great minority.

DR. R. A. HATCHER, New York: There is one point that should not be altogether overlooked. There can be little doubt that the controlling influences in the convention are not in favor of restriction. It might be claimed in the future that by silence we gave tacit assent to the program, and I do believe that our protest may have considerable value, although I doubt very much whether it will have a corresponding amount of influence.

DR. C. S. N. HALLBERG, Chicago: The subject is entirely left open to the Committee on Revision, as Dr. Loevenhart states, but those that know the Committee on Revision know that the members have already made up their minds to adhere to those principles which were under discussion, and that the Committee on Revision is certainly not in favor of any radical proposition. Still I do not object to the proposed action, and I think with Dr. Hatcher that it might do some good, if for no other reason than as a matter of record to protest against the admission of some article which might possibly be objectionable.

[The Section voted in favor of the expression of opinion as suggested by Dr. Loevenhart.]

A SIMPLE BLOODLESS OPERATION FOR HEMORRHOIDS*

LOUIS J. HIRSCHMAN, M.D.
DETROIT

It is my intention to give briefly my technic for the removal of certain forms of internal hemorrhoids without the profuse hemorrhage with which this operation is usually associated in the minds of most practitioners. Having observed that most patients suffering from hemorrhoids of the internal variety are more or less anemic from the continued and constant loss of blood, as a result of their hemorrhoidal trouble, I began three years ago to use a technic which would minimize operative hemorrhage and conserve the patient's blood-supply.

With this aim in view, I have developed and have been using a very simple technic which is applicable under local as well as general anesthesia and therefore can be used in those weak, run-down patients suffering from any of the wasting diseases in whom the use of a general anesthetic would be inadvisable if not positively dangerous. The method is adapted to the removal of any variety of internal hemorrhoids and particularly to the pedunculated and prolapsing varieties.

Interno-external hemorrhoids can also be treated by this method. Very few instruments are required and in many cases dilatation of the sphincters is not necessary. The technic under general anesthesia is much the same as under local anesthesia, and inasmuch as local anesthesia is much safer and fully as satisfactory as general anesthesia for this work, I shall describe the operation as I perform it under local anesthesia.

The drugs which may be used for the production of local anesthesia in this region are various. Cocain, eucain, stovain, novocain, alpin and chlorotone, as well as their various combinations with other salts, have been used in varying strengths of solution and with varying success by different workers.

During the past six months I have been employing for this operation, as well as in many other operations on the anus and rectum, a sterilized 1 per cent solution of quinin and urea hydrochlorid. I am using this solution, which is prepared from the double salt of quinin and

urea (which is made by dissolving quinin hydrochlorid in hydrochloric acid, adding pure urea, filtering the mixture through glass wool and allowing it to crystallize), because of the following advantages over any other anesthetic drug:

First: It is non-toxic and can be given in unlimited dosage. Brewster of Kansas City has used 100 grains intravenously within six hours in a patient suffering from pernicious malaria.

Second: When a solution containing 1 per cent. or over is used the hemostatic effect produced by the deposition and contraction of fibrinous exudate around the blood-vessels is of great value in preventing postoperative oozing.

Third: The anesthetic effect is prolonged; in many cases postoperative anesthesia has lasted from four to five hours to as many days and longer.

Fourth: While equal to cocain in anesthetic power, it has the advantage of being very much cheaper, and is a drug which is almost always available.

One advantage of the operation to be described is the fact that but few instruments are required. Those necessary are: a one-half ounce aseptic hypodermic syringe provided with a fine caliber sharp-pointed needle 2 inches in length, scalpel, pointed scissors curved on the flat, blunt-pointed, long-handled, curved ligature-carrier, my pile forceps, and sometimes a Sims retractor.

The patient is given $\frac{1}{4}$ grain of morphin about twenty minutes before the operation is to be performed, a soap-suds enema followed by a boracic acid enema is given, and the patient is placed on the operating table in the right or left lateral position. After the region of the anus is washed and sterilized the sphincter is anesthetized by the injection of from 10 to 30 minims of sterile 1 per cent. solution of quinin and urea hydrochlorid. The technic which I employ is as follows:

A point one-half inch below and posterior to the posterior commissure of the anus is selected and touched with a swab moistened with pure phenol. After waiting 2 or 3 minutes, or until this point is thoroughly blanched, the needle of the syringe is passed inward, upward and laterally in a V-shaped direction for about three-quarters of an inch, gradually going down into the sphincter muscle, but not entirely through it. While doing this it is well to pull down the sphincter by the index-finger of the left hand passed into the anus while the injection is being made with the right. From 10 to 20 drops of the solution are slowly injected and the needle is retraced to the point of puncture but not withdrawn. It is then pushed up on the other side in the same manner and this side is likewise injected. Three or four minutes are allowed to elapse to allow the anesthesia to become complete. Then a mechanical vibrator fitted with a cone-shaped vibrator, which has been well lubricated, is gently pressed into the anal orifice. About 3 minutes with the rotary stroke will dilate the sphincter to about the caliber of a silver dollar, which is sufficient to allow the operation to be done in a most satisfactory manner.

It is not absolutely necessary to use the vibrator. In its place one may use the index-fingers of both hands inserted opposed to each other and well lubricated, and by separating them with a gentle massage motion the sphincter may be dilated as satisfactorily in from three to four minutes.

After dilatation has been accomplished, the most dependent hemorrhoid is injected with the 1 per cent. quinin and urea hydrochlorid solution, enough being in-

* Read in the Section on Surgery of the American Medical Association, at the Sixty-first Annual Session, at St. Louis, June, 1910.

jected to blanch the hemorrhoid and give it the appearance of a Malaga grape. The lower extremity of the hemorrhoid is then grasped with the pile forceps and pulled down so that it is on the stretch. The long-handled ligature carrier threaded with No. 2 twenty-day, chronicized catgut is passed in through the mucous membrane of one side down to the base of the hemorrhoid and around to the opposite side in such a manner as to include the upper third of mucous membrane covering the pile and the blood-vessels which run longitudinally underneath, but not encircling the whole hemorrhoid as in the old ligature operation. This ligature should be placed just at the juncture of the hemorrhoid and the normal mucous membrane of the rectum. It is then firmly tied, when it will be found that the principal blood-supply of the hemorrhoid has been included in the ligature and shut off. The hemorrhoids on either side are dealt with in like manner and lastly the anterior and upper ones.

A suppository containing orthoform, 3 grains, thymol iodid 3 grains, and quinin hydrochlorid 20 grains, is inserted and the patient kept in the recumbent position for 10 minutes and then allowed to rise from the table. There will be a certain amount of edema or swelling during the first twenty-four hours, but this gradually disappears and is of no consequence. The hemorrhoids gradually shrink until, at the end of three or four weeks, there is nothing left but a small nub of connective tissue which can be painlessly snipped off at any time or left if one so desires.

This, which is the simplest form of technic, is peculiarly adapted to those desperate cases of anemia in which the daily loss of blood from the hemorrhoids is far greater than the patient's blood production. It can be performed in 10 or 15 minutes and involves the least expenditure of endurance on the part of the patient.

In the majority of my cases, when the necessity for haste and conservation of blood-supply is not quite so imperative, I modify the technic as follows:

Anesthetization, dilatation, and ligation are performed as above outlined. The hemorrhoidal tumors are then grasped in order by the pile forceps and incised in their longitudinal axes from a point about one-quarter inch below the ligature and extending down to their distal extremities. After separation of the sides of the incision, the blood-vessels and connective tissue which make up the body of each pile are dissected out *en masse* with the curved scissors and cut off one-quarter inch below the ligature. This longitudinal wound in each case is allowed to remain open and heals in from three to five days without suture. This disposes of the hemorrhoids at once, and does away with much of the swelling which necessarily follows the preceding technic.

In those cases in which there are pedunculated prolapsing hemorrhoids, it is not necessary to dilate the sphincter. After the preparation outlined above, the patient is asked to strain while in the squatting position, or while lying on his side in the Sims position, while the operator is everting and pressing back the anus by manual pressure just outside of the margins of the external sphincters. The same technic as outlined above is carried out in regard to injection of anesthetic, ligation, and excision, and the operation is completed by the insertion of the anodyne suppository already mentioned.

The after-care is very simple. The bowels are kept confined for three or four days; on the beginning of the third day, white petroleum oil is administered in dram

doses before meals and at bedtime. This acts in a purely mechanical way, preventing the formation of hard stools and making the movements very easy. A simple soapsuds enema given through a small soft rubber rectal tube on the third or fourth day will start the evacuation of the bowels, which should be encouraged daily thereafter.

The use of quinin and urea hydrochlorid as an anesthetic possesses the great advantage over other drugs, of keeping up postoperative anesthesia of the parts, in many cases, during the entire convalescence of the patient. I consider that with the simple technic just outlined, and this newest local anesthetic, hemorrhoids can be removed without the patient suffering pain either during the operation or following it.

My experience with this technic under local anesthesia produced formerly under injections of 0.1 per cent. solutions of beta-eucain lactate and latterly under quinin and urea hydrochlorid—in all over 300 cases—leads me at this time to offer it to the members of this Section with the hope that it will prove as satisfactory in their hands as it has in mine.

604 Washington Arcade.

A CASE OF PERNICIOUS ANEMIA

B. P. ROSENBERRY, M.D.
ARCADIA, WIS.

In the following case the patient has been under my observation during the past two years, commencing June 21, 1908. The case is a typical one of the severe type and illustrates the remissions which are so characteristic of the condition and also the manner in which the condition for the time being responds to arsenic.

Patient.—D. N., unmarried, farmer, Irish, aged 58. His father died at 86; his mother died at 73 of pneumonia. Brothers all alive and well; two sisters died in infancy.

History.—He had a broken leg five years ago, otherwise he has always been healthy. He has been an exceptionally hard drinker for a number of years, and is frequently drunk for days at a time. Six months ago he took cold after exposure during a drunken spree and has not recovered. He complains of general weakness especially of the legs, shortness of breath, loss of appetite, sore mouth, dry cough and inability to undergo any ordinary physical exertion.

Examination.—Tall, thin, large frame, skin pale yellowish color; muscles flabby, mucous membranes very pale and gray. Visible forcible pulsation of arterial trunks in neck and abdomen. Teeth poor; no sores in mouth; pulse 80, regular and soft. Soft systolic heart murmur at apex. Arteries very hard; the patient has lost considerable weight, but does not know exactly how much.

Urine Examination.—Amount of sample examined, 4 oz. Very pale, clear, specific gravity 1.004, acid; no albumin, no sugar, no bile, no indican, no sediment. He had been drinking beer previous to voiding this sample.

Blood Examination.—Red blood cells, 952,000; white blood cells, 2,850; hemoglobin, 30 to 40 per cent. Tallqvist; index plus; marked poikilocytosis. Many macrocytes and microcytes; many megaloblasts and a few normoblasts seen; almost no blood plates; polymorphonuclears decreased; small lymphocytes and eosinophils increased; few myelocytes.

A diagnosis of pernicious anemia was made.

Treatment.—Tincture of nux vomica and tincture of gentian compound were given before meals for stomachic and general tonic with Fowler's solution in ascending doses after meals. The patient was told to stop work and to take full nourishing diet.

Course of Disease.—July 22, 1908: The patient gained 12 pounds and felt much stronger. R. B. C. numbered

2,050,000; W. B. C., 2,375; hemoglobin, 50 per cent.; Tallqvist, no megaloblasts and one normoblast seen.

Aug. 24, 1908: Patient gained 14 pounds in all, felt well and was doing light farm work. R. B. C. numbered 3,760,000; W. B. C., 7,725; hemoglobin, 70 per cent.

Nov. 15, 1908: The patient has gained 23 pounds since beginning treatment, and has been doing regular farm work for the last three months. R. B. C. numbered 3,728,000; hemoglobin, 75 per cent.; no megaloblasts or normoblasts; many macrocytes and microcytes; poikilocytosis. The patient has been taking Fowler's solution continuously until the last three weeks.

Dec. 13, 1908: Patient continues about the same; still doing regular farm work and taking no medicine aside from an occasional laxative.

Feb. 26, 1909: Patient feels about the same. R. B. C. numbered 3,904,000; hemoglobin, 60 per cent. Patient shows the beginning of decline.

April 10, 1909: Patient has been feeling weak again for the last three weeks. Temperature, 100 F.; pulse, 95; month feels sore; R. B. C. numbered 1,576,000; hemoglobin, 40 per cent.; few megaloblasts and one normoblast; poikilocytosis. Patient put on Fowler's solution again as before.

From now on patient got stronger and went to work again, and was not seen again until Sept. 16, 1909, when he was weak, short of breath, very pale. R. B. C., 904,000; hemoglobin, 20 to 30 per cent.; marked poikilocytosis, with many macrocytes and microcytes; one megaloblast. Patient put on arsenic again as before.

Nov. 1, 1909: Patient feeling well again; has been in the hospital in bed for the last six weeks. He has been taking Fowler's solution and has gained in weight and strength. R. B. C., 2,224,000; hemoglobin, 60 per cent.; no megaloblasts or normoblasts.

He felt well for some time after this, but did not present himself for further examination. In February, 1910, he began to show evidence of weakness and spasticity in arms and legs. This progressed until by June 1 he was confined to bed almost completely paralyzed. There was loss of control of the bladder and rectum. He became gradually weaker, until he died on June 25.

The severity of the case and the promptness with which the conditions improved on taking Fowler's solution are my reasons for reporting this case.

ADIPOSIS DOLOROSA (DERCUM'S DISEASE) IN MOTHER AND DAUGHTER

ALBERT HYNSON CARROLL, M.D.,

Chief of Clinic for Gastro-Enterologic Diseases, University of Maryland Dispensary
BALTIMORE.

This report of two new cases of adiposis dolorosa will shed no new light on the etiologic factors or treatment. Fifty cases have been reported;¹ eight autopsies have been performed so far. In seven the thyroid was abnormal and in five of them the pituitary body.²

Traumatism, toxemia, continued nervous strain, the menopause, alcoholism, syphilis, tuberculosis and various other causes have been duly considered by various observers. So far, in view of the autopsy findings, the abnormalities of internal secretion of the thyroid and pituitary surely play a most important part.

Cheevers reported a case in which a father and a sister were affected, and Hammond made a report of two cases in sisters. In my cases it is a mother with the disease well advanced and of five and one-half years' duration. The daughter has been affected for eighteen months.

Osler³ has shown us clearly that we must differentiate between adiposis tuberosa simplex, adiposis cerebialis, adenolipomatosis and multiple lipomatosis. Particular care was taken not to confound symmetrical adenolipomatosis with adiposis dolorosa in Case 1.

CASE 1.—(Dispensary No. 21,140. May, 1910).—*Patient*.—Mrs. B., white, housewife, aged 64. Diagnosis: adiposis dolorosa, with anacid gastritis. Family history, unimportant; one sister died of tuberculosis. Four living children, negative to cancer, syphilis or alcoholic excess, insanity, or epilepsy.

Past History.—The patient had the usual children's diseases; no scarlet fever, but she had diphtheria when she was 16 years old. In 1880 she was paralyzed on left side, and again in 1897. She has had severe spells of indigestion for about five years, with almost constant burning pains in her stomach. She is chronically constipated, vomits frequently and has choking spells on lying down. She complains of insomnia, severe pains at back of the neck, in her throat, her legs and over the xiphoid. She is excessively nervous, despondent and low-spirited at times. Her appetite is poor. She complains of "crawling sensations" under the skin.

Examination.—A rather florid woman, 5 feet 3 inches tall, weighing at present 175 pounds. Four years ago she weighed 104 pounds. Examination of head shows nothing. Bilaterally, just above the clavicles are adipose masses, standing out prominently, soft to the touch and painful on pressure. These are ovoid in shape and are about 5 by 9 cm. and 4 by 5 cm. respectively. They do not pit on pressure. A very painful mass is found at about the level of the last cervical vertebra. This is flat and not as soft as the others. There is another over the xiphoid, and others are found in the axillæ. The upper arms are covered with a thick layer of subcutaneous fat, and the breasts are quite pendulous. The mass over the xiphoid is very painful on pressure, and the patient is conscious of its presence all the time. Careful auscultation and percussion by myself and Dr. G. Wilson show no dullness in the upper thorax, and the heart sounds appear normal. The reflexes are normal. There are small areas of hyperesthesia on both arms and in the region of the neck. The lower abdominal region protrudes, forming an almost hemispherical mass, exceedingly hard, dull on percussion over the whole area. An apron of fairly solid tissue extends in U-shape in front, extending at its lowest point to below the level of the symphysis. Masses of fat in the gluteal region are pendulous. Another mass is present over the sacrum. The thighs and legs are small. There are no lumps. The ankles are slightly edematous. Although the face is florid, with numerous small dilated arterioles, the rest of the skin is fairly soft and white. There are no isolated or general areas of perspiration. The outline of the stomach cannot be made out. Neither spleen nor kidneys can be located. Hands, feet and face are normal, no fat masses. Examination of stomach contents (double test meal) shows no free hydrochloric acid and a total acidity of 30, some mucus, no lactic acid, no Oppler-Beas bacilli. Urine and blood examination negative. Hemoglobin 85 per cent. Blood pressure 165 mm. 24 hours urine 1275 c. c.

CASE 2.—(Dispensary No. 21,202. May, 1910).—*Patient*.—Mrs. D., aged 42, married, housewife; daughter of Patient 1, height 5 feet 3½ inches; weight 167 pounds (previous weight 100 pounds, a gain of 67 pounds in one and a half years). Diagnosis, adiposis dolorosa, with gastric symptoms.

Previous History.—The patient had the usual diseases of childhood and has had pneumonia four times. She has one child 21 years old. "She was badly torn and had no doctor when her child was born." She has always menstruated every three weeks; she denies any miscarriages. She came to see me because of vomiting spells which started about a year ago. These have become of late almost a daily occurrence. She has severe headaches and menstruation is very painful. She has pains in the back of her neck and pains in the legs and thighs. She feels cold all the time, and wears heavy clothing even in summer. She seldom perspires; her skin is yellowish. She has worn a pessary for a long time, and has a retroflexed uterus and a very weak perineum. Nursing her mother when she was

3. Osler: Practice of Medicine, 1903.

paralyzed was a great strain on her, and her mother's present state of health is another burden.

Examination.—Stomach contents show free hydrochloric acid absent, total acidity 30, but no apparent atonic condition; some mucus, no lactic acid or Oppler-Boas bacilli. The bowels move every day without aid. The reflexes are normal; the pupils react to light and accommodation. Head, thoracic and abdominal examinations negative. There is one large, soft lipomatous mass over the left collar bone and a smaller one (9 by 5 cm.) on the opposite side, standing out clearly. These are painful and do not pit on pressure. A mass at the back of the neck is extremely sensitive to touch and pressure. The patient has the sensation of some live moving thing in the occipital region. She exhibits in a less marked degree, however, the same neurotic symptoms first observed in her mother. Examinations of blood and urine show nothing. Blood-pressure 149 mm. Hg; hemoglobin 80 per cent.

CONCLUSIONS⁴

If a diathesis existed in the daughter, and nervous strain is considered of etiologic importance, worry over her mother's ill health may have some bearing on her present condition. She took complete charge of her mother during the two paralytic attacks. Then it appears that the birth of her child caused extensive trauma, which is considered by some as of importance.

Most insistent but guarded questioning failed to elicit any past luetic history, in both cases, any miscarriages or any knowledge of a family history of epilepsy or goiter. Alcoholic excess can safely be excluded here as a possible causative factor. Four attacks of pneumonia and diphtheria in the mother, also the two later paralytic attacks, are to be considered.

These two cases are mild, but the symptoms are marked, much more so in the mother, however. In Case 2 the disease has occurred before the menopause. (One case in a patient as young as 12 years of age is on record.) The two hemiplegic attacks occurring in Case 1 would suggest a sclerotic condition not found present in the peripheral vessels.

Although there was a marked increase in weight in both cases, it does not appear in Case 1 to be the adiposity which Marburg found at autopsy to be associated in his case with a tumor of the pineal gland. I cannot account reasonably for the two attacks arising from a general pituitary involvement. In neither case does the thyroid exhibit macroscopic changes. The masses in the older woman are not nodular, but are firmer and less sensitive than in Case 2.

The gastritis, which was real in both cases, with age and poor mastication as predisposing factors, responded to treatment (lavage, diet, strychnin sulphate, etc.). The blood-pressure is high in both cases.

The asthenia, the gastric disturbances, areas of hyperesthesia, and the frequent attacks of melancholia, with the physical findings, convince me that we are dealing with true adiposis dolorosa.

Surgical aid has been attempted.

In one case the removal of the breasts and later a mass from the axilla was followed, for a time at least, by cessation of the distressing local symptoms.

Most observers agree that thyroid extract is a benefit in some cases. Price has seen five patients out of seven distinctly benefited by its use. The present knowledge of the pituitary is too limited to make its use of therapeutic value. Salicylates and bromids are of use. Massage of a gentle nature is advocated by some and a

properly regulated exercise and diet should be insisted on in all cases.

Most patients are obese; the heart often requires attention. The agencies suggested are of doubtful permanent benefit and until the etiologic factors causing this distressing pathologic condition, with the accompanying neurosis and psychic disturbances so markedly illustrated in most cases are discovered, we are working more or less in the dark. It is a satisfaction to know, however, that one positive cure has been brought about by the use of thyroid extract.⁵ In all, about 50 cases have been reported.

NOTE. (Sept. 21, 1910).—Patient 1 has lost weight (19 pounds in four months) is less nervous, and in a better general state of health than formerly. The "lumps" have not decreased in size, but are not so sensitive as before thyroid extract treatment was instituted.

Patient 2 shows no improvement after four months' treatment, except that lavage, diet, etc., have bettered the gastric distress. She has gained in weight. The "lumps" are as sensitive or painful as before treatment began.

ANAPHYLACTIA

A PHENOMENON CAUSED BY THE PROTEINS OF TOMATOES, CRABS, BERRIES, BIVALVES, EGGS AND OTHER FOODS. A PRELIMINARY NOTE

LEONARD K. HIRSHBERG, A.B., M.D. (Hopkins)
BALTIMORE

Without discussing, in this brief paper, the so-called "serum-disease" of von Pirquet, and other phenomena of anaphylaxis described elsewhere, such as the anaphylactic attacks in hay-fever, after tuberculin and the like, I wish to make this preliminary report with regard to another anaphylactic disease.

When some foreign protein is first injected into, or invades, man or other animal, it makes him susceptible to a subsequent injection of the same substance. There is no outward or tangible manifestation of this first injection, but the sensitizing effect is distinctly noticeable when the injection is repeated.

This second injection may show itself as a violent shock, or in the form of respiratory disturbances, dyspnea, edema, tonic muscular spasms, joint effusions, glandular swellings, albuminuria, hyperemias, or urticarial skin eruptions. Any one of these signs, or many of them, may be observed after the second dose of protein.

The causes of the various urticarial diseases are usually classified as predisposing, external, and internal. The predisposing causes have been called "susceptibility," "indigestion," "infancy," "rickets," "jaundice," etc.

Nettles, jelly-fish, mosquitoes, wasps, caterpillars and "bugs" are among the external causes.

Internal causes are foods such as mussels, crabs, lobsters, berries, worms, mushrooms, oatmeal, tomatoes, pork, or even egg-white.

The curative treatment is to remove the offending dietetic irritant.

Now, it is my assumption that certain individuals are sensitized to tomatoes, grapes, berries, or other specific protein, and that the absorption of their particular protein from the food brings on an attack. Since in

1. For a comprehensive review and detailed description of symptoms, see Frankenhimer, J. B.: Adiposis Dolorosa, THE JOURNAL A. M. A., March 28, 1908, p. 1012.

5. Price (Am. Jour. Med. Sc., May, 1909) cites the report of Dereum on this point.

certain cases in which antitoxic horse-serum is repeated in a second dose all of these urticarial eruptions, even angioneurotic edema, have been at various times reported, there is every reason to believe that these rashes are signs of anaphylaxis.

One individual may pass through different degrees of prophylaxis (immunity) alternately with states of anaphylaxis. Thus a tomato may at one time cause no symptoms, at another time in the same individual, erythema multiforme; again angioneurotic edema.

Accordingly, those persons subject to urticarial eruptions from a definite food may be regarded as sensitized to that protein. If the proteins absorbed from the digestive tube inaugurate an attack, they are in a state of anaphylaxis.

These phenomena of hypersusceptibility to food proteins may be congenital, acquired or inherited.

The recognition of the offending protein, whether its invasion is by mouth or by injection, whether it is by the olfactory route or by the circulation direct, is of such clinical importance that internists dare no longer ignore the applications of our present knowledge of anaphylaxis.

There is another example of the clinical application of this anaphylactic reaction which I must mention before concluding this paper. It has never been recognized before. In all of the dermatologic clinics of sea-coast or river towns there is seen, in the crabbing season an erythematous, progressive cellulitis of the hands, due to abrasions from the shells of crabs, lobsters and other shell fish. Hundreds of persons are scratched, injured and "bitten" by crabs, yet only about one-tenth of one per cent. of those bitten show this erysipeloid eruption. It spreads from the point of the finger or hand scratched, steadily, just like its more dangerous analogue, erysipelas.

Dr. T. Caspar Gilchrist studied a number of these cases bacteriologically and found them sterile. There was no associated micro-organism. "Crab-hand" has been a mystery, as far as its immediate etiology is concerned.

When we realize that such a small number of those exposed to this shell reaction really exhibit it, and when all of the other factors associated are taken into consideration, I believe it will be agreed that the condition fits in exactly with what we should expect from those persons who are supersensitive to shell proteins. Two experiments that I had the opportunity of performing this summer go far to verify this. They, with others, will be published in another paper.

It is always a specific condition. Persons subject to anaphylactic shock from crabs are not affected by berries, and *vice versa*.

A further study of this new disease is yet to be completed. We are now isolating the proteins of various dietetic articles and administering them to susceptible persons. The complete results of this work will shortly be published.

1937 Madison Avenue.

Benefits of Anesthesia.—Without a reliable anesthetic where would our surgeons be? We would hear nothing of the wonderful work they are doing. They would be groping in the dark and performing only the minor work—opening boils and an occasional amputation. But to-day, thanks to a drug that robs the patient both of the sense of pain and consciousness, the surgeon unhesitatingly dares to attack the most vital parts of the body.—W. A. Onderdonk, in *American Practitioner and News*.

THE SURGICAL IMPORTANCE OF ACCESSORY RENAL ARTERIES*

DANIEL N. EISENDRATH, M.D., AND
DAVID C. STRAUSS, M.D.
CHICAGO

Under normal conditions each kidney is supplied by a single renal artery which arises from the side of the aorta, a little below the origin of the superior mesenteric. Each renal artery, before reaching the hilum of the kidney which it supplies, divides into from three to five branches, which enter the substance of the kidney independently at the hilum.

The primitive kidney is a segmental organ, and its primitive vessels are probably segmental, *i. e.*, one artery for each segment, so that the persistence of the embryonic condition would mean that each kidney, instead of being supplied by a single renal artery, might receive from two to five renal arteries. Such supernumerary vessels represent a primitive condition, and the accessory arteries may arise close together from the aorta, or their points of origin may be widely separated.

The varieties of accessory arteries which most frequently occur are:

TYPE 1 (Fig. 1).—Two separate renal arteries arise from the side of the aorta to supply the kidney. The two arteries enter

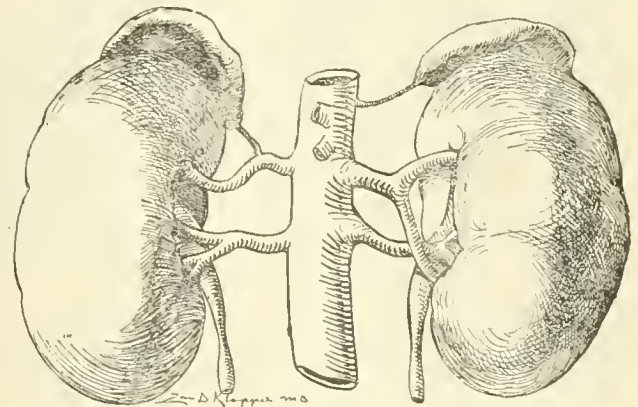

Fig. 1.—Type 1 of accessory arteries. Two separate renal arteries passing to hilum from aorta.

the hilum of the kidney, dividing, just before doing so, into two or more branches. This variety may be called the *two-artery type*.

TYPE 2 (Fig. 2).—A main renal artery arises from the aorta in the normal manner, but a second, *i. e.*, accessory, artery arises from the aorta a variable distance away, passing directly from the aorta to the upper pole of the kidney. This may be called the *superior polar type*.

TYPE 3 (Fig. 3).—The main renal artery arises from the side of the aorta and passes to the hilum in the normal manner.

An accessory renal artery arising separately from the aorta a variable distance from the main trunk passes to the lower pole of the kidney. This is called the *inferior polar type*.

TYPE 4 (Fig. 4).—Three renal arteries arise from the side of the aorta and pass separately to the hilum of the kidney. This is called the *three-artery type*.

TYPE 5.—Four renal arteries arise from the aorta and pass separately to the hilum. This is called the *four-artery type*.

TYPE 6 (Fig. 5).—The accessory artery, instead of having its origin from the aorta, close to the main renal trunk, arises from a vessel at times quite distant from the normal renal artery, most often from the common, external or internal iliaes, rarely from the hepatic, middle sacral, spermatic, in-

*Read at the annual meeting of the American Urological Association, St. Louis, June, 1910.

ferior phrenic, lumbar or even pancreatic or colonic arteries. This may be called the *extra-aortic accessory type*, and is quite rare as compared with the previously described types.

TYPE 7.—Superior or inferior polar branches arise from a single, *i. e.*, normal, renal artery just before it divides to enter the kidney.

These vessels may be called *pseudo, or false accessory, i. e.*, not arising from the aorta. They are of less importance than the true accessory vessels.

Although anatomists have known for many years that such accessory arteries are frequently found, their surgical importance is just beginning to be appreciated. Surgeons have become aware of the fact that accessory renal arteries may not only be the cause of pathologic conditions, *e. g.*, hydronephrosis, but that they may play an important part in producing serious, if not fatal, complications during or after operations on the kidney, such as nephrotomy or nephrectomy. But few books on anatomy in any language, and scarcely a single treatise on general or renal surgery mention the possibility of the presence of such accessory arteries.

The majority of anatomies, such as those of Hyrtl, Henle, Partsch, Sobotta, Poirier and Charpey, Broesike, Lernow, Bardeleben, Joessel, Deaver, Morris, Gerrish, Testut and Langer, either do not mention the occurrence

omy. He calls attention to the fact that hemorrhage after nephrotomy may be due to such accessory vessels.

Israel does not describe any variations of the renal artery, but refers to the rôle which an accessory artery to the lower pole may play in the production of hydronephrosis. In the chapter on nephrolithotomy he refers to the fact that persistent bleeding may be due to accessory polar arteries, which have either not been compressed during a nephrotomy, or from which postoperative bleeding occurs after the heart has regained its activity. He describes a case in which there was an insignificant hemorrhage from the upper pole during a nephrolithotomy, even after a rubber ligature had been placed around the pedicle. After the patient's return to bed a severe hemorrhage occurred, whose source was found at the upper pole, necessitating nephrectomy.

At the 1909 meeting of the French Surgical Association, Pasteau reported a case in which a severe hemorrhage occurred after a nephrectomy, due to overlooking an upper pole artery. He found anomalous arteries in 20 per cent. of eighty-two cases. In one case there were six renal arteries.

The polar arteries are often mistaken for adhesions, and are thus easily torn.

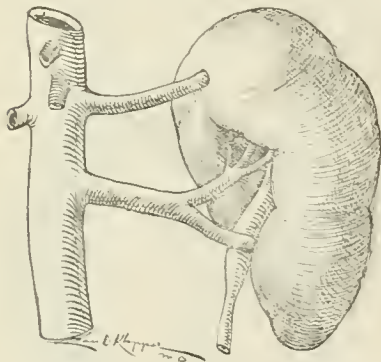

Fig. 2.—Type 2 of accessory arteries. Large artery passes from aorta to upper pole of kidney.

Fig. 3.—Type 3 of accessory arteries. Large artery passes from aorta, close to bifurcation, to lower pole.

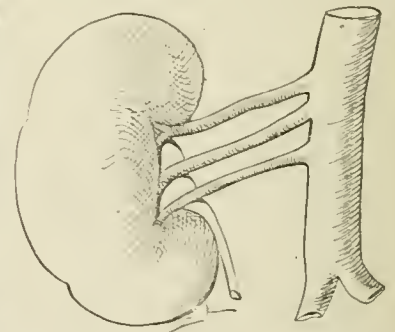

Fig. 4.—Type 4 of accessory arteries. Three separate arteries pass from aorta to hilum of kidney.

of accessory renal arteries or state that they are of no practical importance.

In the standard atlases, like those of Henke, Bardeleben, Zuckerkandl, Spalteholz, Toldt, Sobotta, and Heitzmann, no illustrations of such an anomaly are shown.

Cunningham, Quain, Gray and Piersol describe the occurrence of accessory arteries, Quain stating that they are found in 20 per cent. of bodies. The best description is that given by Piersol:

Accessory renal branches may arise from the abdominal aorta or from the middle sacral, common iliac, internal iliac or the inferior mesenteric. These accessory arteries frequently enter the substance of the kidney elsewhere than at the hilum.

The only reference to these accessory vessels in the books on renal or general surgery are in Schede's chapter in the von Bergmann "System," and in Garrès, Israel's and Albarran's books. Schede says that variations of the renal artery may be of surgical importance and that search should be made for separate vessels entering the upper or lower poles. Preliminary ligation of these accessory arteries is advised.

Garrè simply mentions the presence of double or triple renal arteries and advises ligation of an accessory artery passing to the upper pole, when found during a nephrot-

The only articles which give any accurate information as to the frequency of occurrence of the different anomalies are those of Brewer, Thomson and Seldowitsch, which will be referred to in connection with our own work.

We became interested in the subject of accessory renal arteries after having had a case of very severe postoperative hemorrhage from an overlooked inferior polar artery following a nephrolithotomy. The bleeding occurred after the patient's return to bed, as in Israel's case.

Believing that a knowledge of the frequent occurrence of accessory renal arteries should be more general, we desire to add our observations as to their frequency to those of Brewer, Seldowitsch and Thomson. During the past winter, through the kindness of Dr Bensley of the University of Chicago, Dr. Ransom of Northwestern University, and Dr. White of the University of Illinois, we dissected the kidneys in 100 cadavers, *i. e.*, 200 kidneys, and made the following observations as to the frequency of occurrence of accessory renal arteries:

TABLE 1. ACCESSORY RENAL ARTERIES

Number of kidneys examined.....	200
Accessory arteries (true), (See Figs. 1 to 5 incl.) (Types 1, 2, 3, 5 and 6).....	28

* Only male cadavers. † Not mentioned.

Fig. 5.—Type 6 of accessory arteries. The accessory artery has its origin from an extra-aortic artery, like the common or external iliacs.

A comparison of these statistics shows that abnormal, *i. e.*, accessory, arteries occurred in about 21 per cent. of over 1,200 kidneys. In other words, one can expect to find such accessory vessels in about one out of five kidneys. The most common form of accessory vessel is a second renal artery arising separately from the aorta, as shown in Figure 1. Next in order of frequency are the superior polar, the inferior polar and the remaining types shown in Figures 2 to 5.

This question of the presence of supernumerary renal arteries is not only of interest from an anatomical standpoint, but will be of constantly growing importance in its bearing on renal surgery.

Israel, Ekehorn, Mayo and Braasch have called attention to the rôle which an accessory artery passing from the aorta to the lower pole of the kidney may play in the production of hydronephrosis through kinking of the ureter across such an accessory vessel.

The purpose of our investigations was to direct attention especially to the possibility of severe hemorrhage occurring from such accessory vessels, either during the performance of nephrolithotomy or after the patient has returned to bed. No doubt many cases of serious and in some cases fatal hemorrhage have been due to bleeding from such accessory vessels, especially those passing to the upper or lower poles. In future it would be advisable, before incising a kidney for the removal of renal

calculi or performing a nephrectomy for any condition, to examine the upper and lower poles and the hilum of the kidney for the presence of any supernumerary arteries. If such vessels are found, it is advisable to ligate them separately from the main renal pedicle.

So far as our investigations show, the condition is present as often on one side as on the other.

GANGRENE OF THE LUNG WITH TRICHOMONAS INTESTINALIS AS THE ONLY APPARENT ETIOLOGIC FACTOR

REPORT OF A CASE

G. C. DOLLEY, A.B., M.D.

First Lieutenant Medical Reserve Corps, U. S. Army
FORT LEAVENWORTH, KAN.

The literature in relation to the trichomonas is rather extensive, but relates to the intestinal, urinary and vaginal tracts almost entirely. Observers have noted it in connection with chronic diarrhea, cystitis without bacteria, and rarely with pulmonary abscess and gangrene.

Instances of the invasion of the respiratory tract by mastigophora are very few, so that the report of a case of gangrene of the lung in which the trichomonas was the only discoverable etiologic factor may find a place in the rather scanty records of pulmonary disease due to or associated with this protozoon.

The general consensus of opinion seems to be that the trichomonas is not capable of producing disease *de novo*, but that a previous injury to the tissues must have taken place, and that in such cases only can it play an active part in pathogenesis.

This is the evidence in the report of the following case:

History.—The family, personal and social histories present nothing pertinent to the case of the patient, Private E. C. He had had chills and fever in July, 1909. On June 21, 1910, he was admitted to the post hospital with the same trouble, diagnosed and treated as tertian malaria, and was discharged as cured July 3, 1910. In the winter of 1909-10 he injured the left side of his chest by falling on the pommel of his saddle while mounting his horse and was confined to the hospital for a week.

Present Illness.—July 10, 1910, the injured side began to give him trouble under severe drill, and two days later he began to have a great deal of pain in the left side, and felt sluggish. He also had headache and dull ache over the root of the left lung, which continued throughout the illness. On admission, July 15, 1910, besides the pain, he felt weak and was expectorating blood-tinged sputum.

Examination.—Temperature was 101.8 F., respirations 20 and pulse 80 per minute. There was an area of dulness between the left anterior and posterior axillary lines extending from the third to the fifth rib. Coarse bubbling râles were heard throughout the left chest; otherwise the physical signs were negative. The blood, urine and feces were normal; the latter contained no parasites. The sputum was thin at first, white, with blood-streaks, later much increased in quantity, dark, rusty, prune-juice color and foul odor. It contained elastic tissue, masses of epithelial cells, Charcot-Leyden and hematin crystals. Besides a few bacteria, there were numerous actively motile trichomonads.

During the first twenty-four hours the sputum amounted to but 1 fluid ounce or so, but during the course of the disease it increased to between 3 and 4 fluid ounces per day. During the last week of the disease the amount of sputum gradually lessened, the foul odor disappeared and the quantity of blood in it was reduced until there were only a few cor-

puscles present. In every examination numerous active trichomonads were noted until the last week of the disease, during which they gradually decreased in number and lost their motility. There were still a few present in the sputum on the day of the patient's discharge (August 5, 1910) from the hospital. At no time were there more than a few bacteria present in the sputum.

Course of the Disease.—At no time during the patient's confinement in the hospital did the temperature rise above normal after the first twenty-four hours, but ranged between 97.6 and 98.5 F. The pulse and respiration were normal throughout. The sputum and pain in the side and over the root of the left lung were the only noteworthy symptoms, and on discharge (August 5, 1910) only a slight soreness over the root of the lung remained, the foul and bloody sputum and the pain having quite disappeared. The patient has reported twice since discharged, at intervals of a week, for observation, and at the last visit seemed to be in perfect health.

THE NON-OVIPAROUS FEMALE HOOKWORM*

WILLIAM LITTERER, A.M., M.D.
NASHVILLE, TENN.

In every higher animal we recognize certain more or less definite periods of physiologic activity, and we roughly divide the span of life into three stages, which are in no way sharply outlined. These we call the stages of youth, adolescence, and old age. Youth, characterized by a high degree of vitality, is the period of rapid cell multiplication and growth; organs are formed and perfected, functions are unimpaired and active, and the body is a perfect living thing. The second period is characterized by functional and sexual maturity; the multiplication of tissue cells is less rapid; the organs strengthen and their functions are more perfectly correlated; growth comes to an end. In the perfected animal it is a period for perpetuation of the race, and in conformity with this great function sexual differentiation is fully established. The third period, old age, brings a marked change, the potential of vitality wanes; degenerations of all kinds appear, and cumulative weakness ends natural death. These three periods are all characteristic of all of the higher-celled animals, the last period being rarely seen in nature, because in the wild animals a violent death follows the early functional weakening and inability to fight off enemies (Calkins).

Do we find the same sequence of physiologic changes in the lower many-celled animals, and can we distinguish periods of youth, maturity and old age? Since the fundamental biologic laws are much the same, on *a priori* grounds alone we should expect to find the same series of changes in the lower metazoa and likewise in the protozoa.

Of late I have been greatly interested in the study in the development of the *Uncinaria americana* with special reference to the non-oviparous female, endeavoring to ascertain whether their inability to produce eggs is due to the "old age period" or to other influences not attributable to senile degeneracy. It is affirmed by Bass that more than 7 per cent. of females out of the 247 dissected by him failed to produce ova. He maintains that during the latter third of their existence they cease to lay eggs. This observation, if substantiated, is of paramount importance for the reason that individuals

may be harboring the worm though no ova can be found in their stools.

The limited amount of work that I have done along this line does not correlate with the result of Bass's investigations, as shown from the examinations of specimens obtained from cases coming from the Tennessee Industrial School. At this juncture I wish to express my deep indebtedness to Dr. Thomas Weaver, the physician in charge, for the privilege of studying these cases. Children are brought here from practically every county in the state and are kept under surveillance until they have attained their majority. So far as we could ascertain, there is no evidence that the disease has ever been contracted in the institution. Ground-itch, dew-poison, etc., are unknown among them and the water-supply is perfectly pure. This offers a fruitful field of research for ascertaining just how long the infection may have persisted in a given case and likewise in determining the oviparous and non-oviparous females, with especial reference to their ages. The report in detail follows:

CASE 1.—L. D., a girl, aged 17, admitted March 8, 1899, from Putnam County; eleven years in the institution without interruption; two treatments by thymol (on Feb. 15, 1910, and March 18, 1910) recovered 27 hookworms—22 females and 5 males; all of the females contained many eggs.

CASE 2.—M. G., a girl, aged 18, admitted from Rutherford County; thymol treatment recovered 19 hookworms—13 females, 6 males. The females were all oviparous.

CASE 3.—M. C., a girl, aged 9, admitted May 27, 1905, from Overton County. Only 1 hookworm recovered by thymol. This worm was an egg-bearing female.

CASE 4.—R. S., male, aged 18, admitted Feb. 12, 1904, from Pickett County; six years in school. Three courses of thymol given (March 4, 1910; March 11, 1910, and March 17, 1910). Forty-five hookworms—36 females and 9 males—were recovered. All the females contained many eggs, except one. This non-oviparous female was of average size and, so far as could be ascertained macroscopically, was perfectly normal. Microscopically, the vulva was abnormally situated just in front of the lower two-thirds of the body. The two uterine and ovarian tubes were observed to be quite atrophic, and very much shorter than normal.

CASE 5.—D. C., a boy, aged 13, admitted May 13, 1909, from Blount County. Thymol treatment recovered 18 hookworms—13 females and 5 males. All the females were oviparous.

CASE 6.—F. M., a boy, aged 16, admitted July 13, 1909, from Davidson County. Thymol treatment recovered only 1 oviparous female.

CASE 7.—W. D., a boy, aged 12, admitted Jan. 1, 1910, from Cannon County. Thymol treatment revealed only 1 oviparous female.

CASE 8.—F. C., a boy, aged 16, admitted Feb. 10, 1910, from Scott County. Thymol treatment recovered 3 oviparous females.

CASE 9.—K. B., a girl, aged 9, admitted July 1, 1908, from Macon County. Thymol treatment recovered 2 oviparous females and 1 male.

CASE 10.—B. J., a boy, aged 14, admitted Jan. 25, 1909, from Greene County. Thymol treatment recovered 2 oviparous females and 1 male.

CASE 11.—L. M., a girl, aged 13, admitted Dec. 28, 1907, from Lawrence County. Thymol treatment recovered 7 oviparous females and 4 males.

SUMMARY

In summarizing the above cases it will be seen that 132 worms were recovered and examined—101 females and 31 males. Only one non-oviparous female was ob-

* From the Pathological Laboratory of Vanderbilt University, Medical Department

served out of the entire number. The patient from whom the non-oviparous female was obtained has been in the institution for six years (Case 4). We can assume that the worms recovered from this patient are over six years of age, since there has been no evidence of infection while in the institution. Of absorbing interest is Case 1, possibly the longest infected case on record. Dr. Stiles (personal communication) related two cases in which the infection lasted about eleven years. Our patient has been constantly present at the institution for over eleven years and no outside source of infection was possible.

It is generally conceded that the average infection will last three or four years; the worms die or become dislodged from their firm attachment and are then passed out by the bowel. Two thymol treatments in Case 1 dislodged 27 hookworms—22 females and 5 males. Every female contained enormous numbers of ova. It is evident from the above case that the worms are more than eleven years old. Notwithstanding their extreme age they appear to be producing as many eggs as in the prime of life. This case, however, cannot be taken as a criterion, since it may be an exception rather than the rule.

About two years ago I recovered 89 worms from a patient giving a history of having had the disease a little more than one year. Recently I examined these worms and found 66 to be females and 23 males. Three of the 66 females proved to be non-oviparous. The history of the case follows:

CASE 12.—A boy, 12 years old, had always lived in Massachusetts except for the past year and a half. He had always been healthy and energetic. The family moved from Massachusetts to South Carolina in the early spring of 1907. During the summer the boy went barefooted and contracted ground-itch on two different occasions. Several months later he appeared not to be as well as usual, and throughout the winter months he exhibited a marked lack of energy, lassitude, and stood very poorly in his classes at school. Anemia was present, but was not very marked. In June, 1908, the family moved to Atlanta, and came to Nashville in November, 1908. The case came under my observation several weeks later. Examination of the blood showed red cells 4,115,000, hemoglobin 85; whites, 9,200. The differential leukocyte count revealed 17 per cent. of eosinophils. The increase in eosinophils led me to suspect uncinariasis, so the stools were examined, with the result that a great many hookworm ova were found. Thymol was given, which expelled 67 worms, 53 of which were females and 14 males.

One week later, another course of thymol was given, with the result that 19 worms were obtained—10 females and 9 males. Two weeks later, another course of thymol was given, which expelled 3 females. After this, repeated examinations of the stools failed to show the ova. The patient rapidly improved, and three months after the last treatment, was as healthy and robust as he had always been before the infection.

The unique feature in this case was the finding of three non-oviparous females out of 66 worms, which gave a history of being less than one and one-half years old. From this case it is evident that comparatively young females may be incapable of egg production.

I am of the opinion that the non-oviparous nature of the female is not entirely due to the "old-age period," but is, in all probability, caused by some defects in development, or occasioned by peculiarity in a given strain. Definite conclusions, however, are not warranted, as evidenced by the paucity of the material at hand. Further observations by the writer along this line will be forthcoming in the near future.

CULTIVATION OF ADULT TISSUES AND ORGANS OUTSIDE OF THE BODY*

ALEXIS CARREL, M.D.

AND

MONTROSE T. BURROWS, M.D.

NEW YORK

The solution of many problems of human pathology depends, in a large measure, on the finding of the still unknown physiologic laws of generation, growth and evolution of cells. We must, therefore, develop new methods which permit the discovery of these laws. A few weeks ago, we began to investigate systematically one of these future methods, namely, the cultivation of adult tissues outside of the body. The starting point of our researches was the beautiful work of Harrison on the embryonic tissues of the frog. Some years ago, Harrison observed the development of nerves from the central nervous system of frog embryos cultivated in a drop of lymph. In 1910, Burrows studying with Harrison improved very much this method and adapted it to embryonal tissues of warm-blooded animals. He succeeded in cultivating nerves and mesenchymatous cells of sixty-hour chick embryos.

Then, at the Rockefeller Institute, we tried to develop on this basis a general method which would be applicable to the adult tissues of the mammalia and thus to determine some of the laws of cellular physiology.

The experiments on which we wish to report now were performed on dogs and cats and an adult frog and consisted of extirpating small fragments of tissues of an animal, inoculating it aseptically into a plasmatic medium taken from the same animal, and sealing the materials in hollow glass slides. The slides were placed in an incubator, maintained at a constant temperature of 37° C. The microscope was also placed in a special thermostat which was kept at this temperature. The growth of the cells could, therefore, be observed, over a period of time, with the microscope, kept itself at the body temperature, and the multiplication of cells directly seen.

GENERAL CHARACTERS OF THE GROWTH

The plasmatic media were inoculated with many tissues or organs, of which all were found to multiply or grow. The cultures of the different tissues—as we shall call them—contain common characteristics. The time of the beginning of cellular proliferation depends on the nature of the tissue, the age of the animal and other more or less important factors. In the cultivation of glandular organs of adult dogs, the vegetation starts after thirty-six or forty-eight hours. But, if the young animal is only a few days old, new cells appear in the culture after ten or twelve hours. Four or five days after the inoculation of the medium, the cultures of thyroid, kidney, suprarenal, etc., are in full activity, and remain in this condition as long as the medium allows it. Tissues like cartilage or peritoneum grow, at first, very slowly. After three days, there are in the cultures very few new cells. But about one week after the inoculation, the cultures become very much more active, and are in full vegetation after about nine or ten days. There is also some analogies between the morphologic characters of the cultures of various tissues

*From the Laboratories of the Rockefeller Institute for Medical Research.

and organs. For all tissues, the first indication of growth is the appearance on the edges or the surface of the specimen of a few small and regular granulations. These granulations consist of the cytoplasm of cells, the nucleus and nucleoli of which soon become visible. The cells belong to two general types, spindle and polygonal. The spindle cells appear ordinarily at first and their morphology is about the same in all tissues, bone marrow or kidney, thyroid or cartilage. They are long and slender and radiate from the fragment of tissue or organ through the plasmatic medium. They are derived probably from the connective tissue framework of the organ. At the same time, or a little later, the cells of the second type appear. They are polygonal or multipolar cells in form, but their morphology varies widely according to each tissue and organ. They seem in part to be differentiated cells of epithelial nature. Cartilage produces cartilaginous cells, and thyroid generates cells which look like thyroid cells. Even in the renal cultures, this second type of cells congregates in tubular formations. By using a suitable technic, we can control the growth of one or another of these types. A small fragment of thyroid cleanly cut produces mainly spindle cells, while in tissues more finely divided (scrapings), epithelial-like cells appear.

In the first part of the work we found and studied the growth of adult tissues outside of the body. In the second part we attempted to cultivate thyroid cells in series, and also to activate the growth of a tissue by passage from one plasmatic medium to another. Connective tissue, cartilage, peritoneum, bone marrow and bone, skin, thyroid gland, spleen, suprarenal gland, kidney, ovary and lymph gland, were all cultivated successfully.

CULTIVATION OF TISSUES

Arterial Sheath.—Three days after inoculation of a fragment of arterial sheath, very delicate palm-like cells appeared on the edge of the tissue and ramified through the plasmatic medium in long filaments ending in spindle cells. Vegetation was very weak and stopped entirely after a few days.

Connective Tissue.—Most of the cultures of connective tissue remained inactive.

Conjugal Cartilage.—This started also to grow on the third day. For about one week, very few spindle and spider like cells were found slowly wandering along the edges of the cartilage. From the upper pole of the fragment of tissue, a mass of new cartilage protruded and invaded the plasmatic medium. After a few days, it became so large that it could be seen by the naked eye. Progressively, the rate of growth became faster. Many irregular cells with long arms now appeared in the plasma about the old cartilage.

After nine days, the culture was in full activity, and the old cartilage had thus generated outside of the body a piece of new cartilage two millimeters long.

Peritoneal Endothelium.—This underwent also a slow evolution. For several days, there were only a few beautiful and irregularly-shaped cells along the edges of the tissue. After a week they began to multiply more actively and many very large cells resembling endothelial cells slowly moving through the clear plasmatic medium were directly observed under the microscope. On the twelfth day, the culture was still in full vegetation.

Bone.—During the first hours of the cultivation of fragments of bone marrow and bone, the anatomic elements began to wander away from the tissue. After

three or four days, the little pieces of bone hidden in the bone marrow became visible, because almost all the cells had invaded the plasmatic medium. Around the tissue, there were radiating spindle cells and many red blood corpuscles. Leukocytes with active amoeboid motion and large cells with granular cytoplasm and long pseudopodia had reached the remotest part of the medium. A few large spindle cells were seen crawling along the edges of the fragments of bone.

Epidermis.—We studied the growth of epidermis by cultivating fragments of the skin of an adult frog. Masses of epithelial cells appeared on the edges of the cutaneous fragments after twelve or twenty-four hours. They grew very rapidly. After forty-eight hours, the area of new epidermis obtained in some cultures was twice larger than the old fragment of skin. A few cultures were fixed and stained, and it could be seen that many cells were dividing by karyokinesis.

CULTIVATION OF ORGANS

Thyroid, Spleen, Etc.—Many cultures of glandular organs were made and grew rapidly. The cultivation of the thyroid of adult dogs was very easy. After thirty-six or forty-eight hours, long fusiform cells protruded at one or several points from the edges of the tissue. Often new polygonal cells also could be seen on the upper surface or on the edges of the thyroid. After the fifth and the sixth days, the cultures were generally in full and sometimes wild vegetation, which lasted as long as the plasmatic medium was in good condition. A great many long fusiform cells or chains of fusiform cells radiated from the tissue through the plasma. Polygonal cells were generally closer to the tissue. In a few cultures there was an abundant proliferation of cells resembling epithelial cells, while the fusiform cells were in small number.

The cultivation of suprarenal and of spleen gave also excellent results.

Kidney.—But very much more important were the results of the cultivation of the kidney. Two plasmatic media were inoculated with small fragments of a kidney of a young cat. Twelve hours later, fusiform cells were protruding from the tissue. After twenty-four hours, a great many cells had invaded the plasma all about the renal substance. One day later, the cultures vegetated wildly. On the fifth day, one of the cultures was fixed and stained with hematoxylin. We saw many karyokinetic figures in the cells which had proliferated through the plasma. A tube had begun to grow from the tissue into the medium. The cells showed a condition of great activity.

The other culture was allowed to live to the sixth day and an exceedingly active growth of the cells took place. In the morning, we observed a few tubes growing from the renal substance into the plasma. In the evening, they were very much longer and curved at their blind ends. At the beginning of the seventh day, the culture was fixed and stained. Around the renal tissue a very large number of fusiform and polygonal cells had formed. A few tubes, composed of a lumen limited by epithelial-like cells, had passed from the fragment of kidney for a distance into the plasmatic medium. They had the appearance of renal tubules.

These experiments demonstrate that adult tissues grow very easily outside of the body. Tissues like cartilage, and even like renal substance, can be caused to develop in something like normal manner under entirely new conditions.

REACTIVATION AND CULTIVATION IN SERIES

The second part of our study consisted of modifying the rate of growth of tissues by passing them into a second medium. A few six and seven day old cultures of thyroid were used for the first series of experiments. The thyroid fragments were removed from the old cultures, cut into small pieces and placed into new plasma. Eleven and twelve hours after, new cells protruded from the previously inactive parts of the thyroid substance, as well as from the newly proliferated cells. We found, indeed, that the thyroid of an adult animal had now become as active as the thyroid of an animal a few days old. Afterward the cells invaded very quickly the new plasmatic medium. One of the cultures was fixed a little less than thirty-six hours after the passage into the new plasma and stained with hematoxylin. From one side of the old tissue there was a large mass of fusiform cells radiating through the plasma. From another point, several tubular formations had wandered far into the medium. The wall of these tubules was composed of epithelial-like cells. It seems, therefore, that the passage from one medium into another of the same kind increases the vegetative power of the thyroid cells.

In a second series of experiments, a plasmatic medium was inoculated with cells produced by the cultivation of a thyroid fragment, in order to obtain a second generation of cells. In several instances, this result was achieved. After twenty-four hours, we noted that a few cells had wandered from the old plasma into the new. In one experiment, less than four hours after the inoculation, the new plasmatic medium already contained new cells. One of these cells was fusiform and its activity was so great that we could follow under the microscope the motion of its cytoplasmic gravitations and the changes of its shape. In a few minutes, one end of the cell became very large, while a long tail grew at the opposite end. Finally the cell became multipolar. Other cells appeared at the same time in the new medium. Thirty-six hours later, the culture was fixed and stained and many active cells resembling epithelial and connective tissue cells were found to be present in the new plasma. We had, therefore, obtained a second generation of the first culture of thyroid cells.

CONCLUSION

The main results of these observations can be summarized in a few words: Adult tissues and organs of mammals can be cultivated outside of the animal body.

The cultivation of normal cells would appear to be no more difficult than the cultivation of many microbes. It remains, however, to be determined whether continuous series of cultures can be secured. This method can, therefore, be used for the study of many important problems. For instance, it may render possible the cultivation of certain micro-organisms in conjunction with living tissue cells or alone in plasmatic media. Then it will be of great value in the study of the problem of cancer. We have already succeeded in inoculating a plasmatic medium with sarcoma of the fowl; cells appeared in the surrounding plasma after nine hours and the culture is growing actively at present. We can assume, therefore, that the perfection of the method of cultivating adult tissues of mammals outside of the body will be helpful in the exploration of unknown fields of human pathology.

Work is in progress along the lines indicated, the results of which will be published from time to time.

Therapeutics

DIET IN TYPHOID FEVER

As typhoid fever has its most active pathology in the intestinal canal, and as all ordinary food must traverse this canal, and as in this almost invariably protracted fever nutrition is a matter of serious consideration, the character of the food given in this fever is always a live subject for discussion.

While this subject has been several times touched on in this department, the last word has not yet been said, as evidenced by the repeated discussion of the subject, both in medical journals and in medical societies.

Whether we have under-fed our typhoid patients or over-fed them, it seems that the evidence is very strong that milk alone is not the proper food for these patients. In fact, when we consider the frequent difficulty in its digestion, the large amount of it that must be given to satisfy the system either in calories or in protein, it would seem that we should rule against it as a typhoid diet. These facts immediately cause the decision that our old feeding of typhoid fever was wrong, and that we must select a new or modified food in this disease.

It can not be questioned that the high temperature, rapid pulse, delirium, and that association of nervous symptoms called typhoid are not caused by the typhoid germ alone, but by a double infection, and the double or secondary infection is due to toxins or the products of secondary germs absorbed from the intestines.

Tympanites is an indication not of typhoid fever, but of intestinal putrefaction and fermentation, and a mistake in the management of the bowels and of the food administered. Tympanites need not be a symptom of typhoid fever, and when it is present it is almost invariably a medical mistake. It is too easily a demonstrable fact to require anything more than the assertion that, if the abdomen is flat and not distended, if the bowels have properly moved, and if there is no troublesome diarrhea or obstinate constipation, then the tongue is less coated and is not dry, the temperature is less, the skin is moist, the pulse is better, the delirium is less or generally absent, and such symptoms as carphology and subsultus are absent. The temperature being lower than with such added bowel infection, there is less necessity for disturbing the patient with cold water antipyretic measures, and the less such disturbance the quieter the nervous system and the less loss of nutrition, to say nothing of the less irritation of the heart from rapidity caused by the exercise and nervous excitement due to cold applications.

It stands to reason, then, that primarily such food and arrangement of the movements of the bowels as cause the least tympanites and the least indigestion are of first importance in the management of typhoid fever. Secondly, the food which, so far as possible, satisfies the requirements of the body for nutrition and at the same time satisfies the above requirements of easy and thorough digestion, should be the food of choice.

It must always be considered, of course, that during the fever term there will be a progressive loss of weight, in other words, a denutrition. It is probably impossible to prevent this by any amount or any character of the food, as before sufficient nutriment could be absorbed to prevent loss of weight such indigestion would be caused as to preclude its administration. As it is impossible to determine exactly how much of all of the different elements of food the patient can absorb just inside of his limit of perfect digestion, we must have

a scheme or plan of nutriment that theoretically should be satisfactory to all these typhoid patients, and then individualize this plan to each patient. If we always keep inside of gastric indigestion and prevent tympanites, we are immediately reducing the ordinary fatality of typhoid fever by at least half. In other words, the nervous wear and tear is not so great and the danger of intestinal hemorrhage and perforation are reduced to a minimum.

Before considering the diet in detail, the intestinal condition should be considered, both theoretically and practically. Inflammation of any part of the intestines can not occur without causing increased secretion, increased peristalsis, and more or less diarrhea the character of which will depend on the part of the intestine in which the inflammation is located. There will always be an increased amount of mucus secreted, possibly blood-streaked; and there may actually be a sufficient number of white cells, either alive or dead, in the bowel movements to be termed pus. If there is irritation enough at any one point, irregular peristalsis may occur and pain be present. If there is irritation enough to cause a spastic condition of some part of the bowel, intestinal gas will accumulate above this part, and more pain and distention occurs. If either normally digested refuse products or products of excretion or undigested food reaches the inflamed part, it is more or less retained there by the abnormally adhesive exudate on the mucous membrane, or retained by abnormal and irregular peristalsis, and fermentation, if not actual putrefaction, occurs, with increased intestinal pressure aiding and abetting in the absorption of the toxins produced.

From all these facts, then, and they are facts, Nature's method of removing the undigested food and the products of inflammation by diarrhea should receive our encouragement and not our opposition. It is true that Nature is working just as faithfully for the pathogenic germs as she is for the patient who harbors them; consequently, we can not absolutely trust Nature to cure the patient, but we could not interfere with the natural measures taken by the patient's metabolism itself to get rid of his infection. Neither should we leave it all to Nature's doubtful processes. In other words, the diarrhea should be managed, but constipation neither allowed nor caused in typhoid fever.

The patient, then, should receive at first a cathartic, either calomel or castor oil, and then after the intestinal canal is clean, he should every other day have a dose of the laxative found best in his particular case. Whether the laxative to cause one or two good movements every other day be a vegetable (generally best) or a gentle saline (sometimes best), is a matter of unimportance. If the laxative tends to cause a diarrhea or several movements, a 1/10 grain morphin tablet should be administered after the second movement. This will inhibit peristalsis and cause no other symptoms. The laxative being given every other day, on the intermediate or alternate day a simple rectal injection of 15 c.c. (half an ounce) of glycerin and an equal amount of water should be given. This will cause an evacuation of the lower bowel and expulsion of gas.

Such a management of the bowels will keep the lower part of the small intestine as clean as possible, will prevent the fretty tire and discomfort of a diarrhea, will give rest enough for the intestinal ulcers to heal, and will prevent the stagnation of putrid products, which cause, besides the general symptoms above described, deeper ulceration into the inflamed glands.

A discussion of bowel antiseptics in typhoid fever will be found in *THE JOURNAL*, Oct. 12, 1907, page 1293. Hexamethylenamin, having been proved so harmless and yet so useful a drug, should, perhaps, in small amount, be given constantly during typhoid fever, on the theory that, even if it does not cause any antiseptic action in the bowels, it will prevent the typhoid and colon bacilli from infecting the gall-bladder and the typhoid bacillus from becoming lodged in the kidneys, to say nothing of its ability to inhibit the growth of germs on various serous membranes of the body.

The pendulum has swung from insufficient nutriment through an excessive amount of milk feeding in typhoid to the other limit of a large amount of protein and actual solid food, and now is again swinging, very slowly, however, back to a diet arranged according to food values and to the actual needs of the body. To study the diet from this standpoint it is well to review an article on this subject by Dr. Harris A. Houghton, of Bay-side, L. I. (*Am. Jour. Med. Sc.*, January, 1910). Shaffer (*THE JOURNAL*, Sept. 19, 1908, p. 974) two years ago showed that typhoid patients did not receive within 50 per cent. of the kind of food they required, viz., heat-producing and tissue-saving food or calories, while they did receive more nitrogenous food than they required.

Houghton reviews various physiologic experiments which show that during the fever process the glandular secretions of the digestive tract are more or less insufficient. Even the salivary secretion is less than normal, and may even become acid. This is one of the causes of the dry mouth, coated tongue and sordes, and is an indication for the slight salivary stimulation afforded by lemonade and orange juice. The hydrochloric acid of the stomach is greatly diminished, and it is still further decreased in amount if sodium chlorid is not given with the food. The absence of sodium chlorid from the diet was another long-continued mistake during the milk-feeding period of typhoid fever. The bile is also decreased, and, although there is no experimental evidence to show a diminution of the pancreatic secretion or the secretion of the intestinal mucous membrane, it is safe to infer that these are also diminished. In other words, it has been estimated that the ability to digest food is decreased from 10 to 12 per cent. in the typhoid patient. Hence, as the absorptive toxins are more serious in protein maldigestion than in starch maldigestion, the deduction seems rational that too much protein should certainly not be administered.

Houghton recalls to mind that Chittenden and others have proved that an increased amount of nitrogen with protein indigestion does not ordinarily add nutrition or strength to the system, but is represented by an increased output of nitrogen products in the urine, the body taking up and utilizing but a small part of the nitrogen ingested. This is certainly just as true of a typhoid patient, and, while part of his nitrogen metabolism will be passed in the feces, a large part must pass in the urine, and will enter, on account of his maldigestion, into irritating and even more or less toxic nitrogen compounds before being excreted by the urine. It would therefore seem a sensible deduction to give the typhoid patient just sufficient nitrogen for his needs as it could be approximately estimated and not an excessive amount to his harm. From this same reasoning, as soon as convalescence is established and the patient begins to put on nutrition, he must of necessity need more nitrogen, i. e., more protein. If a mistaken, ill-judged amount of protein food, carrying with it a large amount of nitrogen,

is forced on a patient who is severely ill, and at the same time an insufficient amount of carbohydrate food is given, a careful quantitative and qualitative analysis of the twenty-four hours' urine excreted will show that abnormal urinary products are the result, especially the ammonia compounds, indican and other irritants, and doubtless not only the symptoms present, but actual death may be caused by these toxins, not dissimilar to a uremic death. In other words, such feeding is vicious.

As has been above urged, Houghton reminds us that a large amount of bacterial decomposition is caused by overfeeding of protein, and the obverse is true, viz., that if the protein is limited the bowel fermentation is diminished and the danger from typhoid is reduced. Another effect of the absorption of undesired nitrogen compounds is irritation of the blood-vessels sufficient to cause vasomotor constriction. This constriction of the surface vessels during fever is undesirable, as it prevents radiation and perspiration, and the skin becomes dry and hot and the temperature is increased. If the patient receives an extra amount of protein and an insufficient amount of carbohydrate, starch, etc., during the fever, the increased amount of ammonia compounds excreted by the urine, as just stated, due to maldigestion, may develop an acidosis of the system or a diminished alkalinity of the blood, and again we have an unnecessary death.

It has been shown that during fever the glycogen of the liver is diminished, and if starch foods are not administered it may entirely disappear from the liver, all the glycogen appearing in the muscles. This is suggested by Houghton as probably to represent a need of the cells for combustible material; again, another indication for food that will readily form glycogen. It is also, and has been, a well-known fact that the part of the body that burns first in protracted fever is the fat, and the more fat the patient has, other conditions being equal, the longer will probably his muscular tissue or solid tissue be protected. Also, in the absence of carbohydrate food his body fat will burn to such acid products as diacetic and beta-oxybutyric acids and to acetones, with the result of causing acidosis and death if the food is not corrected. Hence it is wise to conserve this fatty tissue by protecting it, and to prevent acidosis, by the administration of such foods (fats and starches) as will furnish material for the fever process, even though it is probably impossible for the patient, under the conditions, to deposit new fat. In other words, he needs more calories than he has been receiving.

Houghton suggests as a possible cause of a final condition of shock or vasomotor dilatation which so often occurs as a final in typhoid fever, failure of the adrenal glands. The shock condition in ptomain poisoning from absorption of depressent toxins, and the similar condition of surgical shock after abdominal operation in which the sympathetic abdominal plexuses are often of necessity injured, seem to show that absorption, especially of toxins produced by nitrogen decomposition, probably can inhibit the activity of the adrenal glands and cause just the condition of shock which we often see. This is one more reason for preventing this kind of toxemia, viz., that from an excessive amount of protein ingestion in typhoid fever.

While it is well known that glycogen and sugar (in other words, products that burn) can be metabolized from pure protein, as evidenced in true diabetes mellitus, it is certainly a disadvantage to the system to be compelled (and especially during a fever) to make its glycogen and sugar out of protein stuff. Therefore it

seems self-evident that starch should be a large part of the typhoid patient's diet, with the addition of sugar.

The ideal estimated diet of a typhoid patient should therefore be a small amount of protein, enough to represent, if possible, his daily nitrogen loss which will persist throughout the fever but has not been proved to be a cause of final dissolution; as much carbohydrate as he can comfortably digest without the production of flatulence, given in the form best suited to the individual patient; a little sugar, cane sugar, or, perhaps better, milk sugar, for his glycogen need; sodium chlorid sufficient for his hydrochloric acid need; possibly a few drops (not more than five) of dilute hydrochloric acid three or four times in twenty-four hours after a feeding that carries with it protein. The patient should also receive some fat, perhaps best in the form of a little buttered toast or a little cream, whichever it is found he best digests. The amount of water he receives should be sufficient, and it should be enough to cause him to pass at least a quart of urine in twenty-four hours, and better a larger amount.

Houghton suggests a diet and presents it in table form with the amounts of protein, fat, carbohydrate and calories appended. For an adult of ordinary size and weight the following represents his suggestions: His feeding intervals are two hours apart, from 6 a. m. to 8 p. m. (Three-hour intervals are better, perhaps, with longer intervals during the night.) At 6 a. m. he suggests a cup of coffee with 2 heaping teaspoonfuls of sugar and a dessertspoonful of cream, and a choice of 2 thin slices of toast, a breakfast biscuit or zwieback. At 8 a. m. he would give 2 heaping tablespoonfuls of cream of wheat gruel, with a handful of oyster crackers. At 10 a. m. he gives 8 ounces of vegetable soup. At 12 noon he allows a small baked potato mashed and made tasty with a tablespoonful of cream and a piece of butter the size of a domino, 2 thin slices of toast, hot weak tea with 2 heaping teaspoonfuls of sugar. At 2 p. m. he gives 2 tablespoonfuls of tapioca pudding and a handful of oyster crackers. At 4 p. m. he gives rice seasoned with 2 heaping teaspoonfuls of sugar and another domino of butter. At 6 p. m. he gives 2 thin slices of toast, more butter and a heaping teaspoonful of sugar; at 8 p. m., 8 ounces of vegetable soup, with more oyster crackers.

The vegetable soup above mentioned is prepared as follows: "Two ounces each of green or canned French peas, white dry beans, potato, rice, and noodles, and a half ounce of carrot are boiled in water at least four hours. Enough water should be added to make a quart, which would be sufficient for four feedings. The whole yields 760 calories, of which 6.3 per cent. is protein, fat less than 0.2 per cent., and 43.9 per cent. is carbohydrate. When ready to use stir up sediment and allow the patient to eat all (including noodles) with the exception of the pea and bean skins."

Houghton urges that the patient should be fed with a spoon, and that the food should remain in the mouth as long as convenient. He would give water between the feedings, and not with the meals. He recommends the increase of nutriment (probably meaning protein) as soon as convalescence is established. At the height of the fever, if these foods are distasteful or if the patient cannot eat the full quantity, he would substitute milk sugar in considerable amount.

As this diet recommended by Houghton does not contain iron, a patient on such diet should receive a sugar of iron (*Eisenzucker*) tablet, each 3 grains, 2 or 3 times in 24 hours, or 3 or 4 drops of the tincture of the chlorid of iron, in fresh lemonade, 3 or 4 times in 24 hours.

FOREIGN BODIES IN THE HEART

The traditional conception of the heart as the seat of the vital spark and the home of the soul still flavors our thoughts enough to cause interest in those occasional cases in which even considerable injuries to this organ have failed to lead to sudden or even remote catastrophe. And this feeling persists in spite of the growing experience of the surgeons that operative attacks on the heart are entirely feasible, and the common procedure in laboratory work of drawing a few cubic centimeters of blood from the heart of guinea-pigs whenever desired, the last operation being equivalent to tapping a human heart with a large caliber trocar and withdrawing one or two pints of blood. As regards the effect of wounds on the heart, the determining feature is less how much injury than where and how it takes place. Large secondary tumor growths may be found unexpectedly within the heart at necropsy, having produced no effect to indicate their presence, while small gummas in the vicinity of the bundle of His give rise to profound disturbances in function. So, too, with wounds of the heart, oblique penetrating wounds in the thick walls of the ventricles may not leak because closed by the systolic contraction, while wounds in the auricles usually cause fatal hemorrhage, and wounds in the pathways of conductivity are frequently instantaneously fatal.

Perhaps the most spectacular of pathologic conditions in the heart are those in which foreign bodies persist in the heart for long periods without causing manifest harm. This condition has been observed most frequently in cattle, which sometimes take nails, needles and similar pointed objects in their food; these articles may migrate from the stomach or esophagus into the pericardium, and sometimes into the heart itself. Galen knew of a deer which lived for a long time with the point of an arrow in its heart, and Weber, in 1600, describes the finding of an encapsulated bullet in the wall of the heart of a deer. In man such a condition has not been observed so often, but Zesas¹ recently collected and classified reports of 118 cases, which number, of course, represents far less than the actually

known cases. The number is rapidly increasing of late, especially through the use of the *x*-ray, which now sometimes discloses as located harmlessly in the heart a bullet whose whereabouts would otherwise never have been suspected. Increased frequency of necropsies also adds to the number of cases, for occasionally a foreign body is thus found in the heart as a necropsy surprise, as in the case described by Koch, who found a large nail in the entirely healed heart of a man who died from an absolutely unrelated condition. Of the 118 foreign bodies found, described by Zesas, 54 were needles and 38 were bullets, all the other objects being of diverse nature, with but two or three of each sort having been found. From the predominance of needles as foreign bodies in human hearts, and of nails, needles and pins in bovine hearts, it is evident that such pointed articles do tend to migrate from the point of entrance, however conflicting the experimental evidence on this point may be. Bullets, however, sometimes reach the heart most indirectly by way of the blood-stream, there being several instances in which the missiles have entered large vessels, especially the pulmonary veins, and from here have passed by gravity or by the force of the current into the heart. There are also a few striking cases in which bullets entering the heart have after a time escaped into the arterial system and caused embolism of most unusual character.

It would seem that an aseptic foreign body within the heart wall usually causes little disturbance, but if it is within the cavities there may be considerable arrhythmia and cardiac irritability until fibrinous deposits have immobilized and encapsulated it. In one case a bullet in the heart wall caused no trouble for three weeks, then it penetrated into the ventricle, where it could be seen by radioscopy tossing about violently and causing most violent arrhythmia, until it became stationary after six months. Evidently, then, operative interference will seldom be indicated when it is found by radioscopy that a bullet or other foreign body has lodged in the heart, unless infection is feared or pericardial hematoma is present. The possibilities of cardiac surgery in such cases are shown by the case of the patient operated on by v. Mantuffel, in which, after the wound of entrance on the anterior surface of the right ventricle had been sutured, the bullet was removed from the cavity of the same ventricle through an incision in the posterior wall, recovery being uneventful.

ERRORS IN DIAGNOSIS AS REVEALED AT AUTOPSY

The interesting and instructive oration of Cabot which appears in this issue, deserves some comment because of its possible misinterpretation by medical students and by younger practitioners. A general discussion of 1,000 cases in a brief time requires the omission of much detail which would greatly alter the general effect of the paper, though not the absolute figures.

1. Zesas, D. G.: Fortschr. d. Med., 1910, xxviii, 649. Briefly abstracted in THE JOURNAL, July 23, 1910, p. 358.

In every large general hospital a considerable proportion of the cases which ultimately reach the autopsy table are under observation for too brief a time to permit of any thorough study; and, what is more important, the patients reach the hospital already moribund and in such condition that any except the most superficial examination is impossible. Under such circumstances, many errors of diagnosis are made and, as a matter of fact, are quite immaterial. The duty of the physician at such a time is often that of easing the last hours rather than that of making a diagnosis.

Much more important, however, is the fact that while Cabot divides the errors into those of omission and those of commission, he fails to point out that there are very great differences between these two groups of errors. The percentage of errors of omission is determined only by the care of the pathologist. Few bodies are examined after death without showing conditions which were not suspected during life, and it is hardly probable that the science and art of diagnosis will ever reach so high a plane that errors will not be common. Most of the mistakes of this nature are immaterial, so far as the patient is concerned, for they would not usually in any way affect the treatment which the patient received during life.

A summarization of Cabot's table shows 1,535 cases; *i. e.*, many of the 1,000 individual autopsies are included more than once, and there are 602 errors of omission. In the absence of details, it may be admitted that some of these errors are material, but in many cases they are merely defects in anatomic diagnosis. It is, for example, unimportant that in a case of valvular disease of the heart some one or more of the defects are unrecognized clinically. The fact that in a given case the patient has a double mitral lesion instead of the single mitral lesion recognized during life, would in no way affect the treatment. We would not be understood as discrediting every effort at anatomic accuracy in diagnosis, but let us keep distinct in our minds that which is material and that which is not. For example, such a condition as acute pericarditis was overlooked in no less than 38 of 54 cases. It is probable that the great majority of instances of pericarditis occurred in the course of acute pneumonia or acute sepsis with endocarditis, both being such severe diseases, accompanied by such prominent thoracic changes, that an intercurrent acute pericarditis would be easily overlooked even though sought for. In truth such an omission is, from the patient's standpoint, of no consequence at all.

No less than 64 per cent. of the cases of bronchopneumonia were undiscovered clinically; but again lack of detail does not enable one to infer in how many of these cases the area involved was too small to permit of clinical recognition, or in how many of them the bronchopneumonia was a terminal incident in the course of some such affection as apoplexy, uremic coma, typhoid fever or carcinoma.

In contrast with the 602 errors of omission are 126 of commission. In a general way, errors of this sort are of greater importance and are more difficult of explanation although many of these also are easily understood.

The paper is one of great interest, but it may give an erroneous impression which could be avoided only by the inclusion of detail which of course the author did not attempt to give.

A SUPREME COURT OF SCIENCE AND ITS RELATION TO VACCINATION

In view of the fact that many of the issues which divide the country into opposing camps have a basis in some problem coming properly within the scope of scientific investigation, Prof. J. Pease Norton¹ of Yale University suggests that it would be well if we had under government auspices a court of technical experts to decide such issues. He proposes that the cases in question should be argued by legal counsel before a jury of scientists, who should be capable of differentiating between traditional scientific knowledge and scientific knowledge based on evidence.

It so happens that the particular case which Professor Norton uses as his illustration, and the one with which he seems most deeply concerned, is that of vaccination versus antivaccination. Surely nothing could be more satisfactory to the medical profession than to have the evidence of both the efficacy and the imperative necessity of universal vaccination marshaled *en masse* against the trivial claims of those who, unable to weigh the value of evidence, have earnestly, and in most instances with honest good-will, sought to deprive human society of its only effective guard against one of its most hideous adversaries.

Professor Norton himself seems to consider the matter as essentially a financial one, for he says: "Before such a court of science all interested parties could appear with experts; on the one side the virus manufacturers, the physicians, and those public health officials who believe in the practice, and on the other side the taxpayers and the people represented by the government"; and again, "the virus makers and the physicians are not the only interests which are interested in vaccinating the people for something."

Disregarding these insinuations, which seem to bear a *New York Heraldic* device, we would call the attention of the New Haven professor to the fact that this particular problem has long since, and repeatedly, been tried in the court of science, and before just such a jury as he must approve, consisting, as it does, of those scientists who are best fitted for the weighing of the evidence in a case involving disease and human health. Surely he must know that the juries of experts on infectious diseases and immunity, epidemiology and public

health, have always, and practically without a dissenting voice, decided the case in favor of universal, repeated and, where lack of understanding requires it, compulsory vaccination.

Current Comment

COLLEGE ENTRANCE EXAMINATION BOARD'S 1910 REPORT

The tenth annual report of the secretary of the College Entrance Examination Board,¹ recently issued, contains considerable data of interest to those who are trying to solve the problem of entrance examinations to medical colleges. This board was established a decade ago by a number of the leading colleges and universities to conduct entrance examinations, and its policies are controlled by those institutions, now twenty-nine in number. The magnitude of the board's work is shown by the fact that this year 45 college-trained examiners were appointed to frame the questions used at the examination held June 20-25, 1910, and 140 readers were required to grade the papers of the 3,731 students examined. These students represented 785 different secondary schools and sought admission to 70 different colleges and universities, 26 of which have medical departments. The extent of this board's work geographically is shown by the fact that examinations were held this year in 165 different cities and in 40 states, beside Hawaii, Canada, and 4 European countries. In the last five years the board has examined 15,927 students representing 1,688 different high schools, academies and colleges. By the passing of this board's examinations admission may be secured to almost any standard university in the country. The question may fairly be asked: Would it not be advisable for medical colleges to refer to this board for examination all students who do not hold diplomas from accredited high schools? Such action would do away with much of the confusion of tests which at present are employed and would at the same time furnish a sufficient guarantee that the student actually has the equivalent of a four-year high-school education.

TESTIMONIALS

There never was a "patent medicine" firm that did not claim that it had "thousands of unsolicited testimonials," and that "lack of space" was its only reason for not publishing more endorsements of its product. As a matter of fact the testimonial does not come as easily as these claims indicate. To get most of them requires some effort and at least a small expense. The gift of a dozen pictures to the individual who will testify to belief in the curative power of the nostrum is not much, to be sure, yet it is sufficient to make the adjective "unsolicited" an untruth. The fact is, the majority of "patent medicine" testimonials are far from being "unsolicited," as there are men who make a business—and a well-paying one—of getting such endorsements. They do so big a business that it becomes necessary for them to hire men to gather the material; the

employer furnishes the information—or "leads," as it is technically called—regarding the persons to be approached and the preparation for which the testimonial is needed. During the past week the following "classified" advertisement has appeared several times in at least one Chicago newspaper under "Male Help Wanted":

MEDICAL TESTIMONIAL GATHERERS—EX-
perienced; leads furnished; give references.
Address O 355, Tribune.

It would be interesting to learn the name of the concern which requires the services of the "medical testimonial gatherers," and it would be still more to the point to know what nostrums were to get the benefit of the "unsolicited" endorsements thus obtained.

ARSENIC IN PERNICIOUS ANEMIA

The action of arsenic in pernicious anemia is often so favorable as to suggest that it is a specific remedy for this disease. The results for a time are remarkable, and if the observation were terminated when the patient was at his best a cure would undoubtedly be frequently reported. If the remedy in use were some new synthetic a cure would certainly be advertised with great *éclat* without waiting for the final result. Without doubt, there are many cases of pernicious anemia in which arsenic has produced such an apparent cure, which physicians have not put on record because the praise of an official remedy does not afford a sufficient stimulus and because knowledge of the clinical history of the disease leads them to expect a relapse, which usually, but perhaps not always, happens. A case which is reported in this issue¹ is of interest because of this marked improvement referred to and because the author recognized the temporary character of the improvement.

THE FLUELESS GAS HEATER

As a means of warming a room there are few things more pernicious, from a hygienic standpoint, than those oil or gas heating apparatus which are used without a flue pipe to carry off the products of combustion. They not only vitiate the air directly by consuming the oxygen and replacing it with noxious gases, but indirectly they put a premium on insufficient ventilation by making it practically imperative that the windows and doors be shut in order to accomplish the object attained—that of raising the temperature of the room in which they are used. In view of the obvious objections to this form of household heating apparatus, therefore, an advertisement by a gas company which has recently appeared in most of the Chicago papers is much to be deplored. This advertisement sets forth the virtues of a "gas heater" which we are told "needs no flue pipe. . . it consumes less oxygen than one person and really purifies the air by burning dust and germs." Whether the promulgation of such dangerous untruths as these is due to ignorance on the part of the public service corporation which disseminates them or to the unfettered imagination of its writer of advertising copy, makes little difference. It should be stopped.

REVISION OF THE PHARMACOPEIA

Last week¹ we commended the action of the National Confederation of State Medical Examining and Licensing Boards, in suggesting a list of commonly used drugs as subjects of examination in materia medica and therapeutics. We suggest that this action should receive the attention of the Committee on Revision of the Pharmacopeia, which will have the responsible task of deciding the scope of the forthcoming Pharmacopeia. Although no one would contend that the United States Pharmacopeia should be restricted to the list referred to, there can be no question that considerable restriction and weeding-out are desirable. The adoption or rejection of the broad principle of wise restriction will determine whether the United States Pharmacopeia is to be a book of scientific materia medica or merely a book of pharmaceutical formulas and standards; or, in other words, whether the United States Pharmacopeia will be revised in the interest of medicine or in the interest of medicines.

THE INFLUENCE OF CALCIUM ON AMEBOID MOVEMENT AND ON PHAGOCYTOSIS

Recent investigations of the influence that various factors may have on phagocytosis have revealed that certain substances under suitable conditions may stimulate phagocytosis. Thus Hamburger and Hekma² found that small amounts of calcium are able to promote phagocytosis considerably by action on the leukocytes, and Eggers³ has shown that magnesium has a similar effect. These results were obtained from experiments with phagocytic mixtures outside the body; more recently Hamburger⁴ reports that minute quantities of calcium increase the activity of leukocytes in the living body as well. He placed under the skin capillary tubes containing bacterial cultures with and without calcium and then compared the lengths of the columns of leukocytes which entered the tubes; he also injected physiologic salt solutions with and without calcium into the intestinal canal and measured the columns of leukocytes attracted into capillary tubes containing bacteria and inserted under the skin of animals so treated. In both of these sets of experiments the results clearly indicated that the calcium increased the leukocytic immigration into the tubes; special experiments showed further that the calcium also stimulated phagocytic action. These effects were obtained not only with physiologic salt solution containing calcium chlorid, but also with a mineral water which contains a large amount of calcium; if a quantity of this water containing 0.06 gram of calcium was injected daily into the intestines of rabbits the number of leukocytes entering the tubes increased about 40 per cent. above that observed in untreated animals. It is possible that this biochemical property of calcium may prove of great interest from the therapeutic point of view.

Medical News

ILLINOIS

Quarantine Hospital for Moline. Plans have been formulated by Dr. August H. Arp, health commissioner of Moline for a new isolation hospital to be built immediately in the rear of the Moline City Hospital. The building will be of brick and two stories in height.

The Glidden Hospital.—The DeKalb City Medical Society has selected property just south of the city limits for the Glidden Hospital, for which James F. Glidden left a bequest of \$25,000.—The late Col. Isaac L. Elwood, DeKalb, in his will, made provision for the payment of \$25,000 to the institution.

Cases Dismissed.—The trial of Dr. William Hecker, Watseka, at Portage, Wis., charged with being responsible for the drowning of his wife at Fox Lake in August, was concluded, October 7, by the dismissal of the case.—In the case of Dr. Thomas D. Doan, Scottville, charged with an attempt to produce abortion, the jury returned a verdict of not guilty.

Personal.—Dr. Sidney G. Pratt, Buda, who has been ill for a year, has recovered and resumed practice.—Dr. Annie B. M. Alguire, Belvidere, who was operated on at the Presbyterian Hospital, Chicago, September 3, is reported to be doing well.—Dr. Karl F. Snyder, Freeport, suffered a compound fracture of the right arm while cranking his automobile, October 1.—Dr. and Mrs. Daniel B. Bobb, Dakota, celebrated their golden wedding anniversary, October 7.—Dr. Ralph E. Niedringhaus, Granite City, a member of the State Board of Health, was seriously injured in Granite City, September 28, in a collision between his buggy and an ambulance.—Dr. and Mrs. Harry H. Whitten, Peoria, left for Europe October 14.—Dr. Robert S. Denney has been appointed local surgeon of the Burlington System at Aurora, vice Dr. Augustus R. Reder.—Dr. Charles F. Smith, Kankakee, was appointed president of the Big Four Railway Surgeons' Association, at its meeting held in Indianapolis, October 4.

Chicago

Personal.—Dr. and Mrs. Samuel J. Walker and family, and Dr. and Mrs. Corcy H. McKenna have returned from Europe.

Unlicensed Practitioners Fined.—J. Kerasibowska, A. Nowagraska, Mrs. E. Bonanami, and George Drews, charged with practicing medicine without license, are reported to have been fined \$100 each.

Charity Ball.—A charity ball is to be given at the Blackstone Hotel, October 31, under the auspices of the board of managers of the Mary Thompson Hospital, for the benefit of that institution.

Old Hospital Building Demolished.—Wreckers have commenced demolition of the old building of the Presbyterian Hospital, erected in 1883, which will be replaced by a seven-story structure, provided for in the will of the late Thomas Murdoch.

Clinical Fortnight.—A clinical symposium is announced to be held in Chicago from November 7 to 19, consisting of clinics at various hospitals from 8 a. m. to 5 p. m. on each day. Headquarters for this series of clinics are to be maintained at Hotel LaSalle, where visiting surgeons may register and receive their cards of admission to clinics. Full particulars, programs, etc., may be obtained from Dr. Franklin H. Martin, 100 State Street, Chicago. Special society meetings will also be held during the clinical fortnight.

INDIANA

Personal.—Dr. Albert May, Crothersville, was painfully injured by a fall from the window of an interurban car.—Dr. John N. Hurty, Indianapolis, and William F. King, Columbia City, of the State Board of Health, began the "Health Week Campaign" in Warsaw, October 10.

Prevention of Blindness.—At the recent meeting of the Indiana State Medical Association, a committee composed of Drs. George F. Keiper, Lafayette; John N. Hurty, Indianapolis; Thomas B. Eastman, Indianapolis, and Albert E. Bulson, Jr., Fort Wayne, and Prof. Severance Burrage, Lafayette, was appointed to inaugurate a propaganda on the prevention of ophthalmia neonatorum, to work in cooperation with a similar committee of the American Medical Association.

Requests Removal of Member of Board.—The Indiana State Medical Association, at its recent meeting, endorsed the action

1. THE JOURNAL A. M. A., Oct. 8, 1910, p. 1292.

2. Biochem. Ztschr., 1908, ix, 275.

3. Jour. Infec. Dis., 1909, vi, 662.

4. Proc. Roy. Acad. of Sc., in Amsterdam, June 23, 1910.

of the board of councilors, through Dr. William H. Wishard, Indianapolis, chairman, requesting the removal of Dr. Solomon G. Smelser, Richmond, from the Indiana State Medical Board. Dr. Smelser is charged with incompetency and with not being a representative, in any true sense, of the high professional standing embodied by the State Medical Association.

MARYLAND

Chiari in Baltimore.—Dr. Hans Chiari, during his visit in Baltimore, was the guest of Dr. J. Whitridge Williams. Professor Chiari was accompanied by his daughter.

Contract for State Hospital Awarded.—The contract for the new building for the indigent insane at the Springfield State Hospital, Sykesville, has been awarded at an estimated cost of \$30,000.

Poliomyelitis.—The State Board of Health is investigating poliomyelitis, of which eight cases have been reported during the last four months. It is believed that the disease is very prevalent in Maryland. The board is preparing an exhibit showing the causes of infant mortality, including poliomyelitis, to be presented at the meeting of the American Association for the Study and Prevention of Infant Mortality to be held in Baltimore.

Personal.—Dr. John E. Legge, Oakland, sailed for Europe October 8.—Dr. Samuel Johnston, Baltimore, who was recently operated on at the Union Protestant Infirmary for appendicitis, has recovered.—Dr. John W. Chambers, Baltimore, is suffering from an infected hand due to an operation wound.—Dr. Florence Rena Sabin, associate professor of anatomy in Johns Hopkins University, has been given the degree of D.Sc. by Smith College, Northampton, Mass.

MICHIGAN

Detroit Tuberculosis Sanitarium.—The main building of the new tuberculosis sanitarium on Twelfth Street, three blocks from the city limits, is nearly finished and two cottages are practically ready for occupancy.

New Hospital.—Dr. William McBurney's hospital, Stambaugh, is finished and opened to the public. It is a three-story and basement structure and contains five private rooms on the second floor and a public ward on the floor above.

Work on Tuberculosis Hospital Well Under Way.—Good progress is being made on the Marquette County Tuberculosis Hospital at Morgan. Work on the building will be continued throughout the fall and winter and the institution is expected to be ready for occupancy by May 1 next.

Medical Inspection Starts in Saginaw.—Medical inspection of the East Side public schools of Saginaw has been inaugurated and the following medical inspectors have been appointed: Drs. G. Harry Ferguson, J. Neil McLean, Fred W. Edelman, H. Roy Wilson, David E. Bagshaw and John M. Campbell.

Milk Exhibit.—A milk contest was held in Detroit, September 26 and 27. President Larned of the Board of Commerce introduced the speakers, who were Health Officer Guy L. Kiefer and J. C. Weld, chief of the market milk bureau of the U. S. Department of Agriculture. Prizes were awarded and more than 1,600 persons visited the exhibit.

Personal. Drs. Willet J. Herrington and Charles B. Morden, Bad Axe, have returned from a trip to Great Britain.—Dr. Neal L. Hoskins, Detroit, has been appointed an ad interim member of the local board of pension examining surgeons, vice Dr. John F. Bennett, deceased.—Dr. Brett Nottingham, Lansing, has been appointed a member of the State Board of Registration in Medicine.

State Medical Society Meeting.—The forty-fifth annual meeting of the Michigan State Medical Society was held in Bay City September 28 and 29, under the presidency of Dr. J. Henry Carstens, Detroit, and the following officers were elected: President, Dr. Colonel B. Burr, Flint; vice-presidents, Drs. Charles T. Southworth, Monroe, Henry Kremers, Holland, Albert B. Simonson, Calumet, and Isaac L. Spaulding, Hudson. Detroit was selected as the place of meeting for 1911.

Appropriation for Antituberculosis Society.—The city council of Hancock has appropriated \$200 for maintenance in the city of a clinic for indigent sufferers from tuberculosis, and the Houghton County Antituberculosis Society is making preparations for the opening of a building for the clinic in Hancock.—The recent annual ball at Houghton realized more than \$650 for the Houghton County Antituberculosis Society.

New Home for Medical Society.—The new building of the Wayne County Medical Society was occupied for the first time September 12. On this occasion Dr. Angus McLean was inaugurated and a luncheon was given to the society by the retiring president, Dr. Arthur D. Holmes.

NEW MEXICO

Sanatorium Enlarged.—Dr. Abraham G. Shortle, who has been operating a sanatorium east of Albuquerque, will build additions so as almost to double the capacity.

State Tuberculosis Society Meeting.—At the second annual meeting of the New Mexico Tuberculosis Society, held in connection with the meeting of the New Mexico Medical Society at Albuquerque, September 30, the following officers were elected: president, Dr. Francis T. B. Fest, East Las Vegas; vice-president, Dr. John W. Colbert, Albuquerque, and secretary-treasurer, Dr. LeRoy S. Peters, Silver City.

Territorial Society Meeting.—The twenty-ninth annual meeting of the New Mexico Medical Society was held in Albuquerque, September 29 to October 1, and the following officers were elected: president, Dr. Francis T. B. Fest, East Las Vegas; vice-presidents, Drs. Robert L. Bradley, Roswell, and LeRoy S. Peters, Silver City, and secretary and editor of the *New Mexico Medical Journal*, Dr. George S. McLandress, Albuquerque, and member of the council, Dr. James H. Wroth, Albuquerque. The next meeting of the association will be held in Las Vegas.

NEW YORK

Medical Library Association Meets.—At the annual meeting of the Uica Medical Library Association, October 3, the following officers were elected: president, Dr. Raymond L. Baker; vice-president, Dr. Thomas C. Gifford; secretary, Dr. Angeline Martine; treasurer, Dr. John W. Rayhill, and librarian, Dr. Smith Baker.

District Medical Society Meeting.—At the annual convention of the Third District Branch of the Medical Society of the State of New York, held in Albany, October 4, Dr. Mark O'Meara, Kingston, was elected president; Dr. John B. Harvie, Troy, vice-president; Dr. Henry L. K. Shaw, Albany, secretary, and Dr. Sherwood V. Whitbeck, Hudson, treasurer. The next meeting will be held in Kingston.

Personal.—Dr. Elbert A. Palmer has resigned as secretary and manager of Dr. Strong's Saratoga Springs Sanitarium, and will open an office in New York City.—Dr. William Kemble, Kingston, had two ribs broken and sustained internal injuries in an automobile accident, October 7.—Dr. Robert G. Cook of Canandaigua has been appointed manager of the Western House of Refuge for Women.

New York City

Medical Colleges Open.—The College of Physicians and Surgeons, Columbia University, and University and Bellevue Medical College opened on September 28. Dr. William G. MacCallum delivered the opening address at the former institution, on "The Future of Medicine."

Ambulance Service for Insane.—For the first time in the history of the institution, ambulance service for handling cases in the psychopathic ward of Bellevue Hospital has been installed. Heretofore insane patients have been brought to Bellevue by patrol wagons or in private conveyances. Two trained nurses will go out with the ambulance on each call.

Personal.—Dr. Max Hulmer, Dr. Abraham L. Wolbarst, and Dr. and Mrs. Henry Koplik, have returned from Europe.—Dr. Frank E. Wilson, Brooklyn, has been nominated for Congress.—Dr. Joshua M. VanCott, Brooklyn, has been appointed a member of the State Board of Charities.—Dr. Antonio Stella has been appointed a member of the commission to consider the more normal distribution of population.

Columbia Needs Hospital.—Dr. Samuel W. Lambert, dean of the College of Physicians and Surgeons, in his annual report to President Butler and the University trustees, makes an urgent plea for a hospital in connection with the college. For this purpose he wants \$6,000,000 for building and endowment. He also states that the first report of research work done under the Crocker research fund will soon be ready for publication.

Cholera in New York Harbor.—On September 29 a man who had been taken from the SS. *Germania* from Marselles and Naples three days before, died from cholera at Swinburne Island. On September 25, a man died aboard SS. *Santa Anna* and was buried at sea. This vessel is still held in quarantine and there are two suspected cases. There was another suspect

on board the Hamburg-American steamer *Moltke*. Surgeon General Wyman of the United States Public Health and Marine-Hospital Service has conferred with Dr. Alvah H. Doty and the situation is not regarded as at all serious, but it has been deemed wise to enforce a five-day quarantine on all vessels coming from infected ports, and the force of United States inspectors has been increased abroad and passengers embarking for this port will be detained for five days before embarkation. No case of cholera has been brought to this port by a cabin passenger in forty years.

Harvey Society Lectures.—The sixth course of Harvey Society Lectures under the patronage of the New York Academy of Medicine begins October 15, when Prof. Hans Chiari of the University of Strasburg, Germany, delivers a lecture on "The Significance of Pathologic Autopsies and Other Pathologic-Anatomic Investigations." The succeeding lectures are as follows:

November 5: Prof. W. E. Castle, Harvard University, "Unit Characters in Heredity."

November 19: Prof. Jacques Loeb, Rockefeller Institute for Medical Research, "The Prevention of Toxic Action of Various Agencies Through the Prevention of Oxidation in the Cell."

December 10: Prof. Harvey W. Cushing, Johns Hopkins University, "Certain Clinical Aspects of Dyspituitarism."

January 14: Prof. Arthur R. Cushny, University of London, "Therapeutics of Digitalis."

February 14: Thomas B. Osborne, Connecticut State Agricultural Experiment Station, "The Chemistry of the Proteins."

March 25: Prof. H. Gideon Wells, University of Chicago, "Calcification and Ossification."

Work at the Budget Exhibit.—At the budget exhibit of the Board of Health, which is to be open for a month, the New York milk supply has been thoroughly discussed, and Dr. Lederle has asked for 17 additional inspectors, as inspection now must be carried into six states. Dr. Herman M. Biggs has asked for \$103,759 for research laboratory extension. He shows why this request should be granted. The entire cost of the research laboratory to the city was \$58,850 last year. If the city was not producing its own antitoxins it would have been necessary to purchase them at a cost of \$70,635, or nearly \$12,000 more than the laboratory budget for the year. Dr. Walter Benschel called attention to a serious condition at the Willard Parker Hospital, where there were only fifteen physicians last year for 1,500 patients and only 169 nurses, while 38 physicians and 300 nurses were required. He also showed that Riverside Hospital and the Kingstown Avenue Hospital, Brooklyn, were inadequate. Commissioner Drummond of the Charities Department said that the department had under its care 12,000 persons, with a working force of 2,000 in addition. He said that the department was run on a basis of such rigid economy that experts called it phenomenal. He did not see how the cost could be cut down when every day the population of the department increased.

PENNSYLVANIA

Hospital Asks Funds.—The trustees of the State Hospital for the Insane at Norristown, at their annual meeting October 8, decided to recommend to the next legislature an appropriation, aggregating \$290,000, aside from maintenance for building and improvements.

Personal.—Dr. John W. Goodsell, New Kensington, surgeon of the last Peary Expedition, is delivering an illustrated lecture on the trip, entitled "With Peary on the Dash to the Pole."—Dr. Jonathan C. Biddle, superintendent of the State Hospital for Injured Persons, Fountain Springs, was seriously injured in an automobile accident, October 1.

State Society Officers Elected.—At the sixtieth annual meeting of the Medical Society of the State of Pennsylvania held in Pittsburg, October 3 to 5, the following officers were elected: president, Dr. John B. Donaldson, Camonsburg; vice-presidents, Drs. Thomas N. McKee, Kittanning; David S. Funk, Harrisburg; Luther B. Kline, Catawissa, and John S. Mahon, Pittsburg; secretary, Dr. Cyrus L. Stevens, Athens; assistant secretary, Dr. Alexander R. Craig, Philadelphia; treasurer, Dr. George W. Wagoner, Johnstown; and trustees, Drs. Isaac C. Cable, York; George G. Harman, Huntingdon; William L. Estes, South Bethlehem, and Thomas D. Davis, Pittsburg.

Philadelphia

Portrait Presented College of Physicians.—A portrait of Dr. Adam Kuhn, one of the founders and the third president of the college, the gift of Mr. C. Hartman Kuhn, was presented to the College of Physicians at its first meeting, October 5.

Death of Dr. Shoemaker.—As we go to press, the death is announced of Dr. John Veitch Shoemaker, professor of materia medica, pharmacy and therapeutics, and clinical professor of

medicine and skin diseases in the Medico-Chirurgical College of Philadelphia, who died October 11, aged 58. Further notice will appear in the next issue of THE JOURNAL.

Cocain Seller Expelled.—At a meeting of the Retail Druggists' Association, held October 7, the name of Emil Greaff, who was recently convicted for the illegal sale of cocain, was stricken from the membership roll. A further resolution adopted by the association was to drop all "dope" preparations from the shelves of drug stores.

Pure Food Violators Fined.—Three firms of candy manufacturers, prosecuted by the State Dairy and Food Commission, for the alleged violation of the pure food laws, on September 26 paid fines of \$62.50 each in advance of hearings before Magistrate Beaton. Each was charged with manufacturing candy containing sulphurous acid. Ten other manufacturers had hearings October 1.

Seniors Work at Phipps Institute.—The senior class of the Medical Department of the University of Pennsylvania began work in the Phipps Institute for the Prevention and Cure of Tuberculosis on October 3. Four sections of the class will visit the institute each week. There are between 200 and 400 out-patients under the care of the Phipps Institute, and part of the students' work will be visits to the sick, but much time will be spent in the laboratory under the direction of Drs. Henry R. M. Landis and Dr. Paul A. Lewis. The sociological work will be directed by Alexander Wilson.

Personal.—Drs. Charles A. Oliver and William R. Newbold, and Dr. and Mrs. James A. Irwin have returned from Europe. —Dr. William W. Keen is in Berlin as the American delegate to the celebration of the one-hundredth anniversary of the founding of the University of Berlin.—Dr. John A. Kolmer, assistant bacteriologist of the bureau of health, Philadelphia, has been appointed pathologist to the Philadelphia Hospital for Contagious Diseases, vice Dr. Paul G. Weston, resigned. —Dr. DeForrest Willard, professor of orthopedic surgery in the medical school of the University of Pennsylvania, and Dr. J. William White, Barton, professor of surgery, have resigned.

Douglas Hospital Needs Funds.—The creditors of the Frederick Douglas Hospital have been sufficiently satisfied to prevent the sale of the building, but it has been announced, however, that the institution is badly in need of money to carry on its work. This hospital was founded 15 years ago by Dr. Nathan F. Mossell, for the purpose of treating persons of the negro race, opening the way for practical hospital experience to negro doctors and the establishment of a training school for negro nurses. It has treated 40,000 cases; the building it occupies was erected and equipped at a cost of \$100,000, but it bears the burden of a \$64,000 debt. Though the staff of physicians is composed of negroes, there is an advisory board of prominent white physicians. Among these are: Drs. S. Weir Mitchell, William W. Keen, G. H. MacKenzie, Howard F. Hansell, Charles K. Mills, James Tyson, Roland G. Curtin and John M. Baldy.

UTAH

Medical Inspection of Schools.—The Provo City Board of Education has adopted a system of medical examination for the city schools, and has appointed Dr. Ephraim G. Hughes, city physician, as medical inspector.

New Hospital Opened.—The Judge Mercy Hospital, Salt Lake City, opened to receive patients September 10. The hospital will accommodate a number of private patients and the third floor, devoted to employees of the Oregon Short Line, will accommodate fifty patients. The institution will be conducted under the supervision of the Sisters of Mercy.

State Society Meeting.—The Utah State Medical Association held its sixteenth annual meeting in Salt Lake City, October 3 and 4, and elected the following officers: president, Dr. Frederick W. Taylor, Provo; vice-presidents, Drs. Richard A. Pearse, Brigham City, William R. Tyndale, Salt Lake City, and Heber E. Robinson, American Fork; secretary, Dr. W. Brown Ewing, Salt Lake City, and treasurer, Dr. James N. Harrison, Salt Lake City.

WASHINGTON

Personal.—Dr. Frederick T. Hyde, Weston, Mass., has moved to Seattle to practice gynecology. —Dr. George K. McDowell, Spokane, has been elected president of the Southland Rubber Company.

City Hospital Staff Appointed.—Dr. James E. Crichton, commissioner of health of Seattle, announces the following staff

of the City Hospital: Chief medical inspector, Dr. Frank S. Borrus; medicine, Drs. Clarence A. Smith, Walter C. Lippincott and Herbert E. Coe; surgery, Dr. Park W. Willis; gynecology and obstetrics, Dr. Robert M. Stith; otology, laryngology and rhinology, Dr. C. Benson Wood; ophthalmology, Dr. Edmund B. Burwell; pediatrics, Dr. John B. Manning; neurology, Dr. Donald A. Nicholson, and dermatology, Dr. Louis H. Redon.

Hospital Notes.—The trustees of Noble Hospital, Seattle, have elected the following officers: president, Dr. Alfred Raymond; vice-president, Dr. Guy S. Peterkin; secretary, Dr. Louis H. Redon; treasurer, Dr. Frank T. Maxson, and superintendent and general manager, Dr. Charles S. Noble. The hospital will be located at Kilbourne and Woodland Park Avenues. The first section is to cost \$20,000.—The City Hospital has been opened in Montesano by Drs. Joseph H. Fitz and Guy E. Marcy. The building contains a large ward for men, a smaller ward for women and six rooms for private use.—The question is to be agitated in Seattle of the establishment and maintenance on Puget Sound of a floating hospital similar to that which is in such successful operation in Boston.

WISCONSIN

Anonymous Gift to Hospital.—The president of the board of directors of the Kenosha Hospital Association has received a draft for \$10,000 to be placed in the general fund of the hospital, with the announcement that the donor did not desire any name to be used in connection with the gift.

Women Physicians Meet.—At the annual meeting of the Wisconsin Medical Women's Association, held in Milwaukee, September 15, the following officers were elected: president, Dr. Belle P. Nair, Fort Atkinson; vice-president, Dr. Lucia Hoyer, Milwaukee; secretary, Dr. Minnie M. C. Hopkins, Oconto, and treasurer, Dr. Johanna M. Droppers, Milwaukee. The association passed a resolution authorizing the appointment of a committee to confer with the State Board of Health regarding a public educational campaign on germ carriers.

GENERAL NEWS

X-Ray Society Election.—The annual meeting of the American Roentgen-Ray Society was held in Detroit, September 28 to October 1, and the following officers were elected: Dr. Percy E. Brown, Boston, president; Dr. Frederick H. Bactjer, Baltimore, secretary, and Dr. Charles F. Bowen, Columbus, Ohio, treasurer.

Eye Men Meet.—The American Academy of Ophthalmology and Otolaryngology held its annual meeting in Cincinnati, September 19-21. The following officers were elected: president, Dr. John J. Kyle, Indianapolis; vice-presidents, Drs. F. Park Lewis, Buffalo, Samuel Iglauer, Cincinnati, Burt R. Shurly, Detroit; secretary, Dr. George F. Suker, Chicago (reelected), and treasurer, Dr. Secord H. Large, Cleveland. Indianapolis was selected as the place of meeting for next year.

Erie Surgeons Meet.—The nineteenth annual meeting of the Association of Erie Railroad Surgeons was held in Chicago, October 4 and 5. The following officers were elected: Dr. William M. Bemus, Jamestown, N. Y., president; Dr. Herbert F. Gillette, Cuba, N. Y., vice-president; Dr. Bertis R. Wakeman, Hornell, N. Y., secretary-treasurer (reelected); and Drs. John G. Kelly, Hornell, N. Y., Salem Heilman, Sharon, Pa., and H. P. Jack, Canisteo, N. Y., executive committee. The next meeting is to be held in the Astor House, New York City.

Protection of Eyes of Sailors.—A special effort is being made by the Surgeon-General of the Navy to provide for the protection of gun-pointers and other enlisted men whose duties require keen eyesight, and Surgeon Eugene J. Grow has been detailed to the U. S. S. *Solace* for special duty on this subject. The illumination of fire-rooms, of dynamo-rooms, and living spaces generally will have especial study, and recommendations will be made for the improvement of conditions. The eye-conditions of men detailed to adjust carbons on searchlights will be safeguarded in the future by special goggles or screens to cut off the actinic rays.

New Insurance Examiners Society. The Society of Insurance Medical Officers was organized in Chicago, October 3, the avowed purpose being "to establish an organized center of thought and action for the advancement of medical knowledge appertaining to life insurance by personal intercourse of its

members, presentation of papers, discussions, and such other methods as may from time to time be found desirable." The following officers were elected: president, Dr. Allison Maxwell, Indianapolis; vice-presidents, Drs. Calvin H. English, Fort Wayne, and Stephen S. Werth, Chicago; secretary, Dr. Edgar R. Hawley, Chicago, and executive committee, Dr. William F. Milroy, Omaha, C. Naumann McCloud, St. Paul, Joseph W. Johnson, Chattanooga, Russell M. Young, Des Moines, and Mason M. Lairy, Lafayette, Indiana.

FOREIGN NEWS

Cholera Death in England.—Foreign telegrams announce that the first death from Asiatic cholera in England occurred October 6, when a man who had been living in a lodging house in London, died in a public hospital.

Death of Professor Chrobak.—The cable brings word of the death of the noted Vienna gynecologist and surgeon, Professor Rudolf Chrobak, aged 70. He retired from the chair of gynecology two years ago, before reaching the age limit, as he felt the necessity of handing over the newly completed gynecologic clinic to younger men. He has been connected with the university since 1870, and has written numerous valuable articles on gynecology and obstetrics.

Death of von Leyden.—Cable dispatches announce the death, at the age of 78, of Ernst von Leyden, the eminent Berlin internist, to whom the Germans ascribe in large part the transformation in clinical instruction in the seventies. He was at first an army medical officer and then was called to a professorship at Königsberg, then succeeded Traube at Berlin and took charge of the first university medical clinic there in 1885. Since he founded the *Zeitschrift für klin. Medizin*, in 1879, his works have been published mainly in this journal. He was also instrumental in founding, in 1898, the *Zeitschrift für phys.-diätet. Therapie*, with Goldscheider, and with F. Klemperer, has published the *Deutsche Klinik* since 1900. He also, with Gerhardt and B. Fraenkel, published the *Zeitschrift für Tuberkulose- und Heilstättenwesen*, and also issued the *Zeitschrift für Krebsforschung*. All these journals used to contain frequent articles from his pen, especially on nervous diseases and cancer. He founded, in 1881, the Berlin Verein für innere Medizin and was long its president, and was the recipient of numerous honors at home and abroad during his long career.

LONDON LETTER

(From Our Regular Correspondent)

LONDON, Oct. 1, 1910.

Flies as Carriers of Infection

The Medical Department of the Local Government Board has for some time been conducting inquiries into the action of domestic flies as carriers of infections of various kinds, and has just published a third report on the subject. It contains observations by Dr. Graham-Smith on the ways in which artificially infected flies carry and distribute pathogenic and other bacteria, and there is also a summary by Dr. Bernstein of literature relating to the bionomics of *Epsiuma musca*, a parasitic fungus by which large numbers of flies are destroyed. The manner of catching and keeping flies and the general character of the experiments are described. Diagrams are given showing the anatomy of the insects and the manner in which they may deposit tainted material on any surface on which they either feed or walk. Abundant evidence of the infective power of flies which had been fed on pure cultures of disease-producing bacilli has been obtained, but it is regarded as improbable that under natural conditions such feeding could occur. The effects of contaminating flies with non-pathogenic and putrefactive bacteria have not yet been studied, and the effects of season, temperature, atmospheric conditions, different diets, irregular and scanty feeding, and other disturbing factors have not received sufficient attention. The conclusion is drawn that under exceptionally favorable conditions certain bacteria can be recovered from the contents of the alimentary canal and fecal deposits of infected flies for several days after infection and that these flies are capable of infecting certain materials on which they feed, for several days.

Suicide of a Physician in Consequence of an Unfounded Charge

Some time ago, an inquest was held on an old man whose physician committed suicide in consequence of an unfounded charge of causing the man's death. The inquest showed that

the man had died from natural causes and that the physician's treatment had been proper. The inquest on the physician himself has now been held. His name was Quodros and he was of Portuguese nationality. Under the will of the patient, he and members of his family benefited to the extent of \$1,000 in an estate of \$10,000. It is not unusual for patients to show their esteem for their physicians by legacies, but this circumstance seems to have aroused the unfounded suspicion of the relatives of the old man. They communicated with the police, but who made the communication and on what grounds was not disclosed at the inquest.

The detective who interviewed the physician said that the latter answered all questions satisfactorily but was highly nervous, which was attributed to his nationality. Next morning the physician was found dead in bed poisoned by prussic acid. He left a note stating: "I cannot face the disgrace of being charged. I am innocent." The coroner remarked that the unsatisfactory feature of the case was the fact that wrong information had been given to the police. There were, he said, persons with diseased imaginations who often did a great deal of harm by saying things without apparent cause and without understanding fully what they were talking about. The police were not bound to state who gave them the information, but he was sorry that the persons responsible had not come forward and by frankly admitting their mistake make what reparation they could to the relatives. As they had not done so he could only express his contempt at their action. The jury reached a verdict of "suicide during temporary insanity."

PARIS LETTER

(From Our Regular Correspondent)

PARIS, Sept. 30, 1910.

Annual Meeting of French Gynecologists, Obstetricians and Pediatricians

The sixth Congrès français de gynécologie, d'obstétrique et de pédiatrie was held at Toulouse, September 22-27. Although the date conflicted with that of the International Congress of Gynecologists and Obstetricians held at St. Petersburg, there was a large attendance at the French meeting. The date had been fixed a long time beforehand, and most French specialists had remained faithful to it. In the opening address, Dr. Kirmisson, professor of clinical surgery at the Paris college of medicine, who presided, remarked that in view of the danger of depopulation, the physician ought, in all obstetrical cases, to make special efforts to save the child, and therefore it was necessary to have a full and exact knowledge of the entire history. Dr. Kirmisson proposed that a medical record be kept, which should be given to the mother at the time of the birth, in which the physician in charge of the case should have indicated the various incidents of the pregnancy and delivery.

The question of the pathogenesis and the treatment of the pernicious vomiting of pregnancy gave rise to a very interesting discussion. Dr. G. Fieux, agrégé professor at the Bordeaux college of medicine, believes that it is important, in the first place, not to forget the existence of simulators—women who are frightened by pregnancy, and who by force of desire, succeed in vomiting and growing thin to such a degree that they think that the physician's hand will be forced, and that he will be compelled to carry out their wishes. It is necessary, moreover, to differentiate vomiting which is prolonged and aggravated by toxemia from vomiting due to mixed causes, in which the toxic action is due to the nervous state of the patient. In the latter cases, while treatment is easy (suggestion, change of surroundings, isolation in a sanatorium), the condition is all the more deceptive among the patients whose vomiting seems to be really in consequence of the persistent and increasing toxemia. Treatment at the beginning should be almost entirely expectant, although we possess the means of heroic treatment, namely, evacuation of the uterus, which, however, ought not to be used until certain symptoms show that the woman's organism is unable to triumph over the toxemia. While many remedies are recommended in order to put an end to the vomiting while permitting the continuance of the pregnancy, they are mostly useless. Though we possess no means of acting directly on the toxemia of pregnancy itself, we have a means which, by preventing the digestive auto-intoxication from reinforcing the toxemia of pregnancy, will put the patient in better condition for resistance. This is a milk diet. Unfortunately in certain cases, a milk diet may augment the gastro-intestinal intoxication by the putrid transformation of the casein. In

such cases it is better to give vegetable soup, water gruels, or even a little sheep's brains. In cases in which a milk diet is not tolerated, a hydrated diet in all its forms is prescribed (mineral waters, sweetened infusions, etc.). In cases in which the stomach rejects absolutely everything, the rapid dehydration should be combated by artificial serum given by hypodermic injections, or by high enemas. Pinard's experience leads him to conclude that as soon as the pulse-rate of a woman with toxic vomiting is permanently over 100, it is necessary to bring pregnancy to an end immediately (THE JOURNAL, May 14, 1910, p. 1623). Aside from all clinical considerations, such as pulse, temperature, loss of flesh, there are, according to Dr. Fieux, two complications which constitute immediate indications for an interruption of pregnancy; these are the appearance of polyneuritis, or of true icterus, characterized by the passing of biliary pigment in the urine. Whatever be the condition in which one finds one of these patients, it is never right, he says, to refrain from operation. However desperate the situation may seem, it is the physician's duty to evacuate the uterus as soon as possible. This procedure, rapidly executed, sometimes resuscitates an almost moribund patient. The best operative technic is that which without violence will permit total evacuation with the greatest rapidity. The use of laminaria tents, Hegar's bougies, and small Champetier de Ribes' bags almost always permits the rapid, if not easy attainment of a dilatation sufficient for the total evacuation of the uterus.

Dr. Lepage, obstetrician of the Paris hospitals, objects to the essayist's conclusions as too pessimistic. He believes that by appropriate treatment (a diet of milk, or milk and vegetables, with injections of artificial serum), abortion may often be avoided, while it is necessary to watch the patient closely in order to intervene without delay if necessary. It is difficult, however, to define the precise moment at which operation is necessary. A pulse of 100 is not an absolute criterion. In certain cases, moreover, the cessation of vomiting is not a favorable symptom at all; it indicates an extremely grave condition of which it is necessary to warn the family. Dr. Lepage held that in desperate cases operation should be resorted to, and that retention of the urine was an unfavorable sign. Dr. Achard, professor of general pathology at the Paris college of medicine, emphasized the tendency toward vomiting of certain individuals, in whom vomiting persists after the disappearance of the cause. In one case which he had observed, after a prolonged and absolutely useless course of milk diet, the patient's general condition improved and the vomiting ceased on a diet of broth and raw meat. Achard concludes therefrom, that one ought not to persist in a course of treatment which seems inefficacious, but should select another one, however opposed it may seem to the usual course in such cases. Dr. Pinard, professor of clinical obstetrics in the Paris college of medicine, said that he was astonished to hear Dr. Lepage advise against operation in desperate cases. Pinard believes that one should always attempt to save life; and that even when one foresees that the woman may die on the operating table, operation should be tried after the family has been warned.

Death of Professor Raymond

Dr. Fulgence Raymond, clinical professor of diseases of the nervous system at the Paris college of medicine, has just died at the Château de la Planchette, near Poitiers. He was 66 years old. He was educated at the veterinary school of Alfort, where he became, in 1866, head of the department of anatomy and physiology. He wished, however, to become a physician, and at 33 he began the Latin studies necessary for his baccalaureate degree, and entered the medical school. In 1878 he was appointed physician of the hospitals, and in 1880 agrégé professor at the college. He was a pupil of Vulpian and of Charcot, and at the death of the latter he was almost unanimously chosen to occupy his place, which he held from 1894 until his death. He had been since 1899 a member of the Académie de Médecine. He had published his clinical lessons on the nervous system, and a book on the neuroses and psychoneuroses.

Measures Against Cholera

In consequence of the increase of cholera in Italy, the sanitary service has taken new precautions at Marseilles. All ships arriving from the infected regions will undergo quarantine at Friuli. They will be admitted into the port of Marseilles only on presentation of clean bills of health from the French consul of the port of departure. Fruits and vegetables coming from the regions affected by the epidemic will be absolutely excluded at the frontier.

BERLIN LETTER

(From Our Regular Correspondent)

BERLIN, Sept. 22, 1910.

Personal

Prof. L. Kuttner, medical director of the Rudolf Virchow hospital, has been appointed director in chief of the same hospital as the successor of Professor Goldscheider.

Campaign Against Ankylostomiasis

At the second international congress for industrial diseases held in Brussels a short time ago, the subject of hookworm disease was thoroughly discussed by physicians of various nations. An extensive report on this subject was made by the experienced director of the hygienic institute in Gelsenkirchen, Professor Bruns. He commented on the importance, both for prevention and treatment, of the worm-carriers. The difficulty of this task is shown by the fact that there are in the Ruhr coal districts about 350,000 miners. Microscopic examination of the stools seems to be the only reliable means of detecting the presence of the hookworm. The feces are mixed with powdered animal charcoal and placed for several days in the incubator, so that the larvæ develop from the eggs. By this means, devised by Leos, Bruns has obtained twice as many positive results as formerly. Of 8,000 persons with infected stools simple microscopic examinations gave positive findings in 40 per cent, but the cultural method yielded positive results in 90 per cent. For the treatment, extract of male fern was used with the best results. Bruns had 5 cases of blindness in 40,000 treatments. In prophylaxis, the greatest cleanliness is important; especially all contact with the stools must be avoided and no defecation permitted in the mines. As a result of application of these measures there has been a very satisfactory reduction of typhoid and dysentery as well.

Marine Convalescent Home

A seamen's convalescent home has been recently opened in a suburb of Berlin for the reception of the officers and crew of the navy and merchant marine and for the officials of the colonies who have fallen sick on the sea or in foreign countries and are in need of care during their convalescence. Sixty beds are provided; they have been endowed by private benevolence. The kaiser and kaiserin made the first contribution to this sum. The entire cost was \$180,000 (750,000 marks).

Resolutions Voted by the German Medical Press Association

The general assembly of the Freie Vereinigung der deutschen med. Fachpresse was held at Berlin September 17, under the presidency of its business manager, Dr. Spatz, editor of the *Münchener med. Wochenschrift*. His report showed the satisfactory increase of the membership to about 150. Then the first and most important item of business, namely, the "reform in medical publication" was taken up for discussion. The following leading principles were adopted:

To avoid the excessive scattering of medical literature, the concentration of all publications in the regular periodicals is advocated. Especially the issuing of *Festschriften*, special reports, annuals, etc. on the part of the scientific institutions and hospitals should be rigorously limited. The issuing of inaugural dissertations as separate publications is also objectionable. The essential content of such works should be published in brief in some periodical by the author or the director of the institution. In original communications the greatest possible brevity should be the rule. Repeated citation of compiled bibliographies is useless and exasperating. Journals should as far as possible publish only such articles as are suitable to their special field. Preliminary reports should in general present only actual facts. Their publication is to be limited as much as possible. To obtain as complete an outlook over the borderland subjects as possible, it may be advisable for journals publishing abstracts to exchange abstracts. It would be very desirable if the great special societies would favor the development of abstract work by supporting a special abstract journal. J. Schwalbe, editor of the *Deutsche med. Wochenschrift*, stated that, thanks to the united efforts of the medical press and the manufacturing chemists, there had been a marked reduction in the production of medical write-ups for pay. The drug manufacturers who formerly secured for a certain fee the publication of fraudulent articles by physicians have abandoned this mode of advertising since they have learned that the elaborate efforts of these mercenary writers will not be published in the journals belonging to the medical press association nor abstracted if they have appeared in other journals. In accordance with a resolution of the previous general assembly

by the names of physicians whose cooperation for other reasons is not desired by the journals of the association were also placed on the "black list." Finally also those journals whose editorial principles are objectionable on ethical grounds were published by name. In consideration of the fact that many of the designated authors and organs are repentant and have reformed, it was resolved on motion of the speaker presenting the report that their names be stricken from the list, from which it is to be assumed that they will hereafter abide by the principles of the medical press association. Still more important was another motion presented by this speaker which will seriously affect the drug trade. In order to counteract the deception of physicians by the false statements by manufacturers with reference to many medicinal preparations, a resolution was adopted, binding on the members of the association, that advertisements of medicines and other preparations which are objected to by the special committee in charge of the matter shall not longer be accepted by the journals which belong to the association, and of course write-ups of these objectionable preparations will be excluded from publication.

On motion of Dr. Joachim, it was resolved that at the next general assembly the adoption of a uniform method of literary references in medical publications should be discussed and he was empowered to make suggestions. Finally on motion of Dr. Schnirer, editor of the *Klin. therap. Wochenschrift*, who referred to the objectionable occurrences which had accompanied the publication of the results of treatment with Ehrlich's "606," a resolution was adopted to the effect that the association announces that it will in future refuse to accept articles from authors who have communicated to the daily press the contents of an article before its appearance in the professional journal to which it has been presented.

VIENNA LETTER

(From Our Regular Correspondent)

VIENNA, Sept. 29, 1910.

Information About Free Hospital Beds

The decentralization of the hospital management in this city has often led to very alarming conditions; patients have been driven to several hospitals without obtaining a bed. Recently, when on account of climatic conditions there was really a scarcity of such accommodation, it has happened that children died in the arms of their mothers while seeking help for hours and hours without being admitted to the ward. Now in the Vienna General Hospital a bureau has been installed by the government which will receive every morning and every evening from all charitable institutions in this city by telephone authentic information of all vacant beds and beds to be vacated within the next twelve hours. As soon as one of these beds is occupied again, the fact will be telephoned at once to the bureau. Thus, whenever a bed is wanted, any policeman or doctor may at once inquire when and where the patient can be accommodated. This has been done especially under the pressure of the cholera scare, in order to prevent a prolonged stay of an infectious patient in a household.

The Hungarian Institutions for the Care of Children

From the data now obtainable, it appears that upward of 50,000 children are cared for by the government in Hungary, and that an equal number have outgrown this care and either have been given back to their parents or have become independent members of society. There are sixteen such institutions in the country, and every Hungarian-born child has a right to apply for state care, if it has no maintenance or supporter; no documents are asked for, but a special inquiry office tries to find out the true reason why the child is not cared for by its family. The system of bringing up such children, if they are healthy, in suitable state-controlled agricultural households is very useful, for it provides healthy laborers, badly wanted in the country. Ill or weak children are properly cared for in hospitals and other institutions attached to the children's homes. One very commendable feature of this scheme, which altogether costs the state some \$400,000 a year, is the continuation of the family bonds between the child and its relations. The child is, so to say, only entrusted to the state for education, as it was in ancient Sparta, but still the members of the family are free to visit it as often as they choose, provided they exert no bad influence. This very modern—in fact, unique—experiment on a great scale was much commented on by the members of the last Congress in Budapest, and really is due partly to political, partly to social considerations.

Marriages

FREDERIC ATWOOD BESLEY, M.D., to Mrs. Myra E. Busey, both of Chicago, October 6.

DANA WARREN DRURY, M.D., Boston, to Mrs. Elizabeth Small Boyce, at Baltimore, September 30.

HARRY B. HAYWARD, M.D., Hammond, Ind., to Miss Josephine C. Badenoch of Chicago, October 12.

ELMER EATON CURTIS, M.D., U. S. Navy, to Miss Rose Bearwald of San Francisco, September 20.

DANIEL BERNARD HAYDEN, M.D., Chicago, to Miss Julia Howard of Faymer City, Ill., October 8.

HENRY A. PFEIFER, M.D., Jackson, Wis., to Miss Frances Murray of Manawa, Wis., September 21.

HENRY CLAY MICHIE, M.R.C. U. S. Army, to Miss Louise Robertson, at Charlottesville, Va., September 30.

WALTER J. CLUTHE, M.D., Tell City, Ind., to Miss Marguerite Moore of Indianapolis, at Chicago, September 20.

WILLIAM WELDON PASCOE, M.D., Tacoma, Wash., to Miss Helen North Wright, at Dallas, Texas, October 12.

D. E. LYBROOK, M.D., Young America, Ind., to Miss Matilda Browne of Marion, Ind., at Indianapolis, September 26.

WILLIAM BURGESS CORNELL, M.D., Hawthorne, Mass., to Miss Bettie Grace Duncan of Lutherville, Md., October 11.

Deaths

Edwin Mills Nelson, M.D. Miami Medical College, Cincinnati, 1874; a member of the Missouri State Medical Association; for ten years managing editor of the *St. Louis Courier of Medicine*; at one time lecturer in the St. Louis Medical College; clerk of the board of health, and attending physician at the Webster Orphan Asylum and St. Louis Maternity Hospital; one of the organizers of the St. Louis Training School for Nurses; died at his home in St. Louis, September 20, from disseminated sclerosis, aged 62.

Delorme W. Robinson, M.D. Kentucky School of Medicine, Louisville, 1882; a member of the American Medical Association, and the National Association of Railway Surgeons; formerly president, later superintendent and secretary of the South Dakota State Board of Health; local surgeon of the Chicago and Northwestern Railway Company, and chief of staff of St. Mary's Hospital, Pierre; died at his home in that city, September 26, from pneumonia, aged 55.

Abijah I. Beach, M.D. Western Reserve University Medical College, Cleveland, 1856; assistant surgeon of the Ninth Kansas Volunteer Cavalry during the Civil War; formerly United States pension examiner at Council Grove, Kan.; from 1881 to 1883 physician at the Tulalip Indian Reservation, Wash.; for twenty months surgeon of the Washington State Soldiers' Home; died at his home in Renton, Wash., September 25, from nephritis, aged 74.

George Little, M.D. University of Pennsylvania, 1884; a member of the Medical Society of the State of Pennsylvania; formerly president of Schuylkill County Medical Society; health officer of Tamaqua borough; deputy coroner and registrar for Tamaqua district, and local representative of the State Board of Health; died suddenly, while making a professional call in Tamaqua, October 3, from heart disease, aged 48.

Thomas Everett Alsop, M.D. Medical College of Virginia, Richmond, 1887; a member of the Illinois State Medical Society, and formerly president of the Clinton County Medical Society, and Clinton County Board of United States Pension Examiners, and coroner and member of the board of health of Clinton county, and physician to the county almshouse; died at his home in Carlyle, September 22, from heart disease, aged 50.

Hubert Barnard Gudger, M.D. University of Pennsylvania, Philadelphia, 1909; of Asheville, N. C.; died in the Grand Union Hotel, New York City, October 2, from an incised wound of the throat, believed to have been self-inflicted while despondent on account of ill health, aged 25.

Orville William Collins, M.D. Harvard Medical School, 1887; of South Farmington, Mass.; a member of the American Medical Association; local surgeon for the Boston and Albany Railroad for many years; a member of the staff of the South Farmington Hospital; died in Jefferson, N. H., September 5, from intestinal obstruction, aged 59.

George R. Vincent, M.D. University of Vermont, Burlington, 1865; a member of the State Medical Society of Wisconsin; for several years president of the village board of Topsh, and a member of the state legislature in 1879; died at his home, September 11, from cerebral hemorrhage, aged 69.

George W. Shepherd (license, Ind., 1897); a member of the American Medical Association; a veteran of the Civil War, and a member of the local board of pension examiners; the oldest practitioner of Jay county, Ind.; died in Redkey, September 26, from cerebral hemorrhage, aged 71.

Peter E. Richmond, M.D. McGill University, Montreal, 1873; of Mount Pleasant, Mich.; a member of the American Medical Association; and a member of the local board of pension examining surgeons; died suddenly in Saginaw, September 19, from fatty degeneration of the heart, aged 64.

George Franklin Witter, M.D. University of Michigan, Ann Arbor, 1856; of San Jose, Cal.; a member of the American Medical Association, and formerly president of the State Medical Society of Wisconsin; was struck by an automobile and instantly killed, October 2, aged 80.

Joel M. Partridge, M.D. Hahnemann Medical College, Chicago, 1868; of South Bend, Ind.; a veteran of the Civil War; formerly a teacher in Berea (Ky.) College; died in Epworth Hospital, South Bend, September 30, after an operation for disease of the kidney, aged 75.

Fred Norris Brett, M.D. Rush Medical College, Chicago, 1896; a member of the American Medical Association; surgeon to St. Mary's Hospital, Green Bay, Wis.; and a member of the city council; died at his home, September 23, from pulmonary edema, aged 40.

Thomas Drury Edwards, M.D. University of Tennessee, Nashville, 1884; a member of the American Medical Association, and a specialist on diseases of the eye, ear, nose and throat; died at his home in Union City, Tenn., May 15, from gastric ulcer, aged 54.

Jared Spooner, M.D. University of Michigan, Ann Arbor, 1871; University of Pennsylvania, 1890; a member of the Indiana State Medical Association, and a veteran of the Civil War; died at his home in Peru, September 25, from multiple neuritis, aged 64.

Noah Howard Burt, M.D. University of Pennsylvania, 1895; president of the board of health of Ocean City, N. J., and medical inspector of the public schools; died at the University Hospital, September 24, after an operation for appendicitis, aged 50.

Benjamin F. Redshaw, M.D. Northwestern University, Chicago, 1899; of Curran, Ill.; a member of the American Medical Association; was instantly killed in a collision between interurban trolley cars, near Staunton, Ill., October 4, aged 46.

Henry C. Ganaway, M.D. Meharry Medical College, Nashville, Tenn., 1902; of Decatur; a member of the Illinois State Medical Society; was instantly killed, October 4, in an interurban trolley line collision, near Staunton, Ill., aged 35.

Elias Bedell Boyce M.D. Albany (N. Y.) Medical College, 1858; for two terms supervisor and for one term coroner of Rensselaer county, N. Y.; died at his home in Averill Park, September 23, from cerebral hemorrhage, aged 72.

William Cowpe Gardner, M.D. Long Island College Hospital, Brooklyn, 1892; a member of the Medical Society of the State of New York; died at his home in New York City, September 28, from heart disease, aged 55.

Whitfield Stephen Coursen, M.D. College of Physicians and Surgeons, New York City, 1848; said to have been the oldest practitioner of New Jersey; died at his home in Oak Ridge, September 25, from pneumonia, aged 86.

Alexander A. Walter, M.D. Imperial University of St. Vladimir, Kieff, Russia, 1872; for fifteen years a surgeon in the Russian service; died at his home in Grand Rapids, Mich., September 19, from diabetes, aged 55.

Charles D. Moore, M.D. University of Louisville, 1850; a veteran of the Mexican War, and a surgeon in the Federal service during the Civil War; died at his home in Cane Valley, Ky., September 26, aged 84.

Charles Joseph Dowling, M.D. Baltimore Medical College, 1906; of Springfield; a member of the Massachusetts Medical Society; died in Mercy Hospital, Springfield, September 26, from uremia, aged 30.

Archie Allego Sweet, M.D. Ohio Medical University, Columbus, 1905; a member of the Ohio State Medical Association; died at his home in Mingo Junction, September 30, from typhoid fever, aged 30.

Theodore Romeyn Hornblower, M.D. College of Physicians and Surgeons, New York City, 1871; of Jersey City, N. J.; died at his summer home in Allendale, N. J., August 7, from dropsy, aged 65.

Oliver Cromwell Wilson, M.D. Starling Medical College, Columbus, Ohio, 1897; formerly of Benwood, W. Va.; died at his home in McMechen, W. Va., September 24, from heart disease, aged 37.

Archelaus Smith Davison, M.D. Eclectic Medical Institute, Cincinnati, 1891; a practitioner for thirty-five years; died at his home in St. Clair, Mo., February 20, from organic heart disease, aged 68.

Angustus Clay Lucas, M.D. New York University, New York City, 1876; of Minoqua, Wis.; died in that place, September 6, from concussion of the brain following a fall down stairs, aged 56.

John W. Huckins, M.D. California Eclectic Medical College, Los Angeles, 1886; for many years a practitioner of Vallejo, Cal.; died at his home in San Francisco, September 24, from septicemia.

Henry Robert Wilson, M.D. New York University, New York City, 1873; of Santa Barbara, Cal.; died in the Loma Linda Sanatorium, March 27, from acute gall-stone colic, aged 64.

Albert Warren Shoup, M.D. Louisville (Ky.) Medical College, 1894; of Battle Ground, Ind.; died at St. Elizabeth's Hospital, Lafayette, September 12, from hepatitis, aged 53.

Oscar F. Thomas, M.D. Northwestern University Medical School, Chicago, 1882; died suddenly at his home in Lakeland, Minn., September 28, from heart disease, aged 67.

James S. Hollopeter, M.D. St. Louis College of Physicians and Surgeons, 1893; died suddenly at his home in Houston, Ohio, September 20, from heart disease, aged 51.

Roy Samuel Porter, M.D. State University of Iowa, Iowa City, 1903; of Moline, Ill.; died in the Watertown State Hospital, August 31, from general paresis, aged 35.

Louis Edward Cook, M.D. Eclectic Medical Institute, Cincinnati, 1882; of Forest, Ohio; died suddenly in his automobile, September 23, from heart disease, aged 51.

John Erhard, M.D. Long Island College Hospital, Brooklyn, 1896; died at his home in College Point, Flushing, L. I., September 28, from tuberculosis, aged 48.

John F. McKinney, M.D. Eclectic Medical Institute, Cincinnati, 1876; died suddenly at his home in Arcola, Ill., September 14, from heart disease, aged 63.

Frank Johnston, M.D. College of Physicians and Surgeons, Baltimore, 1883; died at his home in Trenton, N. J., September 24, from nephritis, aged 55.

Daniel M. Dunn, M.D. Western University, London, Ont., 1894; a member of the Arkansas Medical Society; died recently at his home in Dell, Ark.

Thomas Andrew Dillon (license, ten years practice, Ohio); an eclectic practitioner of Dayton; died recently at his home, from heart disease, aged 53.

William Burriss, M.D. Pulte Medical College, Cincinnati, 1886; died at his home in Burrton, Kan., September 13, from general breakdown, aged 71.

William H. Woodbury, M.D. Hahnemann Medical College, Chicago, 1866; died at his home in Chicago, October 6, from paralysis, aged 85.

James K. Stout, M.D. Kentucky School of Medicine, Louisville, 1866; died at his home in Omaha, September 26, from anemia, aged 67.

Max Levy, M.D. Tulane University, New Orleans, 1876; died at his home in New Orleans, September 16, from heart disease, aged 59.

Henry S. Smith (license, forty-seven years of practice, Ky., 1894); died at his home in Woodville, Ky., September 18, aged 92.

Lewis Sterling Bowles, a practitioner of Paoli, Ind., for many years; died at his home, September 18, from meningitis, aged 76.

Thomas Hay, M.D. University of Pennsylvania, Philadelphia, 1861; died at his home in Philadelphia and was buried, Nov. 4, 1909.

James Cherry, M.D. Jefferson Medical College, 1871; died recently at his home in Eden, N. Y., from bronchitis, aged 62.

Isaac N. Van Pelt, M.D. Cincinnati; died at his home in Lamar, Mo., July 22, from rheumatism, aged 72.

Pharmacology

Solubilities of the Pharmacopoeial Organic Acids and Their Salts

The determination of solubilities is a matter of great importance and the data given in chemical works are frequently unsatisfactory. It is often assumed that the determination of solubility is a very simple matter, whereas it is sometimes a difficult undertaking and the results obtained even by good observers frequently do not agree. This is probably due to the fact that very few men have worked under identical conditions, either of the purity of the substance or of the solvent, or of equally exact temperature, or regulation or care in securing the saturation of the solution. As data on solubility will enter into the next edition of the Pharmacopoeia, it is important that they should be as accurate as possible.

The work of Atherton Seidell on the solubilities of the pharmacopoeial organic acids and their salts published in *Bulletin* 67, of the Hygienic Laboratory, Public Health and Marine-Hospital Service, is opportune and will be of great value to the Committee on Revision. Some interesting conclusions are pointed out: his results in the examination of 35 compounds show that satisfactory agreement with the figures of the Pharmacopoeia exists only in the case of benzoic, camphoric, gallic and tartaric acids, in the aqueous solutions, and of benzoic acid, ammonium benzoate, ammonium salicylate, salicylic acid and phenyl salicylate in the alcoholic solutions. Of the remaining results, the differences vary from about 5 to 100 per cent. His experiments show that impurities do not affect the solubility sufficiently to make solubility determinations reliable as tests of purity. He does not advise the introduction of a standard method for solubility determinations into the U. S. Pharmacopoeia; he finds that in no case is it possible to predict from the solubility of a substance in alcohol and water separately what it will be in any mixture of these two solvents. The pharmacopoeial statements in regard to the reaction of a number of salts toward indicators should be revised. Seidell recommends certain improvements in the pharmacopoeial methods of assay and quantitative analysis.

This work is another example of the value of the scientific investigations which are being undertaken by the hygienic laboratory, a work which is affording great assistance to the advance of medicine in all its departments.

ADVERTISING SPECIALISTS CONVICTED OF FRAUD

W. H. Hale, A. S. Dyar and Roland Register Receive Heavy Fines and Prison Sentences

Again the federal authorities have done the public a service by protecting it from the machinations of medical impostors. W. H. Hale of Jackson, Mich., a quack with a penitentiary record, connected himself with A. S. Dyar and Roland Register, two "advertising specialists" who operated separate institutions in New Orleans. The scheme was to have Hale pose as a "noted London specialist" who was visiting New Orleans and who had offered to assist each of the local "specialists" in giving professional advice to such victims as they might get as patients. The mailing lists of Dyar and Register were brought into service and a "strictly personal" circular letter was sent to several hundred past and prospective victims of these two "specialists." The letters offered the "patients" an opportunity of getting the "noted" visitor's opinion on their cases if they would call at the office of the local "specialist." The details of the case follow:

Dyar and Hale were charged and tried separately from Register and Hale. In each case the defendants were charged first, with having used the post-office of the United States in the execution of a scheme and artifice to defraud, previously formed; second, with having conspired to commit an offense against the United States, namely, the use of the mail in the execution of the scheme to defraud as set forth in the

first count. The case against Dyar will be described; that against Register was practically identical with it.

The scheme to defraud was executed by the mailing, by the defendant Dyar, in the case in which he and Hale were defendants, of a "form" letter made to appear as if in type-writing, addressed to two thousand or twenty-five hundred different persons, some of whom had been Dyar's former patients, and had ceased to consult him, and others of whom had interviewed him with a view of taking his treatment but who never took treatment from him. The letter follows:

NEW ORLEANS, Feb. 27, 1908.

"Dear Sir:—I hope you will pardon this letter, but when you have read it, I know you will. It is natural that I feel a deep interest in those consulting me regarding their physical condition, and especially in those I have treated and also in those I am still treating. I feel that you know that I have been perfectly sincere and honest in everything that I have done and said, that I have always studied your case carefully and earnestly endeavored to deserve your confidence and friendship—in other words I have tried to act out the Golden Rule.

"The fear that I have not cured you has been causing me some worry. Meeting Professor W. H. Hale, M.D., of London, England, the noted expert in genitourinary diseases, who is just now on a visit to the United States, and with whom some years ago, I had a very close acquaintance, I took the liberty of consulting this noted gentleman about your case. He gave me much light and assured me that there was a safe and permanent cure for your trouble.

"So delighted was I, that I have, after much persuasion, secured Professor Hale's promise to spend next Thursday, Friday and Saturday and Sunday, March 5th, 6th, 7th, and 8th WITH ME, on which occasion he will meet you, give you a consultation and whatever advice necessary, for which there will be no CHARGE WHATSOEVER.

"When you stop to think that as a rule Professor Hale charges from \$100 to \$1,000, for consultation alone, you can possibly understand what it means to you to get the benefit of his valued services without any charge whatever, and because of his personal friendship for me, he has consented to see a limited number of patients, of whom you are one.

"Professor Hale is regarded as one of the greatest living specialists in Nervous, Chronic and Special Diseases. I, therefore, ask you to call at my office on either of the days mentioned: Namely: Thursday, Friday, Saturday or Sunday, March 5th, 6th, 7th, and 8th, at any hour that suits your convenience, between 9 a. m. and 8 p. m., as the doctor will be with me each day during these hours.

"I can hardly express to you the pleasure and satisfaction I experience in having Professor Hale visit me, and I hope that you will avail yourself of my efforts in your behalf.

"Yours in the cause of Health,
A. S. DYAR, M.D."

This letter was evidently designed to deceive those who received it into believing that it was a special letter to each of them. This deception was emphasized by the statement in each letter that Dyar had been much worried by the fear that he had not cured each of the twenty-five hundred individuals, and further by the statement that he had consulted "Professor W. H. Hale, M.D." in regard to the cases of each of the different individuals to whom the letter was sent, and further by the statement that "Professor Hale" had given him (Dyar) much light and had assured him that there was a safe and permanent cure for the trouble of each of the various persons.

The so-called Professor Hale who was represented as being of London, England, just then on a visit to the United States, was, as a matter of fact, and had been, for the last nine or ten years, previous to the mailing of the letter in February, 1908, a resident and a registered voter of Jackson, Michigan. Some years previously Hale operated the "British Medical Institute" at Jackson. This was a typical "lost manhood" concern and did a thriving business until Hale was prosecuted under the medical practice act and his "institute" closed. He then began his itinerant career as the "great London specialist."

Physicians of prominence and standing in the branches of their profession in which Hale was represented to be an expert showed that Hale was not known and had never been heard of by them and that if he had been a noted expert in the branches of the profession mentioned and "one of the greatest living specialists," as represented in the letter, they would have known of him. The proof in regard to Hale, however, went considerably further, and showed that in 1891 he had been indicted in the United States District Court in Denver, Colorado, for the crime of having used the mails in a scheme to defraud.

Hale's method in Denver consisted in practicing under the fictitious name of a Chinese doctor, "Dr. Gun Wa," who by the use of Chinese herbs that he professed to have, claimed to make remarkable cures. After the indictment in Denver, Hale seems to have fled to England, for in 1892 he was indicted in Liverpool, England, for the fraudulent practice of medicine, in connection with some other man, who together promised to cure catarrh and catarrhal deafness, and prem-

One of Dyar's advertisements; Register also advertised in a similar way. Hale for some years operated the "British Medical Institute" at Jackson, Mich. This was a "lost manhood" concern of the usual type.

used to furnish medicines for this purpose, all of which claims were false.

He was tried under this indictment in England, and sentenced to serve a period of eighteen months in the penitentiary at Walton, England. On his return from England to the United States, after the expiration of his sentence in England, he was arrested in New York under the Denver indictment and taken back to Denver where he was tried and convicted and sentenced to serve a period of eighteen months in the penitentiary.

After the expiration of his sentence, he seemed to have gone to New York, for in 1895, he was there indicted in connection with some other man for grand larceny of \$1,500 from one John McCallum, whom Hale told that he was suffering with serious kidney trouble, from which he would soon go crazy or die and of which they would cure him by means of what they called "radium cure." On these representations he charged McCallum \$1,500 for a small vial of "radium cure." Hale pleaded guilty to this indictment and was sentenced to a term of eight months in the penitentiary at Blackwell's Island, New York.

In addition to the above evidence, proving that Hale was not a noted expert, or one of the "greatest living specialists" as he was represented to be in the letter, several physicians from Ohio and Michigan testified regarding Hale's standing in the profession and as to whether or not he was entitled to practice medicine in Ohio where he claimed to have graduated from the American Eclectic College of Medicine, or in Michigan where he resided. The evidence of these physicians, two of whom were secretaries of the state boards of health of Ohio and Michigan, respectively, showed that the American Eclectic College had been investigated by these two states and was not in good standing, and the diplomas therefrom were not recognized as authority to practice medicine and that, although Hale had applied for re-registration under the laws of Michigan, his application had not been granted and he was not and had not been for some years authorized to practice medicine in Michigan. Of course, Hale produced physicians of his class from New York, Chicago and elsewhere, who swore to his excellent standing as a surgeon and diagnostician, and he referred to having license to practice medicine in Maine, Arkansas and Oklahoma.

Hale, Dyar and Register were found guilty and were sentenced to pay fines varying from \$1,000 to \$5,000 and to serve terms in the federal prison of from twelve to eighteen months each. United States District Attorney Charlton R. Beattie and Postoffice Inspector F. J. G. Pulsifer deserve great credit for the successful outcome of these cases; they have done the public a substantial service.

Correspondence

The Part Played by the American Medical Association in the Improvement of Medical Education

To the Editor:—It was with the keenest pleasure that I read your editorial in THE JOURNAL, May 21, 1910, on the reorganization of the Medical Department of Washington University, St. Louis. There is much that is of midnight darkness in American medical education; but, thanks to an awakening realization of conditions, there are also some rays of light, and one of them is this re-born medical school with its magnificent endowments and clinical facilities, its distinguished faculty, and chiefly its true scientific medical spirit, as evidenced in the educational standards laid down and in the selection of the men who will direct its medical destinies. As you suggest, its influence on medical education in that part of the country will be profound. May its educational requirements rise higher every year, and its light gleam brighter.

In this reorganization we see an illustration of what the American Medical Association, through its Council on Medical Education, is accomplishing for decent medical schooling in the United States. Many and diverse are the lines along which the Association is doing yeoman service; but in none of them does it appear that more credit must ultimately redound to this national Association, and a more lasting good to the whole people, than in its work for the reform of medical education.

The education and training of physicians in this country has been, hitherto, largely a commercialized disgrace and a national shame that has made the name of so-called American medical colleges, with a few exceptions, a by-word in other civilized countries. Disastrous enough has been this national crime to a credulous people. Who can compute the fearful toll in blood and life that has been exacted from them through the ignorance and incompetence of youthful, quiz-made physicians, suddenly turned loose on an indiscriminating public? How many of these men were morally and mentally unfit to assume the enormous responsibilities that are of necessity placed on the shoulders of every practicing physician? Armed with the miraculous sesame of M.D., and clothed with mystery, they have marched forth in annual armies to heal and to make glad; but alas, also, to learn many necessary things in sorrow and bitterness to themselves and to their patients. The majority of these men should have been more adequately trained for the practice of their profession, and some of them

should have been eliminated as not being especially qualified for the high calling of physician. Not the least of the advantages of a thorough preliminary and medical education is the remorseless elimination that the process silently accomplishes. A few naturally good physicians may thus fail to get their diplomas, but such an injury to few individuals is not to be compared for a moment with the great good that will come alike to the profession and the laity by the exercise of a long-continued selective and eliminative education that will well test the inherent worth of all candidates for the degree of doctor of medicine. Of course, no system of medical education can give the young doctor just stepping into private practice that knowledge which comes only with long years of experience and observation; but, other good things being equal, the more matured and the more thoroughly trained, the young practitioner, the less he will learn in his early practice at the expense of his patients.

It is high time that the profession as a whole wakes up to its great responsibility for the proper education of medical students. To condone the disgraceful standards that prevailed during the last half of the nineteenth century, and which still exist to a considerable extent, is nothing short of criminal negligence. The country is so well supplied with medical men that there cannot be the slightest danger of an under production, however much the standards for licensure may be raised. We have been paying too great heed to quantity; it behooves us in the future to look sharply to quality.

Already we have a few medical colleges of the first rank, standing out as beacon lights in the educational world; types of what medical schools should be, and will yet be in this country. We all know these schools both old and new and take a just pride in them and their high ideals, and in the power they are exerting throughout the land.

In the meantime, let a united profession strive to make for every school surviving the test, a standard in which a reasonable amount of preliminary education will be demanded for admission to its medical course; in which adequate and wholly satisfactory clinical and laboratory facilities must be furnished in compliance with minimal standards laid down by the proper authorities; in which full nine-month annual sessions are given; and in which at least a one-year hospital internship, or its equivalent, is required before the candidate is eligible to engage in private practice in any of the several states. With such standards or even approximately such standards, prevailing, I believe our dark problem of "150 medical colleges," would be solved for all time, and in an illuminating manner at that.

In conclusion, I wish to congratulate the American Medical Association and its leaders on what it has accomplished, and on the immense good that it will yet accomplish through the work of its Council on Medical Education. It has placed the medical profession and the general public deeply in its debt; and we have every reason to believe that this debt will be greatly increased in the future. The task before it of extricating medical education in the United States from the veritable slough in which it has lain these many years, is a labor and a problem worthy of the patience, perseverance, and intelligence that will finally bring about its solution.

GARFIELD G. MCKINNEY, M.D., U. S. Army.

Lumbar Puncture in Poliomyelitis

To the Editor:—Dr. Flexner's admirable paper on the important work of himself and co-workers on poliomyelitis, in THE JOURNAL, Sept. 24, 1910, p. 1105, interested me greatly. I disagree with him, however, in his advocacy of the routine and early use of lumbar puncture by physicians in suspected cases, and I cannot refrain from commenting on this question.

1. Until we have a definite serum to use, I see no value in determining by examination of the cerebrospinal fluid the presence of a slight lymphocytosis, especially since if done before paralysis has occurred, the puncture may be blamed by the relatives for the succeeding paralysis. As this lymphocytosis occurs early at a period when patients are rarely observed closely, lumbar puncture might be done later than the operator thinks he is doing it.

2. Is this slight lymphocytosis with subsequent clearing of fluid and constant increase of polymorphonuclear leukocytes characteristic of poliomyelitis only? In other words, I cannot see in what way it makes the diagnosis any more definite than the excessive perspiration, the irregular tremor, the irritability and extreme prostration, the frequent suppression of urine, etc., which mark the disease before paralysis occurs.

3. I have not had an opportunity to make many blood counts early, but have made them in over thirty cases shortly after paralysis, when an abnormal number of lymphocytes is present in the blood. Can this, a preferable method, not be used to help in the diagnosis?

4. Without any basis for my belief except personal convictions, I do not believe even so innocuous a procedure as lumbar puncture advisable in these extremely prostrated subjects with their infiltrative edema and hemorrhage of the cord and of the meninges.

Further, until a definite germ and serum or vaccine are determined I believe that physicians should observe great care to counteract flail joints, contractures and consequent deformity after the paralysis has occurred.

EDWARD E. MAYER, Pittsburg, Pa.

[The above letter was referred to Dr. Flexner, who replies:]

To the Editor:—The reason for recommending that lumbar puncture be performed in cases of doubtful infantile paralysis is in order to arrive at the earliest practical moment at a correct diagnosis. We are still very ignorant of the real extent of the epidemics of poliomyelitis and are therefore, prevented from exercising due caution in limiting its spread. What we need especially to learn is the frequency with which cases of poliomyelitis that do not develop paralysis occur, and what the leading symptoms are in these instances, since the so-called abortive cases may be found to be the insidious means of the transmission of the infection. Moreover, there occurs, not uncommonly, a form of anterior poliomyelitis which simulates epidemic meningitis so closely as to be frequently confused with that disease. I can speak with certain knowledge on this point because of the frequency with which we have been called on to supply antimeningitis serum for the treatment of cases of anterior poliomyelitis, in which meningitic irritation was an early and prominent feature.

I am of the opinion, therefore, that lumbar puncture provides the one clinical method at present known for clearing up the diagnosis of atypical cases of poliomyelitis or for determining the nature of the typical affection prior to the appearance of paralysis. Whether the increase in lymphocytes of the circulating blood will suffice for the same purpose I do not know, but the suggestion made by Dr. Mayer is valuable and should be carefully investigated. I do not believe, however, that it is necessary or desirable to defer employing lumbar puncture for purposes of diagnosis until a specific form of treatment is discovered. It would seem necessary merely to recall the great value of lumbar puncture as an aid to the diagnosis of tuberculous and some other forms of meningitis, for which there are at present no specific remedies, to justify the employment of the procedure.

The question as to whether lumbar puncture is likely to be abused in the hands of the unskilled and inexperienced is another matter. Our experience with the antimeningitis serum leads me to think that it will rarely happen that those unskilled or inexperienced will undertake to employ the puncture. Indeed, I should say rather that inexperienced physicians will call on surgeons or others who are familiar with the procedure rather than undertake to carry it out for themselves. It should be noted, furthermore, that in order to arrive at a diagnosis by this means, laboratory knowledge is required, since the fluid secured must be submitted to microscopic and chemical examination, a fact which, in itself, introduces a limitation that would tend also to confine the method to the skillful.

I believe, however, that Dr. Mayer's warning to exercise great caution so that a misunderstanding does not arise on the part of the friends of the patient, who might otherwise attribute the development of paralysis to the puncture, is timely, and I also agree with him in advising that the puncture

be not carried out in instances in which there is danger of such misinterpretation.

In conclusion, I would like to add a word on a point foreign to this letter. Since the publication of my paper in THE JOURNAL, I have learned of the prevalence of epidemic poliomyelitis during the past summer in three southern states, namely, Virginia, South Carolina, and Georgia.

SIMON FLEXNER.

American Medical Association of Vienna

VIENNA, Sept. 26, 1910.

To the Editor: No doubt a great many of the readers of THE JOURNAL, especially physicians who are contemplating coming to Vienna for graduate work, and also those who have studied here, will be interested in hearing that on September 21 the American Medical Association of Vienna left its old quarters in the Café Klinik, where it had been for six years, and moved into new and permanent club rooms at 28 Schloßergasse, opposite the main entrance to the General Hospital.

The club rooms consist of five large, handsomely furnished rooms most conveniently located, and will fill a long-felt want among the physicians who come to Vienna. The lounge-room is furnished with large armchairs, leather-covered divans, piano, etc. The reading-room and library is done in red, and the secretary's or business room in green. A pretty room has been arranged for the ladies, not only for the use of those studying medicine, but also for the wives and daughters of visiting physicians. Beautiful rugs cover all the floors and handsome curtains adorn the windows. The color schemes in each room have been worked out carefully, everything is harmonious and in good taste, and the A. M. A. of Vienna now has a home in which its members take pride. The association is greatly indebted to Dr. C. L. Chambers of Bismarck, N. D., Dr. D. B. Phemister of Chicago, Dr. W. H. Burmeister of Great Falls, Mont., Dr. F. W. Barton of Danville, Ill., and Dr. M. W. Jacobs of St. Louis, as it was owing to their efforts that the club rooms were established. The association selected Dr. Chambers for the presidency at an election held September 9. A good reference library is in the process of formation; a number of valuable medical works have already been contributed, and it is hoped that in a short time all the leading medical journals will be found on the library table.

The club rooms were formally opened with a large reception on the evening of September 21, and it was attended by nearly five hundred guests, including American physicians studying in Vienna, people from the American colony, and the various professors and instructors in the hospitals.

The present officers of the association are: Dr. C. L. Chambers, Bismarck, N. D., president; Dr. N. L. Linneman, Duluth, Minn., vice-president; Dr. M. W. Jacobs, St. Louis, secretary; Dr. R. F. Davis, Seattle, treasurer.

H. F. BENNETT.

Interstate Reciprocity in License to Practice

To the Editor: The subject of interstate medical reciprocity is perhaps trite but is one, I am afraid, which will constantly recur until it is settled right and to the satisfaction of higher-class graduates of from ten to twenty five years' standing. At present the bulk of the state laws are entirely in favor of the inexperienced tyro and the compend brigade. I am thoroughly in favor of good, stringent laws calling for high preliminary and professional requirements and I do not think any older practitioner should expect reciprocity unless he has above the average attainments which were in vogue at the time of his graduation. It is not to be expected that any physician of many years' standing, no matter how good a school he came from or how good his previous education, can successfully complete a state board examination on those fundamentals which he has long since forgotten save in their more or less practical application. In my opinion, boards were created to keep poorly qualified men out, not to harass those in good professional standing.

The question might arise: "How are we to know those of good standing without examination?" In answer I would say: Any man who can show evidence of having had a good preliminary education at the time of commencing the study of medicine and having subsequently graduated from a standard medical college, so recognized at that time, should be permitted to practice anywhere in the country. Any other course, short of a practical examination in the practical subjects, is a tyranny against which the masses of the older practitioners should rise up. A physician, after years of practice, may want to change his location for many reasons, among which may be unsuitable climate, unsuitable surroundings, lack of success owing to undue competition or because he desires to take up a specialty which is precluded in his present location. Now, under such conditions, no man or body of men has the right to say to a competent man, as measured by the standard above laid out: "You cannot practice here until you go through any examination we may prescribe." Take the men of the highest standing and best reputations in this or other countries, put them to such a general test and they will "fall down." See the fuss some of the physicians and surgeons of St. Louis made when it was hinted that they be given a practical examination on the subjects in which they were supposed to be expert. If a lot of theoretical stuff had been suggested they might have had reason to complain. The young graduate is primed for such examinations and it is right that he should take them, but the older competent physician of from ten to thirty years' standing should be exempt from such ordeals. A man of such years has business and family cares which prevent his preparing for examinations and it ought not to be required of him.

Reciprocity as we have it to-day is not reciprocity at all and the older, qualified members of the profession should be recognized, peacefully if possible, but they should be recognized.

H. E. DUNLOP, M.D.

Grim Advocate of Death

To the Editor:—In the Department of Medical Economics, in THE JOURNAL, October 8, page 1313, is an article written in reply to Senator Webster Grim, whose statements were published in the *North American* concerning the Pennsylvania Board of Health. That a board of health, that medical research, that proper hygiene and sanitary work was very important to any state, all this was admitted by Senator Grim, but the expensive scale and the manner in which Pennsylvania was conducting the said work is what Senator Grim denounced. I desire to ask the writer of the above article in THE JOURNAL of the A. M. A. what amount of money he is now receiving either directly or indirectly from the Pennsylvania Board of Health.

J. M. JOHNSTON, M.D., Huntingdon, Pa.

[COMMENT:—We fear that our correspondent did not carefully read the article referred to, or he would have seen that the entire article, with the exception of the introductory paragraph, was quoted from an editorial in the *Philadelphia North American*. As to how much the writer of the article receives from the Pennsylvania Board of Health, we suggest that the question be referred to the editor of the *North American*.—Ed.]

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

DETAILS OF THE WASSERMANN REACTION

To the Editor:—Please give an explanation of the Wassermann reaction and the reason for the different steps.

D. I. W., Cincinnati.

ANSWER. The Wassermann reaction rests on the phenomenon known as fixation of complement. The name "complement" has been given to a substance found in all animal serums. This substance is necessary for the action of the lytic antibodies which are formed in the blood by reaction against various pathogenic agents

or antigens. An antigen is any substance capable of provoking the formation of an antibody. It is believed that complement combines with the antibody and the latter with the antigen, making the reaction of lysis possible. Thus a hemolytic substance in the presence of complement attacks and dissolves red blood cells, setting free hemoglobin and rendering transparent an opaque suspension of red blood cells by taking the blood. If no complement is present the hemolytic antibody will have no effect on the red cells and no apparent change in the blood mixture will take place. Complement is destroyed by heating and may thus be removed from serum containing it.

Bordet and Gengou showed that the union of the antibody with the antigen (infectious virus) removed complement from the serum. Wassermann applied this discovery to the diagnosis of syphilis on the following assumption: If syphilis is active the serum of the patient must contain antibodies and if syphilitic virus or antigen is added to such serum it will combine with these antibodies and with complement and remove the complement from the serum. Later investigations showed that the antigen need not be a specific syphilitic product, although such an antigen is best for use. To test whether complement has been combined, Wassermann employs a hemolytic system consisting of the serum of a rabbit which has been injected with sheep's red blood corpuscles until an antibody has been formed in the animal's serum which is hemolytic against sheep's red blood corpuscles. If the serum of such a rabbit be mixed with sheep's red blood cells the hemolytic agent in the serum, with the aid of the complement in the serum, will destroy the red blood cells and liberate hemoglobin. But if such a serum be heated before it is mixed with red blood corpuscles complement will be destroyed and the serum will no longer be able of itself to cause hemolysis. Such serum is said to be inactivated, because it can no longer act after complement is destroyed. If, to an inactivated hemolytic serum, a serum containing free complement be added, the mixture again becomes capable of causing hemolysis and by this means it becomes possible to determine whether a serum under investigation contains free complement or not.

In order to make a Wassermann test it is necessary first to put together a syphilitic antigen, a serum suspected of containing syphilitic antibodies, and a small amount of guinea-pig serum to furnish the complement. This mixture is incubated for a certain period (45 minutes) at 37 degrees C. At the end of this time if there are syphilitic antibodies in the suspected serum they will have combined with the antigen and with the complement so that there will be no longer be any free complement in the serum. If this serum is now added to a mixture of sheep's blood corpuscles and inactivated hemolytic serum, no hemolysis will take place because complement has been removed. On the other hand, if the suspected serum contained no syphilitic antibodies no combination with the antigen will have occurred and complement will remain free, so that when sheep's corpuscles and hemolytic serum are added, the free complement will cause hemolysis.

A positive Wassermann reaction causes no change in the mixture of blood corpuscles and inactivated hemolytic serum, but in case of a negative reaction hemolysis occurs and the mixture of blood corpuscles and inactivated hemolytic serum becomes transparent and red from the liberated hemoglobin.

For the performance of the reaction the following are needed:

1. The syphilitic antigen obtained from syphilitic liver or extract obtained from the heart of the guinea-pig. These can be obtained ready prepared from certain laboratories. If made by a physician the organ should be ground with sand and warmed in a water bath at 60 degrees C. for an hour with 50 c.c. of 95 per cent. alcohol for each gram of the organ and filtered.
2. Guinea-pig serum to serve as a source of complement.
3. Hemolytic serum. Inject a 5 per cent. mixture of washed sheep's blood corpuscles into a rabbit every week or 10 days for 4 or 5 times. A week or 10 days after the last injection the blood may be removed from the heart, the serum collected, inactivated by heating at 56 degrees C. for half an hour, and kept on ice ready for use. This is also known as an amboceptor. It contains amboceptor (lytic antibody) but no complement.
4. Sheep's blood obtained from the jugular vein of a sheep in a sterile flask and defibrinated by glass pearls. It is washed with salt solution 2 or 3 times and then mixed with salt solution either in the proportion of 5 per cent. or 50 per cent., according as one adheres to the cubic centimeter plan or drop method for measuring quantities.

The blood serum of the patient to be tested is obtained as follows: Collect blood from the vein or finger, allow it to clot; remove the separated serum; centrifugate to clearness; pipette off into test tube and inactivate at 56 degrees C. for one-half hour.

Before the actual performance of a reaction it is necessary: (1) to standardize the amboceptor; (2) to see that extract alone does not bind complement or hemolyze sheep's corpuscles; (3) to see that the blood corpuscles have not hemolyzed; (4) to see that the complement is active.

The performance of the test is as follows: For each serum two small test tubes are required and several tubes for controls of the materials as above, these being repetitions of the tests of the material made before beginning the test. Add 10 drops of salt solution to each tube. Add a drop of serum to each of the 2 tubes used for a given serum. Then add 2 drops of organ extract to one of them. To one of the control tubes add 2 drops of organ extract. To each add a drop of complement. Shake tubes and place in incubator for one hour. Remove and add to each a drop of standardized amboceptor and one drop of 50 per cent. suspension of sheep's

blood corpuscles. Incubate for an hour and a half and then read the result. All controls with serums alone, with normal serums and with organ extract alone should be hemolyzed. If hemolysis has occurred in tubes containing suspected serums and organ extract, they are regarded as negative. If hemolysis has not occurred at all, or only incompletely, the result indicates that the patient furnishing the serum is affected with syphilis.

A list of articles on this subject was published in THE JOURNAL, April 9, 1910, p. 1226.

HOUSEHOLD APPARATUS FOR DISTILLING WATER

To the Editor:—I desire information concerning apparatus for distilling water which may be used in the household.

1. Which is the best type of apparatus?
2. What general principles should such apparatus have?
3. Is distilled water used in the navy and on steamship lines?
4. Are there any serious disadvantages in the use of distilled water for drinking purposes?

CLEVELAND FERREIS, New York.

ANSWER:—1 and 2. Small stills for this purpose can be obtained of chemical supply houses and are usually constructed so as to conduct steam from the tea-kettle or other vessel into a worm surrounded by cold water by which the steam is condensed. Lead pipes and vessels should be carefully avoided. The tubing through which the steam passes should preferably be of pure tin.

3. We understand that distilled water is used in the navy and on some sea-going steamers, but not on steamers plying the Great Lakes.

4. It has been asserted that distilled water is injurious on account of its osmotic properties. Animal cells are unfavorably affected by it and it is supposed that the effect on the mucous membrane of the stomach may be unfavorable. As a matter of fact, however, distilled water is seldom taken into the stomach without the presence of solids, which increase its molecular concentration, and experiment has shown that when distilled water is taken into the empty stomach, solids are secreted from the blood so as to approximate the molecular concentration to that of the blood. Its moderate use, therefore, probably does no harm. The principal sanitary advantage of distilled water can be more economically obtained by simply boiling and filtering.

EXAMINATION OF WATER FOR COLON BACILLI

To the Editor:—Please answer the following questions:

1. In the examination of water for colon bacilli what is the ratio between the total number of bacteria and the number of *B. coli*?
2. Does the increase or decrease in number of fish influence the total number of bacteria? I refer to our lake fish.
3. (a) Is there any fish bacillus known which closely resembles the colon bacillus? (b) If so, how are they distinguished?
4. Can you refer me to any literature on the subjects of Questions 1 and 2?

F. W. LINN, M.D., Cleveland.

ANSWER:—1. In sewage, roughly speaking, about one-tenth of the colonies which develop on ordinary media belong to the colon group. In a relatively pure or uncontaminated surface water there may be only one colon germ to one hundred or even one thousand of other kinds. There is never any constancy of ratio.

2. No such effect has ever been traced. Migrations from polluted to unpolluted waters may possibly explain the occasional presence of *B. coli* in certain waters, since fish living in sewage-contaminated streams have been found to contain *B. coli* in the intestinal contents.

3. No. As stated above, typical *B. coli* have been found in fish inhabiting sewage-contaminated waters.

4. Consult Amyot: "Is the Colon Bacillus a Normal Inhabitant of the Intestines of Fishes?" *Transactions of the American Public Health Association*, 1901, xxvii, 400.

ACUTE INDIGESTION AND SUDDEN DEATH

A correspondent who notes the reference in this department on the above subject, August 20, 1910, calls attention to an article by Dr. Douglas H. Stewart of New York, in the *American Journal of Obstetrics*, vol. lix, No. 3, 1909. The subject of the article is "The Protection of the Accoucheur and His Patient," and the above subject is taken up in the last paragraph. Dr. Stewart believes that acute dilatation of the stomach is responsible for sudden death in pregnant women and states that he has seen two sudden deaths which he cannot attribute to anything else. He further says:

"Theoretically, in a pregnant woman the sudden expansion of the stomach between an immovable uterus and a partly movable heart may be imagined. I am now washing out all painful stomachs and carry a stomach-tube as part of my armamentarium for use at the first symptom of cardioventral disturbance. After an interval of quite characteristic pressure symptoms, varying from one to three hours, the tympanites becomes very marked, the patient gasps and

gives up her life. If the patient has not been stripped and the abdomen examined, the accoucheur may be mortified and regretful. The whole matter may be summed up thus: If a pregnant woman has a dilated stomach with tension, pass the stomach-tube too early, for when the pressure effects show on the pulse at the wrist it will be too late. Never leave a tympanitic abdomen until the stomach-tube has been passed and there is a certainty that the stomach is not distended, for when death does occur it takes place with speed and without warning other than the symptoms of a 'little indigestion.'"

The Public Service

Medical Department, U. S. Army

Changes for the week ended Oct. 8, 1910:

Graham, George D., D.S., Sept. 15, reported for duty at Ft. Shafter, H. T.

Brown, Polk D., M.R.C., Sept. 28, left Ft. Sam Houston, Texas, en route to Ft. Logan H. Roots, Ark., for temporary duty.

Frick, Euclid B., R.-col., will take charge of the office of the medical superintendent, Army Transport service, during the absence of Col. H. S. T. Harris, at Camp Atascadero.

Wells, F. M., R.C., granted leave of absence for two months, to take effect about Nov. 15.

Gapen, Nelson, capt., ordered to report on Oct. 15, 1910, to the commanding officer, Army and Navy General Hospital, Hot Springs, Ark., for duty.

Hanson, Louis H., capt., ordered to Ft. Hamilton, N. Y., for duty, on being relieved by Captain Gapen.

Ford, Joseph H., major, relieved from duty at Ft. Riley, Kan., and ordered to Ft. Wadsworth, N. Y.

Richards, Robert L., capt., granted leave of absence for four months, with permission to go beyond the sea, effective about Oct. 3, 1910.

Brown, Polk D., R.C., ordered to Ft. Logan H. Roots, Ark., for duty during the absence on leave of Major Robert N. Winn, medical corps, which takes effect about Oct. 1, 1910.

Sherwood, John W., R.C., will proceed to Ft. Strong, Mass., for temporary duty.

Davis, William B., col., granted leave of absence for two months, with permission to visit China and Japan.

Medical Corps, U. S. Navy

Changes for the week ended October 8, 1910:

Kennedy, J. T., surgeon, detached from the *Indiana* and ordered to the *Louisiana*.

Olmesorg, K., surgeon, detached from the *Louisiana* and ordered to the *Virginia*.

Dennis, J. B., surgeon, detached from the *Virginia* and ordered to the navy yard, Philadelphia.

Gates, M. E., surgeon, detached from the navy yard, Philadelphia, and ordered to command the *Solace*.

Pickrell, G., surgeon, detached from command of the *Solace* and ordered home to await orders.

Lawrence, H. F., asst.-surgeon, ordered to Washington, D. C., for examination for promotion and then to wait orders.

Casto, D. H., P. A. surgeon, commissioned passed asst.-surgeon from July 12, 1910.

Hightower, C. T., acting asst.-surgeon, resignation accepted, to take effect Oct. 1, 1910.

Pratt, R. B., acting asst.-surgeon, detached from instruction at the Naval Medical School, Washington, D. C., and ordered to the marine recruiting station, Philadelphia.

Huff, E. P., asst.-surgeon, detached from the *New York* and ordered to the Naval Hospital, Camacao, P. I.

Hart, S. D., asst.-surgeon, detached from the *Albany* and ordered to the naval station, Olongapo, P. I.

Wickes, G. L., P. A. surgeon, ordered to the *New York*.

U. S. Public Health and Marine-Hospital Service

Changes for the seven days ended Oct. 5, 1910.

Ranks, Charles E., surgeon, directed to assume temporary charge at Portland (Quarantine), Maine, during the absence of Surgeon J. M. Eager.

Eager, J. M., surgeon, directed to proceed to Naples, Italy, on special temporary duty.

Nydegger, J. A., surgeon, detailed to represent the service at the meeting of the Medical Society of the State of Pennsylvania to be held in Pittsburg Oct. 4-6, 1910.

Lavinder, C. H., P. A. surgeon, granted 7 days' leave of absence from Oct. 1, 1910.

Grubbs, S. B., P. A. surgeon, granted 11 days' leave of absence from Sept. 25, 1910, on account of sickness.

McClintic, T. B., P. A. surgeon, granted 7 days' leave of absence from Sept. 28, 1910, under paragraph 191, Service Regulations.

Rucker, W. C., P. A. surgeon, directed to proceed to Elizabeth, N. J., on special temporary duty. Leave of absence for 10 days from Sept. 14, 1910, amended to read 7 days from Sept. 15, 1910.

Porter, Joseph Y., quarantine inspector, leave of absence for 30 days from Sept. 20, 1910, revoked.

Bean, L. C., acting asst.-surgeon, granted 5 days' leave of absence from Oct. 1, 1910.

Gustetter, A. L., acting asst.-surgeon, granted 6 days' leave of absence from Oct. 1, 1910.

Hallett, E. B., acting asst.-surgeon, granted 7 days' leave of absence from Oct. 1, 1910.

McDaniel, S. E., acting asst.-surgeon, granted 14 days' leave of absence from Oct. 18, 1910.

McLarty, A. A., acting asst.-surgeon, granted 7 days' leave of absence from Oct. 3, 1910.

Small, E. M., acting asst.-surgeon, granted 8 days' leave of absence from Oct. 3, 1910.

Tappan, J. W., acting asst.-surgeon, granted 20 days' leave of absence from Oct. 1, 1910.

Townsend, F., acting asst.-surgeon, granted 4 days' leave of absence from Oct. 6, 1910.

Weimore, W. O., acting asst.-surgeon, granted 1 day's leave Sept. 19, 1910, under paragraph 210, Service Regulations.

Board of Medical Officers convened to meet at Stapleton, N. Y., Oct. 7, 1910, for the purpose of making a physical examination of a cadet of the United States Revenue Cutter Service. Detailed for the Board: Surgeon H. W. Anstin, chairman; Passed Assistant Surgeon W. A. Korn, recorder.

Society Proceedings

COMING MEETINGS

Am. Assn. for Study and Prev. Infant Mort., Baltimore, Nov. 9-11.
American Association of Railway Surgeons, Chicago, October 19-21.
Hawaiian Territorial Med. Assn., Honolulu, November 26-28.
Ohio Valley Med. Assn., Evansville, Ind., Nov. 9-10.
Southern Medical Assn., Nashville, November 8-10.
Virginia, Medical Society of, Norfolk, October 25-28.

KENTUCKY STATE MEDICAL ASSOCIATION

Fifty-fifth Annual Meeting, held at Lexington, Sept. 27-29, 1910

(Continued from page 1309)

Officers Elected

The following officers were elected for the ensuing year: president, Dr. James G. Carpenter, Stanford; first vice-president, Dr. Joseph W. Pryor, Lexington; second vice-president, Dr. Byron E. Gianinni, Coalmont; third vice-president, Dr. David O. Hancock, Henderson; orator in medicine, Dr. William W. Anderson, Newport; orator in surgery, Dr. John R. Wathen, Louisville; delegates to the American Medical Association, Dr. Curran Pope, Louisville; Dr. William W. Richmond, Clinton, and Dr. Arthur T. McCormack, Bowling Green.

Paducah was selected as the place for holding the next annual meeting.

President's Address: Preventive Medicine

DR. J. E. WELLS, Cynthiana: Not all we have aimed at in public health problems has been accomplished, but our hopes have been realized in regard to medical education, and a higher degree of qualification is now required of those who are to become members of the medical profession. Medical societies have been doing work which has evidently been appreciated, as in the Kentucky State Medical Association the increase in membership since 1903 has been from 290 to 2,000. In view of all that has been accomplished in the method of prevention and treatment of such scourges as cholera and yellow fever, typhus and typhoid, scarlatina, diphtheria and epidemic meningitis, it needs little argument to prove the value of quarantine and of efficient medical inspection and protection. The conscientious physician of the present day is devoting his life not only to treating individuals who are already ill, but to combating epidemics. He does this by educating parents and children as to the prevention and spread of disease, and by impressing on them the need of clean and sanitary surroundings. In addition, he preaches the importance of pure food laws, the protection of the water supply, the extermination of parasites and disease germs, the protection of the sex relations, the future legislation of marriage and the crying need of a valiant fight against tuberculosis and other virulent and infectious diseases that are abroad in our land.

The public school should become the object of the physician's solicitude. Hygiene should be taught and a local physician elected as a member of the school boards, whose advice should be sought. Each county should have a paid medical inspector. The aim of modern education should be to foster the physical as well as the intellectual and moral development of the child. A good system of inspection and instruction would soon elevate the standard of our future citizens, as well as promote health and happiness. One of the most

important things within the scope of the doctor's work is the part he can take in medical legislation. Three important bills became laws at the last session of the state legislature: the bill to appropriate \$30,000 to maintain the State Board of Health, and the criminal abortion and the vital statistics bills.

We are proud of all that has been done, yet when we contrast this with what we wish to do, it creates a feeling of sadness among us. The spread of tuberculosis could be easily averted if state and county sanatoriums were established, and free dispensaries were maintained in smaller cities. The law against expectoration in public places should be made more stringent; laymen should be taught the dangers lurking in the public drinking cup and the communion cup; women should be urged to discontinue promiscuous kissing as a greeting, and the kissing of babies should be discouraged. The prevention of marriage between diseased and mentally deranged persons is not impracticable. The time may come when candidates for matrimony will have to produce certificates from physicians stating that they are free from all diseases and fit to perpetuate the race. The sex problem is perhaps the most far-reaching one of the age, and it lies with the physician to aid in solving it, as it is only to him such matters are confided. The world's idea of greatness has changed and it will change more. The great warriors who wore the laurel wreath because they had slain their thousands will not be comparable in greatness with the noble men of science who have laid down their lives for the advancement of the cause they loved.

Kentucky's Opportunity for Vital Statistics—How the Medical Profession Can Aid

DR. CRESSY L. WILBUR, Washington, D. C.: The value of the entire body of statistics collected by the state will depend on their completeness. Ninety physicians out of a hundred may comply with the law, and yet the total results for the entire state may be vitiated by the other ten who refuse or neglect to do so. If one leading physician in a community refuses to take the trouble to register his births, he will soon have imitators, who, very reasonably, will fail to see why there should be any discrimination of persons under the general statute; and in a short time, the whole registration law will become a farce. The remedy for such a condition is the prompt enforcement of the law, in all cases of known violation, and utterly irrespective of the social or professional prominence of the violators. Remember, such a violator of the act is overriding the law of the commonwealth for his personal convenience, impeaching the reputation of the profession for faithful observance of the legislation that it has itself urged, and, perhaps, working an irreparable wrong on the future of a helpless infant, from whose family he has taken money for discharging his proper professional service, which includes the registration of the birth. If any leniency is to be shown in such cases, it should be exhibited toward midwives, whose ignorance may account for neglect, and not toward enlightened physicians, whose knowledge of the scientific and sanitary uses of complete birth registration should render them less excusable for failure to comply with the provisions of a reasonable registration law. Nevertheless, the almost total lack of complete birth registration in the United States is due to the failure and neglect of physicians to observe such laws, and of other physicians, in the executive capacity of health officers, to enforce them. It is frequently true that midwives are much more particular about registering births than physicians. The remedy for this condition lies in the hands of physicians, and, starting out with a new organic law, it should be easy, through state and county organizations, to hold up the hands of the local registrars and of the state registrar in securing such a thorough compliance with the law for the registration of births, that the reproach now resting on the profession in this respect will be removed. It should not be said that physicians prescribe registration laws for others and refuse to obey them themselves. It should be considered professional misconduct to violate such statutes, and the county societies should take pride in scrupulous observance, by their members, of these necessary requirements.

DISCUSSION

DR. W. L. HEIZER, New Haven: It is unfortunate that at present we have no term that would include the sum total of the loss by death, or the loss by sickness, and the mental suffering entailed by diseases that are preventable and that are not prevented. The striking feature of Dr. Wilbur's paper is that only 53 per cent. of the area of the United States is a registration area. In the last analysis it is unquestionably proved that the preservation and perpetuation of human life is the most important factor to be considered. This is true, whether we consider it from the personal, social, state or national standpoint.

DR. W. W. RICHMOND, Clinton: The importance of vital statistics has never been fully appreciated by the average physician. It has been generally regarded a matter of curiosity and satisfaction, belonging chiefly to the statistician as a record for reference, with no direct personal benefit to the public. The prevention of disease and premature death depends largely on the successful operation of a law of vital statistics. A recognized nomenclature is very important, little less than necessary in the operation of the law, and thanks to the American Medical Association, which has brought so many blessings, the great need will doubtless be supplied.

DR. WALTER BYRNE, Russellville: That Kentucky has been one of the first Southern states to enact laws, to gather and compile such valuable assets, is very gratifying, and the enforcement of these laws bearing on vital statistics should be the duty of each and every physician in the state.

The Necessity for Properly Selected and Compensated City and County Health Officers

DR. J. N. McCORMACK, Bowling Green: As previous legislation had made the other health machinery almost perfect, on paper at least, the possibilities for practical life-saving work in every county and community are limited only by the extent to which the local fiscal authorities and people will co-operate in it. It should be known, however, that even with this advanced legislation and liberality there is little promise in this field in any county which does not have a well-trained health officer who can devote his entire time to the duties of his office. In order to make it easier to bring this about, and in the interest of both efficiency and economy, it is suggested that, except in cities of the first class, systematic efforts be made to combine the city and county health offices, so that both may be held by the same person. It should not be a political office, and the tenure should depend on the betterment of sanitary conditions, as shown by a steady decrease in the sick-rate and death-rate. As no one can be a health officer of the kind for which I am pleading and practice medicine, the salary should be such as is given to circuit judges and other officials in whom a high order of capacity and unceasing devotion to duty are required. In fact, it would be just as reasonable to expect judges to support themselves by the practice of law while serving on the bench, as to expect health officers to do their far more important and exacting work, requiring the highest order of training and judgment, and to practice medicine at the same time. Let us no longer deceive ourselves, or permit the people to be deceived, about a matter so vital to them. Until we can have a health officer in each county and city so selected and supported that he can afford to qualify himself fully for it, and make the prevention of sickness his life work, most of what this board and the medical profession stand for is but an idle dream in that jurisdiction. It should be known, too, that all this is even more important to country people and to those of small towns than to the residents of cities. Necessity forces the latter to some observances of the laws of health and, in consequence, the preventable sick-rate and death-rate is much lower with them than with the farmers, who ought to be the healthiest people in the world.

DISCUSSION

DR. JOSEPH M. MATHEWS, Louisville: Dr. McCormack pleads for a well-trained health officer in each county, who can devote his entire time to the duties of his office. There is but one way to bring about this ideal state of affairs, namely,

select the proper man, let him become educated in health affairs, and then compensate him for his labor.

DR. J. G. CARPENTER, Stanford: The health officer should be paid for his services, and the ignorance of the public is the reason that these officers have not been paid in the past. The people do not understand the great financial problems that are confronting them. They do not understand the great taxation we are subjected to from time to time; hence it is necessary to educate them in regard to the efficiency of boards of health and what can be accomplished by them.

DR. W. W. ANDERSON, Newport: As a united profession, let us make it unpleasant for the health officer who is a petty politician, who procures and holds on to his job on this account, and then we shall be able to get men who are sanitarians; or let us make sanitarians out of men we have.

DR. B. W. SMOCK, Louisville: No health officer can do good service and attend to a general practice any more than a physician can divide his time between the practice of medicine and the duties of a minister of the gospel. I have learned one very important fact from experience, and that is that a man is paid according to his ability for the work performed and the results obtained. The services of a good health officer are more valuable to the people than those of the circuit judge.

The Nature and Treatment of Splenic Anemia

DR. B. E. GIANNINI, Coalmont: The employment of drugs for the permanent or temporary relief of splenic anemia cannot be said to have been such as to inspire confidence in our ability to cope with the affection by that class of weapons. Still one reliable author (Taylor) has obtained temporary relief in the simultaneous administration of arsenic, potassium iodid and oxygen gas to the amount of 30 liters daily. The conservative physician will always follow paths that others have found to lead to desirable ends, and I hold that patients treated medically should be given potassium iodid and arsenic, while the inhalations of oxygen should be persevered in. Fowler's solution should be given in doses of 7 minims after meals, while potassium iodid is to be taken in doses of 5 grains in solution an hour before meals. I have great faith in the action of oxygen inhalations, and the patient should, in all cases, receive 30 liters daily.

DISCUSSION

DR. S. R. YORK, Center: I have seen only one case of splenic anemia. The patient was a colored man, aged 65, well developed, weighing about 180 pounds, and living in a malarial district in Tennessee. His previous health had been good. He complained of weakness, and of a large tender spleen. I thought that he had chronic malaria, and put him on quinin, iron and arsenic, but his disease went on, until I thought there was some malignancy about the case. At last he had purpuric spots and hemorrhages from the gums and stomach, when a true diagnosis was made, as we thought; death occurred in about two months after the appearance of the hemorrhages.

DR. J. T. McCLEMONDS, Lexington: I have seen two cases in the last ten years in Lexington. One patient, sent to me with a diagnosis of ulcer of the stomach, had had six hemorrhages, none being under 800 c.c. A diagnosis was not made. None of the symptoms of ulcer of the stomach was present, but an exploratory incision showed the entire mucus membrane of the stomach covered with small hemorrhagic points. The spleen was about one-third larger than normal. It showed a good deal of scarring and many adhesions. These adhesions were broken up; but a diagnosis was not made until two days after the operation, and it was hoped that starting up collateral circulation would have some effect on the disease. The patient died in a month following the operation.

DR. FRANK BILLINGS, Chicago: There are reports of cases on record in which the patients suffered from all the typical signs of splenic anemia, and in which thrombophlebitis, either of the splenic or portal vein, was the primary lesion. This was first written about by Dr. George Dock and by Dr. Warthin. Splenomegaly of the primary form, or splenic anemia, has no distinctive blood picture, except that there is a smaller percentage of hemoglobin than of the red cells. Usually, unless there is some infective process going on at the

same time, the white cells are small in number, and not large. There is a tendency in many patients to pigmentation of the skin, and at the same time these patients are apt to have other points or areas of the skin in which the pigment disappears. I have had several patients showing that feature. Hemorrhage from the stomach is due, in all probability, to the congestion of the splenic vein.

(To be continued)

AMERICAN ASSOCIATION OF OBSTETRICIANS AND GYNECOLOGISTS

Twenty-third Annual Meeting, held at Syracuse, N. Y., Sept. 20-22, 1910

(Concluded from page 1313)

Puerperal Wound Intoxication and Wound Infection; A Historical and Critical Review of Childbed Fever

DR. HENRY SCHWARZ, St. Louis: Isolated cases of puerperal fever have occurred at all times among civilized nations, but the epidemics of this disease appeared with the advent of lying-in hospitals and they became more dreadful when frequent necropsies were made in search of the cause. Oliver Wendell Holmes, in 1843, pointed out the contagiousness of puerperal fever and the means for preventing it. Semmelweis, in 1847, insisted on the same points, and demonstrated the correctness of his views by reducing the mortality from childbed fever in his Vienna clinic.

The medical profession of the United States has almost forgotten that Holmes has equal, if not greater claim, to be remembered as the discoverer of the nature of puerperal fever. Most text-books do not mention him, while they do justice to Semmelweis; the one pleasing exception is that of Barton Cooke Hirst.

At present the medical profession is fully acquainted with the nature of puerperal infection and with the means which will absolutely prevent it. In well-managed institutions, infection has been driven out, but nevertheless thousands of young mothers die yearly in the United States whose lives could be saved. The cause lies partly in the inadequate obstetrical training which the medical schools until recently provided; this cause, however, is now rapidly disappearing.

The principal cause lies in the fact that throughout the United States in the large cities the greater part of the obstetrical work is done by midwives, and that, with few exceptions, no laws exist regulating the practice of midwives. Such laws should be enacted and the schools for midwives should be under control of state boards. In Missonri, Louisiana, Ohio, Wyoming, Utah and the Philippine Islands, the laws provide for examination and registration, but not for control of these schools. Maine and Mississippi especially declare that their medical practice acts do not apply to midwives; the law of Mississippi says: "Females engaged in the practice of midwifery are not prohibited from such practice, but are entitled to engage therein without a license."

Scrotherapy and Bacterial Vaccines in Puerperal Septicemia

DR. HENRY SCHWARZ, St. Louis: Since 1895, I have used the various anti-streptococcus serums in cases of severe acute puerperal sepsis, which seemed hopeless under other forms of treatment. In the first case, in 1896, one of severe pyemia, the patient recovered; no bacteriologic diagnosis had been made. In all other cases cultures made from the blood proved the presence of streptococci; every patient died. When bacterial vaccines were recommended in acute infections, I not only considered such treatment hopeless and illogical, but feared that it would injure the reputation of vaccines in their legitimate field. In acute streptococcus infections billions of streptococci are found in the blood; they die by millions and their bodies are dissolved, liberating thereby the endotoxin. The formation of antibodies under such conditions is very feeble or at a standstill; to inject millions more of dead germs, with their endotoxins, shows as much sense as the injection of morphin into a patient dying with morphin poisoning. To

prove my contentions, I caused to be undertaken a series of experiments on rabbits, which prove the following points:

1. Vaccination after inoculation has no influence on the infection; all animals died in three days, the same as the control animal.
2. Vaccination simultaneously with inoculation has no influence on the infection; all animals died in three days, the same as the control animal.
3. Prophylactic vaccination produces immunity, but it must extend over a considerable period and vaccination must be stopped ten days before inoculation.

Intraperitoneal and intravenous vaccination prolonged the duration of the infection, so that animals so vaccinated died two days later than the control animal. Subcutaneous vaccination alone is effective and animals vaccinated every four days, from July 24 to August 28, and inoculated September 7, remained well, while the control animal died in three days. Excessive vaccination (from 50 to 200,000,000 in average weight animals) produced no ill-effect beyond a temporary refusal of food. The experiments are being continued.

Eight Cases of Acute Hemorrhagic Pancreatitis

DR. JOHN W. KEEFE, Providence, R. I.: These cases are of interest from several standpoints. Two patients recovered. 2 were operated on twice, 1 was operated on for acute hemorrhagic pancreatitis and 1, one-half year later, was again operated on and 4 gall-stones removed from the gall-bladder. Dr. Gile of New Hampshire reports a similar case. He operated for acute hemorrhagic pancreatitis and his patient was operated on about one year later by Dr. Irish and a number of gall-stones were removed. Another patient in this series was operated on for acute hemorrhagic pancreatitis and some months later a pancreatic cyst was removed. The events were reversed in one of the cases: 32 gall-stones were removed, but a stone was left in the common duct. Some months later the patient died from acute hemorrhagic pancreatitis. We should keep in mind the close relationship between infection of the bile passages and disease of the pancreas. While we should strive to make more accurate diagnoses in lesions of the upper abdomen, in obscure conditions, we should not delay but should operate early, as most of the conditions that simulate pancreatic disease require surgical interference.

Two Cases of Perforated Gastric Ulcer Causing Peritonitis

DR. T. B. NOBLE, Indianapolis: The pathology and symptomatology are analogous to perforation of any hollow viscus of the abdomen. The diagnosis must depend on the recognition of a demonstrable peritoneal insult, as evidenced by sudden, severe pain about the umbilicus or epigastrium, with local tenderness, followed by vomiting and the general symptoms of shock. Careful inquiry reveals a period of gastric disorder antecedent to the acute attack. Symptoms of acute peritonitis, more or less general in character, rapidly ensue, and it may be that they will overshadow all others at the time of observation, as happened in his first case. The vomiting of general peritonitis due to other causes has been continuous in my experience. But in these cases it occurred only once, and that very early at the time of perforation. It was not present in either case during the progress of the peritoneal inflammation.

Public and Private Hospitals

DR. JOSEPH PRICE, Philadelphia: Hospitals are extremely important in the education of young physicians and nurses, and in the clinical instruction of practitioners. The private hospital is largely responsible for the important specialties, and I value it most highly for the good work it has done along special lines. In the great medical educational centers—New York, Boston, Baltimore, Philadelphia, Chicago and New Orleans—the specialties should be advanced. If it is necessary for any one to have his wife or child operated on, the best is bad enough in the most refined specialty that we have. We should aim at that refinement of knowledge and skill that obtains in the treatment of diseases of the eye or in other special lines of work.

Cesarean Section

DR. J. H. CARSTENS, Detroit: Mrs. M., aged 40, mother of three children, widow for 10 years, married again one year

ago; she grew very fleshy. She became pregnant and toward the end it was found that the uterus was in a hernial sac and the abdomen pendulous, hanging down to the knee. On vaginal examination the uterus could not be felt. It was pulled up. Cesarean section was resorted to and followed by a smooth recovery.

High Operation vs. Cesarean Section

DR. WILLIAM H. HUMISTON, Cleveland: I believe that Cesarean section should be substituted for the high-forceps operation, which is attended with a mortality to the mother of 10 per cent, and to the child of nearly 21 per cent. The technic employed in the modern Cesarean operation has been so perfected, and the indications for the operation so widened that it is now frequently resorted to in order to give both mother and child greater chances for life. The rapidity with which this operation can be safely performed by an experienced abdominal surgeon is an important factor. Modern aseptic technic and favorable surroundings are essential and will insure practically a *nil* mortality, provided the mother has not already been infected by repeated examinations and efforts to deliver. In all cases in and near a city or town in which hospital accommodations are modern, the patient should be transported to such an institution for operation and convalescence. Many practitioners throughout the United States resort to the use of forceps needlessly, and are not impressed with the fact that the high-forceps operation is a major one, that it requires the hand of an expert obstetrician and a trained mind to avoid serious if not fatal injury to the mother and the sacrifice of the life of the child. Many physicians resort to the high-forceps delivery who would not think of undertaking a Cesarean section. If a physician did, and his technic was as careless as in the high-forceps operation, his mortality would be appalling. The general practitioner should not resort to the high-forceps operation without consultation with and the aid of an expert obstetrician.

Cesarean Section by the Small Median Incision Above the Umbilicus

DR. A. B. DAVIS, New York: Of the 78 Cesarean sections performed by me, the first 3 were done in tenements; the uterus was removed. Since Aug. 12, 1903, I have done the operation 75 times, and in no instance has the uterus been removed from the abdomen. Beginning with Case 4, a much smaller incision was used, half above and half below, and to the left of the umbilicus. In the 7 cases following this one, I gradually made the incision smaller and carried it higher up; until, Nov. 20, 1904, I, so far as I know, first independently conceived and practiced the small, high median incision, entirely above the umbilicus, in a woman, the twelfth in my series, being the second Cesarean section on this woman, the same as in Case 4. More than 2 years after this date the following allusion to the high incision was brought to my attention in Blundell's *Midwifery*, published in 1842. He says:

Some might think, perhaps, that in removing the fetus by the Cesarean incision we ought to make the opening above the navel instead of below. To this opinion, however, I can by no means accede; for if we make the incision above the navel the intestines will protrude more copiously, the region of the placenta will most probably be divided and on the abstraction of the ovum the uterus collapsing into the pelvis will sink below our reach, disappearing beneath the intestines, which fall over it. Place the incision, therefore, below the navel; by this collocation you will avoid these impediments.

Except in very recent writings, this is the only mention of the high incision above the umbilicus known to me. There is no reason why this operation should be singled out from all others as one which must be performed in great haste. It should be done with the deliberation called for in any other abdominal operation. There is great danger in doing otherwise. Several times I have found the intestines in front of the uterus; once it was injured. The incision should be long enough to allow easy delivery of the child, but the abdominal wall at this point in the full-term woman is thin and stretches easily. The small, high incision does not allow easy exposure or escape of the abdominal contents. Not infrequently all that we see is the uterus and a small portion

of omentum. This wound is away from the site of greatest strain on the abdominal wall, at a point reinforced by the recti muscles as they approach each other toward their upper attachments. It is small. I have never seen hernia following it. The liability to adhesion between the abdominal wound and the uterine wound is greatly diminished.

Secondary Repair of Complete Perineal Lacerations; Technic and Results

DR. E. J. ILL, Newark, N. J.: There are still many failures resulting from repair of complete laceration of the perineum. My first operation after the method to be detailed was done Feb. 1, 1891. The patient in a doubtful case of improvement had perfect retention power within a few months. Altogether, 56 cases showed remarkable and uniform success; 26 were complicated by other operations. In my operations I followed the principle laid down by Sanger as the Tait operation in 1887. The operation is essentially a flap-splitting operation, and can be divided into six distinct steps: (1) the incision; (2) the flap splitting; (3) suture of the rectum; (4) suture of the perineum; (5) suture of the vagina; (6) twisting of perineal sutures. Careful attention should be given to the bowels, and the diet should be free from residue as possible. Thorough aseptic conditions before, during and after operation should be had. I operate under constant irrigation. The finger should touch neither the wounded tissue nor the rectum; all handling of tissue should be done by sterile instruments. Incisions are H-shaped, beginning at a point just outside of the orifice of Bartholin's gland, extending downward and backward, just outside of the retracted sphincter. The cross-bar of the H is carried exactly across at the mucous membrane of the rectum and vagina. Two flaps are formed, an anterior and posterior, the posterior one demarcating the ends of the torn sphincter. The suture of the rectum is done with the finest catgut in the denuded tissue of the posterior flap. I prefer silver wire for the perineum. Three sutures take care of the sphincter. The fifth step consists of suturing the anterior flap of the vagina. Exactness must be exercised in coaptation of the wound when twisting down the sutures of silver wire. These sutures are cut on the ninth day. The after-treatment consists of moving the bowels in 48 hours, preceding the act of defecation by a sweet-oil injection. It is best to have the first movement with the patient on the left side, the nurse supporting the newly made perineum. Urination is usually normal. The patient should be well aware of her retention powers at the time the sutures are removed.

Intussusception in Infants

DR. HERMAN E. HAYD, Buffalo: This condition is much more common than is usually accredited, owing to ignorance and carelessness in making first examination. The diagnosis should be made early, as the symptoms and history are frank and dramatic in their onset. Too much importance is placed on the presence of a sausage-shaped tumor. Treatment is surgical and the mortality increases the longer the operation is delayed. Injections, irrigations and insuflations are too uncertain to be practical and scientific, but in recent cases they are often of value in assisting subsequent reduction after the abdomen is opened. The operation should be done quickly and no time should be lost in fruitless manipulations of the bowels. It is better generally to eviscerate at once and reduce the mass outside, than try to effect its reduction within the abdomen. Contrast the terrible mortality of appendicitis and extrauterine pregnancy of 25 years ago under medical treatment with the splendid results of to-day, due in no small measure to the work and teachings of this society, and we must not rest content until the same claim can be made for intussusception in infants.

Conservatism in Operations on the Uterine Appendages

DR. LEWIS C. MORRIS, Birmingham, Ala., read a paper on this subject, in which he drew the following conclusions:

1. No woman under 40 should have all of both ovaries removed except in the presence of tuberculosis or cancer.
2. Resection or amputation of diseased parts and plastic work on the tubes will occasionally be followed by conception.

3. Even in the presence of infection and more or less involvement of both tubes and ovaries plastic work, followed by pelvic drainage and the Fowler position, may be followed by regeneration.

4. Radical or sacrificial surgery and conservative or conservation surgery have about the same mortality but a vastly different morbidity.

5. Occasionally a secondary operation may become necessary which might have been avoided by doing radical work.

Intravenous Injection of Magnesium Sulphate in Bacteremia

DR. R. R. HUGGINS, Pittsburg, Pa.: In the study of drugs causing hyperleukocytosis, it was determined to find out, if possible, whether magnesium sulphate might act in this manner when administered intravenously. After a careful study in both rabbits and the human, it was decided that it did not produce a regular increase in the leucocytes when thus administered. During this study a number of intravenous injections were administered to human beings, and it was determined that the drug could be given intravenously without any apparent harm to the patient. Experiments show that a 1 per cent. solution in a normal saline solution will not produce hemolysis of the human blood. It will not precipitate the globulins when given in this dilution, nor have I seen any effect on the specific gravity of the urine. It was decided that 30 grains of magnesium sulphate in 8 ounces of normal saline solution could be safely administered intravenously to the average individual. It must be given slowly into the vein at a temperature of from 105 to 108 F., the time occupied in allowing this quantity to run into the vein being 20 minutes. If allowed to flow into the vein rapidly respiration becomes embarrassed and the patient complains of heat all over the body. It has been given in this manner 50 times either by me or by my assistants, and the result in many instances has been gratifying. It has been given at intervals of 24 hours for several days. It was during this study that it was determined to try the use of this drug in a patient suffering from puerperal infection. In a number of cases which were beginning a typical course, similar to that in patients who died in spite of all treatment, the patients have been treated by intravenous injections of magnesium sulphate with apparent benefit. Its use has been limited almost entirely to the treatment of puerperal infection, and the number of cases treated are too few to draw any conclusions.

Fibromyomata of the Uterus, Complicating Pregnancy, Labor and the Puerperium

DR. R. W. LOBENSTEIN, New York, read a paper which was based upon a study of one hundred cases occurring at the New York Lying-In Hospital. The chief deductions from this series of cases are:

1. A myomatous condition of the uterus predisposes to sterility. Parvin states that while the average sterility is 1 in 8, it is 1 in 3 in women with myomata. Charpentier's figures correspond closely to these.

2. The tendency to abortion is increased. In the bad cases, both spontaneous and artificial abortion may prove difficult to handle by the natural channel and most dangerous to the life of the individual. In the severe cases in which it is difficult to gain access to the cavity of the uterus proper, and in the presence of real hemorrhage, laparotomy is the operation of choice.

3. The majority of the patients who do not abort early proceed through pregnancy, labor and the puerperium with few or no symptoms; therefore, operative interference is rarely indicated during pregnancy and is as a rule middle-aged midwifery. This statement is made cautiously, as in the minds of many it will be open to criticism. The operation of myomectomy during pregnancy is just now very popular, but it is rarely indicated. The results of myomectomy are none too good. Consider, for instance, the report of Carsten's 150 cases: The operations were performed before the seventh month. There were 22 abortions; 13 deaths. Occasionally it may be wise to do a myomectomy, and occasionally necessary to do hysterectomy, but as a rule conservatism should be the watchword.

4. Nature accomplishes wonders at the time of labor, overcoming any apparent dystocia, in a large percentage of cases; when delivering avoid all possible trauma to the tumor.

5. Finally, with the development of the symptoms of gangrene in a myoma, in the puerperium, operate early, to save the life of the patient.

Puerperal Eclampsia

DR. E. C. ZINKE, Cincinnati, read a paper on this subject, in which he gave a brief analysis of ninety cases of puerperal eclampsia, and a critical review of the treatment of this disease. He drew the following conclusions:

1. Not all cases of puerperal eclampsia are alike; much depends on the extent to which the kidneys and liver are involved. The so-called malignant form, as the term implies, is fatal from the beginning; the so-called benign variety ends in recovery, sometimes in spite of the treatment adopted. The variety of mean gravity is without doubt favorably influenced in its course by careful and judicious treatment.

2. The prognosis for both mother and child is much worse when the convulsions supervene during pregnancy, the maternal mortality ranging from 35 to 50 per cent., and the fetal mortality from 65 to 75 per cent. The prognosis of intrapartum convulsions is more favorable, maternal as well as fetal, and amounts to about 25 per cent. The maternal mortality of postpartum convulsions is as a rule about 7 per cent. In my experience, having had but 2 cases, it is 50 per cent.

3. The most important treatment of puerperal convulsions is prophylaxis before the appearance of symptoms as well as before the eclamptic attacks when prodromal signs exist. The patient must be protected from injury during the convulsions and the duration and frequency of the paroxysms should be controlled and abbreviated, medicinally rather than surgically. Veratrum viride in sufficiently large doses is the remedy *par excellence* to reduce the blood-pressure and the pulse frequency. Hot baths and hot packs judiciously employed, and free but not excessive catharsis, strict milk diet, and the recumbent position are of almost equal importance.

4. Chloral in large doses by rectum, if the patient is very restless during the interval of the attacks, is a good remedy. Chloroform inhalations, especially if of long duration, should be regarded as a source of great danger. The same may be said of frequent and large doses of morphia, both of these drugs having their ardent advocates.

5. Antitoxin treatment may play an important part in the future in the treatment of eclampsia.

6. Saline solution and sugar water instillations can do no harm and may do a great deal of good.

7. If, of late years, the maternal mortality of puerperal eclampsia has been reduced at all, it is the direct result of careful prophylaxis and intelligent medical care. Surgery has contributed nothing to it. The dictum, "assist in labor, but do not induce it," or "treat the convulsion and let the pregnancy take care of itself," is better than the dictum, "empty the uterus as soon as possible in every case of puerperal convulsions, no matter what the period of gestation."

8. Decapsulation of the kidneys, manual, balloon and instrumental dilatation, especially the old-time accouchement forcé, are in my opinion hardly justifiable, and should have no place in the treatment of puerperal eclampsia.

9. If, however, the symptoms are very threatening and the medical care above described fails to bring about prompt amelioration in the patient's condition, an early delivery may be desirable. If the patient be near term, but not in labor, the conservative Cesarean section should be selected. If the patient is just within the period of viability, vaginal hysterotomy is the proper procedure. If the fetus is not viable, before the end of the sixth month of gestation, deep cervical incisions will easily relieve the uterus quickly of its contents.

10. No one has a right to perform any of these three operations unless experienced and familiar with the technic of each. And in every instance the patient must have the benefit of strict asepsis. Without these requirements it is best to rely entirely on the medical care above outlined.

Pelvic Reflexes

DR. ROBERT T. MORRIS, New York: In a certain proportion of patients with pelvic reflexes, there is the neurotic habit. These patients are neurasthenics. If a surgeon takes out one ovary for the pelvic pain the patient is just as badly off as before the operation. If the other ovary is removed she is just the same. The surgeon must deal with neurotic patients with a great deal of intelligence. They represent a class calling for surgery, but the surgeon should beware of patients with pelvic pains, ovarian and tubal troubles, and neuralgic pains, particularly those of the neurotic or neurotic type. We have a group of disturbances proceeding from a sear of the cervix. Most women who have borne children have torn cervixes. Does the cervix require operation for its repair? Do we do the right thing if we operate because we find tears and scars? No. We are not to operate in such cases unless we have definite reasons for doing so. If one should press on a sear of the cervix with the finger nail or with the sharp point of a retractor and bring out instantly that reflex, then the case is one requiring operation for reflex disturbance, but, if one should press on a sear and the patient does not know it, or if one should press on another sear and the patient does not know it we should not operate in that case for relief of reflex disturbances, no matter how much the cervix is torn. One may operate for repair of a torn cervix on general mechanical principles, but not for the purpose of relieving the efferent reflex.

The following papers were also read: "Tumors of the Bladder," by Drs. J. F. Erdmann and J. F. McCarthy, New York; "Adenocarcinoma of the Kidney," by Dr. J. G. Sherrill, Louisville; "Torsion of the Great Omentum," by Dr. W. J. Gillette, Toledo, O.; "Two Right-Sided Femoral Hernias in the Same Patient," by Dr. N. S. Scott, Cleveland, O.

State Boards of Registration

COMING EXAMINATIONS

ARKANSAS: Regular, Little Rock, November 8-9. Sec., Dr. F. T. Murphy, Brinkley; Eclectic, Little Rock, November 8-9. Sec., Dr. G. A. Hinton, Hot Springs.

CONNECTICUT: Regular, City Hall, New Haven, November 8-9. Sec., Dr. Charles A. Tuttle; Homeopathic, Grace Hospital, New Haven, November 8. Sec., Dr. Edwin C. M. Hall, 82 Grand Ave.; Eclectic, Hotel Garde, New Haven, November 8. Sec., Dr. Thomas S. Hodge, 19 Main St., Torrington.

FLORIDA: Palatka, November 9-10. Sec., Dr. J. D. Fernandez, Jacksonville.

ILLINOIS: Coliseum Annex, Chicago, October 19-21. Sec., Dr. James A. Egan, Springfield.

LOUISIANA: Regular, New Orleans, October 18-19. Sec., Dr. A. B. Brown, 108 Baronne Street; Homeopathic, New Orleans, November 7. Sec., Dr. John T. Crebbin, 1207 Maison Blanche Building.

MAINE: City Council Rooms, Portland, November 8-9. Sec., Dr. Frank W. Searle, 806 Congress Street.

MASSACHUSETTS: State House, Boston, November 8-9. Sec., Dr. Edwin B. Harvey.

NEBRASKA: State Capitol, Lincoln, November 9-10. Sec., Dr. E. Arthur Carr, 141 S. Twelfth Street.

NEVADA: Carson City, November 7-9. Sec., Dr. S. L. Lee.

NEW JERSEY: State House, Trenton, October 18. Sec., Dr. H. G. Norton.

TEXAS: Palestine, November 22-24. Sec., Dr. R. H. McLeod.

WEST VIRGINIA: Morgantown, November 14-16. Sec., Dr. H. A. Barbee, Point Pleasant.

Louisiana Homeopathic May Report

Dr. John T. Crebbin, secretary of the Louisiana Homeopathic Board of Medical Examiners, reports the written examination held at New Orleans, May 2, 1910. The number of subjects examined in was 9; total number of questions asked, 80; percentage required to pass, 75. The total number of candidates examined was 2, both of whom passed. Three candidates were licensed through reciprocity. The following colleges were represented:

College.	Year of Graduation.
Chicago Homeopathic Medical College.....	(1897)
Pulte Medical College, Cincinnati.....	(1897)

LICENSED THROUGH RECIPROACITY

College	Year Grad.	Reciprocity with
Hering Medical College	(1903)	Missouri
Hahnemann Medical College and Hospital, Philadelphia, (1904) Virginia; (1908) Pennsylvania.		

Mississippi May Report

Dr. S. H. McLean, secretary of the Mississippi State Board of Health, reports the written examination held at Jackson, May 10-11, 1910. The number of subjects examined in was 8; total number of questions asked, 64; percentage required to pass, 75. The total number of candidates examined was 192, of whom 59 passed, including 31 non-graduates and 133 failed, including 87 non-graduates and one osteopath. The following colleges were represented:

College	PASSED	Year Grad.	Total No. Examined.
University of Alabama		(1910)	1
Howard University, Washington, D. C.....		(1902)	1

Michigan June Reports

Dr. B. D. Harrison, secretary of the Michigan State Board of Registration in Medicine, reports the written examinations held at Battle Creek and Ann Arbor, June 14-16, 1910. The number of subjects examined in was 14; total number of questions asked, 100; percentage required to pass, 75, and at least 50 in each subject.

At the examination held at Battle Creek, the total number of candidates examined was 9, all of whom passed. The following colleges were represented:

College.	PASSED	Year Grad.	Per Cent.
American Medical Missionary College (1904)	84.5;	(1910)	79.2,
	84.6, 85.3, 85.7, 86.8, 87.5, 88.2, 89.7.		

At the examination held at Ann Arbor, the total number of candidates examined was 75, of whom 74 passed and one was conditioned. The following colleges were represented:

College.	PASSED	Year Grad.	Per Cent.
Chicago Homeopathic Medical College.....	(1878)		90.5
American Medical Missionary College.....	(1905)		78.4
Louisville Medical College	(1902)		79.2
Harvard Medical School	(1910)		87.4
Trotter College of Medicine.....	(1903)		77.3
University of Michigan College of Medicine and Surgery (1910)	78.4, 78.5, 78.7, 79.2, 79.3, 79.8, 80, 80.1, 80.1, 80.2, 81, 81.1, 81.1, 81.5, 81.5, 81.7, 81.8, 82.5, 82.6, 83, 83.1, 83.5, 83.6, 83.8, 83.9, 84.1, 84.1, 84.3, 84.4, 84.5, 84.6, 84.6, 84.7, 84.8, 84.8, 84.8, 85, 85.1, 85.2, 85.2, 85.3, 85.4, 85.4, 85.5, 85.9, 85.9, 86.1, 86.1, 86.5, 86.7, 87.2, 87.5, 88.5, 88.8, 88.9, 89.		
University of Michigan Homeopathic College (1910)	78.2, 79, 79.4, 80.3, 82.5, 82.5, 82.8, 83.1, 85, 87.1.		
University of Buffalo	(1909)		85.9
Jefferson Medical College	(1910)		81.7

CONDITIONED

Univ. of Michigan, Coll. of Med. and Surgery.....	(1910)	*75

Indiana January and July Reports

Dr. W. T. Gott, secretary of the Indiana Board of Medical Registration and Examination, reports the written examinations held at Indianapolis, January 11-13 and July 12-14, 1910.

The number of subjects examined in was 16; total number of questions asked, 100; percentage required to pass, 75.

At the examination held in January, the total number of candidates examined was 21, of whom 19 passed and 2 failed. The following colleges were represented:

College.	PASSED	Year Grad	Per Cent.
Chicago College of Medicine and Surgery	75.1; (1909) 75.9, 86.5, 88.		
Jenner Medical College		(1907)	75.2
College of Physicians and Surgeons, Chicago		(1909)	80.3
Northwestern University Medical School		(1909)	77.81.8
Indiana Medical College		(1898)	82.9
Indiana University		(1909)	84.8
Louisville Medical College		(1905)	86.6
Harvard Medical School		(1908)	87.6
Univ. of Michigan, Coll. of Medicine and Surgery		(1904)	88.7
University of Michigan, Homeopathic College		(1910)	85.6
University and Bellevue Hospital Medical College		(1907)	83.8
Medical College of Ohio		(1882) 75.5; (1907)	83.5
University of Pennsylvania		(1906)	84.8
Woman's Medical College of Pennsylvania		(1902)	75.6

FAILED

Indiana University	(1909)	68.5
Medico-Chirurgical College of Philadelphia	(1906)	68.4

At the examination held July 12-14, the total number of candidates examined was 86, of whom 79 passed, including one osteopath, and 7 failed. The following colleges were represented:

College.	PASSED	Year Grad.	Per Cent.
Chicago College of Medicine and Surgery	(1909) 81.8; (1910) 84, 84.4.		
Bennett Medical College		(1910)	91.3
Hering Medical College		(1910)	88.6
Hahnemann Med. Coll. and Hospital, Chicago		(1908)	75.2
Illinois Medical College		(1910)	87.9
Indiana University	(1909) 75; (1910) 75.9, 79.5, 79.5, 80.6, 81, 81.4, 81.5, 82.1, 83, 83.2, 84.3, 84.4, 84.6, 84.7, 84.7, 85.5, 85.5, 85.6, 85.7, 85.7, 86, 86.1, 86.5, 86.6, 87.1, 87.2, 87.3, 87.3, 87.9, 88.2, 88.3, 88.5, 88.6, 88.7, 89.3, 89.5, 89.6, 89.6, 90.2, 90.2, 90.4, 90.5, 90.5, 90.7, 90.9, 91.1, 91.5, 91.8, 92.3, 92.9, 92.9.		
University of Louisville	(1910) 80.8, 81.9, 84.2, 84.3, 85.1, 85.8, 86.5, 88.8, 91.6.

Medical Economics

THIS DEPARTMENT EMBODIES THE SUBJECTS OF ORGANIZATION, POSTGRADUATE WORK, CONTRACT PRACTICE, INSURANCE FEES, LEGISLATION, ETC.

A PRACTICAL BUSINESS BUREAU FOR COUNTY SOCIETIES

H. G. Langworthy, M.D.
DUBUQUE, IOWA

A movement to establish business bureaus for county societies with an attorney who will make a systematic attempt to collect old bills, will doubtless meet the approval of physicians. Older members may not at first regard such a system with favor. They will say, and with some truth, that "such schemes have been tried and failed." This does not prove that the plan is fundamentally wrong, but that it must be practical and sound, or it is pretty sure to fail. But even failures have their lessons.

The plan which I present for your approval and which I have succeeded in having adopted by the Dubuque County Medical Society, simplifies as much as possible the ordinary plan of business cooperation and applies it to county soci-

ties in smaller cities, where it is often badly needed. An elaborate self-running bureau adapted to a city of a million population is not fitted altogether for a business bureau in small communities, I hope that some such plan may be adopted by every county medical society.

The reasons for the creation of a collection bureau for county societies are: 1. If all collections are made by the collection department patients cannot take offense against physicians for collecting through this bureau bills running over twelve months. 2. Many patients now regarded as subject of charity (not through necessity, but simply through unwillingness to pay a doctor's bill) would be induced to pay their bills. 3. The attorney representing the society would be able to make systematic quarterly collections better than anyone else. While the placing of bills in the hands of the attorney should be optional, it would seem clear that an able attorney, making a special business of this work, could handle medical accounts better than some unknown and irresponsible outside collection agency.

I will briefly outline the plan of the bureau at Dubuque, the result of two years' work on this subject. Modifications must be made as time and local conditions demand. I will furnish printed copies of the abstracted plan in detail on application.

INSTALLATION AND PLAN OF BUSINESS BUREAU FOR COUNTY SOCIETIES

WHEREAS, It is deemed advisable that the _____ County Medical Society should adopt a business bureau; therefore, be it

Resolved, In meeting duly assembled, this _____ day of December, A.D. 19____, that the same be, and is hereby, adopted, and known as the business bureau of the _____ County Medical Society, and that the said bureau be conducted along the lines and governed according to the following:

1. That _____ shall act as attorney for the _____ County Medical Society in the capacity of conducting the business of the "Business Bureau" of said society, and pursuant thereto said attorney will call every three months on physicians who are members of the _____ County Medical Society for statements of accounts and will give receipts for same. That he will keep a separate and private file for each physician's accounts and correspondence. That he will keep a complete system on which will be notated the exact status and progress of each account. That he will make quarterly returns direct to the physicians as the business bureau committee may direct. That he will not bring suit on accounts without authorization and private arrangement with the physician. That he will assist the committee in auditing accounts. That each physician's account will be open to his inspection at any time, but to no other physician; and that all other business matters will be kept absolutely private. That due diligence will be exercised in collecting all accounts turned over, and prompt settlement made after collection.

2. That the respective physicians will submit itemized statements of such accounts as they desire to place in the collector's hands. That physicians will receive remittances made directly to them from debtors. That on remittances made directly to the physician on accounts in the attorney's hands, commissions will be paid, but no commission will be allowed on bills remaining unsettled or on money not collected.

3. That the committee of the business bureau of the _____ County Medical Society may, at any time, audit the accounts in the hands of the attorney, and shall in cases of dispute distribute to the attorney the amount of his commission and to the physician the amount due him on such accounts. That the commission to the attorney on accounts collected shall be scheduled as follows, and on accounts collected in payment or installments the schedule per cent., per payment, will prevail:

Collections of \$2 or under	50 per cent. commission
Collections of \$3 or under	40 per cent. commission
Collections of \$4 or under	30 per cent. commission
Collections of \$5 to \$10	25 per cent. commission
Collections over \$10	20 per cent. commission

4. That all expenditures in conducting the collections by way of record files, all paper, envelopes, stamps, etc., shall be borne by the attorney.

5. That said attorney, _____, shall be appointed by the committee for a term of three years, subject, however, to removal by the business bureau committee or society for unwarranted neglect, dishonesty or general incompetency.

6. That the attorney shall arrange a reference list as to financial standing and responsibility of patients, accessible to members of the _____ County Medical Society, but to none others. This list, together with such additional lists and information deemed justly the private property of the society, shall be turned over to his successor in case of withdrawal, dismissal, or for any other reason.

7. These articles and the power given the business bureau committee may be altered or curtailed by a two-thirds vote of members present and voting at any regular meeting, previous notice of such action having been given all members sixty days in advance.

It will be noted in the foregoing that the bureau has been established by the adoption of a simple resolution, and that no iron-clad contract is entered into between the society or the business bureau committee and the attorney. The commission schedule here adopted is the one furnished me by the manager of the Business Bureau of the Chicago Medical Society. While unquestionably a little high, it probably forms the best working basis of any present schedule, especially as many of our first accounts are most undesirable.

REPORT OF BUSINESS BUREAU OF THE DUBUQUE COUNTY MEDICAL SOCIETY FOR FIRST SIX MONTHS

The following report of the attorney to the Business Bureau Committee of the Dubuque County Medical Society will be found of interest:

I herewith submit a statement of money collected by the said bureau for the first six months of the year 1910, ending July 1, 1910, as follows: January, \$105.50; February, \$161.50; March, \$228.50; April, \$109; May, \$23; June, \$29; total, \$656.50. In addition to the above, the bureau has collected in partial payments on bills not yet fully paid the sum of \$213.15. The total amount of bills turned in to the bureau for the first six months was \$8,176.53. There is represented in this amount many dollars of accounts that are absolutely worthless, for the reason that some debtors have left the city, a few cannot be located, some refuse to pay—in that they claim to be unable to make even a very small payment on their bills and will not make any promise of any definite time they will pay even a part, and other bills are what is known as outlawed.

The \$656.50 in money paid into the bureau represents \$958.50 of accounts turned in to the bureau. In other words, in order to collect \$656.50 it was necessary to make reductions in the bills of \$293, which is about a 45 per cent. reduction, which goes to prove the character of the bills so far as collecting them is concerned. In each instance the physician is consulted and the bureau authorized before a compromise or reduction is made. All debtors whose bills have been turned in to the bureau have been written to from one to three or more times, and nearly all who have not responded materially or came in person to the office of the bureau have been personally interviewed. At the end of one year from the time of placing bills the bureau will have been able to collect or report same uncollectable. Of the \$656.50 collected all has been turned over to the physician due him therefrom, excepting \$3, which is still in the hands of the bureau.

Among the experiences of the bureau may be mentioned: (1) Most of the members have at some time availed themselves of the use of the bureau. (2) All bills placed in the hands of the bureau have been carefully investigated in each case and the large majority of debtors visited personally by the attorney. (3) Debts have been divided into the two divisions: (A) collectable, and (B) uncollectable. (A bill on which 50 cents or \$1 a week is being paid is placed in Class A.) (4) Almost without exception early bills turned in have passed through other hands for collection, in some instances repeatedly, without results, making it hard for the bureau to get a good start. (5) A considerable number of first accounts handed in were legally outlawed by the time limit of five years on book accounts. (6) Our attorney has found in some instances families charged practically the usual rate who ought to be considered little better than charity subjects. Doctors should discriminate carefully, and should not overcharge the poor laborer or the struggling clerk. (7) The establishment of a county society business bureau in Dubuque has resulted in a saving to the society of a considerable amount of money the past six months.

Occasionally physicians have thought it best not to hand in accounts unless they have been reported as worthless in other hands, the idea being that the commission rate charged

would not warrant the placing of easy bills with the bureau. We hope that in the future physicians will find it to their interest to call up the bureau and discuss the matter thoroughly before using other agencies. At present our bureau sees no way to lower this scale, which, while a trifle high, forms the best working basis of any schedule which could be adopted. The future must demonstrate the advisability of lowering our scale; the past certainly has not. Whether the bureau will be able eventually to cooperate with the physicians on a slightly different basis should they wish to turn in on the first of every month all fair bills within their possession, remains to be seen.

The bureau has been of value in dealing with delinquents, as it always stands ready to collect at once or to bring early suit in court at a minimum cost without inconveniencing the physician.

In conclusion, I would like to emphasize the value of our bureau in educating delinquents by stirring up the careless and listing those who are really unworthy of credit. The optional feature, allowing physicians to turn in only such accounts as they desire, is also of value. The society is under no expense, as many young attorneys will take up the work on the basis outlined. A business bureau is not necessary in small communities, where each physician knows all about his families or can tell the other doctors the names of the shiftless and unworthy.

POSTGRADUATE COURSE FOR COUNTY SOCIETIES

DR. JOHN H. BLACKBURN, DIRECTOR
BOWLING GREEN, KENTUCKY

[The Director will be glad to furnish further information and literature to any county society desiring to take up the course.]

Third Month—First Weekly Meeting

General Subject for the Month: Surgery of the Kidney and Ureter

ANATOMY

KIDNEY: Situation, surface markings, important relations, size, weight, surfaces, borders, extremities. Means of fixation, by three capsules. Relation of structures entering hilum. Relation of vascular supply to pelvis and calyces. Brödel's white line.

URETER: Structure.—Location, length, diameter, constrictions, dilatations, course, relations. Pelvic relations in male; in female.

SURGERY OF THE URETER

SURGICAL LESIONS OF THE URETER: Surgical injuries, puerperal injuries, congenital fistula, tuberculosis, pyoureter, calculus, malignant disease.

DIAGNOSIS: Pain, urine or purulent discharge in fistula, examination of ureteral orifices by cystoscopy, catheterization of uterers. X-ray in calculus.

TREATMENT

SURGICAL INJURIES: Immediate treatment: technic of ureteral anastomosis; end-to-end, lateral and end-to-side; uretero-vesical anastomosis. Late operations; treatment of ureteral fistula.

CALCULUS OF URETER: Localization of stone. Site of incision. Variations in technic.

TUBERCULOSIS OF URETER: Secondary to renal tuberculosis. Indications for surgical treatment. Technic of nephro-ureterectomy, of ureterectomy.

STRICTURE OF URETER: Diagnosis; treatment.

REFERENCE BOOKS FOR THE THIRD MONTH

- Kelly and Noble: Gynecology and Abdominal Surgery, vol. II.
- Watson and Cunningham: Diseases and Surgery of the Genitourinary System.
- White and Martin: Genitourinary Surgery and Venereal Diseases.
- Caspar: Genitourinary Diseases.
- Morris: Surgery of the Kidney and Ureter.
- Edwards: Surgical Treatment of Bright's Disease.
- Garceau: Renal Tumors.
- Keen: Surgery.
- Bryant and Buck: Surgery.

Book Notices

PRÉCIS DU TRAITEMENT DES FRACTURES PAR LE MASSAGE ET LA MOBILISATION. Par Dr. Just Lucas-Championnière, Chirurgien Honoraire de l'Hôtel-Dieu. Paper. Price, 3.50 francs. Pp. 267. Paris: G. Steinheil, 2 rue Casimir-Delavigne, 1910.

In this little treatise Lucas-Championnière amply justifies his claim to the title of pioneer in the treatment of fractures by massage and mobilization. The first half of the book is largely devoted to a general consideration of massage in its application to fractures and the manner of performing the various passive and active motions. The advantages of these maneuvers are enthusiastically lauded, and justly so, when one recalls the dire functional results of too long immobilization. While the text, on the whole, would be improved by being condensed, and much detail could be omitted, the careful reader will find much in the way of sound advice and wisdom, the fruit of long clinical experience. The author very properly refers to the frequent errors which are made in the interpretation of radiographs, mere shadow pictures, and cautions against disregarding clinical phenomena and the findings of a careful clinical examination.

The book is too radical for the use of students, but should prove both interesting and profitable reading for surgeons interested in fractures. The following are a few extracts from its pages: "It is not immobilization which favors the formation of callus, but motion"—"immobilization interferes with the vitality of the limb."—"Pain is relieved by certain forms of motion. Immobilization is a secondary factor."—"There can be delayed union in spite of immobilization. Stiff joints and useless limbs follow immobilization."—"A certain amount of motion between the fragments favors the development of callus."—"Reduction is in many cases unnecessary, in others positively dangerous." The author admits that he sutures the patella, because the fragments cannot be approximated. In Colles' fracture, reduction is regarded as generally useless unless the deformity is great. Daily massage and motion are indulged in, and the patients are urged to use their arms. The principle throughout the book seems to be to disregard the cosmetic result in favor of restored function, even in the presence of overriding. With the *x*-ray controlling our results nowadays, how long could a surgeon last who went on that principle in America?

Fractures about the elbow in children, and fractures of the clavicle, are daily massaged. The effect of the treatment is to relieve the spasm and relax the muscles, thus eliminating the traction on the fragments, which fall into place.

The enthusiasm of the author has unquestionably carried him too far in attempting to apply to all fractures the principle of massage to the exclusion of all else. The description of the technic in individual fractures is frequently so brief and vague as to preclude imitation. Yet the little book will have fulfilled a most valuable mission if it will recall to the average practitioner and surgeon that he is immobilizing too strenuously, and keeping splints on entirely too long, that the latter can be more often removed for the purpose of massage and passive motion, and better results obtained.

FACTS AND PROBLEMS OF RABIES. By A. M. Stimson. Bull. 65, Hyg. Lab., U. S. P. H. and M.-H. S., June, 1910. Paper. Pp. 90, with illustrations. Washington: Government Printing Office, 1910.

A timely and most excellent review of the "Facts and Problems of Rabies" has just been issued by the Hygienic Laboratory of the Public Health and Marine-Hospital Service, from which the following statements are selected for the purpose of emphasis: "There has been handed down from the ages, when superstition and ignorance had as yet received but little counterbalancing check from the influence of reasonable or scientific investigation, a mass of erroneous belief which, in its extent and fantastic distortions, probably exceeds that to which any other malady has fallen heir." "There still remain persons who are skeptical concerning, or even deny the existence of, rabies as a distinct disease. If they are fair-minded and possess an average amount of intelli-

gence, a visit to a laboratory where scientific work in this direction is being done will suffice to dispel their objections, even if their faith in human nature is so slight that they are able to regard those investigators who have devoted years of disinterested study to the subject as untruthful or very badly mistaken."

"Since it has been demonstrated that, by comparatively simple measures, the disease can be reduced to a minimum or even wholly eradicated, it is raised to an importance disproportionately great to the frequency of its occurrence compared with that of less remediable maladies. The continued existence, not to say increase, of rabies in animals and man is a reproach on the efficiency of organized medical bodies for the suppression of disease." "We have now, and have had for a long time, all the knowledge of rabies necessary to effect its entire suppression. This knowledge can be summed up in a single sentence, to wit: Rabies is perpetuated in the dog through the infliction of bites by a rabid dog, and does not arise spontaneously. If all rabid dogs could be prevented from biting other animals, rabies would in the course of a year be a mere historical curiosity of medicine, an illegitimate field of research for the investigator in pure pathology, a plaything for the controversialist. There are few infectious diseases the prevention of which rests, as in rabies, on a single definite measure."

AN INTERNATIONAL SYSTEM OF OPHTHALMIC PRACTICE. Edited by Walter L. Pyle, M.D., Philadelphia, Member of the American Ophthalmological Society, Therapeutics. By Dr. A. Darier, Paris. Translated by Sydney Stephenson, F.R.C.S., London, Late Honorary Secretary of the Ophthalmological Society. Cloth. Price, \$4 net. Pp. 444, with illustrations. Philadelphia: P. Blakiston's Son & Co., 1910.

This portion of Pyle's "System of Ophthalmic Practice" is devoted to therapeutics and was written by Dr. A. Darier of Paris, who is peculiarly fitted to present this subject. Dr. Darier is fortunate in having his work translated into English by Mr. Sydney Stephenson. The more recent diagnostic methods, both general and special, are dealt with as well as the general treatment indicated in those eye diseases associated with general disease. The complications and after-treatment of surgical procedures on the eye are discussed exhaustively. Nothing is offered regarding the important relations existing between the eyes and the nasal cavities; otherwise the book merits approval. It is compact and practical and presents the latest methods of ophthalmic practice in a clear, concise manner.

A MANUAL OF PERSONAL HYGIENE. Proper Living on a Physiological Basis. By American Authors. Edited by Walter L. Pyle, M. D., Member of the American Ophthalmological Society. Fourth Edition. Cloth. Price, \$1.50 net. Pp. 472, with 131 illustrations. Philadelphia: W. B. Saunders Co., 1910.

This book is for the layman and deals with "the one subject which every fair-minded person admits should be taught thoroughly—namely, how to keep healthy . . ." The way in which this subject is handled by the various authors who contribute to this work is eminently sane, catholic and generally admirable. To the chapters on the hygiene of the digestive apparatus, of the skin and its appendages, of the vocal and respiratory apparatus, of the ear, of the eye, of the brain and nervous system and on physical exercise that appeared in the previous editions have been added ones on body-posture and domestic hygiene. There is also an appendix, and a glossary of such technical terms as have been unavoidably used.

PRÉCIS D'AUTO-SUGGESTION VOLONTAIRE. Par le docteur Geraud Bonnet, d'Oran, Officier de l'Instruction Publique. Paper. Price, 3 francs. Pp. 300. Paris: Jules Roussel, 1, Rue Casimir-Delavigne, 1910.

This book seems to have been written for the layman. The author has great belief in free will and in the power of the individual to control his thoughts in any direction. There are some valuable suggestions, especially in the chapter on concentration of the thought. The book adds nothing to our knowledge. It states in a manner tended to make its point appreciated the strength and value of hypnotism and suggestion whether from without or within.

Medicolegal

Points From Suit Against Alienists for Damages for Alleged Negligence in Examination as to Sanity

The Second Appellate Division of the Supreme Court of New York says that the case of Warner vs. Packer and another (123 N. Y. S. 725) was for negligence. The plaintiff had been confined for a time in an insane asylum on her husband's petition, to which was annexed a certificate of the defendants as examiners in lunacy that she was insane and was a proper subject for custody and treatment in some institution for the insane as an insane person. She complained that the defendants had made a false, pretended, and grossly negligent examination of her as to her mental condition, that she was not insane then or at any time, that the defendants willfully failed and neglected to use or to exercise reasonable and ordinary care, skill, and diligence to ascertain her true mental condition, or to make a prudent and careful inquiry and proof whether she was sane or insane, and failed to exercise their best judgment as to her sanity, but with gross and culpable negligence based their opinions on false and pretended statements made to them by her husband. She gained a verdict for \$25,000, and the defendants appealed from the judgment thereon.

The defendants were feebly by the husband to make an examination. Thereupon they impliedly represented that they possessed the reasonable degree of learning and skill ordinarily possessed by the average examiners in lunacy, and in the rendition of the services they undertook to use such skill and learning, to exert their best judgment in the application thereof, and to exercise reasonable care.

The burden was on the plaintiff to show that the defendants fell short in their qualifications or their obligations. The plaintiff did not advance the proposition that the defendants were not qualified. On the other hand, the evidence showed that they were educated in their profession, alienists who as such had filled important public positions, and were of large experience gained from thousands of examinations. The court therefore need not consider that ground of liability. The question on the appeal was whether the plaintiff made proof to justify the verdict of negligence in the ascertainment of her true mental condition. The defendants testified in detail as to their professional conduct.

The plaintiff's case consisted largely of testimony of lay witnesses, her acquaintances and friends, that in their opinion specified words and acts of hers were rational. She contended that at all times she was sane. Such contention, so far as it related to the time of her examination, was essential, inasmuch as she could not have been harmed by a certificate of the truth unless her insanity did not require restraint and treatment. A certificate of her insanity when she was sane could establish error of judgment, but for that the defendants were not liable; and it could be considered as evidence bearing on the defendants' qualifications or indicating failure to fulfill their obligations as to skill, learning, care, and best judgment in the case. But no presumption of negligence in the defendants arose solely on the establishment of her sanity at the time of her examination by the defendants.

A striking feature in the plaintiff's case was the omission of any scientific or expert evidence as to the course pursued by the defendants in the examination, as to what was done that the average examiner in lunacy would not have done, or as to what was not done which such an examiner would have done under the circumstances of the case.

We know insanity is a mysterious disease, that it may exist without physical indications, is often cunningly concealed so as almost or altogether to baffle detection even by a specialist, or may be so occult as to cause most eminent alienists to clash as to its existence in an instance. The diagnosis of it is recognized as a difficult task. It seems to the court that the very nature of the subject—the question of negligence is a diagnosis—would almost preclude a jury from passing on it by their common knowledge unaided by any scientific or expert information whatever, or by the testimony of any witnesses of special knowledge and skill. Yet there

was not in evidence any standard for comparison of the conduct of the defendants with that which was required of them.

Nor does the court think that any negligence could be imputed in this case to the omission to make further inquiries, although it was recognized in a leading English case (Hall vs. Semple, 1 F. & F., 337) that such obligation might exist. The husband's narrative was of the relations between him and his wife—this plaintiff—of her conduct and her bearing towards him. Husband and wife appeared as living under the same roof, and there was no indication that there was any one whom the defendants could have consulted in corroboration of the husband, save of course, the wife.

There was ground for surmise that the jury found negligence from the premise that the plaintiff was sane at the time the defendants certified that she was insane, for the minutes showed that they "returned their verdict in which they find that Mrs. Warner was, on the 13th day of July, sane and rational and find doctors guilty of negligence and fix the damages at \$25,000." But the finding of sanity was no more a part of their formal verdict than would be a finding in a verdict for the plaintiff in a negligence case that the plaintiff was not chargeable with contributory negligence. On consideration of the case in the light most favorable to the plaintiff, as was her due, the court fails to find sufficient evidence to support the verdict. Wherefore, the court reverses the judgment appealed from and grants a new trial.

Matters on Which Expert Witnesses may be Questioned

The Supreme Court of Florida holds, in Pensacola Electric Co. vs. Bissett (52 So. R. 367), a personal injury case brought by the latter party, that, although an expert witness may not be questioned, either on his direct or cross examination, on an hypothesis having no foundation in the evidence, yet it is not required that the hypothetical case put to him should be an exact reproduction of the evidence, or an accurate presentation of what has been testified to. Counsel may present to him any hypothetical case in accordance with any reasonable theory based on the evidence; but, in the event that the jury should find that the facts on which such hypothesis or theory of the case was based have not been proved, the answer of the expert necessarily falls with the hypothesis.

An expert witness who has given his opinion on any question or hypothesis submitted to him may be further interrogated on his cross-examination as to the reasons for such an opinion. And for this purpose it is within the discretion of the trial court to widen the range of such cross-examination, even so as to include matters not strictly pertinent to the issues, in order to test the witness' means of knowledge, the extent of his information, memory, accuracy, or credibility, and an appellate court will not interfere with the exercise of such discretion, unless a clear abuse thereof is made to appear.

Insufficient Evidence to Sustain Conviction of Wrongfully Going on Street While Afflicted with Small-Pox

The Court of Appeals of Kentucky in Lawrence vs. Commonwealth (127 S. W. R., 1013) reverses a conviction had under the statute of that state which provides that "any person who, having reason at the time to believe himself afflicted with the disease of small-pox, shall voluntarily go on any public highway or street, shall be guilty of a misdemeanor, and, on conviction, shall be fined not less than one hundred nor more than one thousand dollars." It says that the statute states that anyone having reason at the time to believe himself "afflicted" with the disease of small-pox, going on the public highway, etc., commits the offense. There was very slight evidence conducing to show that the accused might have had the small-pox, but there was none to show that he had reason to believe that he had it when he went on the streets and public highways. A Mr. Brown, the man with whom he boarded while working at a rock quarry with more than 50 persons, said to him one evening that he (Brown) believed that he had small-pox, and that he could not let him stay in the house that night, but that he could go to the barn and sleep in the hay. The accused went to the barn, but got so cold during the night that he had to get up and leave. None

of the persons who worked with him at the rock quarry took the smallpox, but several of Brown's family did have it. There was no evidence showing that he went on the streets or public highways after Brown told him that he believed that he had the smallpox, and Brown's statement to him was the first thing to indicate to the accused that he had any reason to believe that he had the smallpox, and he went to the barn, as Brown told him, to sleep, but grew so cold during the night that he had to leave, and went to his home in another county. The accused testified that he did not believe at the time that he had the smallpox, and stated that he did not have it; that the eruption he had on his face was common to him yearly from infancy. He was corroborated in this statement by both his father and brother, and there was no evidence to the contrary. As stated, there was but very slight evidence to the effect that he had the smallpox and none that he had reason to believe that he had it when he voluntarily went on the streets and public highways, and the court should have instructed the jury peremptorily to find him not guilty.

Physician Prevented from Testifying to Account

The Supreme Court of North Carolina says, in the case of Knight vs. Everett, as administrator (67 S. E. R. 328), that it was an action for medical services rendered by the plaintiff, a physician, to the decedent of whose estate the defendant was administrator. The physician was offered as a witness in his own behalf to prove that he attended on the decedent, had an account against him therefor, to prove the items of the account, the number of visits he made, the sum due therefor, and the value of his services. Each of these questions was objected to, and the evidence was properly ruled out. Such evidence was clearly as to "personal transactions" with the deceased, and incompetent under the terms of the North Carolina statute, the defendant administrator not having testified as to these matters, and the statute providing that a party to, or interested in the event of, a suit shall not be examined as a witness in his own behalf or interest against the administrator, etc., of a deceased person "concerning a personal transaction or communication between the witness and the deceased person," except where the administrator, etc., is examined in his own behalf, or the testimony of the deceased person is given in evidence concerning the same transaction or communication. The plaintiff physician could not prove by his own testimony either an express contract, which would be a "communication" with the deceased, nor an implied contract, by showing a "personal transaction," as services rendered.

- 18 *Postoperative Pneumonia Without Mortality in Two Thousand Consentive Surgical Operations at the Free Hospital for Women. W. P. Graves, Boston.
- 19 *Analysis of Seventy-two Cases of Pneumothorax. J. B. Ayer, Boston.

17. **Plastic Surgery of Ovaries and Tubes.**—The patients on whom Seelye has operated in the past two years, 9 single and 12 married, or 21 in all, represent cases of dysmenorrhea and irregularities in catamenia; 10 patients had resection of one ovary; 5 had double resection of ovaries; 6 had resection of one and extirpation of the other ovary. Of these, all but one woman had marked immediate relief from dysmenorrhea, and the relief has held to the present time. In 2 of these cases dysmenorrhea was so severe that the patients had to go to bed for several days at each period. The intervals were shortened, and the patients had only about one week free from pain between periods. These women were not only relieved of dysmenorrhea, but the periods became normal in time. The one patient unrelieved was among the first 10 and one in whom Seelye, says, resection or extirpation of the untouched ovary ought to have been done, for it was large and cystic.

Of the remaining 14 patients, 4 were over 40 years of age and had chronic inflammation of both tubes and ovaries. Total extirpation was performed in each. One had a large cyst combined with a pus tube on one side, which was removed with the tube; 8 had resection of one or both tubes on account of occlusion from past inflammation—the lumen was left patent, and the ovary brought into close contact with the proximal end of the tube. In these 14 patients, the late results in 4 are unknown; the rest have been in good health with no symptoms. No pregnancies have yet been reported. Seelye pleads for more abdominal operations on the pelvic organs in cases of severe dysmenorrhea, and, emphasizes the importance of classification as an aid in determining the mode of procedure in a given case for operation on the ovaries and tubes.

18. **Postoperative Pneumonia Without Mortality.**—As a result of an examination of these cases, consisting of over 1,000 laparotomies, Graves concludes that postoperative lung conditions occur somewhat more frequently and are more fatal in patients previously septic or desperately ill or in the aged and feeble. Operative shock, method of administration, length of time of the anesthesia, age of the patient unless extreme, physical type of the patient, had behavior under ether, wound sepsis, pulmonary embolism, do not seem to bear any constant relationship to the causation of postoperative pneumonia. Postoperative pneumonia and bronchitis occur with great constancy during the cold weather months, and are rare during the summer months. Pre-existing foci of infection in the lungs are almost invariably lighted up or aggravated by operations under ether anesthesia. The following theory of causation is suggested by Graves. Most of the cases of postoperative lung complications are caused by the lighting up or the aggravation of pre-existing focal infection. Many postoperative pneumonias might be avoided by a more careful and more expert preoperative examination of the respiratory tract.

19. **Pneumothorax.**—Tuberculous cases comprised 69 per cent. of all cases of pneumothorax at the Boston City Hospital in twenty-eight years. Most patients were young or middle-aged men, and most had a recent history of less than six month's illness. The left side was most often affected. Pain and dyspnea were by far the most common symptoms at onset. A number of acute symptoms were less frequently of prime importance. The treatment in these cases was for the most part essentially that of the fluid present; the prognosis was anything but encouraging. Two rare cases are reported, one from subphrenic-intrathoracic abscess and one due to echinococcus. Artificial pneumothorax oc-

curred in 19 per cent. and possibly in 32 per cent. of the cases. Roentgen-ray examination has frequently made difficult cases clear, rendered diagnoses more exact, qualified prognosis and explained the effect of treatment. Since this form of examination has come into more constant use in the hospital, pneumothorax has been more frequently diagnosed.

- 23 *Should the Physician Do His Own Dispensing? H. B. Garner, Detroit.
- 24 Arithmetic in Medicine. R. Wallace, Louisville, Ky.

23. **Physician's Dispensing.**—The reasons which are given by Garner why the physician should not dispense his own medicines are in brief as follows: He is a physician and not a pharmacist. His time with a patient must, if it results in the greatest good of the patient, be devoted to the diagnosis and treatment of his case. The country is loaded with an inferior class of goods and he is apt to employ cheap remedies in preference to the better qualities of pharmaceutical preparations. He cannot devote a proper amount of time to the preparation of active and reliable drugs and carry on a general practice successfully. His drugs of necessity must deteriorate. He falls into a routine way of prescribing pills, the formula of which has been studied by someone else, and often does not fill the bill. On the other hand, it is equally important to bring up objections urged against prescription writing. Druggists substitute. Druggists secure the business that rightfully belongs to the physician by counter-prescribing. Patients pay the physician for the prescription and have it refilled any number of times without the physician's knowledge or advice. Garner urges that the medical and pharmaceutical professions join hands, having for their aim honesty, quality, and perfection. The hearty cooperation will bring forth apothecary shops that will be an honor to the owner and a credit to the employes.

34. **Acute Anterior Poliomyelitis.**—Throughout the winter of 1909-10, patients continued to come for after-care, but always reported the acute trouble as having occurred before the end of November, except in two instances, in which the disease developed in December. House saw 31 patients. They came from Portland, from along the lines of the Southern Pacific Railroad, from down the Columbia as far as Astoria, and one from near Weiser, Idaho. The lesion was in the lumbar region in 23, all children under 7, with consequent paralysis of the legs. One case was purely of the cerebral type. The patient, a child of 7, was unconscious and died without exhibiting any characteristic palsy. But the clinical picture seemed typical. Necropsy, performed 4 days after death, after decomposition had begun, revealed absence of gross pathologic lesion, which would be expected under the circumstances. House feels, confirmed the diagnosis. The remaining 6 patients exhibited symptoms of cervical involvement and 3 of them showed marked cerebral symptoms. These 3, all young children, died. Of the 3 patients in whom the lesion appeared to be entirely cervical all were girls of from 16 to 20 years of age. One died from respiratory insufficiency, and the others recovered with palsies to be later described.

So far as House's observations are concerned, there were no definite foci and no definite method of spread, except that the cases from out of Portland all came from along the line of the S. P. and O. R. & N. railroads. Roseburg appears to have been the center of an unusually large number of cases. In Portland the patients came from all parts of the city, without any apparent source of infection which could in any way account for the distribution and without any possibility of direct contagion from one to the other; nor does House know of any household in which two or more cases occurred. Personally, his belief in the infectious nature of this disease is strong, but is not based on any confirmatory evidence obtained from the recent epidemic.

Many of his patients derived relief from mild mustard plasters to the spine. If they were restless, bromids were used in moderate dose, supplemented with codein if pain was severe. If the lesion was in the lumbar region a little phenacetin was used, but never if the lesion was higher up, because of the danger to the already embarrassed respiration. House suggests that in patients in whom the lesion is cervical with the resulting impairment of respiration, atropin will be indicated, and inhalations of oxygen, together with artificial respiration, appear to have a just place in treatment. Rest in bed and quiet was urged, and throughout, a nutritious, easily digested diet was ordered. Attention was given to insure that the bladder was properly emptied. All attempts at massage were discouraged until pain had subsided. At this time small doses of strychnin will be helpful. House states, and electricity is indicated, but must be given with great care. The faradic current apparently is valueless, but the slowly interrupted galvanic current seems to do much good. Treatments should be given daily and should be short, not more than from 3 to 5 minutes to each affected limb. House used about 60 interruptions to the minute and feels confident that most patients derived great benefit from this treatment.

49. **Spontaneous Gangrene.**—A review of the literature of this subject disclosed to the authors 73 cases, which they consider undoubted examples of spontaneous gangrene: 69 patients were males and 4 females. Two patients were under 20 years old, 7 were between 20 and 30; 9 between 31 and 35; 22 between 36 and 40; 12 between 41 and 45; 10 between 46 and 50; 10 between 50 and 60; 1, age not mentioned. Although the symptoms in one case were present for over 20 years—the average duration was from 3 to 5 years. In the 68 cases in which the location was mentioned, the condition occurred 53 times in the legs alone, twice in the arms alone, and 13 times in both upper and lower extremities. In more than one-third of the cases, the pulse in the femoral and all the vessels distal to it, was lessened or obliterated, while in nearly two-thirds the vessels as high as the popliteal were involved. Neither syphilis nor the use of tobacco seemed to play any part in the causation of this condition. The authors report one case seen by them. They believe that it was a case of general arterial thrombosis, exactly similar to that found in the extremities in the condition known as spontaneous gangrene.

52. **Preparation for the Study of Medicine.**—We may assume, says Waite, that everyone preparing to enter the medical profession hopes to work out a successful career. The medical career is one of many points of contact. It is not alone technical; it has its social, sociologic and public relations. Physicians and surgeons are not mere practitioners; they are also human beings. The physician is by his profession a semipublic servant; much more so than are members of most other professions. His calling brings him into contact with all conditions of men and his relation to these is very intimate. He is a factor in the general welfare of the community; not only in its physical welfare, but in its moral, mental and social prosperity as well. He is more than a technician or a tradesman, and he must if he is to succeed be prepared to discharge efficiently all these correlated obligations as well as to execute his main purpose of combating disease. He cannot confine his activities to diagnosis and the giving of medicine. He must be ready as adviser and friend. He must be prepared for public service. He needs the power of trained personality if he is to protect his entire constituency the public at large—in the maintenance and advance of public health. And since he is more than a physician, he needs more than merely a medical training. The high school has given him a certain sort of training of a routine nature. Such is essential at that developing period of a boy's life, but not all-sufficient for the various demands of a medical career. It is different in kind from the college training and it needs supplementing before the technical studies of the medical curriculum are begun. A college training gives the student a breadth of view not obtainable in any other way.

Medicine is no longer an art but has become a science. It is more and more coming to be applied biology, chemistry, physics and psychology. The high school teaching of these subjects must needs be extremely elementary and superficial, and it is by no means adequate as a preparation for the studies of the medical curriculum. Nor can the medical school give these preparatory subjects properly and in logical order. A full four years is needed for the medical studies, without consuming time and energy in doing the preliminary work. The consensus of opinion after all the discussion of the past ten years on the various phases of medical education is that a high school education alone is not enough preparation to enable a student to get a medical education

that is efficient and adequate, and that, if a boy is absolutely prevented from further preparation, he had best not attempt to enter the profession by the back door of the low-grade school, for his hope of a successful career following such a training will probably never be realized. Under these circumstances, it is to his own advantage to seek some other field of effort.

62. **Closing the Urinary Bladder.**—Lower has opened the bladder suprapubically 69 times for various causes, and has made an immediate closure in 35 and has employed drainage in 34. In the drainage cases the patients required from 3 to 4 weeks longer than the immediate closure cases, and generally had an annoying period of convalescence with dirty bladders which required irrigation afterwards. In the closure cases the patients averaged from 2 to 3 weeks for convalescence and generally were up and about in from 10 days to 2 weeks. The bladders were irrigated through the urethra from the start and by the time the patients were ready to leave the hospital, the infection (when present) had progressed well toward recovery. The technic employed is as follows: The bladder is thoroughly washed with a boracic solution and then filled with the same before the patient is anesthetized. Nothing is inserted into the rectum as is often done.

The patient is placed in the Trendelenburg position, a vertical or transverse incision is made, depending on whether or not there is much adipose tissue. After cutting through the sheath of the rectus and separating the muscle, the peritoneum is pushed out of the field and the bladder exposed extraperitoneally. A curved two-pronged tenaculum or hullet forceps catches the bladder on each side, the bladder is lifted and an incision made longitudinally between the two tenacula into the bladder. The tenacula are now removed and the edges of the bladder incision retracted with small smooth retractors (if greater retraction is needed), but at no time, and this is important, are the cut edges caught by a crushing forceps, e. g. like a hemostat. If this is done, it will be impossible to get a close approximation of the cut edges. When the wound is ready for closure, a round, half-curved needle threaded with 00 chromic catgut is used, never linen or silk. Stones almost invariably form if the ligature is nonabsorbable. The first suture is passed through the muscular coat down to the mucosa and a free end is left long for traction; a tenaculum is inserted at the other end of the opening and the cut stretched. The first row of sutures is then made parallel with the cut muscles, never through the mucosa, and is drawn only tightly enough to approximate nicely the cut edges. The next row of sutures is made transversely to the cut and penetrates all the layers of the bladder except the mucosa and is then tied to the free end of the first layer. By keeping the bladder on the stretch and placing the transverse sutures closely together, when the bladder contracts it makes the wound still more firm, but if sutured when the bladder is contracted, then, when the bladder becomes distended, the sutures will be stretched apart and there will be great danger of leakage.

63. **Abnormal Femora.**—These bones were taken from a tall, thin, male adult who had apparently died of tuberculosis. There are no abnormalities in the other bones, with the exception that the upper thirds of both tibiae are rather thicker in the transverse diameter and the curves in the bone were somewhat greater than is normal. The femora are perfectly symmetrical; the surface of the bones is smooth and there is no evidence of periosteal or osteal inflammation; the articular extremities show no evidence of disease. At about the middle of the shaft, each femur begins gradually to flatten anteroposteriorly and the transverse diameter increases till the condyles are reached, thus differing markedly from the more rounded form of the normal femur. A transverse section of the bone would therefore present a transversely oval form. Hamann says that these bones do not correspond in shape or appearance to any of the pathologic modifications of the femur that have been described, indeed as stated above there is no evidence of any inflammatory or hyperplastic process. The density of the bone seems normal, no section has been made to show the interior however,

64. **Varicose Ulcer of Leg.**—The non-surgical treatment of the disease alone is discussed by Coplan. The general treatment employed by him consists in attention to the bowels, building up the general system; removing the cause, if possible, and regulating the habits and diet. Rest for the limb is essential. An elastic stocking should be ordered at once and the patient made to wear it whenever he is on his feet. The treatment of the ulcer itself consists in thorough antiseptics of the wound and surrounding skin, procured by first washing the entire leg with soap and water and then with 1-1000 bichlorid solution, or a saturated solution of boric acid; brushing the ulcer with carbolic acid, then covering it with cotton dipped in alcohol, drying it carefully and dusting on rather thickly bismuth subnitrate and starch powder, in equal amounts; a dressing consisting of a small pad is applied and held by a gauze bandage or by small strips of adhesive plaster. The elastic stocking is then put on. The powder is changed every morning by the patient, the wound is washed once every two or three days as stated above, inspected, and, if necessary, the carbolic acid and alcohol application is again made and the powder reapplied. The indications for the carbolic acid and alcohol applications are when the retrograde changes equal the reparative, or when the former exceed the latter. When the surface of the ulcer is covered with a layer of healthy granulation tissue composed of round cells closely packed together and supplied with a rich capillary network of blood vessels, the above treatment is all that is necessary. If the granulations are irregular, protruding above the edges of the wound, with ill-smelling purulent or seropurulent discharges, the surfaces should be everted thoroughly before the above applications are made.

83. **Excision of the Stomach.**—A previous communication by Levin, Manson, and Levene on the nitrogen metabolism after gastro-enterostomy, showed that when stomach digestion was lacking, the power of the animals to retain and to assimilate the nitrogen of the food was diminished. In the present experiments, Carrel, Meyer, and Levene have attempted to determine the effect of complete excision of the stomach. In one animal they found a high nitrogen retention in experiments performed early after the operation, but no retention in the experiments performed after the tenth week following the operation. They suggest that in this case not only the gastric secretion was missing but also the pancreatic and intestinal secretions were much reduced and at that period the absorbed protein had the character of parenterally introduced protein, i. e., it had undergone only very slight changes by digestion and hence was retained. They think that at the later period the pancreatic and intestinal digestions were restored to their normal power and that the characteristic effect of failure of stomach digestion was exhibited. In the second animal the stomach was completely removed and the experiments were begun on the twelfth week after the operation. Three experiments were performed on the animal and no nitrogen retention was noted in any of them. The necropsy revealed a hypertrophy of the upper end of the duodenum developing after the operation.

87. **Healing of Wounds in Denervated Skin Areas.**—Jacobson operated by cutting first the sensory nerve roots in pigeons and then noting the rate of healing of wounds made in the anesthetic area. Later the motor nerve roots were cut and similar observations made. The author sums up her results in the following conclusions: 1. the results of the experiments reported indicate no diminution in the rate of healing of wounds in a denervated (sensory or sensory and motor) skin area as compared directly with that in a normal area. 2. The variations in the results obtained by different investigators may be explained on the grounds of individual variation among animals. 3. It seems that so-called trophic disturbances may be due to vasomotor changes with increased susceptibility to infection or to the loss of protective reflexes from loss of sensibility to injurious agents.

90. **Prophylactic Action of Atropin.** Auer finds that a prophylactic injection of atropin sulphate in guinea-pigs sensitized by the subcutaneous injection of horse serum saved 18 out of 25 from the lethal effect of the toxic injection; while out of 24 adequate controls only 6 survived. Stated otherwise: the death-rate with atropin was 28 per cent.; without atropin it was 75 per cent. These figures, Auer says, show the distinct therapeutic utility of atropin in immediate anaphylaxis.

92. **Applying Thiersch Grafts to the Orbital Cavity.**—Over the part to be covered, whether within or without the orbit, is laid a piece of sterile gutta-percha tissue and an exact pattern made of this surface by the use of small scissors. This pattern is now removed and laid aside for further use. Next a piece of gutta-percha tissue two or three inches square (for convenience of handling) is laid in a bowl of normal salt solution. The Thiersch graft is cut in the usual way but is allowed to remain on the razor blade and is transferred directly to the gutta-percha tissue. To effect this the tissue is removed from the salt solution and spread evenly on a sterile towel. The upper surface of this tissue must be kept quite moist to facilitate the even application of the graft. The razor blade carrying the graft is dipped gently into the normal salt solution to loosen the adhesion between them preparatory to the next step. The graft is

then applied, raw surface up, to the tissue by holding the edge with a small spatula and gradually drawing the razor backward and dislodging it. The spatula is now brought into play and all wrinkles carefully smoothed. Should any difficulty be experienced a few drops of water sufficient to float the graft may be dropped on its surface.

The gutta-percha tissue should then be lifted slowly by taking hold of one end and the excess of water on its surface allowed to drain away slowly. This will cause the graft to become intimately adherent to the surface of the tissue and permit handling without any fear of wrinkling or dislodgment. With a pair of small and sharp scissors the tissue and the adherent graft are cut at the same time to correspond to the size and shape of the pattern previously described. In case great accuracy is demanded the pattern may be placed beneath the tissue while this shaping is proceeding. The graft thus shaped, together with its companion piece of gutta-percha, is then placed face downward on the surface to be covered and pressed into place with the spatula or any convenient instrument. Here the two may be left in contact or if desired the tissue may be removed by gently insinuating the edge of a spatula.

155. Spread of Malaria Through Other Agencies Than the Anopheles Mosquito.—Chica claims that in Guanajuato popular opinion uniformly accuses the fruits of being the cause of malaria in its worst aspect and people who go to Tierra Caliente ("Warm Land") as the coast is colloquially called among them, assert that if they keep clear of fruits and add brandy to the water they may remain free of malaria. Up to this time the search for malaria germs in fruits has yielded but negative results; but he thinks one thing remains: the anopheles is not the only vehicle for the spread of malarial diseases.

1. Spinal Analgesia.—McGavin tried this method in eighteen cases with almost uniformly disappointing results. He says that four successful cases of high puncture serve, so far as analgesia above the phrenics is concerned, to show that the method has at least some element of possibility in it; it is, however, uncertain, imperfect at present, and of doubtful value in replacing general anesthesia. The unsuccessful cases of high puncture show it to be fraught with danger, and from the human standpoint unjustifiable. The cases of low puncture serve to show very little else than that strychnin can be injected into the spinal canal without inducing spastic symptoms, and that it undoubtedly results in a shortening of the period of analgesia usually resulting from the use of stovain alone. The effects of the analgesic on the cranial nerves appear to be irregular. So far as McGavin has been able to see, the first, second, third and fourth remain unaffected; the fifth is at times under control, as is also the seventh; the sixth, eighth, ninth, tenth and twelfth are unaffected, while the eleventh may or may not be paralyzed. He can see no object in adding strychnin in cases of low spinal analgesia, since he has found no difficulty in carrying out operations under stovain analgesia without it, even when such analgesia has been pushed to the level of the clavicles.

6. Chondrocarcinoma of the Testicle.—Wallis' patient was a man, aged 30, with a strong tuberculous family history, three sisters and one brother having died from phthisis between the ages of 19 and 30. The patient was struck by a hockey stick on the left testicle in February, 1908. He had pain, stopped playing for two minutes, then finished the game. Swelling of the testicle appeared at once and gradually grew larger, and he wore a suspensory bandage; he had no pain and did not lose flesh. In February, 1909, the left scrotum contained a smooth, ovoidal mass, roughly as big as the adult fist, hard, uniform, elastic, not tender and not translucent. Veins were not dilated, testicular sensation was retained at the upper and front part of the swelling, and there was no thickening of the cord. Rectal examination showed nothing abnormal. The testicle and cord were removed through an inguinal incision, the inguinal canal being opened to its outer end. The cord was apparently normal. The patient left the hospital in 14 days with the wound soundly healed. Four months later he noticed an abdominal swelling, hard, elastic, smooth, prominent, slightly tender, reaching from the umbilicus to the symphysis, and from the left anterior superior spine to three inches to the right of the middle line. Slight frequency of micturition was present. There was a slight yellow tinge on the cheeks. The patient died two months later. The tumor was an embryoma in which the hypoblastic layer had undergone a malignant change giving a spheroidal-celled carcinoma.

8. Verminous Appendicitis.—A girl, aged 7, complained of abdominal pain and distention, fever, vomiting and tenderness in the appendix region. The appendix region was more tender, and persistently tender, than any other part of the abdomen, but the pain was diffused over the abdomen and the distention was suggestive of general peritoneal infection. The child was submitted to operation. The cecum was found to be inflamed, but no lymph was present. The appendix, when brought to the surface, was swollen and redder than normal. It was not until the appendix was slit up that a nest of actively moving threadworms was seen, some of which escaped. They were the oxyuris vermicularis. After the operation the usual remedies were given, and a careful search was maintained for a week or more, but no sign of a worm was visible in the motions, which were washed, strained and examined with a lens. Films of blood taken showed a marked polymorphonuclear leukocytosis, but the eosinophil cells were not increased in number, being rather fewer than usual.

14. Syphilis of the Central Nervous System.—DeCrespigny examined the cerebro-spinal fluid of 50 patients suffering from various forms of nervous disease, by means of the Ross and Jones reaction. The results of the investigation are as follows:

- (A) The reaction was positive in the following cases: (a) Parasymphylis: general paralysis, 6; tabes, 8. (b) Tertiary syphilis: cerebral syphilis, 5; syphilitic paraplegia, 1. (c) Probable cerebral syphilis, 2. (d) Non-syphilitic: tuberculous meningitis, 1; secondary carcinoma in vertebra, 1; lead encephalitis, 1.
- (B) The reaction was negative in the following: (a) Probable cerebral syphilis, 2. (b) Non-syphilitic: insanity, 4; vascular cere-

bral lesions, 4; traumatic concussion, 1; neurasthenia, 1; uremic hemiplegia without vascular lesion (verified at autopsy), 1; delirium due to pyemia, 1; idiopathic epilepsy, 2; paralysis agitans, 1; Mènière's syndrome, 1; hydrocephalus, 1; disseminated sclerosis, 2; idiopathic spastic paraplegia, 1; pernicious anemia with combined degeneration, 1; transverse myelitis (unknown cause), 1; syringomyelia, 1; plumbic peripheral neuritis, 1. DeCrespigny regards the test as being of considerable help in the diagnosis of obscure nervous affections.

He concludes: 1. Absence of reaction negatives the existence of general paralysis or tabes. 2. Its presence usually means syphilis of the central nervous system in the absence of tuberculous meningitis or malignancy. 3. Deeply situated cerebral syphilis does not necessarily produce the reaction. 4. Tuberculous meningitis may give the reaction even with a clear fluid. 5. The simplest explanation of the test seems to be as follows: Rapid degeneration of cells in the neighborhood of the cerebrospinal space sets free in the fluid a substance of the globulin class. In the absence of acute inflammation, syphilis, tubercle and cancer are the conditions most likely to cause this degeneration, and consequently to give rise to the reaction.

16. **Hysterectomy and Appendectomy.**—The patient, aged 11 years and 6 months, was abnormally developed. The mammae were well-formed; pubic hair, external genitals and general contour were those of a young woman. Menstruation, though free at first, was apparently normal; there were no clots and absolutely no pain. A fortnight after the first period she again menstruated and the flow continued for a fortnight. Treatment proving ineffective, it finally became necessary to remove the uterus, sections of which showed typical fibromyoma structure.

22 Conservative Operations on the Internal Female Genital Organs. E. B. M. Haarblicher.

20. **Induction of Labor.**—Little says that the necessity for emergency measures in obstetrics varies inversely with the care given to the patient during pregnancy. Timely induction of labor will prevent many mishaps incident to the progress of most of the usual or unusual complications of pregnancy. Such induction is best accomplished by the modification of Krause's method—the use of the large soft bougie introduced with the aid of the stylet. Pelvic contraction is not to be considered as an indication for induction of labor. Prolongation of pregnancy, on the other hand, is more frequently an indication for its employment. The passage of the bougie and the introduction of the pack will usually bring on pains within a few hours, and the labor may be allowed to proceed, or it may be terminated artificially. When the cervical canal is obliterated its dilatation by Harris' method is usually easy and, when carefully done, is safe. The danger from hemorrhage and infection is slight; laceration of the cervix will occur frequently, and such laceration should be immediately repaired. Apart from the fact that the method can be employed without assistance other than the anesthetist and nurse, its advantages are its universality of application, its simplicity, the limitation of the force employed to the fingers of one hand, and, finally, the ability of the hand to recognize and estimate the resistance to be overcome.

21. **Ovarian Pregnancy.**—Lea reports a case of early rupture of an ovarian pregnancy causing symptoms of diffuse intraperitoneal hemorrhage.

28. **Medical Treatment of Cholelithiasis.**—Anderson recommends the use of hexamethylenamin together with the other dietetic and hygienic measures in early cases of cholelithiasis, or in cases where the indications for operation are not urgent. If operation has to follow, the antiseptic action of the drug on the bile may be helpful in preventing septic complications.

29. **Treatment of Pyloric Obstruction.**—Wilkinson tries to show that, after all, surgical treatment of these patients has not yet been of a sufficiently satisfactory character to displace the older, carefully considered and adopted medical means.

35. **Abnormal Ribs as a Cause of Lumbar Pain.**—The patient, a man aged 45, complained of pain in the left renal region for some years. He was an amateur swimmer, and frequently noticed that after a swim the pain in the back was worse. There was no history of hematuria, albuminuria or pyuria. An examination of other negatives revealed to Argyle the presence of abnormal ribs in 6 cases out of 143 radiographic examinations of the renal region. An examination of these plates showed that in some cases the extra rib exists on one side only, while on others there are lumbar ribs on both sides. In all cases, the transverse processes of the first lumbar vertebrae are rudimentary in character, or rather resemble those of the dorsal vertebrae.

37 *Study of One Hundred and Four Cases of Cancer of the Esophagus and Cardia. L. Lamy.

37. **Cancer of the Esophagus and Cardia.**—In 78 of the 104 cases of cancer of the esophagus reported, progressive difficulty in swallowing was the first sign of trouble. There was no pain in 61 cases, but in 5 cases pain preceded the dysphagia by a few days and in 11 cases they came on together. In 29 cases there was no pain until a month or two after the difficulty in swallowing had developed. In 19 of the 40 cases with pain it occurred only while food was being swallowed; in the others it was continuous. Regurgitation was the rule; it was absent in only 17 of the total 104 cases. The appetite remained good in 70 per cent, and there was distaste for meat in only 4 cases. The cancer proved fatal in most cases between 6 and 12 months, but in a few, in from 2 to 4 months. In 7 cases the inability to swallow the food came on suddenly, the patients being apparently in perfect health; one was a man of 32. In 2 of these cases intense pain accompanied the sudden dysphagia, which in 1 case was accompanied by profuse salivation. In 8 cases the sudden difficulty in swallowing proved permanent and no solid food could be swallowed thereafter; in 2 other cases neither solids nor fluids could be swallowed. Cancer is differentiated from spasm of the esophagus by the rapid sequence of the disturbances, gastrostomy becoming necessary in from 1 to 4 months, while spasm of the esophagus may persist for years without requiring this. Copious salivation and mucous vomiting are aids in diagnosing. In one case a woman of 28 had an evident spasm of the esophagus but its persistence, notwithstanding great fluctuations, indicated an underlying organic lesion, confirmed by direct visual inspection and death 5 months after the first symptoms. In 6 cases the cancer did not prove fatal for from 1 to 2½ years. Twelve of the patients developed tuberculosis. The report issues from Mathieu's service at Paris.

40. **Malaria in Children.**—A somewhat similar article by Cardamatis was abstracted in THE JOURNAL, Oct. 9, 1909, p. 1225. His further experience confirms the assumption that young children are immune to malaria, and that the parasites are unable to traverse the placenta. In 20 cases in which the mother's blood swarmed with them none was in the infant's blood. It seems evident that there is some antitoxic substance on the fetal side of the placenta which not only kills the hematozoa arriving from the maternal blood but confers immunity on the infant for a year or two. In 838 children with malaria, only 87 were under 2; the tertian form of malaria predominates among children as among adults in Greece, but all forms are encountered at various ages. In 1,287 cases fully 75 per cent. were of the chronic form. The spleen is not always much enlarged in the children, even with grave cachexia.

42. **Fatigue as Factor in Nocturnal Enuresis.**—In a number of cases encountered by Nicoletopoulos the enuresis was evidently the result of sleep so profound by the exhausted children that the desire to urinate did not awake them as under ordinary conditions. In the cases reported, a little care on the part of the parents and children to prevent over-fatigue speedily cured the tendency to enuresis.

- 50 *General Peritonitis from Unknown Cause. (Péritonites cryptogéniques.) R. De Bovis.

49. **Operative Treatment of Adhesive Pericarditis.**—Roux-Berger reviews the history and applications of cardiolysis or precordial thoracotomy as it is better entitled, stating that there are records now of over 28 cases in which this operation has been done, besides 2 from his own experience. In 21 cases the results were favorable, the improvement being evident even during the course of the operation in some of the patients. In 7 cases the operation failed to benefit, and study of these cases shows that the intervention is applicable only in the cases of actual adhesive mediastino-pericarditis, and only when the symptoms observed depend on the adhesion of the heart to the chest wall. Unless the myocardium is in good condition there is little prospect of much relief from the operation. This can be estimated by the strength and regularity of the pulse and by the influence on the disturbances in the circulation of rest in bed, dieting and heart stimulants. The persistence unmodified of dyspnea, cyanosis and edema, notwithstanding vigorous medical treatment, should contraindicate the operation as proving that it has little chance for success. His review embraces European literature only.

50. **General Peritonitis from an Unknown Cause.**—De Bovis comments on the way in which the field of idiopathic peritonitis is being reduced by discovery of previously unsuspected causes for peritonitis. With the exception of a few still unexplained cases, such as Cull's case of primary pneumococcus

peritonitis, it seems evident that peritonitis is always secondary to some lesion elsewhere, but it may be preceded by a general infection—most often due to the pneumococcus or streptococcus—or it may be secondary to some abdominal lesion. In the case of general infection a laparotomy is of doubtful utility. In any event, it should be restricted to simple evacuation of the pus. When the peritonitis is secondary to some abdominal lesion its gravity depends on the character of the latter. If migration of germs from the stomach into the gastrohepatic omentum has led to glandular suppuration, as in Dahlgren's case, it is evident that the peritonitis may be threatening and an early laparotomy is usually indicated. But if, on the other hand, some mild enteritis seems to be the cause of the diffuse peritonitis and the latter seems moderate, expectant treatment may be justified; Lennander advocates this. In case there is severe paralysis of the bowel, enterotomy may be applied with multiple Witzel's fistulas or lavage of the intestine. Monks successfully applied the latter in a streptococcus peritonitis, flushing the intestinal canal with a salt solution through multiple enterotomy openings. De Bovis reviews in detail the recent literature on this so-called idiopathic peritonitis.

54. **Diagnostic Importance of Ferments in the Feces.**—Balint and Molnar conclude from their study of the diarrhea in exophthalmic goiter that it was not due to insufficiency of the external secretion of the pancreas. On the contrary, this secretion seemed to be unusually copious. The stool resembled that with pancreatic insufficiency but the large ferment content contradicted this assumption. The phenomena observed suggest that there is an overproduction of a peristaltic hormon in exophthalmic goiter which would explain the azotorrhea and steatorrhea with abundance of ferments. It seems plausible that the excessive functioning of the thyroid is responsible for this, especially as obstinate constipation seems to be the rule with myxedema. Further research showed that tests for the diastase in the stool are useful in diagnosis of cancerous obstruction of the outlet to the pancreas. In conclusion, they urge further study of the physiologic secretion of the pancreas which may throw light on many dark points in the pathology of the pancreas. It is better for this purpose to take the total diastase for the 24 hours as the standard.

63. **Pregnancy Toxemia.**—Hofbauer has been studying the toxicity of the placenta by anaphylaxis reactions; the results show that there does not seem to be any great biologic difference between the albumin of the mother, of the fetus and of the placenta. At the same time the development of the fetus and its membranes reacts on the maternal organism in such a way that severe auto-intoxication may result. This is evident in the degenerative processes in the kidney and liver, liable even with a normal pregnancy; also a hyperplastic process occurs in the glands with an internal secretion. Eclampsia and pernicious vomiting are the extreme manifestations of the toxemia of pregnancy on which histologic and biochemical research have thrown much light and now point the way to prophylaxis and treatment.

64. **Bronze Diabetes.**—Ridder had opportunity to observe the development of bronze diabetes in a man of 35, four years after pigmentation on the extremities and slight edema of the legs with some physical depression. A year later, signs of liver disease became apparent and it was diagnosed as hypertrophic cirrhosis of the liver with brownish pigmentation of the skin; there was no diabetes or intolerance of sugar. This condition persisted for nearly 2 years when typical bronze diabetes developed and the patient died in 4 months. Ridder ascribes the bronze diabetes to injury of the liver cells from some unknown cause. The pancreas measured 19 by 3 by 2 cm. and was bronze colored and of a tough consistency.

67. **Tuberculin Treatment in Open Pulmonary Tuberculosis.**—Löwenstein states that 989 patients have been given specific treatment at Beelitz since the beginning of 1908 and that 682 received the Koch tuberculin alone. The tubercle bacilli vanished from the sputum in 57.94 per cent. of the 409 patients treated with old tuberculin; in 42.05 of the 204 treated with new tuberculin and in 55.07 per cent. of the 69 treated with both combined. This specific treatment was restricted to patients free from complicating affections and the old tuberculin was given the preference when a tendency to production of connective tissue was apparent and in the cases with recent destructive processes, the aim being to help the organism in throwing off dead tissue and walling off the lesions by a vigorous local reaction. The expectoration was promoted by inhalations, etc., to help in throwing off the infectious material; the local reaction, he states, is one of the most important curative factors in the response to tuberculin under these conditions. The new tuberculin was given the preference when it was necessary to avoid much of a local reaction, especially with extensive destructive processes with much breaking down of tissue. The patients were about equally divided among the various stages of the disease.

68. **"Normal" Skiagraphs.**—Bloch accepts as progress the system of standard radioscapy with the tube exactly 70 cm. from the body, on the median line, for Roentgen examination of the heart. This does not give the actual size of the heart, but it supplies a standard which is much more instructive for purposes of comparison. The exact measurements are facilitated by an L square, one arm on the median line and an adjustable arm pivoting about the center of the horizontal arm to outline the outer margin of the side of the heart, a graduated circle at the base of the pivoting arm indicating the number of degrees in the angle thus formed. As the skiagraphs are always taken under the same conditions they can be superposed for estimation of the progress under treatment in each case and for comparison with normal findings.

69. **Influence of Momburg Belt Constriction on the Circulation.**—Tornai has applied the Momburg technic in 20 cases, merely to study the effect on the heart and circulation. The subjects were mostly young and with normal circulation and nervous system or with well-compensated heart defects. In every case the number of systoles and the blood-pressure were notably increased by the procedure. As the constricting

belt was removed, the pulse grew weaker, in some cases becoming very weak and irregular. His experience suggests the necessity for careful examination of the functional capacity of the heart beforehand, testing it by the Katzenstein or other reliable method. Any suspicion of heart disease or arteriosclerosis, exophthalmic goiter, nephritis or plethora should contra-indicate the method. He tabulates the findings in one typical case as recorded at 10 intervals.

71. **The Castor-Oil Plant in Ancient Egypt.**—Wätzold gives some quotations from a recently published translation of the Berlin papyrus, showing the extensive use made of the ricinus in ancient Egyptian medicine. The crushed seeds seem to have been used for local application in headache and to cure baldness, and many references are to the purgative action of the oil. He adds that there are many of these ancient papyrus manuscripts awaiting translation in the Berlin museum, which are sure to contain much of interest to medical men. The one just published dates from fifteen centuries before Christ.

72. **Suppurative Processes in Kidneys and Urinary Passages in Infants.**—Thiemich has encountered a number of cases of suppuration in the urinary apparatus in young infants. The trouble was a pyelocystitis and generally of hematogenic origin. Pyelocystitis seems to be of a milder nature than pyelonephritis in infants; the latter, in his experience, occurred only in very ill infants with very low vitality. The urine does not accumulate in the infant's tiny kidney pelvis to such an extent as in adults, and the passage can be effectually flushed by artificially induced diuresis. But this, even with antiseptics, does not seem to influence materially a pyelonephritis as the urine does not flush the foci in the kidney tissue. As they do not tend to confluence but rather to spontaneous healing by absorption, not much benefit can be anticipated from surgical measures, especially in view of the difficulty in diagnosing multiple abscesses in the infant kidney and the depressed state of the child thus affected, even apart from its kidney trouble. Treatment therefore should be directed to the underlying cause. If this succeeds, and dietetic measures here are the main reliance, then the pyelonephritis may be likewise arrested and even heal. In one of his two cases of the kind the child succumbed to the progress of its dyspeptic disturbances which it proved impossible to check; necropsy showed well-advanced healing processes in the kidneys. In the other case the child was restored to health on breast milk and the urine findings showed the progress to a complete cure. The child's illness lasted for several months but seemed to be closely and exclusively connected with the kind and success of the dietetic measures, the influence of the urinary affection being scarcely perceptible. In several of his cases there seemed to be some connection between the exudative diathesis and the urinary disease. The possibility that the healed pyelonephritis or persisting latent bacteriuria may cause trouble in later life must not be forgotten; this may be the source of pyelitis in adults in some cases. His necropsy findings indicate that the kidney becomes infected by the creeping up of an infectious process in the urethra in girls, but in boys the infection is probably by way of the blood. He reports the details of 5 cases in male and 3 in female infants with 3 other cases

in female infants who had died from pneumonia and necropsy unexpectedly revealed a suppurative process in the kidneys—the multiple abscesses were as extensive in this latter group as in any of the others.

76. Heart Functioning with Extrathoracic Heart.—The heart was entirely outside of the body and presented a rare opportunity for study of the functioning of its various parts, the apex lying outside on the left hypogastrium. The third day after birth fibrinous pericarditis developed, proving fatal on the sixth day. The right auricle continued to beat rhythmically for 5 minutes and irregularly for 15 minutes longer after the death of the rest of the heart. The electrocardiograms and other findings are reported and discussed. Once during the first day of life the heart stopped beating in consequence of being accidentally hit, but resumed its regular action after 2 minutes of direct massage.

82. The Tuberculin Focal Reaction.—Wolfsohn regards as the greatest advance in tuberculin treatment the recent tendency to avoid any reaction, either local or general, but he thinks that much further progress may be realized if internists and surgeons will work together in cases of surgical tuberculosis under tuberculin treatment. In the surgical affections, under direct inspection the focal reaction to the tuberculin may afford most instructive information which will apply to the lungs. As a typical instance he reports the case of a woman of 34 with multiple tuberculous abscesses in the left breast and the sear of a tuberculous hip-joint affection which had healed 22 years before. The abscesses were evacuated and a course of tuberculin instituted under which the breast process rapidly healed, but the old hip-joint process flared up again. He regards the breaking out anew of the old coxitis as a specific focal reaction to the tuberculin in the strictest sense of the term. The tuberculin had been given in minutest doses for two months and was suspended at the first signs of redness in the old hip sear. The case shows that a clinically latent focus may respond to tuberculin and may progress even on suspension of the tuberculin. Such an occurrence in the lung could not be so readily controlled as with an accessible surgical lesion, as in this case. It is not impossible, he concludes, that the tuberculin treatment may fan an old latent apical process into a flame, and this focal reaction in the lung might terminate fatally. In his case the promptly favorable influence on the breast affection was remarkable, suggesting a local fluctuation in the defensive processes in favor of recent lesions.

87. Symposium on "606" in Syphilis.—The second of the 10 questions asked in the question blank sent out by the *Medizinische Klinik* is in regard to by-effects, and 7 of the 9 writers report occasional higher temperature and local pains as the only by-effects observed. But from Klingmüller's clinic at Kiel and by F. Pinkus of Berlin are reported 1 case of gangrene, 3 of local necrosis, 2 of abscesses, 3 of toxic erythema, 1 of detrusor paralysis, 1 of tenesmus and a case in which pre-existing diabetes became aggravated and still persists thus to date.

89. Surgery of the Blood Vessels and Transplantation of Organs.—The extensive work reported by Enderlin and Borst confirms the importance of biochemical individual conditions. These are sufficient to interfere with the success of homoplastic transplantation of organs. Only those of autoplasmic origin promise complete success. He doubts whether it will ever be possible to overcome this difficulty of the biochemical individual peculiarities in transplanting organs.

90. Therapeutic Puncture of the Brain.—Finkelnburg reports a case of chronic hydrocephalus in a youth of 16, evidently the result of a trauma of the head 6 years before. The symptoms indicated progressive compression of the brain, some of them suggesting a tumor in the cerebellum, especially the pain in the back of the head, the stumbling gait, deafness, etc.; the pulse was only 56, the pupil reflex was sluggish, the eyes protruding, with extreme choked disc and nystagmus. The brain was punctured near the left motor centers to a depth of 5 cm., and about 20 c.c. of fluid was released under high pressure. The headache and vomiting subsided and the patient was able to walk without support and by the sixth day the choked disc was much less pronounced, while the hearing also had improved. Improvement continued to progress so rapidly that no further operation was attempted and the young man is now, 3 years after the operation, apparently well with a suspicion of nystagmus and slight exaggeration of the knee-jerk as the only traces of his former trouble. The necropsy in another case, the patient dying before puncture of the brain had been heard of, showed the feasibility of operative treatment in these cases. The only explanation of the rapid improvement after release of such a small amount of fluid is that the accumulated fluid by its compression had induced a kind of valve-like closure of the opening between the skull and the spinal canal.

96. Technic for Artificially Inducing Pneumothorax.—Holmgren states that it is possible to apply this method of treatment of unilateral pulmonary tuberculosis even in cases in which the adhesions between the sheets of pleura apparently contra-indicate it. This can be accomplished by injecting physiologic salt solution under pressure sufficient to detach the adhesions and spread apart the walls of the pleural sac. Without removing the needle it is then connected with the tank of gas which can then be injected without further difficulty to make the therapeutic pneumothorax.

98. Peritonitis with Gonorrhoea.—Bodenstern explains the peritonitis in the case reported as due to chemical irritation from the silver nitrate solution injected so high as to reach the seminal vesicles and thence the peritoneum.

100. Diagnosis of Pulmonary Tuberculosis. Köhler is in charge of a large sanatorium for pulmonary disease and his experience has shown that the tendency is to diagnose tuberculosis in many cases in which it does not exist. He warns that nervous-toxic processes, in combination with a special excitability of the heat center, play an important part in the reaction to the tuberculin test. They may induce a positive reaction even in the non-tuberculous. He obtained a positive reaction in 21.7 per cent. of numerous patients given a sup-

posed injection of tuberculin when either nothing was injected or merely sterilized water. The reaction to this sham tuberculin test could not be distinguished from the ordinary positive reaction. Lorenz has reported similar findings; he ascribes them to a neurasthenic or hysterical tendency. Elliesen has also reported recently positive reactions with chlorosis and once, in a case of Werlhof's disease, the intense tuberculin reaction and slight physical anomalies in the lungs indicated tuberculosis but not a trace of it could be detected at necropsy. Neumann and others have obtained a positive reaction in syphilis alone, others in actinomycosis, carcinoma and leprosy, and A. Fränkel obtained an unusually large proportion of positive reactions with patients with various diseases. However, when a positive reaction is obtained with minute doses, up to a maximum of 1 or 2 mg., the presumption is in favor of tuberculosis. In industrial accidents the shock to the whole nervous system may promote a positive reaction in the absence of tuberculosis. In one such case 4 test injections of 0.2 up to 1.5 mg. elicited an intense positive response each time, but the lung findings were normal and the course of the case confirmed the absence of tuberculosis. In another case the trauma had lacerated the lung and aggravated an existing tuberculosis process, but repeated tuberculin tests up to 8 mg. were negative. A positive response to the tuberculin test merely indicates that the heat-forming apparatus is unusually excitable, and this is peculiarly marked in the tuberculous, but it does not follow that every one with excitability of this apparatus is necessarily tuberculous. He has also observed numerous cases in which the symptoms of the tuberculosis persisted unmodified although there was no apparent response to tuberculin. New foci may develop even in the course of tuberculin treatment and without disturbing the sensitiveness to the tuberculin. Even more important than the physical signs and the tuberculin reaction, is a tendency to loss of weight or increasing anemia. Köhler warns further that not every deviation from normal in the auscultation findings is necessarily of tuberculous origin. The changes with mouth breathing or dropping back of the tongue or as the patient swallows must not be ascribed to tuberculosis. Repeated examination on different days will disclose the inconstancy of the findings from these causes. Accumulation of fat in the corpulent may induce a pseudocrepitation over the apices. Even constant râles may be induced by a chronic streptococcus process as he cites by several examples, necropsy demonstrating the absence of all traces of tuberculosis, even in one case in which there had been repeated hemoptysis. It was explained finally as hemosiderosis from destruction of blood corpuscles from pernicious anemia. Everything in this case had pointed to pulmonary tuberculosis and the necropsy findings were a great surprise as there had been nothing to suggest the necessity for examination of the blood. With a tuberculous process in the lower lobe the patients may keep well nourished; he has had a case of this kind under observation for 6 years. This patient, now 21, could not stand tuberculin treatment as he reacted with high fever to the smallest doses, but his general health is still good, although he has 2 or 3 moderate hemorrhages every year. Köhler emphasizes that the physical findings merely indicate the physical condition of the lung but not the underlying cause of the changes observed, whether old or recent or whether due to the pneumococcus, streptococcus, or tubercle bacillus. The predominantly central tuberculous processes are more frequent, he declares, than is generally recognized. Enlargement of the glands in the neck is an important aid in diagnosis, as also the subjective disturbances, particularly a continuous sense of fatigue. One is tempted to ascribe such merely to a neurasthenic origin when in fact some concrete organic cause is responsible for it.

 102 *The Lung Suction Mask and Its Therapeutic Application in Pulmonary Disease, Anemia, Asthma, Weak Heart Action and Insomnia. (Die Anwendung der Lungen-Saug-Maske.) E. Kuhn. Commenced in No. 8.
 103 Serotherapy of Epidemic Meningitis. (Die Serumtherapie bei Genickstarre.) F. Goppert.

101. Heart Disturbances.—Plehn calls attention in particular to the disturbances ascribed to the heart when its outlines are normal in every respect and a dozen knee-bending exercises do not make the patient breathe much faster and, although the pulse may increase by 10 or 20 beats, yet there is no shortness of breath. These findings exclude actual organic disease, and for all forms of heart disease determination of the shape and size of the different parts of the organ is of primal importance; this alone, he declares, permits correct interpretation of the auscultation findings. It must be borne in mind, however, that the compensating dilatation and hypertrophy after an endocarditic process take some time to develop so that during or after acute articular rheumatism a systolic murmur and weak heart action require extreme caution and strict bed rest until normal heart action is restored. The biologic relations between the innervation and the muscles are particularly close in the heart, he continues, and the action of toxins, tobacco and alcohol, of the toxins generated in exophthalmic goiter, and of emotions is the main factor in heart disturbances without enlargement of the organ. The reflex heart neuroses proceed from the gastrointestinal or genital sphere, either directly or from emotional depression. The connection between the heart and the stomach is closer than is generally recognized, he states. Acute pericarditis, for example, is usually accompanied by violent gastric symptoms and dilatation of the stomach by serious symptoms on the part of the heart. A mild pericarditis is a frequent occurrence and may pass unsuspected unless the physician examines the heart when he will find the dulness extending a little farther than usual and sharply defined while careful percussion will reveal that the heart-liver angle can no longer be detected. With an exclusively nervous heart disturbance, angioneurotic edema of the ankles is common; mechanical disturbances in the peripheral circulation occur comparatively late and only after such have developed in the liver, kidneys and lungs. If there are no signs of this or of organic changes in the heart, moderate edema need not be regarded with pessimism. He treats acute articular rheumatism so perseveringly with the salicylates that endocarditis rarely develops among his patients, and he suggests prompt salicylic medication to be resumed again with every infectious sore throat in persons who at any time have displayed a tendency to endocarditis during acute rheumatism or other infection. Energetic salicylic medication may ward off endocarditis and valvular defects even after pericarditis or myocarditis is already installed. He adds that any one who has ever had acute rheumatism should guard carefully against getting chilled or wet through and against over-exertion. An extra-hygienic life should be followed by persons with a family tendency to arteriosclerosis, apoplexy, obesity, diabetes or gout, and the obese should bring their weight down before the heart has suffered severely. At the same time he warns that too severe restrictions are liable to bring on hypochondria which may react unfavorably on the organic trouble.

102. Mask to Induce Passive Hyperemia in the Lungs.—Over four years have now elapsed since Kuhn introduced his "lung suction mask" to induce passive congestion in the lungs by obstructing respiration. He here reviews his own and others' experiences, all confirming the absolute harmlessness of the measure and its efficient action in impeding the inspiration, which is nasal, while expiration proceeds unobstructed both by mouth and nose. As Tileston explained, in THE JOURNAL, April 11, 1908, page 1182:

The effect of impeded inspiration is to produce negative pressure in the thorax, lasting almost throughout inspiration; the inspiratory muscles are brought into strong contraction, inspiration is prolonged, and the rate of respiration is lowered. The most important effect, however, is the marked aspiration of blood from the right side of the heart into the lungs, due to the prolonged negative pressure. The lungs are, therefore, supplied with an increased amount of blood. Moreover, since expiration is not obstructed, it will be short, and the blood will not have time to escape entirely to the left side of the heart. Thus, after wearing the mask for a while, a considerable degree of congestion is obtained, as has been proved by animal experimentation. This hyperemia differs, of course, from the passive congestion of heart disease, in that there is no obstruction to the pulmonary circulation. The increased amount of blood in the lungs is of the greatest benefit, for it is conceded that it is the relatively poor supply of blood or lymph to the apices which predisposes those parts to tuberculosis.

Not only is the blood aspirated into the lungs but the circulation of the lymph also is materially promoted; other methods of inducing passive hyperemia in vogue check the lymph current. The promoted circulation of lymph and blood induces rapid absorption of effusions while toning up the tissues in every way. Another advantage Kuhn claims for the method is that as the number of inspirations becomes reduced, the lungs are correspondingly rested; the respiration is exclusively costal but the diaphragm is sucked upward by the prolonged negative pressure above and thus the space for the lungs is even less than with ordinary unobstructed breathing, as he shows by a number of illustrations and skiagraphs. The ribs expand mightily, Kuhn states, and this in time has naturally a most beneficial influence on tuberculous lesions in the lungs. At the same time the blood-producing apparatus feels the effect of the lower oxygen tension and responds as it does to the air of high altitudes, the number of red cells in the peripheral circulation becoming permanently increased. He insists that no other measure has yet been discovered that proves so effectual in promoting blood-production as this simple partial obstruction of the respiration. On account of the negative pressure in the chest, the blood pours more abundantly through the heart and the myocardium becomes better nourished and works more effectually, as can be traced by the auscultation and other findings. Zabel has reported great benefit in two cases of severe cardiac defects and others in pericarditis, bronchial asthma, emphysema, pleurisy, bronchitis, anemia and hemoptysis. Cough and dyspnea are allayed, râles, expectoration and bacilli subside in the tuberculous, the complexion and appetite improve, and a gain in weight naturally follows. Except for a slight feeling of oppression in the head for the first day or so, there are no by-effects, Kuhn says, unless the muscles of the chest may ache a little at first from the unwonted exercise. An interesting effect of the impeded respiration is the drowsiness that ensues. Dogs drop promptly to sleep even when suspended in uncomfortable positions, and patients wearing Kuhn's mask lie drowsy most of the time, so that it is proving excellent in combating insomnia. When the dogs with the mask are roused from sleep they are lively at once, which demonstrates that the drowsiness can not be due to carbon-dioxid intoxication; it is evidently the result of the aspiration of blood away from the brain plus the diminished oxygen tension in the respiration center. The respiration is sometimes reduced to 7 or even 6 inspirations a minute in animals under the influence of the mask. The mask is a celluloid cap tied over the nose and mouth, with an adjustable arrangement shutting off more or less of the intake of air to the nose while valves permit its free outward escape. The application of this method of inducing passive hyperemia does not conflict with any other measures that may be applied, but for permanent benefit it is evident that it must be used for many months to modify the conditions in the chest permanently. The only contra-indication, he says, is a very weak heart, and even with this the mask is useful, but it should be applied only for brief periods at a time. In conclusion we quote again from Tileston who states that he found an extraordinarily low percentage of pulmonary tuberculosis in 128 cases of mitral stenosis and in no case was there any evidence of active tuberculosis. This relative immunity is due, he thinks, to the passive hyperemia of the lungs consequent on the mitral lesion.

106 *Sensitization to Light as Factor in Pellagra. W. Hausmann.

107 *Experiences with Operations on the Neck. (Die Krankheiten des Halses.) K. Ewald. Commenced in No. 35.

106. Etiology of Pellagra.—Hausmann has been conducting extensive research on the sensitizing action of hematorporphyrin, a product of the decomposition of hemoglobin, seen in the urine after destruction of red-blood corpuscles. The phenomena observed seem to prove that it has a sensitizing action so that exposure to the light afterward induces various

pathologic changes. He is convinced that this sensitization plays an important part in the production of pellagra, and quotes certain other writers whose recent research has led to the same conclusion.

107. Operations on the Neck.—Ewald reviews the experiences in this line at the Sophia Hospital at Vienna since 1902. The list includes 96 operations on the thyroid, for exophthalmic goiter in 7 and carcinoma in 3. Only 23 of these patients were males, pregnancy being probably responsible for enlargement of the goiter in many instances. In some cases the enlargement occurred suddenly, threatening suffocation, and being probably the result of hemorrhages in the gland. It seems evident that the thyroid may become enlarged under nervous influences alone. In 65 cases he operated under local anesthesia, but this has so many disadvantages that now he always gives a sedative beforehand. There was some fever during healing in all but 4 cases, but no tetany in any instance and severe postoperative pneumonia appeared in only 2 cases; the sputum was hemorrhagic in these cases, suggesting an embolic focus. Three of the patients succumbed soon after the operation on the thyroid; one was a young man, a semi-imbecile, with persisting thymus and enlargement of the lymph follicles, especially at the base of the tongue. This hypoplasia of the organism seems to reduce the resisting powers. The general anesthesia was not responsible for the fatality in this case as was shown by the second fatality in which the operation had been done under cocaine local anesthesia. This patient was a woman of 62, with goiter for 15 years, rapidly increasing in size towards the last, with a suspicion of malignancy. She seemed to be doing well during the night after the operation and the next morning breathing was superficial but not labored and there was no trace of dyspnea. An hour later she died suddenly without stridor, and necropsy disclosed unsuspected edema of the glottis. Only laryngoscopy would have revealed the trouble and nothing was observed to suggest the necessity for this. In the third case, a man of 50 required both cocaine and chloroform and roused from the anesthesia with left hemiplegia; he soon became unconscious and died the third day; necropsy revealed 2 foci of acute leptomeningitis but nothing to connect it or the fatality with the operation. Ewald discusses the ultimate cosmetic outcome of the various operations on the neck, 72 of the patients being examined several years later. The goiter recurred in 20 cases, and in 7 a second operation was necessary. The ultimate outcome in exophthalmic goiter was disappointing in all but one case. In 10 other cases the operation was required for acute inflammation in the thyroid, without preceding goiter in 5 cases. In the 6 cases of torticollis good results were obtained although no attempt at systematic after-treatment was made, the patients being merely instructed to exercise the neck muscles after the contracting fibers had been severed. Only a few patients with enlarged tuberculous glands were operated on, as he does not approve of opening up a lymphoma unless it has persisted for years unmodified, isolated and never softening. Under other conditions an operation is liable to be followed by recurrence, while the opening up of the lesion exposes it to secondary infection. So long as the glands are growing in size, general hygienic measures alone are applied, the patients tranquilized, and when the glands enter a quiescent stage, they are generally so small that their removal is no longer desired. If the gland softens and the inflammation compels interference, he cruettes out the cheesy masses, avoiding sound tissue, believing that as the disease is not local but general, it is impossible to eradicate it by removal of even all the infected glands.

108 *Subcutaneous and Intravenous Nourishing Infusion of Sugar. (Ernährung mit Traubenzucker nach Kausch.) J. Berendes.

108. Alimentary Infusion of Sugar Solution.—Berendes reports the experiences in 40 cases in which the patients were nourished by subcutaneous or intravenous infusion of a 5 or 7.5 per cent. solution of grape sugar in 0.9 per cent. salt solution. This represents from 200 to 300 calories to the

liter. The infusion causes no more pain or inconveniences than saline infusion, and seemed to be free from any by-effects. There was no glycosuria unless the infusion was repeated for several days in succession and then it was slight. The temperature was not affected except in 2 cases in which there was a chill and the temperature rose to 39.5 and 40 C. after the intravenous infusion of 1 liter of an 8 per cent. solution of grape sugar; in both these cases a little adrenalin had been added to the fluid. The sugar thus introduced is evidently oxidized in the body, and it is thus possible to supply a considerable amount of nourishment in this way.

112. Congestion and Visceral Hemorrhages in Influenza.—Ghedini gives a long list of records of various forms of congestion and visceral hemorrhages observed by numerous authors, all due to influenza, and then reports a case in which the influenza bacillus was cultivated from the blood and was evidently responsible for the swelling, congestion and hemorrhagic tendency in the lungs, stomach, intestines, liver, spleen and kidneys. The patient was a young man and the severe syndrome ran its course to apparently complete recovery in less than a month.

119 Anaerobic Germs in Suppurative Processes. V. Gaudiani.

114. Nephrectomy.—Federici states that Tansini has lost only one out of 51 patients on whom he has done nephrectomy, and this fatality was in 1895. In his last 4 cases the kidney was removed on account of tuberculosis, concretions or deformity. The results were good in each case. He does not lay much stress on the findings of the functional tests, although he never fails to apply them. One factor in his success is his method of clamping the hilus after exposing the kidney by an incision parallel to the ribs, resecting if necessary the twelfth and eleventh ribs. Clamping the hilus permits the rapid mobilization of the rest of the organ, so that the whole operation is complete in a few minutes as no time is wasted in ligating the vessels separately.

116. Amputation of the Breast for Tuberculosis.—Cignozzi reports a case in which he removed the breast and axillary glands for an extensive tuberculous process, and covered the defect left by a large flap drawn around from the back, according to Tansini's method. The results were unusually good, the patient being able to use the arm and shoulder even after 2 weeks, and in 45 days, under iodid treatment, she was dismissed apparently cured.

120. Viability of Cholera Germs in Salt Water.—Jacobsen writes from the Serum Institute at Copenhagen to relate the results of tests to determine how long cholera germs will survive in salt water in ship ballast tanks and also in tanks after they have been thoroughly rinsed out with sea water and filled anew with non-contaminated water. The vibrios were found alive in some of the tests up to 47 days, showing the danger from this source if a ship, for instance, fills its tanks with harbor water at St. Petersburg and reaches its destination in less than this number of days. The tests further showed that flushing the tanks with fresh sea water is not sufficient to free them from cholera germs lurking in the slime and crevices. The last epidemic of cholera in Holland and Belgium, he states, was traced to infected water taken from the river at St. Petersburg and brought in the ballast tanks to the other countries. The tests made during the summer showed a comparatively brief survival of the germs, from 7 to 17 days, the presence of other microbes, more prevalent during the summer, probably checking the growth of the vibrios.

JAMES B. HERRICK, M.D.
CHICAGO

Severe substernal pain coming on after exertion, radiating to the left arm, lasting a brief moment, yet compelling the patient to remain immobile from the physical suffering and from a mental anguish that overwhelms him with a sense of imminent death—this picture is looked on by all as that of typical, true, cardiovascular angina, and especially when the arteries are found to be sclerotic and the blood-pressure high. A prognosis is made of sudden death in the near future from a recurrence of the paroxysm, a prediction only too often correct.

So indelibly is this image of the phenomena and course of the affection fixed in the minds of many physicians that they are unable to admit any deviation from its details as consistent with this disease. In this way there have become prevalent several notions concerning angina pectoris that are more or less erroneous, chiefly in that they fail to recognize the atypical manifestations.

It is the object of this paper to present some of these views that seem to me erroneous, chiefly because they are too narrow and do not give room for the exceptional case.

Considering the lack of definite unifying knowledge of the pathogenesis of angina pectoris, one is not surprised to find that there is confusion in the interpretation of the symptom-complex. This confusion is seen especially when the attempt is made to separate an organic cardiovascular form from a toxic or from a neurotic type. I have no intention to discuss the necessity or advisability of making such a distinction, but shall limit what I say to the so-called "true angina" of organic cardiovascular origin. This tacitly assumes that a grouping of somewhat similar symptoms on a purely neurotic basis, no matter how closely resembling true angina, is not the real disease; that to this unreal disease the term "neurotic angina" or "pseudo-angina" is not inapplicable. In taking this position one realizes a certain inconsistency in the use of terms, and that one is open to the charge of not being in line with the latest trend of thought, of being at variance with the views of many leading medical men, and of exposing oneself to the shafts of ridicule of such a master of physis and English as Sir Clifford Allbutt. "Either a case is angina or not angina," says MacKenzie. "Pseudo-angina is pseudodiagnosis," says Allbutt. With all of which I agree, but feel that a clinical distinction between true and false is justified on practical grounds.

DEMONSTRABLE ARTERIOSCLEROSIS, HIGH BLOOD-PRESSURE, AND AORTIC VALVE LESIONS

Since Jenner proved that John Hunter, who died of angina, had coronary sclerosis, the conception of coronary sclerosis as the essential underlying lesion has been deeply rooted. That coronary sclerosis is often associated with sclerotic aorta, roughened aortic valves and wide-spread arteriosclerosis is also well known. From this frequent association has arisen the expectation of finding in all cases of angina evidences of this wide-spread arterial change, with its accompanying high blood-pressure and cardiac hypertrophy. But this, as has been pointed out by many, is by no means always the fact. Arterial change may be wide-spread and the coronaries sclerotic, yet there may be no hypertrophy of the heart and no rise in blood-pressure, the very sclerosis that is probably the cause of the angina producing also, through obstruction to blood-flow, poorly nourished, weakened or fibrous myocardium. Or the sclerotic or atheromatous process may be quite limited, involving only the first portions of the aorta, but encroaching on the coronary arteries. Particularly in syphilis are the changes thus localized to the beginning of the aorta. In these cases the peripheral vessels may be normal.

Even with markedly sclerotic coronary, the peripheral vessels, and aorta as well, may show little or no change from the normal. Such a heart I saw in a man of 60, dying in his first attack of angina, or, rather, in his second, which came on twelve hours after the first. The coronaries were stiff-walled from calcareous deposits, and his heart not large. One may rightly urge the presence of peripheral sclerosis, murmur over the aorta, and large heart as strongly suggesting coincident sclerosis of the coronary, but one cannot exclude such sclerosis in the vessels of the heart or pronounce a cardiac pain as non-anginal because the peripheral vessels are normal.

Not a few seem inclined to discredit the possibility of angina unless the blood-pressure is persistently high, or at least is high just preceding or during an attack. That there is often persistently high blood-pressure is true. It is often true that preceding an attack there may be a rise. In some instances one may predict an oncoming attack because of the rise in pressure. In a case which I was privileged to see, the physician had the opportunity of measuring the change in pressure in the fatal attack. He had just finished reading the pressure, 160 mm. Hg, when the pain occurred and the mercury rose to 190 mm., death occurring before a hypodermic could be administered.

But one must be prepared for normal or subnormal readings. In some of the most serious cases, in fact, there is low blood-pressure, indicating perhaps a weakened myocardium. In a man of 54, with no general arteriosclerosis, I have seen the rough-walled left coronary plugged in its anterior branch with a thrombus,

* Read in the Section on Practice of Medicine of the American Medical Association, at the Sixty-first Annual Session, held at St. Louis, June, 1910.

producing sudden excruciating precordial pain. For the fifty hours that the patient lived the heart tones were barely perceptible, and the peripheral pressure extremely low. But in cases in which there is no such acute and extensive myomalacia cordis as was present in this instance, the pressure may be low for a long time and the patient busy about his work, though interrupted at times by the attacks.

Most physicians regard the existence of an aortic valve lesion of a sclerotic character as tending to strengthen their belief in the organic origin of the painful attacks, that is, such a finding points toward a true angina, and away from a so-called pseudo-angina. The same is true if the arch of the aorta is dilated uniformly, or in circumscribed aneurismal manner. The sclerotic or atheromatous lesion of the aorta or the valves leads one to suspect a similar trouble in the coronaries, or perhaps only at their mouths. And those who, like Allbutt, see in the aortic ring the seat of anginal pains, naturally interpret evidence of anatomic change in this locality as proof of the organic origin of the attack. Much depends on one's conception of the cause and nature of this disease. Some, however, hold so rigidly to the theory of coronary origin that, if aortic regurgitation or aortic aneurism be made out, or if there be strong reason to suspect aortitis, they will not call the seizures anginal, though the pain and other phenomena may be classic in every respect. They speak of such seizures as merely "the pain due to aneurism, aortic regurgitation," etc., but not the pain of angina pectoris; that is, coronary disease. This view, while held by only a few, is too narrow.

NUMBER AND DURATION OF ATTACKS

Another fallacy is connected with the number of attacks. Not a few physicians have been heard to express the opinion in concrete cases that, because the attacks were frequently repeated, they could not be anginal for, they assert, an individual never has more than a few; he succumbs if there are numerous recurrences. This is utterly wrong. Repeated attacks of severe type may occur during periods varying from many days to many months. And it is no uncommon experience to meet patients whose milder attacks—the angina minor of some—are repeated several times in a single day. Neusser mentions a woman with twenty attacks a day. In one patient seen many times I witnessed over a period of three years the sufferings of this disease, there being at times as many as six and eight paroxysms in a day.

The attack is usually brief, being over in a few seconds or a few minutes. But in other instances it is more prolonged. After the acme of pain has been reached, there is a moderation, but still a residual pain, a soreness of skin in the precordia, and a numbness or pain extending down the arms, especially the left, to the elbow or fingers. The patients may suffer, therefore, for many minutes, or the pain may last for hours. In the patient already referred to, the one who had coronary thrombosis, the agonizing substernal pain lasted three hours, though death did not follow until fifty hours. Morison describes a case of coronary thrombosis with anginal pain, lasting twenty-three hours. This patient had previously suffered from milder attacks of angina. Opinions might differ as to the propriety of speaking of this more chronic state as angina, though it has the characteristics of the acute paroxysm, only less in degree, and longer drawn out as to time.

Where the status anginosus exists, one attack is rapidly followed by another, even on the slightest provo-

cation or after no appreciable cause; some pain and soreness persist between the attacks, so that the patient is in a state of continuous pain and suffering, with frequently recurring exacerbations.

EXCITING CAUSE

The exciting cause of the attack is usually exertion, especially rapid walking. Some strange anomalies are at times seen. Thus a man may have an attack that is brought on by the mere effort of walking about the room, while he dresses, or simply by stooping to lace his shoes. After his breakfast he may be obliged to stop two or three times on his way to take his train; yet for the rest of the day he is free, even though he may walk a considerable distance and eat rather freely at luncheon and dinner. One of my patients, in a suburb, could ride a bicycle to the station with fewer seizures than if he walked, though the streets were level and when afoot he never hurried. Another patient, a woman, has for two or three years been unable to walk two blocks without pain, necessitating her stopping to rest or to take nitroglycerin. She can remain for days together free from pain if she sits or lies still. Charles Sumner had attacks that at times seemed to be brought on by some sudden move, as by turning in his revolving library chair. Yet at other times, as when speaking in the Senate, he could be on his feet for hours, with all the mental excitement, bodily activity and gesticulation of earnest debate, and still be free from pain. It is well known that a fit of anger, a breath of cold air, an overloaded stomach, may precipitate a seizure.

These irregularities are to be remembered, and they are here referred to, because the opinion is at times expressed that attacks come on only after exertion; and, on the other hand, that, if an individual with supposed angina is able to walk briskly without an attack, it is proof against the existence of angina. While exertion and the other causes mentioned are the common provocative ones, these causes may produce an attack at one time and not at another, and often no cause can be clearly assigned for the outbreak any more than for some epileptic seizures.

INFREQUENCY IN WOMEN

All agree that true angina is comparatively rare in women, some statistics showing less than 5 per cent. Heberden saw three women in one hundred patients with angina. Undue importance is sometimes attached to the infrequency in women, and one may thus be influenced away from a correct diagnosis. The error is easily understood, too, when in an individual case there are evidences of a strong neurotic taint. The undue excitement, the tendency to introspection and to exaggeration of symptoms, the desire for attention and sympathy, perhaps even the pronounced hysterical manifestations, may easily mislead one to the diagnosis of a functional, neurotic or so-called false angina. No inviolable rule can be given for the sure differentiation, but a study of the cardiovascular condition, the age, the exciting cause, the radiation of pain, the behavior and attitude during rather than after the attack will all be of help. It is certainly a cause for regret and chagrin to diagnose pseudo-angina and in a week or two have the woman die in an attack. In the case of a woman seen by many different physicians, all agreed as to the existence of a cardiac valvular lesion, and all agreed as to the existence of a marked neurotic, even hysterical, element, aggravated by a free habitual use of morphia. There was, however, a wide divergence of opinion as to the organic

basis of the anginal attacks, some regarding them as wholly of the false type. A rest-cure, with breaking off of the morphin habit and marked improvement in every respect, lent color to the theory of pseudo-angina, but the woman died suddenly some two or three years later, as in angina. One has to keep clearly in mind what has been often said, but what is easily forgotten, that the cardiopath is often a neuropath. The hysterical woman may have underlying the nervous manifestations a serious pain-causing disease.

PAIN, UNCONSCIOUSNESS, IMMOBILITY, ETC.

Certain facts concerning the pain itself are worth repeating, for it is easy to have a stereotyped picture in mind, while in reality there are not a few variations.

I have never seen a case that I recognized as angina sine dolore, but since its description by Gairdner, it has been a recognized form, and one cannot question its existence. Not long ago I heard Dr. J. M. Patton describe his experience in being called to the home of a colleague whom he found lying on the couch. In answer to the question as to what was the matter, the reply of the patient was that he did not know, he had no pain, but an indescribable sensation in the cardiac region, and an appalling sense of the presence of death, and "I'm mighty glad to see you," he said. In a minute more he suddenly expired. There was no feeble, rapid, irregular pulse; no dyspnea; no cyanosis; no pain—apparently angina save the pain.

It is surely wrong to state dogmatically that pain, in order to be anginal, must be severe, excruciating, unbearable. There are milder degrees. What is called angina minor must be viewed as in its essence of the same nature as the angina major. In one sense its recognition may be of greater importance than that of the major type, for it may lead to appropriate advice that may prolong life in cases in which were the disease unrecognized, a faulty mode of life might lead to early death.

The most typical radiation of pain is to the left side of the neck and down the left arm. But one must be prepared for odd radiation. The radiation is often down the right arm. In one of Morison's patients the right arm radiation was associated with sclerosis of the right coronary only. The pain may run down both arms. It often goes down the ulnar side. It may stop at the elbow, the wrist, or run to the little finger. Pain may start in the fingers, run up the arm, and finally centralize at the heart, seemingly a centripetal rather than centrifugal course. Pain, numbness and tingling may be complained of in the intervals between the attacks, and may be regarded as rheumatic and articular in origin. Pain to the jaw, to the ear, to the back may be described. And particularly confusing are the cases in which such odd radiations as to the epigastric, lumbar, renal and testicular region are seen. Tenderness of the skin, as described by Head, may at times be made out. One of my patients, a woman, often has most profuse salivation with the substernal pain, that radiates to the left shoulder and arm. MacKenzie mentions this same salivation in his experience.

Unconsciousness, though unusual, is yet seen at times. On two occasions I have known a sufferer from angina to become unconscious, once at the climax of a paroxysm. Osler and others mention the same occurrence.

Immobility is a characteristic feature. The patient is afraid to move for fear the pain will be aggravated. He sits or stands motionless, at times almost statue-like; he will not lie down. Yet there are exceptions to these rules. Charles Sumner often walked about his library
